ABSTRACT

The Auroral Electrojet index (AE) is discussed and a detailed description is given of the derivation of 2.5-min AE indices for 1970. Tables are given of hourly average indices for each day of the year and of the stations which supplied the extreme deviations from quiet time levels for each hour. Graphs of the variations of the indices are included for each day.

SECTION I

1. Introduction

The Auroral Electrojet Index, AE, is designed to provide a global, quantitative measure of auroral zone magnetic activity produced by enhanced ionospheric currents flowing along the margin of the auroral oval. Ideally it is the total range at an instant of time of the deviations from quiet day values of the horizontal magnetic field (H) around the auroral oval. Defined and developed by Davis and Sugiura [1966], AE has been shown to be especially useful to delineate the onset and progressive development of high latitude magnetic disturbances which are recognized as one aspect of polar and magnetospheric substorms [Akasofu, 1968]. It has been shown to correlate strongly with the integrated southward component of the interplanetary magnetic field [Pudovkin, et al., 1970; Arnoldy, 1971] and to be intimately related to the growth of the geomagnetic ring current during magnetic storms [Davis and Parthasarathy, 1967]. For these various roles AE possesses advantages over other geomagnetic indices, in particular:

(i) it can be derived on an instantaneous basis or from averages of variations computed over any selected interval;

(ii) it is a quantitative index which, in general, is directly related to the physical processes producing the observed magnetic variations;

(iii) its method of derivation is relatively simple, digital, and objective and is well suited to present computer processing techniques; and

(iv) it may be used to study either individual events or statistical aggregates.

Increasingly frequent reference to AE in journal articles concerned with solar-terrestrial interactions and magnetospheric physics as well as requests to World Data Centers for AE indices are indications of its utility. Also, IAGA Resolutions 2 and 15 [Alldredge, 1969]; the Joint COSPAR-IUCSTP Second Report on IMS [1972]; and several ad hoc conferences of users of geomagnetic data further document the need for systematic, timely derivation of AE indices. In order to satisfy this need of the scientific community, the Environmental Data Service of NOAA has undertaken to resume 2.5-min digitization of magnetograms and to perform the data processing necessary to derive AE. This report is one means of distributing a summary of the results. More detailed information and data may be obtained from World Data Center A for Solar-Terrestrial Physics, Boulder, Colorado, U.S.A.

1.1 Prior Derivations of AE

AE indices were calculated and published on a systematic basis by the Geophysical Institute of the University of Alaska for the years 1957 through 1964 [T. N. Davis, et al. 1967, 1968]. These values were based upon the standard tabulations of hourly-average scalings of the horizontal magnetic field for selected auroral zone magnetic observatories. Later, AE indices were derived at the NASA Goddard Spaceflight Center under the direction of D. Fairfield. These were derived from 2.5-min digitizations of H from selected observatories and they covered the interval from September 1964 through June 1968 [King, 1971].

The network of stations whose magnetograms were used to derive AE changed slightly from year to year. Originally, some high latitude, southern hemisphere stations were used to fill gaps in the longitudinal distribution of the available northern hemisphere auroral zone stations. Critically located new stations were incorporated from time to time and they significantly improved the station distribution and, thus, the approximation to "ideal" AE. However, because of delay in availability of magnetograms from some stations, the AE indices for the years 1966 through 1968 were "preliminary" and were based on an inadequate distribution of stations. Arnoldy [1971] has pointed out one effect of the biased station distribution for the published 1967 AE indices. Also, omission from the AE station network of high latitude stations such as Barrow or Inuvik may have sometimes severely limited the amplitude of detected events [K. Kawasaki, R. L. McPherron, private communications]. Because of a history of H-baseline problems, Barrow magnetograms were not used in the NASA derivation of the 2.5-min AE indices. In the EDS derivation of AE(11) for 1970, Barrow contributed 18.6% of the extreme positive deviations (AU) and 12.8% of the negative extreme values (AL).

1.2 Definition and Computation of AE

AE was originally derived by Davis and Sugiura [1966] from horizontal magnetic field (H) data from a group of seven auroral zone magnetic observatories. They derived a quiet time H level for each observatory and subtracted this value from observed instantaneous values of H. The result was a time series of deviations from the undisturbed field, $\pm\Delta H(t)$. Superposition of the seven time series produced a set of interwoven lines bounded by an upper and lower envelope formed by connecting the set of extreme ΔH values. The upper and lower envelopes were designated AU and AL respectively and the range between them at any instant, AU-AL, was defined as AE for that time. In the absence of other sources of variations, AU is a direct function of the current flowing in the eastward auroral electrojet while AL is similarly related to the westward flowing current.

A second index derived from AU and AL was their mean, AO = (AU+AL)/2. It is an approximate measure of the equivalent zonal currents affecting the auroral zone whether arising in the ionosphere or magnetosphere. It illustrates the presence or absence of symmetry in the variations of the oppositely directed electrojets and may provide a correlation with ring current effects in the auroral zone. The units of AU, AL, AE, and AO are gammas (1 gamma = 1 nanotesla = 1×10^{-5} Gauss).

The stations they selected to contribute to AE were chosen to lie in the auroral zone and to be as evenly distributed in longitude as was practical. Ideally, each station should lie just below the instantaneous auroral oval around the time of local geomagnetic midnight. In practice, the network of stations used must be relatively uniform in longitudinal coverage and include a reasonable distribution of latitudes.

1.3 Station Selection for 1970 AE

Conversations with Davis, Sugiura, Akasofu, and others led to selection of the eleven stations listed in Table 1 for the determination of 1970 AE(11). The station positions are shown in Fig. 1 relative to the geographic and geomagnetic north poles. The station names are given along with their mnemonic abbreviation (EDS-NOAA), geographic and geomagnetic coordinates to the nearest hundredth degree, and the universal time of geomagnetic midnight at equinox.

Delay in magnetogram acquisition from some observatories may lead to the future use of a subset of the given observatories for the derivation of "preliminary" AE. Availability of new stations may increase the list. We have chosen to indicate the number of stations contributing to a given determination by a parenthetical number following the letters AE.

This basic list of eleven magnetic observatories may be supplemented with other stations in future derivations to improve the approximation of "ideal" AE. For example, there are longitude gaps between Fort Churchill and College and between Cape Uelen and Tiksi Bay which may be filled. Also, because the auroral oval varies in areal extent with the level of magnetic activity, we will attempt to supplement the present network with meridional chains of stations. The addition of any standard station to the present network represents a significant increase in the work of digitization to secure 2.5-min values. For this reason, we are interested in continuing to review the desirability of retaining all stations used for deriving 1970 AE(11). In general, we have chosen to use records from standard magnetic observatories and to avoid the use of records from temporary installations although the latter may have been well-situated to

supplement the network. In this way we hope to produce comparable indices from year to year and to standardize our technique of magnetogram processing.

In addition to the geographic position of contributing stations, another factor in station selection is the promptness with which their records become available through the World Data Center system. This means not only the timely submission of microfilm or other copies of magnetograms but also the availability of calibration data such as scale values, baseline values, and temperature correction factors. Also of great importance is the availability of auxiliary storm magnetograms and their calibration information. This is because during active periods (of greatest interest for AE) the registration of normal magnetograms is often incomplete, necessarily resulting in missing data from these periods unless storm magnetograms are available. The effect of missing data at a critical station may be observed in the graphs of daily variation of the indices (Section III).

TABLE 1

Observatories Used for the Derivation of 1970 AE(11)

*Local Geomagnetic Midnight (LGM) at equinox
Geomagnetic coordinates and time calculated for inclined dipole field

#Sometimes given as; Cape Wellen, Tixie Bay, and Dixon Island.

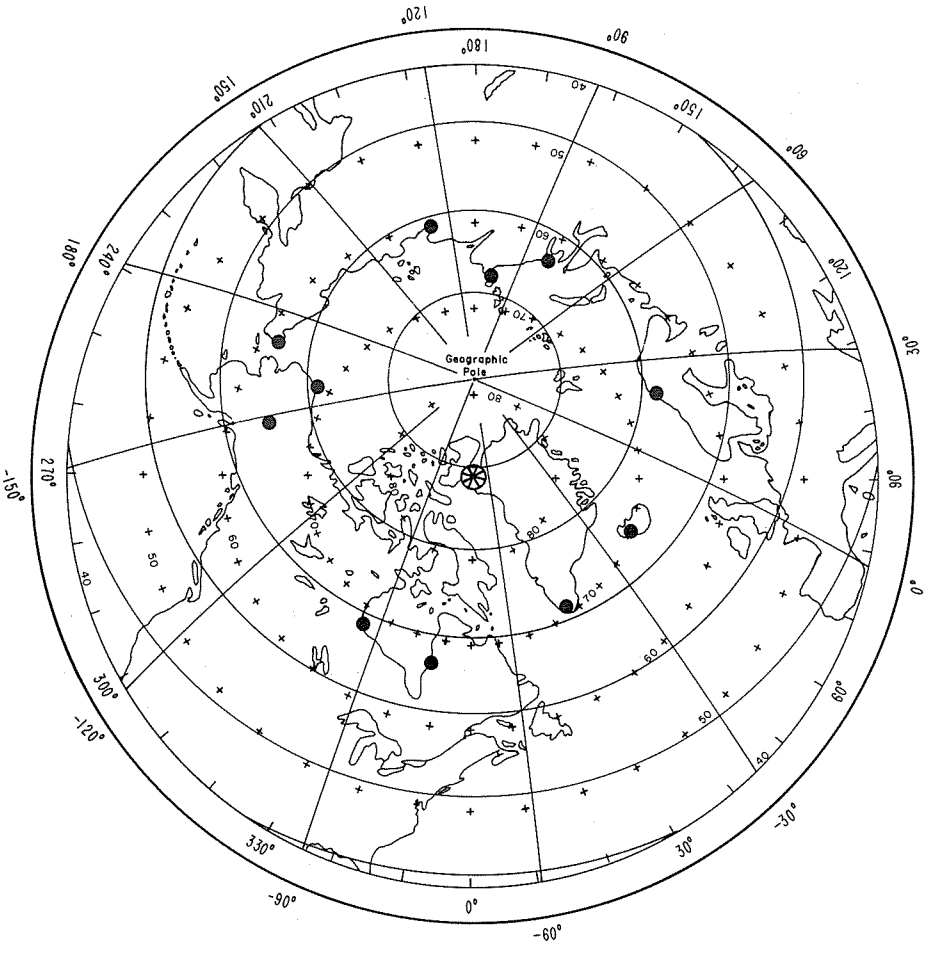

Fig. 1 Stations contributing to 1970 AE(11) are shown by solid filled circles. Polar equal-area projection centered on north geomagnetic pole with geographic and geomagnetic coordinate grids.

Geographic latitude is indicated by the concentric circles of solid lines. Geomagnetic latitude is indicated by the numbered concentric circles formed by + signs. Geographic longitude is given by the outer circle of numerical values with meridians shown as solid lines every 30°. Geomagnetic longitude is given by the inner circle of numbers and the border of hash-marks at 10° intervals.

1.4 Quiet Time Reference Levels

There are several techniques which could be used for deriving the quiet time reference level of the horizontal field at each AE station. We have selected the following as being simple, essentially objective, and easily performed on the computer. It is also the technique used by Davis and his associates [1967, 1968] for hourly AE for 1957-1964. A monthly quiet time average value of H is computed for each station from all the 2.5-min values on the internationally adopted 5 quiet days of each month. This provides a set of twelve monthly reference values for each station for a year. The average month-to-month absolute change in reference level during 1970 was about 13γ and the greatest change observed was 40γ. These changes introduce small discontinuities into AU and AL at each month's end and, therefore, into AE. This technique does not attempt to remove Sq variations; however, our computer program includes an option to derive monthly quiet time means for each 2.5-min interval from the 5 Quiet Days or any other selection of days.

As computed for 1970 AE(11) and given in the first table of Section II, the monthly H reference levels for each station include the H baseline value at that location. So long as each H variometer maintains stability relative to its baseline during a month of recording then the absolute value of the baseline is not important. However, as discussed below (subsection 2.2), when there is component drift relative to the baseline this can introduce errors into the AE indices. Effects of such instrumental drift or shifts can be compensated when absolute H observations are taken at critical times to permit H baseline determinations. For this reason we have computed our reference levels including baseline values instead of simply using average millimeter amplitudes of H or other alternative reference levels. For some Russian and Canadian observatories we did not have current adopted baseline values. Either arbitrary preliminary values were used or else the most recent adopted values available for dates near to 1970. In this way AE was derived on a more timely basis without our being forced to await final adoption of baselines. We are prepared to apply adopted baseline values when they become available and will circulate updated tables of reference levels and any changes necessary in the AE indices. We do not expect these to be significant although they might increase AE slightly in some cases.

1.5 Computation of Indices

The monthly reference levels for each station were subtracted from the observed values of H giving ΔH deviations for each 2.5-min UT. In practice these values were grouped in hourly blocks by month and with data for the 11 stations ordered by geographic longitude. The ΔH values were then scanned by computer techniques and the extreme deviations identified for each 2.5-min interval. These extreme values became AU and AL for that time and the observatories which produced them were also recorded. AE and AO were computed from AU and AL and all indices were recorded on magnetic tape. At the same time, hourly averages of all indices were computed.

Daily graphs of all the 2.5-min indices were produced on the computer's cathode ray tube plotting unit and microfilmed. Tables of hourly average indices were printed in monthly blocks. For hours of high AE the complete set of station deviations for each 2.5-min interval was listed. Quality control programs were used to check each stage of the derivation and sample statistics were kept on the frequency of station selection for AU and AL.

Section II of this report reproduces the tables of station reference values, hourly average indices tabulated by month, and monthly lists of stations contributing AU and AL for each hour. Section III reproduces the microfilm graphs of index variations for each day. Brief comments on these tables and graphs are given at the beginning of Sections II and III.

2. Problems in Derivation of AE

Users of these indices should be aware of the following types of problems:

(i) those inherent in the method of derivation of the index;

(ii) those arising from observatory procedures and the magnetograms; and

(iii) those produced by the digitizing process.

2.1 Inherent Problems

At an AE observatory the deviation from quiet time H will be the same either for an enhanced electrojet current or for a constant current which moves spatially relative to the fixed observatory. With a limited number of stations and for a small event, no approximation to AE will distinguish between these two sources of H deviations. Also, small electrojet variations could occur in the gaps between observatories and not show in AE. Further, failure to remove any Sq variations in computing the H deviations probably accounted for the small diurnal variation noted in AE by Pudovkin, et al. [1970]. Restriction of the set of contributing stations to the northern hemisphere should introduce a seasonal variation in the AU and AL ratios as noted by Afonina and Fel'dshteyn [1971].

2.2 Data and Recording Problems

The operating problems which may arise at an auroral zone magnetic observatory are many and varied. Those which particularly affect the derivation of AE are any which change the baseline of the H trace during a month; any which change the H scale values; and any setting of the H trace on the magnetogram which permits it to go off the edge of the photographic paper during times of moderate or large excursions.

An example of baseline drift effects is shown in Fig. 2. The relatively high yet unvarying level of AU for many hours of January 6 and for the first three hours of January 7 are obviously erroneous. For several days of the first week in January the H trace at one contributing observatory appeared to drift relative to its baseline. Apparently the problem was resolved by instrumental adjustments for after twenty four hours of blank record following 0300 UT, January 7, the magnetograph recordings were resumed and offered no further problems.

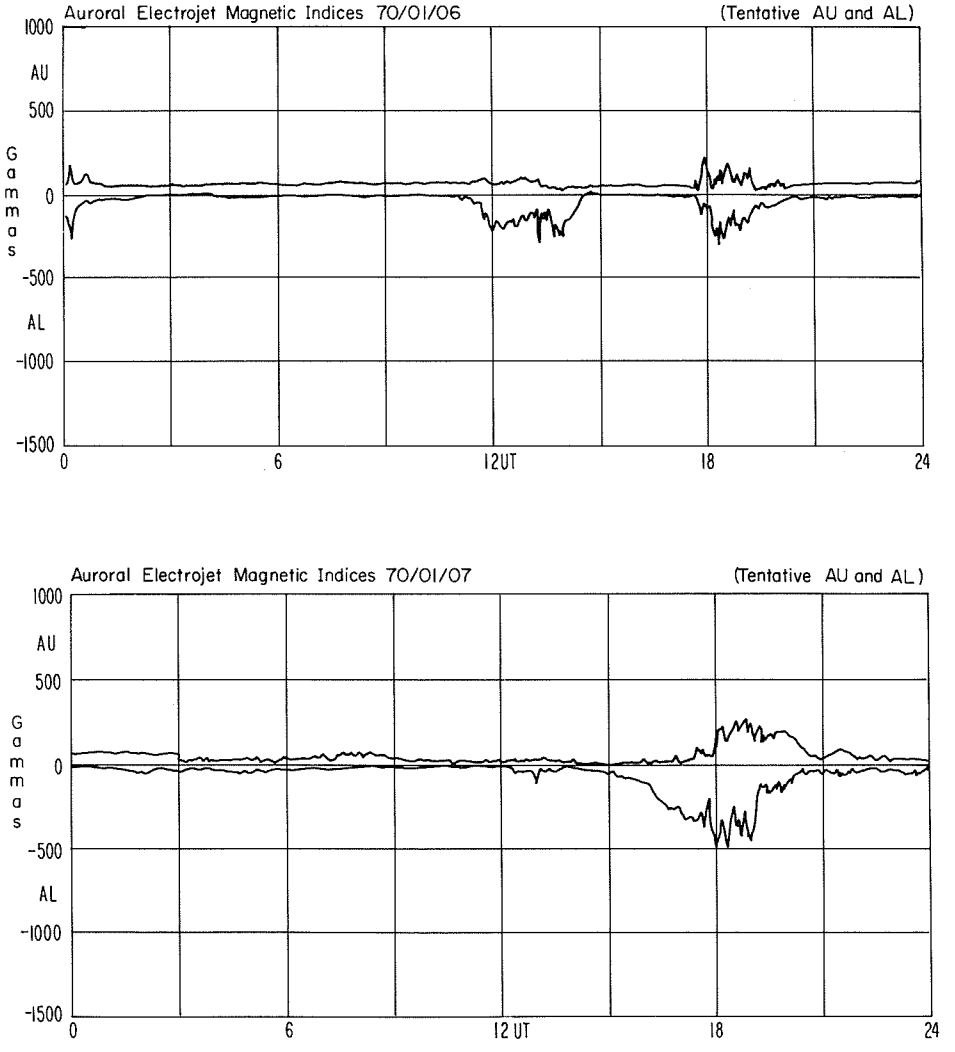

Fig. 2 Uncorrected index graphs of AU, AL for January 6-7, 1970.

This difficulty was compounded by the fact that we had no current baseline calibration data for that observatory and could make no attempt to compensate for the observed drifts. For the interval January 1-8 we derived AE(10) and excluded the drifting data. Lack of current baseline information is only serious for such times during which significant change occurs. Otherwise the process of deriving ΔH eliminates the baseline and any arbitrary value can be assumed so long as baseline stability is assured.

Some of the records processed in deriving 1970 AE had irregularly spaced hour marks arising from erratic time drives in the magnetographs. This caused unique problems for our semi-automatic digitizing equipment. In some instances difficulty with the time drive was also associated with multiple days of recording on a single magnetogram. This produced a complex network of overlapping traces which were difficult to separate.

Another problem encountered in deriving AE produces a characteristic effect easily seen in the graphs of the AU and AL indices (Section III). During moderate magnetic activity the H trace at some observatories may pass off the magnetogram and if there is no secondary trace some data will be lost. At other times the H trace simply becomes so faint that it cannot be digitized. On the other hand, during some large magnetic events the magnetogram traces become so mixed that they cannot be distinguished from one another for digitization. Unfortunately, many of the observatories selected for deriving AE do not routinely supply storm magnetograms. If for any reason the H trace is "lost" at a critically located station during a time when it is supplying either the AU or the AL values of the AE index then a "missing data effect" results. At such times the network of the AE stations is effectively reduced and the station recording the next most extreme H deviation is used to supply AU or AL. The two most outstanding such events can be seen in the graphs in Section III for AU on 70/03/08 at 1430 UT and 1900 UT and on 70/07/21 at 1330 UT. These missing data effects are characteristically rectangular bays in AU or AL with a sharp decrease toward zero, apparently normal variations for a few minutes to hours, then a sharp increase back to a higher value. During the great magnetic storm of 8 March 1970, data were missing from as many as eight stations during parts of the day. We were reduced to deriving AE(3) for those intervals and the three stations supplying H deviations were located in the North American sector.

This problem of missing data effects can be greatly mitigated at the observatories. Adjustment of the position of the H trace on the magnetograms, installation of secondary H mirrors on the variometers, and the inclusion of auxiliary storm magnetograms for active times would solve most missing data problems in the records supplied to the World Data Center system. When storm magnetograms are supplied appropriate calibration data should also be furnished.

2.3 Digitizing Process Problems

Quality control of the digitizing process proved to be more difficult than expected. It is not useful to discuss these problems in detail in this report, but we must admit the possibility that not all errors introduced in digitization were removed. We are not aware of any erroneous index values in the tables of this report or in the archived 2.5-min values. However, unless a digitizing mistake produced a suspiciously non-natural appearing variation on the index graphs it may have been missed. At any instant of time AE is the result of measured H deviations at only two stations and not the average of many measurements. For this reason it is especially susceptible to digitization errors. Currently, we have adopted the procedure of computer-plotting synthesized magnetograms from the raw digitized values and from the values obtained after application of calibration data. Large discontinuities in the H trace are easily observed. By this means we hope to reduce the number of errors in AE derivation which characterized our first attempts with 1970 data. We request that anyone detecting questionable values in 1970 AE(11) communicate with WDC-A concerning this matter. If necessary, corrections will be issued from time-to-time and distributed to the scientific user community, including statements in later reports in this series.

3. Availability of Indices

This report presents hourly average indices, some statistical summaries, and graphs of the 2.5-min indices for each day of 1970. Users of the indices desiring computer listings of 2.5-min values may obtain them upon request from WDC-A. In addition these indices are available on digital magnetic tape. They can be supplied in either 7- or 9- channel, 556 BPI, BCD format, IBM compatible modes. Other conversions are possible upon special request. Microfilm copies of the index graphs are also available. In general, WDC-A will attempt to supply the data for 1970 in any way which will meet user needs and which facilitates data distribution. We welcome suggestions concerning different means of effective data distribution.

4. Acknowledgements

The program to derive 2.5-min AE indices on a systematic and timely basis from records supplied by many geomagnetic observatories is necessarily a complex operation whose success depends upon many interacting parts. Many different people are involved at each stage: observers at remote auroral zone stations, processors of records in each country, the staff of the World Data Center system, and curve followers and geophysicists responsible for the final product. All play essential roles in the production of AE. It is our hope within EDS that all the many contributors will continue to exert their best efforts to secure a timely flow of high quality data through the system and that the indices will be made quickly available to the user community.

We have been greatly assisted in the work of deriving 1970 AE by informal contacts with representatives of the international scientific community and data service groups, especially at the 1971 IAGA Moscow meetings. Dr. A. F. Treshnikov, Dr. V. M. Driatsky, and Dr. A. N. Zaitsev contributed to improving the flow of data into the World Data Center system. Advice and encouragement from Dr. M. Sugiura, Dr. T. N. Davis, and Dr. S. Akasofu have helped in many ways. C. A. Abston (EDS) supervised the digitizing effort, rewrote his bulk data processing programs for the Boulder computer system, and did much of the original programming which produced the present results. In this work and the extensive quality control effort he has been assisted by L. D. Morris.

Dr. W. N. Hess and A. H. Shapley are thanked for their encouragement and support in the preparation of this report.

SECTION II

TABLES

Table of Monthly H Reference Values

The monthly quiet-time H reference values are given for each observatory. These values are the base from which the ΔH deviations were derived and they were computed as the average of all 2.5-min digitized H values from the internationally adopted 5 magnetically quiet days of each month. The given values are in gamma units and are absolute in the sense that they include the applied scale value and provisional baseline used for each observatory's magnetograms. While subsequent changes in adopted baselines may shift the reference values slightly they should not affect the derived indices because the method of derivation eliminated the H baseline value (see text).

Tables of Hourly Mean Indices

The following tables contain monthly listings of average hourly indices: AE, AL, AU, and AO. These hourly values were computed as the mean of the 2.5-min instantaneous values and the first hour of each day covers the data interval from 0000-0100 UT. All times are given in Universal Time and the indices are given in gammas. On March 8, UT hours 15, 16, and 20 had hourly AL values more negative than -1000γ. This was also true for UT hour 12 on November 7 and for UT hour 8 on December 14. These values appear in the tables as underlined positive numbers because there was not sufficient space to print a four digit value and negative sign.

Tables of Stations Supplying Hourly AU and AL

As described above, the hourly average indices are computed from the 2.5-min instantaneous indices derived for that hour. Each pair of instantaneous values of AU and AL arise from data recorded at only two stations and the station-pair contributing these extreme values may change from one 2.5-min data interval to the next during an hour. In order to designate a single station as the source of hourly AU or AL some convention must be adopted as a basis for selection. We have chosen to designate the station having the maximum average ΔH for the hour as the "contributor" of hourly-AU. Likewise, the station having the most negative ΔH is the contributor of hourly-AL. Two empirical observations from deriving AE indices support this decision. During disturbed times (when hourly AE exceeds 150γ) it is most common for one pair of stations to be both the most frequent contributors of AU and AL and to also have extreme hourly average ΔH values. During quiet times (hourly AE lying in the range 20-60γ), one station-pair may supply AU and AL for most of an hour only to be displaced by another station-pair critically situated to record the onset of an AE event. Generally, there is little difference between ΔH at the stations supplying the AU and AL indices during quiet times and the other stations of the network. Thus large deviations associated with an event are sufficient to raise the hourly average ΔH of the critically located stations above the corresponding values of the station-pair which supplied most of the quiet-time values. For such hours the stations indicated as supplying AU and AL are the ones which responded to the event.

These tables serve to illustrate the nonuniform contribution to AU and AL made by different stations of the network. Barrow, Fort Churchill, Cape Chelyuskin, Dikson Island, Great Whale River, and Narssarssuaq supply about 71% of the extreme values used in deriving 1970 AE(11). In particular, Barrow, Dikson Island, and Cape Chelyuskin supplied almost 50% of the AU indices.

TABLE OF MONTHLY H—REFERENCE VALUES

Units: Gammas

SECTION III

GRAPHS OF INDICES

Daily Graphs of 2.5-min Auroral Electrojet Indices

The following graphs are computer drawn plots of variations of the 2.5-min indices AU, AL, AE, and AO for each day of 1970. They are printed from microfilm produced by the computer but with drafted labels to improve legibility of the small characters. The dates are given as year/month/day in descending order (1 April 1970 is 70/04/01).

Publication Notice

WORLD DATA CENTER A for SOLAR-TERRESTRIAL PHYSICS REPORT UAG
(Prepared by World Data Center A for Solar-Terrestrial Physics, NOAA, Boulder, Colorado)

These reports are for sale through the National Climatic Center, Federal Building, Asheville, NC 28801, Attn: Publications Subscription price: $9.00 a year; $2.50 additional for foreign mailing; single copy price varies. These reports are issued on an irregular basis with 6 to 12 reports being issued each year. Therefore, in some years the single copy rate will be less than the subscription price, and in some years the single copy rate will be more than the subscription price. Make checks and money orders payable to: Department of Commerce, NOAA.

Upper Atmosphere Geophysics Report UAG-1, "IQSY Night Airglow Data" by L. L. Smith, F. E. Roach and J. M. McKennan of Aeronomy Laboratory, ESSA Research Laboratories, July 1968, single copy price $1.75.

Upper Atmosphere Geophysics Report UAG-2, "A Reevaluation of Solar Flares, 1964-1966" by Helen W. Dodson and E. Ruth Hedeman of McMath-Hulbert Observatory, The University of Michigan, August 1968, single copy price 30 cents.

Upper Atmosphere Geophysics Report UAG-3, "Observations of Jupiter's Sporadic Radio Emission in the Range 7.6-41 MHz, 6 July 1966 through 8 September 1968" by James W. Warwick and George A. Dulk, Department of Astro-Geophysics, University of Colorado, October 1968, single copy price 30 cents

Upper Atmosphere Geophysics Report UAG-4, "Abbreviated Calendar Record 1966-1967" by J. Virginia Lincoln, Hope I. Leighton and Dorothy K. Kropp, Aeronomy and Space Data Center, Space Disturbances Laboratory, ESSA Research Laboratories, January 1969, single copy price $1.25.

Upper Atmosphere Geophysics Report UAG-5, "Data on Solar Event of May 23, 1967 and its Geophysical Effects" compiled by J. Virginia Lincoln, World Data Center A, Upper Atmosphere Geophysics, ESSA, February 1969, single copy price 65 cents.

Upper Atmosphere Geophysics Report UAG-6, "International Geophysical Calendars 1957-1969" by A. H. Shapley and J. Virginia Lincoln, ESSA Research Laboratories, March 1969, single copy price 30 cents.

Upper Atmosphere Geophysics Report UAG-7, "Observations of the Solar Electron Corona: February 1964-January 1968" by Richard T. Hansen, High Altitude Observatory, Boulder, Colorado and Kamuela, Hawaii, October 1969, single copy price 15 cents.

Upper Atmosphere Geophysics Report UAG-8, "Data on Solar Geophysical Activity October 24-November 6, 1968", Parts 1 and 2, compiled by J. Virginia Lincoln, World Data Center A, Upper Atmosphere Geophysics, ESSA, March 1970, single copy price (includes Parts 1 and 2) $1.75.

Upper Atmosphere Geophysics Report UAG-9, "Data on Cosmic Ray Event of November 18, 1968 and Associated Phenomena" compiled by J. Virginia Lincoln, World Data Center A, Upper Atmosphere Geophysics, ESSA, April 1970, single copy price 55 cents.

Upper Atmosphere Geophysics Report UAG-10, "Atlas of Ionograms" edited by A. H. Shapley, ESSA Research Laboratories, May 1970, single copy price $1.50

Upper Atmosphere Geophysics Report UAG-11, "Catalogue of Data on Solar-Terrestrial Physics", compiled by J. Virginia Lincoln and H. Patricia Smith, World Data Center A, Upper Atmosphere Geophysics, ESSA, June 1970, single copy price $1.50.

Upper Atmosphere Geophysics Report UAG-12, "Solar-Geophysical Activity Associated with the Major Geomagnetic storm of March 8, 1970", Parts 1, 2 and 3, compiled by J. Virginia Lincoln and Dale B. Bucknam, World Data Center A, Upper Atmosphere Geophysics, NOAA, April 1971, single copy price (includes Parts 1-3) $3.00.

Upper Atmosphere Geophysics Report UAG-13, "Data on the Solar Proton Event of November 2, 1969 through the Geomagnetic Storm of November 8-10, 1969", compiled by Dale B. Bucknam and J. Virginia Lincoln, World Data Center A, Upper Atmosphere Geophysics, NOAA, May 1971, single copy price 50 cents.

Upper Atmosphere Geophysics Report UAG-14, "An Experimental Comprehensive Flare Index and its Derivation for 'Major' Flares 1955-1969", by Helen W. Dodson and E. Ruth Hedeman, McMath-Hulbert Observatory, University of Michigan, July 1971, single copy price 30 cents.

Upper Atmosphere Geophysics Report UAG-15, "Catalogue of Data on Solar-Terrestrial Physics", prepared by Research Laboratories, NOAA, Boulder, Colorado, July 1971, single copy price $1.50. (Supersedes Report UAG-11, June 1970.)

Upper Atmosphere Geophysics Report UAG-16, "Temporal Development of the Geographical Distribution of Auroral Absorption for 30 Substorm Events in each of IQSY (1964-65) and IASY (1969)" by F. T. Berkey, V. M. Driatskiy, K. Henriksen, D. H. Jelly, T. I. Shchuka, A. Theander and J. Yliniemi, September 1971, single copy price 70 cents.

Upper Atmosphere Geophysics Report UAG-17, "Ionospheric Drift Velocity Measurements at Jicamarca, Peru (July 1967 - March 1970)", by Ben B. Balsley, Aeronomy Laboratory, National Oceanic and Atmospheric Administration, Boulder, Colorado, and Ronald F. Woodman, Jicamarca Radar Observatory, Instituto Geofisico del Perú, Lima, Peru, October 1971, single copy price 35 cents.

Upper Atmosphere Geophysics Report UAG-18, "A Study of Polar Cap and Auroral Zone Magnetic Variations", by K. Kawasaki and S. I. Akasofu, Geophysical Institute, University of Alaska, June 1972, single copy price 20 cents.

Upper Atmosphere Geophysics Report UAG-19, "Reevaluation of Solar Flares 1967", by Helen W. Dodson and E. Ruth Hedeman of McMath-Hulbert Observatory, The University of Michigan, and Marta Rovira de Miceli, San Miguel Observatory, Argentina, June 1972, single copy price 15 cents.

Report UAG-20, "Catalogue of Data on Solar-Terrestrial Physics", prepared by Environmental Data Service, NOAA, Boulder, Colorado, October 1972, single copy price $1.50 (supersedes Report UAG-15, 1971.)

Report UAG-21, "Preliminary Compilation of Data for Retrospective World Interval July 26 - August 14, 1972", compiled by J. Virginia Lincoln and Hope I. Leighton, WDC-A for Solar-Terrestrial Physics, November 1972, single copy price 70 cents.
