## Preface

This bibliography has been prepared in the NOAA Central Library on the occasion of the Symposium on the 50<sup>th</sup> Anniversary of Operational Numerical Weather Prediction, 14 – 17 June 2004, at The University of Maryland, College Park, Maryland. The focus of this selection is on the early publications in numerical weather prediction mainly by the staff members of the U.S. Joint Numerical Weather Prediction Unit and later by the National Meteorological Center. The bibliography also incorporates the list of historical publications selected by Dr. Eugenia Kalnay, Dept of Meteorology, University of Maryland, and prepared by Major Jimmie Trigg, USAF, Air Force Liaison Officer to the NOAA's National Centers for Environmental Prediction (NCEP). Most of the included publications are available in print in the NOAA Central Library and/or in an electronic format via NOAALINC, its online catalog at: <http://www.lib.noaa.gov/uhtbin/webcat> . Many early publications have been scanned and are available in full text, in PDF format, either directly online or from the included CD-ROM. Some of the entries are accompanied by an abstract. The bibliographic citations have been based on Chicago Manual of Style, 15<sup>th</sup> edition and are organized in the author and title order. Notes and explanations are included in brackets. Symbols “less than” (<) and “greater than” (>) are used to indicate first and/or latest issue consulted. The bibliography was compiled using the Microsoft Word program. To access full text documents hold CTRL key plus click to follow link(s).

Thanks go to Doria Grimes and Diana Abney, Librarians, and Dr. Elaine Collins, Information Specialist at the NOAA Central Library, and to Kenneth Campana of the NOAA's National Centers for Environmental Prediction (NCEP) for support and help with creating this bibliography.

Allen, Roger A. 1942. A review of some methods of long range forecasting: a technical note. Washington, D.C.: U.S. Dept. of Commerce, Weather Bureau.

Abstract: "The results of these studies have been compiled in individual reports which have been published as a group in Supplement No. 39 of the Monthly Weather Review, entitled 'Reports on Critical Studies of Methods of Long-Range Forecasting.' Credit for the work goes entirely to the authors of the separate reports; the purpose of this present paper is only to summarize briefly the methods and conclusions as to their reliability as given in the published report."

Clapp, Philip F. 1968. *Northern Hemisphere cloud cover for selected late fall seasons using TIROS nephanalyses.* Suitland, Md.: U.S. Dept. of Commerce, Weather Bureau. *ESSA Technical Memorandum*; 44. "December 1968."

Abstract: "Northern Hemisphere fields of mean cloudiness were constructed using TIROS nephanalyses for the late-fall seasons (Oct. to Dec.) of 3 years, 1962-64. These may be useful in studies of cloud climatology and year-to-year variations of the earth-atmosphere heat budget; and for designing and testing cloud-modeling procedures in numerical experiments. Shortcomings were revealed in the present subjective nephanalysis documentation which hopefully will soon be corrected by the promising work now going on in digitizing the video pictures."

Cressman, George P. 1957. *An objective analysis study*. Washington, D.C.: Joint Numerical Weather Prediction Unit. Mimeograph. *Technical memorandum (Joint Numerical Weather Prediction Unit (U.S.));* no. 12. "June 1957."

Abstract: "The method of objective analysis used by Joint Numerical Weather Prediction Unit is described. The 12-hour forecast is used as a starting map. The height field of the forecast is modified to eliminate large scale height errors from the forecast and is then used as a preliminary map for the final objective analysis. The final analysis fits the data around each point to a quadratic surface representing the height field. The 12-hour forecast wind and the preliminary heights, suitably weighted, are used as auxiliary data. In collaboration with Major H.A. Biedent, a modification of this method of analysis has been developed for nongeostrophic objective analysis, i.e., one in which the relation between winds and heights is described by the balance equation. The results of preliminary tests are given."

Atmospheric Administration, National Weather Service, National Meteorological Center. *NOAA technical memorandum NWS NMC*; 69. "June 1989."

Abstract: "A new NESDIS technique to produce temperature profiles from radiance information measured by satellite-borne sensors has been evaluated. The new procedure relies on explicit knowledge of the physical processes involved, while the previous operational procedure required only a set of a priori statistics. The evaluation was performed using data impact studies, a departure from the previous NMC practice of using only collocation statistics to make such evaluations. Two real-time data impact studies were performed. The results of the second data impact study led to operational use of temperature retrievals produced by the new method, beginning on September 20, 1988. The experiments demonstrate the necessity for a close cooperation between a data producer (NESDIS) and a data user (NMC) as the meteorological community moves toward an era of consolidated data assimilation procedures."

Washington, D.C.: U.S. Dept. of Commerce, National Oceanic and Atmospheric Administration, National Weather Service, National Meteorological Center. *NOAA technical memorandum NWS NMC*; 52. "February 1973."

Abstract: "Results of investigations indicate that many of the problems that prevent rawinsonde data from reaching the user can be rectified by proper quality control procedure. Methods have been developed to test the effectiveness of quality control, and these have resulted in significant Improvements in data usage in NMC. Typically, data utilization from U.S. moving ships in the Pacific was increased from 35% to 95% in less than 3 years; from the NWS Pacific Region, data procurement and use more than doubled between 1968 and 1972; and improvements in data from conterminous U.S. stations could be projected to indicate an increase of 5,000 additional observations being processed annually at NMC. Data quality can be improved and sustained only while active monitoring and deficiency notification programs are in operation. When such programs are terminated, data quality deteriorates to original levels. An effective program to adequately control data quality must involve integrated functions at data sources, communications centers, processing centers, and, most importantly, headquarters elements."

"February 1970."

Abstract: "A diagnostic study of the mechanism responsible for producing high wave number oscillations (noise) in the numerical solution of the nonlinear equations governing a free surface, barotropic, atmospheric model is reported. The oscillations are identified as predominantly the result of the lattice of the difference equations and the boundary conditions employed to specified the solution. The analytic methods employed involved the use of space and time sections of the numerical solutions to provide a set of hypotheses. These are tested utilizing a one-dimensional linear analog of the model equations. The solution of the linear equations is obtained analytically, by the method of characteristics, and numerically. Several possibilities for removing the noise are suggested. Some improvement is demonstrated when the suggested methods are used in the linear one-dimensional analog."

Abstract: "Investigations of the computational stability of finite difference formulations of the equations governing shallow water, non-linear gravitational oscillations are reported. The investigations consist of empirical analyses of the results of numerical integration of the quasi-two-dimensional and fully two-dimensional versions of the equations. The results obtained in the quasi-two-dimensional experiments suggested the formulation of filters for use in approximating the non-linear terms. By filtering certain high frequency non-linear interactions, it is found possible to archive relatively well-behaved long term integrations. A number of efforts to extend this result to the fully two-dimensional equations are indicated. One procedure was found to be practically successful, but is finally rejected on the basis of the instability of its linear counterpart. The paper concludes a critique of possible extensions of the investigation."

Abstract: "Air Pollution Potential (APP) is definable as a measure of the inability of the atmosphere to adequately dilute and disperse pollutants emitted into it based on values of specific meteorological parameters of the macroscale features. To delineate areas on the macroscale in which high APP has the greatest probability of occurring, a stagnation index has been developed independent of mixing height and transport wind speed data. The associated stagnation conditions are usually manifested stable stratification, weak horizontal wind speed components and little, if any, significant precipitation. We describe the numerical and subjective means by which stagnation areas are delineated, mixing height and transport wind speed calculated, and how high APP conditions are transmitted to our users via facsimile and teletypewriter. The resulting program is a joint effort of the Development Division of the National Meteorological Center (NMC) and the Division of Meteorology of the National Air Pollution Control Administration (NAPCA)."

Mimeograph. *Technical memorandum (National Meteorological Center (U.S.))*; no. 31.

Abstract: "This memorandum describes the current NMC numerical system of deriving first-guess fields for constant-pressure height and temperature analyses up to 500 mb. This system, which became operational at NMC in February 1965, insures reasonable static stabilities as implied by the objective height analyses. It reduces the amount and variety of bogus data previously used and allows the monitoring analyst to concentrate on two key analyses only, i.e., the 1000 mb and 500 mb analyses."

*Technical note (United States. Weather Bureau) ; 30. Technical memorandum (National Meteorological Center (U.S.)); no. 35. "January 1966."*

Abstract: "The requirements for a complete moisture parameter include not only measure of the degree of saturation but also a measure of the quantity of water vapor. "Saturation Thickness" meets these two requirements when the thickness of the layer is also considered. The saturation thickness is defined as a hypothetical thickness required to produce saturation, given the moisture quantity and lapse rate of the layer. Tables of saturation thickness are given for the moist and dry adiabatic, and U.S. Standard Atmosphere lapse rate over a temperature range at 1000 mb of -40°C to +40°C. The 1000-500 mb layer has been divided into the three layer intervals corresponding to the standard radiosonde levels. The tables should obviate the efforts of other investigators to derive this information. The significance of errors arising from assumptions and computational approximations is investigated in the Appendix."

**Abstract:** “Certain truncation errors occur in numerical weather prediction models when a grid-point representation of the variables is used to simulate advection phenomena. The errors are manifest by excessive values of the variables and upstream propagation of small-scale noise. The mechanism causing these errors is studied by numerical experiments and harmonic analysis. Several ways to avoid or prevent errors of this kind are cited. Inclusion of a horizontal diffusion term in the scheme may be necessary to remove the errors completely.”

Abstract: “The main purpose of the present memorandum is to describe and compare the results of the two experiments in 1000 mb prognosis. In section 2, the modeling assumptions and computational procedures of the Eulerian experiment are reviewed. The results of the experiment are evaluated subjectively in section 3 and some sample forecasts are shown. The background

of the quasi-Lagrangian experiment is outlined in section 4. Finally comparisons of the Eulerian and Lagrangian solutions in a limited number of cases are presented in section 5.”

"August 1967."

Abstract: "With the recent availability of numerical means of calculating pseudo-adiabatic lapse rates, it has become possible to perform rather detailed sounding analyses in a routine operational manner. A number of stability and energetic parameters derived from sounding analysis, which are computed at NMC, are described. Also, with the inclusion of various moisture parameters into the six-layer primitive equation (PE) forecast model, it is possible to make forecasts of a somewhat simpler stability parameter, the lifted index. The method of calculation of this quantity and some sample forecasts are presented."

Thompson, Philip Duncan. 1955. *A theory of large-scale disturbances in nongeostrophic flow*. [Washington, D.C.: Joint Numerical Weather Prediction Unit.] "30 March 1955."

**Abstract:** "The primary aim of this paper is to derive a complete system of modified hydrodynamical equations, which govern a large class of 'meteorological' motions of the atmosphere, but which cannot generate solutions corresponding to sound and gravity waves. The latter have no significant effect on the behavior of the large-scale disturbances; they do, however, create serious computational difficulties through the mere possibility of their mathematical extreme), and cannot be resolved by measurements at widely separated points. By a detailed analysis of the motion of a linear system, it has been found that the omission of the total derivative of the horizontal divergence from the divergence equation is necessary to exclude gravity wave solutions. In effect, this modification diverts all of the transformed internal and potential energy into the wave energy of the large-scale disturbances. In slightly stronger form, this type of modification is also sufficient to exclude gravity wave solutions from the general

nonlinear equations, and is essentially a generalization of the 'filtering approximations' introduced by Charney (1948). The scheme proposed for integrating the modified nonlinear equations is an iterative method, whereby a conditionally convergent sequence of approximate solutions can be generated from a known initial distribution of pressure. this method is applied to the solution of a system of equations which are one order of approximation higher than the equations of quasi-geostrophic motion, and provides basis for practicable method of numerical forecasting.”

Wagner, A. James. 1967. *Objective numerical prediction out to six days using the primitive equation model-A test case*. Suitland, Md.: U.S. Dept. of Commerce, Environmental Science Services Administration, Weather Bureau, National Meteorological Center. *Technical memorandum (National Meteorological Center (U.S.))*; no. 39. "May 1967."

Abstract: "This report is a brief summary of the results of a test case study using the primitive equations to make numerical predictions out to six days after the initial time. Daily and select 5-day mean chart of 500-, 700-, and 1000-mb height and 1000 to 500- and 1000 to 700-mb thickness, along with their departures from normal, were produced directly from the model. For comparison, the barotropic 500-mb forecast heights were also obtained, and both primitive and barotropic forecasts were compared with the observed heights and thicknesses."

Wolff, Paul M. 1958. *The error in numerical forecasts due to retrogression of ultra-long waves*. Washington, D.C.: Joint Numerical Weather Prediction Unit. Mimeograph. *Technical memorandum (Joint Numerical Weather Prediction Unit (U.S.)); no. 13*. "April 1958."

Abstract: "Error charts for the numerical barotropic forecasts prepared at the Joint Numerical Weather Prediction Unit since October, 1957 have revealed retrogressive patterns of very long wave-length. These errors are shown to be due to changes in the large scale components predicted by the numerical model. These components are actually quasi-stationary in the atmosphere. Forecasts prepared with an approximation to these components held unchanged show significantly increased accuracy. Finally, some of the difficulties in developing a more acceptable physical approach to this problem are outlined."

Youngkin, Russell J. 1967. *A snow index*. Suitland, Md.: U.S. Dept. of Commerce, Environmental Science Services Administration, Weather Bureau, National Meteorological Center. Mimeograph. *Technical memorandum (National Meteorological Center (U.S.)); no. 40*. "June 1967."

Abstract: "Information contained herein should be of primary interest to the short-range forecaster dealing with the snow versus rain problem. Also, those experimenting with obtaining snow forecasts from numerical prediction precipitation models may find it informative as to lower tropospheric thermal structure during important snowfall. The substance of this technical memorandum is taken from an unpublished report written in 1957 by R.J. Youngkin entitled, '1000-850-mb and 850-700-mb thickness-precipitation type relations.'"
