CENTRAL FLORIDA REGIONAL

HURRICANE SHELTER PLAN

Prepared for

Florida Department of Community Affairs
Bureau of Disaster Preparedness

By

Central Florida Regional Planning Council

October, 1982

The preparation of this report was primarily supported by a grant from the U.S. Office of Coastal Management, National Oceanic and Atmospheric Administration; and the Florida Office of Coastal Management, Department of Environmental Regulation through the Coastal Zone Management Act of 1972, as amended. Supplemental funding was provided by the Florida Department of Community Affairs.

ACKNOWLEDGEMENTS

The Central Florida Regional Planning Council wishes to thank the Department of Community Affairs, Bureau of Disaster Preparedness for its guidance on this project. We also wish to thank the East Central Florida Regional Planning Council and the Withlacoochee Regional Planning Council for their cooperation and assistance. Most importantly, we wish to thank the members of the Central Florida Inland Shelter Advisory Committee (in particular, the Polk County Public Safety Division, the DeSoto County Civil Defense Department, the Hardee County Civil Defense Department, the Highlands County Civil Defense Department, the Okeechobee County Civil Defense Department, the Lakeland Area Chapter of the American Red Cross, the Ridge Area Chapter of the American Red Cross, the Lakeland Police Department and the School Boards and Sheriffs Departments of DeSoto, Hardee, Highlands, Okeechobee and Polk Counties) for their support and guidance.

ABSTRACT

Title:	Central Florida Regional Hurricane Shelter Plan
Publisher and Author:	Central Florida Regional Planning Council
Date of Publication:	October, 1982

Number of pages:	260
Abstract:	The Central Florida Regional Hurricane Evacuation Plan is designed to provide multi-county data on coastal and inland evacuation and sheltering demands under various hurricane scenarios. It is also designed to be part of a coordinated statewide hurricane evacuation and shelter plan having the goal of minimizing the loss of life and property during a major hurricane.

I. INTRODUCTION

The State of Florida has always been vulnerable to the destructive forces of hurricanes.[1] The Gulf coast of the State has been particularly susceptible to damage from hurricanes due to the relatively shallow waters of the Gulf of Mexico, and the very low elevations of the Gulf coastline. These elevations are as low as 20 feet above Mean Sea Level (MSL) 20-25 miles inland from the coast (as in Collier County). With the tremendous growth of Florida's population over the last thirty years, the potential for loss of life and property has also increased dramatically.

While the population most vulnerable to major hurricanes in the Gulf is obviously that along the coast, a substantial portion of the population of inland counties is also vulnerable. As the population of the State increases, the need for realistic hurricane evacuation and sheltering plans becomes more acute; not only for coastal areas, but for inland areas as well.

Two coastal hurricane evacuation plans have been completed as of this writing. One covers the six-county Southwest Florida planning region of Hendry, Glades, Collier, Lee, Charlotte, and Sarasota Counties.[2] The other covers the four-county Tampa Bay planning region of Hillsborough, Manatee, Pasco and Pinellas Counties.[3] These detailed plans illustrate the large areas of the Gulf coast which are vulnerable to the wind, flooding, and storm surges of a major hurricane. They identify the number and location of people in each county of the respective planning regions which would need to evacuate prior to eye landfall of hurricanes of differing characteristics. They identify the number of evacuees which would seek shelter outside the regions. They identify the routes which would be used by evacuees to reach areas of safety. They summarize behavioral surveys which indicate the tendencies of people in a hurricane situation. Most importantly, however, these plans have, for the first time, quantified the time required to safely evacuate vulnerable coastal areas prior to eye landfall of hurricanes of different paths and intensities. This "evacuation time" is the sum of the time it takes to move the vulnerable population from their homes to their destinations and the time prior to eye landfall when roads become inundated or when sustained gale-force winds begin. It is , in several cases, much greater than the amount of time (12 hours) during which the National Weather Service can accurately predict the eye landfall of a hurricane. Lengthly evacuation times (up to 17½ hours, depending on the strength and path of the storm), mean that evacuation orders must be issued earlier in relation to eye landfall, as the Tampa Bay study points out.[4]

As the coastal population grows, so must the coastal evacuation times. Therefore, the Tampa Bay study asserts, there will be instances when evacuations will be ordered for areas which ultimately will be spared by

a hurricane which has changed course. "The 'crying wolf' situation is one that must now be accepted as a necessary precaution for areas of intensive coastal residential development," because more accurate hurricane forecasting by the National Weather Service is unlikely in the forseeable future.[5]

The implications of long evacuation times and the "cry wolf" situation extend beyond the coastal counties. Hurricane Donna was the last major hurricane to directly affect the Central Florida Region.[6] Because of the growth and development of Central Florida during the last 20 years, many communities and local officials may not be aware of the potential impact a landfalling or parallelling storm in the Gulf will have on their emergency response capabilities. This report will give local officials specific information with which they can update their local plans as they relate to multi-county hurricane evacuation scenarios.

II. OBJECTIVE AND SCOPE

The objective of this plan is to provide local elected officials, disaster preparedness and law enforcement agencies with information which will be used to prevent or reduce the loss of life and property during a major hurricane. This information, presented in quantified terms, will reduce the speculation and guesswork which has predominated in hurricane evacuation and sheltering plans. No plan can predict the future with 100% certainty, however, especially when natural disasters and human nature must be considered. In fact, this plan is based on several assumptions made necessary because of a fortunate lack of major hurricane activity in this area in the recent past. (These assumptions will be noted at appropriate points in the text.) This plan, however, is based upon the best available data as well as accurate first-hand research.

This plan is regional, or multi-county in scope. This is a relatively innovative approach to hurricane planning, as opposed to much of the planning of the past which has focused on local or county-wide responses to a hurricane emergency. Obviously, major hurricanes do not damage one or two square city blocks, one or two square acres, or even one or two square miles. They can cause serious destruction in several counties or several states, as history has demonstrated many times. The State of Florida, recognizing its vulnerability and the multi-county impacts of major hurricanes, contracted with three regional planning councils (Central Florida, East Central Florida, and Withlacoochee) to draft interrelated inland shelter plans which address impacts such as the inter-regional evacuation of thousands of people. One purpose of this plan, then, is to show local officials the "big picture" of several hurricane scenarios and outline to them the implications for their jurisdictions of a major landfalling or parallelling

---

[5]Ibid, p.2

[6]Donna was classified as a Category 3 hurricane on the Saffir/Simpson Scale as it passed over Central Florida.

hurricane. This plan will not provide detailed local information such as the intersections at which police officers should be deployed. It will, however, provide specific information from which local officials may develop detailed plans.

A. Study Area

The Central Florida Region consists of five land-locked counties (DeSoto, Hardee, Highlands, Okeechobee, and Polk) covering an area of over 4,900 square miles. With the exception of the Lakeland-Winter Haven (Polk County) urban area, the region is rural with approximately 67% of the land in agricultural holdings. The 1980 population of each county and the percent increase in population from 1970-1980 are as follows:

DeSoto:	19,039/45.8
Hardee:	19,379/30.2
Highlands:	47,526/61.1
Okeechobee:	20,264/80.4
Polk:	321,652/40.8

The topographic features of the Central Florida Region exhibit much the same pattern as the entire State of Florida. The four basic land formations in the region are highlands, ridges, intermediate plains, and lowlands. The highlands areas are primarily located in the northern section of the region: in Polk County, northern Highlands, and Hardee Counties. Ridge areas are scattered throughout Polk County through the western section of Highlands County. Intermediate plains cover the southern areas of the region. Lowlands areas are found in the northwest tip of Polk, the southwest portion of DeSoto and the northeast section of Okeechobee County.

Major floodplains exist along the Peace River (extending from Lake Hancock north of Bartow in Polk County to Charlotte Harbor near southeast DeSoto County) and its tributaries of Saddle Creek, Peace Creek Canal, Bowlegs Creek and Payne Creek. Other major floodplains exist along the Kissimmee River, in the Green Swamp of northern Polk County, in a large portion of Okeechobee County, and in the more densely populated areas around lakes in the region.

B. Work Tasks

The major tasks accomplished during the ten (10) month study period are as follows:

1. Identification of potential number of inland residents that may require shelter in the event a Category 3, 4, or 5 storm strikes or parallels the lower or central Gulf coast of Florida.

2. Inventory of designated inland county public shelters, and analysis of shelter capacity.

3. Determination of the feasibility of using current public shelters in relation to their location, elevation, potential wind hazards, and potential flood hazards.

4. A statistically significant investigation of behavioral tendencies of potential inland county evacuees.

5. Determination of additional shelter space needed to house coastal evacuees from the Southwest Florida and Tampa Bay planning regions.

6. Determination of intra and inter-regional evacuation routes and shelter assignments.

7. Identification of shelter checkpoint sites.

8. Development of an institutional framework for a coordinated inter-regional evacuation.

9. Establishment of a regional disaster preparedness committee.

Again, in keeping with the contractural requirements of this study, and to retain a measure of continuity with existing and ongoing regional hurricane evacuation and sheltering plans, this report is not intended to serve as the detailed operations plan for each unit of local government in the region. The implementation of any evacuation plan is a local function. Therefore, the actual deployment and assignment of manpower and equipment to carry out the evacuation is best planned for at the local level. However, this report sets forth the types and magnitude of activities that must be carried out to prevent large scale loss of life. The data provided by this report will enable the local governments of the region to draft specific operating procedures for the relocation of their vulnerable populations. This study does not address hurricane recovery or the direct protection of personal and real property.

III. HURRICANE EVACUATION ORGANIZATION AND AUTHORITY

The warning and response functions associated with hurricane evacuation are carried out by several entities at the Federal, State, and local levels.

A. National Weather Service

There are two major elements of the National Weather Service directly involved in the hurricane evacuation process. These are the National Hurricane Center and the Local Weather Service Offices.

1. National Hurricane Center

The need for hurricane evacuation is determined from a warning system that originates from the detection and monitoring of tropical cyclone activity by the National Hurricane Center (NHC) of the National Weather Service. The NHC, located in Miami, Florida identifies such activity as a tropical depression and monitors its development into

a tropical storm. At this point, the disturbance is named. As the tropical storm intensifies and the maximum sustained surface winds exceed 74 miles per hour, the disturbance becomes a hurricane. Throughout the monitoring of tropical cyclones, the NHC forwards information on the characteristics of the disturbance to a network of local National Weather Service offices throughout the country. This information is normally channeled in the form of advisory bulletins to the local offices at six-hour intervals. These advisory bulletins include the location and characteristics of the storm as well as forecasts as to what can be expected over the next 12 to 24 hours. As the hurricane comes closer to striking land (hurricane landfall), the six-hour interval advisories may be supplemented by intermediate advisories every three hours or even less if needed. The advisory bulletins and other information to local preparedness agencies also include any evacuation recommendations by the NHC. In addition, local and state disaster preparedness agencies are provided restricted information on the hazard potential of the hurricane as the storm moves within 72 hours of projected landfall. This information is channeled over the National Warning System (NAWAS) and normally categorizes the hurricane on a general descriptive scale of hazard potential. This scale, the Saffir/Simpson Hurricane Scale, defines the "category" of the hurricane based on several measurable characteristics or parameters of the storm. The scale appears as Appendix B.

2. Local Weather Service Offices

As the NHC forwards information on the hurricane to local National Weather Service offices, each office records and interprets the information relative to how it could be expected to affect its area of responsibility. DeSoto, Hardee, Highlands and Polk Counties fall under the responsibility of the Tampa Area Office of the National Weather Service located in Ruskin, Florida. Okeechobee County falls under the Palm Beach office of the National Weather Service. As the hurricane approaches a particular coastal area (e.g., the Tampa Bay Region), the local weather service office adds local statements to the advisory bulletins from the NHC. These local statements are forwarded via NAWAS to those county disaster preparedness agency communications centers included in the area addressed by the advisory bulletin. Local statements include recommended precautionary and response actions to be carried out and estimated times by when they should be completed. They include existing local conditions of winds and tides as monitored by local wind and tide gage systems. Local statements from the Tampa area office also include a description of any areas recommended to be evacuated from the approaching hurricane. Currently, such general descriptions entail the listing of estimated distances in blocks or miles from water bodies of land areas that should be evacuated. These areas are defined entirely by land elevations. Currently, Tampa office local statements would include one of two general lists of areas to be evacuated: (1) areas vulnerable to a 10 foot storm surge, or (2) areas vulnerable to a 20 foot storm surge.

B. State of Florida

The two major entities at the state level directly involved in the hurricane evacuation process are the Governor and the Florida Bureau of Disaster Preparedness.

1. The Governor

Authority to order evacuation from approaching hurricane is conferred to the Governor by Chapter 252.36 (5) (e); stating that the Governor may:

> "Direct and compel the evacuation of all or part of the population from any stricken or threatened area within the state if he deems this action necessary for the preservation of life or other disaster mitigation, response, or recovery."

2. Bureau of Disaster Preparedness

The Bureau of Disaster Preparedness under the Division of Public Safety Planning and Assistance, Department of Community Affairs is responsible for directing and coordinating disaster mitigation, preparedness, response, and recovery activities of the State. Included in the many duties under these activities is the power to make official recommendations for prevention and preparedness measures designed to eliminate or reduce disasters or their impact. Consequently, the Bureau performs the primary staff function to the Governor during disaster emergencies and recommends to the Governor the nature, extent, and timing of the issuance of the evacuation order.

The Bureau is linked to the NHC and local weather service offices by communications channels including NAWAS. In addition, emergency communications with local governments are maintained over NAWAS and through a network of four area coordination offices throughout the State.

C. Local Government

At the local level; elected officials, local disaster preparedness agencies, and other departments of local government all become involved in the evacuation process.

1. Elected Officials

The same power to order evacuation from an approaching hurricane conferred upon the Governor under Chapter 252.36 (5) (e), Florida Statutes, is also delegated to the governing body of each political subdivision of the State by 252.32 and Executive Order 80-29. The term "political subdivision" is defined under the Statute as "any county or municipality created pursuant to law." Therefore, the chief elected official of both counties (chairman of the board of commissioners) and municipalities (mayor) is delegated the power to order the evacuation from an approaching hurricane.

2. County Disaster Preparedness Agencies

Just as the Bureau of Disaster Preparedness recommends emergency measures to be ordered by the Governor, county disaster preparedness agencies serve the same staff function to the governing body of the political subdivision. Hurricane evacuation orders are normally issued by the chief elected official based on the recommendation of the director of the county disaster preparedness department, or previously established disaster advisory council/ committee. Such recommendations should be based on previously formulated evacuation plans.

3. Municipal Disaster Preparedness Agencies

Although not mandated by Chapter 252, Florida Statutes, as counties are, municipalities are authorized by the same Statute to create and establish a local disaster agency for disaster operations and planning. Just as with counties, the decision of the governing body to order an evacuation normally results from a recommendation from the municipal disaster preparedness director or disaster advisory council.

4. Local Government Departments

The actual execution of an evacuation requires local resources normally based in several key county or city departments. These key departments include law enforcement, fire, public works, utilities, health services, and traffic engineering. Disaster preparedness or response activities of the manpower and equipment of such departments are coordinated by the local disaster preparedness department upon declaration of emergency conditions. Although normally directing a departmental function in day-to-day governmental operations, the disaster preparedness director automatically assumes the direct line function of primary advisor to the governing body for disaster activities.

D. American Red Cross

The local chapters of the American Red Cross are responsible for the overall management of public natural disaster shelters as designated by local government. This includes the provision of trained staff, food supplies, and registration procedures throughout the duration of the shelter stay. Such responsibility has been delegated by Congressional charter under Public Law 58-4.

E. Coordination of Government Action In Emergency Evacuation Decisions

The descriptions of organizational authorities in the preceding sections of this chapter show that the decision-making and evacuation ordering power has been conferred or delegated to three different levels of government; state, county and municipal. Further, the advisory authority of the National Weather Service at the Federal level is an essential component of the warning and evacuation procedure. Such emergency powers at the various levels of government are innate

responsibilities of the particular jurisdictions to safeguard the lives of their citizens. However, this diffusion of the authority to issue an evacuation order demands firm interjurisdictional coordination. An uncoordinated evacuation order could have a devastating impact on the safety of not only the citizens of the jurisdiction issuing the order, but also the surrounding jurisdictions of an urban region.

Chapter 252, Florida Statutes, the Governor's Executive Order 80-29, and the Florida Natural Disaster Plan empower any local political subdivision (county or municipality) to order an evacuation of its endangered population without prior order by other levels of government. Therefore, in the event that the state fails to order evacuation as early as required by specific local conditions, a county may order evacuation within its physical boundaries. However, evacuation orders of higher levels of government are binding upon lower levels of government. For example, a State order is binding upon counties and a county order is binding upon a municipality.

There is an obvious need for coordination of emergency action with other levels of government and private agencies to ensure the availability of adequate resources to support evacuation. As long as the evacuation decision-making forum includes all relevant jurisdictional entities communicating while analyzing the approaching hurricane hazard from a common data base, negative impacts of an evacuation should be minimized.[6]

1. Framework for Inter-regional Coordination

Because of the great strain that will be placed on manpower and resources in the Central Florida Region by an evacuation of coastal areas, it is imperative that Civil Defense and law enforcement agencies in Central Florida be informed about a coastal evacuation. The framework for this notification process centers on the Bureau of Disaster Preparedness Area Coordinators. (The Central Florida Region falls under two Bureau of Disaster Preparedness Areas, the South Florida Area, which covers DeSoto, Highlands and Okeechobee Counties; and the Central Florida Area which covers Hardee and Polk Counties.) The timely relay of a message regarding coastal evacuation to Central Florida counties is essential for these inland counties to initiate plans for the reception or pass-through of evacuees. Inland Civil Defense directors, upon being notified by the Area Coordinators, will inform their county commission chairmen, their county law enforcement agencies, the Red Cross, and other applicable departments and agencies about the impending coastal evacuation. During evening hours, or other periods when Civil Defense directors are off duty, the county sheriff would be notified first. The sheriff would then notify the Civil Defense director who will notify the commission chairmen, etc. Concurrent to the notification process, all intra-county emergency activities will take place per each county's emergency operations plan.

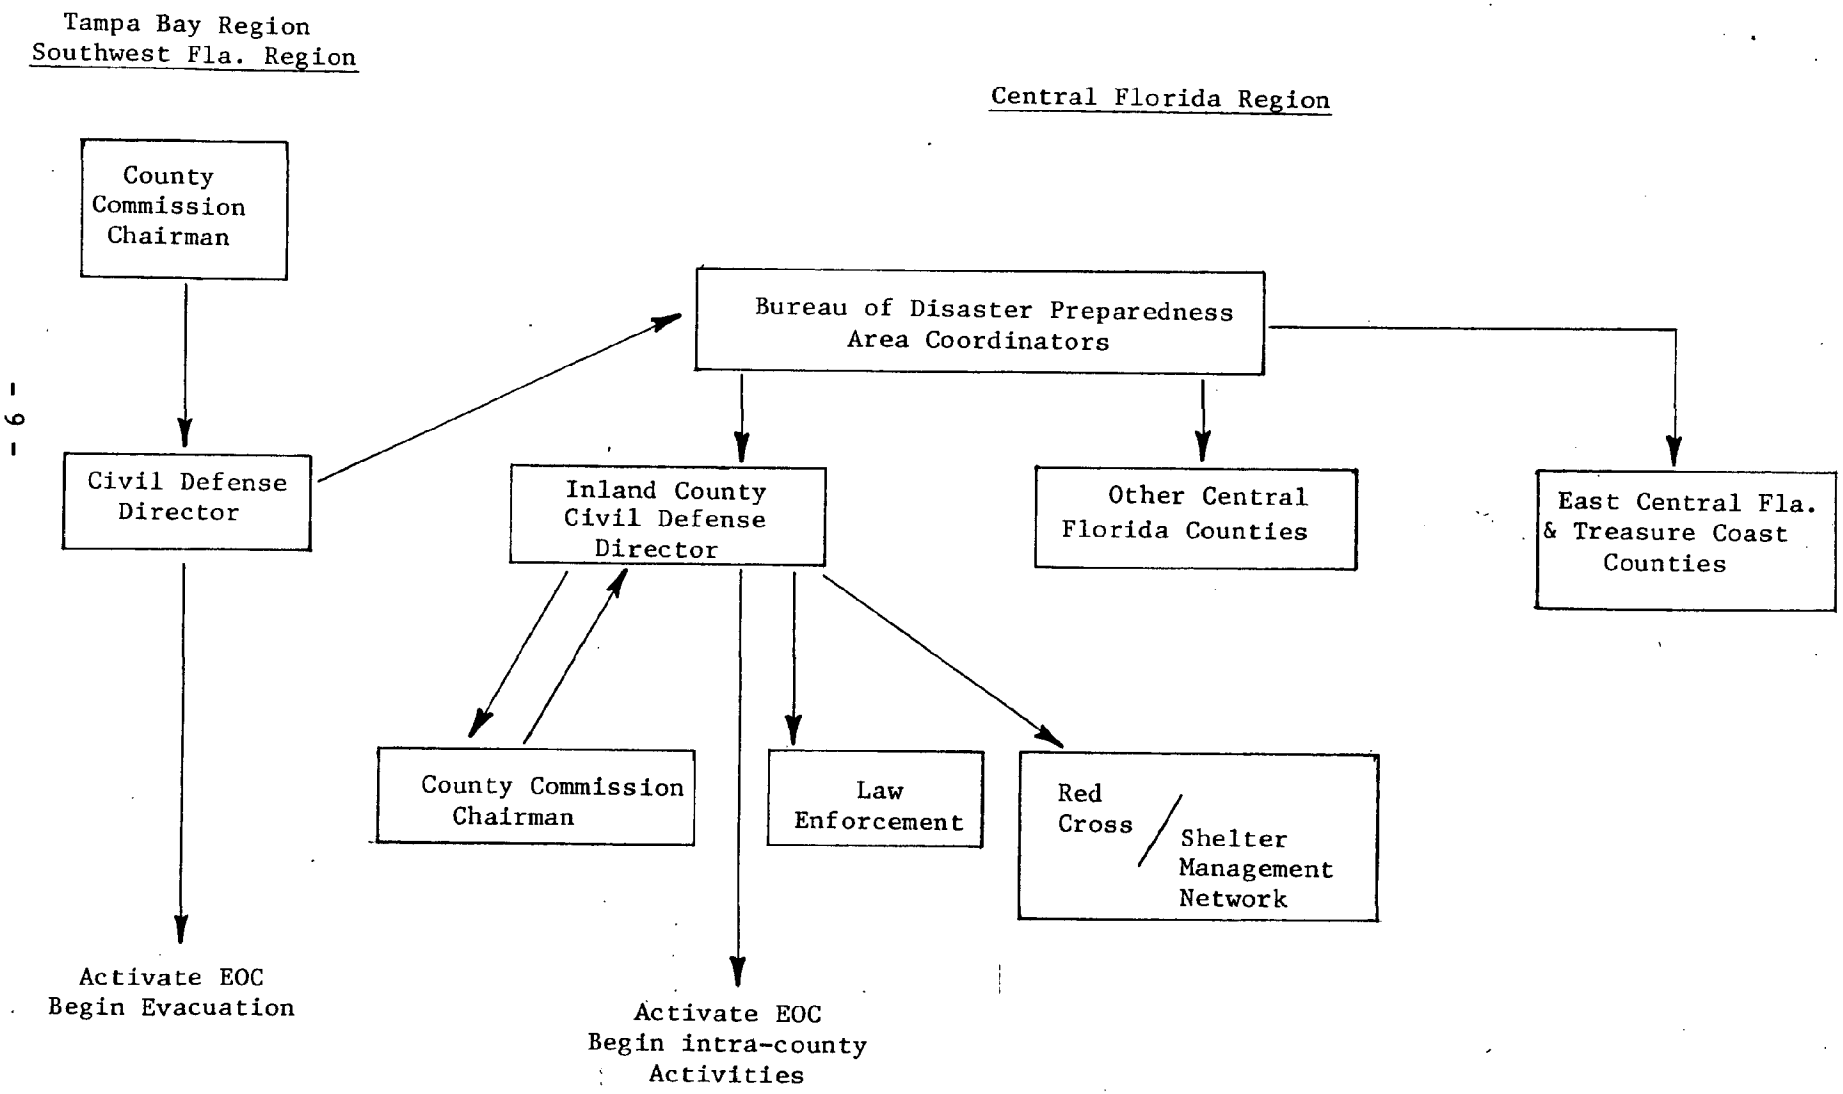
Figure 1 illustrates the proposed institutional framework.

---

[6]The preceding outline on Evacuation Organization and Authority is reprinted from the Tampa Bay Regional Hurricane Evacuation Plan, pp. 7-11.

FIGURE 1

FRAMEWORK FOR INTER-REGIONAL EVACUATION



IV. METHODOLOGY, BACKGROUND, AND RESEARCH

The formulation of a comprehensive and quantitative hurricane evacuation plan requires extensive data collection and analysis. Because a hurricane is created by nature and responded to by man, the unpredictability of both forces must be addressed through various assumptions when planning for an evacuation. This planning effort includes several such assumptions. However, attempts were made to quantify as many of the factors contributing to hurricane-vulnerability as possible with available resources. The methods by which the factors were quantified and brought together as the findings of the study, are described below. Included are the identification of the sources of existing data, and data analysis procedures.

A. Coastal Evacuation and Demand for Shelter

Prior to the eye landfall of a major hurricane (or the close approximation to the coast of a major parallelling hurricane), the Central Florida Region will receive thousands of coastal residents who have been ordered to evacuate the most vulnerable coastal areas. To accurately estimate this probable demand, estimates of the potential number, location and probable destinations of evacuees in the Southwest Florida and Tampa Bay regions were taken from the evacuation plans completed in those respective regions. These data were then augmented by information provided by the Bureau of Disaster Preparedness, which outlined the number of vehicles and vehicle occupancy rates per evacuation route entering the Central Florida Region for each of 12 hurricane scenarios.[7] (Appendix C)

The 12 scenarios developed by the Bureau represent possible hurricanes of varying paths and intensities in the Gulf of Mexico. "Regional Scenarios" 1 through 4 represent worst-case (Saffir/Simpson Category 5) hurricanes making landfall in Pasco, Pinellas, Hillsborough, and Manatee Counties respectively (the Tampa Bay Region). Regional Scenarios 5, 6, and 7 represent worst-case landfalling hurricanes in Sarasota, Charlotte and Lee/Collier Counties. Scenarios 8 through 11 represent less-than-worst-case landfalling hurricanes in Southwest Florida, and Scenario 12 represents a worst-case parallel storm.

Each of the 12 regional scenarios generates differing numbers of evacuees in each of the coastal counties. Thus, aside from differing regional weather conditions in each scenario, the demand on the regional road network in Central Florida and the demand on shelters in the Central Florida Region will be different in each scenario. In other words, just as Regional Scenario 3 (a worst-case hurricane striking Hillsborough County) will create the most severe conditions in Hillsborough County

---

[7] Report on the Expected Coastal Demand for Inland County Shelter Facilities from the Tampa Bay and Southwest Florida Planning Regions, Department of Community Affairs, Bureau of Disaster Preparedness, 1982.

and less severe conditions in adjacent coastal counties, Scenario 3 will, in the Central Florida Region, create the most severe demand on roads and shelters in Polk County and less severe conditions on roads and shelters in the region's other four counties. On the other hand, a worst-case hurricane striking any Southwest Florida County (Scenarios 5 through 7) will affect the Tampa Bay area very little, while severely taxing the entire Central Florida road and shelter network. This latter condition is due to the fact that the more rural counties of DeSoto and Hardee (which would receive coastal evacuees from Southwest Florida first) would be unable to shelter the majority of those evacuees and would have to pass them through to other counties in the region.

For the purposes of efficiently completing this plan, and as a matter of coordination with the East Central Florida Regional Planning Council which is conducting a similar study, the CFRPC staff has selected three possible worst case hurricane scenarios for detailed analysis. The three scenarios selected are: 1) A worst-case storm making landfall in Hillsborough County; 2) A worst-case storm making landfall in Sarasota County; and 3) The worst-case parallel storm.(See Figure 2) These scenarios were chosen because, in terms of vehicles and evacuees generated, they represent the worst case landfalling storms in the Tampa Bay and Southwest planning regions, and the worst of possible parallel storms. From summaries of the number of potential coastal evacuees in each regional scenario (Table 1), and the summary of routes to be used by evacuees entering the Central Florida Region (Table 2), one can see that, depending upon the storm track, the number of vehicles and evacuees, as well as the evacuation routes used, will vary significantly. It is important to note the effect of a major hurricane striking the lower Gulf coast, causing a large number of coastal evacuees to directly enter DeSoto and Hardee Counties and to indirectly enter Polk and Highlands Counties. It is also important to note the effects of a landfalling storm in the Tampa Bay region as well as a parallel storm. A landfalling hurricane in the Tampa area will cause a large number of evacuees to enter Polk County. A worst-case parallel storm will generate evacuees from Tampa Bay to the lower Gulf Coast. It is assumed, however, that a parallel storm will not generate evacuees from this region, as the wind and rain fields will not extend far enough inland to cause significant damage. The three selected scenarios as they affect Central Florida in terms of inter-regional evacuation routes, and the number of vehicles and persons evacuating, are illustrated in Figures 3,4, and 5.

With regard to the numbers of vehicles, evacuees, and evacuation routes entering this region, the following summarizes the assumptions made in the Bureau report on shelter demand:

1. Behavioral Assumptions

   (a) Of the population evacuating out of the Tampa Bay Region, the following may be seeking shelter in interior counties: Pasco County, 49.5%, Pinellas County, 33.8% Hillsborough County, 38.6%; Manatee County, 34.0% (Source: Tampa Bay Hurricane Evacuation Plan Technical Data Report).

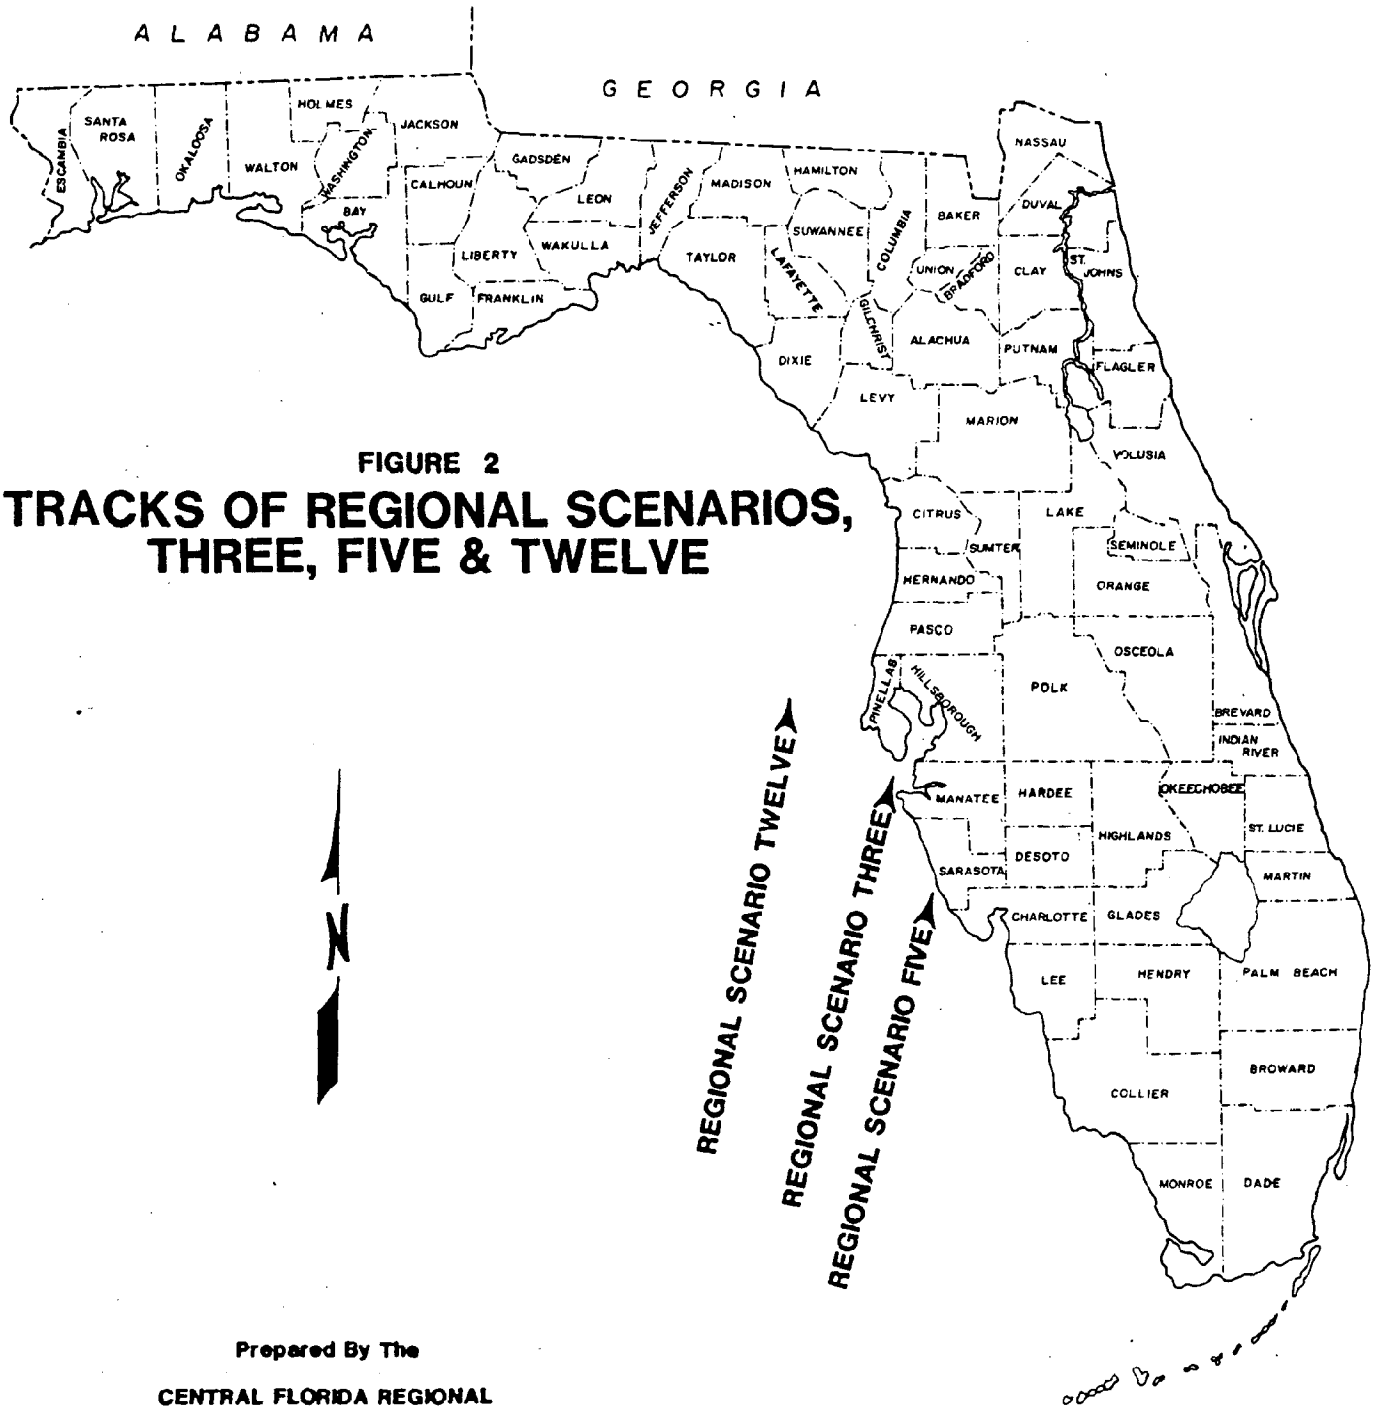


FIGURE 2

TRACKS OF REGIONAL SCENARIOS, THREE, FIVE & TWELVE

Prepared By The

CENTRAL FLORIDA REGIONAL

PLANNING COUNCIL

October 1982

(b) 34% of the Southwest Florida Planning Region's population effected by hurricanes will evacuate out of the region (Source: Southwest Florida Regional Hurricane Evacuation Plan).

(c) 45% of the Southwest Florida Planning Region's population effected by hurricanes will seek shelter (Source: Southwest Florida Regional Hurricane Evacuation Plan).

(d) That portion of the population seeking shelter who cannot find it due to an inadequate supply within their county will evacuate out of both Tampa Bay and Southwest Florida Planning Regions.

2. Conversion of Population to Number of Vehicles

(a) Vehicle occupancy rates for the Tampa Bay Region were derived from 1970 Census Data updated to 1979 data (Source: Tables G-11 through G-15, Tampa Bay Regional Hurricane Evacuation Plan Technical Data Report).

(b) Vehicle occupancy rates for the Southwest Florida Region were derived by dividing the number of people evacuating out of each county by the number of vehicles to be used in such an evacuation (Source: Southwest Florida Regional Hurricane Evacuation Plan).

3. Regional Traffic/Population Assignments

(a) Traffic assignments on routes out of the Tampa Bay Region were derived from Appendix G, Tampa Bay Regional Hurricane Evacuation Plan Technical Data Report.

(b) Traffic Assignments on routes out of the Southwest Florida Region were based on the routes' abilities to handle traffic based on their roadway capacities. In this manner, maximum use of the regional transportation networks is achieved while providing the shortest evacuation time possible.

- That portion of a county's population evacuating on I-75 would remain on that route until they leave the region.
- Evacuees using U.S. 41 would gravitate towards I-75 as they leave their respective counties.
- Evacuees from Collier, Lee, Charlotte, and Sarasota remaining on I-75 will be routed northeast on I-4.
- Traffic entering Manatee County on U.S. 41 and U.S. 301 from the Southwest Florida Planning Region will be routed east on S.R. 70.

- Traffic entering Sarasota County on U.S. 41 from Collier, Lee and Charlotte Counties will be routed east on S.R. 72.

- S.R. 765 in Lee County will not be used as an evacuation route by those evacuees from Collier County.

- S.R. 775 in Charlotte County will not be used as an evacuation route by those evacuees from Lee and Collier Counties.

- S.R. 31 in Charlotte County will be used primarily by evacuees from Lee County.

The behavioral assumptions listed above were based on a telephone survey of residents of the Tampa Bay Region, and a newspaper survey of residents of the Southwest Florida Region. The main question asked in these surveys was, to paraphrase, "If you were to evacuate, what would be your destination?" By combining the percentage of those who said they would go to a public shelter and the population expected to evacuate out of the coastal region(s), the demand for public shelter in Central Florida was derived.

B. Hurricane Hazards and Vulnerable Populations

Because of its relatively close proximity to the Gulf coast, and because of its topography, the Central Florida Region will be the area where most coastal residents who evacuate out of their region(s) will seek shelter. Moreover, depending upon a hurricane's characteristics and path, there will be evacuees from Central Florida who will be seeking public shelter as well.

To determine the number of inland residents which will need to evacuate in the event of a hurricane, an analysis of the hurricane-related hazards which may threaten the lives and property of Central Florida residents was appropriate.

The most destructive force of a hurricane is the "storm surge". This mound of seawater pushed ahead of a hurricane (reaching as much as 18 feet above the level of the tide) is the biggest killer of coastal residents. It is the threat of the storm surge and accompanying saltwater flooding, along with the threat of high winds, which will trigger coastal evacuations. The storm surge is obviously not a threat to Central Florida residents.

Two other hazards related to hurricanes will threaten residents of the Central Florida Region, however. These are freshwater flooding caused by heavy rain, and hurricane-force winds.

Rainfall cannot be predicted for any given hurricane. There are no rainfall standards that may be applied to the regional hurricane scenarios developed by the Bureau, for example. As a rule of thumb, however, a hurricane can be expected to produce from 6 to 12 inches of rain. Hurricanes can be "wet" (producing much more than 12 inches in a short period of time), or "dry" (producing very little rain).

With regard to heavy rainfall, most of the Central Florida Region is relatively secure from large-scale freshwater flooding. Again, the populated areas most vulnerable to flooding are along the Peace River (particularly in DeSoto County), parts of Okeechobee County, and the more densely populated areas around lakes. Other less populated areas susceptible to flooding are in northern Polk County (the Green Swamp area) and along the Kissimmee River. While flooding in the Green Swamp or along the Kissimmee may not threaten many lives, flooding along the Peace River and around lakes may threaten hundreds of lives. Flooding in any or all of the above-mentioned areas may hinder evacuation or transportation through those area(s).

Even before the onset of flooding, rainfall will slow traffic movement on the regional road network because of poor drainage of road surfaces. This problem is especially acute on older, two-lane roads, which make up the bulk of the regional road system.

There were several problems related to analyzing flood hazards in Central Florida. First, up-to-date floodplain maps and information generally were not available. Second, ascertaining the exact threat posed by flooding was difficult. Questions remain as to how high flood waters will rise in 100 year or 500 year floods. In June, 1982, DeSoto County experienced a 10 year flood which caused the evacuation of low-lying areas near the Peace River, inundated cars and other vehicles near the River, and caused at least one regional road to be closed temporarily (S.R. 72).

According to the National Weather Service, the Central Florida Region can expect to experience a storm no stronger than a Category 3 hurricane on the Saffir/Simpson Scale (Appendix B). This is because hurricanes lose strength as they move overland, and a Category 4 or Category 5 hurricane would be expected to dissipate to a Category 3 by the time it reached this region.

Obviously, the wind speed of a hurricane is easily measured and categorized. Wind damage can thus be more easily predicted than flood or rain damage, as the descriptions of the categories of the Saffir/Simpson Scale in Appendix B illustrate. The only unpredictable wind hazards related to hurricanes are gusts, which can be considerably higher than the storm's sustained winds; and tornados which may be generated in or near a hurricane.

Aside from severe damage to signs, utility poles, and trees (and possible road blockage as a result), other wind damage will occur.

Buildings of differing structural integrity will withstand hurricane force winds differently. Large, well constructed buildings will sustain little damage in a Category 3 storm. Similarly, well constructed homes will sustain minimal wind damage. The housing type which is most likely to sustain serious life-threatening damage is the mobile home. By their nature, mobile homes are light weight and can be easily overturned by high winds as has been demonstrated many times in all parts of the country. Although some mobile home residents believe that they live in a relatively new unit with its required tie-downs, and that their unit will weather a hurricane, they should know that state regulations do not require the mobile home to withstand hurricane force winds. Similarly, tie-downs cannot be counted on to secure the mobile home in high winds. Moreover, windborne debris can severely damage the most securely tied down mobile home.

(Appendix D illustrates the path and intensity of Hurricane Donna, a Category 3 storm as it crossed Central Florida in September, 1960. Note the sustained wind speeds, wind gusts, rainfall amounts, and the extreme drop in barometric pressure recorded at Ft. Myers and Lakeland.)

The most vulnerable populations in the Central Florida Reigon, then, have been determined to be mobile home residents and people residing in flood prone areas (Table 3). While mobile home residents can be enumerated with reasonable accuracy, people living in flood plains can only be estimated due to the lack of up to date flood maps and the absence of any previous census of these residents. The following estimates are relatively accurate; however, they should be considered conservative. Residents-in-flood-plain estimates are for 100 year flood plains. Available maps for the Region do not indicate significantly larger areas for 500 year flood plains, so it is assumed that the population in a 500 year flood plain is not substantially larger than that in a 100 year flood plain.

Regarding differences in storm magnitude, both of these vulnerable populations in totality would be evacuated prior to the onset of gale-force-winds. Since the onset of gale-force winds generally approximates the onset of freshwater flooding in a hurricane, both mobile home and flood plain residents would become vulnerable at the same time.

There is some overlap between mobile home and flood plain residents; however, the exact number of mobile homes in flood plains is not known.

Estimates of the mobile home population assume a household size of 2.2 persons and a seasonal vacancy rate of 25%. The vacancy rate was applied across the board even though vacancies vary by type of resident. That is, a retiree is likely to be a permanent resident of a county whereas a "snowbird" is not likely to reside in the county during the hurricane season. In mobile home parks, the seasonal vacancy will vary with the tenure of its residents. Some parks experience a vacancy rate as high as 30%, and some less than 25%.

The estimates which follow in Table 3 were derived from several sources; the University of Florida Bureau of Economic and Business Research (Florida Statistical Abstract, 1981), the U.S. Bureau of the Census, available flood insurance and other flood plain maps, and various local department and agency representatives.

TABLE 3

POPULATIONS VULNERABLE TO HURRICANES
IN CENTRAL FLORIDA - 1980

County	Mobile Home Residents*	Flood Plain Residents*
DeSoto	4,118	8,000
Hardee	1,892	5,000
Highlands	11,400	5,500
Okeechobee	4,660	9,000
Polk	57,900	42,000
Region	79,970	69,500

C. Central Florida Shelter Facilities

The second task of this study (following the formation of the Central Florida Inland Shelter Advisory Committee) was to inventory the designated public shelters in the five-county region. This time-consuming effort has yielded the most complete set of data on public shelters ever compiled in any of the counties. Using an inventory form similar to that developed by the East Central Florida Regional Planning Council, detailed information was gathered on each shelter's location, construction sources of power, wastewater and potable water facilities, and areas of safety, based on 20 and 40 square feet per person.

CFRPC staff originally tried to visit each shelter to conduct an inventory but later relied on individual school principals or school board representatives, clergymen, and other building owners to complete an inventory form as best they could and return it to the staff. The accuracy of the most important information on the inventory sheet (shelter adequacy and capacity) is thus limited by the judgement of the person who completed the inventory. While CFRPC staff has no evidence to show inaccuracies in the shelter data, Red Cross and/or Civil Defense officials may want to verify the information contained on the inventories, and as part of this process, involve a local building official to reassess each structure's ability to withstand hurricane forces. Several buildings designated as shelters in the Region were found to be unfit for one reason or another. More than one school was found to be inadequate because it was constructed in a finger wing configuration with fully one side of each wing on the campus being glass. Moreover, these schools had restrooms which were separate from the wings (i.e., one must go outside to

another wing to use the restroom). Several of the newer schools in the Region have been designed to be dependent on air conditioning systems. These schools generally have a small number of windows (if any), and are without auxiliary power. Thus, if the power is cut off during a storm, such schools will be without lights and ventilation. It will be recommended that these schools, if used, house a minimum number of evacuees. With the exception of about five designated shelters, auxiliary power is unavailable to shelters. Schools in unincorporated areas generally are served by package wastewater treatment facilities. These treatment facilities obviously would be inoperable if power was cut off.

Nearly all designated shelters (with the exceptions of obviously unfit buildings alluded to above) may be used to shelter evacuees in the event of a hurricane. All appear to have structurally sound shelter areas and relatively adequate parking facilities. Most shelters, however, appear to be unequipped or underequipped to provide extended meal service, communications, transportation, first aid, and again, auxiliary power.

The Central Florida Regional Planning Council has found that formally trained shelter managers in the Region are in short supply. As of October, 1982, Red Cross and Civil Defense officials in most Central Florida counties were recruiting volunteers to be trained as shelter managers. School principals are expected to participate in managerial duties at their respective schools, and CFRPC staff, in its contacts with principals in the region, have found most to have an intimate knowledge of their facilities. Staff was surprized, however, to find several principals who had a poor knowledge of their school's layout; especially areas which may be used to shelter evacuees. Several others, while being knowledgeable about their facilities, had never considered how the facilities would be used in a hurricane emergency or how they would participate in emergency activities. Because of the great strain which will be placed on disaster-response agencies during a major hurricane, "on the job training" of shelter managers or assistant managers should be avoided to the greatest possible extent. The school boards, Red Cross chapters and Civil Defense officials should, at the very least, instruct principals as to exactly what will be expected of them during an emergency.

Designated public shelters in each Central Florida county which were inventoried and determined to be adequate to withstand hurricane hazards are listed below in Table 4. Note the county totals at the end of each county list. Shelter locations for DeSoto, Hardee, and Okeechobee are mapped in Figures 8,9, and 10 respectfully. Shelter locations in Highlands County are mapped in Figures 11 (a) and 11 (b). Shelters in Polk County are mapped in Figures 12 (a), 12 (b), 12 (c) and 12 (d).

This list of shelters should not be considered permanent and inflexible. The list will be evaluated periodically by local officials and individual shelters may be added or deleted as necessary, thus changing the total shelter capacity of the individual counties and the Region.

D. Shelter Usage

While Table 3 illustrates the estimated number of Central Florida residents who will be most vulnerable to wind and flood hazards, not all of

these residents will evacuate to public shelters in the Region. Some may evacuate to a more substantial conventional home of a friend or relative. Some may seek shelter at a hotel or motel. Some may evacuate out of the Region, and unfortunately some will refuse to evacuate at all. The majority of the vulnerable inland populations are expected to seek public shelter, however.

To better evaluate the tendencies of inland evacuees, the CFRPC contracted with the University of South Florida to conduct a survey of residents of each county. The telephone survey of 1,257 people was representative of each county's mobile home and non-mobile home populations. Because mobile homes are most vulnerable to hurricane hazards, mobile home residents were slightly oversampled. Information derived from the 13-item questionnaire is presented in tabular form in the University of South Florida's report (Appendix E); and is broken down by county. Some of the most important highlights are as follows:

1. The population in general and especially those who live in mobile homes is elderly. (Appendix E, Table 5)

2. Although a relatively small percentage of the residents need special assistance to evacuate or are without transportation, in absolute numbers this could be a substantial amount of people. (Appendix E, Tables 7,8,9)

3. Although a substantial percentage of the respondents indicated experience with hurricanes, this experience except for Okeechobee County was with Donna in 1960. (Appendix E, Table 15)

4. The National Weather Service is the source of advice, as to whether and when to evacuate, that people most frequently mentioned. (Appendix E, Table 19)

5. Most people will evacuate when ordered to do so, and mobile home dwellers would tend to evacuate prior to the order to do so. (Appendix E, Table 21)

6. If family members are home, respondents indicated they could be ready to leave almost immediately. (Appendix E, Table 20)

7. In general only one vehicle per resident will be used. (Appendix E, Table 26)

8. Most people would evacuate to public shelters within their own county. Based on these data, there will be a great demand placed on public shelters. (Appendix E, Table 29)

9. A substantial proportion of respondents do <u>not</u> know where their public shelter is. (Appendix E, Table 28)

The most important finding of the survey relates to anticipated public shelter use by inland residents. Referring to Table 29 of Appendix E, it is clear that a majority of mobile home residents in each county who named the type of shelter they would seek, indicated they would go to a public shelter. However, if one adds the percentage of mobile home residents who don't know where they would go to the "public shelter" respondents, the potential demand for public shelter is tremendous. Further, if the percentages of non-mobile home respondents who said they would seek public shelter or don't know where they would go, actually seek public shelter, the demand for public shelter in Central Florida increases dramatically. It is therefore important that local officials discourage people who live in substantially constructed conventional homes (and others who know of a non-public shelter), from going to a public hurricane shelter.

If one compares the expected coastal and inland demand for public shelter in Central Florida with the total shelter capacity in this Region, a deficit of space is evident for each regional scenario (Table 5).

E. Alternate Public Shelters

Knowing that a substantial public shelter deficit would exist, CFRPC staff developed a list of potential alternate shelters (Table 6). This list was derived mainly from crisis relocation plan host area facility listings, and other sources in the business and religious communities. It is a resource to be used to shrink the gap between the potentially tremendous number of evacuees seeking shelter, and the total number of designated shelters and shelter spaces.

As a caution, the buildings listed are potential alternate shelters. The majority of owners of the facilities listed were contacted with regard to using their facilities in a hurricane emergency (Appendix F), and as of October, 1982, approximately thirty (30) have responded in the affirmative.

The counties of DeSoto, Hardee and Okeechobee, which already have a minimal number of designated shelters, also have a minimal number of potential alternate shelters. Because of the rural nature of these counties, businesses, civic association buildings and other potential shelters are small - most too small to be considered for use as shelters.

A secondary objective in developing this list obviously was to reduce the tremendous volume of traffic which would enter the Region from coastal areas. In terms of safety, law enforcement, and traffic control, the more cars that can be removed from the regional road network, the better.

The question of an adequate pool of shelter managers to serve at these facilities resurfaces here. Aside from the fact that these potential shelters have not been inventoried, a shelter manager would be needed at each facility if it were to be used.

V. INTER-REGIONAL EVACUATION

This section and those following it form the essence of the Central Florida Regional Hurricane Shelter Plan. They incorporate and tie together the research explained previously. This section identifies who will be evacuating prior to hurricane landfall, where the evacuees will come from and where they will go. The regional impact of a hurricane will be clearly illustrated in this section.

As mentioned earlier, three regional hurricane scenarios, as developed by the Bureau, were selected for analysis: 1) A worst-case storm making landfall in Hillsborough County (Regional Scenario 3, illustrated in Figures 2 and 3); 2) A worst-case storm making landfall in Sarasota County (Regional Scenario 5, illustrated in Figures 2 and 4); and 3) The worst-case parallel storm (Regional Scenario 12, illustrated in Figures 2 and 5).

Obviously, evacuees will be crossing county lines in large numbers, and the actions taken in one county (coastal or inland) will affect the actions taken in several other counties.

The Tampa Bay and Southwest Florida regional evacuation plans have identified "evacuation time" as the most important element to be considered for regional evacuation. "Evacuation time" is defined as the sum of the time needed for mobilization of evacuees, the travel time involved in evacuation, the delay time caused by traffic volume exceeding roadway carrying capacity, and the time preceeding the onset of gale-force winds and/or roadway inundation. This concept is illustrated as Figure 6. The evacuation time of a region increases when several counties evacuate concurrently. In the Central Florida Region, because of the limited numbers of regional roads, and their configurations and conditions, carrying capacity will greatly influence evacuation time. Most roads in this region are two lane facilities with limited carrying capacities due to a combination of limited passing sight distances, deteriorated surfaces and/or poor surface drainage, and inadequate (narrow) shoulders. In several cases, the loading of vehicles onto the regional network will be slowed by limited carrying capacities. (To analyze traffic flow, the Florida Department of Transportation, 5th District, recommended that the following standards, based on Level of Service "E" be used[8]:

Undivided Higheays:	850 cars/hour/lane
Divided Highways:	1000 cars/hour/lane
Interstate Highways:	2000 cars/hour/lane)

The situation in Arcadia is illustrative of this point. Five two- lane roads (S.R. 72, Kings Highway, U.S. 17, S.R. 70, and S.R. 31) enter DeSoto County from the west and south, and converge at Arcadia. Only two two-lane roads

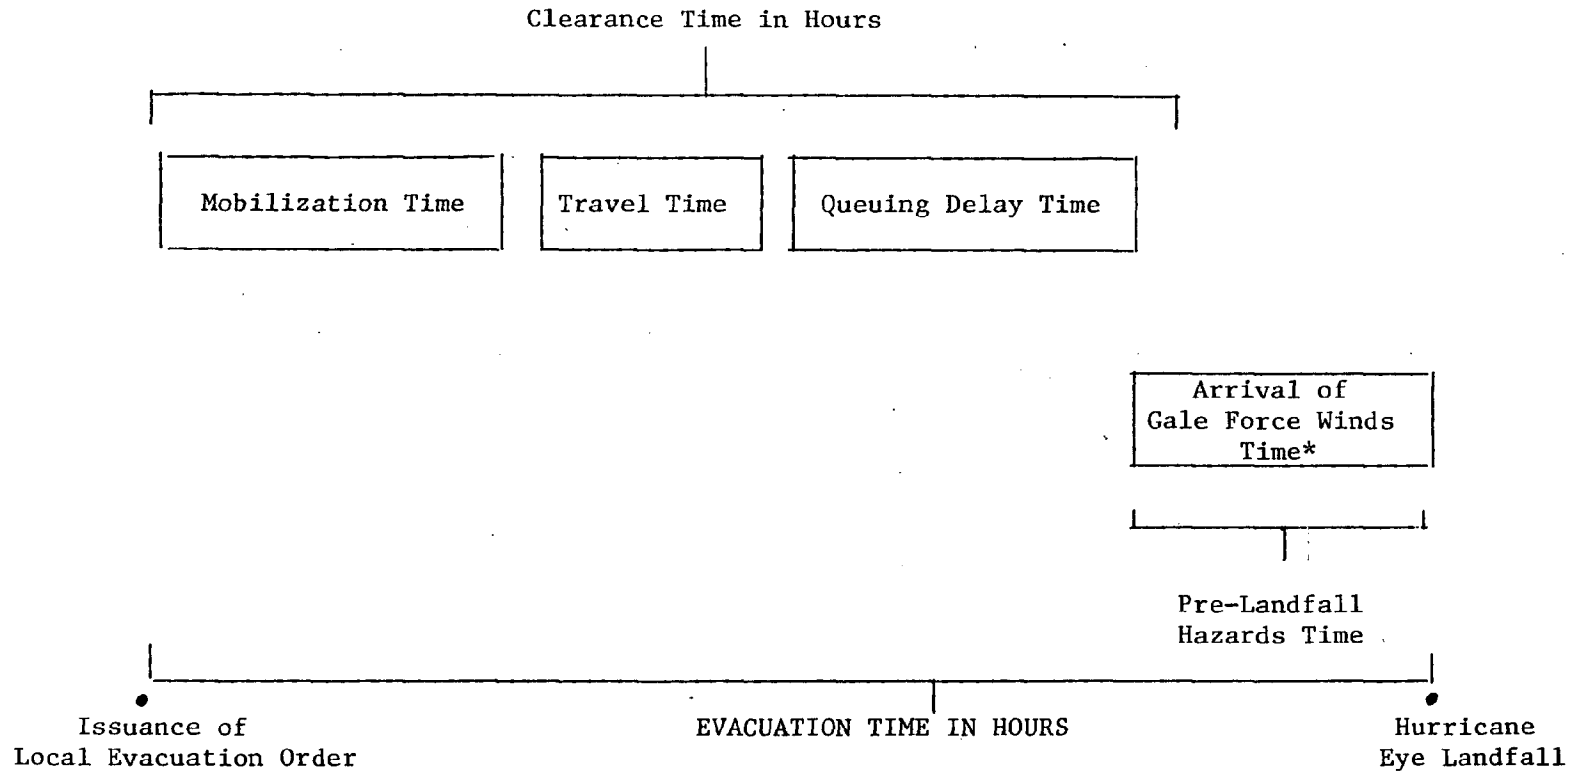
---

[8]"Levels of Service" (L.O.S.) are: A,B,C,D,E, and F; L.O.S. "A" being the best. L.O.S. "F" applies to a road with heavy, stop and go traffic. Thus, L.O.S. "E" is used as a conservative standard.

FIGURE 6

EVACUATION TIME CONCEPT

COMPONENTS OF EVACUATION TIME



*Also includes roadway inundation time.

are the means of egress from the city. (U.S. 17 to the north and S.R. 70 to the east). Using the evacuation schema for Scenario 12 as an example, one can see that once vehicles from Kings Highway, U.S. 17 and S.R. 31 are loaded onto S.R. 70 East, it would take some 29 hours for all 25,123 vehicles to reach U.S. 27. As one looks farther north at Hardee and Polk Counties, one sees a similar situation; more roads enter the counties to the west of U.S. 17 (a mostly two-lane, north-south route) than exit the counties to the east. This funnelling effect will increase the queuing and overall evacuation time of evacuees.

The inter-regional evacuation schemas for Scenarios 3,5, and 12 route traffic in such a manner that vehicles will not cross through intersections, thus keeping the traffic moving as smoothly as possible throughout the region. Further, the overall inter-regional evacuation plan centers on U.S. 27, a four-lane, north-south divided highway. U.S. 27 will be used as the major evacuation route in the region because of its capacity. As was alluded to above, however, getting vehicles to U.S. 27 may take some time, due to loading and queuing on the adjacent two-lane roads. To utilize U.S. 27, vehicles must first be loaded onto U.S. 17. As one moves north from DeSoto County on U.S. 17, vehicles are loaded onto U.S. 17 and turned north, while other vehicles already on U.S. 17 are diverted on east-west routes to U.S. 27. The volume on U.S. 17 is thus kept constant or lessened where possible, while the volume is increased on U.S. 27. To appreciate the increased carrying capacity of U.S. 27, one can again examine the evacuation schema for Scenario 12. Once the 12,123 vehicles are turned onto U.S. 27 in Highlands County, the divided highway's increased capacity will reduce the evacuation time to move all of the vehicles to some 12 hours.

Because of very limited shelter space in this Region, low roadway carrying capacities, and expected high loading and queuing time, the use of optimum evacuation routes to carry evacuees to the nearest shelters is not possible in most cases. Using the schema for Scenario 12 again, if one follows the traffic flow from one end of the Region to the other, one can see that some evacuees will be traveling for a long period of time. With the heavy volume of traffic expected in this Region in various scenarios, this situation is unfortunately unavoidable. (Because of this concern, and because the southern portion of the Region will be relatively unaffected in Scenario 3, a minimum number of evacuees are diverted through Okeechobee County in that particular scenario.)

With high evacuation times in this Region for several landfalling storms, comes the threat of the arrival of sustained gale-force (40 mph) winds and freshwater flooding. As was noted earlier, the onset of freshwater flooding generally approximates the onset of sustained gale-force winds. Both of these hazards will occur prior to eye landfall of a hurricane as wind and rain fields move across the state. In discussions with officials in each Central Florida county, CFRPC was able to identify sections of the regional road network which may be or will be susceptible to inundation. (See Figures 3,4, and 5)

Because of its low elevation and proximity to Charlotte Harbor, DeSoto County may have several roads breached by flooding. These include S.R. 72, Kings Highway, U.S. 17, and S.R. 31 - all regional roads and primary evacuation routes. Sections of roads which may be inundated are circled on the accompanying maps. Obviously, the objective of this planning process is to complete the inter-regional evacuation before the hazards preceding actual hurricane eye landfall make safe evacuation impossible. Local officials must consider that sustained gale-force winds may occur several hours before eye landfall.

Due to limited available shelter space, coastal evacuees will be assigned to shelters on a first-come, first-served basis. As shelters reach capacity, evacuees will be passed to other areas of the Region where shelter space exists. When all shelters in the Region reach capacity, evacuees will be passed to shelters in the East Central Florida Region.

Movement of traffic will be facilitated by traffic control points at critical intersections which will be manned by at least one law enforcement officer. Officers will set up road blocks using patrol cars, and other barricades, plus signs (if available) which will allow vehicles to pass through to local public or private shelters while maintaining orderly movement of inter-regional traffic. Obviously, adequate communication must exist between public shelters and traffic control points so that officers at the traffic control points will know when shelters are nearing capacity. Without proper organization and deployment of officers at critical intersections, the already high evacuation times alluded to above can only increase. Details of deployment of officers should be worked out by regional meetings of local law enforcement agencies, the Florida Highway Patrol, and Civil Defense authorities. The Inland Shelter Advisory Committee is the obvious coordinative mechanism through which such meetings can take place.

Lane use modification was discussed in several advisory subcommittee meetings and was rejected as a means to reduce clearance time. Reasons for rejection were that there are few regional evacuation routes which could be modified in the first place; emergency response to accidents or breakdowns may be hindered; and, according to FDOT and the Lakeland Traffic Engineer's office, modifying a four (4) lane road to allow three (3) lanes of traffic to flow in one direction would not decrease evacuation times because of motorists' unfamiliarity with such a configuration and because on-loading and off-loading of traffic on the facility would be relatively difficult (requiring additional manpower, etc.).

The volume of traffic entering into the Central Florida Region during a major evacuation makes accidents and breakdowns likely. As was mentioned above, most regional roads are two lane facilities with limited passing sight distances, deteriorated surfaces and/or poor surface drainage, and inadequate (narrow) shoulders. Narrow shoulders is the most significant of the roadway limitations. The removal of disabled vehicles to the side of the road must be immediate, especially on a two-lane road. As with inefficient traffic control points, any delay in the removal of accidents or disabled vehicles can only increase already high evacuation times. Two recommendations made by the Tampa Bay Hurricane Evacuation Plan regarding accidents and disabled vehicles may be applied to this Region:

First, where manpower resources make it possible, the critical traffic control points identified should be manned by two traffic control persons. This would allow one person to continue directing constant traffic movement while the other person supervised and facilitated the removal of any potential disabled vehicles away from the critical evacuation path of the intersection.

Second, special monitoring of historically inundated evacuation routes from freshwater should take place. The propensity for stalled and abandonded vehicles on these routes will naturally be higher. It is recommended that the identification and mapping of such routes throughout the Region be utilized as a guide for the emergency pre-positioning and dispatch of towing and rescue equipment.

VI. INTRA-REGIONAL EVACUATION

The Central Florida Region cannot shelter both the vulnerable inland (Central Florida) population and coastal evacuees. The Region, in fact, will be hard pressed to shelter inland evacuees alone. Based upon estimates of the vulnerable inland population expected to seek shelter (mobile home and flood plain residents)[9], Okeechobee, Highlands, Hardee, and DeSoto Counties will not have sufficient shelter space available for its evacuees. Polk County will have approximately the same number of shelter spaces available as Polk County evacuees. This shelter deficit will obviously be compounded if a significant number of non-mobile home residents seek public shelter. The Inland Shelter behavioral survey asked both mobile home residents and non-mobile home residents where they would evacuate. The percentage of non-mobile home residents in Polk, Hardee, Okeechobee, Highlands and DeSoto who said they would go to a public shelter was 52.6%, 33%, 32.9%, 51% and 44.2% respectively. If the percentages of non-mobile home residents who said they didn't know where they would go (over 24% in each county) were added to the figures above, as was done to estimate public shelter demand for mobile home residents, one can see that an overwhelming number of regional residents could evacuate to public shelters, whether they need to do so or not.

Intra-regional evacuation in Central Florida will be structured around evacuation zones, as illustrated in Figure 7. Because public shelters are concentrated in the major cities of DeSoto, Hardee and Okeechobee Counties, each of these counties was designated as an evacuation zone unto itself (Figures 8,9, and 10). Because shelters are dispersed in Highlands and Polk Counties, multiple zones were delineated in those two counties. Evacuation zones in Highlands County are illustrated in Figures 11(a) and 11 (b). Zones in Polk County are illustrated in Figures 12 (a) and 12 (b). Table 7 defines the boundaries of the Highlands County and Polk County evacuation zones, the intra-regional evacuation routes within each zone, and the specific primary shelters assigned to each zone.

Intra-regional sheltering will be on a first-come, first-served basis. Evacuation routes will be the shortest routes from an evacuee's residence to a public shelter. Evacuees who do not find space at the closest shelter

---

[9]Central Florida mobile home and flood plain residents expected to seek shelter are estimated to be 83,127 (region-wide).

will be sent to the next closest shelter. Counties which have inadequate space for their own residents will send local evacuees who have not been sheltered to the closest county with adequate shelter space.

Intra-regional evacuation should be facilitated by the following factors, based on the findings of the behavioral survey: 1) Nearly all inland residents will seek evacuation advice from National Weather Service reports broadcast on radio or T.V. Other than the National Weather Service, a majority of residents (ranging from 56% in DeSoto County to 72% in Hardee County) will seek advice from local government or law enforcement officials; 2) Most households will be ready to evacuate quickly and when ordered to do so, even if the weather is not threatening; 3) Most households would evacuate in one vehicle. On the other hand, intra-regional evacuation could be hindered by the following factors: 1) Over 40% of all mobile home households are age 65 or older (in Highlands County nearly 79% of mobile home households have someone 65 years old or older); 2) The median number of years in the Region for mobile home residents is 15 years or less. (Hurricane Donna was the last major hurricane to strike the Region, in 1960. Thus, the great majority of mobile home residents moved to the area following that storm.) 3) Although most residents are familiar with the road network in their area, most do not know where the nearest public shelter is located.

Intra-regional evacuation will be facilitated by at least one law enforcement officer at critical intersections on the local road network as well as at the junctures of regional and local road networks. These traffic control points will also consist of roadblocks which allow for passage of local traffic. Details as to how officers and roadblocks will be deployed should be worked out through meetings of law enforcement and Civil Defense officials through the Inland Shelter Advisory Committee.

Local officials should identify sites of potential localized flooding and prepare alternate evacuation routes so that flooded areas can be avoided. Local officials should also prepare for the prompt removal of accidents and disabled vehicles.

Concern was raised in the discussion of inter-regional evacuation (above) that the onset of sustained gale-force winds and flooding may occur prior to completion of inter-regional evacuation. Conversely, at the local level, people may be told to evacuate even though a hurricane may not present an immediate inland threat. In such an event, school boards may not make their schools available promptly, and other local officials may be slow in recognizing the urgency of developments on the coast or elsewhere inland. While all evidence indicates that local officials will act expeditiously, appropriate state officials should be prepared to facilitate emergency inter and intra-regional operations.

VII. SHELTER CHECKPOINTS

The shelter checkpoint issue was the most difficult to resolve in this study. Instructions from the Bureau of Disaster Preparedness were to "specify the location of checkpoint sites at strategic points that would serve coastal evacuees. The purpose of these centers will be to provide

supporting services and guidance to evacuees seeking arrangements for shelter; to provide a control mechanism for officials keeping track of (evacuees);" and to distribute maps and directions to shelters. The Bureau asserts that communication with evacuees who need directions is essential, as is the need to determine who is headed for a friend or relative's house or hotel as opposed to those seeking public shelter.

After several discussions and meetings with Bureau staff and Civil Defense officials, the locations of shelter checkpoint sites or reception areas were established in Polk, Hardee, Highlands and Okeechobee Counties. Sites in Polk, Okeechobee and Highlands Counties are based on sites identified in those counties' Nuclear Civil Protection Plans. DeSoto County, because of its location (the primary point of ingress of Southwest Florida evacuees) and because of its severely limited shelter capacity, will not establish checkpoint sites. Shelters in DeSoto County will reach capacity within a short period of time after the initiation of a coastal evacuation. Thus, shelter checkpoints in DeSoto will be superfluous. After absorbing as many evacuees as possible, directing evacuees through DeSoto to other counties will be the major concern of DeSoto County officials.

Related to this point is the assertion by Bureau staff that the primary purpose of checkpoints is for local officials to communicate with those evacuees who do not know where to go and direct them to public shelters. Moreover, once shelters reach capacity, checkpoints may be dismantled and evacuees still on the regional road network will be directed to areas where shelter space is available. Thus, as shelters to which certain checkpoints have been directing evacuees reach capacity, those checkpoints may be closed. It is assumed, then, that checkpoints in counties with limited shelter capacity (relative to other counties in the Region), such as Hardee and Okeechobee, will be open for a relatively short period of time.

The following are the locations of shelter checkpoints and reception areas in the Central Florida Region.

DeSoto	. None
Hardee	. Wauchula State Bank - Southeast corner of U.S. 17 and Main Street, Wauchula
	. Ernest Plaza - Northeast corner of U.S. 17 and Main Street, Wauchula
	. Wauchula State Bank - U.S. 17, Bowling Green
Highlands	. Venus Post Office - Junction of S.R. 731 and U.S. 27
	. St. Regis Co. Warehouse - S.R. 70 west of U.S. 27
	. Avon Park Airport

Okeechobee	. Rodeo Arena (Reception Center) - North of Okeechobee City limit on U.S. 441
Polk	. Lake Wales Plaza - Junction of S.R. 60 and U.S. 27
	. Lake Wales Shopping Center - S.E. corner of Junction of S.R. 60 and U.S. 27
	. Golden Gate Shopping Center - S.E. corner of Junction of U.S. 60 By-pass and U.S. 98, Bartow
	. Bartow Mall (Reception Center, if necessary) - N.E. corner of Junction of S.R. 60 By-pass and U.S. 98, Bartow
	. Mulberry Restaurant (Scenario 12 only) - S.R. 60, east of S.R. 37, Mulberry
	. Lake Miriam Square Shopping Center (Scenarios 3 and 5) - Junction of S.R. 37 and Lake Miriam Drive, Lakeland
	. 40 Acre Truck Stop (if necessary) - Junction Memorial Boulevard and Wabash Avenue, Lakeland

Shelter checkpoint sites for Hardee and Okeechobee Counties are mapped in Figures 8,9, and 10 respectively. Checkpoint sites in Highlands County are mapped in Figures 11 (a) and 11 (b). Checkpoint sites in Polk County are mapped in Figures 12 (a) and 12 (b).

To augment the function of checkpoint sites or reception areas, local officials may want to select specific gas stations along major evacuation routes to be supplied with county or regional evacuation and/or shelter maps (cost of reproduction to be incurred by the county or combination of counties). The availability of these maps should be noted by the gas station on a prominent sign.

VIII. COORDINATION

The first and perhaps the most important accomplishment of this study was the formation of the Central Florida Inland Shelter Advisory Committee. This committee's membership includes not only representatives of emergency response agencies, but representatives of hospitals, planning agencies, and the news media. (The Advisory Committee membership as of October, 1982 is listed in Appendix G.) This rather diverse membership illustrates multi-agency and mulit-county concern with the impact a major hurricane will have on the five county Central Florida Region. This advisory committee is the first of its kind in the Central Florida Region. For the first time, emergency response officials and other interested parties have had the opportunity to meet with their counterparts in neighboring cities and counties to discuss the implications of a major hurricane striking Central Florida. At the outset, the Inland Shelter Advisory Committee elected to divide itself into five county-based subcommittees for the purpose of

guiding and assisting CFRPC staff in completing this plan. The few full-committee meetings that were held were mainly informational meetings at which CFRPC staff presented individual "work products" or progress reports to the members. Working sessions were held on an informal basis at the subcommittee level in each county. Other informal meetings between CFRPC staff and key subcommittee members were also held during the study period. The main reason for holding infrequent and informal meetings was the belief of members that staff would risk losing members' interest if frequent, formal, and "uneventful" meetings were scheduled. A high level of interest was maintained throughout the study period, yet CFRPC staff feels that more frequent meetings should be scheduled during the upcoming study period which will focus on hurricanes in the Atlantic Ocean. Staff feels that at the risk of losing some members's interst, the full membership's understanding of the study process and the information gathered during the study can be improved. Staff also believes the committee should be perpetuated beyond these two study periods. As was discussed earlier in this plan, the Inland Shelter Advisory Committee is the logical vehicle to maintain the multi-county continuity, coordination and communication necessary in hurricane planning. By holding regular meetings, the committee members will become more familiar with each other, and thus facilitate future coordination of emergency response planning.

IX. RECOMMENDATIONS

One purpose of intra and inter-regional advisory committees on this project was to assist regional planning council staff by offering expert opinions and suggestions on evacuation and sheltering. The following are a few of the suggestions which the CFRPC staff believes should be pursued and implemented.

Regarding inter-regional evacuation, two significant proposals have been advanced by members of the East Central Florida Technical Advisory Subcommittee. The first proposal is for "predesignation" of shelters for coastal evacuees. This would entail pre-assignment of coastal evacuation zones to certain inland reception centers. CFRPC staff believes that with detailed and extensive discussions between coastal and inland regions, predesignation may be a workable concept. On a related issue, an East Central Florida subcommittee proposed that the State provide a network of hurricane shelter signs based on "Emergency Snow Street" signs in many northern states. (The "Snow Street" signs are typically posted on major city streets indicating that parking bans are in effect following a declaration of a snow emergency.) CFRPC staff endorses this idea as a way to lessen the burden on traffic control points and checkpoint sites. It is recommended that the State erect a network of signs on inter and intra-regional roads which indicate directions to shelters, and on major local roads to ban parking during a hurricane emergency.

A less expensive system of signs may also be developed whereby coastal evacuees could communicate their needs to traffic control officers. As radio or television announcements inform coastal and inland residents to evacuate and which amenities they should take with them, the announcer may

instruct evacuees to state their needs or destinations on simply worded signs to be displayed on their vehicle's dashboard (e.g., "Need Shelter", or "To Friend's House", or "Need Directions"). Traffic control officers may also be provided with simple signs such as "To Shelter", "Local Traffic Only", or "Shelters Full". CFRPC staff believes such a system is at least as workable as other routing or signage systems, and would also lessen the burden on traffic control officers and information centers.

On the local level, it has been noted that the Lakeland Police Department intends to designate one city shelter as the place where dependents of the L.P.D. who need to evacuate are to be taken. This idea was subsequently endorsed by each Central Florida Advisory Subcommittee as a way to allay officer's concerns for the safety of their families. County law enforcement, Civil Defense and Red Cross officials are urged to incorporate this suggestion into their local plans. It should be noted that because of the potential shortage of shelter space, the only families which should be evacuated are those whose homes will be vulnerable to damage in a hurricane.

Finally, it has been suggested that detailed hurricane information (i.e., shelter locations, etc.) be incorporated into local telephone books. This suggestion, advanced by members of both East Central and Central Florida Advisory Committees is worth pursuing and refining. Public information efforts are greatly needed in hurricane evacuation and shelter planning. The various news media should be involved to a greater extent in the planning processes. Recognizing the different needs of the media and local officials, input should be obtained from both parties as to the best form and content for press releases or public information presentations.

Appendix B

Saffir/Simpson
Hurricane Scale

THE SAFFIR/SIMPSON HURRICANE SCALE

The Saffir/Simpson Hurricane Scale is used by the National Weather Service to give public safety officials a continuing assessment of the potential for wind and storm surge damage from a hurricane in progress. Scale numbers are made available to public safety officials when a hurricane is within 72 hours of landfall. Scale assessments are revised regularly as new observations are made, and public safety organizations are kept informed of new estimates of the hurricane's disaster potential.

Scale numbers range from 1 to 5. Scale No. 1 begins with hurricanes in which the maximum sustained winds are at least 74 mph, or which will produce a storm surge 4 to 5 feet above normal water level, while Scale No. 5 applies to those in which the maximum sustained winds are 155 mph or more, which have the potential of producing a storm surge more than 18 feet above normal.

The Scale was developed by Herbert Saffir, Dade County, Florida, consulting engineer, and Dr. Robert H. Simpson, former National Hurricane Center director, and projects scale assessment categories as follows:

Category No. 1 - Winds of 74 to 95 mph. Damage primarily to shrubbery, trees, foliage, and unanchored mobile homes. No real damage to other structures. Some damage to poorly constructed signs. Storm surge 4 to 5 feet above normal. Low-lying coastal roads inundated, minor pier damage, some small craft in exposed anchorage torn from moorings.

Category No. 2 - Winds of 96 to 110 mph. Considerable damage to shrubbery and tree foliage; some trees blown down. Major damage to exposed mobile homes. Extensive damage to poorly constructed signs. Some damage to roofing materials of buildings; some window and door damage. Coastal roads and low-lying escape routes inland cut by rising water two to four hours before arrival of hurricane center. Considerable damage to piers. Marinas flooded. Small craft in unprotected anchorages torn from moorings. Evacuation of some shoreline residences and low-lying island areas required.

Category No. 3 - Winds of 111 to 130 mph. Foliage torn from trees; large trees blown down. Practically all poorly constructed signs blown down. Some damage to roofing materials of buildings; some window and door damage. Some structural damage to small buildings. Mobile homes destroyed. Storm surge 9 to 12 feet above normal.

Serious flooding at coast and many smaller structures near coast destroyed; large structures near coast damaged by battering waves and floating debris. Low-lying escape routes inland cut by rising water three to five hours before hurricane center arrives. Flat terrain 5 feet or less above sea level flooded inland 8 miles or more. Evacuation of low-lying residences within several blocks of shoreline possibly required.

Category No. 4 - Winds of 131 to 155 mph. Shrubs and trees blown down; all signs down. Extensive damage to roofing materials, windows, and doors. Complete failure of roofs on many small residences. Complete destruction of mobile homes. Storm surge 13 to 18 feet above normal. Flat terrain 10 feet or less above sea level flooded inland as far as six miles. Major damage to lower floors to structures near shore due to flooding and battering by waves and floating debris. Low-lying escape routes inland cut by rising water three to five hours before hurricane center arrives. Major erosion of beaches. Massive evacuation of all residences within 500 yards of shore possibly required, and of single-story residences on low ground within two miles of shore.

Category No. 5 - Winds greater than 155 mph. Shrubs and trees blown down; considerable damage to roofs on many residences and industrial buildings. Extensive shattering of glass in windows and doors. Some complete building failures. Small buildings over-turned or blown away. Complete destruction of mobile homes. Storm surge greater than 18 feet above normal. Major damage to lower floors of all structures less than 15 feet above sea level within 500 yards of shore. Low-lying escape routes inland cut by rising water three to five hours before hurricane center arrives. Massive evacuation of residential areas on low ground within five to ten miles of shore possibly required.

Dr. Neil Frank, present National Hurricane Center director, has adapted atmospheric pressure ranges to the Saffir/Simpson Scale. These pressure ranges, along with a numerical breakdown of wind and storm surge ranges are:

SCALE NUMBER	CENTRAL PRESSURES MILLIBARS	INCHES	WINDS (MPH)	SURGE (FT.)	DAMAGE
1	980	28.94	74- 95	4- 5	Minimal
2	965-979	23.5 -28.91	96-110	6- 8	Moderate
3	945-964	27.91-28.47	111-130	9-12	Extensive
4	920-944	27.17-27.88	131-155	13-18	Extreme
5	920	27.17	155+	18+	Catastrophic

Appendix C

Report on Expected Coastal Demand for Inland Shelter Facilities

REVISED

REPORT ON THE EXPECTED COASTAL DEMAND FOR INLAND COUNTY SHELTER FACILITIES FROM THE TAMPA BAY AND SOUTHWEST FLORIDA PLANNING REGIONS

Prepared By:

Department of Veteran and Community Affairs
Division of Public Safety Planning and Assistance
Bureau of Disaster Preparedness

INTRODUCTION

As a result of the implementation of Florida's Coastal Management Program, The Department of Veteran and Community Affairs was awarded funding to conduct an inland hurricane shelter study. The majority of work to be accomplished with this grant will be carried out by the Central, East Central, and Withlacoochee Regional Planning Councils.

As part of its support to the study effort, the Bureau of Disaster Preparedness was assigned the task of providing the following information to these agencies:

A. Expected coastal demand for shelter facilities resulting from hurricanes striking the Tampa Bay area, the southwest Florida area, and for a hurricane parallelling Florida's west coast.

B. Identification of evacuation routes to be used by coastal evacuees seeking refuge.

C. Identification of the number of vehicles and people expecting to enter inland counties for shelter, by evacuation route.

The following report presents the results of this research effort, explains the methodology used in the analysis, and provides a summary of the work effort's findings.

METHODOLOGY

The procedure used for determining the expected coastal demand for inland shelter facilities consisted of three steps:

A. Identifying regional evacuation scenarios to use as a basis for determining coastal demand for shelter.

B. Identifying routes evacuees will use in entering inland counties.

C. Estimating the number of coastal evacuees entering inland counties by these evacuation routes.

The sources used to derive this information were the Tampa Bay Regional Hurricane Evacuation Plan, Technical Data Report; public information tabloids published for dissemination throughout the Tampa Bay Planning Region; the Southwest Florida Regional Hurricane Evacuation Plan; and discussions with coastal county civil defense directors and staff from the Tampa Bay and Southwest Florida Regional Planning Councils. Each step of this methodology is discussed in more detail in the following section.

Step A. Identify Regional Scenarios

Hurricanes with parallelling and landfalling tracks were chosen for regional evacuation scenarios if they met the following criteria:

A. That the exposure from this track represented the worst probable case for evacuation for each county in each planning region, or

B. That the track produced one of the five disaster potential intensities on the Saffir-Simpson Hurricane Scale for each county in the two regions.

Using this criteria, hypothetical hurricane tracks simulated by either the Tampa Bay or the Charlotte Harbor SLOSH (Sea Lake Overland Surge Height) Model were selected, from which the number of people to be evacuated were identified from the two hurricane evacuation studies. The resulting evacuation scenarios and their regional impact are depicted in Table I. For the purpose of this analysis, letter rather than number designations represent the differing levels of vulnerability posed by the regional scenario: "A" corresponds to a category one hurricane and "E"

represents a category 5 hurricane.

Step B. Identify Evacuation Routes

Highways or roads to be used for interregional evacuation were identified from the two coastal regional hurricane evacuation studies and from discussions with coastal county civil defense directors. These routes are identified in Figure 1.

Step C. Estimate The Number Of Coastal Evacuees Entering Inland Counties By Evacuation Scenario

This portion of the methodology consisted of three steps:

1. Applying knowledge derived from the behavorial studies conducted for each hurricane evacuation study to estimate the percentage of coastal evacuees, who would leave the county or region.

2. Converting evacuation population into vehicle counts using regional specific vehicle occupancy rates.

3. Calculating traffic/population route assignments.

Each of these steps required a number of assumptions before calculations could be undertaken. These assumptions are identified in Figure 2.

The results of this analysis are shown in two series of tables. The Table II series identifies, by regional evacuation scenario, the total number of vehicles and people evacuating into inland planning regions by evacuation route regardless of trip destination (e.g., public shelter, hotel-motel, or friend or relative). The Table III series provides a breakdown by evacuation scenario of the number of evacuees from coastal counties entering either the Central Florida or Withlacoochee Planning Regions that are expected to seek public shelter.

Note the tables identifying the number of evacuees seeking

FIGURE 2

ASSUMPTIONS USED IN DETERMINING COASTAL COUNTY DEMAND FOR SHELTER FACILITIES IN INLAND COUNTIES

I. Behavorial Assumptions

A. Of the population evacuating out of the Tampa Bay Region, the following may be seeking shelter in interior counties: Pasco County, 49.5%; Pinellas County, 33.8%; Hillsborough County, 38.6%; Manatee County, 34.0% (Source: Tampa Bay Hurricane Evacuation Plan Technical Data Report).

B. 34% of the Southwest Florida Planning Region's population effected by hurricanes will evacuation out of the region (Source: Southwest Florida Regional Hurricane Evacuation Plan).

C. 45% of the Southwest Florida Planning Region's population effected by hurricane will seek shelter (Source: Southwest Florida Regional Hurricane Evacuation Plan).

D. That portion of the population seeking shelter who cannot find it due to an inadequate supply within their county will evacuate out of both Tampa Bay and Southwest Florida Planning Regions.

II. Conversion of Population to Number of Vehicles

A. Vehicle occupancy rates for the Tampa Bay Region were derived from 1970 Census Data updated to 1979 data (Source: Tables G-11 through G-15, Tampa Bay Regional Hurricane Evacuation Plan Technical Data Report).

B. Vehicle occupancy rates for the Southwest Florida Region were derived by dividing the number of people evacuating out of each county by the number of vehicles to be used in such an evacuation (Source: Southwest Florida Regional Hurricane Evacuation Plan).

III. Regional Traffic/Population Assignments

A. Traffic assignments on routes out of the Tampa Bay Region were derived from Appendix G, Tampa Bay Regional Hurricane Evacuation Plan Technical Data Report.

B. Traffic Assignments on routes out of the Southwest Florida Region were based on the routes' abilities to handle traffic based on their roadway capacities. In this manner, maximum use of the regional transportation networks is achieved while providing the shortest evacuation time possible.

FIGURE 2 (CONTINUED)

1. That portion of a county's population evacuating on I-75 would remain on that route until they leave the region.

2. Evacuees using U.S. 41 would gravitate towards I-75 as they leave their respective counties.

3. Evacuees from Collier, Lee, Charlotte, and Sarasota remaining on I-75 will be routed northeast on I-4.

4. Traffic entering Manatee County on U.S. 41 and U.S. 301 from the Southwest Florida Planning Region will be routed east on S.R. 70.

5. Traffic entering Sarasota County on U.S. 41 from Collier, Lee and Charlotte counties will be routed east on S.R. 72.

6. S.R. 765 in Lee County will not be used as an evacuation route by those evacuees from Collier County.

7. S.R. 775 in Charlotte County will not be used as an evacuation route by those evacuees from Lee and Collier Counties.

8. S.R. 31 in Charlotte County will be used primarily by evacuees from Lee County.

public shelter from counties in the Southwest Florida Planning Region are structured differently than the information for counties in the Tampa Bay Region. This is due to a slightly different method for calculating vehicle/population route assignments based on the data provided (see row four for the number of people expected to seek public shelter).

FINDINGS

The demand for inland shelter services, whether it be a public shelter, a hotel or motel, or a friend or relative, ranges from a low of 77,693 to a high of 460,568 people. Those evacuees desiring a public shelter range from a low of 36,152 to a high of 226,212. In all cases, however, the number of people expecting to find refuge within the inland counties of the three planning regions may exceed present capabilities.

The parallelling hurricane produces the greatest impact on inland counties for shelter services. The greatest impact to the Withlacoochee Planning Region is likely to result from a hurricane striking either Pinellas or Hillsborough County (Regional Scenarios 2 or 3). The greatest impact to the Central Florida Planning Region from a landfalling hurricane is one that strikes Sarasota County (Regional Evacuation Scenario 5). Although the landfalling hurricane producing the greatest impact to the East Central Florida Planning Region cannot directly be inferred from this analysis, it is expected that a hurricane striking Pinellas, Hillsborough, or Sarasota County would produce substantial demand for shelter services in this region.

(continued)

APPENDICES

INTRODUCTION

The purpose of this study was to provide the Central Florida Regional Planning Council with behavioral data concerning residents' evacuation plans in the event of a hurricane. Data from this study will be used by the Council in developing an evacuation plan for the five county region (Polk, Hardee, Okeechobee, Highlands, and De Soto counties). Although not a coastal region, hurricanes preparedness is necessary for the region because of: (1) the necessity to evacuate mobile home residents because of high winds and the possibility of tornadoes, (2) the need to evacuate residents from flood prone areas and (3) the large influx of coastal residents who would flee inland if a hurricane struck the coast.

METHODOLOGY

Questionnaire Design

The Request for Proposal specified nine questions that the study needed to answer. These questions were:

1. The tendency to evacuate immediately if officially ordered by authorities even if storm conditions do not appear threatening to the resident.
2. When residents would tend to evacuate.
3. From what sources would the resident seek advice on whether and when to evacuate?
4. The desired destination of the resident when evacuating.
5. Route the evacuee would take to reach desired destination.
6. Number and type of vehicles at the place of residence.
7. How many vehicles would the household use in an evacuation?
8. Household characteristics:
   a. type of dwelling unit
   b. number of persons in household
   c. does household need transportation assistance?
   d. number of handicapped persons

9. Previous hurricane experience of resident.

Based upon these questions and the study conducted by H. W. Lochner, Inc. for the Tampa Bay Regional Planning Council, a questionnaire was developed which formed part of the proposal to conduct the study. This draft was modified after consultation with CFRPC staff and a pretest of 20 randomly chosen residents of the five county area. The final questionnaire (see Appendix A), in addition to being designed to answer the specific questions of the Request for Proposal, contained questions relating to the age of the residents, the length of time they had lived in the five county area and where residents would go if evacuated.

Sampling Design and Data Collection

The sampling design employed involved systematic sampling of residence listings in the phone directories covering the five-county area. This type of sampling is considered a close approximation to random sampling for studies such as the present one, and provides a nearly complete coverage of households because the vast bulk of households nowadays have listed phones. Sampling was done separately for each county to help ensure a sufficient sample size from the less populous counties. To help ensure a sufficient numbers of mobile home households for analysis, a slight oversample of mobile homes was effected; it is estimated that the proportion of mobile home residences in the sample was 4.0% higher than in the population. The total number of completed interviews was 1257; the number of cases upon which each of the statistics presented in this report is based are indicated in the tables in which the data are displayed.

Interviewing was done by women from the Tampa Women's Survival Center, who were trained and supervised for accuracy by the principle investigators. Phone calls to sample members were made from 9:00 A.M. to 9:30 P.M. seven days

a week to help ensure variation in which household member answered the phone. Unless a particular phone number was not a working number or otherwise was unusable, an effort was made to make four attempts to reach someone at each number, to minimize bias which might occur by completing interviews only for persons who are easy to reach. The overall interview completion rate was 78.9%; that is, 21.1% of persons reached by phone refused to participate in the survey or the interview could not be completed because the individual being interviewed was hard of hearing or ill. This completion rate is within the range typically achieved for surveys of this type.

Information from the completed questionnaires was coded by the principle investigators and by trained assistants supervised by them. Coded data were keypunched by the University of South Florida's Keypunch Services. Apparent mispunches (which were few) were identified through the use of appropriate computer analysis by the principal investigators, and those potential mispunches were checked against the survey forms and corrected if a keypunching error had occurred. The data are stored on magnetic tape so that further analyses can be undertaken to address any future questions planning agencies may have.

Several cautions which derive from the sampling methodology should be observed when interpreting the findings from the study. First, because of the oversample of mobile homes, analyses which aggregate mobile home with non-mobile home residences likely will include a larger proportion of mobile home households than is the case for the actual five-county population. However, this is not expected to be a major biasing factor for most analyses because the oversample of mobile homes was not large (see above). A second caution which should be observed in interpreting the findings involves results which are based on small numbers of cases (the numbers of cases are indicated

in the each of report's tables). Sampling error is likely to be larger when small numbers of cases are involved than when results are derived from analyses based upon a large number of survey respondents.

So that the reader will have a better idea of the accuracy of the sampling, Appendix B contains the means, standard errors, and 95% confidence intervals for selected study variables, by county. The standard error aids judgment of the accuracy of the sampling because it helps in determining the potential degree of discrepancy between the sample mean and the population mean; in our case, between the means calculated from the data we collected and the actual means one would be able to calculate if one had complete data on everyone, rather than just a sample of persons, from each county. Information on the exact statistical procedures for estimating standard errors for studies such as ours; that is, for which the researcher has data from one sample and does not know the true population means, can be found in most good texts dealing with inferential statistics for survey research.

Another measure which helps in judging the accuracy of sampling is the 95% confidence interval. A 95% confidence interval is calculated from the sample mean and the standard error. This means that there is a 95% chance that the population mean lies within this interval.

Because of the possibility, in any sampling procedure, of discrepancy between the values observed in the sample and the true population values, users of this report or of any study based on sample data should proceed with caution when it appears that the sampling may introduce inaccuracies large enough to meaningfully bias conclusions drawn from the data. Due to the nature and complexity of the information contained in the present report, confidence intervals or related statistics are not presented for all findings in this report. However, the standard errors and confidence intervals

presented in Appendix B provide a useful guide to the degree of precision in the samples employed. Users of this report who have a need for information on the sampling accuracy relevant to particular report findings should contact the principal investigators of the study prior to employing the study results for planning decisions.

SURVEY RESULTS

This section of the report will present findings relevant to the nine questions specified in the Request for Proposal and restated under "Questionnaire Design," above. The findings are organized into two broad categories. First, demographic and household characteristics are presented. These are characteristics which help describe the nature of the people in the five-county area -- for example, what type of housing do people have, how many households consist of an elderly person living alone, and so forth. These demographic and household descriptions are important because they can help identify some of the special needs of the population in an evacuation. Second, evacuation-related findings are presented. These findings deal with such issues as individual's willingness to evacuate, the route they might take in an evacuation, and so forth.

Household Characteristics

Number of persons and age of oldest person in household. Information on household size and on the number of elderly residents is important because it can help pinpoint the number of people who would evacuate and the proportion of elderly residents who live alone. Household size varies somewhat from county to county (see Table 1). For example, about one in five (20.7%) households in Highlands county consists of a lone resident. The analogous

percentages for Polk and De Soto counties are 16.9 and 14.6, respectively, but in Hardee (9.9%) and Okeechobee (8.6%) counties less than one in ten households are comprised of a single person living alone. Breakdown of these data separately for mobile home and non-mobile home residents (Table 2) suggests only fairly small differences between these two types of residences with regard to the proportion of single person households.

The potentially critical nature of the above information is highlighted when one examines the age data. As can be seen in Table 3, for example, between 28.9% (Okeechobee county) and 44.4% (DeSoto county) of households in the five-county region include a household member age 65 or over. Furthermore, in each county a large proportion of these households consists of an elderly (over age 65) person living alone or with one other person also age 65 or older (Table 4). Combining the above information from Table 3 with that from Table 4 allows us to calculate the percentage of total households in each county which consist of an aged individual living alone or with one other person who is elderly also. These percentages are 26 for Polk, 18.3 for Hardee, 12.6 for Okeechobee county, 32.8 for Highlands, and 27.5 for DeSoto. The large number of families which contain at least one elderly individual, and especially the high proportion of households which consist of an aged person living alone or with one other person over 65, suggests that planners may wish to give extra consideration to the special needs of the aged when designing evacuation programs, planning for the operation of public shelters, and so forth. (See the discussion on special needs and Tables 7, 8, and 9 below.)

One additional aspect of households with an aged resident or residents should be mentioned. In each county, mobile homes are more likely to contain an elderly household member than are non-mobile home households (Table 5).

That this dwelling type (mobile homes) which is especially susceptible to wind damage is also especially likely to house the aged further complicates the evacuation planning. An estimate of the proportion of households in each county which are mobile homes is shown in Table 6; these percentages range from 50.0 for Okeechobee county to 16.2 for Hardee county. The reader should keep in mind, however, that these figures are slight overestimates because of the required oversampling of mobile homes.

Need for special evacuation assistance. In order to help determine the independent ability of people to evacuate, we asked whether anyone in the household would need special assistance to travel, whether outside assistance would be required to evacuate those persons, and whether transportation such as a bus or taxi would be needed. Data relevant to these questions are presented in Tables 7, 8, and 9.

Shown in Table 7 are both the proportions of households which contain someone who needs special assistance to travel, as well as the specific reasons given for the need for assistance. The percentages of households with such needs are 8.6 for Polk, 11.3 for Hardee, 5.3 for Okeechobee county, 9.2 for Highlands, and 5.1 for DeSoto. The percentages of households for which outside assistance would be needed, due to the handicaps in Table 7, for evacuation are 5.5 for Polk, 7.7 for Hardee, 3.3 for Okeechobee county, 7.5 for Highlands, and 2.2 for DeSoto (Table 8). Outside assistance in the form of bus or taxi transportation will also be needed for some households; the percentages of households which need assistance of this type are, for the above counties, respectively, 2.8, 2.8, 3.3, 5.2, and 1.5 (Table 8). These data are disaggregated in Table 9 so that the percentages are calculated separately for mobile home and non-mobile home dwellers.

Transportation resources. Survey respondents were asked to specify the number of cars and trucks in the household, and to indicate the types of vehicles owned (sedan, station wagon, jeep, pickup truck, or van). This information is presented in Table 10 and is decomposed for mobile home and non-mobile home residents in Table 11.

The data from this portion of the survey are consistent with that regarding needs for evacuation assistance (see above) in suggesting that only a small proportion of households is without household-owned transportation. For example, the proportions of households with no vehicle range from 5.2% in Highlands county to 2.6% in Okeechobee county. Furthermore, these percentages are, for each county except Highlands, higher than those indicating the proportion of persons needing transportation such as a bus or taxi (see Table 8). These results imply that members of some households with no vehicle may be able to get transportation from a neighbor or friend. In any event, the vast bulk of households have at least one vehicle, and when one considers that few households contain more members (see Table 1) than can fit in a typical car or truck, it becomes clear why so few households specify a need for bus or taxi transportation.

Length of residence in area, seasonal residence, and previous hurricane experience. Length of residence in the area can be an important factor in a hurricane because persons who are relative newcomers may not be familiar with the local civil defense system, public shelter network, roads, and other elements crucial to a successful evacuation effort. As can be seen in Table 12 at least one out of ten persons in each county has lived in the region for four years or less; for Okeechobee county and Highlands county the proportions are almost one in four (23.7%) and close to one in three (29.9%), respectively. Inspection of Table 13 reveals that the "typical" mobile home

dweller is likely to have more recently settled in the area than is the case for his non-mobile home counterpart. In each county, the median number of years in the area is lower for mobile home residents than for non-mobile home residents.

It will also be useful in developing an evacuation plan to know how many persons have experienced a hurricane previously, and how many have been evacuated. This type of information provides yet another indication of the extent of the public's inexperience with hurricane evacuations. As can be seen in Table 14, the vast majority of the region's residents have never been evacuated due to a hurricane. The county with the highest proportion (21.7%) of residents which have experienced an evacuation is Okeechobee. And, about one in three (32.9%) of Okeechobee respondents said they had experienced Hurricane Frederick in 1979. With regard to the other counties, much smaller percentages of residents than is the case for Okeechobee have been evacuated, and the most common hurricane experience involved Hurricane Donna, which occured more than twenty years ago, in 1960. It would seem, then, that experience with previous hurricanes and hurricane evacuations is not widespread in the five-county region, and thus planners will not be dealing with a populace which has had widespread direct familiarity with hurricane conditions.

The breakdown of these results by residence type (Table 15) shows some interesting patterns. In all counties except De Soto, mobile home residents are less likely than non-mobile home residents to have been in a hurricane. Yet in three of the five counties, mobile home residents are more likely to have been evacuated. These data are consistent with findings to be presented later (Tables 21 and 23) which will show that mobile home residents are more likely than non-mobile home residents to say they will evacuate, will evacuate

immediately upon an evacuation order if the weather were fine, and will leave before an official order if a hurricane were to make landfall. These various findings suggest that mobile home residents may be aware of the particular dangers a hurricane will pose for them and are by and large willing to evacuate, and to do so in short order, if the need arises.

Tables 16 and 17 show that most residents of the region are year-round residents. It is important to note, however, that for several counties the proportion of mobile home residents who are seasonal is high. For example, 20.1% of mobile home residents in Polk county are seasonal, and the analogous figures for Highlands and De Soto counties are 17.9% and 15.1%, respectively. As might be expected, the bulk of these seasonal residents are "snowbirds" who are here from November/December to April/May.

Evacuation Behavior

The information presented thus far has concerned the household and demographic characteristics of the residents of the five county region. Of more direct concern is the anticipated behavior of those residents in an evacuation. The present section of this report will present selected findings relevant to the prediction of evacuation behavior. These findings will address the issues of (1) the sources from which individuals will seek evacuation advice, (2) if and when residents will evacuate, (3) the vehicles they will use to evacuate, and (4) the desired and anticipated shelters, and their locations, to which evacuation will occur, as well the roadways which evacuees will use to travel to those locations.

Anticipated sources of evacuation advice. Survey respondents were asked from whom they would seek advice on whether and when to evacuate. Four sources--neighbor, friend, local government or law enforcement officials, and

National Weather Service advisories on radio or television -- were presented to the persons interviewed, who were encouraged to specify all sources from which they would seek information. As can be seen in Table 18, for each county more than 9 out of every 10 respondents specified National Weather Service advisories as a source from which they would seek evacuation advice. These percentages are high for both non-mobile home and mobile home residents (Table 19). These results suggest that, while ideally all available media should be employed to ensure that publicity of an evacuation reaches as many persons as possible, from the standpoint of efficiency or in a situation of limited resources National Weather Service advisories may provide the most effective single source for disseminating evacuation information.

Anticipated time respondent would evacuate. Persons interviewed were asked, "If a hurricane were to hit the coast when, if ever, would you evacuate: (a) before an official order to do so, (b) when given the official order to do so, or (c) would not evacuate." Individuals who indicated that they would evacuate before an official order to do so were asked how soon before the hurricane was expected to hit the coast they would leave, and persons who said they would leave when given the official order to do so were asked how soon, assuming everyone were home, they would be ready to leave.

Results for these survey items are presented in Table 20 for all types of residences combined, and separately for mobile homes and non-mobile homes in Table 21. The percentages of respondents who would not evacuate even if given an official order to do so range from 9.9 (for Okeechobee county) to 24.1 (for Hardee county), although in each county the proportion of mobile home residents who say they would not evacuate is much lower than the analogous percentage for non-mobile home residents (Table 21). The fact that at least roughly one in ten respondents, and as high as almost one in four persons

interviewed (in Hardee county), said they would not evacuate suggests that evacuation orders should stress the necessity of evacuating and perhaps be worded in such a way that persons understand the risks involved in failing to evacuate.

In this regard, one important factor which helps identify those persons who are reluctant to evacuate is long-term residence in the five county area (Table 22). In three of the five counties studied, respondents who have resided in the area for 30 years or more are substantially more likely than are their neighbors who are more recent arrivals to say they will not evacuate. For those three counties (Polk, Hardee, and Highlands) evacuation personnel may wish to try to orient evacuation announcements toward these "old timers," if possible.

Most respondents, however, indicated that they would evacuate, and the most frequently stated time of evacuation, for both mobile home and non-mobile home dwellers, is when given the official evacuation order rather than before such an order is issued. Yet, it should be stressed that in general mobile home residents exhibit substantially greater evacuation readiness than do their non-mobile home counterparts (Table 21). As stated above, mobile home dwellers are more likely to evacuate, and they also are more likely to evacuate before an official order than are non-mobile home residents. Regardless of residence type, the data suggest that, typically, individuals will be ready to leave almost immediately, assuming everyone is home. In no category in Table 20 or Table 21 is the median time needed to be ready to leave over one hour. These results suggest that residents of the five-county region do not feel that they will need a long time period to pack up or otherwise put things in order, and that delays of this type are not likely to be a problem in a hurricane evacuation in this area. The reader should

remember, however, that the survey question assumes that all household members are home, and that a substantial proportion of individuals surveyed say they will not evacuate at all (see discussion above).

The information in Tables 20 and 21 can serve as a rough guide for planners and others in estimating the time sequencing of demands on roadways, shelters, and the like in the event of an evacuation. What these data provide is a means for estimating the numbers of people who will evacuate before an evacuation order, and how long before that order those persons will evacuate; the numbers of individuals who will leave when the evacuation order is forthcoming and how soon those persons would be ready to leave; and the numbers of individuals who would not evacuate at all. This type of information can be critical in judging the gradualness or suddenness of the "phase-in" of traffic build-up, need for special evacuation assistance, influx to public shelters, and so forth. However, it should be stressed that these data should be employed in a judgmental sense rather than as an exact predictive model. The reason for this is that the phase-in may diverge from that suggested by Tables 20 and 21 as the conditions associated with the particular hurricane vary. For example, it seems reasonable to assume that more people would evacuate before an official evacuation order if the order were given very late and the weather appeared very ominous, than if the evacuation were given early on and the weather were fine.

To get a perspective on this particular issue, we asked what respondents would do if told to evacuate but the weather were fine. Between 62.7% and 78.4% of persons in each county said they would leave immediately (Table 23), and, except for Okeechobee county, mobile home residents are more likely than non-mobile home residents to do so (Table 24). Additional details are available from Tables 23 and 24.

Vehicles to be used for evacuation. Data concerning the number and types of vehicles which survey respondents anticipate they would use if they were to evacuate are shown in Tables 25 and 26. Perhaps the most relevant point here relates to the proportions of respondents who specified that two or more vehicles would be employed. These proportions are generally low for both mobile home and non-mobile home dwellers. This finding jibes with the information on household size (Tables 1 and 2) presented earlier, and that regarding number of vehicles per household (Tables 10 and 11), which suggests that the vast bulk of households have a vehicle and are small enough that all household residents probably can fit in that vehicle. The likelihood that the overwhelming majority of households will use one vehicle to evacuate can be used in conjunction with data from Tables 20 and 21 (when they would evacuate) to help judge the extent of traffic in an evacuation. Again, however, this information should be used in a judgmental sense because such factors as the number of persons who would not evacuate may change with specific conditions (for example, the weather) associated with a particular hurricane.

Anticipated evacuation destinations, locations, and routes to be taken. Persons interviewed were asked both where they would like to go if evacuated and where they would go. Responses were sought both in terms of the type of evacuation destination (public shelter, friend or relative, or motel), its geographic location, and the major streets and highways respondents would use to travel to the destination.

Data on respondents' desired evacuation destinations are given in Table 27. The most frequently mentioned such destination is a public shelter. Around half the persons interviewd from each of the three counties Polk (49.4%), Hardee (51.2%), and Highlands (54.4%) specified this type of facility; the analogous percentages for Okeechobee and De Soto counties are

39.6 and 58.5, respectively. Planners thus should keep in mind that in an evacuation in these five counties, demand for public shelter space may be very high, and that the public shelter system may well be asked to accommodate between four and six out of every ten households. In this regard, it should also be noted that the vast bulk of households (between 89.6% and 98.6%) may want to use a public shelter in the county of residence rather than in another county.

Besides public shelters, the next most frequently mentioned desired evacuation destinations, in order of frequency of mention, are "friend" and "motel". Roughly one-fifth to one-third of respondents specified friend, and about one-tenth to one-fifth of persons interviewed mentioned motel. It is worth noting that evacuees are more likely to desire to travel out of county to reach these two types of destinations; this is especially true for Hardee county residents desiring to go to a motel. It should also be mentioned that between 8.1% (for Hardee county) and 16.6% (for Polk county) of survey respondents indicated that they do not know what type of shelter they would like to travel to in an evacuation. Additional details on desired evacuation destinations and locations are available from Table 27.

It is perhaps worth stressing again the heavy demand on public shelters which may be likely to occur in an evacuation. Not only do many people state outright they would want to go to a public shelter (see above), it is also true that among respondents who said they would want to go to a friend or relative, for each county more than half specified the location of the friend or relative as within the same county as that in which the person being interviewed resides. Of course, it is possible or perhaps even likely that the friend or relative that the survey respondent had in mind when answering would himself have to evacuate. In such a case, the friend or relative would

not constitute a viable evacuation destination, and such evacuees may show up at a public shelter (a motel may also not be a suitable location for the same reason).

The above data on persons' desired destinations parallel those regarding where respondents feel they would go (Tables 28 and 29), at least as far as the ordering of frequency of mention of destinations is concerned. That is, the most frequently mentioned destination remains public shelter, followed by friend or relative and motel in that order. This pattern holds both for all residents and separately for mobile home dwellers and non-mobile home residents. However, mobile home residents (except those in Polk county) are somewhat more likely to say they would go to a public shelter than are their non-mobile home counterparts, and are somewhat more likely to know what shelter type (public shelter, friend or relative, or motel) they would seek (again, Polk county is the exception). In general, as might be expected, respondents were more likely to say they don't know where they would go (Tables 28 and 29) than to say they don't know where they would like to go (Table 27).

If we assume that respondents who indicate they do not know where they would go will end up at a public shelter, the proportion of evacuees who will have to be taken care of by public shelters ranges from 82.1% in Highlands to 59.9% in Okeechobee County.

One finding from Table 28 which planners will want to heed involves the large proportions of persons who say they would go to a public shelter, who do not know where that public shelter is located. These proportions range from 38.8% (Polk) to 83.6% (De Soto). One possibility here is that individuals know which facilities are likely to be used as public shelters but do not know which particular shelter they would use. But another possibility is that

people do not know the locations of their public shelters or likely public shelters at all. Thus, planners fruitfully might give some thought to providing clear and intensive information about public shelter locations prior to a potential hurricane landfall, to ensure that confusion about where the public shelters are located is kept to a minimum during the actual evacuation. As a possible aid in such publicity efforts, Table 30 disaggregates information on where people would go by number of years of residence in the five-county area.

In addition to knowing the types of facilities people would seek out in an evacuation, it will be useful to know how many individuals feel they will travel out-of-county or out-of-state. Information of this sort for each facility type and with regard to where individuals would <u>like</u> to go is presented in Table 27 and was summarized briefly above. Tables 31 and 32 show these results aggregated for all facilities and with regard to where persons say they <u>would</u> go. All three of the tables just mentioned suggest that people generally will travel within their county of residence rather than going out-of-state or out-of-county. This pattern holds both for all dwelling types as a group, and separately for mobile homes and non-mobile homes. But, between 31.9% (Okeechobee county) and 12.2% (De Soto county) of residents do expect to travel beyond their county line, and evacuation personnel may wish to use the information in Tables 31 and 32 to estimate the amount and directions of inter-county travel. However, these data should be used as a rough guide only, in conjunction with the specifics of the particular threatening hurricane. For example, although 11.0% of Hardee respondents said they would evacuate to Polk county, that figure may be lessened if weather reports are forecasting extensive damage in the Polk area. As a last observation regarding Tables 31 and 32, it is interesting to note how many

respondents specified they would go out-of-state (including Georgia) or "north". For all counties except De Soto, roughly one out of ten persons interviewed so responded. Interestingly, for DeSoto the comparable figure is only 2.4%.

Tables 33 and 34 show the most frequently mentioned routes respondents said they would take in an evacuation. For Polk county residents, routes 60 (18.0% mentioned this route) and 27 (22.8%) may experience heavy travel, as to a lesser extent may route 98 (8.8%), I-4 (6.0%) and I-75 (11.2%). Hardee county residents say they will use routes 17 (31.3%), 64 (11.9%) and 27 (8.9%). For Okeechobee county, a variety of roadways were mentioned, most commonly routes 441 (37.4%) and 70 (18.7%). Highlands county residents overwhelmingly say they will use route 27 (45.9%), along with local roads (43.2%), and some will use I-75 (9.4%). De Soto county residents mentioned two routes most frequently: 17 (35.2%) and 70 (25.3%). It should be noted that in addition to the routes mentioned above, in all counties local roads are likely to be fairly heavily traveled. The percentages of respondents who mentioned local roads are 28.8 for Polk, 47.8 for Hardee, 12.1 for Okeechobee, 43.2 for Highlands, and 30.1 for De Soto.

In using these results for planning purposes, two things should be kept in mind. First, as with some of the other data presented in this report (see above), road usage may vary somewhat with the particulars of the hurricane involved. Second, it is likely that many individuals mentioned the most major routes they might use. Planners should be sensitive as well to the possibilities for heavy traffic problems on more minor routes, such as short access roads leading from population centers to the more major thoroughfares shown in Tables 34 and 34.

General Conclusions

In this section we will present some of the most important highlights for plannings purposes.

1. The population in general and especially those who live in mobile homes is elderly.
2. Although a relatively small percentage of the residents need special assistance to evacuate or are without transportation, in absolute numbers this could be a substantial amount of people.
3. Although a substantial percentage of the respondents indicated experience with hurricanes, this experience except for Okeechobee county was with Donna in 1960.
4. The National Weather Service is the source of advice most frequently mentioned.
5. Although most people will evacuate when ordered to do so, a substantial proportion would never evacuate and mobile home dwellers would tend to evacuate prior to the order to so.
6. If family members are home, respondents indicated they could be ready to leave almost immediately.
7. In general only one vehicle per residence will be used.
8. Most people would evacuate to public shelters within their own county. Based on these data, there will be a great demand placed on public shelters.
9. A substantial proportion of respondents do <u>not</u> know where their public shelter is.

HURRICANE PREPAREDNESS QUESTIONNAIRE

Name_____ Interviewer Code No. ____

Address_____ Respondent Code No. ____

Phone No. _____

	1	2	3	4
Date of Attempt				
Time of Attempt				
Result of Attempt				

Person and Time to call back _____

Hello, I am _____ of the University of South Florida. We are doing a study for the Central Florida Regional Planning Council regarding peoples' plans for hurricane evacuation. I hope that you will answer the few questions we need to ask so that evacuation plans can be developed. All your responses will remain anonymous in that after the data are coded all identifying information will be destroyed.

Is this Mr. or Ms. _____?
If no, do you live at this residence? yes__ no__
If yes, continue. If no, find out when residents will be there.

1. What type of home do you live in?

__single family house

__two family house

__apartment

__mobile home

2. How many persons live in your house or apartment? _____

What are their ages? _____ _____ _____ _____ _____

Does anyone in your home have special transportation needs or need special assistance to travel . . . for example is anyone handicapped or elderly?

__yes __no

If yes, why do they have special needs? _____

_____

Would you need outside assistance to evacuate them?

__yes __no

3. How many cars or trucks are there in your household? _____

What kinds of vehicles are they?

sedan__ station wagon__ Jeep__ pickup truck__ van__

other (specify) _____.

(If zero to question 3): Would you need transportation such as a bus or taxi?

yes__ no__

4. If you were to evacuate, which of the vehicles would you use?

Specify_____.

5. From whom would you seek advice on whether and when to evacuate?

   Neighbor:

   yes__ no__

   Friend:

   yes__ no__

   Local government or law enforcement officials:

   yes__ no__

   National Weather Service advisories on radio or TV:

   yes__ no__.

6. If a hurricane were to hit the coast when, if ever, would you evacuate?

   a. ___ Before an official order to do so.

   b. ___ When given the official order to do so.

   c. ___ Would not evacuate.

   (If a.) How soon before the hurricane was expected to hit the coast would you leave? _____ hours.

   (If b.) Assuming everyone is home, how soon would you be ready to leave? _____ hours.

7. What would you do if told to evacuate but the weather was fine outside? (e.g., wait, leave immediately). If wait, when would you leave? _____ hours (0 hours for leave immediately)

8. If you evacuated, where would you like to go?

___ Public shelter in the five-county area (DeSoto, Hardee, Polk, Highlands, Okeechobee) (If yes, in which county? _____)

___ Friend or relative (if yes, where do they live? _____ city and county)

___ Motel (if yes, where _____ city and county)

___ Don't know (Do not say this)

9. If you evacuated, where would you go? _____ (city and county, also record don't know)

Do you know where that is?

yes___ no___ (If no, go to question 11).

10. What route would you take to get there, especially major streets and highways? _____

_____

11. How long have you lived in the five-county area? _____

12. Do you live here all year round?

yes__ no__

If no, during what months do you live here? _____

13. Have you ever been in a hurricane?

yes__ no__

If yes, where and when _____

Have you ever been evacuated because of a hurricane?

yes__ no__

Thank you for your help.

Dear

Early results of a hurricane shelter study conducted by the Central Florida Regional Planning Council show a deficit of shelter spaces in this county to house evacuees in a major hurricane. The county's primary shelters, mostly public schools, simply cannot accommodate all of our mobile home residents, as well as those who live in flood-prone areas, plus evacuees from coastal areas who will enter this county during a hurricane. Moreover, we cannot look to other central Florida counties for help, becaus the same situation exists elsewhere.

We are very concerned about this lack of shelter space because it means an increased ri to lives and property due to increased traffic on our roads and increased confusion as evacuees seek shelter.

With the help of the Regional Planning Council, law enforcement officials and others, w are trying to identify additional shelter space to ease this burden. We are asking you and others in our business and religious communities if we can count on the availabilit of at least a portion of your building to be used as shelter during a hurricane. You m be interested in knowing that Chapter 252.51, Florida Statutes, states that private businesses serving as shelters cannot be held liable for accidents or injury.

Please contact any of us if you can assist in this important project. In the meantime, thank you for your attention. Sincerely,
