ABSTRACT

An Economic Base Study of Coastal Louisiana analyzes and describes certain basic sectors of a regional economy. Unique among base studies of local economies is inclusion of a chapter on investment in human capital in the region.

The fundamental methodological problems of base studies stem from inability to separate economic data into regional components, lack of data for many economic activities, and inability to analyze a regional economy as a closed system. Therefore, primary emphasis is toward systematization and generalization with reference to very large economic sectors that are most obviously related to regional characteristics. These sectors are commercial fisheries, mineral extraction, and water transportation. The potentially important tourist and recreation sector, because of severe data limitations, is described only briefly. Certain miscellaneous sectors are examined, and a list of Standard Industrial Classifications is given for industries dependent upon or related to the coastal economy.

Population projections for the region are made through use of cohort-survival techniques. Shift-share analysis is used to analyze economic growth trends. Substantial data are accumulated on trends in income growth, and the employment structure of the region is explained.

Inasmuch as economic activity involves transformation of natural resources into finished products, either to be directly consumed or to serve as tools for further production, the study should emphasize not only these resources but the effects of productive activities on the natural environment. Some suggestive material concerning environmental impacts is included, but the absence of economic data makes the analysis unsatisfactory. Accordingly, environmental impact information in the study is fragmentary.

The major accomplishment of the study is the amassing of rather sizable amounts of economic data on the coastal economy to provide a benchmark for more in-depth and more narrowly scoped research efforts.

ACKNOWLEDGMENTS

The authors are indebted to many individuals who contributed to preparation of this study. John Eckalbar, David John, John Shoemaker, and Jose Paniza researched various chapters. Professor Roger Burford and Sylvia Murzyn greatly aided our computer programming. Billie Townsend, assisted by Margaret Stafford, typed the numerous drafts and revisions without loss of good humor, a not insignificant accomplishment. Dr. Jack R. Van Lopik, Director of the Center for Wetland Resources and the Office of Sea Grant Development, provided administrative guidance and support.

This investigation was sponsored by Louisiana State University's Office of Sea Grant Development. LSU's Sea Grant Program is a part of the National Sea Grant Program, which is maintained by the National Oceanic and Atmospheric Administration of the U.S. Department of Commerce.

PART I

ANALYSIS OF ECONOMIC AGGREGATES IN COASTAL LOUISIANA

CHAPTER I

INTRODUCTION: THE LOUISIANA COASTAL REGION

The Louisiana coastal region is in many respects the State's most valuable geographic feature, for it is at this juncture of the land, the sea, and the great rivers that most of the State's trade, commerce, industry, and population are located. This is a region with abundant deposits of hydrocarbon fuels and minerals, one whose estuaries comprise a significant part of the nation's most productive fish and wildlife habitat. Louisiana's estuaries--"the doorways between the ocean and the land mass" (Cronin, 1971)--are stressed by human activities throughout the watershed of the State and are subjected to the most intensive use of any of the natural-resource areas. It is here that processes of urbanization, sedimentation, chemical contamination, and general economic development reveal the delicate balance between man and his environment.

These characteristics are sufficient justification for an economic base study of the coastal region, but other reasons are also compelling, for the uses of the coastal region of the State are matters of intense and sometimes conflicting concern. Public and private interests are not always in harmony, nor are the interests of Federal, State, and local governments always compatible. The desire for economic development increasingly is tempered by the price costs such activity may exact from the environment. But protecting the environment from man has a reciprocal in the need to protect man from the environment--a serious need in an area, for example, where tropical storms are frequent occurrences. Accordingly, it is entirely appropriate to consider measures for positive manipulation of the rivers, bays, marshes, and lakes of coastal Louisiana, for if adequately protected this region is capable of providing not only sources of income for the citizens of the State but also unique and valuable opportunities for recreation.

Population growth in the coastal region surpasses the rate of growth for non-coastal areas. Such population growth in the coastal region, when coupled with increased income and leisure time, inevitably creates pressures for access to the estuaries and the sea. Contamination or destruction of beaches, marshes, waterways, and shorelines may, however, deny the recreational use of sea and shore to the expanded population. Moreover, expanding populations create vast amounts of wastes, which find their way to the rivers and estuaries and ultimately to the sea.

Clearly the use of coastal Louisiana's land and water resources is accelerating. Delays in understanding the consequences of multi-purpose use alternatives can only mean excessive and perhaps irreversible damage to the Louisiana coastal region. Proper planning and recognition of the long-term importance of maintaining the productive quality of coastal Louisiana is necessary if the citizens of the State are to be assured of sound utilization of the coastal resources and the coastal environment.

Before successful management measures can be taken, it must be generally recognized that much of coastal Louisiana has the characteristics of a common property resource. To economists the primary feature of common property resources--air, water, fisheries, etc.--is that processes of private economic activity cannot be expected to assign accurate relative values to alternative uses of the resource. In the words of the economist Allen V. Kneese (1971), "Now that many properties of the natural environment have clearly become scarce resources, we are confronted with a vast asymmetry in the ability of our property institutions to form the basis for efficient resources allocation." Moreover, "unless decisive counter measures are taken, leading to more technically efficient use of materials and energy, we can expect this problem to grow more intense" (Kneese, 1971). What is needed over much of the Louisiana coastal region, again in Kneese's words, "is to view the various aspects of the natural environment as multiple purpose - multiple use natural assets, owned in common, which must be managed through some collective choice mechanism if they are to be developed, used, and conserved efficiently."

The authors of this report are fully cognizant of the need for operational analytical methods to explore the types of interdependencies occurring from multiple purposes - multiple uses of the resources of coastal Louisiana. Candidness compels us, however, to warn the reader that only partial headway is made in this report in meeting the needs for analytical assessment. This is so because of two facts: (1) the tools of analysis are themselves not readily available, and (2) when they are available they are very expensive to apply. These facts are regrettable, for the need for such measures is acute. Nevertheless, given these difficulties, about the best economists can do is to follow the advice of one member of their profession, E. J. Mishan (1970), who notes that the fact that

no estimates have been made, or are likely to be made shortly, about the magnitude of some untoward social effect arising in the normal pursuit of commerce, need not intimidate the economist from occasionally respecting the plain and inescapable evidence of his own senses. Nor should such a fact inhibit his reasonable conjectures about future consequences if present trends remain unchecked.

What this report does accomplish is to present a comprehensive data survey of economic activity in coastal Louisiana. Perfection is not implied, for the report is a working document to be expanded and updated in the future. Moreover, as is true in most data-gathering efforts, there are omissions of items considered important by some and inclusions of items considered trivial by others. Accordingly, suggestions for improvements shall be most welcome.

Delineation of the Louisiana Coastal Region

There is no incisive definition of the coastal region of Louisiana. The State's shoreline has much too complex a configuration to permit sharp

distinction. We can speak of a marine environment, and in this sense the Louisiana coastal region may be considered to be the land area affected by the sea and the sea area affected by the land. This definition permits extension of coastal Louisiana as far north as Baton Rouge, the terminus of deep-draft navigation on the Mississippi River. Accordingly, coastal Louisiana is defined as a 24-parish (county) area which includes the shoreline and the estuaries formed by the lower portion of the Mississippi River, as well as major portions of other rivers such as the Atchafalaya, Calcasieu, Sabine, Mermentau, and Pearl. The inner continental shelf is also included in the coastal region because of its growing importance in mineral resource supply. Because economic data follow political boundaries, some entire parishes are included when it would be preferable to use only their areas contiguous to rivers or lakes which connect to the ocean. Figure 1 depicts the limits of coastal Louisiana chosen for this study. Recognition is granted that perhaps too many or too few parishes are included. On balance, the choice made seems sufficiently logical to allay most criticism.

Economic Approach to Resource Analysis of Coastal Louisiana

The essential thrust of economic analysis of the region considered to be coastal Louisiana is to explore the interrelationship of land-based economic activities with the estuaries and the Gulf of Mexico. The analysis is structured around two focal points: replenishable and nonreplenishable resources. Replenishable resources are such items as fish, wild animals, waterfowl, timber, etc. Nonreplenishable resources, insofar as coastal Louisiana is concerned, are minerals, especially oil, natural gas, and sulfur. The authors have also included a section on population and human resources in coastal Louisiana. Not only does this inclusion seem justified on the basis that human capital should be valued in economic terms, but there is the all-important justification that the wisdom to develop properly and appreciate the problems of coastal Louisiana is a function of the skills and talents brought to bear on these problems.

The basic weakness of economic analysis stems from the lack of effective tools to explore the interrelationships between replenishable and nonreplenishable resource use. In short, economists have to rely upon static rather than dynamic methods, and for reasons detailed earlier the full social costs of many economic activities are not quantifiable. For example, the impact of mineral extraction upon the replenishable resource base is not readily subject to economic analysis at present.

In terms of statements about industries that are visibly dependent upon the land-estuary-sea interface, the report relies on Standard Industrial Classification (hereinafter SIC) procedures (U.S. Bureau of the Budget, 1972, Standard Industrial Classification Manual). At least five general industry groups can be identified by project or service especially oriented toward coastal Louisiana. These five are fisheries, mineral industries, marine transportation, tourism and recreation, and a catch-all category titled "other industries" which includes fur trapping.

Fig. 1. Louisiana coastal region.

CHAPTER II

PHYSICAL CHARACTERISTICS OF THE LOUISIANA COASTAL REGION

The 24 parishes that constitute the Louisiana coastal region occupy 15,695 square miles, which is 34.7 percent of the State's total. The region covered in this study extends eastward from the Sabine River to the Pearl River (see Fig. 1).

The Louisiana coastal region lies within a physiographic unit known as the West Gulf Coastal Plain. Four natural regions are distinguished in this area: the coastal marshlands, the Mississippi flood plains, the terraces, and the hills. These regions are shown in Figure 2.

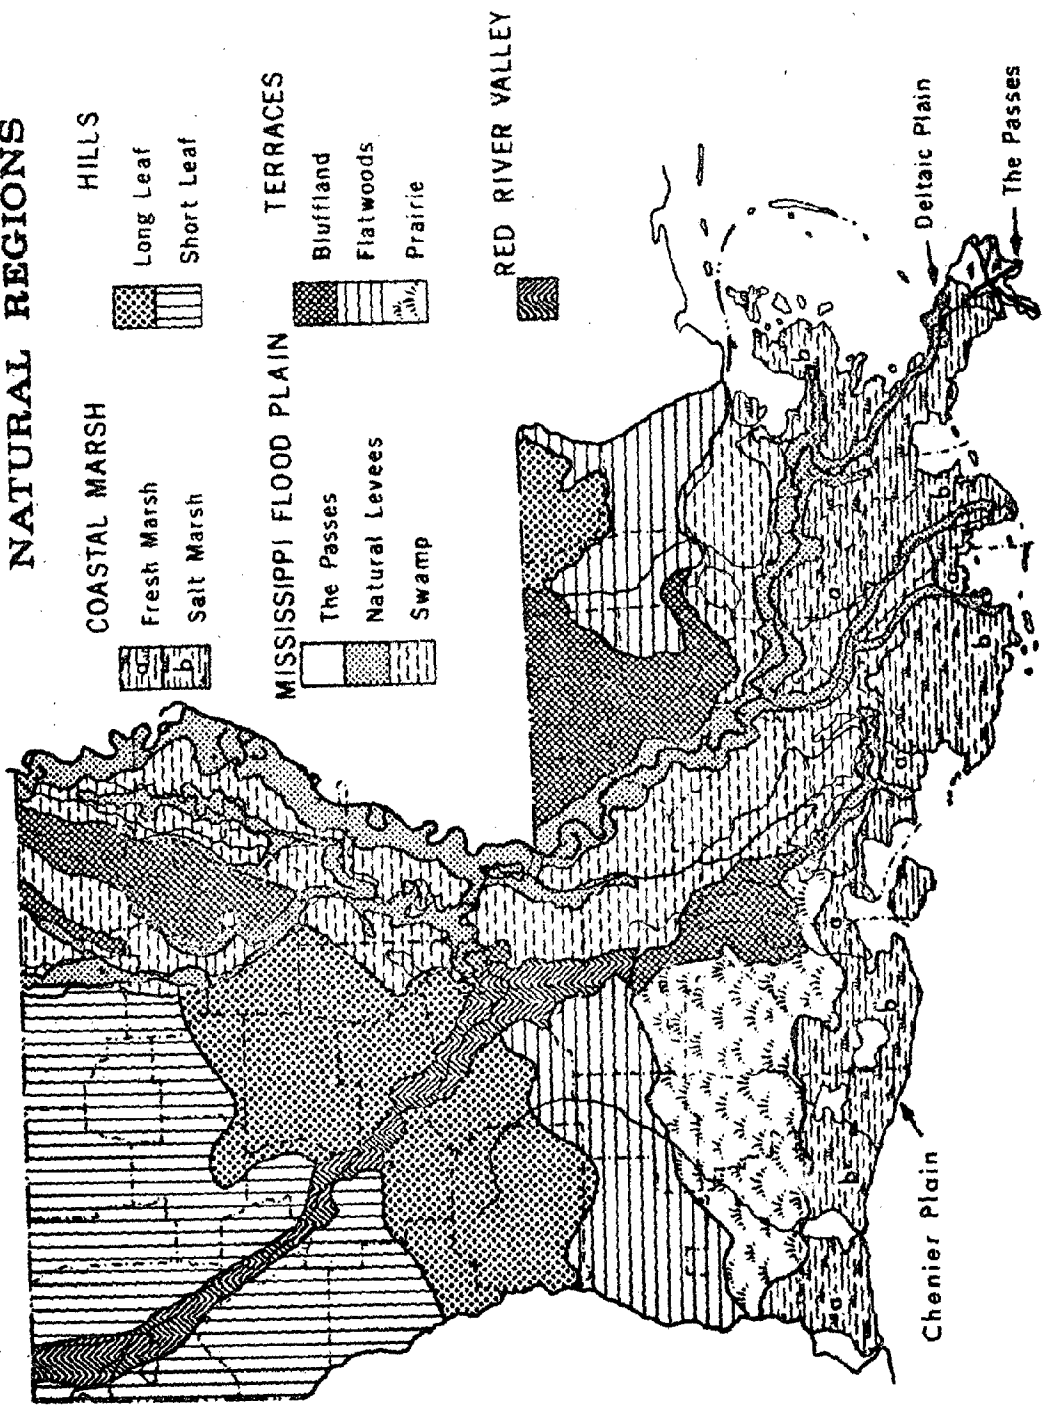

The deltaic plain of the Mississippi River and the chenier plain of southwestern Louisiana constitute the coastal marshlands. The deltaic plain, which makes up the main part of the marshlands, extends for nearly 200 miles between the Mississippi Sound on the east and Vermilion Bay on the west. The chenier plain is only 25 to 30 miles wide; it extends from the Sabine River on the west to Vermilion Bay on the east (Fisk, 1956). These regions have developed owing to shifting sites of Mississippi River sedimentation and to regressional and progradational shoreline processes (Gould and Morgan, 1962).

The Prairie Terrace, north of the chenier plains and flanking the Mississippi River, is underlain by fluvial sediments laid down in late Pleistocene time. Now locally dissected 20 to 30 feet, the Prairie surface forms the "uplands" bordering lakes Maurepas and Pontchartrain in southeastern Louisiana (Fig. 3).

Cut within Prairie age deposits and burying them downvalley is a heterogeneous mixture of sediments laid down by the Mississippi River within approximately the last 10,000 years. Physiographically, this alluvial plain is characterized by major natural levee systems flanking modern and abandoned distributaries. Ranging in elevation from a few to about 15 feet above the adjacent backswamps, these levees have long been cleared and brought into cultivation. Their relative freedom from inundation and the inherent fertility of their pedologically youthful soils makes levee terrain some of the best agricultural land in the State.

As shown in Figure 3, within the last 5,000 years at least seven Mississippi deltaic systems and sublobes have built out along the Gulf Coast (Kolb and Van Lopik, 1958). These formed when the Mississippi River abandoned old courses for new ones, which generally had higher gradients and shorter distances to the sea. Sediments deposited along radiating distributaries then caused progradation of the shoreline.

NATURAL REGIONS

CARTO. SECT., SCH. OF GEOSCIENCE, LSU

Fig. 2. Natural regions of the State of Louisiana.

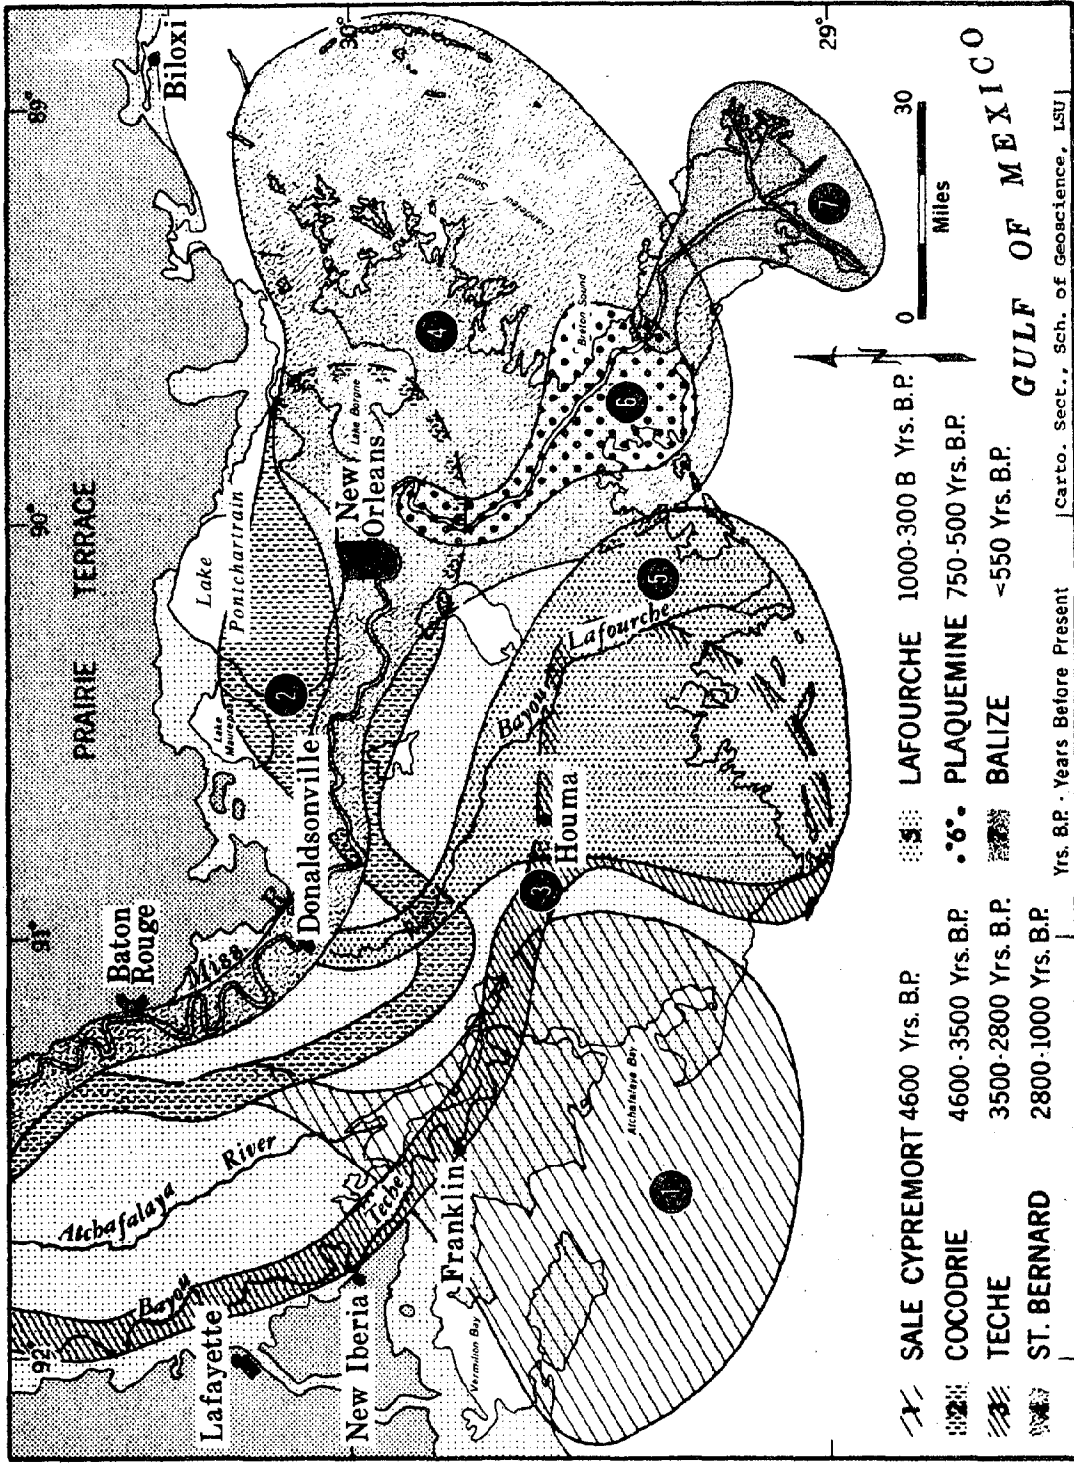

Fig. 3. Succession of Mississippi deltas. Source: Kolb, C. R., and J. R. Van Lopik, 1958, Geology of the Mississippi River deltaic plain, Southeastern Louisiana. U.S. Army Engr. Waterways Experiment Station, Vicksburg, Miss., Tech. Rept. 3-483.

Upon the Mississippi River's taking a new course, the old deltaic areas were deprived of sediment nourishment and slowly recessed under wave attack and subsidence. The contemporary Mississippi Delta, the Balize, has built out and attained its form only within the last 600 years (Fig. 3). In fact, if it had not been modified by man, the present Mississippi River would have been diverted down its major distributary, the Atchafalaya, thereby abandoning the modern course via Baton Rouge, New Orleans, and the Balize Delta (Fisk, 1952).

The prairie terrace is located north of the chenier plain. Firm, arable land is formed on the terrace, which is the remnant of a huge Pleistocene deltaic plain. Bisecting the terrace is the Mississippi flood plain, a region consisting mainly of natural levees and swamps. Tangipahoa Parish has the highest elevation of the Louisiana coastal region, reaching a maximum just over 200 feet above sea level.

The major structural element in the Gulf Coast as described by Bornhauser (1958) is the Gulf Coast geosyncline, a huge downwarp of the earth's crust, the axis of which has been gradually shifting seaward. A steady eastward migration of the sediment in the geosyncline occurred throughout Tertiary time because of the changing influence of the river systems delivering sediments to the geosyncline (Antoine and Gilmore, 1970). The Rio Grande, in early Tertiary, and now the Mississippi River, which discharges more than 1 million tons per day of sediment, have contributed the major sediment load. The Atchafalaya River, the principal distributary of the Mississippi, enters the Gulf of Mexico approximately 150 miles west of the Mississippi bird-foot delta. This important source of shelf sediment introduces a daily load of at least 100,000 tons of silt and clay. At present little sand reaches the Gulf via the Atchafalaya River, for most coarse-grained sediments have been deposited in lakes some 50 miles inland. However, as these lakes or natural stilling basins fill, more sediments will enter the shallow Atchafalaya Bay, and a subaerial delta is expected to appear in the next few years. In fact, complete filling of the 200 mi² bay is thought likely to occur within the next 50 years (Shlemon, 1972).

The Gulf Coast area offshore of Louisiana is also characterized by diapiric salt structures, which strongly influence its localized occurrence of mineral resources in the coastal area. The major hydrocarbon fields in the coastal area exist basinward from the Mexia-Talco fault system. The presence of salt domes in the Louisiana coast has also influenced the localization of oil and gas deposits. Much of the oil and gas production of offshore Louisiana is from reservoirs associated with piercement type salt domes (see Fig. 4).

The most important minerals found in the Louisiana coast, besides oil and gas, are clays, sand and gravel, salt, and sulfur. Louisiana is second among the states as a producer of oil, natural gas, and natural gas liquid.

The mineral resources found in the Gulf of Mexico partially account for the importance of the Gulf to the Louisiana coastal region. However, the Gulf itself, being among the ten largest bodies of water in the world,

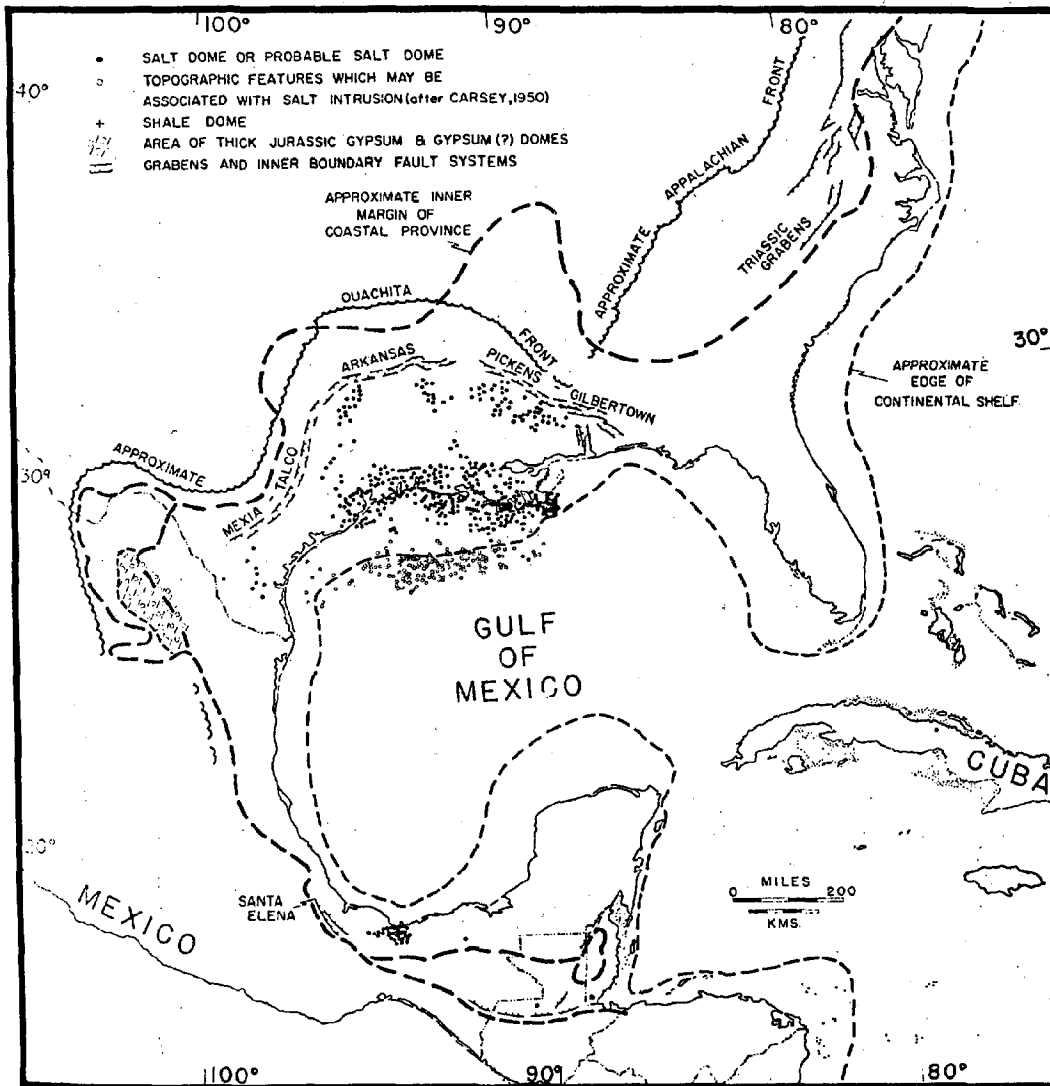

Fig. 4. Map showing known distribution of salt domes in Gulf of Mexico basin in United States, Mexico, and Cuba. Solid dots are proven domes, open circles are probable domes. Source: Murray, G. E., 1961, *Geology of the Atlantic and Gulf Coastal Provinces of North America*. New York (Harper and Brothers), p. 203.

is an important marine resource to the State. Fishery products taken from Gulf waters have long contributed to the economy of Louisiana. There are 37 species common to the Gulf Coast which are listed as commercially important by the National Marine Fisheries Service, and Louisiana's major rivers are the principal nutrient sources that make coastal Louisiana one of the most productive estuarine areas in the world.

Climate

The climate of the Louisiana coastal region is determined mainly

by the subtropical latitude of the area and its proximity to the Gulf of Mexico. January average temperature in this region is 54°F and that of July, 82°; the annual average temperature is 68°. The number of frost-free days averages 270 per year. The marine tropical influence is obvious in the fact that the average water temperature of the Gulf along its northern shore ranges from 64°F in February to 84° in August.

Average annual precipitation is 60 inches, of which approximately 55 percent occurs during the period from April through September. July and August are the wettest months, average monthly precipitation being 7.1 and 6.0 inches, respectively. Much of this precipitation is associated with afternoon thundershowers, which occur almost daily during certain periods of the summer.

Storms and hurricanes are important factors. A 3-year period during which one of these storms fails to strike the Louisiana coast is rare. Such events cause extensive damage to homes, business establishments, and offshore structures. The oyster grounds in St. Bernard Parish, east of the Mississippi River - Gulf Outlet channel, appear to have sustained substantial damages from Hurricane Camille in 1969.

CHAPTER III

ECONOMIC GROWTH IN COASTAL LOUISIANA

Introduction

In recent years people have become increasingly aware of regional influences within national boundaries. In particular, economic development within the United States presents a pattern of regional diversity. Thus the most important goal of overall economic progress and growth must be the emulation of national trends by the underdeveloped constituents. The establishment of this and similar prescriptions have been originated in the context of a relatively new subdiscipline, regional economics. Regional economics is the study, from the viewpoint of economics, of the differentiation and interrelationships of areas in a universe of unevenly distributed and imperfectly mobile resources; particular emphasis in application is on the planning of the social overhead capital investments and private market motivations to mitigate the social problems created by these circumstances (Dubey, 1970). It is the objective of the following chapters to analyze the Louisiana coastal region within the established methodology of regional economics.

It is particularly desirable that quantitative analysis be used in lending guidance to practice. First Count 1970 Census tapes facilitate a preliminary survey of some of the quantitative changes in the past decade, and it is such changes and their relative differences that set many of the economic norms. However, in some cases data for 1970 were not accessible at the time this report was written; therefore, the year closest to 1970 for which data were available was substituted. This proxy does not distract significantly from the trend but makes the contemporary analysis less precise.

The Economic Setting of the Louisiana Coastal Region

Economic growth may be most simply defined as the expansion of output. However, there are tacit components of output which must be revealed if output is to be a valid measure of economic expansion. Even among professional economists the focus on economic growth is less than precise. In some cases the definition pinpoints increasing productive capacity as the prerequisite to and ultimate determinant of economic progress. For others, the measure of growth is ex post of the production channels, i.e., real consumption per capita. In either case, welfare, as measured by the increased availability of goods and services, is the raison d'être of economic growth.

The Federal concern with economic growth was accentuated in June 1970 when President Nixon established the National Commission on Productivity. The background for the Commission was concern over the inflation problem and its link with labor costs per hour. However, the interests of the Commission extend beyond the immediate problem of inflation to a broad realization of the importance of economic growth in the future and the contribution that all sectors and regions can make (Economic Report of the President, 1971). Therefore, the growth of Louisiana and its coastal area are a logical application of this concern.

The policies and prospects for economic growth in the Louisiana coastal region will be discussed later. For the present it is proposed that hindsight be used in dissecting the region. In 1960, 58.84 percent of Louisiana's population resided in the 24-parish coastal area. In 1970, this proportion had increased to 61.46 percent. Of the net change in the State's population from 1960 to 1970, 83.72 percent occurred in the designated coastal zone. To the extent that increases in population contribute to a rise in product per capita, the potential growth center for Louisiana appears to be the coastal area. One direct contribution of such population increases is the greater opportunities for economies of scale or, more commonly, the economies of mass production.

Economic growth is presented here in terms of real income changes. This definition correctly recognizes that the standard of living of any economy is meaningfully portrayed by real income per capita. Real income refers to monetary income after adjustments have been made for price changes inasmuch as the money value of different years' outputs can be accurately compared only if the value of money itself does not change because of inflation or deflation. A price index, which is a percentage comparison from a fixed point of reference (the base period), is used to compare prices through time. Table 1 summarizes the money per capita personal income for 1959 and 1968 by parish and the real per capita income during the 1957-59 base period. The first 24 parishes listed represent the coastal zone; they are followed by the remaining parishes of the State. The data, compiled by the Regional Economics Division of the Office of Business Economics, Department of Commerce, are collected for Standard Metropolitan Statistical Areas (hereinafter referred to as SMSA) and the non-SMSA parishes; therefore, individual parishes within SMSA's are not delineated. Also, three non-SMSA parishes--Livingston, Plaquemines, and St. John the Baptist--do not have data available because of the extensive commuting out of the parishes to places of employment in contiguous parishes.

In column 3 of Table 1, headed real per capita income, 1968, the parishes are ranked (the rankings are denoted in parentheses) in decreasing order, i.e., from the highest to the lowest. For the nation in 1968 the money per capita income was \$3421. This figure compared to a Louisiana average of \$2645, 77.3 percent of the United States average. When these two per capita figures are converted to real per capita income, 1968, using the index 121.2 (1957-59 = 100), their values are \$2823 and \$2182, respectively. Only two Louisiana parishes, Vernon and Webster, show values in excess of the national average. Within the State, 15 parishes have per capita values greater than the State average; of these, 10 are coastal region parishes. Computation of the average value of income for the coastal zone parishes in column 3 yields a value of \$2144 as compared to an average for the rest of the State of \$1598. Note that these figures do not represent real per capita income in the coastal zone versus the rest of the State but are merely an average of the individual parishes contained therein.

Table 2 summarizes annual growth rates of real per capita income, 1959-68, for the Louisiana parishes. The United States growth rate for

this same period was 3.6 percent, and the State of Louisiana had a growth rate of 4.5 percent. The disparity between the United States rate and the State value is consistent with, and explanatory of, the fact that the ratio between Louisiana's per capita income and the United States' total converged toward one in the last decade. In 1960 Louisiana's per capita income was 75.7 percent of the U.S. average, but by 1968 this percentage had increased to 77.3 percent. Of course, this does not imply a convergence in absolute amounts, only in percentages.

Another measure of economic growth is the relative growth chart developed by Edgar M. Hoover and Joseph L. Fisher (1949). This chart brings together data on relative (percentage-wise) changes in population, total income, and per capita income in order to show the interplay of the key elements in regional growth. The relative growth chart is shown in Figure 5, where the solid horizontal axis measures 1968

population as a percentage of 1959 population and the solid vertical axis measures 1968 total personal income in current prices as a percentage of 1959 total income, also in current prices. The data for each parish, summarized in Table 3, are plotted on a double logarithmic scale, which is characterized by equal distances representing equal ratios. The origin of the diagram (A) is at 100 for population, which represents population unchanged between the two dates, and at 119.4 for total personal income at current prices. Since prices increased by 19.4 percent between the two dates, as measured by the consumer price index, an increase in total money income of 19.4 percent between 1959 and 1968 is the same as an unchanged total real income.

Each parish, or SMSA, is represented by a point on the graph; coordinates are determined by percentage changes in population and in total personal income between the two dates. Any point to the right of the solid vertical axis represents an increase in population; any point above the solid horizontal axis, an increase in real total personal income.

The solid diagonal line drawn through the origin in Figure 5 is the locus of all points on the chart for which per capita income in current dollars increased 19.4 percent, or for which per capita real income remained unchanged between 1959 and 1968. Any point above this line represents an increase in per capita real income.

The origin of the dashed areas shown in Figure 5 (B) is the United States average increases from 1959 to 1968--12.7 percent for population, 79.6 percent for total personal income in current prices, and 57.9 percent for per capita income in current prices. Any point to the right of the dashed vertical axis represents a population increase greater than the national average, and any point above the dashed diagonal axis, a per capita income increase greater than the national average.

The various combinations of increases or decreases relative to the national average are as follows:

I. Above-average increases in population, total income, and per capita income:

The non-SMSA coastal zone parishes fall mainly into this category; St. Mary and St. Charles parishes lead in both relative population increase and relative increase in total income. Only one SMSA, Monroe, is located in this quadrant, and only two of the non-SMSA parishes not in the coastal zone are represented.

II. Above-average increases in total and per capita income, below-average increases in population:

A large proportion of the non-coastal parishes fall into this group. In one parish--West Feliciana--population actually declined between 1959 and 1968, whereas total income and per capita income increased quite substantially. Three coastal zone parishes--Cameron, Iberville, and St. James--are located in this category, and all three outranked the majority of non-coastal zone parishes in terms of total and per capita income increases.

III. Above-average increases in per capita income, below-average increases in population and total income:

All of the non-SMSA parishes in this category are non-coastal zone parishes. Two of those included showed actual declines in population for the designated period. One SMSA, Lake Charles (coastal), falls into this category.

The groups of parishes comprising the first three categories have the common feature of an above-average increase in per capita income. In the three remaining categories, per capita income increased less rapidly than for the nation as a whole.

IV. Above-average increases in population and total income, below-average increases in per capita income:

Three SMSA's, all in the coastal zone, are located in this category. The East Baton Rouge SMSA falls extremely close to the line denoting "national average increase in per capita income," and the Lafayette and New Orleans SMSA's are not too far removed. Only one parish, Lincoln, falls into this area.

V. Above-average population increases, below-average increases in total and per capita income:

The parishes in this category are predominantly non-coastal. Only three coastal zone parishes--Assumption, Lafourche and Tangipahoa--have the characteristics of this quadrant. Four of the parishes in this category deviate significantly from the national trend in per capita income: Avoyelles, Beauregard, Concordia, and Lasalle, all non-coastal area parishes.

VI. Below-average increases on all three counts:

One SMSA area falls into this category, Shreveport (non-coastal). The majority of the parishes are those of north and central Louisiana, e.g., Desoto, Bienville, East Carroll, Jackson, etc. Only one coastal area parish, Vermilion, is part of this category.

Percentage-wise increases in per capita income for the State have not been at all closely correlated with growth in population. Of the 31 parishes in which per capita income increased more rapidly than the national average, 22 had a below-average increase in population.

Of the total classifications in Figure 5 (Table 4), 52.7 percent are parishes, or SMSA's, fitting into the first three categories, i.e., categories featuring above-average increases in per capita income. Within category I--above-average increases in population, total income, and per capita income--70 percent are coastal zone parishes. Of the coastal zone parishes not in category I, 42.9 percent are in either II or III.

As to the various causes of economic growth, much of the model building for regional economies attempts to reproduce a highly simplified form of the prevailing relations between population changes, investment in capital (whether material or embodied in human beings), and technological changes as the independent variables and per capita product as the dependent variable. In addition, natural resources and geographical factors are recognized as significant contributors to

Categories are described on pages 20 and 21.

economic growth. In Louisiana much of the growth to date has been directly related to mineral resources (Melton, 1969). This dependency is seen through the somewhat disproportionate mineral production that has occurred within the State. In 1966 Louisiana contributed 14.97 percent of the dollar value of minerals produced in the United States; and of this State total, 80.49 percent originated in the coastal zone.

In general, the potential sources of growth are many. For example, levels of capital per worker, education per worker, average hours worked, and the allocation of resources all contribute to output. The main thrust of these and other factors of economic growth comes from increasing the output per unit of input. Basically, there are five groups of reasons for changes in output per unit of input.

1. Advances in technological and managerial knowledge, including business organization, permit more production with the same inputs.
2. At any time there is some allocation of resources that would yield a maximum total product. This allocation would be such that every input--each individual worker, in the case of labor--is used where the value of its marginal product is greatest.
3. Obstacles against the most efficient utilization of resources may be deliberately imposed by governments, business, or labor unions in the use to which they are put. Changes in these restrictions may affect the growth rate.
4. Enlargement of markets makes possible the reduction of unit costs by greater specialization and thus increases output per unit of input.
5. The above reasons are from the "supply" rather than the "demand" side of the determinants of actual output. But a region's actual output may also be altered because of changes in the extent to which its available resources are used (Denison, 1967).

Investment, or technological advancement, as means of increasing output has several forms. Three of these types--real capital accumulation, investment in human capital, and migration as an investment--will be discussed briefly below and treated in detail later. With regard to the other reasons for changes in output listed above, (2) and (3) have experienced extended scrutiny in Louisiana. For example, it has often been asserted that the State has unlimited resources and that only corruption is holding it back economically (Smith, 1971). The degree of potential within the State is extremely speculative. Nevertheless, Louis J. Rodriguez (1971) concludes that it appears that the level of Louisiana's economic performance is not commensurate with its natural resources potential. However, the State's resource base is not as unlimited as many would like to believe. If Louisiana is to achieve a much needed improved rate of economic growth, it must cast aside its traditional reliance on natural resource superiority to do the job.

As to point (4) above, the extent of Louisiana's proximity to final markets is adequate to a limited degree. The State's geographical location makes it, via the New Orleans Port, a gateway to the mid-continent of the United States, and the deepwater ports at Baton Rouge and Lake Charles provide additional access to foreign regions. However, in spite of these advantages the State is poorly situated relative to important United States markets, e.g., Atlanta, Georgia, a fact which is a deterrent to industrial location in the area because of the increased cost of transporting finished products (Chaffin, 1968).

The rate of real investment, or capital formation, is the means by which the stock of plant and equipment is increased--a vital force in the changing structure of per capita output. There appear to be no serious barriers to the flow of capital either interstate or intrastate within our national boundaries. However, the opportunities and inducements for investment in a particular region are varied. In 1963 only 1.85 percent of the capital expenditures in the United States were made in Louisiana. In this respect Louisiana presents a substandard performance in the one function which is mentioned more than any other as a factor of economic growth. Furthermore, of this somewhat meager outlay on capital expenditures, the coastal zone, heretofore hailed as a major source of economic growth, provided only 54.3 percent of the State total.

Recently another form of capital investment, investment in human inputs, has captured the attention of economists and others interested in the maximum use of all available resources. It is not obvious that all skills and knowledge that people acquire are a form of capital. However, it has been observed in Western societies that most national outputs have grown faster than the accompanying increases in non-human inputs. Investment in human capital is probably the major explanation (Schultz, 1961). Although the benefits to our national economy from the overall progress of human investment are apparent, Louisiana has suffered from a somewhat inferior program. In fact, a principal factor holding back the State's rate of economic growth is the skill level of the people (Melton, 1969). The median years of school completed by persons 25 years and older in Louisiana in 1960 was 8.6 for the male population and 9.0 for the female counterpart, and the composite figure was 8.8 years.¹ Given this total value, only two states in the coterminous United States [Kentucky (8.7) and South Carolina (8.7)] had a lower median value. A detailed analysis of education and the returns to schooling will be given later.

Among various sectors of the national economy, manufacturing is one of the largest and most dynamic in terms of total employment and output. In 1965, 31 percent of the national income originated in manufacturing. A useful measure of manufacturing activity is provided by value added by manufacturing, which is a "net" figure derived by subtracting the cost of raw materials, semi-manufactured parts and components, supplies, fuels, purchased electrical energy, and contract work from the value of shipments of manufacturing establishments. This measure avoids duplication in the value of shipments which results from the use of products of some establishments as materials by others. As

¹It is accepted here that "average (or median) years of schooling" is not a precise measure of knowledge, especially across regions. Many factors, above and beyond mere time spent in a classroom, determine the quality of output. However, in quantitative analysis, such a measure is a reasonable proxy.

such, it constitutes the best value available for comparing the relative economic importance of manufacturing among regions. Louisiana, in 1963, had 1.00 percent of the national value added by manufacturing, while 0.83 percent of the total U.S. employees in manufacturing were located in the State. There are various reasons for regional concentration of manufacturing activities. In particular, such a factor as straight-forward ties with intermediate manufacturing markets is likely to be important. Hence the Middle Atlantic and the East North Central states produce over one-half of manufacturing activity, both in terms of number of employees and value added.²

More generally, the employment structure of Louisiana's nonagricultural sectors is noticeably disparate vis-a-vis the national distribution. The complete percentage distribution of employment (Table 5) shows that mining and contract construction are two areas in which the Louisiana economy finds greater concentration than the national distribution. The State's focus on mining operations stems from the resource base which, in 1968, placed Louisiana second in the U.S. in the value of mineral production, with the principal elements being petroleum, natural gas, natural gas liquids, and sulfur. The value of construction contracts in Louisiana in 1968 represented 1.77 percent of the national total. Furthermore, 8.3 percent of the national mining employment and 2.4 percent of the contract construction total occurs within the State boundaries.

As a barometer of industrial income-generating power in the United States, the percentage of national income originating in each of the sectors of Table 5A is presented in Table 5B.

Mining and construction produce a diminutive proportion of national income: 6.0 percent of the total. Louisiana pays 6.9 percent of its total wage and salary disbursements to the mining population and 10.2 percent to the contract construction sector. Furthermore, of these State totals, 81.1 percent of the mining disbursements and 77.4 percent of the contract construction payments are made within the 24-parish coastal zone.

The importance of agriculture in the aggregate income of a state is clearly related to its level of economic advancement. Farm families account for much poverty and, consequently, a large agricultural sector usually indicates a less highly developed economy. The agricultural drag on a state's economy has been verified in several empirical studies (McDonald, 1961). Specifically for 1960, cross-sectional computation of State patterns renders a simple correlation coefficient of -0.38 between State per capita income and percentage of income originating in the agricultural sector, i.e., high per capita income figures follow relatively in phase the indexes of low agricultural dependency (Rice, 1970).

²The Middle Atlantic states are New York, New Jersey, and Pennsylvania. The East North Central states are Ohio, Indiana, Illinois, Michigan, and Wisconsin.

Fortunately, Louisiana does not suffer from a large agricultural dependency. In 1967 only 4.2 percent of the total State employment was in agriculture, and, furthermore, this percentage represented a declining trend from 1959, when the figure was 8.2 percent. These values compare with national averages of 8.5 percent employed in agriculture in 1960 and 6.7 percent in 1967. Hence, the relatively decreasing importance of agriculture as an income generator (in 1950, 7.01 percent of national income originated on farms, whereas in 1967 this percentage had declined to 3.04) does not substantially place Louisiana in the agriculture syndrome that pervades many states and functionally contributes to their underdevelopment.

The farm income generated within Louisiana in 1969 represented 1.27 percent of the total U.S. farm receipts. The principal commodities for the State, in order of cash receipts for that year, were rice, cattle, soybeans, and sugarcane. This hierarchy of cash crops shifted somewhat during the 1960's. For example, in 1964 cotton was the top cash-producing crop for the State of Louisiana. Also, in 1967 Louisiana produced 6.29 percent of the total farm value of cotton and cottonseed in the U.S., but by 1969 this percentage had dropped to 5.09. This declining trend, plus the decreasing farm value of cotton nationally, accounts for the declining cash receipts from cotton in Louisiana. In 1960 the farm value of cotton, excluding linters, was \$2,150 million, whereas preliminary reports on the 1969 produce indicated a value of \$1,076 million. The crop which supplanted cotton as Louisiana's chief cash crop, rice, has made significant national gains. The farm value of rice in 1960 was \$248 million, but by 1969 this figure had increased to \$449 million.

Within Louisiana, the coastal zone is less dominant in the percentage of agricultural production than in industrial output. For example, in 1968, of the State's total earnings in contract construction, the coastal zone produced 77.27 percent, and in manufacturing, 69.62 percent of the total, whereas it provided only 27.97 percent of total farm earnings. In the production of specific crops, particularly the leading cash crops of the State, the coastal zone produces less than half the total output; e.g., in 1963, 41.13 percent of the total State production of rice and only 2.59 percent of the total cotton output was produced in the coastal region. However, as emphasized above, the prospects for economic growth and increased output in Louisiana are not highly dependent on a strong agricultural sector. This trend is corroborated by the fact that in 1967 only 0.65 percent of the State's income disbursements went to agriculture. This fact is somewhat a function of low per capita farm incomes vis-a-vis other sectors, although Louisiana did produce net income per farm which was 104.9 percent of the United States value, but it also reflects the diminutive proportion of the population which depends on farming. Even nationally the farm population had diminished to 5.1 percent of the total population in 1969 compared to 15.3 percent in 1950.

To present a sketch of the total Louisiana economy and the relative importance of the coastal region, Figure 6 delineates the total State

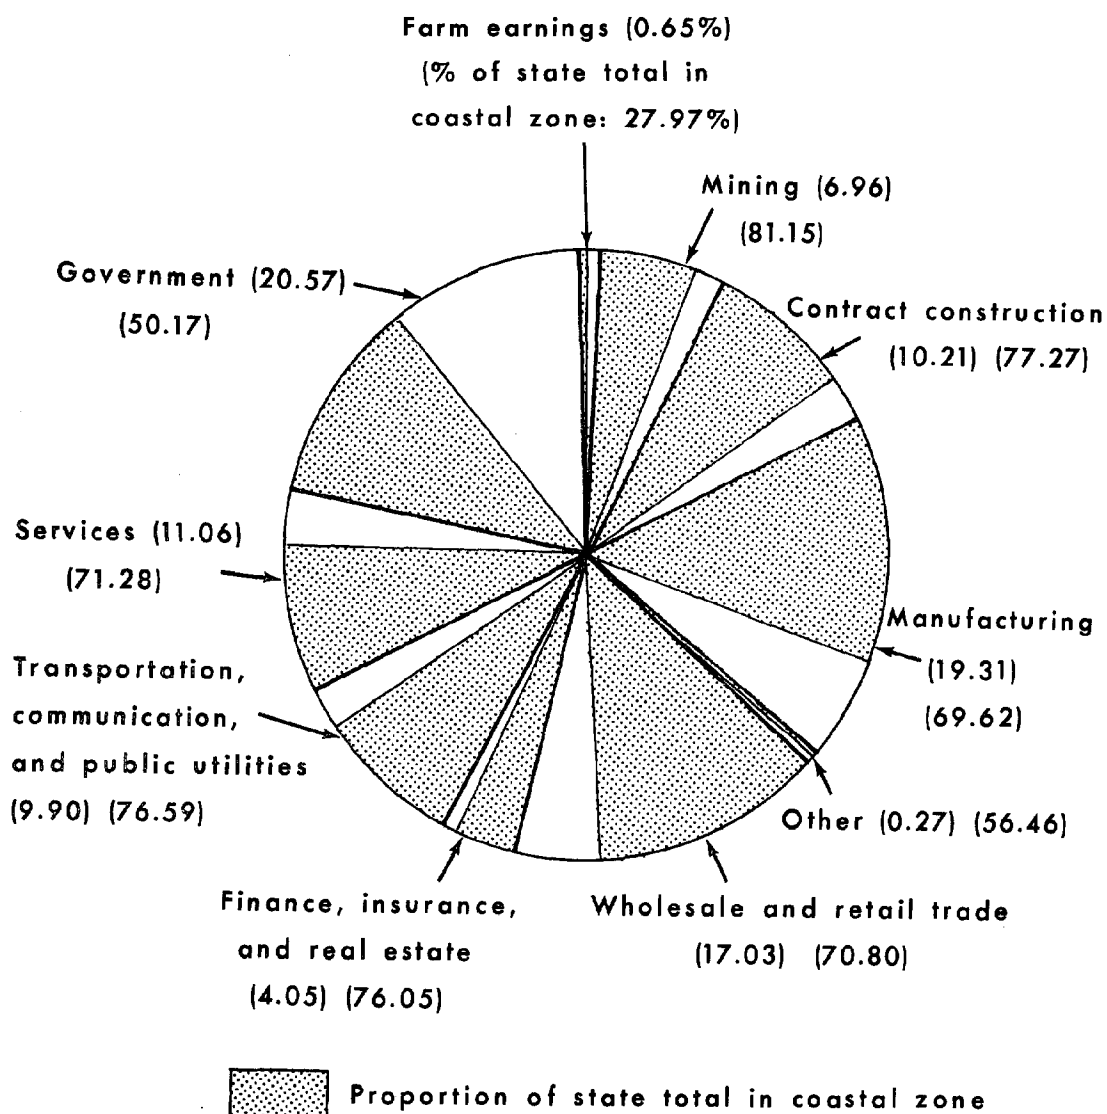

Fig. 6. Percentage distribution of income payments to individuals in Louisiana and percentage of State distribution in coastal zone, 1967-1968. First figure in parentheses following industry designation indicates percentage of State income payments to this sector; second denotes percentage of sector located in the coastal zone. Sources: Percentage of income payments to the various sectors from U.S. Department of Commerce, 1969, Personal Income by States since 1929, in Survey of Current Business. Percentage of State totals in coastal region based on specially requested data from the 1 percent Social Security sample, Regional Economics Information System, Office of Business Economics, U.S. Department of Commerce, Washington, D.C.

income payments among the various sectors. Within each sector, the percentage of income originating in the coastal region is denoted by the shaded area.

CHAPTER IV

SHIFT-SHARE ANALYSIS AS A TOOL FOR REGIONAL AND STATE ECONOMIC ANALYSIS

Employment Shift Ratios

One of the basic and most frequently used tools of measurement of employment and income change in a region is the shift ratio. If employment is the relevant variable to be studied, then calculation is made to determine the rate of growth of employment in a given industry over a 10-year intercensal period on an overall or national basis. Then, for each region or state, computation is made to ascertain the difference between the actual employment in the industry and the employment that would have resulted had the region or state's rate of growth in the industry conformed to the national rate. A shift of industry into a region or state is signified by a positive sign; for the opposite situation the sign is negative. The shift ratio for an industry involves summing all the positive or negative shifts in employment to express the result as a proportion of total industry employment (Bretzfelder, 1970).

Data are not available at present for the 1960-1970 intercensal period. Accordingly, analysis of employment shift data for the 24-parish coastal area is presented in Table 6 for the periods 1940-1950 and 1950-1960.

In Table 6 the term "national growth" represents the employment increase in each particular industry that would have occurred in the Louisiana coastal economy if the particular industry had grown at the national rate for all industries combined--it equals employment in industry *i* in the base year times the national growth rate for all industries. "Industrial mix" represents adjustment for the fact that the national growth rate for industry *i* was greater than or less than the employment growth rate for all industries in the nation--it equals employment in industry *i* in this region for the base year times the national growth rate for industry *i* minus the national growth rate for all industries. "Regional share" reflects the fact that employment in industry *i* expanded more or less rapidly in the coastal economy than in the nation as a whole over the period of measurement--it is equal to employment in industry *i* in the base year times the growth rate for industry *i* in the coastal economy minus the growth rate for industry *i* for the nation (Blizzard and Burford, 1971).

Shift-Share Ratios

Shift-share ratios of income provide an analytical tool for analyzing trends in the growth of regional personal income. Use of the shift-share technique permits decomposition of the growth of a region or state's

personal income into three components, which facilitates identification of factors underlying income trends in the study area.

The income growth of a region relative to the national growth can be factored into two elements: (1) The effect of differences between the income structure of the region and that of the nation (the component-mix effect) and (2) the effect of differences between regional and national growth rates in each source of income (the regional-share effect). The regional-share effect provides the major explanation of the relative income experience of a region, as evidenced by the high correlation between it and relative growth in total income. Where the regional share effect is positive, one would anticipate above-average growth in total income, and where negative, below-average income gains would be anticipated.

Components of income growth. The components of income growth for Louisiana from 1959 to 1969 are shown in Table 7. The data are categorized by income source as fast growth (growing at above-average rates) and slow growth (growing at below-average rates).

In Table 7 a regional increase in share of a fast-growing component increases that region's income growth, and the size of the increase depends on the proportion of the component located in the area. At the same time, a rise in a slow-growth factor has a negative effect on differential income growth. But this effect is relative inasmuch as an increase in any income component will raise total income. If a large proportion of an area's total economy consists of industries or types of income that are growing slowly nationally, total income in the area might expand at less than the national average rate even though each income source in the area were increasing at a rate above the average.

The competitive position of Louisiana. The regional-share effect may also be regarded as an indicator of the competitive position of a given geographic area vis-a-vis other areas. This is so because the regional-share effect compares the performance of an industry in a given area with that of the same industry in other areas. Of course, this economic interpretation of the regional-share effect requires distinction between industries whose markets are largely outside the region and those that supply primarily intraregional demand.

During the 1960's, the most rapid income growth occurred in the Southeast, where total personal income more than doubled while the nation gained only 95 percent. However, very little of the gain in the Southeast is attributable to Louisiana growth, where the component mix was negative and the regional share was small. Moreover, the competitive gain in Louisiana was quite low for the period. See Table 8.

For the Southeast as a whole, the component mix was negative over the period 1959-1969. This was so because of the importance of farm income to the region. Farm income had the smallest growth rate over the decade, and so income growth was retarded. Mining payrolls showed

a small rate of growth, a fact which especially slowed Louisiana income growth because of the high proportion derived from mining payrolls (oil, gas, sulfur, etc.). Considering all southeastern states, only West Virginia and Alabama lagged behind Louisiana in terms of competitive gains.

The Southeast did manage to make competitive gains in all but 4 of the slow-growth components of income, but Louisiana made gains in only 18 of the 38 components. Of these 18, 11 were slow-growth components.

The entire competitive gain--the regional share--for Louisiana was just adequate to offset the negative effects of the component mix and thereby yield for the State a positive net relative change in income. Louisiana placed at the bottom in a ranking of fast-growing states.

Louisiana clearly has an economy highly dependent upon slow growth, so that competitive gains are barely sufficient to offset the relative declines from adverse industrial mix. Furthermore, most of the competitive gains which were made during the 1960's were in these same slow-growth industries. This scarcely bodes well for the future. Future prospects are made even bleaker by the finding that the great bulk of income growth in Louisiana during the 10 years from 1959 to 1969 resulted solely from aggregative national growth. Only approximately 0.5 percent of the net income growth during this period resulted from local factors, and only 2.8 percent of the net income growth was a result of competitive gains.

coastal parishes in 1967. Of the 21 major industry groups, all but 4 are in the category of slow growth, and one of these, ordnance, has undoubtedly slipped considerably because of the decrease in the National Aeronautics and Space Administration budget.

In spite of over-reliance on slow-growth manufactures, there are some offsetting features for the coastal economy, though not for the State as a whole. The category of fast-growing components (see Table 7) includes several items in which the coastal economy ranks high within Louisiana. Table 10 compares, as a percentage of the U.S. total, coastal region personal income by major sources and earnings by broad industrial sector with the rest of Louisiana for the years 1950, 1959, and 1968. The following components are considered fast growing for the nation, and they are components that are highly concentrated in the coastal economy: other labor income; property income; contract construction, and wholesale and retail trade. Moreover, the coastal economy is not, as a percentage of the U.S., very far behind the national average in the fast-growing components of services; state and local government; and finance, insurance, and real estate.

Given the shift-share ratios for Louisiana manufacturing and personal income, one has to be quite skeptical about the future of the State economy at large and in the coastal region. What is not known is how other major variables may alter the future. For example, regional realignments in population, private investment expenditure, and public spending on ports, waterways, highways, and recreational facilities may significantly change or modify the shift-share ratios. What is obviously needed in Louisiana is to seek ways of increasing the State's share of fast-growing components--if, of course, that is the wish of the citizens of Louisiana.

CHAPTER V

POPULATION IN COASTAL LOUISIANA

From 1960 to 1970, Louisiana's population increased from 3,257,022 to 3,641,306, an 11.8 percent gain. In the coastal region the population increased from 1,916,414 to 2,238,021, whereas the rest of the State experienced a net change of 62,677, only 16.31 percent of the total State increase. The population of the parishes in 1960 and 1970 and the percentage changes are shown in Table 11; the first 24 parishes again represent the designated coastal zone. In certain parishes the population increased relatively more than in adjacent parishes. In the jargon of regional economics, such areas may be called "growth centers." One characteristic of a growth center is that its rate of growth is larger than the State's average (11.8 percent). Of the 20 parishes in the State which met this criterion, 15 were in the coastal region.

Only 2 of the coastal area parishes--Calcasieu and Orleans--had decreases in population between census counts, whereas in the rest of the State 18 of the 40 parishes had decreasing populations. To some degree relative population changes imply intrastate migration, which results most often from economic incentives arising from disequilibrium across spatially separated labor markets. One dominant factor which affects income differences is the agglomeration of the population within an area, since often the scale of subeconomies determines the type of work readily available to the individual. The residents of large metropolitan areas generally have a wider choice of industries in which they may seek employment. One approach by the Bureau of the Census to organize the economic landscape of the United States into areas of functional integration is the designation of Standard Metropolitan Statistical Areas (SMSA). The principle of the SMSA is that areas tied to the same central node should be considered a region. Essentially, an SMSA is defined (except in New England) as a county (parish) or group of contiguous counties (parishes) that contain at least one city of 50,000 inhabitants or more, or "twin cities" with a combined population of at least 50,000. In addition to the county or counties containing such a city or cities, contiguous counties are included in an SMSA if (1) 15 percent of the workers living in the county work in the central county of the area, (2) 25 percent of those working in the county live in the central county of the area, or (3) other measures such as telephone calls from the county to the central county and newspaper circulation indicate their integration with the central county (U.S. Bureau of the Budget, 1964).

There are six SMSA's in Louisiana. Table 12 shows the coastal parishes designated as SMSA's and their SMSA label. Also, it shows that of the total State population 54.82 percent resides in SMSA

parishes. However, within the coastal zone, 70.87 percent of the population is within SMSA boundaries. To the extent that certain economies accompany metropolitan agglomerations, the coastal area is relatively superior to the rest of the State. The hypothesis of urbanization's contribution to economic development has been positively verified throughout the literature.¹ For a causative explanation, industrialization is commonly taken to be the prime motivating force behind city formations. Given the dichotomous demarcations of Louisiana, the coastal region and the rest of the State, there exists a marked disparity between population distribution and SMSA distribution. In particular, 1970 census counts show that 61.46 percent of the State's population resides in the coastal region, but 79.46 percent of the State's SMSA population is in the coastal region. This relative concentration of individuals provides a better basis for industrial growth than is available to northern and central Louisiana.

Concomitant with the SMSA distribution is the location of the population in a rural or an urban setting. As mentioned above, the agglomeration of people in metropolitan areas provides some external economies which arise from locational advantages, e.g., wider choice of occupations and the opportunity to develop a higher degree of specialization. In fact, as an empirical rule, families living in metropolitan areas show

¹For example, Schnore, L. F., 1961, The Statistical Measurement of Urbanization and Economic Development. Land Economics, 37:229-245.

a marked superiority in average income.² Concentration of people and economic activity, however, involves costs as well as benefits. In particular, traffic congestion and air pollution increase with city size; also, commuting time rises and recreation areas become less accessible as the city expands. In addition, expenditures for police protection, welfare, and waste disposal are higher per person in very large cities. The distribution of the Louisiana population, by parish, is delineated into rural and urban classifications in Table 13. The definition of urban population as used here and in the 1970 Census is all persons living in urbanized areas and in places of 2,500 inhabitants or more outside urbanized areas. More specifically, the urban population consists of all persons living in (a) places of 2,500 inhabitants or more incorporated as cities, villages, boroughs, and towns, but excluding those persons living in the rural portions of extended cities; (b) unincorporated places of 2,500 inhabitants or more; and (c) other territories, incorporated or unincorporated, included in urbanized areas. The population not classified as urban constitutes the rural population.

The 1970 Census reports Louisiana as having a population that is 66.1 percent urban and 33.9 percent rural. The urban population is 2,406,150; 1,235,156 live in rural areas. If we arbitrarily label parishes "urban" when 50 percent or more of their residents are classified "urban" by the Census definition and "rural" when less than 50 percent, 21 are urban and 43 are rural statewide (Fig. 7). Ten of these urban parishes are in the coastal zone.

Changes in the urban and rural populations from 1960 to 1970 are illustrated in Figures 8A and 8B. The 1970 State urban population represents an increase of 16.8 percent from 1960. Considering individual parishes, 20 exceeded the State's rate of growth in urban population. Vernon Parish surpassed all others in the percentage increase, 592.7 percent, reflecting the reactivation of Fort Polk in August 1961. Within the coastal zone, 54.2 percent of the parishes showed a rate of increase greater than the State's total. The rural population of 26 parishes statewide increased at a rate greater than that of the State from 1960 to 1970. The parish experiencing the largest percentage increase, 57.9 percent, was St. Tammany. For the coastal zone parishes, three-fourths had a greater growth rate in rural population than the State as a whole.

Many of the problems that are commonly attributed to excessive population are actually caused by uneven distribution. In Louisiana, there are 81 persons per square mile compared to the U.S. average of 58. Table 14 gives the population density for each of the Louisiana parishes, and Figure 9 shows the corresponding distribution. These figures compare with an extremely diverse distribution within the United States, which ranges from 5,327 persons per square mile in the New York City area to

²For example, in 1969 families living in metropolitan areas of a million or more had average incomes 13 percent higher than those of families in smaller metropolitan areas and 37 percent higher than those of families outside metropolitan areas (Economic Report of the President, p. 113, February 1971).

3.4 for Wyoming and only one person for each 2 square miles in Alaska (Economic Report of the President, 1971, p. 111). The interpretation of population density as it pertains to economic well-being is far from precise. But we do know that in all the social sciences there is no more fundamental relationship than that between man and land. However, this relationship must consider all the environmental aspects, both natural and cultural. A high population-density figure may indicate overpopulation; but even a region with low population density may be overpopulated. Only the qualitative and critical appraisal of human wants and abilities and of the resources available can render conclusive evidence (Zimmerman, 1951). According to Zimmerman (1951), there are several ways to express the optimum population density:

1. The population density at which the optimum is attained depends primarily on the amount of foreign energy, particularly inanimate energy, available.

Since foreign energy can be made available only by means of capital equipment, the same principle could be expressed as follows:

2. The population density at which the optimum is attained depends largely on the amount of capital equipment available.

Furthermore, since a low density is compatible with a high degree of civilization only if the sparse population is very mobile, we can express the same idea a third way:

3. The population density at which the optimum is attained depends on the relative mobility of the population.

Zimmerman continues, "Hence, every improvement in the technique of transportation and communication reduces the space handicap, lowers the weight of the overhead burden, and thus brings us closer to the optimum." In the transportation category, Louisiana's expenditures for construction and maintenance of State-administered highways represented 1.94 percent of the United States total in 1966 as compared to 2.27 percent in 1950. In 1969, of Louisiana's total nonagricultural employment, 0.78 percent was engaged in railroad transportation; 5.24 percent, in transportation excluding railroads; and 2.87 percent, in communication, electric, gas, and sanitary services. These percentages compared with national values of 1.81, 2.96, and 2.46, respectively. For the communication sector, data show that in 1966 there were 1,440,000 telephones in Louisiana, representing a 41.7 percent increase from 1960; the national percentage increase, for the same period, was 32.9. However, the total net paid circulation of daily newspapers in Louisiana increased by only 3.8 percent from 1960 to 1967 versus a national increase of 4.5 percent.

A demographic characteristic which typically influences inter-regional income distributions is the age composition of the population. Different age categories traditionally impose either significant earning potential or onerous impacts on an economy. More specifically, an index of dependency might be computed as the percentage of population outside the range between 15 and 65 years of age. The parish values for this index are presented in Table 15. Although this index is not completely accurate in articulating the extent of dependency, it serves as a satisfactory proxy.

Two age categories specifically represent potential buoyancy for an economy. First, those individuals between the ages of 21 and 34--the young adults--provide a reservoir of new knowledge and initiative. If this proportion were to diminish, the burden upon development would be obvious in that the residual population would reflect inordinately large numbers of older people and children. The percentage of population in each parish between the ages of 21 and 34 is summarized in Table 15. In 1970, 19.0 percent of the coastal region population was in this age group, compared to 16.4 percent for the rest of the State. The percentage for the rest of the State excludes the data on Vernon and West Feliciana parishes because of the excessively skewed age distributions of Fort Polk

TABLE 15
AGE DISTRIBUTION OF POPULATION, BY PARISH, 1970

and Angola Penitentiary, respectively. The second age category which represents potential buoyancy for an economy is the 35-44 group, which encompasses the peak years of earning power. Table 16 presents the percentages of the total parish populations within this age category.

As noted in several studies, the differential in income between the South and other regions is in part attributable to the low economic status of nonwhites.³ Nationally, in 1968, 10 percent of the white population had incomes below the Census-designated poverty level, compared to 34.7 percent for the nonwhite population. To ascertain the

regional impact of this concentration, note that in 1960 59.9 percent⁴ of the total Negro population resided in the southern census regions. The plight of the nonwhite, the vast majority of whom are black, appears to be related in part to several kinds of economic discrimination in job opportunities and to be an indirect result of poor education obtained in schools with relatively low standards. Additionally, nonwhite families have backgrounds that allow less economic mobility than other families (Morgan *et al.*, 1962).

⁴The census region designated as "South" includes three subdivisions: (1) South Atlantic--Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida; (2) East South Central--Kentucky, Tennessee, Alabama, and Mississippi; and (3) West South Central--Arkansas, Louisiana, Oklahoma, and Texas.

The percentage of each parish's population in 1970 which was nonwhite is summarized in Table 17. For the broader regional classifications, 28.6 percent of the coastal region population was nonwhite, compared to 36.6 percent for the rest of the State. Of the 21 parishes which had nonwhite populations representing 40.0 percent or more of the total population, only 5--Iberville, Orleans, St. James, St. John, and West Baton Rouge--are located in the coastal region. Such a distribution of population groups helps to explain per capita income differences between the two regions, coastal and the rest of the State.

Population Projections

One of the most useful sets of data in regional analysis relates to future population numbers. The projections for a region mirror such future conditions as market demand, demographic stratification, and industrial potential. Within the framework of projection methodology, one of the more precise variations is the "cohort-survival" method, which simulates the exact process of population change. In cases where vital rates are fairly reliable and where in-migration and out-migration numbers are reasonable, this method is very useful. However, it must be kept in mind that migration estimates for open areas, i.e., areas where population flows are not directly determined by government policy, are not generally congruent in successive time periods and thus should be viewed with discerning care. Nevertheless, the cohort-survival method of analysis, by considering temporal changes in the composition of a regional population, is relatively efficient.

In general, the population of any age-race-sex group at a given time can be stated conceptually as follows:

$$P_{i,j,k,t} = P_{i-1,j,k,t-1} + B_{i,j,k,t} - D_{i,j,k,t} + M_{i,j,k,t} \quad (1)$$

$P_{i,j,k,t}$ represents the population of the area in question in age group i , race j , and sex k at time t . $P_{i-1,j,k,t-1}$ is the population in the area in the age group one period younger in race j and sex k in the preceding time period. $B_{i,j,k,t}$ is the number of births in age group i , race j , and sex k , between time $t-1$ and t . Of course, for all but the youngest age group, $B = 0$. $D_{i,j,k,t}$ is the number of deaths between time $t-1$ and t of persons who were of age $i-1$ in period $t-1$ for race and sex groups j and k . Finally, $M_{i,j,k,t}$ is the net migration (difference between in- and out-migration) between periods $t-1$ and t for people aged $i-1$ in $t-1$ and for race and sex groups j and k , respectively. It is now obvious that, if $P_{i-1,j,k,t-1}$, $B_{i,j,k,t}$, $D_{i,j,k,t}$, and $M_{i,j,k,t}$ are all known, then the population by age, race, and sex in time t can be determined exactly.

Consider in more detail each of the three components of change in population (B , D , and M). Look first at births. It has already been indicated that $B_{i,j,k,t} = 0$ for all $i \neq 1$. Therefore, it is necessary

TABLE 17
PERCENTAGE OF POPULATION NONWHITE, BY PARISH, 1970

St. Martin	34.8	Pointe Coupee	50.4
St. Mary	28.6	Rapides	28.2
St. Tammany	19.5	Red River	42.2
Tangipahoa	31.9	Richland	40.9
Terrebonne	17.9	Sabine	20.0
Vermillion	13.9	St. Helena	56.7
West Baton Rouge	42.9	St. Landry	41.4
Acadia	19.9	Tensas	59.6
Allen	24.1	Union	33.7
Avoyelles	27.8	Vernon	11.7
Beauregard	18.8	Washington	32.7
Bienville	47.0	Webster	31.2
Bossier	20.0	West Carroll	19.5
Caddo	36.7	West Feliciana	66.2
Caldwell	26.6	Winn	30.4

to consider only $B_{1,j,k,t}$. Suppose that $B_{i,j,k,t}$ is the age-race-sex specific birth rate which holds in period $t-1$ to t ; that is, $B_{i,j,k,t}$ is the number of births in race j and sex k born per mother in age i within the time interval $t-1$ to t . Hence, assuming $k = 2$ for females,

$$B_{1,j,k,t} = \sum_{i=1}^n b_{i,j,k,t} (P_{i-1,j,2,t-1} + M_{i,j,2,t} - D_{i,j,2,t}) \quad (2)$$

where there are n age groups of women. Of course, $b_{i,j,k,t}$ can be expected to be zero for the very young or the older age groups. $M_{i,j,2,t}$ is the number of females (net) in age and group i and j , respectively, who migrated into (or out of) the area in time interval $t-1$ to t , and $D_{i,j,2,t}$ is the number of females who died. This method assumes that women who migrated into or out of the area have had babies at the same rate as others but that women who died had no babies during that period. If it is assumed that deaths (and births) occur evenly throughout the period,

then, instead of $D_{i,j,2,t}$, we can substitute $(D_{i,j,2,t})/2$ into the equation to allow for births before the death of the mother.

Assuming that $D_{i,j,k,t}$ is the age-race-sex specific death rate for the area, then

$$D_{i,j,k,t} = d_{i,j,k,t} (P_{i-1,j,k,t-1} + M_{i,j,k,t}) \quad (3)$$

for all ages except the first age group. For the first age group, the age-race-sex specific death rate for the area is

$$D_{1,j,k,t} = d_{1,j,k,t} (B_{1,j,k,t})$$

Finally, assuming $m_{i,j,k,t}$ to be the migration rate,

$$M_{i,j,k,t} = m_{i,j,k,t} (P_{i-1,j,k,t-1} + B_{i,j,k,t} - D_{i,j,k,t}) \quad (4)$$

Looking now at the population at time t and taking into account each component of change, we have

$$P_{1,j,k,t} = \sum_{i=1}^n (b_{i,j,k,t}) (P_{i-1,j,2,t-1}) (1-d_{i,j,2,t}) (1 + m_{i,j,2,t}) (1-d_{1,j,k,t}) \quad (5)$$

for the number of people in the youngest age group by race and sex; and for all other age groups we have

$$P_{i,j,k,t} = P_{i-1,j,k,t-1} (1-d_{i,j,k,t}) (1 + m_{i,j,k,t}) \quad (6)$$

The first of these equations (5) indicates that the number of people in the youngest age group is given by the surviving $(1-d_{1,j,k,t})$ babies born during the period $t-1$ to t to women in the area by age and race in time $t-1$ plus the women migrating in and minus the women who died during this period. This assumes that women who died during the period had no babies. This formulation could be modified slightly to allow for the possibility that some women might have given birth during the period before they died. If it is assumed that the probability of giving birth is the same for all women in a given age and race group, regardless of subsequent death, and if it is assumed that the deaths take place uniformly throughout the time period, then the factor

$(1 - 0.5d_{i,j,2,t})$ can be substituted into (5) in place of $(1 - d_{i,j,2,t})$. Equation (6) should be reasonably self-explanatory. Equations (5) and (6) are the basic equations for the cohort-survival method. The results for each parish are summarized in Table 18.

West Baton Rouge	19,518	23,123	27,109
TOTAL	2,794,732	3,678,149	4,891,285

The projections in this table assume migration rates to remain identical to the rates prevailing in the decade 1960-1970. Projections based on migration rates of 0.25, 0.50, 0.75, and 1.25 of 1960-1970 migration are available upon request. Projections based on age, race, and sex group for each period are also available upon request.

CHAPTER VI

INVESTMENT IN REAL AND HUMAN CAPITAL

Real Capital Accumulation

In dissecting the United States growth record in recent decades, it has been roughly estimated that increased output can be attributed proportionally to inputs as follows: Expansion in the size and improvement in the quality of the labor force accounts for about 1/2, increased productivity for about 1/3, and the enlarged stock of capital for the remainder (Shapiro, 1966). In the National Income Accounts compiled by the Department of Commerce, private domestic investment--the means by which we change our stock of capital--includes basically three things: (1) all final purchases of machinery, equipment, and tools by business enterprises; (2) all construction; and (3) changes in inventories. Perhaps the second item needs some explanation. It is clear that the building of a new factory or a warehouse is a form of investment. Residential construction is included in the investment statistic because apartment buildings are clearly investment goods on the basis of their income-earning potential; furthermore, owner-occupied houses could be rented to yield a money income return, even though the owner does not choose to do so (McConnell, 1969). The data on housing units constructed in Louisiana show that, of the total dating from January 1959 through March 1960, 60.1 percent were located in the coastal region. In 1965, total expenditures for new plants and equipment in the State represented 1.9 percent of the United States total, compared to 2.4 percent for Alabama, 0.7 percent for Mississippi, and 6.2 percent for Texas.

Financial institutions such as commercial banks, mutual savings banks, investment companies, savings and loan associations, credit unions, etc., are the intermediaries for many investment funds, i.e., they allow saving and investment functions to be performed separately by those economic units best equipped to do so. In 1969, 2.1 percent of all domestic insured commercial banks, domestic life insurance companies, insured savings and loan associations, and active credit unions were located in Louisiana. This percentage is compared with 1.8 percent in Alabama, 2.9 percent in Florida, 2.2 percent in Georgia, 1.1 percent in Mississippi, and 2.1 percent in Tennessee. Within Louisiana, 40.2 percent of all commercial banks, as of June 30, 1966, were located in the coastal region; yet, of the total amount of dollar deposits in the State, 68.3 percent were in banks in the coastal zone. As for savings and loan associations, there were 103 statewide on September 30, 1967. Of this total, 67 (65.0 percent) were located in the coastal area; and, of the savings capital available through these associations, 76.0 percent was of coastal zone origin.

Investment in Human Capital

The contemporary interest in the economics of education, and more broadly in the economics of all processes which augment knowledge, represents an approach to a number of diversified problems, including such matters as the economic value of education and the contribution of education to past economic development in advanced countries (Schultz, 1962).

The treatment of currently or potentially productive human beings as capital deviates from the more traditional concept of capital, which is defined as that portion of the non-human, material, manmade stock of wealth which is utilized directly in further production (Shaffer, 1968). The application of the capital concept to man is not without its critics. T. W. Schultz (1961), in his 1960 presidential address to the American Economic Association, points out some of the more salient arguments. Among these are the moral and philosophical issues--the accepted mores proclaiming free men to be first and foremost the end to be served by economic endeavor, not property or marketable assets. However, he concludes that "knowledge and skill are in great part the product of investment and, combined with other human investment predominantly account for the productive superiority of the technically advanced countries. To omit them in studying economic growth is like trying to explain Soviet ideology without Marx" (Schultz, 1961, p. 3).

The model. In empirical studies of human capital, the concern and the theory have centered on the disparity in human investment as an explanation of the skewed distribution of incomes within geographical boundaries (Chiswick, 1968). In most capital markets the amount invested is not the same for everyone nor rigidly fixed for any given person but depends in part on the rate of return. Persons receiving a high marginal rate of return would have more incentive to invest (Becker, 1964). The total earnings of any person after he has invested in human capital can be said to equal the sum of the returns on his investment and the earnings from his original human capital (Becker and Chiswick, 1966). To illustrate, we can designate Y_n as the perpetual annual earnings after N years of training and Y_0 the perpetual earnings if there had been no training. A person without training would earn Y_0 every year, as is shown in row 1 of Table 19. A person who invested for 1 year is assumed to have foregone Y_0 ; that is, he received no net earnings during that year.¹ This is shown by the zero in the second row of the first column. If a rate of return of r were received on his investment, he would earn $Y_1 = Y_0 + rY_0$ ($1+r$) in year two and all subsequent years, where rY_0 is the perpetual return on the investment Y_0 . This is shown in the second row of Table 19. If the rate of return were the same for all years of training, a person with 2 years of training would have received no earnings during years one and two and after that an amount equal to:

¹This point is not entirely viable because people who invest in a year of schooling do not usually complete the year without some net earnings, e.g., summer work, GI Bill, etc.

TABLE 19
ANNUAL EARNINGS DURING AND AFTER TRAINING

Years of Training	Year							
	1	2	3	...	N-1	N	N+1	...
0	Y_0	Y_0	Y_0	...	Y_0	Y_0	Y_0	...
1	0	$Y_0(1+r)$	$Y_0(1+r)$...	$Y_0(1+r)$	$Y_0(1+r)$	$Y_0(1+r)$...
2	0		$Y_0(1+r)^2$...	$Y_0(1+r)^2$	$Y_0(1+r)^2$	$Y_0(1+r)^2$...
...			
N	0	0	0	...	0	0	$Y_1(1+r)^N$...

$$Y_2 = Y_0 + r(Y_0) + r(Y_0 + rY_0) = Y_0(1+r)(1+r) = Y_0(1+r)^2$$

A person with N years of education would receive nothing during the first N years and

$$Y_N = Y_0 + r(Y_0) + rY_0(1+r) + \dots + rY_0(1+r)^{N-1}$$

or

$$Y_N = Y_0(1+r)^N$$

after the investment period (Chiswick, 1967).

This is a basic, simplified model, illustrating the concept of investment in human capital. Variations of this theme and format could include the following: the rate of return not being the same for all years of training; relaxing the assumption of no earnings during the period of investment; distinguishing among the various types of training (on-the-job training, formal schooling, etc.); and recognizing the effects of differences in health, discrimination, and luck.

Data on money investments in human capital are scarce. They are particularly scarce for formal on-the-job training programs and the amount of learning through experience (see Mincer, 1962). There is, however, considerable information on the number of years of schooling, and this is used in the subsequent analysis. Limiting the analysis to years of schooling results in the sacrifice of much precision to obtain an adequate supply of data. Furthermore, the empirical application below draws upon 1960 Census data owing to the nonavailability of the 1970 figures, and therefore the contemporary interpretation suffers. However, the method and the model are presented here for 1960 to provide a benchmark for comparison and a framework for 1970 empirical subjection.

If years of schooling were the only explanatory variable pertaining to income inequality, the relevant earnings equation would be approximately

$$\text{Ln } (Y_s, i) = \text{Ln } \bar{Y}_0 + r_i S_i + U_i \quad (7)$$

where Y_s, i is income after S_i years of investment in schooling for the i th person, \bar{Y}_0 is the average zero schooling level of income, r_i is the adjusted rate of return from schooling,² and U_i is the residual (Chiswick, 1967).

There exist scattered Louisiana data on earnings cross classified by years of schooling for which a regression of the form of equation (7) could be calculated. Then,

$$\text{Ln } Y_s, i = (\text{Ln } \bar{Y}_0) + r S_i + U_i \quad (8)$$

where r and $(\text{Ln } Y)$ are the ordinary least-squares linear regression estimates of the average adjusted rate of return from schooling and the zero schooling level of earnings, respectively, and U is the residual whose squared deviation from the regression line is minimized.³ The residual contains the effects of differences in luck, tastes, ability, investments in human capital other than schooling, wealth, etc.

Empirical analysis. The regression estimate of the internal rate of return from schooling for Louisiana in 1960 is 0.11. The internal rate of return is defined implicitly as the rate of discount equating the present value of returns to the present value of costs (Lutz and Lutz, 1951). The Louisiana rate is very similar to that of other Southern states, which as a rule are higher than their non-Southern counterparts. At the present, data are not available for intrastate estimates of rates of return from schooling. However, in studies relating average rates of return from schooling to income inequality, it has been found that a positive, significant relationship exists between the two variables, i.e., a larger rate of return correlates in direct phase with a greater degree of income inequality (Chiswick, 1968). For Louisiana, the distribution of incomes within parishes for 1960 is available.⁴ The calculations show that the

²For each individual, r_i is the average rate of return from his investment in schooling adjusted for the fraction of earnings foregone during the period of investment. See Becker, G. S., and B. R. Chiswick, 1966, Education and the Distribution of Earnings. *The Am. Econ. Rev.*, 56:363-364.

³For an explanation of ordinary least-squares see Johnston, J., 1963, *Econometric Methods*. New York (McGraw-Hill), pp. 106-115.

⁴It is generally agreed that the best single measure of income

coastal region exhibited a greater degree of income equality than the rest of the State. This array is manifested by the fact that, of the 10 parishes with the greatest degree of income inequality, not one is included in the 24-parish coastal region. Furthermore, of the 10 parishes with the greatest degree of income equality, 8 are in the coastal zone.

If the linear functional relationships between income inequality and rates of return from schooling apply across parishes in a fashion similar to the interstate form, it can be concluded that the rates of return from schooling are not as great in the coastal zone as in the rest of the State. This conclusion is consistent with other socio-economic factors relating to human capital theory, e.g., it has been found that lower levels of income tend to increase the rate of return from schooling, which, in light of the per capita income pattern in Louisiana, corroborates the above conclusion.

Research pertaining to investment in man is noticeably incomplete. The scarcity of regional theory and empirical applications of the human capital approach is particularly acute for intrastate demarcations. Thus, it is proposed that data collection for such purposes--an absolute requisite in evaluating one of our most important resources, human capital--be undertaken.

Migration as Investment

An economic model of migration. The hypothesis that geographical mobility of workers is primarily a response to economic incentives has been tested and verified in recent empirical studies (Bowles, 1970). The purpose of this section is to provide a model of interparish migration as an economic process using data on net migration for 1950-1960. This period is chosen to test the hypothesis because the variables included in the model require the breadth of knowledge found only in completed census accounts.

The basic model concentrates on net migration as a response to income differentials. It is probably more meaningful to consider the present value of the expected income gain from moving rather than the conventional income measures; but, for the simplified model presented here, median income values are used. Further, the level of schooling appears to increase the effect of income gain on the probability of moving, and age appears to reduce it. Significant racial differences also apparently influence migration patterns (Bowles, 1970).

In addition to the monetary benefits of moving, a more pleasant social or physical environment may influence the changes. However, such subjective and micro-considerations will not be attempted in this model. Furthermore, there are costs involved in moving, such as direct expenses and the psychic

inequality is the Gini coefficient. For a brief explanation of this measure see: Verway, David J., 1966, A Ranking of States by Inequality Using Census and Tax Data. The Review of Economics and Statistics, 48:314-321.

costs resulting from breaking old ties. Also, assuming that risk aversion is a general phenomenon, further costs may arise from the uncertainty of a move (Bowles, 1970). However, because specification of these dimensions is tenuous at best, the present model deals only with the readily quantifiable concepts. The hypotheses can be spelled out succinctly as follows:

1. The migration rate is expected to be positively associated with the income differences between origin and destination.
2. The effects of schooling increase the responsiveness of individuals to economic incentives and hence provide more active migration patterns.
3. It is expected that the income gains from moving are greater for younger workers.
4. It is possible that blacks and whites respond to the income incentive in different ways. We might expect to find socially induced differences in subjective attitudes such as risk aversion and time preference arising from the objective social and economic environment (Bowles, 1970). There is scattered evidence that blacks are more risk-averse and have higher rates of time preference than whites (Lefcourt, 1965). Although the psychological studies yielding this evidence are based on experiments and game situations, the results are plausible and are consistent with some observed market behavior (Bowles, 1970). Thus the fourth hypothesis is that blacks exhibit a lower migration response to income incentives.

Empirical analysis. The models for testing the various migration hypotheses are composed of structural equations which show the relationship between the dependent variable, migration rates (Y), and the various variables (X_1, X_2, \dots, X_n) in the form

$$Y = a + b_1X_1 + b_2X_2 + \dots + b_nX_n$$

The statistical technique of ordinary least-squares is used to estimate the parameters (see Johnston, 1963). The final empirical models are selected on theoretical and statistical grounds. Theoretically, the model must conform with a priori considerations; statistically, the coefficients must be significantly different from zero, i.e., the variable must significantly explain variations in the dependent variable. The test used for ascertaining statistical significance employs Student's t distribution. If the computed t value exceeds that corresponding to a prespecified level of significance, it is concluded that the coefficient differs from zero. Several combinations of variables in the multiple linear form are possible. The results of the various formulations often differ, even when much the same group of variables is included, owing to interacting effects

between highly correlated variables. Hence it becomes difficult to separate and estimate their relative effects. In the jargon of econometrics, this malady is called "multicollinearity."

Acronyms for the variables used in the analysis are as follows:

- MIGRAT = Net migration rate, 1950-1960
- MEDY59 = Median income, 1959
- EDUC = Median school years completed for individuals
25 years old and older, 1960
- PCNW60 = Percentage nonwhite, 1960
- PC4050 = Percentage of population 40 years old and older,
1950

The simple correlation matrix for cross-sectional parish data is as follows:

	MIGRAT	MEDY59	EDUC	PCNW60	PC4050
MIGRAT	1.0000	0.8131	0.5095	-0.3937	-0.3002
MEDY59		1.0000	0.5481	-0.5469	-0.3582
EDUC			1.0000	-0.3401	-0.0675
PCNW60				1.0000	-0.2910
PC4050					1.0000

This matrix shows migration rates to be positively related to median income, i.e., the higher the median income, the greater the net in-migration. Also, the educational index, median school years completed, is positively related to net migration rates. Percentage of nonwhite and percentage 40 years old and older are inversely correlated with migration rates. This indicates that for the 1950-1960 decade, parishes predominantly nonwhite and/or characterized by an older population base had a smaller net migration pattern. The one-variable linear equation of each of these variables is as follows (the value in parentheses is the value for each parameter):

$$1. \text{ MIGRAT} = -68.319 + 0.0211 \text{ MEDY59} \quad R^2 = 0.66 \quad (9)$$

(-11.52) (11.00)

$$2. \text{ MIGRAT} = -85.922 + 9.910 \text{ EDUC} \quad R^2 = 0.26 \quad (10)$$

(-4.99) (4.66)

$$3. \text{ MIGRAT} = 18.011 - 0.716 \text{ PCNW60} \quad R^2 = 0.16 \quad (11)$$

(2.26) (-3.37)

$$4. \text{ MIGRAT} = 72.224 - 2.650 \text{ PC4050} \quad R^2 = 0.09 \quad (12)$$

(2.25) (-2.48)

Each equation shows that the respective independent variable is statistically significant at the 95 percent confidence level. The explanatory ability of the respective equations decreases as one reads down the list from "median income" as the independent variable to "percentage of the population 40 years old and older" as the explanatory index (note the R^2

values). The coefficients, given that the 1950-1960 socio-economic-cultural environment persists, imply the following conclusions: (1) a \$100 increase in median income leads to a 2.1 percent increase in the net migration rate; (2) one additional year of education, evaluated at the median, quite substantially influences net migration rates; (3) an increase of 5 percent in the value "percentage of population nonwhite" decreases the net migration rate across parishes by 3.6 percent; and (4) a shift in the age distribution of a parish explains a small proportion, 9 percent, of the differences in net migration rates.

In the equations with more than one explanatory variable, median income dominates the correlated variation to the point of rendering the other variables statistically insignificant. For example, note the following formulation:

$$\text{MIGRAT} = -78.713 + 0.020 \text{ MEDY59} + 1.776 \text{ EDUC} \quad R^2 = 0.67 \quad (13)$$

(- 6.74)
(8.64)
(1.03)

The dominance of median income, which explains 66 percent of the differences in net migration according to equation (9) above, produces an overwhelming percentage of explanatory ability within this specification, even to the extent of showing median school years (EDUC) insignificant at the 95 percent confidence level. A test of the model using all the designated variables, excluding median income, renders signs consistent with a priori reasoning but explains only 36 percent of the total variability in net migration rates. These results tend to corroborate previous empirical studies in their contention that geographical mobility is in fact primarily a response to pecuniary incentives.

CHAPTER VII

CONCLUSIONS FROM ANALYSIS OF ECONOMIC AGGREGATES IN COASTAL LOUISIANA

Much of the economic environment, both past and present, portrays the resources and the trends which will guide the State throughout the next decade. An inventory of these various demands must be taken to assure that Louisiana allocates wisely and chooses the path of greatest efficiency.

Many of our current decisions have future implications. Decision making can become better or worse, depending on the quality of the forecasts which underlie the decision-making process. Quantitative economics has made noticeable progress toward developing a scientific approach to economic prediction, one which is not purely mechanical nor devoid of judgment but which does present a framework of objectivity. However, the methods of forecasting cannot stand alone; inputs must be adequate. The absolute prerequisite of forecasting is germane data, temporally appropriate and aggregated to the specified degree. The lack of such information is a substantial drawback for the economic planning of the Louisiana coastal region. The 1970 Census data provide the most complete compilation available, yet the infrequency of such information makes time series analysis often spurious. For proper planning, more complete and frequent data must be made available.

Probably the most thorough set of projections of consumer demand for the first half of the present decade has been published by Professors H. S. Houthakker and Lester D. Taylor (1970). The study projects that owner-occupied housing will increase at an annual rate of 3.2 percent between 1970 and 1975, gas as a household utility at a 4.5 percent rate, and gasoline and oil at a 2.7 percent rate. These values seemingly have much relevance for the Louisiana economy and especially for the coastal region, with its concentration of mining and contract construction. However, there is something naive about adhering to these projections. The early benchmark year (1964) of the Houthakker-Taylor study is temporally removed to a significant degree from the take-off point (1970), particularly within the framework of our volatile economy. Therefore, with this constraint, general directions of course seem to be the most judicious approach to planning for the coastal region, at least until adequate contemporary data are available.

Recently the Council for a Better Louisiana (CABL) provided an "Agenda for Louisiana for the Seventies."¹ Among the suggestions, each of which

¹The Agenda for Louisiana was published in a series of articles appearing in the Baton Rouge, Louisiana, Morning Advocate beginning June 16, 1971.

seems appropriate in the context of this study, are policies to assure confidence among investors, such as the stability of governmental policies, equity of taxes, and a cooperative governmental attitude in solving problems which affect industry. In addition, Louisiana's economic growth can be enhanced by specific efforts to make cities more attractive to industry, e.g., by dealing with congestion (Baton Rouge, Louisiana, Morning Advocate, June 17, 1971). The "city of the future" portends the megalopolis, the city which stretches between polar concentrations of activity. Within the Louisiana coastal region, Baton Rouge-New Orleans connection appears imminent.

Public concern about the environment creates vast uncertainties about the next decade. It is in this area that the most visible expansion of government's role occurs, for no one can buy his share of clean air or water in the open market. The Gulf Coast and the Mississippi River are particularly urgent points of consternation. Attention must be immediately directed toward the environs of these water resources.

An underlying conclusion for the coastal region's economy is the need for intervention, even exhortation. The Louisiana economy can grow, and grow at a rate comparable to national trends; however, to expect the natural order to provide adequate guidance is ludicrous. The 1970's are obviously dominated by uncertainty. For example, will the Federal government intervene sufficiently to attain goals of simultaneous full employment and price stability? Depending on the direction of national priorities, the Louisiana economy must remain reasonably flexible and able to cater to new demands without immoderate lags.

PART II

ANALYSIS OF MAJOR COASTAL INDUSTRIES

CHAPTER VIII

LOUISIANA COMMERCIAL FISHERIES

Introduction

This chapter begins with a general overview of the fishing industry in the United States. Particular attention will be directed toward foreign trade, supply, per capita consumption and utilization, prices, and principal species. The importance of the Gulf region in general and of Louisiana in particular will receive special note. Various portions will focus on the general characteristics of the Louisiana fishing industry and the principal species.

An Overview of the United States Fishing Industry

United States fishermen caught 4,292 million pounds of fish and shellfish in 1969. This was the largest catch since 1966. Of the 1969 total, 2,246 million pounds were used for human consumption and 2,046 million pounds were used for industrial purposes. The 1969 catch sold for \$518 million, which was 31 percent higher than the previous 10-year average and the highest dollar value in our history (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

The rising importance of the Gulf region to United States commercial fishing is indicated in Table 20. Most of the gain is due to the growth of the menhaden and shrimp industries. By volume, the Gulf region in 1969 accounted for 38 percent of the total United States catch--or 1,622 million pounds. Of these, 1,013 million pounds were landed by Louisiana fishermen. Louisiana led all 50 states in volume of catch in 1968, 1969, and 1970 and accounted for 24 percent of the total domestic catch in 1969. Louisiana's 1969 catch represents the second highest catch for any state in the history of the United States fishing industry. It is surpassed only by California's outstanding 1936 catch of 1,760 million pounds (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

By dollar value, the Gulf catch in 1969 was \$152.5 million, or 29 percent of the total value of the United States catch. Of this, Louisiana landings accounted for \$56.2 million. Louisiana moved from fifth place in 1968 to third in 1969 in the ranking of states by dollar value of catch. Texas ranked fourth with \$46.9 million (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

Foreign trade. The United States fishing industry ranks fifth in world production, behind Japan, Peru, Russia, and China. In 1969

TABLE 20

QUANTITY AND VALUE OF GULF REGION CATCH,
VARIOUS YEARS, 1940-1969
(Millions of pounds, millions of dollars)

Source: U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970, Fisheries of the United States, 1969. Pp. 10-12.

foreign trade in fishery products for the United States was worth a record \$948.8 million. This represents an increase of \$58.4 million over the 1968 value. Imports for 1969 were valued at a record \$844.3 million, as compared to \$822.7 for 1968. In 1969 the United States imported 1.7 billion pounds of edible fishery products. Exports of domestic fishery products were valued at a record \$104.5 million in 1969, an increase of \$36.8 million over the 1968 value of \$67.7 million. Principal causes for the increased dollar value can be traced to increases in the export of salmon, shrimp, and menhaden oil. The export of domestic fresh and frozen shrimp more than doubled from 12 million pounds in 1968 to 25.2 million pounds in 1969; a substantial part of this increase is directly attributable to the excellent brown shrimp season in Louisiana. In spite of the large increase in fishery exports, however, the United States suffered a balance of payments deficit in the fishery industry of \$739.8 million in 1969 (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

Domestic supply. The National Marine Fisheries Service defines the domestic supply of fishery products as the domestic catch plus imports. In 1969 the domestic catch was 4,292 million pounds, and imports amounted to 7,510 million pounds; the total domestic supply of both edible and industrial fishery products was 11,802 million pounds. This represents a substantial decline from the 1968 figure of 17,337 million pounds, but the quantity of edible fishery products actually increased from 5,528 million pounds in 1968 to a record 5,599 million pounds in 1969. The supply of industrial fishery products accounted for the entire decline, falling from a record 11,809 million pounds in 1968 to 6,203 million pounds in 1969. Despite this abnormal decline, however, the total domestic supply of both edible and industrial fishery products has increased 40 percent since 1959.

The changing structure of the United States supply of fishery products is also of interest. In 1959 the total supply consisted of 39 percent imports and 61 percent domestic catch. In 1969 the figures were

64 percent imports and 36 percent domestic catch (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a). These figures give some indication of the reasons some observers have referred to United States commercial fishing as a declining industry. It is also questionable as to whether imports will be sufficient to meet the rising demand for fishery products in the future.

Per capita consumption. Per capita utilization is the total supply of fishery products (as defined above), both edible and industrial, divided by the total population as of July 1 in any year. Per capita consumption figures are derived from the total edible quantity available per period. Per capita consumption figures take into account beginning and ending stocks, as well as exports. In 1969 the per capita consumption of commercially caught fish and shellfish was 11.1 pounds. Historically, the United States per capita consumption figure has been between 10 and 12 pounds, but the 1969 figure is the highest since 1954. Compared with foreign consumers, the United States consumer is not an avid purchaser of fish products. For example, Japan was the leading country in per capita consumption of fishery products with 67.7 pounds, followed by Portugal with 47.5 pounds, Denmark with 46.7 pounds, Sweden with 45.1 pounds, and the Philippines with 36.2 pounds (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

Of particular interest to the Gulf region and Louisiana is the growth in per capita consumption of shrimp. Table 21 shows the dramatic increase in per capita shrimp consumption from 1936 through 1969. Per capita consumption of shrimp increased 400 percent in 33 years (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

Prices. Prices for fishery products in 1969 were generally higher on all levels of trade, including exvessel, wholesale, and retail. Fishermen received a record high average of 12.08 cents per pound in 1969 as compared to 11.46 cents in 1968 and 10.84 cents in 1967. As measured by the indexes of exvessel prices, the average prices paid to fishermen in 1969 were 13 percent above the 1968 level. Prices paid for finfish and shellfish were up 14 percent in 1969, and shrimp prices were up 9 percent (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

Principal species. The 1969 menhaden catch of 1,548 million pounds accounted for 36 percent of the total domestic catch of all species. The 1969 catch was 12 percent above the 1968 catch and the largest since 1965. Gulf fishermen landed a record catch of 1,155 million pounds, surpassing the previous record, set in 1962, of 1,057 million pounds. The Gulf catch in 1969 was 40 percent above the 1968 catch. Gulf fishermen accounted for 75 percent of the total United States menhaden catch. Despite the adverse effects of Hurricane Camille, Louisiana fishermen produced a record 856 million pounds, or 55 percent of the total domestic menhaden catch (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1970). Menhaden is a key industrial species, used for meal, oil, and solubles. The excellent menhaden season had a very favorable effect on United States exports of domestic fish oils, which totaled 196.1 million pounds in 1969--a 201 percent increase over the 1968 figure (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

TABLE 21

UNITED STATES PER CAPITA CONSUMPTION OF SHRIMP, 1936-1969

Year	Pounds	Year	Pounds
1936	0.35	1955	0.95
1937	0.45	1956	0.90

The domestic shrimp industry is the most valuable fishery in the United States. It accounted for 24 percent of the total United States exvessel value for all species in 1969. A record 195.5 million pounds of shrimp (heads off) were landed in the United States in 1969. Fishermen were paid a record \$122.9 million for their 1969 catch. These figures represent a 9 percent increase by weight and an 8 percent increase by value over the 1968 shrimp catch. Table 22 shows Gulf region shrimp landings by state for the period 1964 through 1969. Although Gulf region shrimp landings were somewhat lower in 1969 than in 1968, the Gulf region accounted for 66 percent of the total United States shrimp landings. Louisiana led the nation in shrimp landings with 52.8 million pounds. Louisiana shrimp landings in 1969 accounted for 40 percent of the Gulf region shrimp landings and 27 percent of the total United States shrimp landings (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

An Overview of Louisiana Commercial Fishing

This section will provide a general overview of the Louisiana commercial fishing industry. It will consist of a brief geographic sketch, an examination of the principal landing locations, fish processing firms, vessels, and employment, and general catch specifications. The menhaden and shrimp industries will receive only cursory attention here, as they will be more rigorously examined in a later section.

Geography. The Gulfward margin of Louisiana's coastal region is a flat, treeless expanse dotted by thousands of small, shallow salt-water lakes and lagoons. The land is covered with sedge grass, rushes, and other marsh vegetation. The land meets the sea in a highly irregular and ragged shoreline of small bays, inlets, and coves. Because of this irregularity, the Louisiana shoreline is estimated to be approximately 1,500 miles, whereas the coastline is only about 400 miles.

TABLE 22

GULF SHRIMP LANDINGS BY STATE, 1964-1969
Heads-off Weight (Millions of Pounds)

State	1964	1965	1966	1967	1968	1969
Florida	27.9	27.1	21.3	17.8	20.2	17.6
Alabama	4.6	6.0	6.6	9.0	9.6	9.4
Mississippi	4.0	5.2	4.7	6.0	6.3	5.5

The many shallow inlets and estuaries on the Louisiana coast provide essential grounds for the post-larval development of shrimp. These areas offer food and shelter for the young shrimp before they move out into the deeper waters of the Gulf of Mexico.

Principal landing locations. In the listing of the ten most active United States commercial fishing ports, Louisiana appears four times. Table 23 shows the volume and value of landings at these ten ports. Louisiana's four main ports are at Cameron, Dulac-Chauvin, Morgan City, and Empire, which in 1969 accounted for 742.4 million pounds of fish and shellfish valued at \$31.6 million. These figures represent 73 percent of all Louisiana landings by volume and 56 percent by value. Figure 10 shows the location of these key Louisiana ports (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1970).

The general catch. Louisiana fishermen landed 1,013 million pounds of fish and shellfish valued at \$56.2 million in 1969. This placed Louisiana first in the state rankings by volume (for the third consecutive year) and third in the rankings by value. Preliminary figures for 1970 indicated that Louisiana landings were 1,084 million pounds valued at \$61.2 million. These figures represent a gain of 7 percent in volume and 9 percent in value over the 1969 figures. Table 24 shows the volume and value of Louisiana fish and shellfish for 1969 and 1970 by species (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1970).

The menhaden catch consistently constitutes the greatest share of Louisiana landings by volume, and the shrimp catch accounts for most of the value. The economic impact of the shrimp and menhaden fisheries will be examined in a later section.

The oyster industry is the third most valuable fishery in Louisiana. Oyster landings for 1969 amounted to 9.2 million pounds of meats valued at \$4.0 million. These figures were down 30 percent by volume and 25 percent by value from the large 1968 oyster catch. This is in part attributable to the heavy damage inflicted in August 1969 by Hurricane

TABLE 23

VOLUME AND VALUE OF LANDINGS AT CERTAIN U.S. PORTS, 1969

	Thousand Pounds	Thousand Dollars
San Pedro, California	406,900	40,500
Cameron, Louisiana	323,900	8,200
Pascagoula-Moss Point, Mississippi	256,000	6,600
Dulac-Chauvin, Louisiana	185,300	11,200
Kodiak, Alaska	140,300	18,000
Reedville, Virginia	124,200	1,900
Morgan City, Louisiana	122,000	6,400
Beaufort-Morehead City, North Carolina	118,100	2,400
Empire, Louisiana	111,200	5,800
New Bedford, Massachusetts	107,800	17,400

Camille. Substantial damage was reported in both private and State-owned oyster beds east of the Mississippi River. The Louisiana Wild Life and Fisheries Commission received a grant of \$176,388 to be used for restoration of the damaged oyster reefs (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1971).

The Louisiana oyster industry employed 1,111 fishermen in 1967. Oysters are harvested by dredges, tongs, or by hand. Dredging operations account for all but a fraction of the total catch. In 1967 some 225 large vessels and 191 smaller motor boats were engaged in oyster dredging operations (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969).

Hard crab landings for 1969 amounted to 11.6 million pounds valued at \$1.1 million. This production represents a gain of 21 percent in volume and 33 percent in value over the 1968 catch. At just over 9 cents per pound, the prices received by fishermen were well above those of previous years. Preliminary figures for 1970 indicate a decline of 32 percent in volume and 30 percent in value from the 1969 crab catch (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1971).

Fish processing plants. More plants producing canned and industrial fishery products are located in Louisiana than in any of the other seven South Atlantic and Gulf states. The Louisiana Directory of Manufacturers for 1972 lists 35 firms dealing in fresh or frozen packaged fish and seafoods, 27 in canned and cured fish and seafoods, and 6 in animal and marine fats and oils. Table 25 lists the locations and number of firms involved in each category. Figure 11 shows their locational dispersion (Louisiana Department of Commerce and Industry, 1972; U.S. Department of the Interior, Bureau of Commercial Fisheries, 1970a).

Canned fishery products. There are 27 plants producing canned fishery products in Louisiana. This figure compares favorably with those of other Gulf states inasmuch as Mississippi has 10, Florida 3, and Texas 2 plants. The value of Louisiana canned fishery production in 1970 was

In 1967 there were 131,752 fishermen in the United States. Table 27 disaggregates these figures for the Gulf region and shows that there were 37,029 fishermen in the Gulf states in 1967. Of these, 12,529 were employed in Louisiana. Louisiana employed 9.4 percent of all United States fishermen and ranked second only to Alaska in total employment of fishermen. The United States fishing industry employed 88,624 shoreworkers in 1967. The Gulf region averaged 21,099 shoreworkers for the season and 14,944 for the year, or 23 percent of the national total. Of these, 5,664 were employed in Louisiana (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969 and 1970a).

Table 26 shows the growth in the number of large fishing vessels (5 net tons and over) in the period from 1930 to 1967. There were 12,874 large fishing vessels in the United States in 1967. Of these, 6,034 (47 percent of the national total) were employed in the Gulf region. Louisiana had 1,698 large vessels in 1967 and ranked fourth in total number of vessels, behind Alaska, California, and Texas. Of the 856 large fishing vessels added to the United States fishing fleet in 1968, 419 (or 48 percent) were added to the Gulf fleet. Most of these vessels were in the 300 to 399 horsepower range. All but a fraction of the large fishing vessels employed in Louisiana are utilized in the shrimp, menhaden, and oyster fisheries (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969 and 1970a).

The Louisiana fishing fleet also employed some 6,133 smaller boats in 1967. The shrimp fishery utilized 3,765 of these. The remainder were variously used in the crab, oyster, menhaden, catfish, and crawfish industries (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969).

Principal Species of Louisiana Fisheries

Analysis of the Louisiana commercial fishing industry is essentially an analysis of the shrimp and menhaden fisheries. The two species together accounted for 93 percent of all Louisiana landings by volume and 82 percent of all landings by value in 1969. The shrimp and menhaden fisheries employed about 90 percent of all Louisiana fishermen, about 89 percent of all larger vessels, and about 83 percent of the smaller boats in 1967 (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1971; U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969).

The menhaden fishery. Table 28 shows the substantial growth of the menhaden fishery in Louisiana over the period from 1966 to 1970. Over the past 5 years, both the volume and the value of the menhaden catch have increased significantly: a 73 percent gain in volume and a 97 percent gain in value of the menhaden catch from 1966 to 1970. In 1966 the Louisiana menhaden catch, valued at \$9.6 million, accounted for 24 percent of the value of total Louisiana landings; the 1970 menhaden catch, valued at \$18.9 million, accounted for about 30 percent of the value of the total Louisiana catch. By volume, the relative share of the menhaden catch increased from 85 percent in 1966 to 89 percent in 1970 (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1966-1970).

In spite of the very large menhaden catch off the Louisiana coast, biologists report that the present rate of menhaden harvesting is consistent with sound economic and ecological resource utilization. Orville M. Allen, supervisory fishery reporting specialist from New Orleans, writes: "Based on research findings by the Beaufort Biological Laboratory, 93 percent of the Gulf menhaden catch consisted of fish in the one and two-year-old groups. Due to the short life span and high natural mortality rate of menhaden, the harvesting of these age groups was considered by biologists as being ideal in obtaining the optimum yield in the Gulf area" (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1971).

TABLE 28

LOUISIANA MENHADEN CATCH, 1966-1970

Year	Volume (Pounds)	Value (Dollars)
1966	555,852,100	\$ 9,557,646
1967	510,414,000	6,134,338
1968	622,291,300	7,739,602
1969	856,250,600	12,764,098
1970 (Preliminary)	959,809,840	18,930,641

Source: U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1966-1970, Louisiana Landings.

The menhaden season normally runs from April to October, and the heaviest fishing occurs in June, July, and August. Table 29 shows menhaden landings by month from 1967 through 1969. During these years, there were no menhaden landings in January, February, March, November, or December. It is not uncommon for Louisiana menhaden vessels to travel to Florida at the end of the menhaden season in order to participate in the thread herring fishery (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1967-1969).

Menhaden are gathered in purse seines, which are large nets with floats along the top and weights on the bottom. The purse seine is strung in a large circle, enclosing the fish. In 1967 the Louisiana menhaden industry utilized 60 large vessels (5 tons and over), 120 smaller motor boats, and 60 purse seines. In the same year, 1,051 fishermen were directly employed in the Louisiana menhaden industry (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969).

Although the menhaden industry employs only about 10 percent of Louisiana's fishermen, it accounts for a substantial portion of the employment in Louisiana's fish-processing firms. The Louisiana menhaden industry is by far the largest in the nation, supplying 55 percent of the total domestic supply (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969 and 1970a).

The Louisiana shrimp industry. Table 30 shows the pounds and value of the Louisiana shrimp catch over the years from 1966 to 1970. Also shown in Table 30 is the value of the Louisiana shrimp catch as a percentage of the total value of the Louisiana catch. Although the shrimp catch increased 45 percent in volume and 42 percent in value in the 5 years from 1966 to 1970, its relative share of the total value of the Louisiana catch declined somewhat. This is largely attributable to the growth of the menhaden fishery during the same time period. The shrimping industry is, however, the largest fishery in the State, consistently accounting for over half the total value of the Louisiana catch (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1966-1970).

The Louisiana shrimp industry employed 8,875 fishermen in 1967. This figure represented about 80 percent of all Louisiana fishermen in 1967. Most of the shrimp were harvested by means of otter trawls, which are large, baglike nets that are dragged along the sea bottom by the shrimping craft. The otter trawl technique generally accounts for about 90 percent of the shrimp harvest. There were 8,148 Louisiana fishermen working on otter trawls in 1967; this figure represented about 92 percent of all Louisiana shrimp fishermen. Of these, 3,782 fishermen worked on large vessels, of which there were 1,421. Another 4,366 worked on the 3,402 smaller motor boats utilizing the otter trawl technique (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969). The remainder of the shrimp were harvested by means of butterfly nets, pots, and traps. Of these three methods, butterfly net shrimping was by far the most significant, employing 726 fishermen on 22 vessels and 363 motor boats in 1967 (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969).

Table 31 shows the fluctuation in landings of salt-water shrimp by months from 1967 to 1969. The heaviest landings are normally in the months from May to November, but, unlike the menhaden fishery, shrimping activity goes on year-round (U.S. Department of Commerce and Louisiana Wild Life and Fisheries Commission, 1967-1969).

The shrimp industry is the most valuable fishery in the United States; in 1969 it accounted for 24 percent of the value of all United States landings. Louisiana is a principal shrimp supplier, providing, in 1969, 27 percent of the total domestic shrimp supply (U.S. Department of the Interior, Bureau of Commercial Fisheries, 1969 and 1970a). These figures reveal the importance of the Louisiana shrimp industry both to Louisiana and to the nation as a whole.

Summary and Conclusions

The Louisiana commercial fishing industry is among the largest in the United States. Louisiana leads all 50 states in volume of catch and ranks third in value of catch. Louisiana accounts for 55 percent of the domestic menhaden catch, 30 percent of the industrial fishery production, and 27 percent of the domestic shrimp catch. Preliminary figures for 1970 indicated that the dockside value of the Louisiana catch was \$61.2 million. Figures for 1967 show that the Louisiana commercial fishing industry employed 12,529 fishermen (the second highest number in the nation), 5,664 shoreworkers, 1,698 large vessels, and 6,133 smaller boats.

The fishing industry in Louisiana is a vital component of the national fishing industry and of the Louisiana economy.

CHAPTER IX

MINERAL INDUSTRIES IN COASTAL LOUISIANA

Introduction

For many years the production of crude oil and natural gas has been a major industry in Louisiana. Oil and gas have provided the State with many benefits, not only directly in the form of severance taxes and lease royalties, but indirectly through the provision of the livelihoods of many of the State's people. The production of oil and gas has also attracted allied industries such as refining and chemicals, all of which contribute greatly to the welfare of the State and its people.

During the last several years a change has appeared in the geographical pattern of the oil and gas industry within the State. The production of crude oil has been diminishing in the older fields of north Louisiana and increasing in coastal Louisiana. Indeed, oil and gas production has not stopped at the shoreline but has been extended outward into the offshore regions.

This chapter will attempt to give a picture of the recent past of this industry and make some projections for the future. The change in the geographical distribution of the industry has a number of implications of profound importance for the State as a whole and for the coastal parishes in particular. For this reason the effects of the change will be emphasized in several of the following sections.

The sulfur industry, the second most important extractive mineral industry, is confined to the Gulf Coast region and represents a much smaller portion of the State's revenues and employment. Accordingly, sulfur is given brief treatment.

The Oil and Gas Industry of Louisiana

Geography

The Louisiana Oil and Gas Commission has divided the State into two regions--North Louisiana and South Louisiana. South Louisiana is depicted in Figure 12. Much of the data which are available are tabulated according to this division. In many cases this paper will refer to the coastal parishes. These parishes include most but not all of the area included in South Louisiana. Unless otherwise specified, the data which follow include the offshore area as part of South Louisiana or as part of the parish adjacent to the particular offshore area.

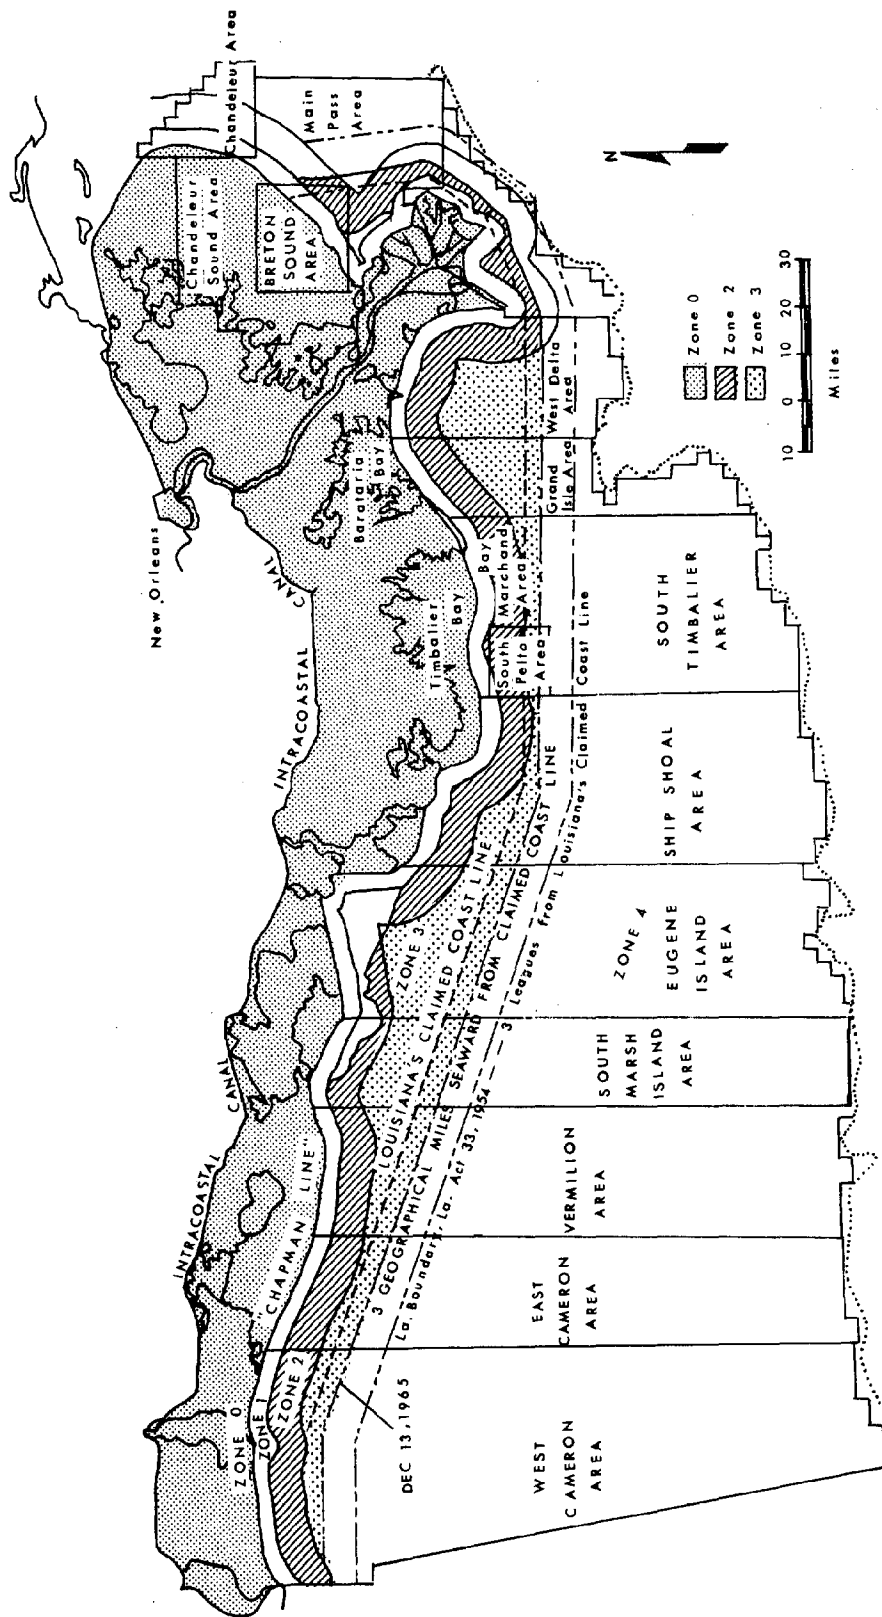

Fig. 12. Location of Intracoastal Canal, the Chapman Line, and Zones 0, 1, 2, 3, and 4, offshore Louisiana. Source: Weaver, L. K., C. J. Jirik, and H. F. Pierce, 1969, Impact of Petroleum Development for the Gulf of Mexico. U.S. Department of the Interior, Bureau of Mines, Information Circular 6408, p. 12.

Another complication arises from the prolonged litigation between the State and Federal governments over the right to ownership and control over the offshore areas. At present the State has won control of zones 0 and 1, the Federal government of zone 4, and zones 2 and 3 are still disputed. The entire dispute centers on the location of the seaward boundary of the State and is too complex to be described herein.

Drilling

The drilling of new oil and gas wells is best expressed in terms of well completions in a given period because these figures indicate the actual numbers of new wells coming into actual or potential production. The revenues which the State derives from mineral leasing are found under the section on production, below.

Oil well completions. Table 32 and Figure 13 show the trends in drilling since 1960. The most prominent trend is the large decrease in the number of new wells since 1965. This results largely from the movement of the drilling industry out of North Louisiana. The drilling rate for the South Louisiana onshore area has also shown a decrease over the period, but the offshore drilling rate is fairly constant. These figures show only the number of wells being drilled and not their depth or potential productive capacity. The new wells in South Louisiana and offshore tend to be more productive than the ones in North Louisiana. Nevertheless, the figures do indicate that the future of the oil production industry in Louisiana is to be found in South Louisiana. If the present trends continue, more oil wells will be completed offshore than onshore in South Louisiana. This means that the coastal parishes should enjoy an increasing proportion of the economic benefits of oil production in Louisiana for the near future. The question of whether this increased proportion will be of a smaller pie will be explored more fully under the discussion of reserves, below.

Gas well completions. The number of new gas wells completed per year in Louisiana has been quite stable through time. Table 32 and Figure 14 show that a decrease in North Louisiana has been matched by an increase in the offshore region. The onshore part of South Louisiana was remarkably stable from 1965 to 1969.

As with oil, the trends in new gas wells indicate that South Louisiana, and especially the coastal and offshore regions, will gain the majority of new wells and reap the economic benefits therefrom.

Economics of offshore drilling. The economics of drilling offshore from the Louisiana coast are such as to indicate that the economic returns of development of an offshore oil or gas field are heavily dependent on the size of the field and the production rate which can be realized from the field (Wilson, 1969). These two factors combine to limit the development of offshore deposits to large fields

TABLE 32

LOUISIANA WELL COMPLETIONS, 1960-1969

with productive wells. The marginal producers are never developed at all. This means that on the average the new offshore well is more productive than the older onshore well.

Reserves

The reserves of crude oil, natural gas, and natural gas liquids are summarized every year by the American Petroleum Institute and the American Gas Association.

Crude oil and natural gas liquids. Louisiana possesses substantial reserves of crude oil and natural gas liquids. At the end of 1969, Louisiana accounted for about one-sixth of the total U.S. reserves of crude oil and almost one-third of the total U.S. reserves of natural gas liquids. Table 33 and Figure 15 show how this reserve picture has changed over the last few years. While total reserves for the U.S. have dropped rapidly since 1967, Louisiana's reserves of crude oil have remained on a slow increase since 1950, and the rate of increase seems almost constant in recent years. Reserves of natural gas liquids in both the U.S. and Louisiana have fallen off somewhat since 1968,

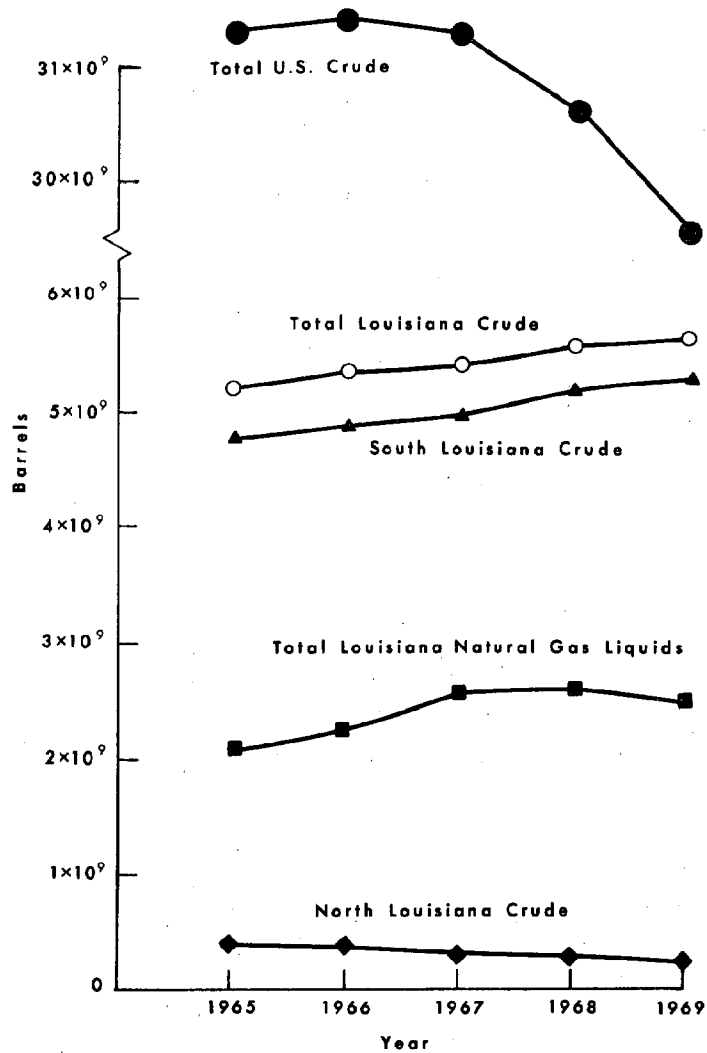

Fig. 15. Reserves of crude oil and natural gas liquids at end of years 1965-1969.

but the rate of decrease seems small. When the geographical distribution of these reserves is considered, it is seen that the reserves of both crude oil and natural gas liquids in North Louisiana are small and almost stable.

South Louisiana, including the coastal region, has 95 percent of the State's reserves of natural gas liquids and over 90 percent of the crude oil reserves. While the figures given in Table 33 and Figure 15 are not broken down into the offshore and onshore areas, it is apparent that the new reserves being discovered are increasingly offshore. This

conclusion comes from the data from the drilling and production sections of this report where data are shown for the offshore region.

The State government appears to be very pleased with the crude oil reserve position. The Annual Oil and Gas Report for 1969 states (Louisiana Department of Conservation, 1969, p. 11):

It can be surmised that Louisiana is still enjoying a greater reserve producing capacity of crude oil than at any time in the past. In summary, it may be safely stated that Louisiana's oil and gas reserves will continue to increase although only slightly. Indications are that the oil and gas industry will continue to develop our natural mineral resources at a favorable rate.

This statement is true for the State as a whole, but some qualifications may be in order for specific areas as the geographic distribution of the industry changes. Specifically, as the reserves move farther and farther offshore the State will reap a decreasing share of the revenue from production and leasing. In addition, the economic benefits of oil exploration and production will be increasingly concentrated in those areas which service the offshore industry.

Natural gas reserves. The natural gas reserves shown in Table 33 and Figure 16 appear to be dropping off about as rapidly for the U.S. as a whole as the reserves of crude oil. For Louisiana the total reserves of natural gas have been fairly stable since 1965, but a slight dropoff was observed in 1969. Since Louisiana has almost one-third of the total U.S. reserves, this decrease may be significant for the nation as a whole unless it is reversed. As was found for the crude oil reserves, the amount found in North Louisiana is small and decreasing very slowly. Within the South Louisiana area the offshore reserves are a major part of the total; and, while figures are not available, it is expected that these are increasing as the onshore reserves are falling off to maintain the relatively stable reserve position for the State as a whole. This conclusion results from the drilling and production data found in those sections of this report. As with the oil reserves, the movement of an increasing proportion of the reserves offshore means that the economic benefits of their exploitation will increasingly accrue to the Federal government and to those areas in which bases for offshore industry are located.

Production and State Revenues

Production of crude oil and condensate. Louisiana has held a major role in the production of crude oil and condensate for many years. This production expanded very rapidly from a total of 215 million barrels in 1950 to almost 850 million barrels in 1969. Expansion was particularly rapid from 1965 to 1967. Since 1967 the increase has been more modest and appears to be falling off. This raises questions about the continued

Fig. 16. Reserves of natural gas at end of years 1965-1969 (MCF 60°F 14.73 PSIA).

growth of this industry and its future contribution to the welfare of the State and its citizens.

The geographical breakdown of the crude and condensate production reveals drastic changes in the pattern of production over time. Tables 34 and 35 and Figures 17 and 18 show that in 1969 South Louisiana contributed almost 94 percent of the crude and condensate production and North Louisiana contributed only 6 percent. The coastal parishes contributed 90 percent of the total, and of that almost half was offshore. The production in the northern portions of Louisiana has remained almost static at near 50,000,000 barrels per year for 20 years. By contrast, the production in South Louisiana, and especially that of the coastal

Fig. 17. Louisiana crude oil and condensate production, 1965-1969.

parishes, has expanded continuously. Offshore production has been responsible for most of the increase in production since 1967. Prior to that time the increase was about equal for both onshore and offshore. The offshore picture is complicated by the continuing legal battles between Louisiana and the Federal government over the rights to royalties and taxes on the offshore oil fields.

The offshore area is divided into five zones (see Fig. 12). In zones 0 and 1 the State has obtained jurisdiction, and in zone 4 the Federal government has established its authority. The remaining zones, 2 and 3, are still the subject of litigation. Consequently, the receipts from those areas are being held in escrow until a final decision is rendered.

While the ownership controversy may not affect such things as employment in and purchases for the offshore oil fields, it has a profound effect on the finances of the State government inasmuch as severance taxes are a vital part of State revenues. Since 1965 the major part of the increase in offshore production has occurred in zone 4. Production in zones 0, 1, 2, and 3 is essentially static. This leads to the conclusion that unless there is an alteration in current trends the State government can expect no increase in revenues from oil production offshore and, as reserves are depleted, it seems likely that a decrease will develop in the next few years.

Production of natural and casinghead gas. The production of gas in Louisiana appears to be expanding at a rapid rate. Tables 36 and 37 and Figure 19 show that the rate of expansion of gas production has probably increased in the last year or two. The geographical pattern of the increase shows the same characteristics as did the expansion of oil. The production from North Louisiana, the State-controlled offshore zones 0 and 1, and the disputed zones 2 and 3 is almost static. The major increases are in the Federal offshore zone 4 and the onshore and intermediate zones of South Louisiana. This pattern, while similar to that in crude oil and condensate, reflects a prospect for the expansion of State revenues from gas production for some time.

Oil and gas production and State revenues. An analysis of the revenues of the government of the State of Louisiana derived from severance taxes on mineral production and from mineral leases is shown in Table 38 and Figure 20. For the 6-year period from 1964 to 1970 the State received about 27 percent of its total revenues from these two sources. In absolute terms the revenue has risen from near \$300,000,000 in 1964-1965 to near \$400,000,000 in 1969-1970. The yearly severance taxes had been rapidly increasing up to 1967-1968, but the rate of increase since then has been minimal, reflecting the changing industry pattern. Severance taxes on gas surpassed those for oil in 1968-1969. If current trends continue, the oil revenue may be expected to decrease gradually over the next few years as production moves farther offshore and out of State jurisdiction. The revenues from gas production should increase slightly to hold the overall figure nearly constant.

Source: State of Louisiana, Annual Report of the Department of Revenue and Financial Statements.

The Public Affairs Research Council has released a report stating that total revenues to the State from oil and gas should remain almost constant for the foreseeable future. If true, this study indicates that this cessation of growth will have drastic effects on future Louisiana State budgets (Baton Rouge, Louisiana, Morning Advocate, May 16, 1971, pp. 1A, 6A).

Oil and Gas Pipelines in Louisiana

The oil and gas pipeline system of Louisiana is so widely distributed and so extensive that it is very difficult to describe in words or even on a map of reasonable scale. For that reason only a description of the major corridors will be attempted here (Louisiana Department of Conservation, 1964).

Oil pipelines. The northern areas of Louisiana have relatively few major oil pipelines. There are a number of fairly small lines in and around the oil fields of extreme northwestern Louisiana. The major lines are the 20-inch "Little Inch" crossing northwestern Louisiana and a 22-inch pipeline connecting the northwest field to Baton Rouge. A third large line of 20-inch diameter runs across the extreme north end of the State.

In South Louisiana, including the coastal region, the system of oil pipelines is far more complex. There is a network of major lines extending across the State from the Texas border, west of Lake Charles, to near Lafayette. The corridor then splits. The main branch runs east to Baton Rouge and then northeast out of the State. The secondary branch heads southeast from south of Lafayette along the coast to New Orleans and the delta. Major lines also follow both banks of the Mississippi from Baton Rouge to New Orleans.

Gas pipelines. The distribution of gas pipelines in Louisiana is similar to that of the oil lines except that they are more numerous and more widespread.

In North Louisiana the lines tend to follow a southwest-northeast direction from the Texas border between Many and Shreveport through the major fields north of Monroe and then east or north out of the State. The gas fields of southwestern Louisiana are also connected with the Monroe area.

In South Louisiana, the entire coastal region may be regarded as one giant gas pipeline corridor extending from the Texas border to New Orleans and Baton Rouge. An outline map of the 1968-1969 offshore gas pipeline projects is found in the Oil and Gas Journal, January 20, 1969, p. 51. Another map showing the major offshore lines for both oil and gas is available (U.S. Department of Interior, 1969) and is shown as Figure 21.

Employment and Payrolls from Oil and Gas Production

All data in this section are drawn from U.S. Department of Commerce, Bureau of the Census, 1965-1969, County Business Patterns.

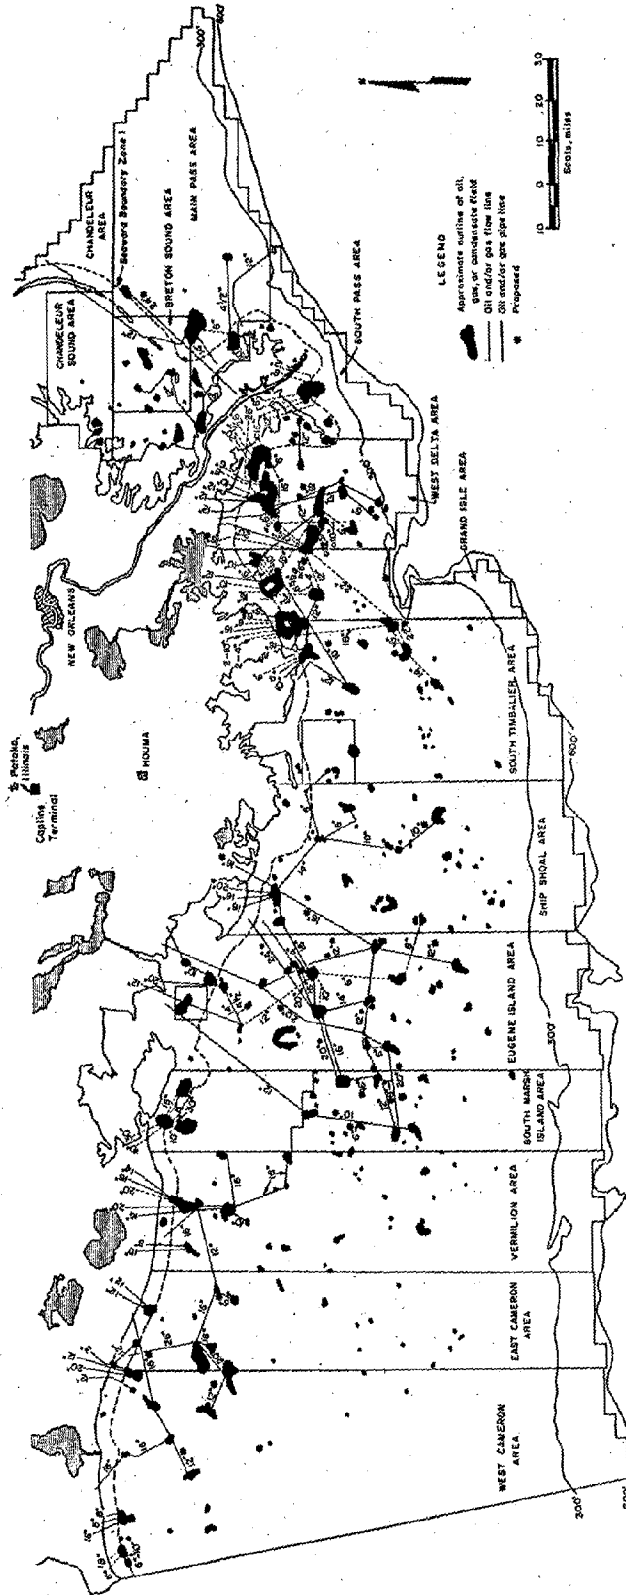

Fig. 21. Approximate locations of the proposed and existing pipeline-flowing system, offshore Louisiana, March 1968. Source: U.S. Department of the Interior, 1969, Petroleum and Sulfur on the U.S. Continental Shelf.

National and State employment. The employment derived directly from the production of oil and gas is found in Standard Employment Classification Series 13. The classifications and the categories which they represent are as follows:

<u>Standard Industrial Classification</u>	<u>Category</u>
13	Crude Petroleum and Natural Gas
131	Crude Petroleum and Natural Gas
132	Natural Gas Liquids
138	Oil and Gas Field Services
1381	Drilling Oil and Gas Wells
1382	Oil and Gas Exploration Services
1389	Oil and Gas Field Services not Elsewhere Classified

Since 1965 the total number of employees in Louisiana in Series 13 has been almost constant. It has been near 39,000, and only minor variations of $\pm 1,000$ or so occur. Nationally, the number of employees diminished from the 1965 level of 232,192 to the 1969 level of 223,796. A complete breakdown is shown in Table 39 and Figure 22. The number of Louisiana field service employees in category 138 has been extremely stable, and most of the variation which has existed in category 13 is derived from Number 131, crude oil and gas production.

Coastal parish employment. The totals for the coastal parishes are subject to considerably more variation than the U.S. or Louisiana figures. In part this is because of the deletion of certain values from the individual parish reports in order to maintain the confidentiality of the source data in the County Business Patterns (U.S. Department of Commerce, Bureau of the Census). In addition, there appears to be an upward trend in employment in all categories in the coastal parishes inasmuch as the oil exploration and production activities are more and more concentrated there (see Fig. 22). Surprisingly, the coastal parishes account for only a little more than half of the total employment in the State from this industry, even though the production in the coastal parishes is almost 90 percent of the total. This large discrepancy cannot be easily explained by the omission of values. The fundamental difference seems to be that the production per employee is very much higher in the coastal offshore area than elsewhere. This is explained by the much larger production per well in the coastal area.

Mid-March production payrolls. Although the number of employees engaged in petroleum production in Louisiana remained fairly static between 1965 and 1969, the payrolls did not. Except for a dip in 1968, payrolls in all categories statewide increased gradually over the period.

When only the coastal parishes are considered, a more jagged pattern develops. This irregularity results chiefly from the fact that these figures are summations of individual parish figures. In many cases

Fig. 22. Employment versus time in the Louisiana oil and gas production industry.

the Census Bureau has deleted values for some of the parishes in some years. Table 40 and Figure 23 show a few places where the data for all of the coastal parishes were deleted in SIC categories 132 and 1382. Deletions were common in all categories for at least some parishes.

The data show that the coastal parishes now receive the major portion of the oil and gas production payroll. Moreover, this proportion is increasing. This is one more confirmation of the movement of the oil industry into South Louisiana and offshore.

Over time it is probable that the employment will localize itself still further into those parishes providing bases from which to service

the offshore fields, since it is apparent that in the future the production of oil and gas will be moving farther and farther offshore. This concentration may have a profound effect on the economics of what might be called the hinterland coastal parishes because they may, over time, lose their shares of the payrolls. These are considerable; in 1969 the payroll in category 13 was \$54 million for the March pay period.

Sulfur

The second major mineral resource of the coastal regions of Louisiana is sulfur. Three-quarters of the U.S. production comes from elemental sulfur in Gulf Coast salt domes (U.S. Department of the Interior, 1969). The production has been mainly onshore, but since 1960 two offshore

Fig. 24. Louisiana sulfur production.

deposits have been mined by the Frasch process. The major offshore producer, the Grand Isle dome, yields about 1.5 million tons of sulfur per year (U.S. Department of the Interior, 1969).

Table 41 and Figure 24 show the production of sulfur in Louisiana for the year 1960 and for 1965-1969 (Louisiana Department of Conservation, 1960, 1965-1969). A plot of the data in Table 41 shows that the production has been fairly constant over the latter period. The severance tax revenue which the State receives from this production appears in Table 39, in the section on oil and gas production. Since the rate is constant, the revenue has been near \$2,600,000/year over the period. The rise in production was considerable between 1960 and 1965.

The largest use of sulfur is for sulfuric acid, which then is used in fertilizer manufacture. Accordingly, sulfur production correlates with the supply and demand structure in the fertilizer industry. At present there seem to be ample reserves, and production depends on the market price.

Environmental Impact of the Extractive Industries

Figure 25 shows some of the structures and byproducts imposed upon the coastal environment by the various extractive industries. This matrix and those in Figures 33 and 34 were designed specifically for the California coastline but have sufficient generality to relate to Louisiana as well.

CHAPTER X

WATER TRANSPORTATION AND SHIP AND BOAT BUILDING

Introduction

Louisiana has always derived considerable income from water transportation. Since the early days of national history the Port of New Orleans has served as a link between the central interior of the nation and the sea. New Orleans is now, as it has been in the past, one of the great ports of the world. Among United States ports New Orleans is second only to the Port of New York in tonnage handled, and it is the largest port on the Gulf of Mexico. Upstream from New Orleans on the Mississippi River is the Port of Baton Rouge, third among Gulf ports in tonnage handled and the seventh-ranked port in the nation in terms of tonnage. Bulk cargoes, petroleum and petroleum products, grains, and ores give Baton Rouge its high ranking among United States ports, though considerable general cargo flows through the port. Lake Charles, the State's third deepwater port, ranks tenth in tonnage among the Gulf ports and twentieth in the nation. Lake Charles has large bulk cargo operations, consisting primarily of petroleum and its derivative products as well as moderate amounts of general cargo. The top 20 ports in the nation are ranked in Table 42 by tonnage handled in 1969. Figures 26 and 27 illustrate the foreign trade routes between Gulf ports and the world.

Foreign Shipping

In terms of foreign shipping Louisiana ports accounted in 1968 for almost 12 percent of the United States total. Tables 43-47 provide a summary of the total tonnage handled by Louisiana ports from 1959 to 1969. The Port of New Orleans' foreign waterborne commerce is depicted in Figures 28-30 and Table 48. Specific data for the ports of Baton Rouge and Lake Charles are less detailed than those for New Orleans.

In 1970 the Port of New Orleans handled 123.6 million tons of cargo, 10.3 million tons more than in 1969. Baton Rouge tonnage totaled 45.5 million tons in 1970, 4.7 million tons more than in 1969. Lake Charles handled 17.6 million tons in 1970, 1.5 million tons more than in 1969 (U.S. Army Corps of Engineers, New Orleans District Office, 1971).

The Port of Baton Rouge's 1970 tonnage of 45.5 million tons consisted of the following categories: foreign imports, 7.2 million tons; foreign exports, 6.8 million tons; coastwise receipts, 762,000 tons; coastwise shipments, 8.8 million tons; barge receipts, 7.9 million tons; barge shipments, 13.9 million tons; and local traffic, 208,000 tons (U.S. Army Corps of Engineers, New Orleans District Office, 1971).

Gasoline, at 5.3 million tons, was the largest tonnage item in the Baton Rouge port data. Other tonnages in 1970 were corn at 2.9 million

tons; soybeans, 2.2 million tons; iron ore and concentrates, 1.1 million tons; aluminum ores and concentrates, 4.5 million tons; manganese ores and concentrates, 1.4 million tons; crude petroleum, 4.6 million tons; distillate fuel oil, 3.9 million tons; residual fuel oil, 1.7 million tons; and asphalt, tar, and pitches, 1.4 million tons (U.S. Army Corps of Engineers, New Orleans District Office, 1971).

The Port of Lake Charles handled 17.7 million tons of cargo in 1970, the overwhelming portion of it consisting of coastwise shipping. The 1970 tonnage was composed of 1.7 million tons of foreign exports; 193,000 tons of foreign imports; coastwise receipts of 32,500 tons; coastwise shipments of 3.4 million tons; barge receipts of 8.6 million tons; barge shipments of 3.6 million tons; and local movements of 225,000 tons (U.S. Army Corps of Engineers, New Orleans District Office, 1971).

Crude petroleum at 8.5 million tons was the largest single item moved through the Port of Lake Charles. Gasoline totaled 1.7 million tons. Rice was the largest foreign export, at 503,000 tons. Coke, petroleum, asphalt, and solvents accounted for 398,000 tons (U.S. Army Corps of Engineers, New Orleans District Office, 1971).

Intracoastal Shipping

Aside from deep-draft ocean shipping, Louisiana is a key focal point for inland waterway traffic. Inland barge traffic not only links the deepwater ports to the interior of the nation but also provides important support for the industrial structure of coastal Louisiana. Figure 31 shows inland water routes for Louisiana.

In terms of cargo destined for ocean shipping, the principal commodities carried on the inland waterways are petroleum and petroleum products, grains and grain products, aluminum ores, concentrates and scrap, soybeans, and liquid and dry sulfur. The domestic cargo tonnage moved along Louisiana waterways consists primarily of petroleum and petroleum products, grain and grain products, soybeans, sand, gravel, crushed rock, iron and steel products, sulfur, and other chemicals. See Tables 49-52 for tonnage data on the inland waterways to and from Louisiana.

Barge traffic is especially important to the petroleum and chemical industries in Louisiana since it not only supplements pipelines to a considerable extent but also provides low-cost movement of refined petroleum and chemicals to the interior of the nation and to the deepwater ports for transshipment. The existence of barge service is a stimulus for industrial location along waterway routes, as evidenced by the concentration of petrochemical facilities adjacent to water sites in Louisiana.

Table 53 depicts employment and taxable payrolls for the several facets of water transportation in Louisiana in 1969.

Ship and Boat Building

Ship and boat building is a major industrial activity in Louisiana. The huge Avondale yards near New Orleans are a major producer of civilian and military deep-draft vessels. The Avondale yards and other smaller yards specialize in supplying the needs of the offshore oil industry--drilling platforms, tugs, barges, crew boats, and other specialized vessels are constructed in Louisiana. Boats for commercial fishing and pleasure use are built in small yards scattered across the coastal region. Repair yards are numerous. In March 1969, 14,311 workers were employed in ship and boat building and repairing (SIC 373) in 103 firms in coastal Louisiana. Taxable payrolls for the first quarter of 1969 totaled \$27,422,000. Assuming that this component is representative of yearly totals, payrolls in this economic activity were approximately \$109,688,000 in 1969.

Disaggregation of SIC 373 into its subclassification of ship building and repairing (SIC 3732) illustrates that the former dominates. Ship building and repairing included 12,589 employees in 40 firms, compared with 1,722 employees in 63 boat building and repairing firms. Four ship building and repairing firms had over 500 employees in 1969, five firms had from 250 to 499 employees, and six firms had from 100 to 249 employees. Boat building and repairing had no firms with over 500 employees, though

two firms had 250 to 499 employees and three had from 100 to 249 employees. On the other end of the scale there were 20 firms with three or fewer employees.

Predictions

The future for Louisiana deepwater ports is excellent. New Orleans already is the major containership port on the Gulf, and certainly one of the major world ports for this type of cargo handling. In fact, the shipping industry is experiencing rapid technological change which will bring increased need for new port facilities and better waterway access to these ports. Inescapably, the thrust for deeper channels, new channels, construction of offshore cargo-handling facilities for supertankers, etc., conflicts with other considerations such as preservation of fishery spawning waters in estuaries, prevention of salt-water intrusion, and destruction of fresh-water marshes. The benefits from expanded shipping operations must be weighed against these considerations if true benefit-cost calculations are to be made. This does not imply that expanded shipping facilities cannot be justified--far from it. What is implied is that construction of such facilities must be accomplished in such fashion as to avoid, or at least minimize, ecological damages. The ecology of the coastal region is a generating force for considerable income in Louisiana. Some impressions of environmental impact of marine transportation can be gained from the matrix in Figure 32, prepared for California's coastal zone.

Uses

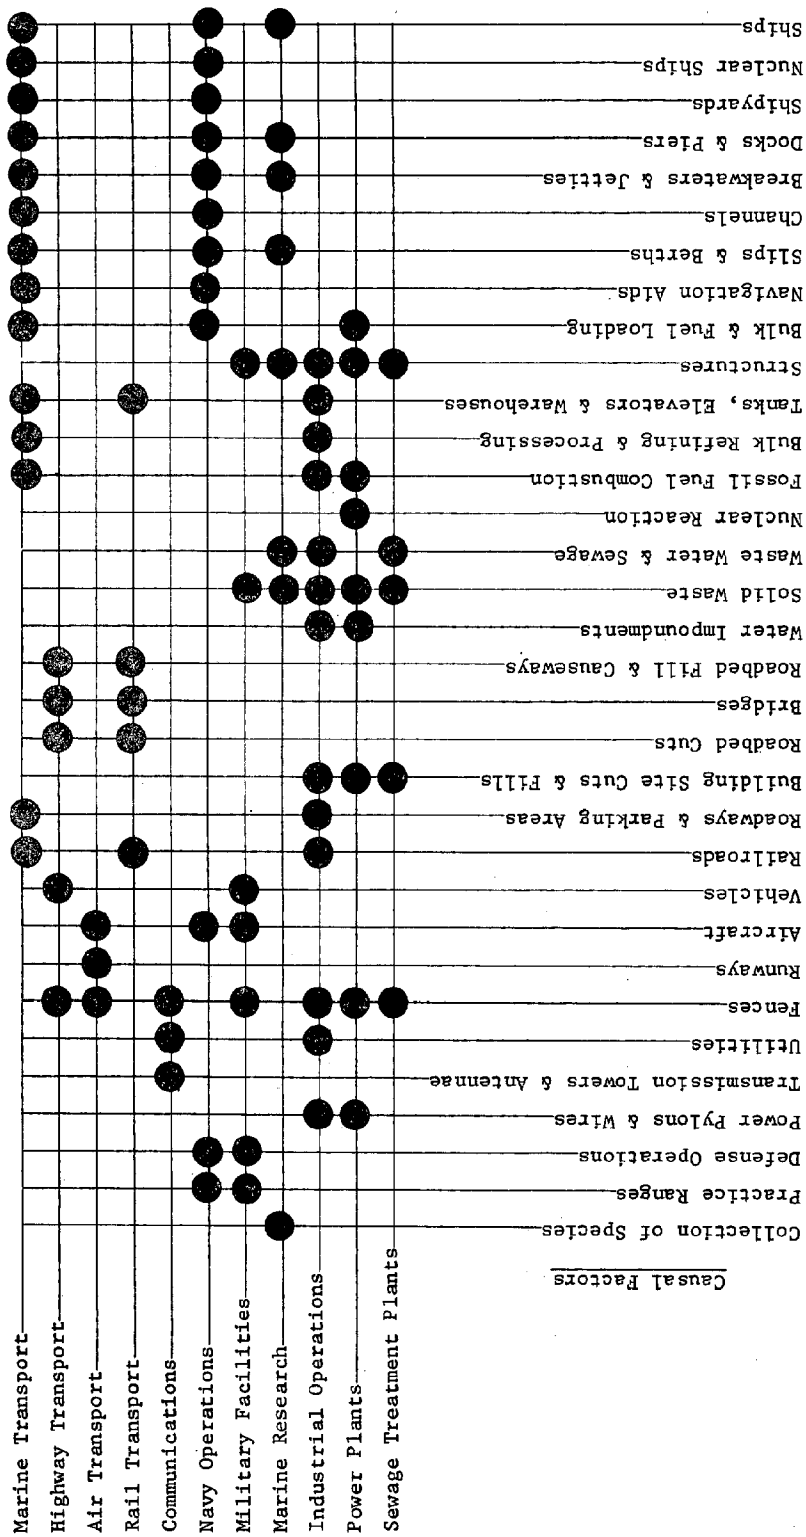

Fig. 32. Environmental impact of industrial and transportation activities in California's coastal zone. Source: Sorensen, J. C., 1970, State of California, Department of Navigation and Ocean Development.

CHAPTER XI

TOURISM AND RECREATION IN COASTAL LOUISIANA

Tourism and recreation are important sources of economic activity in Louisiana. The direct importance of this sector of the Louisiana economy to the coastal region stems from two features: First, more than 50 percent of all recreation activities in the United States are water oriented, and second, east-west movement of tourists along Louisiana coastal routes accounts for approximately 24 percent of all visitors to the State.

New Orleans is, of course, a major tourist attraction, but many other areas of the State derive income from tourists, not only out-of-state but intrastate tourists as well. The Louisiana Travel Promotion Association estimates that 264 million out-of-state visitors entered the State in 1968. Tourist traffic to publicly owned attractions in Louisiana is displayed in Table 54.

Travelers in Louisiana seem to spend in the following proportion: 33.7 percent for food and drink; 26.8 percent for transportation; 13.3 percent for recreation and entertainment; 23.4 percent for lodging; and 2.8 percent for miscellaneous expenditures. Total expenditure for all categories in 1969 was an estimated \$580 million, \$373 million of which came from out-of-state visitors. The \$580 million spent by all travelers is divided as follows: 34.1 percent for personal income to individuals; 50.0 percent for purchases from other industries; 12.2 percent for State and local taxes; and 2.1 percent for other categories. Table 55 illustrates tourist expenditures by category for 1969.¹

The coastal region clearly dominates the tourist and recreation activity in Louisiana. New Orleans is a great attraction for both in- and out-of-state tourists. Marine-related recreation is heavily concentrated in the coastal region, as exemplified by the fact that 101,084 registered boats over 12 feet in length, with motors exceeding 10 horsepower, existed in the coastal parishes in September 1970 (Louisiana Wild Life and Fisheries Commission, 1970). Commercial vessels are included in this total, but most of the registered boats are for private recreational use. Private marinas dot the coastal area's lakes, rivers, and bays, and there is every reason to think that rising consumer incomes will produce continued expansion of boating activities.

Closely allied to boating activities are waterfowl hunting and fishing. The waterfowl in Louisiana have always been a great attraction to hunters; waterfowl hunters increased from 76,053 in the 1969-1970

¹Louisiana Travel Promotion Association data derived from the report by Lewis C. Coleland, 1968. The Copeland report is an annual study. The Louisiana Travel Promotion Association is a trade group without formal headquarters. Copies of the Copeland report may be obtained from the Louisiana Tourist Development Commission, State of Louisiana, Baton Rouge, Louisiana. However, the Tourist Development Commission does not contribute to the costs of publication of the Copeland reports.

season to 97,529 in the 1970-1971 season, a 28.2 percent increase (Louisiana Wild Life and Fisheries Commission, 1970). Both fresh-water and salt-water fishing are popular, with the latter being concentrated off Grand Isle, one of the leading deep-sea charter boat ports on the Gulf. In 1968, 293,000 fishing licenses and 422,000 hunting licenses of all types were issued in Louisiana (Louisiana Wild Life and Fisheries Commission, 1970).

Assessing the direct impact of tourism and recreation in the coastal region is difficult. Data are virtually nonexistent, except for scattered surveys of poor quality. However, intuition predicts expansion of marine-oriented tourism and recreation, as well as accompanying developments such as camping, motel, and marina facilities. Personal services to meet the various demands of increased numbers of

visitors to Louisiana will rise. Inevitably there will be pressures on land uses as promoters seek to develop tourist and recreation attractions. In general, there is good reason to suggest that some standards governing types, qualities, and locations of tourist and recreational attractions should be developed by the State. The national government, for example, has recently moved to control discharge of human wastes from private boats. Undoubtedly other standards to control far more serious adverse environmental consequences will soon follow. Similar needs exist at the State level to control, for example, road and canal construction where blockages of water flows are involved.

Tourism and recreation are now very important in the Louisiana coastal economy. That these activities should be recognized as potentially growth oriented is quite proper. However, their growth need not be synonymous with blight and destruction of the natural beauty of the coastal prairies, marshes, and water bodies. Many state and local governments are currently sacrificing tremendous economic benefits, as well as recreational opportunities, by consciously permitting their streams to be used as carriers of inadequately treated industrial and municipal wastes. Louisiana's waterways are too important to suffer this sort of fate. Moreover, the long-run economic costs of neglecting the quality of the waterways will be extraordinarily high if the only harm is to turn away tourists and seekers of recreational outlets.

Figure 33 indicates typical structural and environmental consequences associated with various recreational activities.

Exhibit 1 is a newspaper editorial which evaluates the recreational potential of the Atchafalaya Basin. This editorial presents an excellent assessment of the recreational potential of coastal Louisiana watershed areas and provides useful insight for other projects of similar scope.

National Recreation Area For Atchafalaya Basin?

Editor's Note: The following fact sheet on the National Recreation Area possibilities of the Atchafalaya Basin was prepared by a former undersecretary of the Interior now returned to his post at LSU here.

By DR. LESLIE L. GLASGOW

The Atchafalaya Basin is a major floodway formed by the waters of the Red River and the Mississippi River. The lower Atchafalaya Basin is the largest remaining hardwood forest in the United States, and the most productive fish, wildlife and plant life swamp in the world. The prime ecological area is between the guide levees below Krotz Springs and I-10 to Morgan City.

As eroded soil flows into the Atchafalaya Basin the speed of the water is reduced, causing the silt to drop out and fill up the swamps and lakes of the Basin. As the land becomes high and dry many thousands of acres of timber are being cleared for soy beans and other uses. The U.S. Army Corps of Engineers reported that most of the Basin will fill in by 1978. If steps are not taken now to maintain the swamps and hardwood forests the Atchafalaya Basin will be lost.

New Recreation Concept

1. National Recreation Areas were created by Congress as a new concept to provide recreation to the masses of people.

2. They are administered separate and apart from the National Parks which were established to preserve the scenic wonders of the United States.

3. The activities that can be carried on within a National Recreation Area are determined by the Congressional Act that establishes each individual area.

4. Although boundaries for the Basin NRA have not been determined, the area under serious discussion lies between the east and west guide levees and is bounded on the north by the I-10 crossing and on the south by an indefinite line just above the more heavily settled area north of Morgan City.

5. The Federal Government would purchase an insignificant acreage, perhaps 500 acres for an administration site and visitor center. Any other land purchase would be from a willing seller. The government would take only an easement over the remainder of the land.

Disposition of Camps

6. Persons having camps within the final boundary would be permitted to use them in a normal manner until death. At that time they would be removed.

7. In every locality in which an NRA has

been established, it has given the local and state economy a tremendous boost. An Atchafalaya Basin NRA would result in a significant increase in tax revenues to the surrounding parishes and to the State of Louisiana.

8. The major objectives which are very simple are to:

(a) Always keep the Basin in timber.

(b) Always keep the Basin open for public use.

9. Establishment of an NRA would not interfere with the Corps of Engineers flood control program.

No Timber Ban

10. The land owner would continue to harvest timber according to normal timber harvest practices.

11. Mineral rights would be retained by the land owner and exploration for, and production of oil and gas would continue according to normal practices.

12. The harvest of wildlife and fisheries resources would continue under the jurisdiction of the Louisiana Wild Life and Fisheries Commission. Commercial fishing, sport fishing, crayfishing, deer hunting, waterfowl hunting, trapping, etc., would be encouraged.

What's Possible

The plan envisions but is not limited to the following:

1. A mushrooming of tourism business surrounding the Basin.

2. The outlay of 15-20 million dollars to develop the recreation potential of the Basin.

3. Construction of visitor center complete with interpretive services depicting the natural history and phenomena of the area.

4. A gigantic water hyacinth control program.

5. A large increase in the number of boat launching ramps with adequate parking facilities.

6. Marking and maintenance of boat trails (scenic and fishing), throughout the Basin.

7. Marking and maintenance of hiking trails on ridges and levees.

8. Wildlife observation vantage points and towers.

9. Natural history tours conducted by experienced naturalists.

10. Physical improvements that would increase wildlife and fisheries resources of the area.

11. Emergency equipment such as radio communication, and boats and personnel experienced in coping with most accidents.

CHAPTER XII

MISCELLANEOUS SECTORS

This chapter contains three sections. Section I covers fur trapping in coastal Louisiana, Section II describes the available Standard Industrial Classification listings applicable to coastal Louisiana, and Section III describes the marine-related expenditures of the Federal and State governments in Louisiana.

Section I

Fur Trapping in Coastal Louisiana

The ponds, lakes, and bayous in the broad, flat coastal marshes of Louisiana form an important base for valuable fur-bearing animals such as the mink, muskrat, otter, and nutria. The water areas are used by these animals for travel lanes and as sources of aquatic vegetation for food. The coastal marshes have kept Louisiana first among the states in fur production for most of this century. Moreover, the Louisiana fur industry, valued at \$5,000,000 to \$10,000,000 annually and involving 25 dealers, 125 buyers, and more than 4,000 trappers, leads the nation with approximately 30 percent of total fur production. The most important wild fur bearers are nutria, which yield approximately 95 percent of the world's supply of fur, and muskrat, which yield approximately 20 percent of the world's supply. Certainly, it is not true that fur trapping is a major industry, but it is one that provides important supplemental winter income for approximately 5,000 individuals in coastal Louisiana. Moreover, in a sense the industry is a symbolic representation of the dependence of man upon wildlife preservation.¹

The comparative takes and dollar values of fur animals in Louisiana are presented in Table 56, which also contains a section on the meat sales from fur bearers. The meat from fur-bearing animals was formerly sold to commercial growers of mink, but the decline of that industry has led to exclusive sales of the meat as a food supply for the screw worm fly sterilization program. Screw worm flies are raised on meat from fur-bearing animals and are subsequently sterilized by cobalt 90 radiation. The flies then are released over a 200-mile-wide band extending from the Gulf of Mexico to the Pacific Ocean in order to neutralize reproduction of this species of fly, thereby limiting damage to cattle herds.

Section II

SIC Listings

The following list (Table 57) of Standard Industrial Classifications of industries dependent upon or related to the economy of coastal Louisiana

¹Data on fur trapping were supplied by Ted O'Neil, Chief, Fur Division, Louisiana Wild Life and Fisheries Commission.

TABLE 56

COMPARATIVE TAKES OF FUR ANIMALS IN LOUISIANA, 1969-1970 SEASON

	No. of Pelts	Approximate Price to Trapper	Value
Muskrat (Eastern)	432,052	\$ 1.00	\$ 432,052.00
Muskrat (Western)	800,000	1.35	1,080,000.00
Mink	46,294	5.00	231,470.00
Nutria (Eastern)	704,175	1.60	1,126,680.00
Nutria (Western)	900,000	3.00	2,700,000.00
Raccoon	103,725	2.25	233,381.25
Opossum	7,648	.50	3,824.00
Otter	6,632	23.00	152,536.00
Skunk	108	.50	54.00
Fox	636	3.00	1,908.00
Bobcat	110	5.00	550.00
Beaver	646	5.00	3,230.00
Wolf	3	5.00	15.00
TOTAL PELTS	3,002,043		\$5,965,700.25
<u>Meat</u>	<u>Pounds</u>		
Nutria	9,500,000	.08	760,000.00
Muskrat	550,000	.08	44,000.00
Raccoon	380,000	.20	76,000.00
Opossum	50,000	.20	10,000.00
TOTAL MEAT	10,480,000		\$ 890,000.00
TOTAL PELTS AND MEAT			\$6,855,700.25

NOTE: The number of pelts taken is a function of the demand for particular fur types and does not imply physical limitations on takes.

is presented to illustrate the total scope of potential economic analysis. The basic problem, however, is that data are available from normal sources for very few of the listed industries. Nevertheless, inclusion of the list aids conceptual evaluation of the Louisiana coastal economy.

Section III

Marine-Related Federal and State Expenditures

Tables 58-60 display marine-related Federal and State expenditures in recent years. The data are not exhaustive, and in some instances the relation to marine activities is indirect. Nevertheless, they reveal substantial involvement on the part of both levels of government in marine-related activities. Present trends indicate greatly expanded Federal outlays to marine-related programs. Although many of these activities do not occur in the coastal zone, they may ultimately affect the quality of the coastal zone.

APPENDICES

APPENDIX I

INCOME AND POPULATION STATISTICS FOR LOUISIANA IN SELECTED YEARS

Personal Income in Selected Years, 1929-1968
(Thousands of Dollars)

	1929	1940	1950	1959	1962	1965	1968
Louisiana, Total	863,430	852,110	3,021,057	5,343,772	5,893,020	7,405,549	9,811,326
Louisiana, Coastal Region	523,599	518,903	1,861,781	3,543,028	3,878,709	4,969,887	6,527,492
Louisiana, Rest of State	339,831	333,207	1,159,276	1,800,744	2,014,311	2,435,662	3,283,834

Per Capita Personal Income in Selected Years, 1929-1968
(Hundreds of Dollars)

	1929	1940	1950	1959	1962	1965	1968
Louisiana, Total	414	360	1,120	1,666	1,747	2,080	2,645
Louisiana, Coastal Region	507	440	1,270	1,877	1,972	2,328	2,929
Louisiana, Rest of State	323	280	941	1,364	1,432	1,708	2,217
Total United States	705	592	1,496	2,161	2,368	2,760	3,421

Per Capita Personal Income, Percentage of National Average in Selected Years, 1929-1968

	1929	1940	1950	1959	1962	1965	1968
Louisiana, Total	59	61	75	77	74	75	77
Louisiana, Coastal Region	72	74	85	87	83	84	86
Louisiana, Rest of State	46	47	63	63	60	62	65

Earnings by Broad Industrial Sector, 1950, 1959, 1968
Louisiana Coastal Region Compared with Rest of State
(Location Quotient for Non-farm Earnings)

	1950		1959		1968	
	Coastal	Rest of State	Coastal	Rest of State	Coastal	Rest of State
Total Non-farm Earnings	100.00	(100.00)	100.00	(100.00)	100.00	(100.00)
Government Earnings	1.00	(1.36)	0.93	(0.43)	0.75	(1.66)
Total Federal	0.91	(1.21)	0.74	(1.14)	0.47	(1.89)
Federal Civilian	0.95	(0.69)	0.69	(0.74)	0.65	(0.79)
Military	0.85	(2.06)	0.82	(1.72)	0.21	(3.57)
State and Local	1.10	(1.52)	1.10	(1.70)	0.99	(1.49)
Private Non-farm Earnings	0.99	(0.95)	1.01	(0.92)	1.05	(0.86)
Manufacturing	0.66	(0.57)	0.60	(0.54)	0.63	(0.61)
Mining	1.64	(4.75)	5.47	(4.38)	7.23	(3.73)
Contract Construction	1.23	(1.20)	1.22	(1.28)	1.85	(1.21)
Transportation, Communication, and Public Utilities	1.48	(1.03)	1.45	(1.11)	1.45	(0.99)
Wholesale and Retail Trade	1.09	(0.99)	1.09	(1.05)	1.09	(1.00)
Finance, Insurance, and Real Estate	0.97	(0.56)	0.99	(0.70)	0.95	(0.66)
Services	1.09	(1.11)	1.01	(1.03)	0.95	(0.85)
Other	2.14	(2.02)	1.25	(2.37)	1.21	(2.03)

The location quotient is merely a device for comparing a region's percentage share of a particular activity with its percentage share of some basic aggregate; in this table the basic aggregate is non-farm earnings. To borrow an example from Isard's Methods of Regional Analysis, "If Region A accounts for 10 per cent of the national total of say, hat manufacture and the region's total income is 5 per cent of the nation's total, the region's location quotient (with income as base) for hat making would be 2." Location quotients are rough benchmarks, but precision is not one of their characteristics. Their prime usefulness is to sharpen intuition about the coastal Louisiana economy.

Total Population in Selected Years, 1929-1968,
Adjusted to Bureau of Census State Totals as of July 1

	1929	1940	1950	1959	1962	1965	1968
Louisiana, Total	2,086,000	2,370,000	2,697,000	3,208,000	3,374,000	3,561,000	3,710,000
Louisiana, Coastal Region	1,033,190	1,180,312	1,465,526	1,887,570	1,967,172	2,134,753	2,228,467
Louisiana, Rest of State	1,052,810	1,189,688	1,231,474	1,320,430	1,406,828	1,426,247	1,481,533

Earnings by Broad Industrial Sector, 1950, 1959, 1968
Louisiana Coastal Region
(Percentage of Total Earnings)

	1950	1959	1968
Total Earnings	100.00	100.00	100.00
Farm Earnings	5.54	2.55	1.92
Total Non-farm Earnings	94.46	97.45	98.08
Government Earnings	11.83	13.41	12.98
Total Federal	5.49	5.51	3.49
Civilian	3.57	2.84	2.89
Military	1.93	2.31	0.60
State and Local	6.33	8.26	9.49
Private Non-farm Earnings	82.63	84.04	85.10

Wholesale and Retail Trade	21.44	19.87	18.16
Finance, Insurance, and Real Estate	4.25	5.16	5.02
Services	12.66	13.06	14.12
Other	0.86	0.39	0.34

These data represent percentages within coastal Louisiana. They do not represent comparison with the rest of Louisiana.

Personal Income by Major Sources and Earnings by Broad Industrial Sector, 1950, 1959, 1968
Louisiana Coastal Region Compared with Rest of State
(Percentage of U.S.)

	1950	1959	1968
Total Personal Income	0.82 (0.51)	0.92 (0.47)	0.95 (0.48)
Total Wage and Salary Disbursements	0.80 (0.44)	0.91 (0.41)	0.96 (0.43)
Other Labor Income	0.85 (0.48)	0.93 (0.42)	1.03 (0.32)
Proprietors Income	0.74 (0.71)	0.83 (0.67)	0.85 (0.75)
Property Income	0.86 (0.38)	1.06 (0.43)	1.03 (0.44)
Transfer Payments	1.15 (0.94)	0.91 (0.71)	0.86 (0.64)
Less Personal Contribution for Social Insurance	0.77 (0.45)	0.85 (0.41)	0.93 (0.39)
Total Earnings	0.79 (0.49)	0.90 (0.45)	0.95 (0.47)
Farm Earnings	0.50 (1.03)	0.51 (1.09)	0.57 (1.47)
Total Non-farm Earnings	0.82 (0.44)	0.92 (0.42)	0.96 (0.43)
Government Earnings	0.82 (0.60)	0.86 (0.61)	0.72 (0.72)
Total Federal	0.75 (0.53)	0.69 (0.48)	0.46 (0.82)
Federal Civilian	0.78 (0.30)	0.64 (0.31)	0.63 (0.34)
Military	0.69 (0.91)	0.76 (0.73)	0.20 (1.55)
State and Local	0.90 (0.57)	1.01 (0.72)	0.92 (0.65)
Private Non-farm Earnings	0.82 (0.42)	0.93 (0.39)	1.01 (0.37)
Manufacturing	0.54 (0.25)	0.55 (0.23)	0.61 (0.26)
Mining	1.34 (2.11)	5.05 (1.86)	6.97 (1.62)
Contract Construction	1.00 (0.53)	1.13 (0.54)	1.78 (0.52)
Transportation, Communication, and Public Utilities	1.21 (0.46)	1.33 (0.47)	1.40 (0.43)
Wholesale and Retail Trade	0.89 (0.44)	1.00 (0.45)	1.05 (0.43)
Finance, Insurance, and Real Estate	0.79 (0.24)	0.92 (0.30)	0.91 (0.29)
Services	0.89 (0.49)	0.93 (0.44)	0.92 (0.37)
Other	1.75 (0.90)	1.15 (1.00)	1.14 (0.88)

Data for Rest of Louisiana are in parentheses. For example, total personal income in 1950 as a percentage of the U.S. was 0.82 for coastal Louisiana and (0.51) for the Rest of Louisiana.

APPENDIX II

PARISH EMPLOYMENT AND TAXABLE PAYROLLS BY INDUSTRY FOR 1st QUARTER 1969

Industry	Number of Employees	Taxable Payrolls (Thousands of Dollars)	Total Reporting Units	Number of Reporting Units, by Employment Size Class
