6.3 Freshwater Habitat Strategies and Actions

This plan proposes a strategy to protect and improve ecosystem functions and restore normative ecological processes. The components of the strategy are, first, to protect and maintain existing high quality and/or unimpaired habitats and ecosystem functions; and, second, to restore degraded habitat where appropriate, through passive and active measures.

- Protection and maintenance of existing high quality habitats is a broad, economical approach to species recovery. Many objectives are likely to be met through habitat protection and the associated natural recovery of upland and riparian areas. Protection and maintenance includes compliance with existing rules and regulations, such as the State Forest Practices Act, Klickitat County

Shorelines Master Plan and Critical Areas Ordinance, and other state and county regulations designed to protect aquatic habitat. Protection may also incorporate a wide range of voluntary actions such as fencing riparian areas, participation in the various agricultural land reserve programs, and voluntarily implementing programs that help to avoid impacts to aquatic resources. Land acquisitions, conservation easements, cooperative agreements, and protective land designations can also be used to facilitate high quality habitat protection.

- Restoration and enhancement of habitat conditions for salmon and steelhead populations should improve population production. The value of these actions to the viability of the population will depend on whether or not they address the factors currently limiting the population or threats associated with factors that are now, or are trending toward, becoming limiting, e.g. climate change. The success of these strategies is further enhanced when actions build from existing restoration efforts and incorporate a range of project types that address the many interrelated habitat impairments related to the limiting factors.

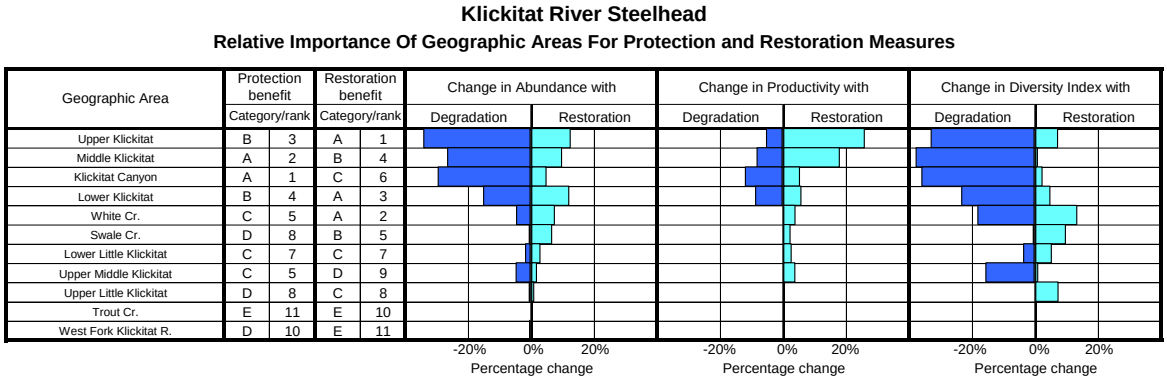
The overall strategy is further differentiated into the following types of action to address potential limiting factors and threats for Klickitat steelhead production: 1) protect stream corridor structure and function; 2) restore passage and connectivity between habitat areas; 3) restore floodplain function and channel migration processes; 4) restore riparian condition; 5) restore altered hydrographs to enhance instream flows during critical periods; and 6) restore degraded water quality, including water temperatures. Finally, more specific management actions are described.

Priority Geographic Areas

Geographical areas within the Klickitat subbasin that may have greater restoration value than others for the health and productivity of Klickitat steelhead were identified through three related efforts: the Northwest Power and Conservation Council's 2004 subbasin planning process; the Klickitat Lead Entity process performed under the Washington State Salmon Recovery Planning process SB2496; and Yakama Nation's 2005 and 2006 EDT model runs (unpublished), which incorporated major spawning areas.

- The purpose of the Northwest Power and Conservation Council's subbasin planning process was to "provide a basin-wide approach to developing locally informed fish and wildlife protection and restoration priorities," and to "bring people together in a collaborative setting to improve communication, reduce conflicts, address problems, and, wherever possible, reach consensus on biological objectives and strategies that will improve coordinated natural resource management on private and public lands." One of the subbasin goals, similar to the broad-sense goal proposed by the Yakama Nation for this recovery plan, was "to restore and maintain sustainable, naturally producing populations of spring Chinook and stelhead that support tribal and non-tribal harvest and economic practices while protecting the biological integrity and the genetic diversity of the subbasin."

The 2004 Klickitat Subbasin Plan ranked geographic areas based on analysis of EDT model outputs of environmental and survival attributes, and the potential benefit to population parameters that the model identified. Various EDT outputs, such as a reach analysis and a breakdown of relative importance of geographic areas for protection and restoration measures (both standard outputs as well as outputs normalized to correct for weighting of reach length), rank population performance parameters by individual life stage, as well as averaged across all life stages.



- The Klickitat Lead Entity's Citizens Committee also identified the equivalent of broad-sense goals and, with assistance of the Lead Entity's Technical Committee, identified and prioritized reaches with corresponding habitat and restoration actions for the purpose of prioritizing projects for grant funding and assisting with voluntary conservation efforts of priority basin fish species (steelhead, rainbow trout, mountain whitefish, Chinook salmon, bull trout, etc.). The Klickitat Lead Entity Strategy was developed for use by the Lead Entity Organization for non-regulatory purposes and has not been subject to peer review or other quality assurance processes appropriate for regulatory application of its contents (Klickitat Lead Entity, 2006, 2007, 2008). The Lead Entity Organization developed a matrix of priority areas considering community interests and used a mix of existing data from habitat assessments, fish distribution surveys, and spawning ground surveys, as well as knowledge of professionals familiar with the subbasin. Data sources included published reports from Yakama Nation Fisheries, WDFW, WDOE, consulting firms, as well as unpublished databases maintained by these agencies and professional judgment.

Identification of Potential Projects

Actions to address limiting factors in the Klickitat basin were identified using EDT modeling, other processes, and best professional judgment. The 2005 and 2006 EDT models were also used to identify primary limiting factors by life stage and reach and to rank the relative restoration and protection potential of the six major spawning areas and five minor spawning areas identified by Yakama Nation Fisheries in the Klickitat drainage (Figure 6-1). This information, as well as costs, quantitative and qualitative assessments of project time frames, implementability, time to implement, time to realize benefits and impact of those benefits on limiting factors and VSPs at 10 and 25 years out, were all fed into a custom-built relational database for prioritizing salmon recovery actions in the Klickitat subbasin. It is important to note that the accuracy of any modeling effort depends on the assumptions and information put into the model. This and other modeling will be revisited as more data are collected on habitat conditions in the basin through ongoing and proposed monitoring and research.

The delineations of the spawning areas identified by the Yakama Nation differ from those identified by the ICTRT in a few areas (see Appendix II, Table II-1). Nevertheless, findings from the EDT analysis were useful in developing the suite of freshwater habitat strategies and actions.

Figure 6-1. EDT Estimate of Relative Importance of Major and Minor Spawning Areas for Protection and Restoration Measures for Klickitat Steelhead (2005 YN EDT model analysis, unpublished data).

Freshwater habitat strategies and actions to improve the viability of the Klickitat steelhead population are described in Tables 6-1 through 6-6. The strategies address the key factors and threats potentially limiting population viability and are based on results from EDT analysis and other assessments, including the ICTRT's viability assessment for the populations. [3]

Primary freshwater actions identified for steelhead focus on restoring ecological functions in the watershed. These actions include: increasing floodplain channel and roughness, reconnecting side-channels, improving floodplain connectivity, relocating floodplain infrastructure and roads, improving maintenance, rehabilitating and decommissioning roads as appropriate, re-establishing and/or enhancing native vegetation within floodplain, implementing practices that leaves naturally occurring sources of large woody debris instream, and/or artificially introduce large debris or other structure. The tables also identify priority locations where implementation of actions under each strategy will reap the greatest benefits.

Results from Ecosystem Diagnosis and Treatment (EDT) modeling in 2005 by Yakama Nation Fisheries (unpublished) provide some indication of the change in steelhead production that might be expected to occur if all historical habitat areas above Castile Falls were fully seeded. The modeling effort measured intrinsic productivity, equilibrium abundance, and capacity of the system for steelhead within spawning locations defined by resource specialists. Two scenarios were developed: 1) full blockage, with Castile Falls completely blocking upstream fish passage — as was the case from the early 1960s until modifications were completed in 2005 — and 2) full passage, with 100 percent passage at Castile Falls and assuming that all habitat above it had been fully seeded with anadromous fish (currently passage is open, but the area is only beginning to be re-colonized, a process that might require years to fully take place unaided).

[3] Tables 6-1 through 6-6 were not developed through the Klickitat Lead Entity Strategy or the Lead Entity process.

Modeling results for the full blockage scenario suggest that the theoretical intrinsic productivity (current with harvest) of the system with no passage above Castile is 3.6, and equilibrium abundance is 1,064 steelhead. In contrast, under the full passage scenario, with 100 percent passage and habitat seeding above Castile, intrinsic productivity increased to 3.7 and equilibrium abundance to 1,628. The potential increase in capacity of fully opening habitat above Castile rose from 1,475 to 2,222 steelhead. These EDT projections, however, do not represent the return for any given year, but rather the potential return if the population is not limited by density-dependent factors, natural disasters or other mortality factors. The projections represent the potential for a population to recover when conditions improve. It is possible that some factors might be under- or overestimated. It is always necessary to adjust the results after comparing with actual observations, other data, and expert opinion.

Table 6-1. Strategy 1: Protect Stream Corridor Structure and Function.

Protect stream corridor structure and function					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
a) Protect existing habitat from future degradation through conservation easements, acquisitions, reclassification of lands as natural areas, enforcement of land use regulations. b) Riparian forest management and planning: plan to leave buffer strips in riparian forest zones. c) Limit riparian livestock grazing. d) Assess effects of groundwater development on tributary flow. e) Manage diversions to maximize instream summer flows.	Many factors, including key habitat quantity, habitat diversity, sediment load, water quality, altered flow regimes, predation	Floodplain infrastructure; timber, agricultural and grazing practices; habitat fragmentation due to land development	Productivity, abundance, spatial structure	All	Protecting functioning floodplains and channels that are in balance with their ability to transport water and sediment is one of the highest priorities. All streams will have some level of erosion, because a stream channel is never static. Having some erosion is essential for recruitment of spawning gravel and other important ecological functions (such as distributing fine sediments needed for riparian plant growth). Existing quality habitat may be protected through land acquisition and/or conservation easements by WDFW or a land trust. WDNR parcels that are currently in State Lands in the upper Klickitat could be reclassified as Natural Areas. Protecting base stream flows from further appropriations is a very important function of protecting existing high quality habitats.
Priority Locations (geographic areas)					
Mainstem Klickitat and throughout MaSA watersheds. Highest priorities: Klickitat River from RM 70.5 to RM 87.05, Piscoe Creek, Diamond Fork, Butte Meadows Creek, Chaparral Creek.					

Table 6-2. Strategy 2: Restore Passage and Connectivity between Habitat Areas.

Restore passage and connectivity between habitat areas					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
a) Replace culverts. b) Monitor effectiveness of passage improvements at Castile Falls. c) Improve passage at Lyle Falls. d) Study passage at mouths of spawning tributaries relative to flow and alluvial fan morphology. e) Monitor and continue restoration efforts in Snyder Creek mill reach (flume passage improvements and riparian re-vegetation.) f) Determine extent of problem for inadequately screened intakes. g) Ensure that pump intakes are adequately screened.	Passage obstructions, altered flow regimes, key habitat quantity, water withdrawals	Inundation by Bonneville Pool, undersized/ inadequate culverts, irrigation diversions, instream structures, past riparian logging and stream cleaning, floodplain infrastructure, insufficient flow at tributary mouths	Spatial structure, abundance, productivity	All, particularly adults and age 0-2 juveniles	Partial-barrier culverts exist near the mouth and upstream on Piscoe Creek, near the mouth of McCreedy Creek, and on some Little Klickitat tributaries (numerous), on White Creek and its tributaries limiting upstream movement of juveniles from rearing habitat to perennial refugia. Passage at mouths of some tributaries restricts access to spawning areas due to alterations in flow and alluvial fan morphology (research is needed). Steelhead and spring Chinook are expected to begin re-colonizing spawning and rearing habitat above Castile Falls now that passage has been improved; monitoring of effectiveness of passage improvements is needed. Disconnecting roads can improve watershed and water retention.

Restore passage and connectivity between habitat areas					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Priority Locations (geographic areas)					
Piscoe Creek, McCreedy Creek, White Creek and tributaries, Little Klickitat tributaries, upper Klickitat mainstem, West Fork Klickitat, Trout Creek. Highest priorities: Castile Falls and culverts on several tributary streams					

Table 6-3. Strategy 3: Restore Floodplain Function and Channel Migration Processes.

Restore floodplain function and channel migration processes					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
a) Place LWD or other structures to stop headcutting. b) Restore stream length. c) Restore cross-sectional morphology and roughness. d) Augment gravel. e) Increase pool quantity and quality; pool: riffle ratio. f) Improve pool cover and hiding refugia. g) Restore floodplain and side-channel connectivity. h) Increase floodplain and channel roughness. i) Re-vegetate riparian areas. j) Relocate/ soften floodplain infrastructure. Modify historical railroad grade. k) Disconnect roads from stream network to improve watershed and water retention. l) Improve surface and drainage characteristics of roads in tributary watersheds. m) Perforate roads to allow peak flows to move onto floodplain. n) Relocate/ abandon mid-slope roads where possible; relocate/abandon valley-bottom roads where possible. o) Close/relocate ORV trails. p) Limit riparian livestock grazing. q) Investigate off-channel livestock watering. r) Promote no-till cropping and riparian buffers in agricultural areas, s) Modify land-uses and/or implement structures to retain storm flow and decrease time of concentration from watershed upstream of canyon (Swale Creek).	Habitat diversity, key habitat quantity, sediment load, altered flow regimes, altered food web, water temperature, predation	Hydroconfinement; floodplain infrastructure; timber and grazing management activities; habitat fragmentation due to subdivision, land-clearing and development	Productivity, abundance, spatial structure	All	There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows. Instream structures can improve channel stability, trap sediments and raise the stream bed so that the stream can more effectively interact with the floodplain. Typical structures include debris jams, rootwads, boulder clusters, whole trees, and rock weirs where appropriate. Any restoration actions will be ineffectual unless floodplain clearing and grading can be restricted, regulated or eliminated.

Restore floodplain function and channel migration processes					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Priority Locations (geographic areas)					
Highest priorities: Chaparral Creek, Coyote Creek, McCreedy Creek, Butte Meadows Creek, Klickitat R. from Castle Falls (RM 65.75) to RM 87.05, upper Diamond Fork					

Table 6-4 Strategy 4: Restore Riparian Condition.

Restore riparian function and condition.					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
a) Re-vegetate riparian areas. b) Limit riparian livestock grazing. c) Monitor and continue restoration efforts in Snyder Creek mill reach (flume passage improvements and riparian re-vegetation.) d) Investigate off-channel livestock watering. e) Control/eradicate noxious invasive plant species from priority habitats..	Habitat diversity, key habitat quantity, sediment load, altered flow regimes, altered food web, water temperature	Floodplain infrastructure; timber and grazing management activities; habitat fragmentation due to subdivision; channel incision	Productivity, abundance, spatial structure	All	Primary methods of riparian enhancement include riparian corridor fences to exclude livestock, changes in grazing management that promote riparian recovery, and planting of native vegetation. The ecological effects of restoration actions include increased floodplain roughness, bank stability, nutrients and recruitment opportunity for future large wood.
Priority Locations (geographic areas)					
Trout Creek, Upper Little Klickitat, Lower Little Klickitat, Klickitat Canyon, Swale Creek, Lower Klickitat, Middle Klickitat, White Creek, Upper Klickitat. Highest priorities: Chaparral Creek, McCreedy Creek, Piscoe, Diamond Fork, Coyote, Butte Meadows, Klickitat R. from Castile Falls (RM 65.75) to RM 87.05					

Table 6-5. Strategy 5: Restore Altered Hydrographs to Enhance Instream Flows during Critical Periods.

Enhance instream flow during critical periods.					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
a) Obtain instream flow right for mainstem Klickitat. b) Restore floodplain connectivity in tributaries. c) Assess effects of groundwater development on tributary flow. d) Manage diversions to maximize instream summer flows. e) Re-introduce beaver.	Habitat diversity, key habitat quantity, sediment load, altered flow regimes, water temperature, water withdrawals	Floodplain infrastructure; road, timber, agricultural and grazing management activities; hydroconfinement; water withdrawals, beaver removal	Abundance, productivity, spatial structure	All, particularly 0-1 age life stages	Hydrologic routing in watershed has been modified, and flow timing, discharge, distribution of LWD and sediment altered. Shortened flow paths for storm flow, changes associated with reduced canopy interception, and changes in the upland plant community due to land management have reduced precipitation infiltration rates, resulting in higher peak flows and lower base flows. Removal of large wood, reduced ability for large wood recruitment and

Enhance instream flow during critical periods.	
	incision in streams also increases water velocities and reduces the ability of the stream to hold water for gradual release.
Priority Locations (geographic areas)	
Lower Klickitat, Middle Klickitat, Lower Little Klickitat, Upper Little Klickitat, White Creek, Trout Creek, Swale Creek Highest priorities: streams in the lower and middle Klickitat watersheds, including Knight Canyon, Dillacort, Wheeler, upper Canyon, Beeks Canyon, and Dead Canyon creeks, and portions of White Creek.	

Table 6-6. Strategy 6: Restore Degraded Water Quality, including Water Temperatures.

Restore degraded water quality, including water temperatures.					
Actions	**Limiting Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
See actions for Strategy 3. a) Short-term fertilization of stream with carcasses or carcass analogs. b) Improve road drainage characteristics and surfacing. c) Re-vegetate riparian areas to reduce stream temperatures. d) Conduct pathogen sampling and monitoring. e) Investigate off-channel livestock watering f) Assess nutrient and dissolved oxygen levels in the Little Klickitat River, particularly downstream of Goldendale.	Sediment load, altered flow regimes, water temperature, water quality, altered food web, pathogens	Road, timber and grazing management activities, particularly in riparian areas; incision	Abundance, productivity, spatial structure	All life stages	Riparian vegetation is limited in many parts of the drainage. Roads and other infrastructure have altered floodplain, confined river and tributaries and contribute fine sediment to stream channel. Loss of LWD and other structure limits availability of pools and other thermal refugia. Reduced sediment inputs will increase aquatic insect production for food. Carcasses will provide temporary food source for juveniles.
Priority Locations (geographic areas)					
Highest priorities: Klickitat River from RM 70.5 to RM 87.05, Chaparral Creek, Diamond Fk., Piscoe Creek					

6.4 Harvest-Related Strategies and Actions

WDFW will continue to manage Klickitat tributary sport fisheries for selective fisheries that target marked hatchery summer steelhead. Tributary fisheries will be managed under a Fisheries Management and Evaluation Plan for Middle Columbia River steelhead submitted to NMFS by WDFW, which is currently going through NMFS review. Columbia River mainstem harvest of steelhead will continue to be managed through the *U.S. v. Oregon* process, and will be subject to consultations with NMFS. Enhanced public education and fisheries enforcement will be incorporated along with new selective fisheries regulations to ensure understanding and compliance.

Treaty Native American fishing rights in the Columbia basin are under the continuing jurisdiction of the U.S. District Court for the District of Oregon in the case of *United States v. Oregon*, No. 68-513 (filed in 1968). The parties to *U.S. v. Oregon* are the United States acting through the Department of Interior (USFWS and Bureau of Indian Affairs) and Department of Commerce (NMFS), the Warm Springs, Umatilla, Nez Perce, Yakama, and Shoshone-Bannock Tribes, and the states of Oregon, Washington, and Idaho. In *U.S. v. Oregon*, the Court affirmed that the treaties reserved for the tribes 50 percent of the harvestable surplus of fish destined to pass through their usual and accustomed fishing areas.

Starting in 1977, tribal and state fisheries subject to *U.S. v. Oregon* have been regulated pursuant to a series of court orders reflecting court-approved settlement agreements among the parties. The last long-term agreement, known as the Columbia River Fishery Management Plan (CRFMP) was adopted and approved by the Court in 1988 and expired in 1999. Since 1999, Columbia River mainstem fisheries have been managed via short term settlement agreements adopted by the Court. Artificial propagation programs upstream of Bonneville Dam have also been incorporated into these agreements, because of their importance to providing fish for harvest. Harvest plans for tributary fisheries are developed cooperatively by the management entities with primary management responsibility in the respective subbasin. A new *U.S. v Oregon* Management Agreement has been completed and NMFS has completed a Section 7 Biological Opinion addressing the impacts of the fisheries management action and hatchery production in the new agreement (https://pcts.nmfs.noaa.gov/pls/pcts-pub/biop_results_detail?reg_inclause_in=('NWR')&idin=107547). The new management agreement will cover Columbia River fisheries management and hatchery production actions for the period from 2008 to 2017.

During the last 10-15 years, harvest has been managed pursuant to the CRFMP and successor agreements that contain restraints on the fisheries necessitated by ESA listings. The agreements quantify and allocate harvest between tribal and non-tribal fishing subject to ESA-imposed constraints for listed species. The current *U.S. v. Oregon* harvest constraint for steelhead is set to protect Group "B" index fish returning to Idaho with impacts from Non-Native American fisheries limited to 2 percent and tribal fisheries to 15 percent. Group "A" index fish (including those returning to the Klickitat River) are affected by tribal fisheries at a substantially lower rate than Group "B" index fish. The

new agreement sets an impact limit on naturally produced Mid-Columbia River steelhead of no more than 2 percent in non-treaty fisheries but does not set a limit for treaty fisheries. However, NMFS expects impacts from the treaty fisheries to continue to be in the range observed since 1998, averaging around 6.64 percent.

In 2002, WDFW instituted a sport fishing rule change for the Klickitat River proposed by the Yakama Nation. The rule change closed fishing for rainbow trout in lower subbasin tributaries of the Klickitat River (Swale, Wheeler, and Snyder Creek). The purpose was to protect rearing steelhead juveniles from take and harassment.

Strategy 1. Study and limit impacts of harvest practices on Klickitat steelhead population.

Enforcement of sport and tribal fishing regulations and control of illegal fishing on and off the reservation is a priority. Poaching and harassment of steelhead in the Klickitat subbasin occurs at an unknown rate.

Actions

- Enforce tribal and sport regulations to eliminate illegal harvest.

6.5 Mainstem Columbia Hydrosystem and Estuary -- Strategies and Actions

The plan for current mainstem hydro operations, as summarized in the Hydro Module (NMFS 2008c), and any further improvements for fish survival that may result from the ongoing Federal Columbia River Power System (FCRPS) collaborative process, represent the hydropower recovery strategy for all listed salmonids that migrate through the mainstem Columbia River, including the Middle Columbia steelhead populations.

The Hydro Module summarizes the general effects of Columbia River mainstem hydropower projects on all 13 ESA-listed salmonids in the Columbia basin, including the limiting factors and threats and expected actions (including site-specific management actions), or strategy options, to address those threats. This module is a synthesis of information that has undergone public processes for review, including, but not limited to, the Federal Columbia River Power System (FCRPS) 2008 Biological Opinion (NMFS 2008b), Federal Energy Regulatory Commission (FERC) licensing proceedings, and Habitat Conservation Plans (HCPs). It may be updated as additional information becomes available.

The Reasonable and Prudent Alternative (RPA) for the FCRPS (2008b) takes a comprehensive approach to ESA protection that includes hydro, habitat, hatchery, harvest and predation measures to address the biological needs of salmon and steelhead in every life stage. The RPA is the product of the collaboration between NMFS and the Action Agencies ordered by the court. It is based on a comprehensive analysis of the salmon life cycle conducted down to the level of the populations that make up the listed species. Section 8.8 and the "Reasonable and Prudent Alternative Table" in the 2008 FCRPS

Biological Opinion describe actions that should positively affect Middle Columbia River steelhead.

The current plan for operation of the FCRPS through 2018 (NMFS 2008a) contains the following actions intended to address the needs for survival and recovery of ESA-listed salmon and steelhead:

- Continue adult fish passage operations that have resulted in improved survival.
- Improve juvenile fish passage: install removable spillway weirs or similar surface bypass devices at John Day and McNary dams, an extended tailrace spill wall at The Dalles Dam, and various modifications at Bonneville Dam. Passage for steelhead smolts at each of the four Lower Columbia River mainstem projects must reach 96 percent survival.
- Continue and enhance spill for juvenile fish passage.
- Continue reservoir operations and river flows to benefit spring migrating juveniles.
- Develop dry water year operations to better protect migrating juveniles.
- Develop and implement a kelt management plan.

The Estuary Module, which NMFS prepared in collaboration with the Lower Columbia Estuary Partnership (NMFS 2007), focuses on habitat in the lower Columbia River below Bonneville Dam and how that habitat affects the survival of ESA-listed chum, steelhead, Chinook, and coho from throughout the Columbia River basin. It identifies and prioritizes limiting factors and threats in the estuary, then identifies 23 broad actions whose implementation would reduce the threats and thus increase survival of salmon and steelhead during their time in the estuary. The module also estimates the cost of implementing each action over a 25-year period. A description of monitoring, research, and evaluation needs that are appropriate to the management actions is included as an appendix to the module.

6.6 Potential Effects of Proposed Recovery Actions

This section presents an analysis of the potential effects of proposed recovery actions on the abundance and productivity of the Klickitat population of Middle Columbia River steelhead, based on the 2005 and 2006 EDT modeling done by Yakama Nation Fisheries (unpublished). Estimated levels of effectiveness for the proposed actions were generated and used as inputs into quantitative models to project the potential impacts of those changes on the population. This quantitative analysis provides an opportunity to evaluate the efficacy of proposed recovery strategies in light of current knowledge regarding population functioning, including relationships with habitat conditions. Equally important, the quantitative models used in the assessment provide a framework for productively targeting evaluation efforts as well as for revisiting key assumptions in the

future as more information becomes available (e.g., from monitoring responses to initial implementation or from evaluation efforts targeting key uncertainties).

The analysis was performed sequentially, first by projecting effects for tributary habitat actions alone, then sequentially adding in hatchery, hydro, predation, estuary, and harvest actions. The results at each step provide a means for comparing estimated relative benefits of the proposed suites of actions, and, finally, the potential benefit of all the proposed actions to the Klickitat steelhead population.

Two models were used: Ecosystem Diagnosis and Treatment (EDT) and the All-H-Analyzer (AHA). The EDT model has commonly been used in regional planning efforts to evaluate potential responses to tributary habitat restoration efforts. The EDT model uses derived relationships between habitat characteristics and fish survival to calculate changes in survival, abundance, and productivity that could result from changes in the habitat. Use of the EDT model requires a set of inputs that describe current habitat conditions and the expected changes in habitat conditions that would result from a proposed action scenario. This model could be used, for example, to calculate the improvement that would be expected from a 10 percent drop in water temperature during the period of egg incubation in a certain tributary reach. The AHA model encompasses prospective relationships between all the "H" factors: habitat, hatcheries, hydro, and harvest. Thus, the results of the EDT model become one set of information fed into the AHA model to produce an estimate of the benefits of all the proposed actions.

It is important to note that the modeling results relative to recovery criteria are a function of the input information and key assumptions associated with the translation of actions into habitat changes, habitat and life-stage survival relationships, and population dynamics. Although the modeling provides valuable insight into the potential responses to recovery actions, the estimated potential responses are dependent on the assumptions and information put into the models.

Abundance and productivity are projected to increase for all scenario combinations analyzed for Klickitat River steelhead (Table 6-7; note that performance values in the table are direct output from EDT/AHA). The largest contribution to performance improvements results from the combination of tributary habitat actions throughout the basin and recolonization of the upper watershed (recolonization of the upper watershed is possible because of passage improvements at Castile Falls). In contrast, relatively small increases are attributable to mainstem actions.

Table 6-7 shows estimated population performance (productivity and abundance) of Klickitat River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly from EDT/AHA and were not converted to ICTRT-equivalent performance values (the ICTRT was unable to empirically estimate baseline performance measures for this population because of a lack of data). Results are shown with and without recolonization of the upper watershed. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under

relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario.

Table 6-7. Estimated Productivity and Abundance of Klickitat River Steelhead Associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric			
		Productivity		Abundance	
		Actions without recolonization of upper watershed	Actions with recolonization of upper watershed	Actions without recolonization of upper watershed	Actions with recolonization of upper watershed
Base		1.77		939	
Base-Current		1.92	1.92	1,118	1,118
Current-Prospective	Habitat	2.12	2.38	1,319	2,320
	Hydro	2.24	2.50	1,468	2,572
	Predation	2.29	2.56	1,538	2,692
	Estuary	2.36	2.62	1,630	2,850
	Harvest	2.36	2.62	1,630	2,850
	Ocean ±25%	2.01-2.64	2.27-2.90	1,181-2,026	2,088-3,539

This is a rough estimate, given the current data gaps and uncertainties, useful simply as an indication that if recovery actions are implemented, the population is likely to trend toward viable status. As we learn more about this population, implement proposed actions, and improve modeling methods, the analysis will be refined.

7. Implementation and Preliminary Cost Estimates

NMFS recognizes that there are significant uncertainties about the underlying biology and the best approaches to improving conditions for steelhead. NMFS is committed to an ongoing effort to address these uncertainties and work through associated disagreements over management approaches as part of implementing this recovery plan. This will require rigorous application of an adaptive management process that identifies key uncertainties, proposes competing hypotheses, and uses recovery actions and appropriate research and monitoring to test these hypotheses and adjust management accordingly.

Implementation of this plan depends on the voluntary actions and cooperation of local entities and citizen groups. An important part of implementation will be working cooperatively to develop a detailed research, monitoring, and evaluation plan addressing the additional information needs described in Chapter 8. It will be essential that a collaborative implementation structure be set up to improve communication and work on a shared sense of priorities.

7.1 Implementation

NMFS has worked independently with the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, and other local entities to develop the recovery plan for the Klickitat steelhead population. NMFS encourages the formation of a planning group for the Washington Gorge Management Unit, a forum or entity that would take responsibility for coordinating implementation of the plan. Implementing the proposed recovery actions for steelhead in the Washington Gorge Management Unit, including the Klickitat subbasin, would be a primary task for a Washington Gorge Area Regional Board, subject to concurrence by state, tribal and local governments and the opportunity for involvement and comment by the public.

The Washington Gorge Area Regional Board could consist of representatives from Klickitat, Yakima and Benton counties, local landowners, and the Yakama Nation. The Board could also provide an opportunity for coordination with the Lower Columbia River Fish Recovery Board (LCFRB), since the Washington Gorge Management Unit includes both the Middle Columbia River Steelhead DPS and the Willamette/Lower Columbia ESUs for Chinook, coho, and chum ESA-listed populations, which are covered by the LCFRB.

The Washington Gorge Area Regional Board could use the considerations identified in Chapter 6 to prioritize recovery actions in the Klickitat subbasin and other areas within the Washington Gorge Management Unit to respond to the interests identified by various stakeholders in the area.

The prioritization of projects for funding should be based on a balance between the biological benefit of the project, its cost, and feasibility of implementation. Projects that

address primary limiting factors, have high biological benefit, are relatively inexpensive, and are feasible should receive highest funding priority. Projects that have high cost, low biological benefit to listed fish species, and relatively low feasibility should receive lowest funding priority.

Funding sources for salmon and steelhead recovery actions in the Columbia Basin are varied. They include:

- Pacific Coastal Salmon Recovery Fund (PCSRF) (states and tribes)
- Salmon Recovery Funding Board (SRFB) (a combination of PCSRF and Washington State funds)
- Columbia Basin Fish Accords
- Congressional appropriations (Federal agencies)
- State appropriations (state agencies)
- Northwest Power and Conservation Council Fish and Wildlife Program (states and tribes)
- Federal / state grants
- Non-profit organization programs and grants

The 2008 Columbia River Fish Accords Memorandum of Agreement (MOA) between the Three Treaty Tribes and FCRPS Action Agencies (Columbia Basin Accords 2008) identifies funds for hatchery planning and operations and maintenance covering some of the existing and expanded activities in the Klickitat River basin. The MOA identifies hatchery capital funds for the design and construction of the hatchery and passage facilities in the Klickitat River basin except the Wahkiacus Hatchery facility, and includes language that states that the Action Agencies will work toward finding funding for this facility.

7.2 Preliminary Cost Estimates

Preliminary cost estimates are provided for the three major categories of strategies and actions: RM&E, hatcheries, and habitat. The highest priority strategies for the Klickitat basin address data gaps (see Section 6-1). As such, these priority strategies fall into the category of research, monitoring, and evaluation. The costs associated with these efforts are detailed in Chapter 8. Table 8-1 estimates the cost of ongoing and expanded RM&E activities to be up to $4,484,402 for years 1 through 3, and up to $15,142,783 for years 4 through 10. Information gained through filling the priority data gaps will help to refine the actions needed to reach recovery.

Costs for actions to address hatchery-related effects are distributed among research, monitoring and evaluation, detailed in Chapter 8, and capital costs and operations and maintenance costs that have been included in programs proposed under the NPCC Fish and Wildlife Program or are ongoing under that program or the Mitchell Act administered by NMFS. Capital costs for hatchery and fish passage improvements are shown in Table 7-1, which is drawn from the Klickitat River Anadromous Fisheries Master Plan. The plan was submitted by the Yakama Nation to the NPCC to fulfill the requirements for step one of a three-step process for the approval of major projects

(Sharp et al. 2008). The costs are estimated based on the current status of the design and may change as the design is finalized. Since these operations and maintenance costs are ongoing, they were not included in the future costs of recovery actions (Plummer 2006).

Table 7-1 Klickitat Subbasin capital construction costs estimates in FY07 dollars (Sharp et al. 2008).

Description	Estimated Cost
Lyle Falls Fishway Passage Improvements and R, M&E Station	$5,750,000
Castile Falls Enumeration Facility	$1,149,000
Klickitat Hatchery Infrastructure Upgrades with Reform Measures[4]	$16,100,000
McCreedy Creek Steelhead (Conservation) Acclimation Site	$234,000
Wahkiacus Hatchery & Acclimation Facility Construction[5]	$18,400,000
TOTAL	*$41,633,000*

Habitat recovery actions, estimated costs, and time frames based on current information are listed in Table 7-2. The cost estimates are based on a number of efforts: the recommendations and priorities from the NPCC subbasin planning process; expert opinion of resource professionals working in the watershed; local knowledge; current cost estimates of YN project dollars (e.g., Klickitat Watershed Enhancement Project activities); and land values derived in conjunction with the Columbia Land Trust. It should be noted that the habitat cost estimates below are for Yakama Nation-defined MaSAs. For correlation with the ICTRT-defined MaSAs, see Appendix II, Table II-1.

The total estimated cost for completing all of the habitat projects identified inTable 7-2 is estimated to be up to $129,451,630 ($25,890,326.00 for years 1-10, and $103,561,304.00 for years 11-50). Estimates are expressed in 2007 dollars. Estimated costs are general range summaries arranged to align with the Klickitat River Anadromous Fisheries Master Plan (Sharp et al. 2008) and Yakima/Klickitat Fisheries Project.

The actions listed in Table 7-2 do not include or account for out-of-subbasin effects or future degradation or damage to the watershed.

[4] In July 2009, BPA initiated the EIS process for the Klickitat Hatchery Program and Step III of the Klickitat River Anadromous Fisheries Master Plan, with an anticipated final EIS document in early 2011.

[5] Fish Accord Agreement language states that the Action Agencies will work toward finding funding for the Wahkiacus Hatchery Facility (Columbia Basin Accord 2008, Attachment B).

Table 7-2. Habitat actions and costs for Klickitat steelhead by Major and Minor Spawning Areas.

MaSA	Type/Subtype[a]	Unit[a]	# Units	Cost / Unit	Cost
Upper Klickitat MaSA	Fish Passage - Culvert Replacement	# of installations	7	$100,000	$700,000
	Instream - Streambank Stabilization	length treated in miles	2	$100,000	$200,000
	Instream - Channel Connectivity	length treated in miles	12	$65,000	$780,000
	Instream - Channel reconfiguration (includes channel roughening)	length treated in miles	4	$475,200	$1,900,800
	Instream - Deflectors/ barbs	length treated in miles	1	$35,000	$35,000
	Instream - Off channel habitat	length treated in miles	1	$105,600	$105,600
	Instream - Spawning Gravel Placement	length treated in miles	1	$90,000	$90,000
	Instream - Log (control) weirs	# of structures	10	$2,500	$25,000
	Instream - Rock (control) weir	# of structures	14	$2,500	$35,000
	Instream - Large Woody Debris	# of structures	20	$1,000	$20,000
	Instream - Structure/ Log Jam	# of structures	125	$15,000	$1,875,000
	Instream - Beaver Introduction	# of beavers introduced	20	$350	$7,000
	Riparian - Livestock Water Development	# of installations	3	$6,000	$18,000
	Riparian - Water Gap Development	# of installations	0	$1,200	$0

8. Monitoring, Research, and Adaptive Management

This chapter summarizes current monitoring and research efforts in the Klickitat subbasin and also lists additional RM&E needs. Part of the recovery strategy for this subbasin is the collaborative development of a monitoring plan to address the additional information needs that statkeholders and scientists have identified.

Comprehensive, empirical monitoring data on fish populations and habitat are needed to identify appropriate projects and locations, populate habitat/production capacity modeling efforts (such as EDT, AHA, or other appropriate models), and inform adaptive management for the salmonid recovery plan. Information on fish distribution, abundance, productivity, habitat conditions, genetic diversity, pathogen levels, and other population parameters, as well as on population limiting factors, is necessary to help direct and evaluate these efforts. A coordinated monitoring program is needed to ensure that these various needs, including salmonid recovery planning, are met.

As part of implementing the Klickitat steelhead recovery plan, a detailed monitoring and evaluation program will be designed and incorporated into an adaptive management framework based on the principles and concepts laid out in the NMFS' guidance document, *Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance* (NMFS 2007*)* http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf.

8.1 Adaptive Management

Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. It is a process of adjusting management actions and/or directions based on new information. It means taking an experimental approach to a complex task, making one's assumptions clear, and continuously evaluating them in light of new information. It works best when the collection of performance data and methods of evaluation are designed to get the information managers need to make sound decisions.

As outlined in the NMFS *Adaptive Management* guidance document, several types of monitoring are needed to support adaptive management: (1) implementation and compliance monitoring, which is used to evaluate whether the recovery plan is being implemented; (2) status and trend monitoring, which assesses changes in the status of an ESU and its component populations, as well as changes in status or significance of the threats to the ESU; and (3) effectiveness monitoring, which tests hypotheses and determines (via research) whether an action is effective and should be continued. (These three types of monitoring are discussed in more detail below.) In addition, it is important to build in some research to illuminate the many unknowns in salmon recovery—the "critical uncertainties" that make management decisions all the harder. Critical uncertainty research may seem expensive or unnecessary in light of basic information needs; however, in the long run, it may reduce monitoring and implementation costs.

NMFS' guidance document presents a decision framework that can guide the design of a research, monitoring, and evaluation plan. The framework (Figure 8-1) contains two basic sorts of questions: (1) questions regarding ESU status (biological viability criteria) and (2) questions regarding statutory listing factors and factors limiting recovery (limiting factor and threats criteria). Evaluating a species for potential delisting requires an explicit analysis of both types of criteria.

The guidance document contains a more detailed discussion of the framework and identifies the specific questions that should be answered to evaluate ESU status. These specific questions take the form of a series of decision-question sets that address the status and change in status of a salmonid ESU and the risks posed by threats to the ESU. The decision-question sets are designed to elicit the information NMFS needs to make delisting decisions. For recovery planners, the framework can guide future decisions about strategies and actions aimed at achieving recovery goals.

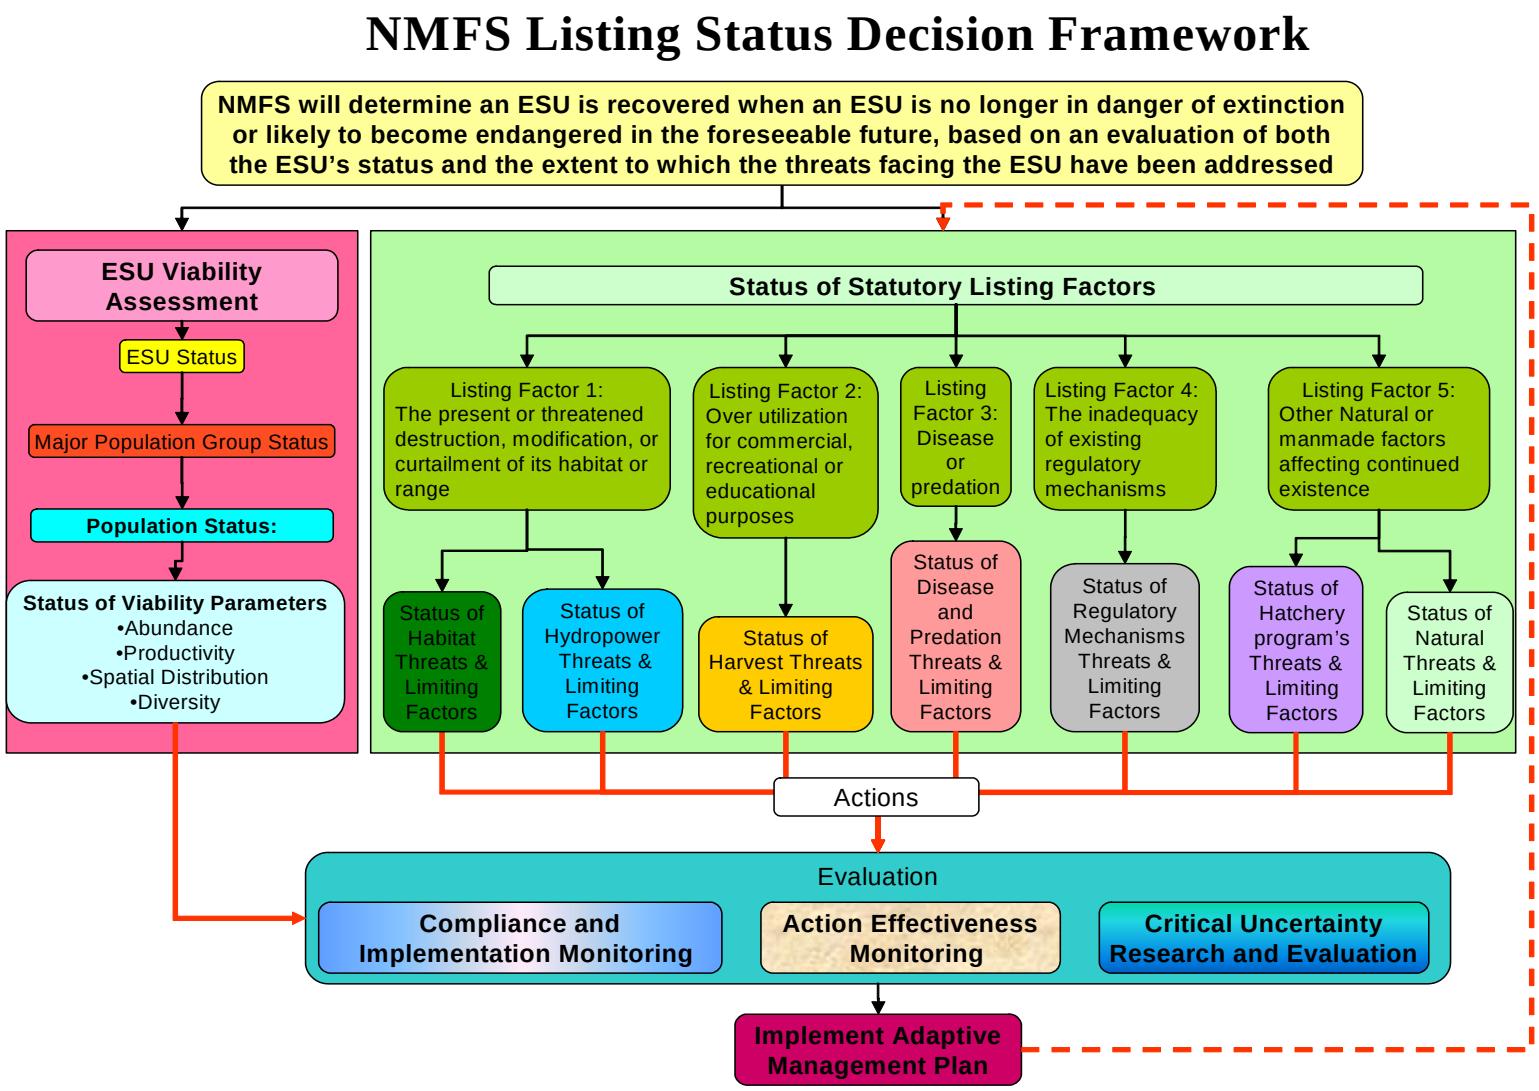

Figure 8-1 NMFS Listing Status Decision Framework.

8.2 Designing a Monitoring and Evaluation Program to Support Adaptive Management

Because of the length and complexity of the salmonid life cycle, there are many uncertainties involved in improving salmonid survival. Simply identifying cause-and-effect relationships between any given management action and characteristics of salmon populations can be a scientific challenge. It is essential to design a monitoring and evaluation program that will answer these basic questions: How will we know we are making progress? How will we get the information we need? And how will we use the information in decision making?

Designing an effective monitoring program for salmon recovery involves the following initial steps:

1. Clarify the questions that need to be answered for policy and management decision making. Include the full ESU and the full salmonid life cycle.
2. Identify entity or entities responsible for coordinating development of this program.
3. Identify:
    - Which populations and associated limiting factors to monitor
    - Metrics and indicators
    - Frequency, distribution, and intensity of monitoring
    - Tradeoffs and consequences of these choices
4. Assess the degree to which existing monitoring programs are consistent with NMFS guidance.
5. Identify needed adjustments in existing programs, additional monitoring needs, and strategy for filling those needs.
6. Develop a data management plan (See Appendix B of *Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance (May 1, 2007)* http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf.
7. Prioritize research needs for critical uncertainties, testing assumptions, etc.
8. Identify entities responsible for implementation.

A monitoring and evaluation program will provide (1) a clear statement of the metrics and indicators by which progress toward achieving goals can be assessed, (2) a plan for tracking such metrics and indicators, and (3) a decision framework through which new information from monitoring and evaluation can be used to adjust strategies or actions aimed at achieving the Plan's goals.

Implementation and compliance monitoring simply check on whether activities were carried out as planned, and whether specified criteria are being met as a direct result of an implemented action. For example, if a fence is planned for 20 miles of stream corridor to keep livestock off the stream banks so that riparian vegetation will rebound, implementation monitoring would verify the presence of the fence. Compliance monitoring would take note of the presence or absence of livestock in the fenced-off area.

Status and trend monitoring is a simple compilation of data-based descriptions of existing conditions. To be useful in decision-making, the raw data, or metrics, must be reduced to a

more directly applicable form or indicator. For example, if the question is "What is the annual spawning population size of steelhead in the X River?" the indicator would be total spawning numbers of steelhead over one season for the entire river basin; however, the metric, or directly measured thing, would be something quite different, perhaps steelhead redds sighted on weekly passes over known spawning grounds. Thus, the metric must be processed to translate it from the metric data type (e.g., redds) into the indicator data type (e.g., spawners), and then reduced to generate the indicator required (e.g., list of weekly counts on spawning grounds to annual total for watershed). The ICTRT identified deficiencies in the currently available data and/or data-gathering techniques for Middle Columbia River steelhead. These are described in Section 10.4, below.

Effectiveness monitoring specifically addresses cause-and-effect questions. Demonstrating the direct and indirect impact of management actions requires supporting all steps in the logical chain that connects the action to its expected impact. This chain is rarely short and usually contains several hypotheses. For this reason, it's better to build the effectiveness monitoring into the recovery action strategies, with, for example, pilot-scale tests or other methods carefully thought out beforehand. Monitoring and evaluation will only provide the answers to the questions they were designed to address; they do not provide the framework for revising these questions if they are ill-posed, evaluating the assumptions upon which the strategy was built, or incorporating learning into future decisions on actions and strategies—this is the role of adaptive management.

8.3 Existing Monitoring and Research

The development of the Klickitat Recovery RM&E Plan should begin by evaluating existing monitoring and research programs to determine if they are sufficient to answer the questions identified in NMFS' *Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance*. Research, monitoring and evaluation activities currently underway in the Klickitat Basin address the following categories:

Current/Recently Completed M&E Tasks	Purpose
1. Status and Trends Monitoring	Compilation or data-based description of existing conditions and long-term trends
2. Effectiveness Monitoring	Address cause and effect questions
3. Critical Uncertainty Research	Gather information to test critical assumptions or theories

There follows more specific information regarding current monitoring and research programs being conducted by the Yakama Nation, the WRIA 30 Watershed Planning Implementing Governments, and other parties. WRIA 30 Implementing Governments are state and local agencies tasked with implementing the WRIA 30 watershed management plan; the Governor has designated the Washington Department Ecology (Ecology) to represent state agencies (e.g., WDNR, WDFW, WDOH). These programs should be reviewed further when developing the final RM&E Plan for recovery, in the context of the NMFS' guidance.

8.3.1 Status and Trends Monitoring

- Temporal outmigration patterns and relative abundance for wild and hatchery salmon and steelhead populations are being monitored annually at 3 rotary screw trap locations (upper, middle, and lower mainstem Klickitat).
- Length frequency and age composition for wild salmon and steelhead populations are being monitored at 3 rotary screw trap locations.
- Temporal and spatial redd distribution for steelhead has been variably monitored throughout the subbasin since 1990.
- Global Positioning System (GPS) locations have been recorded for redds since 2003 by the Yakama Nation.
- Sport harvest is monitored by WDFW and tribal harvest is reported annually by the Yakama Nation.
- Habitat surveys have been conducted by State and private timberland owners using the Timber, Fish, and Wildlife (TFW) Ambient Monitoring Protocol since 1996. To date, approximately 80 sites on 40 streams have been surveyed by the Yakama Nation, including all major tributaries (many with multiple sites) and, multiple sites on the upper mainstem Klickitat. Some sites have been surveyed a second time; most sites are planned for resurvey on a 5 to 10-year basis.
- Klickitat County recently completed a study that provides baseline information regarding current shade levels throughout the Little Klickitat and Swale subbasins (Aspect and WPN 2009). This information will serve as baseline information to support long-term trend monitoring by Klickitat County Ecology, and the WRPAC.
- In cooperation with WDFW, an adult monitoring/trapping facility at Lyle Falls has been in operation since the summer of 2004.
- Gravel samples have been collected and analyzed annually from 12 sites distributed over the mainstem and major tributaries since 1999.
- Water temperature has been monitored continuously by the Yakama Nation since 1996 at 28 sites (36 sites since 2003) distributed throughout the subbasin.
- Basic water quality parameters have been monitored on a seasonal basis by the Yakama Nation since 2000 at most of these sites.
- Water quality (numerous parameters, including temperature) monitoring is conducted annually by the City of Goldendale, Central Klickitat Conservation District, and Ecology.
- Flow in the mainstem has been continuously monitored by the USGS for 82 years.
- Flow in the Little Klickitat is monitored by Ecology, the Central Klickitat Conservation District, the City of Goldendale, and Klickitat County. Flow was previously monitored in the Little Klickitat by the USGS, but was discontinued in 1968. The Yakama Nation is also monitoring flow at various sites.
- A SNOTEL snow monitoring station was established in the Simcoe Mountains in 2008 by NRCS and the WRIA 30 Implementing Governments http://www.or.nrcs.usda.gov/snow/maps/Washington_sitemap.html
- Groundwater quality is monitored by Ecology and the City of Goldendale. In addition, a study of groundwater quality was conducted in 2005 by Klickitat County.
- A well database is maintained by Ecology.
- Groundwater levels have been monitored in Swale Creek since 2001 by the City of Goldendale and Klickitat County (Germiat and Flynn 2007).

- The status and trends of fish habitat on state and private forest lands are being monitored under the State of Washington's Forest and Fish Agreement.
- In 2002-2004, approximately 1000 pathogen samples were collected from various sites throughout the subbasin; samples were analyzed by the U.S. Fish and Wildlife Service (USFWS) using protocols of the National Wild Fish Health Survey.

8.3.2 Effectiveness Monitoring

- Preliminary rotary screw trap efficiency estimates are being evaluated by the Yakama Nation.
- Preliminary adult trap efficiency at Lyle falls is being evaluated by the Yakama Nation.
- The effectiveness of the State Forest Practices rules are being evaluated under Washington State's Forest and Fish Agreement.
- Cameras to support video monitoring of passage at Lyle and Castile falls are being installed.

8.3.3 Critical Uncertainty Research

- Genetic sampling and analysis to date has yielded information regarding genetic divergence between hatchery and natural spawning summer steelhead and information on potential subpopulations of *O. mykiss* within the basin (Narum et al. 2006).
- Critical uncertainties regarding the effectiveness of the State Forest Practices rules are being researched under Washington State's Forest and Fish Agreement.
- A groundwater availability study was completed by Klickitat County in Swale Creek subbasin in 2007.
- Presence/absence surveys for juvenile and resident salmonids have been completed in the majority of subbasin tributaries and in the upper mainstem by the Yakama Nation.
- Abundance estimates have been completed in numerous tributaries by the Yakama Nation.
- An EDT reach analysis of spring Chinook was completed in the summer of 2000 and multiple EDT model iterations for steelhead were conducted in 2002-2005. EDT was utilized to run Proper Functioning Condition (PFC) within the Klickitat by the Yakama Nation.

8.4 Additional Needs

The following information is a list of preliminary monitoring and research needs that have been identified in the Klickitat subbasin. These preliminary needs may be further refined as the recovery plan RM&E Program evolves.

Five primary objectives of future RM&E have been identified:

A. *Monitor Klickitat subbasin fish population's viability attributes*
B. *Monitor Klickitat subbasin habitat conditions*
C. *Evaluate Klickitat subbasin in relation to habitat limiting factor status*
D. *Evaluate Klickitat subbasin hatchery actions in relation to limiting factor status*
E. *Answer key questions/uncertainties*

A. Monitor Klickitat subbasin fish population's viability attributes

Adult counts

- *Redd counts* (spawner surveys) - Regular foot and/or raft surveys will be conducted within the known geographic range for each species. Individual redds will be counted and their locations recorded using handheld GPS units. Counts of live fish of all salmonid species and carcasses will also be recorded. Carcasses will be examined for sex determination, egg/milt retention, and presence of CWT or PIT-tags or external experimental marks. Scale samples will also be taken from carcasses. Spawning ground surveys will be conducted for steelhead from late January through early June. Attempts will be made to cover the entire known spawning range. Stream reaches will be surveyed multiple times during the spawning periods, with most reaches receiving 3 passes.

- *Adult counts at Lyle Falls Fishway adult trap* – Trap is currently in operation with WDFW as partner. Salmonid species are counted as they are released from trap within the Lyle Falls Fishway on lower Klickitat. Trap efficiencies will be estimated from floy tagging of fish and recapture in sport fisheries or resighting during spawner/carcass surveys. Genetic and scale samples, along with fish length, will also be collected.

- *Adult counts at Castile Falls Fishway* – Adult trap, video monitoring, and PIT-tag detection equipment will be installed at Castile Falls Fishway (RM 64). Adult counts will be used for upper subbasin production estimates, fish-per-redd estimates, and Castile Fishway improvement effectiveness monitoring. Genetic and scale samples, along with fish length, may also be collected.

- Additional methods for adult enumeration should be investigated.

Juvenile production and survival estimation

- *Juvenile production estimation* – Floating rotary screw traps located just above Lyle Falls (RM 2.8) and at the Klickitat Hatchery (RM 43) will be operated on a year-round basis. A rotary trap located above Castile Falls (RM 64.6) will be fished seasonally from early summer through fall. Environmental and trap data (weather conditions, water temperature and clarity, trap revolution speed, and debris load) will be recorded along with bio-data (fork lengths, weights and smoltification stage), and additional fish will tallied by species. Trap efficiencies will be estimated regularly by mark/recapture trials using fin clips, fin markings, and/or PIT-tags. Feasibility of intermittent juvenile trapping on lower White Creek will also be investigated (in conjunction with an instream PIT-tag detector; juvenile production estimates may be possible).

- *Smolt-to-Adult Return estimation* – PIT-tagging of wild and hatchery smolts. Detection will be at instream detectors (White Creek), screw traps, and Bonneville Dam as smolts; at Bonneville Dam, adult traps, and on spawner surveys as adults.

Age structure and sex ratio sampling

- *Adult scale, sex, origin (i.e., HOF or NOF), and length sampling* – at adult traps and spawner surveys
- *Juvenile scale and length sampling* – at screw traps
- *Scale analysis* – Scale age will be determined by technicians trained in WDFW methodology.

Juvenile and resident fish monitoring

- *Presence/absence surveys* – Electrofishing and snorkel surveys will be used to determine presence/absence of fish species in selected tributaries.
- *Abundance estimates* – Multiple pass electrofishing sampling and snorkel surveys will be used to estimate abundance in selected stream reaches, including selected habitat enhancement sites.

B. Monitor Klickitat subbasin habitat conditions

Stream habitat monitoring

- *Stream habitat surveys* – Habitat surveys will be conducted on approximately 5-10 stream reaches per year using TFW methodology, Reference Point Survey, and Large Woody Debris Survey.
- *Spawning gravel/sediment sampling* – core samples will be collected from approximately 12 sites (in the Klickitat mainstem and major tributaries) per year.
- *Stream temperature and water quality monitoring* – Water temperature will be continuously monitored at approximately 36 sites throughout the subbasin using thermographs plus approximately 29 sites in the Little Klickitat and Swale Creek subbasins. Basic water quality parameter measurements (pH, conductivity, dissolved oxygen, turbidity) will be recorded seasonally (4-6 times per year) at approximately the same sites. Riparian vegetation and effective shade will be monitored (approximately every five years, depending on availability of new aerial photography) in the Little Klickitat Basin and Swale Creek.

C. Evaluate Klickitat subbasin in relation to habitat limiting factor status

Limiting factors identification and assessment of anthropogenic effects on limiting factors identified

- To date, not all the factors limiting steelhead production in the Klickitat basin have been quantitatively assessed. Limiting factors identification and assessment of possible anthropogenic effects need to continue in order to ensure that actions taken are adequately addressing the factors and threats.

Fish passage improvement effectiveness monitoring

- *Radio telemetry study* – This study will radio-tag and monitor movements of steelhead and spring Chinook salmon; passage at Lyle Falls, Castile Falls, Little Klickitat Falls, and other passage impediments will be evaluated.

- *Reach-scale spawner surveys (redd counts)* – Spawner surveys in reaches upstream of passage improvements will be conducted, as a part of the larger ongoing subbasin-wide spawner survey effort, to evaluate culvert replacement projects, and passage upstream of impediments (e.g., Castile Falls).

Instream habitat enhancement effectiveness monitoring

- *Subbasin-scale juvenile production estimation* – Screw trapping and resulting wild smolt production estimates will be used for comparison of before and after habitat actions. The general hypothesis to be tested is that wild smolt production will increase following habitat restoration/ enhancement actions (although multiple years of data will likely be necessary to detect any real trends in abundance over year-to-year variations). Additionally, in conjunction with redd counts and fecundity estimates (derived either from literature or proposed hatchery production in the Klickitat), the feasibility of generating valid and precise egg-to-smolt survival estimates (before and after habitat actions) will be investigated.

- *Tributary-scale juvenile production estimation* – The feasibility of juvenile trapping in lower White Creek for production/abundance estimation (in conjunction with instream PIT-tag detector) will be investigated.

- *Reach-scale abundance estimates* – Will conduct multiple-pass electrofishing removal sampling and snorkel surveys in selected reaches or localized sites that receive habitat actions. The general hypothesis to be tested is that instream habitat actions increase abundance of fish locally.

- *Reach, tributary, and subbasin scale habitat quality and quantity estimates* – The effectiveness of actions designed to improve instream habitat needs to be evaluated to determine if actions are effectively improving habitat. If not, actions should be modified based on the results of the monitoring and assessment to improve effectiveness.

Local technical review panel involvement

- *Klickitat Technical Committee* – a local technical review panel is part of the Washington Salmon Recovery Funding Board process for reviewing and funding habitat restoration/enhancement projects.

EDT modeling and/or other appropriate models (e.g., Habitat Assessment Model)

- *Incorporate new habitat data* – Data from ongoing habitat surveys will be incorporated for future model runs.

- *Incorporate new biological data* – Data from adult trap facilities, genetic analysis, scale age analysis, and harvest estimates will be incorporated for future model runs.
- *Perform model runs* – To assist in identifying sites and/or potential benefits of future habitat restoration/enhancement projects.
- *Validate Model***.**

D. Evaluate Klickitat subbasin hatchery actions in relation to limiting factor status

Smolt-to-adult return estimation

- *PIT-tagging of hatchery and wild smolts* – detection at screw traps and Bonneville Dam and comparison of wild to hatchery survival rates. In general, the hypothesis to be tested is that smolt-to-adult return rates of hatchery steelhead adults are not significantly different than wild steelhead adults. Differences between hatchery rearing strategies will also be tested. Tagging numbers for steelhead are as follows:

    - 10,000 hatchery steelhead smolts (from native broodstock for rearing study)
    - 10,000 Skamania Hatchery steelhead smolts (feasibility and contract development will be coordinated with WDFW)
    - Approx. 2000 wild steelhead smolts (see also additional PIT-tagging on White Creek)

Adult spawner monitoring

- *Spawner surveys* – sampling of steelhead, coho, and fall Chinook salmon carcasses on spawning grounds and estimation of wild/hatchery ratios.

Demographic characteristic comparisons

- *Age structure, sex ratio, and length-at-age* – Using scale, sex, and length sampling that occur at adult traps and on spawner surveys, comparisons of these demographic characteristics will be made between hatchery and wild returning adults. The hypothesis to be tested is that hatchery adults are not significantly different than wild adults in these characteristics.

Genetic sampling and analysis

- *Genetic sampling* –To gain a thorough understanding of the genetic make-up of target stocks in order to maintain long-term genetic variability (within- and between-population) and minimize the impacts of domestication on supplemented stocks (spring Chinook salmon and summer steelhead), samples will be collected at adult traps, screw traps, and via electrofishing.

- *Genetic analysis* – DNA analysis will be carried out by CRITFC geneticists under subcontract. Results will help assess the level of domestication and

interbreeding between hatchery and wild stocks pre- and post-supplementation. As identified in the draft Klickitat subbasin Anadromous Fishery Master Plan, summer steelhead will be collected for broodstock at Lyle Falls. A thorough knowledge of baseline genetic conditions and dip-in rates by out-of-subbasin adults is important in order to adhere to the YKFP genetic guidelines.

Fish health sampling and analysis

- *Pathogen sampling* – A baseline data set will be augmented by describing existing levels of pathogens in wild resident trout and naturally produced steelhead in order to determine if supplementation increases the incidence of pathogens. YN field crews will collect samples within the range of anadromy within the Klickitat subbasin. Samples will be examined for pathogens by the USFWS Lower Columbia River Fish Health Center.

Hatchery releases of introduced Species

- Identify the abundance of naturally spawning coho and fall Chinook utilizing the spawner surveys, redd counts, and trap data. Ensure that spawner surveys for coho and Chinook are extended to cover the full distribution of known steelhead spawning.
- Develop estimates of abundance and productivity of naturally spawning coho and fall Chinook.
- Evaluate the overlap in habitats utilized by steelhead, coho, and fall Chinook for spawning and rearing.
- Evaluate the effects of competition between steelhead, coho, and fall Chinook.
- Estimate the amount of steelhead habitat displaced by hatchery released and naturally spawning coho and fall Chinook.
- Estimate the effects of coho and fall Chinook on steelhead viability.

EDT and AHA modeling and/or other appropriate models (e.g., Habitat Assessment Model)

- *Incorporate new habitat data* – Data from ongoing habitat surveys will be incorporated for future model runs.
- *Incorporate new biological data* – Data from adult trap facilities, genetic analysis, scale age analysis, and harvest estimates will be incorporated for future model runs.
- *Perform model runs* – To guide supplementation efforts.
- *Validate the models***.**

E. Answer key questions/uncertainties

Determine migration behavior, passage delays, habitat use, and life history characteristics of steelhead and spring Chinook salmon

- *Radio telemetry study* – Using radio telemetry techniques, the travel times, passage delays, tributary usage, and spawning and holding locations of steelhead and spring Chinook salmon will be described. Differences in these traits between wild and hatchery steelhead, and summer and winter steelhead,

will be determined and will provide a baseline to assess any changes that occur following proposed supplementation, and to provide proportional use information for abundance estimates that result from redd counts. Effectiveness of passage improvements at certain sites can also be evaluated. Specific questions that can be addressed include:

1) Tributary use vs. mainstem use.

2) Spawning areas, holding phase locations.

3) Migration behavior/migration phase travel times/spawning site search phase distances traveled.

4) Frequency and consequences of fallback at Lyle Falls.

5) Amount of delay at Klickitat Hatchery weir.

6) Amount of delay/passage at Castile Falls.

7) Post-spawn kelt survival, movement, and emigration.

Methods that will be used are as follows: Fish will be captured at Lyle Falls adult trap and implanted with radio tags and PIT-tags; fixed telemetry receiver sites will be installed at various locations in the Klickitat subbasin (potential passage impediments and major tributary confluences) to detect fish locations; mobile tracking (via foot, raft, or automobile) will be employed on a weekly or biweekly basis, fish locations will be recorded using GPS receivers, and PIT-tags will allow for fish identification after the radio-tag battery expires, Bonneville Dam detection, and returning kelt detection. Approximate number of steelhead tagged per year would be as follows:

- 2007 – 50 wild steelhead, 50 hatchery steelhead
- 2009 – 50 wild steelhead, 50 hatchery steelhead

This project will be conducted as a cooperative project between YN/YKFP and USGS Columbia River Research Laboratory. USGS staff would perform radio tag implanting and radio tracking (with assistance from YN staff), as well as most data management and analysis, under a subcontract with YN. USGS staff would provide and install fixed telemetry receiver site equipment as an in kind contribution.

Determine migration and rearing patterns in White Creek watershed

- *Install instream PIT-tag detector on lower White Creek* – An instream PIT-tag detector would be installed on lower White Creek to detect outmigrating juveniles and determine outmigration timing and relative abundance. The White Creek watershed has been the most heavily used Klickitat tributary watershed by adult steelhead in recent years, yet many reaches go dry due to

lack of base flows and pool habitat. Determining migration and rearing patterns will help assess importance of White Creek vs. mainstem Klickitat rearing habitat and help evaluate habitat improvement actions. USGS Columbia River Research Laboratory staff would install PIT-tag detector and assist with data management (under subcontract with YN). PIT-tagging would be conducted by YN staff, with approximately 1500 fish tagged per year via electrofishing in the White Creek watershed.

Evaluate Little Klickitat passage frequency

- *Reach-scale spawner surveys (redd counts)* – Additional reaches in the upper Little Klickitat River watershed will be targeted for spawner surveys in an ongoing attempt to describe passage frequency of adult steelhead over Little Klickitat Falls (RM 6). Adult steelhead have been observed above the falls during high flow years, but passage frequency is unknown. This information will assist in EDT modeling purposes, and for evaluation of potential future habitat projects.

Steelhead rearing study

- *Assessment of survival and residualism in hatchery-raised steelhead using differential growth regimes* – Abundance of wild indigenous summer steelhead within the Klickitat subbasin has been depressed for a number of decades. Continued releases of a domesticated, non-endemic (Skamania) stock poses unacceptable risks to the native Klickitat summer steelhead population. Future management actions are proposing to phase out Skamania-origin releases in favor of developing a new, integrated hatchery program using Klickitat indigenous steelhead as a broodstock source. Goals for the long-term development of the program include:

- Conserve and restore indigenous stock to historical distribution and abundance levels
- Minimize residualism rates
- Maximize survival and adult return rates
- Mimic natural growth patterns and size of wild counterparts
- Improve tribal and sport fishing opportunities

Table 8-1 Summary of ongoing and expanded RM&E cost estimates (Sharp et al. 2008, Klickitat County, personal communication 2009).

	FY 2008	FY 2009	FY 2010	FY 2011	FY 2012	FY 2013	FY 2014	FY 2015	FY 2016	FY2017

YN Staff cost estimates assume a 2.5% inflation rate (starting with FY 2008 dollars)
Klickitat County cost estimates do not apply an inflation rate

8.5 Data Management

A formal and documented approach to data management is essential to adaptive management. A well-designed data management plan can help to ensure that data of a specified quality and quantity is available, at a specified time, to meet specified data analysis needs.

Protocols, metrics, and other data standardization tools such as common data entry methods are a top priority for recovery plans. Coordination across existing monitoring programs and projects will be underpinned by an integrated monitoring and data management framework. The framework would, for example, require the use of common methodologies for sample design, data collection, data validation, and data sharing in order to address common questions. Data management systems should be developed and coordinated with national and regional efforts for consistency with regional and national data standards. Project implementation data management

should be consistent with PCSRF protocols where appropriate and with guidance from PNAMP's effectiveness work group. Further guidance on data management is provided in the NMFS guidance document, *Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance*.

8.6 Consistency with Other Monitoring Programs

This recovery plan will utilize existing monitoring programs to evaluate the status/trend and effectiveness of recovery actions within the Klickitat Basin. Specifically, this approach should incorporate strategies, indicators, and protocols described in the Yakima Klickitat Fisheries Project, the WRIA 30 Watershed Management Plan, the Upper Columbia Monitoring Strategy, the Comprehensive Statewide Monitoring Strategy, and Collaborative Systemwide Monitoring and Evaluation Project (CSMEP). The development of other regional monitoring programs may result in modifications to the monitoring programs used in the Klickitat Basin. These other programs, in various states of development, include such approaches as Pacific Northwest Aquatic Monitoring Partnership (PNAMP). As these programs develop more fully, they will provide guidance on valid sampling and statistical designs, measuring protocols, and data management. This information may be used to refine and improve the existing monitoring and evaluation programs in the Klickitat Basin. The intent is to make monitoring and evaluation programs in the Klickitat Basin consistent with programs throughout the ESUs and Columbia Basin.

8.7 Coordination

Many entities have been or will be implementing recovery actions within and downstream from the Klickitat Basin. Monitoring programs to coordinate with include:

- Yakima Klickitat Fisheries Project,
- NOAA Fisheries RME Program,
- Washington Salmon Recovery Funding Board Program,
- PACFISH/INFISH Monitoring Program,
- Pacific Northwest Interagency Regional Monitoring Program,
- USFWS, USGS, and BOR Monitoring Programs,
- WDFW and WDOE Monitoring Programs,
- Local Underwood Conservation District Monitoring, and
- WRIA 30 Implementing Governments.

It is critical that these programs be consulted to emphasize utility, reduce redundancy, increase efficiency, and minimize costs.

8.8 Evaluation Schedule

Tracking progress or needs for adaptive management in the Klickitat subbasin by evaluating information from the recovery plan's research and monitoring programs could be one of the roles of the Washington Gorge Area Regional Board. Appropriate time intervals and triggers/goals need to be established to evaluate project implementation, compliance and effectiveness, the status and change in status of a population's viability attributes, the status of population's limiting factors and the evaluation of research identified in the recovery plan.

Appendix I. Major Creek

Major Creek, a small tributary to the Columbia River, lies just downstream of the Klickitat River drainage (Figure I-1). Major Creek is believed to support Middle Columbia steelhead. This appendix provides an overview of the Major Creek watershed and current knowledge concerning steelhead use. Section 5 proposes further research.

1 Physical Setting

Major Creek drains directly into the Columbia River adjacent to the Klickitat subbasin. The Major Creek watershed covers about 28 sq. miles or 7,200 acres of land. Two forks of Major Creek, East and West Fork, converge, flowing 4.1 miles downstream to the Columbia River, dropping 620 feet in elevation. The West Fork originates at two catch basins at 2,100 feet, flowing 5 miles through a narrow box canyon, then through a valley to the confluence with the East Fork, losing 1,360 feet in elevation. The East Fork flows from a drainage basin 5.1 miles through a narrow, v-shaped valley, losing 1,490 feet in elevation, to join the West Fork.

The Major Creek watershed is under a mix of ownership, including U.S. Forest Service, BIA trust lands, Washington Department of Natural Resources, and private landowners. Most of the Major Creek drainage lies within the Columbia Gorge National Scenic Area and is managed by the USFS. It is one of the few riparian corridors connecting the Columbia River and the highlands (USFS 2005). Other riparian corridors in the area connecting the Columbia River to the highlands include the White Salmon, the Klickitat, and Rock Creek.

2 Ecosystem Conditions

The main channel of Major Creek in the anadromous reaches averaged 7 percent gradient to 8 percent at the confluence of the East and West forks. The average gradient in the fish-bearing reaches of the West Fork was measured at 8 percent, while the lower section of the East Fork had an average gradient of 15 percent. There is a 30-foot waterfall at RM 1.37 on the West Fork and another waterfall at RM 1.2 on the East Fork that likely limit upstream *O. mykiss* distribution, though precise extent of distribution remains to be determined.

Major Creek has a relatively straight, high energy, swiftly dropping channel incised into the Columbia River basalt layers. Streamside vegetation is relatively dense, and the rate of downcutting generally does not seem to be outstripping the rate at which the riparian vegetation can stabilize the stream banks. Water quality appears to be high. The Major Creek landscape is canyon-dominated with very little road contact, and except for the uppermost portion of the watershed, the watershed is very lightly managed. The vegetation is dominated by grasslands and oak woodlands in the lower sections, while the higher elevations are more forested, with Douglas and grand fir, and some intermittent

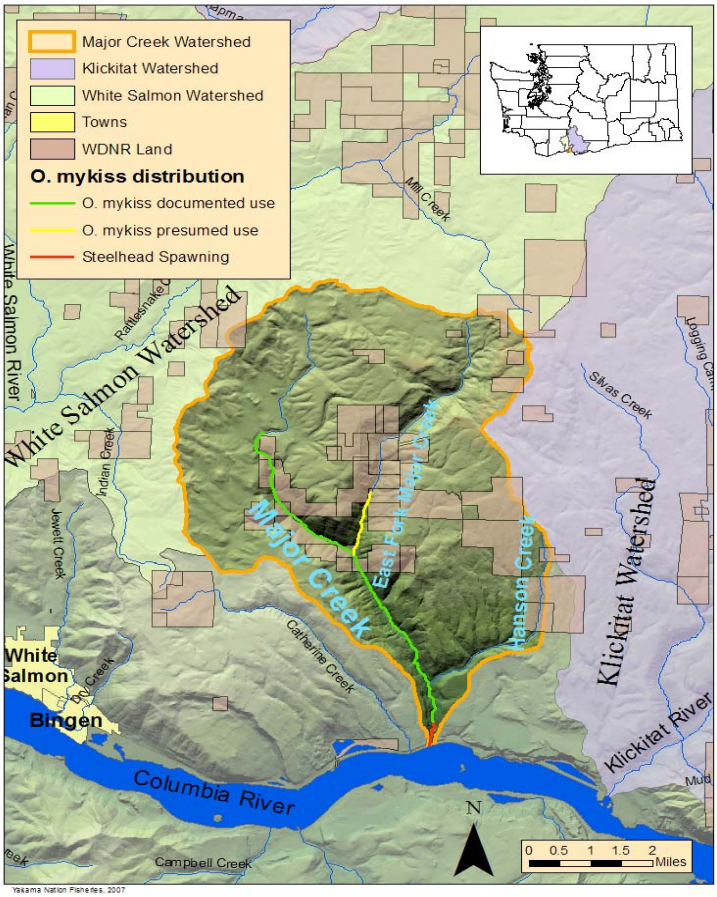

Figure I-1. Map of the Major Creek Subbasin in Southern Washington showing steelhead distribution. (YN Fisheries, personal communication 2007).

oak woodlands and hay lands. The riparian areas along the lower stretches of Major Creek have a good diversity of oak, ash, alder, willow and big leaf maple. Despite impact from human activities, most of the ecological functions are intact (USFS 1994).

Major Creek has a "flashy" hydrograph, especially during rain-on-snow events. Surface flow is at least 1 cfs throughout the driest portions of the summer in all but the first one-quarter mile. Low flow to sub-surface flow conditions exist in the bottom one-quarter mile above the confluence to the Columbia, mainly due to percolation through alluvial material in this reach.

Water temperatures in Major Creek exceed water quality standards during the summer; however, several springs and numerous large pools help provide cooler rearing habitat. Water temperatures in Major Creek range from 0.5ºC in the winter to 21.5°C during the summer in the upper watershed and from 0.1°C in the winter to 24°C during the summer in the lower watershed. Dissolved oxygen (DO) and pH in Major Creek are good year-round.

Habitat conditions in the Major Creek watershed display impacts from past and present land use activities. The largest human impacts on the Major Creek watershed are from SR 14, the railroad along the Columbia River, and, in the higher reaches, road and logging impacts. In the headwater sections of the West Fork of Major Creek, land clearing for farming and residential development has caused habitat fragmentation and loss of wetland functionality. The East Fork is still largely owned by commercial timber interests. Clearing, subdivision and development have not occurred with similar intensity; however, widespread habitat fragmentation has occurred as the result of timber harvest. Years of fire suppression, draining and ditching of wet meadows, and other land uses have changed the composition of the vegetation, resulting in an absence of large woody debris, a vital component of structure for fish habitat in the stream. It is also unclear what effect a seven-mile-long log flume, in operation in the early 1900s in Major Creek, had on the channel conditions and blockage at the barrier falls (USFS 2005).

The area of the watershed within the Columbia Gorge National Scenic Area (NSA) has been influenced more heavily by grazing and forest practices than by residential and agricultural uses. Wetlands have been drained and overgrazed, meadow areas converted to agricultural land, and large areas of forest cleared. Sedimentation, likely due in part at least to roads and timber harvest, has increased over historical conditions, while forest and agricultural practices, including the application of fertilizers and herbicides, have had a heavy impact on water quality (USFS 2005). Logging is likely to continue to the north and east of Major Creek. Grazing still occurs in private, BIA trust, and privately owned timber lands. Concomitant impacts of grazing — bank erosion, sedimentation, loss of fish habitat, and reduction in other aquatic life — are being documented with increasing frequency (USFS 2005).

3 Current Status

The ICTRT groups small downstream mainstem tributaries with the closest upstream population drainage, in this case the Klickitat River (ICTRT 2003). Thus, steelhead in Major Creek are considered part of the Klickitat population of Middle Columbia River steelhead.

The ICTRT has identified intrinsic habitat within Major Creek, but has not yet assessed the population because of lack of data. A barrier identified as a complete block at RM 0.32 in earlier subbasin reports and Salmonscape limited previous assessments of habitat in this watershed to the very lowest reaches. More recent information provided by the Yakama Nation and described in this section suggests that steelhead were able to maneuver this barrier under some flow conditions. If so, the ICTRT may conclude after further evaluation that the additional upstream habitat contains enough intrinsic spawning branch area to form an additional MiSA within the Klickitat population.

Steelhead, as well as fall Chinook salmon and coho salmon, spawning activity has been documented in the lower one-third mile of Major Creek (YN Fisheries, personal communication 2007; USFS 1994). Adult steelhead, some with adipose fins, have been observed in this same section in spring (R. Gerstenberger, written communication 2006) staging below each of the lower falls (E. Jones, personal communication 2006) and attempting

to jump the triple step falls (R. Gerstenberger, written communication 2006). *O. mykiss* have been observed up to a natural fish barrier at RM 1.4 on the West Fork and to the natural barrier at RM 1.2 on the East Fork (USFS 1994). *O. mykiss* spawning has been observed up to the Old Hwy. 8 culvert/crossing, and fry have been observed as far as 0.5 to 1 mi. above the Acme Rd. crossing on the West Fork. Two steelhead redds were observed in the lower 0.25 miles of the creek in March 2007 (G. Morris, YN, unpublished data, 2007).

Above the first one-third mile, Major Creek is limited primarily to *O. mykiss* due to a triple step falls with a total drop of approximately 20 feet (G. Morris, YN unpublished data, 2007); each step appears to be less than 6 feet (R. Gerstenberger, written communication 2006). This barrier was originally used as a complete block in the ICTRT's intrinsic potential analysis. Winter and spring flows are sufficient to enable some steelhead to negotiate the obstacle, and steelhead have been seen above the falls, though passage frequency is unknown (YN, unpublished data). A steelhead carcass was observed in a pool above the step falls in May 2006 (R. Gerstenberger, written communication 2006).

Further field studies need to be conducted in the middle reaches to characterize the habitat and potential barriers, as well as to ascertain the uppermost limit of use of Major Creek by steelhead.

4 Potential Limiting Factors and Threats

This section summarizes potential limiting factors and threats for steelhead in Major Creek.

Apparent factors limiting steelhead productivity in the Major Creek system include lack of adequate spawning gravel in all but the lower 0.32 miles, a lack of large woody debris (except for a few large debris jams), and a low pool-to-riffle ratio. The triple falls on the main branch of the creek at RM 0.32 form at least a partial fish barrier, as do several falls higher up on the East and West forks (at RM 1.2 and 1.4, respectively). Water volume and temperature are possibly also issues, particularly in those reaches where the flow diminishes during the summer months. Although the canopy of riparian vegetation is intact in much of the watershed, there are areas where the vegetation is thin. An open canopy exists in the lowest, anadromous reach (RM 0.0-.32), with an estimated 19 percent shade cover, while in upper reaches shade ranges from approximately 20 percent (adjacent to private pasture land) to 60 percent in more densely wooded and/or steep canyon sections (USFS 1994). There is also a relative overall scarcity of large trees for future recruitment to provide stream structure and cover for adult fish. Lack of LWD, stream bank instability and siltation may also affect habitat in the East Fork (USFS 1994). A fairly extensive stream survey was conducted in 1994, and spawning surveys are conducted sporadically; however, an extensive survey is needed to determine the extent of anadromous fish use, and the extent of habitat change that may have occurred as the result of the 1996 flood and other floods (scouring, bank erosion, debris jams), effects of upland land use, roads, etc.

5 Management Actions

The Yakama Nation has proposed several actions to address limiting factors and threats for steelhead production in Major Creek. The actions propose biological, physical, and watershed

assessments to gain needed baseline information to determine future restoration and protection needs in the Major Creek watershed (Table I-1).

Table I-1. Needed Actions, Estimated Time to Implement, and Cost for Assessment of Wild Major Creek Steelhead Provided by Yakama Nation Fisheries Staff.

Actions	Affected Sites	Time to Imple ment	Time to Real-ize Bene-fits	Imple-menting Entities	Esti-mated Cost	Imple-ment-ability (L-M-H)	Comment
Physical habitat assessment: assess flow and temperature regime, riparian cover, substrate, map and quantify stream habitat	Mainstem Major Creek, East Fork, West Fork	< 3 Years	5 - 10 Years	Yakama Nation, USFS, USGS	$0 -- 100,000	High-	Determine location and volume of any spring inputs
Biological assessment: assess use of watershed by steelhead; frequency of steelhead passage at lower falls; fish species composition, health, and life history; genetics and spawning distribution.	Entire watershed: below and above the falls (RM 0.3) into all of accessible upper watershed.	< 3 Years	5 - 10 Years	Yakama Nation, USFS, USGS	$0 -- 100,000	High	Actions will provide baseline information on Major Creek fish populations: distribution, productivity, life history, relationship between upper and lower watershed *O. mykiss* and relationship to ESU/MPG.
Watershed assessment: assess roads, passage structures, land use, water withdrawals and identify potential restoration sites.	Entire watershed.	< 3 Years	5 - 10 Years	Yakama Nation, USFS, USGS, private landowners	$0 -- 100,000	High	Investigate water withdrawal location and amounts, including legal maximum water rights.
Investigate feasibility of placing/place margin structures.	Entire watershed	3 - 5 Years	3 - 5 Years	Yakama Nation, USFS, USGS, private landowners	$500,000 – 1,000,000	Moderate	Margin structures would retain some spawning gravel patches, would create holding habitat (slow water pockets) and provide cover for adult fish heading upstream, as well as for juveniles moving downstream.

6 Cost Estimates

The Yakama Nation Fisheries staff provided estimated habitat action costs for research/evaluation and channel/floodplain modification for Major Creek. Costs over a 10-year period are estimated to be $0.45 million ($0.15 million for years 1-3 and $0.3million for years 4 to 10).

Appendix II. Potential Limiting Factors and Threats Identified by Yakama Nation Fisheries

This appendix describes the potential limiting factors and threats identified by Yakama Nation Fisheries staff for Middle Columbia River steelhead in the Klickitat subbasin. Limiting factors are described qualitatively in relation to the biological needs of the species and threats are described as those activities (natural or anthropogenic actions) that lead to the limiting factors.

Yakama Nation Fisheries biologists consider the following conditions to be the top habitat factors (physical and biological) limiting the viability of the threatened Klickitat *O. mykiss* population. The Yakama Nation staff identified the factors based on 10 years of fisheries and physical habitat data, EDT model outputs, and the professional opinion of biologists and other scientists working in the watershed.

- ***Degraded riparian condition.*** Riparian corridors have been affected and eroded by past, and in some cases current, timber practices, poor road construction and management, inadequately sized stream crossings, off-season use of wet roads, and cattle grazing in riparian areas. McCormick Meadows, in the tribally designated Primitive Area on the upper Klickitat River, was heavily grazed for approximately 60 years. Compromised riparian conditions reduce channel stability and pool frequency, and thus key habitat quantity and habitat diversity, degrading juvenile rearing habitat. Reduced riparian cover also affects fish survival and productivity by reducing stream shade, which leads to an increase in maximum water temperatures, and by limiting recruitment of large woody debris needed to provide future instream habitat complexity. Channel instability contributes significantly to increased sediment loads. Creation of Bonneville Pool inundated the lower reaches of the subbasin and resulted in the loss of critical wetland riparian habitat.

- ***Decreased floodplain function and channel migration processes.*** Abandoned and active roads, highways and a railroad prism in the floodplain along the lower Klickitat mainstem and lower Swale Creek, and active logging roads in the upper watershed confine and harden banks causing channelization, incision of tributaries, disconnection of side-channels and river meanders, and other disruption of natural hydrologic and riparian processes.

- ***Altered hydrology.*** Increased peak flows and diminished base flows in several parts of the subbasin have degraded habitat for fish. White Creek, Swale Creek, the Little Klickitat River and many of its tributaries have been identified as having insufficient instream flows to support fish populations (anadromous and resident). Swale Creek and six reaches on the Little Klickitat, Blockhouse, Bloodgood, Bowman and Mill creeks were considered “water quality impaired” on the 1998 state 303(d) list for instream flows.

- ***Degraded channel structure and complexity.*** In-channel large woody debris in the watershed has declined as a result of reduced recruitment potential (from bank hardening and historical riparian logging), historical "stream cleaning," and altered hydraulic conditions associated with increases in peak runoff and channel simplification. This reduction of in-channel structure and its concomitant effects has deprived fish of needed hiding, resting and rearing habitat.

- ***Obstructions to fish passage and connectivity.*** A number of culverts in the subbasin block fish passage. Reduced low flows have led to loss of connectivity of habitats in some streams, effectively cutting off migratory paths and isolating fish. High temperatures during low flow periods effectively act as barriers preventing fish from moving between spawning, rearing and migration habitats. Historical torrents associated with road crossing failures may have exacerbated passage difficulties in localized areas (e.g. lower Trout Creek).

- ***Altered sediment routing.*** Sediment loads (the percentage of fines in spawning gravel, embeddedness and turbidity) in the Klickitat have increased over historical conditions. Actions contributing to increased sediment delivery include forest practices (skidding and road building, clearing of upland forests and stream banks), agricultural practices (rill irrigation, streamside grazing) and land clearing and excavation in or near riparian areas related to residential and commercial construction. Increased sediment loads are a key problem for steelhead, particularly during the egg incubation stage. In addition, runoff from Mt. Adams' glaciers, carried downstream by such streams as Big Muddy Creek, is a significant source of natural sediment in the Klickitat River.

- ***Degraded water quality, including water temperatures.*** While most of the mainstem Klickitat and most tributaries maintain fairly healthy temperatures for anadromous fish, elevated summer and in certain reaches extremely low winter stream temperatures restrict steelhead production in several areas. Reaches on the East Prong, West Prong and mainstem Little Klickitat River, Butler Creek (a major tributary to the Little Klickitat) and Swale Creek were listed on WDOE's 1998 303(d) list for temperature (Anderson 2004; Brock and Stohr 2002). Nine reaches on these streams violated thermal water quality criteria. Degraded channel and riparian conditions, reduced summer low flows and lack of shading are presumed to exacerbate the elevated temperatures, though temperatures in some water bodies may naturally exceed state water quality criteria. Reduced flows, lack of pools and inadequate riparian cover also contribute to unfavorably low temperatures and the formation of anchor ice in some stream sections, particularly in the uppermost mainstem Klickitat and Diamond Fork.

- ***Altered food web – decreased salmon carcasses and subsequent reduction of nutrients.*** Diminishing run sizes limit salmon carcasses, a critical source for marine-derived nutrients, from enriching streams, negatively affecting food availability in the upper watershed.

Primary Limiting Factors identified through EDT Analysis

Yakama Nation Fisheries staff recently identified limiting factors for steelhead in 11 areas of the Klickitat subbasin based on EDT analysis. Results for summer and winter steelhead are combined due to difficulties in distinguishing run timing, abundance, and spawning and rearing areas for the two runs.

To conduct their analysis, Yakama Nation Fisheries scientists grouped EDT reaches that had been previously established during the subbasin planning process into larger spawning areas. They identified 6 major spawning areas and 5 minor spawning areas based on geomorphologic and biological considerations, as well as survey data representing habitat accessible or potentially accessible to anadromous and resident fish.

The spawning areas delineated by Yakama Nation Fisheries staff differ in some respects from those identified by the ICTRT for Middle Columbia River steelhead within the Klickitat subbasin. However, the differences are not substantial in terms of the distribution of relatively contiguous reaches with moderate to high historical production potential. Table II-1 compares the areas delineated by the ICTRT and Yakama Nation. The spawning area delineations diverge primarily in the Yakama Nation's Klickitat Canyon and Upper Middle Klickitat MiSAs. The ICTRT considers Surveyors Creek its own MiSA, which does not contain branched habitat from the mainstem Klickitat River, whereas the Yakama Nation includes lower Surveyors Creek with Klickitat River mainstem reaches above the hatchery in the Klickitat Canyon MiSA. The Yakama Nation's Upper Middle Klickitat MiSA overlaps with the ICTRT's Middle Mainstem MaSA (HUC boundaries) between the Summit and White Creek confluences with the mainstem Klickitat, but does not contain ICTRT-modeled branched intrinsic habitat.

Table II-1. Correlations between ICTRT Major and Minor Spawning Areas for Klickitat Steelhead, and Yakama Nation Fisheries Klickitat Spawning Areas in Order of Priority.

ICTRT Klickitat Steelhead Spawning Areas	YN Klickitat Steelhead Spawning Areas
Upper Mainstem MaSA[6]	Upper Klickitat MaSA
White Creek MaSA	White Creek MaSA
Middle Mainstem MaSA[7]	Middle Klickitat MaSA
Lower Mainstem MaSA	Lower Klickitat MaSA
Upper Little Klickitat MaSA	Upper Little Klickitat MaSA
West Fork Klickitat MaSA	West Fork Klickitat MaSA
Trout Creek MiSA	Trout Creek MiSA
Lower Little Klickitat MiSA	Lower Little Klickitat MiSA
Swale Creek MiSA	Swale Creek MiSA
Surveyors Creek MiSA[8]	*Klickitat Canyon MiSA*
	Upper Middle Klickitat MiSA

Yakama Nation Fisheries staff ran the EDT model using their newly defined MaSAs and MiSAs to identify those areas with the highest restoration or protection potential based on the primary limiting factors acting upon those areas. The EDT run confirmed that the dominant limiting factors by reach previously identified in other assessments were consistent. Table II-2 is a qualitative assessment of the relative combined impact of all limiting factors across all life history trajectories in all stream reaches by MaSA on steelhead survival based on EDT. The scenario modeled was that of "no passage" at Castile Falls, meaning that the habitat above Castile Falls is not yet seeded (current conditions).

In addition to EDT modeling results, field biologists and geomorphologists have identified physical degradations (such as in fluvial geomorphology) that may be contributing to limiting biological production of Klickitat steelhead and may need to be addressed to restore properly functioning conditions in the watershed.

[6] The MaSA identified by Yakama Nation Fisheries staff is similar, but begins at the top of Castile Falls (0.8 RM above the confluence with the West Fork Klickitat).
[7] The Middle Klickitat MaSA identified by Yakama Nation Fisheries staff is relatively congruent with the ICTRT's Middle Mainstem MaSA, but does not include the watershed area between the Summit and White Creek confluences with the mainstem Klickitat.
[8] The Klickitat Canyon MiSA as identified by Yakama Nation Fisheries encompasses the Klickitat River mainstem from the Klickitat Hatchery to the base of Castile Falls and includes Surveyors Creek.

Table II-2. EDT Strategic Priority Summary for Protection and Restoration of Klickitat Steelhead by the Yakama Nation's Identified MaSAs and MiSAs, and Primary Limiting Factors Note: The major and minor spawning areas used in the EDT analysis input were identified by the Yakama Nation Fisheries staff, and differ from those MaSAs and MiSAs identified by the ICTRT for recovery planning purposes (Table II-1 above).

Limiting Factors and Threats in ICTRT Spawning Areas

Tables II-3 through II-12 show the limiting factors and threats identified by Yakama Nation Fisheries biologists within each of the ICTRT's major and minor spawning areas. Information used to identify these factors and threats came from several sources: 1) the analysis completed through the Northwest Power and Conservation Council's 2004 subbasin planning process; 2) the Klickitat Lead Entity process performed under the Washington State Salmon Recovery Planning process, SB2496; 3) and a Yakama Nation 2005 EDT model run incorporating major spawning areas. The tables provide for each area: limiting factors, problem location, VSP parameters and life stages affected, threats, significance and severity of the problem, and actions needed to address the problems.

The "predation" limiting factor is generated from EDT model parameters. Specific predation studies that were used to develop the EDT "predation" attribute and rule making can be found at www.mobrand.com and include Weber and Fausch (2003).

Table II-3. Potential Limiting Factors for Middle Columbia River Steelhead in the Upper Mainstem MaSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor/s	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected	Significance (Scope/Severity)	Actions
Blocked or impaired passage	Spatial structure	Culverts on several tributary streams	Obstruction of juvenile, and possibly adult, movement at culverts.	PM	At least one partial barrier culvert near the mouth of Piscoe Creek and 3 more possible barriers upstream, and a partial barrier near the mouth of McCreedy Creek may be replaced by BIA timber sale improvement plan.	Replace culverts.
Altered sediment routing	Abundance, productivity	Chaparral Creek, McCreedy Creek, Piscoe, Diamond Fork, Coyote, Butte Meadows, Klickitat R. from Castile Falls (RM 65.75) to RM 87.05	Increased road densities and drainage extension; ORV trail use.	E, F	Point source delivery of fine sediment from roads; stream bank mass wasting. High impact in McCreedy, mainstem from RM 71.49-75.36, RM 76.99- 87.05, and Diamond Fork RM 0 - 12.22, in Piscoe Creek and Butte Meadows; moderate impact on F from RM 8.76-12.22 of Diamond Fk., E and F stages in Coyote, and on E in Klickitat mainstem RM 65.78-68.82; extreme impact on E stage in Coyote Creek Actions will decrease run-off/peak flows and sediment introduction, decrease interception and incision of shallow groundwater flows, and restore valley-bottom morphology and potential for channel migration. Spawning and rearing habitat will be improved; egg-to-fry survival will increase.	Disconnect roads from stream network; relocate/ abandon mid-slope roads where possible; relocate/abandon valley-bottom roads where possible. Improve surface and drainage characteristics of roads in tributary watersheds. Riparian forest management and planning: leave buffer strips in riparian forest zones. Reduce fine sediment introduced from streambank mass wasting. Limit riparian livestock grazing.
Degraded water quality, water temperatures	Abundance, productivity	Piscoe Creek, Chaparral Creek, Diamond Fork, Coyote Creek	Road densities; floodplain roads; past grazing.	R0, I0-1, R1, R2+	Lack of riparian canopy and pool habitat. High temperatures during summer low flows and formation of anchor ice in winter caused by lack of cover and pools limit productivity. High impact on R0, R1 in Piscoe and Chaparral; moderate impact in Diamond Fk., in Klickitat mainstem RM 8.76-10.04)., and on I0-1 and R1 in Coyote; moderate impact on R1 and R2+ in upper Diamond Fk. Rearing habitat, juvenile survival will be improved.	Riparian re-vegetation. Restore channel morphology. Disconnect roads from streams. Limit riparian livestock grazing. Eradicate non-native invasive plant species from critical watershed areas.
Channel instability , loss of floodplain function and channel migration processes, degraded riparian condition	Abundance, productivity	Chaparral Creek, Coyote Creek, McCreedy Creek, Butte Meadows Creek, Klickitat R. from Castle Falls (RM 65.75) to RM 87.05, Upper Diamond Fork	Historical grazing; channel confinement due to armoring; streamside ORV trails (avulsion risk), roads, road failures.	S, E, F	Extreme impact on E in Coyote; high in Chaparral, upper Piscoe and upper Diamond Fk., and from RM 75.36 - 87.05; moderate on S and F, and on E in Butte Meadows, from Chaparral to McCreedy, McCreedy Creek and upper Diamond Fork. Actions will lead to improved floodplain connectivity, pool quality, gravel sorting and stability, thus increasing available refugia, improving rearing habitat, and juvenile and egg-to-fry survival.	Relocate/ soften floodplain infrastructure. Perforate roads to allow peak flows to move onto floodplain. Close/relocate ORV trails. Place LWD or other structures to stop headcutting. Vegetate riparian areas. Limit riparian livestock grazing. Eradicate non-native invasive plant species from critical watershed areas.
Reduced key habitat quantity from lost floodplain function and channel migration processes, degraded riparian condition	Abundance, productivity	Klickitat River from RM 70.5 to RM 87.05, Piscoe Creek, Diamond Fork, Butte Meadows Creek, Chaparral Creek	Hydroconfinement; floodplain roads; historical overgrazing. Potential habitat fragmentation.	S, E, F, R0, I0-1, M1, R1, R2+, M2+, PM, PH	High impact on all life stages except TR2+ in upper reach of Diamond Fk.; moderate impact on all except TR2+ (high impact on S, E, PH) in lower Diamond Fk.; moderate on all except TR2+ in upper Piscoe and high impact on PH; moderate impact on E stage in Chaparral and S and E stages in Butte Meadows. Improved side-channel habitat, pool quality and quantity will	Restore floodplain and side-channel connectivity. Restore stream length. Place LWD. Short-term introduction of spawning gravel. Protect existing habitat from future degradation. Limit riparian livestock grazing.

Limiting Factor/s	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected	Significance (Scope/Severity)	Actions
					improve rearing habitat and juvenile growth and survival. Numerous private sections in the upper portion of the Diamond Fork watershed were purchased by a developer. WaDNR parcels that are currently in State Lands could be reclassified as Natural Areas.	
Reduced habitat diversity, riparian condition, floodplain function and channel migration processes	Abundance, productivity	Klickitat River from RM 70.5 to RM 87.05, Piscoe Creek, Diamond Fork, Butte Meadows Creek, Chaparral Creek	See above.	S, F, R0, I0-1, R1, M1, R2+	Moderate impact on S, F, I0-1, M1, R1 in upper Piscoe, lower Diamond Fork; high impact on F and moderate on all I0-1 stages in Coyote Creek, moderate impact on S in Diamond, and S and F in Chaparral.	See above.
Reduced food web	Abundance, productivity	Klickitat River from RM 70.5 to RM 87.05, Chaparral Creek, Diamond Fk., Piscoe Creek	Loss of salmon carcasses.	F, I0-1, R1	Greater impact of reduction in food web on fry colonization in mainstem than in tributaries. Moderate impact on F from Castile to Diamond Fk., lower Chaparral, upper Piscoe, also on I0-1 in lower Diamond Fk. Reducing sediment inputs will increase aquatic insect production for food. Carcass analogs may provide a temporary food source for juveniles. Actions will improve primary and secondary productivity by improving substrate conditions.	Improve channel complexity and connectivity (see above). Short-term fertilization of stream with carcasses or carcass analogs. Decrease fine sediment production and delivery from roads and other land uses.
Harassment/ poaching	Abundance	Upper Klickitat mainstem	Illegal harvest.	S, PH	Infrequent/episodic occurrence but with moderate to high impact when it does occur.	Eliminate illegal harvest by enforcing tribal regulations

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-4. Potential Limiting Factors for Middle Columbia River Steelhead in the White Creek MaSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameter Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Altered hydrology	Abundance, productivity, spatial structure	White Creek to RM 1.46, RM 9,59 - 13.88; Brush Creek; Tepee Creek, and NE tributary to Tepee Creek (less impact than the rest of Tepee Creek)	Past riparian logging; some stream cleaning; floodplain roads.	F, R0, I0-1, R1	Channel incision resulting in reduced perennial and hyporheic flows; scour of spawning gravels, incision related to increased peak flows. Reduced LWD. Moderate impact on F in White Creek RM 0 -1.46, RM 2.40 - 13.88, upper Tepee, in NE trib. and W. Fk.; moderate on R0 in White Creek RM 2.40 m – 10.6., in Brush and Tepee; moderate on I0-1 in Brush from RM 3.46 – 8.03, in White Creek RM 4.86-9.59, RM 10.42 – 13.88, in NE trib., to RM .19, in Tepee from RM 3.58-9.91; moderate on R1 in White Creek RM 4.86-9.59 and R, 10.42-10.60. Egg-to-smolt survival ratio is closely related to summer flow conditions.	Restore floodplain connectivity; increase floodplain and channel roughness. Disconnect road network to improve watershed and water retention.
Reduced key habitat quantity, floodplain function and channel migration processes, degraded riparian condition	Abundance, productivity, spatial structure	White Cr to RM 1.46, RM 2.4 - RM 16.3; Brush Creek; Tepee Creek	Past riparian logging; some stream cleaning; road densities and floodplain roads. Potential habitat fragmentation via subdivision, land-clearing, and development.	S, E, F, R0, I0-1, M1, R1, R2+, M2+, PM, PH	Channel simplification and disconnected floodplain side-channels due to incision. Reduced LWD. Increased run-off. High impact on S and E in White Creek RM 0 -1.46 and in Brush Creek to RM 3.46; on S, E, F and R0 in White RM 10.42-13.88, and E, F, R0 in Brush Creek RM 3.46-8.03, , in Tepee (also on PH) and upper White; moderate impact on other affected stages in Brush, upper White and Tepee. Loss of spawning gravel (habitat) below Brush Creek due to scouring. Rearing limited from Brush Creek to above the IXL road. Lack of perennial flows. Actions would reduce incision; restore channel roughness and complexity to better handle peak flows and augment base flows; increase pool abundance and rearing capacity; improve sorting of sediments and gravel retention. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Disconnect road network to improve watershed and water retention. Place LWD. Augment gravel. Excavate pools. Restore floodplain connectivity. Limit riparian livestock grazing. Protect existing habitat from future degradation.
Reduced habitat diversity, lost floodplain function and channel migration processes	Abundance, productivity	White Creek to RM 1.46, RM 4.86 - 16.3; Tepee Creek; W. Fork White Creek	Primarily road densities and floodplain roads. Potential habitat fragmentation via subdivision, land-clearing, and development.	S, F, R0, I0-1, R1, M1, R2+, M2+	Channel simplification and disconnected floodplain due to incision. Reduced LWD, increased run-off. High impact on F in White Creek RM 4.86 - 9.59; moderate impact on S, F, R0 and I0-1 in White Creek to RM 1.46 and RM 2.40 – 4.86; moderate also on I0-1, R1, M1, R2+, M2+ RM 4.86-9.59. Loss of spawning and rearing habitat.	Investigate off-channel livestock watering in Tepee Creek Improve pool: riffle ratio; add LWD; increase riparian cover; add spawning gravel. Increase floodplain connectivity by correcting channel incision and relocating or modifying floodplain roads. Protect existing habitat from future degradation.

Limiting Factor	VSP Parameter Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Blocked or impaired passage	Abundance, spatial structure	White Creek RM 4.86 -9.59; Tepee Creek; NE tributary to Tepee Creek; Fork White Creek	Inadequate culvert sizing and installation at 2.7 miles upstream of IXL road crossing in upper White Creek	E, R0, R1, R2+, (to a lesser degree M1, M2+), TR2+	Upstream movement of juveniles from rearing habitat to perennial refugia limited. Moderate impact.	Culvert replacement.
Altered sediment regime	Abundance, productivity	White Creek to RM 1.46, RM 9– headwaters; Brush Creek; NE tributary to Tepee Creek; W. Fork White Creek	Point source delivery of fine sediment associated with road drainage.	S, E, I0-1	High impact on E in upper Brush, White Creek RM 9 - headwaters, in Tepee, NE Trib., and W. Fork, moderate in upper White and lower Brush. Potential additional minor contribution of sediment from aerial deposition due to road traffic.	Improve road drainage characteristics and surfacing. Disconnect roads from stream. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones. Address fine sediment introduction from streambank mass wasting by modifying channel morphology and restoring floodplain connectivity
Degraded water quality, water temperature	Abundance, productivity, spatial structure	White Creek to RM 1.46; RM 4.86 - RM 16.3; Brush Creek; Tepee Creek; W. Fork White Creek	Past riparian logging; some stream cleaning; Land use practices that increased run-off (primarily from road densities) and floodplain roads; channel incision.	S, E, F, R0, R1, R2+	Reduced perennial and hyporheic flows, reduced riparian canopy. Reduced LWD. Extreme impact on E in upper Brush; high impact on E in the mouth of White Creek and from Brush Creek to ~16 mi. upstream, in W. Fork, Tepee, and upper Brush; also extreme on S and R0 and high impact on E, F, R1 and R2+ life stages in W. Fork White to RM 1.91	Restore floodplain connectivity. Re-vegetate riparian zone and floodplain. Eradicate non-native invasive plant species from critical watershed areas.
Reduced food web	Abundance, productivity	White Creek to RM 1.46, RM 9.59 - RM 13.88; Brush Creek; Tepee Creek; NE tributary; W. Fork White Creek	Reduced LWD from past riparian logging, some stream cleaning; increased run-off (primarily from road densities) and floodplain roads.	F, R0, I0-1, R1	Potential reduction in macroinvertebrate densities due to low flows or lack of perennial flow upstream and high fine sediment load. High impact on F in upper Tepee; moderate impact on F in lower White, lower Brush, lower Tepee, White from Brush to ~16 mi. upstream and in lower W. Fork; moderate on I0-1 from bottom of 1st meadow to Tepee, (also on R1) in upper Tepee	Restore floodplain connectivity. Disconnect road network to improve watershed and water retention. Improve road drainage characteristics and surfacing. Place LWD. Increase pool quantity and quality; improve pool/riffle ratio. Augment gravel. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones. Investigate off-channel livestock watering in Tepee Creek Place carcass analogs.
Reduced floodplain function and channel migration processes, channel stability	Abundance, productivity	Mainstem White from ~RM 3 to IXL Road; Tepee Cr from mouth to ~RM 10; Brush Creek from mouth to ~RM 8.	Channel incision.	E, F, I0-1	Moderate impact on affected life stages.	Restore floodplain connectivity, profile and cross-sectional morphology. Decrease amount of water delivered to stream network by roads.

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-5. Potential Limiting Factors for Middle Columbia River Steelhead in the Middle Mainstem MaSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Altered sediment routing	Abundance, productivity	Klickitat R. from Little Klickitat River to Dead Canyon. (RM 20.44 – RM 31.46); Dead Canyon; Beeks Canyon; Summit Creek; Klickitat R. from Summit Creek to White Creek (RM 37.73 – 40.27)	Increased road densities and drainage extension; delivery of fine sediment from upstream tributaries (primarily glacial, but also from road runoff).	E, F, I0-1, R0, R1, R2+, TR2+	High impact on E, F, I0-1 in mainstem from Beeks to Summit, Dead Canyon, Summit; moderate from Little Klick to Beeks. Road densities contribute to turbidity and clog interstitial spaces, interfering with rearing and feeding.	Disconnect road network from streams. Improve road surface and drainage. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones.
Reduced key habitat quantity, reduced floodplain function and channel migration processes	Abundance, productivity	Klickitat R. from Little Klickitat R. to Summit Creek (RM 20.44-RM 37.73), Summit Creek to Hatchery (RM 37.73 – 42.5); Dead Canyon, Summit Creek	Hydroconfinement. Habitat fragmentation via subdivision, land-clearing, and development.	S, E, F, R0, I0-1, M1, R1, R2+, M2+, PH	Channel simplification and disconnected side-channels. Reduced LWD. High impact on S and E in Beeks and Summit, on E, F and R0 in Dead Canyon; moderate impact in Klickitat R. from RM 20.44-31.46; moderate on S and F in lower Dead Canyon, on R1, PM and holding in Dead Canyon RM 5-3.54, moderate on PH from RM 20.44-37.73 in mainstem Klickitat. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore floodplain and side-channel connectivity. Restore stream length. Short-term introduction of spawning gravel. Place LWD. Protect existing habitat from future degradation.
Reduced habitat diversity, loss of floodplain function and channel migration processes	Abundance, productivity	Klickitat R. from Little Klickitat River to Summit Creek (RM 20.44-RM 37.73) and Summit Creek to Hatchery (RM 37.73 – 42.5); Dead Canyon	Hydroconfinement; floodplain infrastructure; historical overgrazing. Habitat fragmentation via subdivision, land-clearing, and development.	S, F, R0, I0-1, R1, M2+	Channel simplification and disconnected side-channels. Moderate impact on S and F in mainstem Klickitat RM 20.44- 25.95 and Summit Creek, moderate on F in lower Dead Canyon; moderate on F, R0 and I0-1 in Dead Canyon RM 2.55-3.54. Actions would create refugia. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore floodplain and side-channel connectivity. Restore stream length. Short-term introduction of spawning gravel. Place LWD. Protect existing habitat from future degradation.
Degraded water quality, water temperature	Abundance, productivity	Beeks Canyon; Dead Canyon to RM 2.55	Road densities, floodplain roads; possibly some grazing and past riparian logging impacts.	S, E, F, R0	Lack of riparian canopy and pool habitat; reduced perennial and hyporheic flows, sediment load. High impact on E in Beeks, moderate in Dead Canyon, moderate on S from RM 31.46-37.73 in the mainstem Klickitat	Riparian re-vegetation. Eradicate non-native invasive plant species from critical watershed areas. Restore channel morphology. Disconnect roads from streams. Obtain instream flow right for mainstem Klickitat.
Harassment/ poaching	Abundance	Klickitat R. from Little Klickitat R. to	Post-release mortality from fishing, poaching of wild fish, by-	S, PH, PM	Moderate impact	Enforcement of fishing regulations, tackle restrictions, shorter sport

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
		Summit Creek (RM 20.44-RM 37.73);	catch during whitefish season			season
Altered hydrology	Abundance, productivity	Dead Canyon; Summit Creek (also Beeks Canyon historically)	Reduction in forest canopy; incision of headwater (non-fish-bearing) reaches; reduced forest and floodplain storage.	F, R0	Altered watershed hydrology; shorter flow duration (low flows), higher peak flows, and increased incision. High impact on R0 in lower Dead Canyon, moderate on F and R0 in Dead Canyon RM 2.55-3.54 (low flows); I0-1 stages affected by higher peak flows.	Restore floodplain connectivity. Disconnect road network to improve watershed and water retention.
Predation	Abundance, productivity	Little Klickitat River to Summit Creek (RM 20.44-RM 37.73); Summit Creek to Hatchery (RM 37.73 – 42.5)	High density of hatchery-origin smolts; dewatering.	F, R0	Dewatering intensifies impact from avian and terrestrial predators. Moderate impact	Change stocking practices with regards to numbers, location and timing of smolt outplanting. Research interaction with hatchery fish, native and non-native predators.
Competition with hatchery fish	Abundance, productivity	Klickitat R. from Little Klickitat R., to Summit Creek (RM 20.44-RM 37.73), Summit Creek to Hatchery (RM 37.73 – 42.5)	High density of hatchery-origin smolts (coho, fall Chinook salmon and steelhead); size of *O.mykiss* smolts released; fall Chinook salmon releases may also be an issue.	R0, R1, R2+	Moderate impact. R0 affected by fall Chinook salmon releases.	See above.
Channel instability, loss of floodplain function and channel migration processes; degraded riparian condition	Abundance, productivity	Klickitat R. from Little Klickitat River to Summit Creek (RM 20.44-RM 37.73), Summit Creek to Hatchery (RM 37.73 – 42.5)	Channel confinement; armoring of embankment adjacent to road.	S, E	Channel confinement: stream too (artificially) stable laterally causing vertical instability. Moderate impact	Relocate/soften floodplain infrastructure. Perforate roads to allow peak flows to move onto the floodplain. Place LWD or other structures to stop headcutting. Vegetate riparian areas. Eradicate non-native invasive plant species from critical watershed areas. Close/relocate ORV trails.
Blocked or impaired passage	Abundance	Tributary mouths	Lack of access to spawning tributaries.	PM	High impact in low water years; likely occurred naturally, but human impacts have likely increased frequency	Study passage at tributary mouths relative to flow and alluvial fan morphology.

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-6. Potential Limiting Factors for Middle Columbia River Steelhead in the Lower Mainstem MaSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Reduced key habitat quantity, loss of floodplain function and channel migration processes; degraded riparian condition	Abundance, productivity	Klickitat R. to top of Bonneville Pool (to RM 1.19); Snyder Creek to RM 1.57	Inundation by Bonneville Pool, anthropogenic influences e.g. hydroconfinement, alteration of riparian zone by road, railroad prism and Snyder Creek mill complex; habitat fragmentation via subdivision, land-clearing, and development.	S, E, F, I0-1, R1, R2+, M2+, PH, PM	Extreme impact on I0-1, R1, R2+ in impounded lower reach of Klickitat R. to RM 1.19; extreme impact on PH and high impact on F, I0-1, R1, R2+, M2+ and PM in Snyder Creek to RM .58; high impact on S, E and PH in Snyder within mill flume reach. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Encourage dam operations that mimic natural flow regimes. Restore floodplain and channel connectivity. Place LWD. Monitor and continue restoration efforts in Snyder Creek mill reach (flume passage improvements and riparian re-vegetation). Protect existing habitat from future degradation. Eradicate non-native invasive plant species from critical watershed areas.
Reduced habitat diversity, loss of floodplain function and channel migration processes; degraded riparian condition	Abundance, productivity	Klickitat R. to top of Bonneville Pool (to RM 1.19), RM 5.72 – 9.72, RM 11.29 - 20.44; Snyder Creek	Inundation by Bonneville Pool, channel simplification due to hydroconfinement by road and railroad prism; habitat fragmentation via subdivision, land-clearing, and development.	S, F, R0, I0-1, M1, R1, R2+ and M2+	Extreme impact on I0-1 and R1 and high impact on R2+ and moderate on M1 and M2+ in the Klickitat R. below RM 1.19; high impact on S and F between Snyder and Swale Cr RM 14.63-17.88; and on F in Snyder to RM .58; moderate on S, F, R0 in the Klickitat R. RM 11.29 - 14.63 , and for M1 and M2+ in the mainstem to RM 1.19; moderate on I0-1 and R1 from Lyle Falls to Logging Camp Canyon RM 2.61 – 9.72, and on S, F, and R0 from Wheeler to Snyder RM 11.29 – 14.63; moderate on S, R0, I0-1, R1, R2+, and M2+ in Snyder to RM .58, and on S, F and R0 RM .58 – 1.57 ; moderate on R0, I0-1, M1, R1 and M1 from Snyder to Swale Creek RM 14.63 – 17.88. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	See above.
Reduced food web	Abundance, productivity	Snyder Creek; Klickitat R. to top of Bonneville Pool (to RM 1.19)	Inundation by Bonneville Pool; hydroconfinement.	F, R0, I0-1, R1	Reduced benthic community; channel simplification. Extreme impact on F, R0, I0-1, R1 in Snyder Creek; moderate impact on I0-1 and R1 from mouth of Klickitat to top of Bonneville Pool at RM 1.19.	Encourage dam operations that mimic natural flow regimes. Restore floodplain and side-channel connectivity. Place LWD.
Degraded water quality, water temperatures	Abundance, productivity	Snyder Creek	Mill site; roads and past grazing practices in headwaters.	F, R0	Reduced riparian canopy in mill reaches and reduced hyporheic flows. High impact on affected life stages in Snyder Creek	Restore channel morphology. Re-vegetate riparian areas. Eradicate non-native invasive plant species from critical watershed areas.
Altered sediment routing	Abundance, productivity	Mainstem Klickitat from Snyder Creek to Little Klickitat R.	Headwater forest practices and roads.	E	Moderate increase in fine sediment delivery over background levels. High impact from Snyder to Little Klickitat RM 14.63 – 20.44, upper Snyder; moderate	Disconnect roads from stream network; relocate/ abandon mid-slope roads where possible; relocate/abandon

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
		(RM 14.63 – 20.44), Snyder Creek (RM .58 – RM 1.57)			impact Wheeler to Snyder RM 11.29-14.63.	valley-bottom roads where possible. Improve surface and drainage characteristics of roads in tributary watersheds. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones.
Predation	Abundance, productivity	Klickitat R. to top of Bonneville Pool (to RM 1.19), from Wheeler Canyon to Little Klickitat R. (RM 11.29-20.44)	Increased densities of native and non-native predators in Bonneville Pool reach; hatchery stocking practices.	F, I0-1, M1, R1, M2+	High densities of hatchery outplants. Moderate impact on affected life stages in Klickitat mouth; and on F from Wheeler to Little Klickitat R.	Change stocking practices with regards to numbers, location and timing of smolt outplanting. Research interaction with hatchery fish, native and non-native predators.
Competition with hatchery fish	Abundance, productivity	From top end of Bonneville pool to Little Klickitat R. (RM 1.19 – 20.44)	High densities of hatchery outplants.	R1, R2+	Moderate impact	See above.
Blocked or impaired passage	Abundance, spatial structure	Mouths of spawning tributaries	Altered hydrograph; channel morphology	R0, R1, R2+	In low precipitation years there is often insufficient flow for adult passage through alluvial fans of spawning tributaries.	Study passage relative to flow and alluvial fan morphology.
Channel instability, loss of floodplain function and channel migration processes	Abundance, productivity	Mainstem Klickitat	Roads	E, F, I0-1	Confinement has contributed to incision and bed coarsening.	Restore floodplain connectivity.
Impaired passage	Productivity	Mainstem Klickitat	Unscreened pump intakes	F, R0, R1	Increases juvenile mortality	Ensure that pump intakes are adequately screened. Determine extent of problem for inadequately screened intakes.
Altered hydrology	Abundance, productivity, spatial structure, diversity	Mainstem Klickitat and tributaries	Dewatering in tributaries. Future water demand for out-of-channel use in mainstem.	S, R0, R1, R2+	Dewatering is currently a problem in tributaries and potential future problem in mainstem.	Obtain instream flow right for mainstem Klickitat. Restore floodplain connectivity in tributaries. Assess effects of groundwater development on tributary flow.
Harassment/ poaching	Abundance	Mainstem, tributaries	Poaching.	PM	Moderate and periodic problem	Reduce/eliminate poaching by both sport and tribal fishermen. Further restrict sport fishing in lower basin tributaries, e.g. Logging Camp Creek.

Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-7. Potential Limiting Factors for Middle Columbia River Steelhead in the Upper Little Klickitat MaSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Reduced habitat diversity, degraded floodplain function and channel migration processes	Abundance, productivity	Spring Creek, W. Prong, E. Prong, Little Klickitat R. from Spring Creek to Cozy Nook (RM 9.02 – 20.34)	Hydroconfinement and channel incision; roads; grazing and forest practices; habitat fragmentation via subdivision, land-clearing, and development.	S, F, R0, I0-1, M1, R1, M2+	Disconnected side-channels and channel simplification; reduction in LWD. Moderate impact on affected life stages. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore side-channel and floodplain connectivity. Excavate pools. Place LWD. Augment gravel. Protect existing habitat from future degradation. Eradicate non-native invasive plant species from watershed areas.
Altered hydrology	Abundance, productivity	Little Klickitat R. from Spring Creek to W. Prong (RM 9.02-26.61); Spring Creek to RM 3.53; Bloodgood Creek; W. Prong; E. Prong; Butler Creek; Dry Creek	Diversions; road densities.	F, R0, I0-1, R1	Channel simplification, channel incision and disconnected floodplain side-channels; reduced perennial and hyporheic flows. Moderate impact on affected life stages in lower Spring Creek and upper Little Klickitat watershed	Manage diversions to maximize instream summer flows. Disconnect roads from stream. Improve road drainage characteristics and surfacing.
Altered sediment routing	Abundance, productivity	Spring Creek, Bloodgood Creek to RM 2.23, W. Prong; E. Prong; Little Klickitat R. from Spring Creek to W. Prong (RM 9.02-26.61); Butler Creek; Dry Creek	Increased road densities in headwater tributaries and untreated forest road segments; runoff from agricultural lands.	S, E	Runoff, surface and re-distribution of in-channel fine sediment in the form of bank mass wasting; delivery of fine sediment from upstream tributary sources; agricultural sediment in Spring Creek, unnamed tributaries to Spring Creek, and Little Klickitat R. from Spring Creek to Bloodgood (downstream of Goldendale). Extreme impact on E in lower Spring and lower Bloodgood, in lower Klickitat R. from Cozy Nook to ~RM 24, W. Prong, and E. Prong from Dry Creek to Idlewild Canyon RM 2.73 – 4.81, Butler and Dry Creek; high impact on E RM 15.46 – 20.34, from ~RM 24 to W. Prong; mouth of E. Prong	Disconnect roads from stream. Reduce sediment inputs. Improve road drainage characteristics and surfacing. No-till cropping. Promote riparian buffers. Restore floodplain connectivity/channel morphology; decrease mass wasting of banks.
Degraded water quality, water temperatures	Abundance, productivity	Little Klickitat R. from falls to Hwy 97 (RM 6.38 – RM 26.68); Spring Creek; E. Prong; W. Prong	Roads; grazing; lack of riparian cover.	F, R0, R1, R2+, TR2+	Reduction in base flows and canopy cover, change in channel morphology (width to depth ratio). High to extreme impact on F and R0 in mainstem Little Klickitat from Spring Creek to W. Prong; high impact on R1 from Cozy Nook to ~RM 24; moderate impact on S from Spring Creek to Hwy. 97	Re-vegetate riparian areas. Increase riparian cover. Leave riparian buffer. Limit riparian grazing. Eradicate non-native invasive plant species from critical watershed areas. Restore floodplain connectivity and channel morphology.

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Reduced key habitat quantity, floodplain connectivity and function	Abundance, productivity	Little Klickitat R.; W. Prong; E. Prong; Butler Creek	Primarily past riparian management; habitat fragmentation via subdivision, land-clearing, and development.	S, E, F, I0-1, PH,	Channel simplification and disconnected floodplain side-channels due to incision. High impact on S, E ~RM 24 to 26.6 and in W. Prong, E. Prong and Butler to Hwy. 97; rearing stages affected downstream of approximately Cozy Nook Creek; impact on S upstream of there. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore side-channel and floodplain connectivity. Excavate pools. Place LWD. Augment gravel. Protect existing habitat from future degradation.
Degraded water quality, pathogens	Abundance	Little Klickitat R. from Spring Creek to Idlewild Canyon (RM 9.02 – RM 4.81 on E. Prong); Spring Creek to RM 3.53; Butler Creek	Hatchery stocking; riparian grazing; anecdotal indications of illegal stocking of rainbow trout in tributaries to the Little Klickitat R.	R0, R1, R2+, TR2+	Presence of hatchery fish. Elevated stream temperatures. High impact in Little Klickitat from Cozy Nook to ~RM 24, in E. Prong from Butler to Dry Creek, moderate impact elsewhere	Re-vegetate riparian areas to reduce stream temperatures. Increase riparian cover. Leave riparian buffer. Limit riparian grazing. Restore floodplain connectivity and channel morphology. Curtail hatchery releases.
Predation	Abundance, productivity	Spring Creek to RM 3.53, Little Klickitat from Spring Creek to Idlewild (RM 9.02 – RM 4.81 on E. Prong); W. Prong; Bloodgood Creek to RM 2.23; Butler Creek	Increased number of fish taxa present; hatchery outplants and dewatering may be factors in the mainstem.	F, R0	Reduced summer base flows (stranding); lack of refugia, cover habitat. Moderate impact on F in all affected reaches; also on R0 from Butler to Dry Creek	Change stocking practices with regards to numbers, location and timing of smolt outplanting. Research interaction with hatchery fish, native and non-native predators.
Blocked or impaired passage	Abundance, spatial structure	West Prong at RM .07, RM 21.16; E. Prong at RM 25.41, RM 18.4 on Jenkins Cr;., RM 21.35 on Butler Creek, RM 23.99 on Dry Creek, and RM 25.59 on Idlewild Canyon Creek	Box culverts under highway impede upstream fish passage.	PM, R0, R1, R2+, TR2+,	Extreme impact at box culvert barrier under Hwy. 97 at RM .07; varying passage at other culverts may present limited impediments to fish passage in good water years.	Replace culverts.
Reduced food web	Abundance, productivity	Little Klickitat R. from Spring Creek to Idlewild (RM 9.02 – RM 4.81 on E. Prong); Spring Creek to RM 3.53; Bloodgood Creek; W. Prong, Butler Creek; Dry Creek	Agriculture and grazing practices.	F, I0-1, R0, R1	Reduction in benthic community; nutrient enrichment, elevated temperatures and fine sediment delivery. High impact on F in mouth of Bloodgood, and from there to Cozy Nook in mainstem L. Klickitat; high also on F in Dry Creek from Hwy. 97 to ~ RM 2.5 and in E. Prong from Dry Creek to Idlewild.	Restore floodplain connectivity and channel morphology. Disconnect roads from stream. Reduce sediment inputs. Improve road drainage characteristics and surfacing. No-till cropping. Promote riparian buffers. Increase riparian cover. Investigate off-channel livestock watering.

Limiting Factor	VSP Parameters Impacted	Affected Sites	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Competition with hatchery fish	Abundance, productivity	Little Klickitat R. from Bloodgood Creek to Cozy Nook Creek (RM 15.46 – 20.34); Bloodgood Creek to RM 2.23	Resident rainbow stocking from Goldendale Hatchery.	R0, R1, R2+	Moderate impact on active rearing life stages	Modify hatchery outplant practices with regard to number, location and timing of smolt releases.
Channel instability, loss of floodplain function and channel migration processes; degraded riparian condition	Abundance, productivity	Spring Creek, Little Klickitat R. from Spring Creek to Cozy Nook (RM 9.02 – 20.34); Bloodgood Creek to RM 2.23, W. Prong; E. Prong from W. Prong to Idlewild (RM 0 – 4.81)	Hydroconfinement, active historical stream clearing in upper tributaries; hardened banks on road segments, infrastructure and bank armoring in agricultural lands.	E, F	High impact on E in lower Spring Creek, mouth of Bloodgood, W. Prong to RM 1.93, and in E. Prong from Dry Creek to Idlewild	Restore floodplain connectivity and channel morphology. Place LWD or other structures to stop headcutting. Vegetate riparian areas. Perforate roads to allow peak flows to move onto floodplain.
Impaired fish passage	Productivity	Throughout MaSA	Unscreened pump intakes.	F, R0, R1	Extent of problem needs to be researched.	Ensure that pump intakes are adequately screened. Determine extent of problem for inadequately screened intakes.
Degraded water quality, oxygen	Abundance, productivity, spatial structure	Primarily downstream of Goldendale	Insufficient oxygen in mainstem Little Klickitat River.	R0, R1, R2+	Needs to be monitored and assessed.	Assess nutrient and dissolved oxygen levels in Little Klickitat River, primarily downstream of Goldendale

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-8. Potential Limiting Factors for Middle Columbia River Steelhead in the West Fork Klickitat MaSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Blocked or impaired passage	Abundance, spatial structure	Natural barriers at RM .45 and 4.43	Naturally occurring	PM	Passage and spawning frequency of this watershed largely undocumented, assumed to be minimal	Collect more data on passage frequency and spawner distribution
Altered sediment routing	Abundance, productivity	Roaded portions of MaSA	Sediment delivery from upstream road failures	E, I0-1	Protect streams from adverse effects of forest practices (particularly roads).	Prevent introduction of road-derived sediment; replace undersized crossings; disconnect roads from streams.

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-9. Potential Limiting Factors for Middle Columbia River Steelhead in the Swale Creek MiSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Degraded water quality, water temperatures	Abundance, productivity	Swale Creek mouth to S. tributary at RM 12	Railroad prism in floodplain.	S, E, F, R0, M1, R1, M2+, PM	Reduced riparian canopy, reduced perennial and hyporheic flows due to altered channel morphology and disconnected floodplain. Extreme impact on E stages and high on F and R0 in whole section; high on M1, R1 to RM 8, moderate there to RM 12; moderate impact on spawners throughout	Re-vegetate riparian areas. Eradicate non-native invasive plant species from critical watershed areas. Restore channel morphology.
Reduced key habitat quantity, floodplain function and channel migration processes	Abundance, productivity	Swale Creek mouth to S. tributary at RM 12	Railroad prism in floodplain. Habitat fragmentation via subdivision, land-clearing, and development.	All stages except TR2+	Channel simplification and lack of riparian vegetation to provide cover and recruit wood (creates pools for holding and rearing habitat and sorts substrate for spawning habitat).High impact on F and R0 to RM 4 (moderate on all other life stages in this reach); extreme on F and high on E, R0, M1,R1 and PH RM ~4-8, high impact on S, E, F and R0 ~RM 8-12. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Place LWD. Excavate pools. Augment gravel. Restore floodplain connectivity. Protect existing habitat from future degradation.
Altered sediment routing	Abundance, productivity	Swale Creek mouth to NW tributary at ~RM 8	Sediment delivery from agricultural sources in the highlands of the Swale Creek Basin.	E	High impact to RM 8	Promote no-till cropping and riparian buffers in agricultural areas.
Degraded water quality, pathogens	Abundance	Swale Creek mouth to S. tributary at RM 12	Hatchery stocking practices: presence of hatchery-origin fish (spawning and rearing coho/steelhead); railroad prism in floodplain.	R0	High density of hatchery-origin fish. Elevated stream temperatures due to lack of canopy cover, instream structure. Reduction in LWD related to railroad prism. High impact throughout the section	Re-vegetate riparian areas to reduce stream temperatures. Change stocking practices with regards to numbers, location and timing of smolt outplanting. Conduct pathogen sampling and monitoring.

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Reduced food web	Abundance, productivity	Swale Creek mouth to S. tributary at RM 12	Railroad prism in floodplain.	F, R0, I0-1, R1	Potential reduction in macroinvertebrate densities; channel simplification, intermittent flows and high temperatures. High impact on F from ~RM 4-8 and moderate impact in other reaches; moderate impact on other affected stages from ~RM 4-8	Re-vegetate riparian areas. Eradicate non-native invasive plant species from critical watershed areas. Restore channel morphology. Place LWD. Excavate pools. Augment gravel. Restore floodplain connectivity.
Reduced habitat diversity, degraded floodplain function and channel migration processes	Abundance, productivity	Swale Creek mouth to S. tributary at RM 12	Hydroconfinement; railroad prism in floodplain; habitat fragmentation via subdivision, land-clearing, and development.	S, F, R0, I0-1, M1, R1, TR2+ M2+	Disconnected side-channels and channel simplification; channel incision; reduction in LWD. High impact on F between ~RM4-; moderate impact on S and F to RM ~4; moderate on S, R0, I0-1, M1, R1, and M2+ ~RM 4-8; moderate on S, F and R0 ~RM 8-12. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore floodplain and side-channel connectivity. Place LWD. Excavate pools. Augment gravel. Protect existing habitat from future degradation.
Predation	Abundance, productivity	Swale Creek mouth to S. tributary at RM 12	Hatchery stocking practices; loss of cover.	F, R0	High density of hatchery-origin fish; reduction in LWD and pools for cover. Moderate impact in whole section	Increase LWD and pool hiding cover. Change stocking practices with regards to numbers, location and timing of smolt outplanting. Research interaction with hatchery fish, native and non-native predators.
Altered hydrology	Abundance, productivity	Swale Creek mouth to S. tributary at RM 12	Upstream diversions (irrigation season); railroad prism in floodplain.	F, R0, I0-1, R1	Reduced summertime base flows, channel incision, reduced perennial and hyporheic flows; increased peak flows. Reduced LWD. Moderate impact on F and R0 to ~RM 4; moderate on F, R0, I0-1, and R1 ~RM 4-8; moderate on F ~RM 8-12	Reconnect floodplain. Manage diversions to maximize instream summer flows.
Channel instability, loss of floodplain function and channel migration processes	Abundance, productivity	Canyon reach.	Incision and channel instability.	I0-1, R0, R1, R2	Degraded habitat, low pool frequency and quality.	Restore cross-sectional morphology and roughness. Modify historical railroad grade. Modify land-uses and/or implement structures to retain storm flow and decrease time of concentration from watershed upstream of canyon.

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Table II-10. Potential Limiting Factors for Middle Columbia River Steelhead in the Surveyor's Creek MiSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Location of Impacts	Threats	Life stages affected*	Significance (Scope/Severity)	Actions
Altered sediment routing	Abundance, productivity	Klickitat R. from Big Muddy Creek to Castile Falls step pool habitat (RM 54.87– 65.42); Trout Creek to RM 1.09, Bear Creek, Surveyors Creek	Increased road densities and drainage extension.	S, E, F, I0-1	Point source delivery of fine sediment from upstream tributary sources. Moderate impact on S & E from Big Muddy to Surveyors, on S in Surveyors from cascade barrier to Cedar Creek and from Surveyors to step pool habitat within Castile cascades; and on E in Trout Creek from mouth to cascades	Disconnect roads from stream network; relocate/ abandon mid-slope roads where possible; relocate/abandon valley-bottom roads where possible. Improve surface and drainage characteristics of roads in tributary watersheds. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones.
Reduced food web	Abundance, productivity	Klickitat R. from Trout Creek to Castile step pool habitat (RM – 65.42); W. Fork Klickitat below falls (RM .45)	Reduction in salmon carcasses (spring Chinook salmon).	F, R1, I0-1	Moderate impact from Trout Creek to Surveyors and from Soda Springs to step pool habitat within Castile cascades, lower W. Fork	Fertilize stream with carcasses or carcass analogs

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0-1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage

Table II-11. Potential Limiting factors for Middle Columbia River Steelhead in Lower Little Klickitat MiSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
Degraded water quality, water temperatures	Abundance, productivity	Little Klickitat R. to RM 1.24, from Mill Creek to L. Klickitat Falls (RM 3.75-6.38); Canyon Creek; Bowman Creek	Upstream diversions and channel morphology; past grazing; floodplain road; upper watershed grazing; possible dewatering in upper reaches of Canyon Creek	S, E, F, R0, R1	Reduction in base flows. Reduced canopy cover upstream and in lowermost section of Little Klickitat R. around Hwy. 142 bridge and where road parallels Bowman Creek High impact on R0, R1 and E in lower Little Klickitat, on S, E and F between Canyon and Little Klickitat Falls, high on E in Bowman from mouth to falls. Moderate impact on S in Little Klickitat to falls.	Restore floodplain connectivity and channel morphology, riparian vegetation in upper watershed.
Degraded water quality, pathogens	Productivity	Little Klickitat R. to L. Klickitat Falls (RM 6.38); Bowman Creek	Hatchery stocking; grazing in upper watershed.	R0	Elevated stream temperatures exacerbated by lack of riparian cover. Moderate impact	Re-vegetate riparian areas to reduce stream temperatures in upper watershed. Change stocking practices with regards to numbers, location and timing of smolt outplanting. Conduct pathogen sampling and monitoring.
Altered sediment routing	Abundance, productivity	Little Klickitat R. to L. Klickitat Falls (RM 6.38); Canyon	Increased road densities in headwater tributaries and untreated forest road segments,	E	Runoff, surface and re-distribution of in-channel fine sediment in the form of bank mass wasting; delivery of fine sediment from	Disconnect roads from stream. Reduce sediment inputs. Improve road drainage characteristics and surfacing. No-till cropping. Promote riparian

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/Severity)	Actions
		Creek; Bowman Creek	agricultural run-off.		upstream agricultural and tributary sources. Extreme impact in lower Canyon and Bowman, high impact in mouth of Little Klickitat	buffers. Restore floodplain connectivity.
Reduced food web	Productivity	Little Klickitat to RM 1.24	Nutrient enrichment; agricultural practices and grazing.	F, I0-1, R1	Reduction in benthic community. Elevated temperatures and fine sediment delivery. Moderate impact	Actions in upper watershed to affect limiting factors in lower watershed: Restore floodplain connectivity and channel morphology. Disconnect roads from stream. Reduce sediment inputs. Improve road drainage characteristics and surfacing. No-till cropping. Promote riparian buffers. Increase riparian cover. Eradicate non-native invasive plant species from critical watershed areas. Investigate off-channel livestock watering.
Reduced key habitat quantity, loss of floodplain function and channel migration processes	Abundance, productivity	Canyon Creek	Hydroconfinement. Habitat fragmentation via subdivision, land-clearing, and development.	S, E	Channel simplification and reduced riparian function. Moderate impact. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore floodplain connectivity. Place LWD. Short-term introduction of spawning gravel. Protect existing habitat from future degradation.
Predation	Abundance, productivity	Little Klickitat R. to L. Klickitat Falls (RM 6.38); Canyon Creek; Bowman Creek to RM .15	Hatchery stocking practices; dewatering.	F, R0, I0-1, M1, M2+	Predation is hypothesized by EDT model. High density of hatchery-origin smolts due to stocking of catchable rainbow trout from Goldendale Hatchery in Little Klickitat R. and anadromous stocks in mainstem Klickitat R. Dewatering intensifies impact from avian and terrestrial predators. Moderate impact in all affected reaches	Change stocking practices with regards to numbers, location and timing of smolt outplanting. Research interaction with hatchery fish, native and non-native predators.
Altered hydrology	Abundance, productivity	Little Klickitat R. to L. Klickitat Falls (RM 6.38); Bowman Creek; Canyon Creek	Upstream diversions.	F, R0	Decrease in summertime base flows. Moderate impact on F, R0 in Little Klickitat from mouth to Mill Creek, Canyon and Bowman creeks	Manage diversions to maximize instream summer flows.
Reduced habitat diversity, floodplain function and channel migration processes	Abundance, productivity	Canyon Creek to RM 1.09; Little Klickitat R. to RM 1.24	Hydroconfinement. Habitat fragmentation via subdivision, land-clearing, and development.	S, F, R0, I0-1	Channel simplification and reduced riparian function. Moderate impact. Habitat protection through land acquisition/conservation easement by WDFW or land trust.	Restore floodplain and side-channel connectivity. Short-term introduction of spawning gravel. Place LWD. Protect existing habitat from future degradation.
Competition with hatchery fish	Abundance, productivity	Bowman Creek; Little Klickitat from Mill Creek to L. Klickitat Falls (RM 3.75 – RM 6.38)	Resident rainbow stocking from Goldendale Hatchery and mainstem Klickitat smolt planting (coho, steelhead).	R0, R1	Moderate impact	Change stocking practices with regards to numbers, location and timing of smolt outplanting. Research interaction with hatchery fish, native and non-native predators.

Table II-12. Potential Limiting Factors for Middle Columbia River Steelhead in the Trout Creek MiSA (provided by Yakama Nation Fisheries Staff).

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/ Severity)	Actions
Altered sediment routing	Abundance, productivity	Trout Creek from top of falls to Bear Creek (RM 1.09 - RM2.62); Bear Creek to meadow at RM 3.10	Increased road densities and drainage extension; to a lesser degree, water withdrawal for watering roads (dust abatement).	E, I0-1	Delivery of fine sediment from upstream tributary sources. Point source delivery of fine sediment associated with road drainage. Extreme impact on E in Bear Creek from mouth to meadow at ~RM 3.1; high impact in Trout Creek from cascade to Bear Creek; moderate on I0-1 throughout	Improve road drainage characteristics and surfacing. Disconnect roads from stream. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones.
Reduced food web	Abundance, productivity	Trout Creek from top of falls to Bear Creek (RM 1.09 – RM 2.62); Bear Creek to meadow at RM 3.10	Road densities, past riparian logging.	F, R0, I0-1, R1	Elevated temperatures and fine sediment levels. High impact on F in Trout Creek from cascade to Bear Creek and in Bear Creek to ~ RM 3.1; moderate impact on R0, I0-1, R1 in Bear Creek	Restore floodplain connectivity. Improve road drainage characteristics and surfacing. Disconnect roads from stream. Re-vegetate riparian zone and floodplain. Eradicate non-native invasive plant species from critical watershed areas. Riparian forest management and planning: plan to leave buffer strips in riparian forest zones.
Degraded water quality, particularly water temperatures	Abundance, productivity, spatial structure	Trout Creek from top of falls to Bear Creek (RM 1.09 – RM 2.62);	Floodplain roads; past riparian logging.	S, E, F, R0	Reduced riparian canopy; reduced perennial and hyporheic flows. High impact on E and moderate impact on S, F, R0 in Trout Creek from cascade to Bear Creek	Restore floodplain connectivity. Re-vegetate riparian zone and floodplain.
Reduced key habitat quantity, loss of channel structure and floodplain connectivity	Abundance, productivity	Trout Creek from top of falls to Bear Creek (RM 1.09 – RM 2.62); Bear Creek to meadow at RM 3.10	Hydroconfinement; road densities, floodplain roads, past riparian logging.	F, R0, M1, PH	Channel simplification and disconnected side-channels. Reduced LWD. Moderate impact on F, R0, M1, PH in Trout Creek from cascade to Bear Creek, and on F, PH in Bear Creek to ~RM 3.1	Place LWD. Disconnect roads. Excavate pools. Augment gravel. Restore floodplain connectivity.
Reduced habitat diversity, degraded channel structure, floodplain connectivity	Abundance, productivity	Trout Creek from top of falls to Bear Creek (RM 1.09 – RM 2.62); Bear Creek to meadow at RM 3.10	Hydroconfinement.	S, F, R0	Channel incision and disconnected side-channels. Reduced LWD. Moderate impact on affected life stages in Trout Creek from cascade to Bear Creek, and in Bear Creek to ~ RM 3.1	See above.
Altered hydrology	Abundance, productivity	Trout Creek from top of falls to Bear Creek (RM 1.09 – RM 2.62); Bear Creek to meadow at RM 3.10	Channel incision related to roads; increased peak flows. Reduced perennial and hyporheic flows associated with incision and extension of the drainage network by forest	E, F, I0-1,R0	Increased peak flows; reduced perennial and hyporheic flows. Moderate impact on F, R0 in Trout Creek from cascade to Bear Creek, and in Bear Creek to ~ RM 3.1	Restore floodplain connectivity. Disconnect road drainage from stream network to decrease runoff peaks and increase retention. Restore channel morphology and overbank flow frequency…reconnect floodplains.

Limiting Factor	VSP Parameters Impacted	Sites Affected	Threats	Life Stages Affected*	Significance (Scope/ Severity)	Actions
			roads.			
Blocked or impaired passage	Abundance, spatial structure	Waterfall reach and upstream	Numerous (>10) naturally occurring cascades and waterfalls (6-8'); at least four road crossings that act as partial barriers (all four are upstream of the waterfall reach).	R0, R1, R2+, TR2+, PM	Though no one cascade is beyond the published ability of adult steelhead in terms of sheer size, there are several with very challenging hydraulics. Cumulatively, they likely restrict nearly all passage. Passage and spawning frequency of this watershed largely undocumented, assumed to be minimal above high gradient reach within lower 1.5 miles. May have been higher historically, but debris torrent associated with road failures in 1974 is believed to have radically altered channel morphology in lower five miles of Trout Creek. Passage conditions prior to torrent are unknown.	Provide passage where existing culverts block passage.

* Key to life history stage codes: S=Spawning; E=Egg incubation; F=Fry colonization; R0=0-age active rearing; I0-1=0,1-age inactive; M1=1-age migrant; R1=1-age active rearing; R2+=2+-age active rearing; M2+=2+-age active migrant; TR2+= 2+-age transient rearing; PM= pre-spawning migrant; PH= pre-spawning holding. **Bold** style denotes high to extreme impact on that life stage.

Appendix III. Current Efforts and Regulations

Numerous projects have been completed recently or have been initiated to address factors affecting salmonid production in the Klickitat subbasin. Additionally, there are numerous rules and regulations in place that will prevent or minimize future effects on salmonid production. These actions and regulations are described in the following sections.

Habitat Restoration Actions

Positive change is underway to address limiting factors and threats to improve steelhead habitat conditions. A number of actions are proposed, being planned, or are already being implemented in the subbasin to address these conditions and the affected populations.

Castile Falls Fishway

One major change is the renovation of the Castile Falls Fishway. Castile Falls, a natural barrier consisting of multiple cascades and barriers, was a historical obstruction to the upstream migration of anadromous fish into the upper Klickitat watershed. The fishway was first constructed in the early 1960s. Design flaws and improper maintenance contributed to the failure of the first attempt to provide passage over the falls. Recently, the Castile Falls Fishway was renovated to bring it into compliance with NMFS fish passage standards and facilitate anadromous fish passage to habitats in the upper subbasin. From 2003-2005, work was completed on the two fishway tunnels within the Castile Falls complex. Design improvements consisted of conversion from a pool-weir style fishway to a vertical slot fishway to allow passage over a wider range of river flow conditions and to reduce maintenance needs. Project engineers and biologists have measured improved flow, attraction flow and energy dissipation factor (EDF) within the weir—all of which are consistent with industry standards and which meet criteria for fish passage. Funds were appropriated after the major 1996 flood to perform major maintenance activities to this NOAA Fisheries/Mitchell Act-funded fishway. The first complete season that these facilities will be operational ends in 2006. At this time, a performance evaluation will be made (YN and Harbor Engineering Co. 2006).

The Castile Falls Enumeration Facility (CFEF) will provide the ability to enumerate escapement into the upper Klickitat subbasin, and assess recent improvements to the Castile Falls Fishway. A counting station will be placed in the upper CFEF. This structure will be installed at the fishway exit of the Castile Falls 10/11 Fishway tunnel and will include video monitoring and PIT-tag detection capabilities, as well as the ability to trap salmon and steelhead for biological and DNA assessment. The recounting structure will allow fisheries managers to: (1) determine escapement of Klickitat spring Chinook and summer steelhead into headwater habitats; (2) assess stock status and future trends as needed to calculate natural production and adult-to-adult return rates, and to refine EDT and run forecasting models used to guide supplementation and habitat

restoration actions and set harvest objectives; (3) conduct video monitoring to gain critical biological data such as species, run timing, size, and sex ratio of returning adults; and (4) collect age and DNA information on returning adults.

Lyle Falls Fishway

Improvements are also planned at Lyle Falls Fishway to address limited adult fish passage through the fishway into the Klickitat subbasin. Engineering assessments (Harbor Consulting Engineers, Inc. 1996) identified the following factors currently restricting passage at the fishway:

1. Inadequate attraction water
2. Location of the fishway entrance
3. Configuration of the fishway entrance ports
4. Location of the fishway exit, with fish exiting into swift water
5. Trash rack debris accumulations
6. River shoaling at the fishway exit

A subsequent HEC-RAS hydraulic model report, using fisheries criteria in accordance with the accepted design criteria approved by fishery agencies (NOAA and WDFW), outlined repairs, modifications, and retrofits that would facilitate increased passage into the Klickitat subbasin for all fish at nearly all flow conditions.

The completion of on-going engineering and design work for Lyle Falls will establish a facility that allows a high proportion of returning fish to be physically examined at a location in the lower watershed. A video monitoring and PIT-tag detection system would enable escapement monitoring, provide run-timing information, and improve enumeration of natural- and hatchery-origin recruits returning to the subbasin. It could also determine the presence/absence of a fluvial bull trout population. The collection facility would support data collection that bears on the scientific justification for particular supplementation activities proposed for the subbasin. See ISRP 2005-16. The facility would support monitoring and evaluation strategies in the proposed Klickitat Anadromous Fishery Master Plan (KMP) that can be undertaken prior to implementation of supplementation activities, including the following:

- *Strategy SC3d. Use radio telemetry, mark-recapture, and/or run reconstruction to determine passage and entrainment rates at Lyle and Castile Falls and to track natural spawners to their spawning grounds.*
- *Strategy SC5a. Collect DNA samples and morphometric data from fish passing through the Lyle Falls and Castile Falls traps. Use findings from Yakima and other Columbia Basin studies in conjunction with information from these samples to target genetic studies in the Klickitat subbasin. Convene meetings of tribal and state geneticists as necessary to further develop sampling rates, protocols, and evaluation measures.*

- *Strategy SC6b. Update and maintain all Klickitat-related databases with historical and current harvest data.*
- *Strategy SC6c. Use run reconstruction methods developed for Yakima Basin spring Chinook to reconstruct Klickitat run and harvest to the Columbia River mouth.*

Fish passage barriers

Current culvert replacement projects throughout the subbasin are ensuring that passage structures will allow movement of all life stages of salmonids by maintaining a natural stream bottom and stream width, and allowing for natural floodplain function. These bottomless arch culverts and bridges allow for the natural movement of sediments, bedload material, and large woody debris needed for the formation of pool and complex rearing habitats.

Washington State Parks recently replaced a railroad trestle that was impeding steelhead migration in Logging Camp Creek. Klickitat County, Yakama Nation Fisheries, WDFW, two private landowners, Mid-Columbia Regional Fisheries Group and community volunteers recently completed a fish passage and habitat restoration project that enables steelhead to access habitat in Snyder Creek.

Habitat enhancement projects

Habitat enhancement projects are also being implemented by a variety of different entities in many parts of the watershed to improve spawning and rearing conditions. The Underwood Conservation District, which includes some western portions of the Klickitat watershed, repaired a headcut in 2004 in upper Snyder Creek, the result of previous incision and downcutting in the headwaters, which they continue to monitor.

The Mid-Columbia Fisheries Enhancement Group is involved in a number of habitat restoration projects in the Klickitat River subbasin in conjunction with YKFP, Federal and state agencies, local partners and private landowners. In the spring of 2006, Mid-Columbia Fisheries began a riparian restoration project along 2,000 linear feet of river bank on the lower mainstem Klickitat. Mid-Columbia Fisheries was a partner in a project on the Little Klickitat River sponsored by the Central Klickitat Conservation District. This project restored a 350 ft. section of the Little Klickitat River within the Goldendale City limits. The goal of the project is to improve water quality, stabilize eroding stream banks, reduce sediment, increase riparian cover, and reduce water temperature. As part of the project, old abutments made from dilapidated barrels and other debris was removed from the river banks. Banks were re-shaped, large woody debris was installed and the area is being re-planted.

A number of habitat projects are underway to address the temperature TMDL (Anderson 2004) for the Little Klickitat. The City of Goldendale rehabilitated Bloodgood Springs which feeds Bloodgood Creek, a source of cold water for the Little Klickitat River. Bloodgood Springs has been abandoned as a city water source, and the water rights were

transferred to a well in the Simcoe Mountains.. The pumping infrastructure neat the Bloodgood stream has been removed. (David McClure, personal communication).

In 2003, the City of Goldendale abandoned its use of Bloodgood Springs at the head of Bloodgood Creek and moved its water right for these springs to a well in the Simcoe Mountains. Additionally, this well in the Simcoe Mountains has been added to the authorized points of withdrawal for the City of Goldendale's "Mountain Springs" water right. This water right change has enabled the City of Goldendale to decrease its use of the springs which are in the headwaters if the Little Klickitat River. In recent years, the City brought the "Basse Well Field" on line and reduced the City's dependence on the springs in the Little Klickitat River's headwaters. The City of Goldendale historically land applied wastewater, now the City's new wastewater treatment plan puts treated effluent directly into the Little Klickitat River, improving stream flow in the river. The City is following-up on work started under the WRIA 30/Klickitat River watershed planning effort by obtaining grant funding and implementing more intensive investigations of aquifer storage and recovery opportunities for addressing climate change/variability concerns as they relate to the City's water needs and Little Klickitat River stream flows. In support of implementing the *Klickitat River Management Watershed Plan*, the City has obtained grant funding and initiated a project to improve its water conveyance system and achieve significant water conservation objectives, which are anticipated benefit Little Klickitat River stream flows.

The Central Klickitat Conservation District also has a number of projects in progress to address water quality and/or bank stability in the Little Klickitat watershed in conjunction with the Washington Conservation Corps, the Northwest Service Academy, Klickitat County and others through EQIP (Environmental Quality Incentives Program), CREP (Conservation Reserve Enhancement Program and CCRP (Continuous Conservation Reserve Program). Additionally, TMDL implementation work (e.g., stream flow and temperature monitoring, riparian planting) by the conservation district is support by a chapter 319 grant and related conservation programs or grants.

The USDA Forest Service is working on restoring an approximately 25-acre parcel near the mouth of the Klickitat River on the west bank. The goal of the project is to re-establishing the native riparian and wetland plant communities.

The Klickitat Public Utility District (KPUD) participates in the WRIA 30/Klickitat watershed planning process which addresses water quantity, water quality, and fish habitat within the Klickitat Basin. A recent project with potential benefits to water quality involved replacing the town of Klickitat's wastewater collection system piping with interceptor tanks and new pipe to reduce the affects of storm water and flooding. KPUD replaced the wastewater treatment plant. The plant employs an ultraviolet light treatment system to provide pathogen reduction (to kill fecal coliform) and to eliminate the daily use of chlorine as the main means of germicide. This treatment method will eliminate the discharge of chlorine into the Klickitat River from the plant. These two projects received approval by members and Elders of the Yakama Nation in 2004.

Construction was completed in May of 2007 (Tim Furlong, Klickitat PUD, personal communication, 2009).

Habitat restoration activities are a key component of the Yakima/Klickitat Fisheries Project (YKFP), an effort co-managed by the Yakama Nation Fisheries Program (lead agency) and Washington Department of Fish and Wildlife aimed at recovery of native anadromous salmonid populations in the Yakima and Klickitat River basins. The principal focus of the YKFP is to increase natural production of and opportunity to harvest salmon and steelhead in the Yakima and Klickitat subbasins using supplementation, harvest augmentation and habitat improvements. The YKFP is sponsored in large part by the Bonneville Power Administration with oversight and guidance from the Northwest Power and Conservation Council (NPCC) (Yakama Nation Fisheries 2006).

The Klickitat Watershed Enhancement Project (KWEP) conducts protection and restoration projects in the Klickitat River and tributaries to subbasin supporting native anadromous fish production. The goal of the KWEP, in keeping with the objectives of the Klickitat Subbasin Plan, the Klickitat Lead Entity Strategic Plan and the 1994 NPCC Fish and Wildlife Program, is to restore watershed health to aid recovery of salmonid stocks in the Klickitat subbasin. Restoration activities are aimed at restoring stream processes by removing or mitigating watershed perturbances and improving habitat conditions and water quality. Protection activities complement restoration efforts within the subbasin by securing refugia and preventing degradation of habitat. Actions under these projects include instream large woody debris placement, culvert replacements and other passage improvements, forest road rehabilitation, floodplain reconnection, and habitat acquisition; all of these habitat actions are consistent with objectives described in the subbasin plan (NPCC 2004, pp. 333-352). Assessment, monitoring and data management are also crucial components of the KWEP Program. Cooperation with state, Federal, tribal, and private entities ensures maximum effectiveness in 90 percent of the off-reservation project area in private ownership (Conley 2006).

The *Klickitat Watershed Management Plan* was completed and approved under chapter 90.82 RCW. This watershed plan (available at http://klickitatcounty.org/NaturalR/default.asp?fD=3) will guide management of water resources in those areas of the Klickitat Basin that are outside of the Yakama Reservation and tribal trust lands. The purpose of the watershed plan is to incorporate broad-sense interests (e.g., aesthetic and recreational values, consideration of species not listed under the ESA) that eclipse the purposes of the ESA. As provided in state statute, a detailed implementation plan, *Detailed Implementation Plan Klickitat River Basin (WRIA30)* (Aspect 2008) (available at http://klickitatcounty.org/NaturalR/Content.asp?fC=23&fD=3), was developed during the first year following watershed plan approval. Primary responsibility for implementing the watershed plan is assigned to the "Implementing Governments," which are Klickitat County, state agencies (represented by the Department of Ecology), Klickitat PUD, City of Goldendale, and Central Klickitat Conservation District. Action-specific

responsibilities and terms of commitment (e.g., rules, ordinances, or agreements), funding sources, and schedules with milestones for project completion are specified in the detailed implementation plan. Grant funding for the first five years of watershed plan implementation is provided for in chapter 90.82 RCW. Actions completed pursuant to the watershed planning process have included various assessments pertaining to water quality, water quantity, and fish habitat in the Klickitat Basin, and installation and maintenance four continuous flow monitors on the Little Klickitat River and three continuous flow monitors on Swale Creek, and, installation and maintenance of a SNOTEL precipitation monitoring station in the Simcoe Mountains. Priority goals in the watershed plan include those pertaining to the following key concerns:

- Current and future water demand (which consider stream flow needs of fish);
- Summer stream flow in the Little Klickitat River;
- Little Klickitat River temperature;
- Swale Creek temperature;
- Fish habitat restoration and protection; and
- Potential effects of population growth on fish habitat.

Klickitat County is actively engaged in projects and programs benefiting ESA-listed fish species within the county. The County is the lead agency for watershed planning and *Klickitat Watershed Management Plan* implementation, as well as the lead entity for the "SRFB process" through which PCSRF and state finding is obtained for salmon and steelhead habitat projects within the Klickitat and White Salmon River basins. Over the last five years the County has sponsored approximately a dozen salmon and steelhead habitat restoration projects, conducted in cooperation with a range of partners including the EKCD, Mid-Columbia Regional Fisheries Enhancement Group, Yakama Nation Fisheries, and WDFW. The County has also contributed matching funds for such projects as the Klickitat Wastewater Treatment Plan upgrade and "in-kind match" for such projects as the conservation district's implementation of the Little Klickitat River Temperature TMDL.

Regulatory Protection

Various state, tribal and county regulatory mechanisms are in place to protect riparian areas from current and future threats posed to listed species through habitat loss and degradation caused by human land uses and development. Numerous voluntary programs are also available to address habitat conservation. In addition, some areas receive special protection through designation, such as Wild and Scenic River reaches, primitive areas, and wildlife refuges.

NOAA Fisheries and/or U.S. Fish and Wildlife Section 7 Consultations

Section 7 of the Endangered Species Act directs all Federal action agencies to consult with NOAA Fisheries and the U.S. Fish and Wildlife Service to ensure that their actions will not jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat. Actions include not only direct Federal actions, but also actions funded with Federal dollars. A Biological Assessment or Biological Evaluation is usually developed and submitted to NMFS for review prior to implementation of the project. The reader can find additional information regarding the consultation process at: www.cit.noaa.gov/nosign/default.asp?action=ConsultationGuide.

Clean Water Act

The Federal Clean Water Act addresses the development and implementation of water quality standards, the development of total maximum daily loads (TMDL), filling of wetlands, point source permitting, the regulation of stormwater, and other provisions related to protection of U.S. waters. The Clean Water Act is administered in the State of Washington by the Department of Ecology (Ecology) with oversight by the EPA. State water quality standards are set to protect beneficial uses, which include several categories of salmonid use. Ecology has a water quality certification program under which it reviews projects that will discharge dredged or fill materials into waters of the U.S. and issues certifications that the proposed action meets State water quality standards and other aquatic protection regulations, if appropriate. Ecology also issues National Pollution Discharge Elimination System (NPDES) permits, and develops water quality cleanup plans (TMDL) to address water quality limited streams.

National Environmental Policy Act (NEPA) Review

NEPA requires Federal agencies to consider the probable impacts of their proposed activities, programs, and projects (including funding of state, local, and private actions) on the quality of the human environment. NEPA reviews help agencies decide whether to undertake a proposed action. In most cases, the NEPA review requires the development of an Environmental Assessment (EA) or Environmental Impact Statement (EIS) that addresses the probable effects of a project and its alternatives on various elements of the environment, including soils, geology, landscapes, atmospheric conditions, vegetation, fish and wildlife, and cultural resources. Many Federal funding programs are covered under a general NEPA review completed when the funding program was developed.

Watershed Planning Act

In 1998 chapter 90.82 RCW was amended with the passage of ESHB 2514. This law is also known as the Watershed Planning Act. The Watershed Planning Act was established to address the diminishing water availability and quality, and the loss of habitat for fish in the State of Washington. The Watershed Planning Act provides a framework for local citizens, tribes, and state and local agencies to work together to develop and implement Watershed Management Plans for entire watersheds.

As part of the planning process, a watershed assessment is completed for each Water Resource Inventory Area (WRIA) to evaluate water supply and use. Once the watershed assessment is complete, a management plan, followed by a detailed implementation plan, is developed to address water quantity, water quality, and fish habitat issues identified in the assessment. A watershed assessment has been completed for the Klickitat subbasin (WRIA 30) (WPN and Aspect 2005a) and the *Klickitat River Watershed Management Plan* (WPN and Aspect 2005a) and *Detailed Implementation Plan Klickitat River Basin (WRIA30)* (Aspect 2008) have been approved.

State Environmental Policy Act (SEPA)

SEPA regulations require an environmental review of actions taken by the state and local agencies, including funding and permitting. Some actions, such as the construction of single-family dwellings, minor road repair, and issuance of business licenses, are exempt. A SEPA review evaluates the probable environmental effects of a proposed project. This information is used to determine if the action should be taken as proposed, if mitigation is necessary, or if the proposal should be rejected.

Forest & Fish Regulations (Washington State)

The Washington Forests & Fish Law (ESHB 2091) was signed into law in 1999 as part of The Washington State Forest Practices Act (Title 76.09 RCW), passed in 1974. The Forests & Fish Law, based on the Forests & Fish Report, resulted in changes to forest practices rules to protect riparian and aquatic resources on more than eight million acres of private forestland. It is intended to meet the provisions of the Federal Clean Water Act concerning non-point source silvicultural practices. Changes to the law included:

- Updates of the stream typing system in the state to improve mapping of fish-bearing waters,
- Increases in buffer widths along fish bearing and non-fish bearing streams,
- Changes in forest practices to protect against landslides
- Mandatory requirements to update the forest road system to hydrologically disconnect roads from streams and minimize sediment delivered to streams,
- New regulations on pesticide applications to prevent or avoid drift of chemicals into streams,
- Increased protection of wetlands
- Changes in enforcement,
- Establishment of a scientifically based adaptive management and monitoring process for evaluating the impact of forest practices on aquatic resources,
- Establishment of a process for amending the forest practices rules to incorporate new information as it becomes available, and
- Establishment of a small landowner office to assist non-industrial landowners.

Additional information regarding the Forest Practices rules can be found at: http://www.dnr.wa.gov/forestpractices.

- The Washington Department of Natural Resources, on behalf of the State of Washington, submitted applications to NMFS and the U.S. Fish and Wildlife Service for incidental take permits under section 10 of the Endangered Species Act. Issuance of these permits would provide assurances that all forest practices activities in compliance with the state forest practices rules and administrative program will satisfy ESA requirements for aquatic species. The two services released the final HCP, the final environmental impact statement (FEIS), and implementing agreement in a ***Federal Register*** *Notice* on Jan. 27, 2006. This notice provides an opportunity for the public to review the final documents and the responses to public comments on the draft documents.

Klickitat County Shorelines Master Plan

In 1971 the Washington State Legislature passed the Washington Shoreline Management Act (SMA), adopted by public referendum in 1972. The purpose of the Act is "to prevent the inherent harm in an uncoordinated and piecemeal development of the state's shorelines" by requiring every county and many cities to develop a Shoreline Master Plan to govern development in shoreline areas http://www.ecy.wa.gov/programs/sea/sma/st_guide/intro.html). Klickitat County's Shorelines Master Plan (SMP) was first adopted in 1975 and has been updated periodically since then. The SMP and brochure on the shorelines permit program can be accessed from the Klickitat County Planning Department's web site: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788.

The Klickitat County's (SMP) regulates "development" within the "shorelines" of the Klickitat River and other water bodies in Klickitat County's jurisdiction. "Development" is broadly defined as: construction or exterior alteration of existing structures; dredging; drilling; dumping; filling; removal of any sand, gravel or minerals; bulkheading; driving of piling; placing of obstructions; or any project of a permanent or temporary nature which interferes with the normal public use of the surface of the waters overlying lands subject to the SMP regulations at any state of water level. "Shorelines" are those lands extending landward for 200 feet in all directions as measured from the ordinary high water mark, floodways and contiguous floodplain areas landward 200 feet from such floodways;, and all wetlands and river deltas associated with the streams and lakes. The SMP applies to the shorelines of the main stem of the Klickitat River as well as the shorelines of all tributaries with a mean annual flow of 20 cfs or more.

The SMP designates various shorelines of the Klickitat River and its tributaries as "environments", which determine the level of protection that is warranted. Much of the Klickitat River is designated either "Natural Environment" which prohibits most development within its shorelines or "Conservancy Environment", which allows a limited scope of development, subject to conditions (i.e. shoreline conditional use permit).

Each development proposal is subject to review pursuant to the shoreline environment within which it is to be located. One or more shoreline permits must be secured prior to implementation: Substantial Development Permits (SDP) are required for any

development for which the total cost or fair market value exceeds $5,000, or any development which materially interferes with the normal public use of the water or shorelines; Shoreline Conditional Use Permits (CUP) are required for development types that warrant conditions to ensure consistency with the SMP; and Variances (VAR) are issued to grant relief from specific bulk, dimensional, or performance standards of the SMP in order to avoid unnecessary hardship, provided that extraordinary circumstances are shown to exist and the public interest shall suffer no substantial detrimental effect. Some types of development, such as a single-family residence, normal maintenance and repair, or construction of a normal protective bulkhead for a single family residence, are exempt from the requirement of a substantial development permit, but are still subject to all other provisions of the SMP.

Existing structures and developments that were established prior to adoption of the SMP are considered legally established "non-conforming" uses. Since adoption of the SMP, all developments within shorelines, including modifications to non-conforming uses, have been reviewed by the County and Washington Department of Ecology (Ecology) to ensure compliance with the goals and requirements of the SMP.

The Department of Ecology reviews the County's permit decisions and has final authority to approve or deny conditional use permits and variances. Persons may appeal the final decision to the Shorelines Hearings Board.

Klickitat County Critical Areas Ordinance

Klickitat County adopted a Critical Areas Ordinance (CAO) in 2001 and, with the concurrence of Washington Departments of Fish and Wildlife, Community Trade and Economic Development, and Ecology, amended it in 2004. The CAO extends beyond the geographical scope of the County's SMP to protect wetlands, critical fish/wildlife habitat, geologically hazardous areas, aquifer recharge areas, and frequently flooded areas. The CAO is, in effect, an overlay on existing land use regulations. The CAO provides for standard setbacks of 300' from Category I wetlands; 200' from Category II; and 75' from Category III and IV. The CAO provides for standard buffers of 200' from Type 1 & 2 waters; 150' from Type 3 waters; 50' from Type 4 waters; and 25' from Type 5 waters. A wildlife habitat management plan is required for new development that will likely impair habitat functions and values. As with the SMP, developments and uses that existed prior to the adoption of the CAO are considered legally established "non-conforming" uses. The CAO and brochures land use permit programs can be accessed from the Klickitat County Planning Department's web site: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788.

Klickitat County Floodplain Management Ordinance

The Klickitat County Floodplain Management Ordinance (FPO) regulates all development and activities that may increase flood hazards. A permit is required for development within areas of special flood hazard (with at least one percent chance of flooding). The applicant for a non-residential structure must include a certification and

flood analysis conducted by a professional engineer. In general, development that will does not meet the specific criteria in the ordinance for development in these areas, to protect public health and safety, will be denied. The FPO and brochures land use permit programs can be accessed from the Klickitat County Planning Department's web site: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788.

Klickitat County Zoning Ordinance

The Klickitat County Zoning Ordinance (CZO) was adopted in 1979 and has been amended over time. Much of the Klickitat River watershed is zoned by the CZO as "extensive agriculture" which requires a 20-acre minimum lot size for the purpose of dividing properties, and new development/uses are restricted to resource management uses/activities and other compatible uses. One permanent residential dwelling is allowed per lot. Some areas of the watershed are zoned for residential development. The allowable minimum lot size for new lots is either 1 or 2 acres; and one residential dwelling is allowed per lot. Other than residential development, most new development/uses in these zones is either prohibited or allowed per a zoning conditional use permit. The CZO and brochures land use permit programs can be accessed from the Klickitat County Planning Department's web site: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788.

Klickitat County Environmental Ordinance (CEO)

The Klickitat County Environmental Ordinance (CEO) was adopted pursuant to the State Environmental Policy Act (SEPA). The CEO and SEPA require an analysis of probable significant adverse environmental impacts that may result from a proposed development. The CEO and SEPA require a threshold determination for each proposed development that is not exempt. The threshold determination is a determination that a project will or will not have probable significant adverse environmental impacts. If a project has probable significant adverse impacts, and environmental impact statement (EIS) is prepared. Any proposed development/use that is not specifically exempt in SEPA, chapter 43.21C RCW, or the SEPA rules adopted by the Department of Ecology, chapter 197-11 WAC, is required to comply with SEPA. Klickitat County provides applicable state agencies and tribes, as well as the public, the opportunity to review threshold determinations and EISs.

Washington State Water Pollution Control Act (Chapter 90.48 RCW)

This act gives Ecology the authority to protect water quality in the state and to promulgate regulations as needed to achieve this goal. The Act makes discharges of pollutants into waters of the state unlawful and has provisions for enforcement of violations, including the authority and process for issuing compliance orders and civil penalties, and for seeking criminal penalties. The Act also provides for permitting processes, cooperation with other entities, water quality monitoring, grants, and numerous other subjects regarding management of water quality issues in the state.

Washington's statewide monitoring program

In 2001, Substitute Senate Bill (SSB) 5637 was signed into law. This act related to monitoring of watershed health and salmon recovery. The Monitoring Oversight Committee developed a comprehensive statewide strategy that addresses the actions identified in SSB 5637 (WPN and Aspect Consulting 2005). Among other things, the Plan is intended to provide information regarding trends in fish, water, and habitat conditions and assess effectiveness of actions taken to improve watershed health and provide for salmon recovery. The strategy includes documentation of fish population trends in some areas of the state; however, the Klickitat River watershed is not one of the areas included to date in that monitoring effort. The strategy is also monitoring the effectiveness of habitat restoration efforts funded by the state. The monitoring of project effectiveness follows the Monitoring and Evaluation Strategy (Washington Salmon Recovery Funding Board 2003) that was developed in support of the Comprehensive Statewide Strategy. The Monitoring and Evaluation Strategy specified methods to assess a wide range of restoration and protection projects.

On-Site Sewage Systems

Chapter 246-272 of the Washington Administrative Code (WAC) regulates the on site disposal of sewage in the state. The law is applicable to septic systems as well as larger on-site systems. The rule addresses location of systems, site evaluations, design, installation, inspection, operation and maintenance, repair, abandonment, and other areas of concern. The rule helps to prevent the discharge of sewage into fish-bearing streams.

Hydraulic Code

Chapter 75.20 RCW governs construction projects within the waters of the state. The law requires hydraulic project approvals from the Department of Fish and Wildlife for wharves, bulkheads, bridges, culverts, fish habitat restoration projects, and other construction activities within the ordinary high water mark. This regulation helps to protect fish and fish habitat during construction.

Regulation of Dairy Farms

Chapter 90.64 RCW, the Dairy Nutrient Management Act, includes a number of requirements designed to protect water quality from dairy operations. These are in addition to NPDES requirements in the Federal and state Clear Water Acts for concentrated animal feeding operations. The Act requires inspection of all dairy farms, implementation of dairy nutrient management plans, technical assistance and enforcement (including civil penalties) against significant polluters. The intent of the regulation is to protect water quality and, subsequently, fish habitat. Ecology is the primary regulatory authority under this Act.

Other Rules and Regulations

There are over 100 additional rules and regulations applicable to the protection of water quality and fish habitat in the State of Washington. These rules cover a broad range of

subjects such as groundwater quality standards, application of pesticides, well construction, motor oil disposal, utilities, solid waste disposal and recycling, water supply facilities, mining, energy facilities, dikes and levees, aquiculture, etcetera. Lists of applicable laws and rules and links to the specific requirements of those laws and rules can be found at: www.ecy.wa.gov/laws-rules.

Yakama Reservation Forest Management Plan

The Yakama Nation has a variety of protective land use regulations in effect on reservation lands. One of these is the Forest Management Plan (FMP). Under the 1993-2002 FMP, the Yakama Administrative Forest was divided into 11 Land Use Management Areas (LUMA). Each LUMA was managed for multiple uses with emphasis on dominant resource features and objectives. The draft FMP soon to be ratified changes the designation of LUMAs to Management Emphasis Areas (MEA), which will be managed within the forest habitat types (USDI Bureau of Indian Affairs and Yakama Indian Nation 2004). The forestry program is using historical species composition and stand densities as references for the desired future stand conditions. Just as with the health of aquatic systems, forest health describes the ability of a forest ecosystem to remain productive, to maintain a diversity of plants and animals, aesthetic appeal, and resource sustainability, and to withstand disturbances over time. In addition, a healthy forest is resilient to periodic disturbances such as drought, insects, diseases, fires, climatic change, and management practices.

The Forest Management Plan prescribes the number of miles and density of roads allowed to be built for the purpose of harvesting timber from the Administrative Forest, and forest treatments such as thinning and prescribed burns are being put into place to move the forest vegetation more toward the historical condition of seral stands rather than dense, late successional forest cover. Streams are classified according to their flow, use for domestic purposes and use by fish for spawning, rearing and migration, and buffers and harvest restrictions are set accordingly. The objectives are the preservation of stream bank and riparian cover, water quality and flow maintenance and soil stabilization (USDI Bureau of Indian Affairs and Yakama Indian Nation 1993).

The draft Yakama Nation Forest Management Plan (FMP) designates Management Emphasis Areas that provide for special management emphasis within the closed area (closed to non-tribal members) of the reservation. Table III-1 lists the Management Emphasis Areas within the Klickitat subbasin, as well as the acreage and goal of each.

Table III-1. Trust Forest and Non-Forest Areas by Management Emphasis (BIA and YN 2004).

Management Emphasis Area	Forest (Acres)	Non-Forest (Acres)	Total (Acres)
General Forest	228,623	11,697	240,320
Wildlife Winter Habitat	99,684	52,131	151,815
Safety Corridor	7,086	523	7,609
Old-Growth	14,485	0	14,485
Canyon	50,500	11,749	62,249
Alpine	41,035	7,062	48,097
Riparian	10,403	628	11,031
Primitive	30,990	5,197	36,187
Tract D Recreation	10,072	6,794	16,866
Traditional Use	1,934	407	2,341
Total Acres	**494,812**	**96,188**	**591,000**

Court-mandated buffers on salmon-supporting waters

In January 2004, the U.S. District Court for the Western District of Washington at Seattle ordered protections to prevent the potential adverse effects of any of 54 pesticides on threatened and endangered salmonids. Under the order, buffer zones are required for the application of any of the 54 pesticides that received a "likely to adversely affect" determination as a result of EPA review. The order prohibits ground applications of these pesticides within 20 yards (60 feet) of streams and other water bodies accessible to salmon. The order also requires a buffer zone of 100 yards (300 feet) for aerial applications. The buffer zones remain in effect until the conclusion of the EPA consultations with NMFS. The U.S. Court of Appeals for the Ninth Circuit upheld the January 2004 order in June 2005. The no-spray buffers will remain in effect until EPA and NMFS complete the pesticide consultation process (WSDA 2006). Streams in the Klickitat subbasin that are subject to these buffers are: Blockhouse Creek, Butler Creek, East Prong and West Prong Little Klickitat River, mainstem Klickitat River, Little Klickitat River, Snyder Creek, Swale Creek, and White Creek (WSDA 2006).

Conservation Reserve Enhancement Program (CREP)

The Conservation Reserve Enhancement Program (CREP) is a joint partnership between the State of Washington and USDA, and is administered by the Washington State Conservation Commission and the Farm Services Agency (FSA). The agreement was signed in 1998 and provides incentives to restore and improve salmon and steelhead habitat on private land.

The land enrolled in CREP by voluntary landowners is removed from production and grazing under 10 or 15-year contracts. In return, landowners plant trees and shrubs to stabilize the stream bank and to provide a number of additional ecological functions. Landowners receive annual rent, incentive and maintenance payments and cost share for practice installations. These payments made by FSA and the Conservation Commission, can result in no cost to the landowner for participation (http://crep.scc.wa.gov/).

Special Land Use Areas

Yakama Reservation Primitive Area

The Primitive Area, established by Tribal Council Resolution, consists of the upper reaches of the Klickitat River, roughly half of which drains into the West Fork of the Klickitat, with the other half draining directly into the Klickitat. The 1993–2002 FMP stated that the Primitive Area was to be maintained in its natural state and that natural ecological events should be allowed to occur as freely as possible, provided adjacent lands are not unreasonably affected. The Primitive Area runs from just north of Potato Hill through the Two Lakes, Howard Lake, and Fish Lake areas, then north of Jennie's Butte, through McCormick Meadows, and ending just east of Diamond Butte. The Cascade crest forms the western edge of the Primitive Area, including Cispus Pass. Much of the Forest Service land north and west of the Primitive Area is also managed as reserve, notably the Goat Rocks Wilderness.

Columbia River Gorge National Scenic Area

"The National Scenic Area was created to protect and enhance the scenic, natural, cultural and recreational resources of the Columbia River Gorge while encouraging economic development" (www.fs.fed.us/r6/columbia/). Part of the NSA has been designated along the southernmost portion of the Klickitat subbasin, adjacent to the Columbia River. All new development and land uses must be reviewed in the National Scenic Area to determine if they are consistent with the Act and the implementing land-use ordinances. The development guidelines of the management plan are implemented through land-use ordinances which must be consistent with the management plan.

Klickitat Wildlife Area

The Klickitat Wildlife Area is owned and managed by WDFW. The area covers approximately 14,000 acres in the western portion of Klickitat County. It lies on the east slope of the Cascade Mountains about halfway between the Columbia River Gorge to the south and Mt. Adams to the north. The Klickitat River forms a deep, twisting canyon on its way south to the Columbia River. This twisting characteristic has created juxtaposing areas of forage on south slopes and thermal cover on north slopes. General vegetation types include the forest riparian zone along the Klickitat River, south-facing hillsides of open grasslands, north-facing hillsides forested with conifers, and the flatter plateau covered by mixed forests of oak and pine interspersed with small grassland (http://www.wdfw.wa.gov/lands/r5klick.htm).

Conboy Lake National Wildlife Refuge

The Conboy Lake National Wildlife Refuge (NWR) is managed by USFWS. The refuge is located approximately 10 miles east of Trout Lake and 7 miles southwest of Glenwood, in the Glenwood Valley/Camas Prairie area. The NWR contains 5,184 acres of marsh, meadows, grasslands, and forest. The former mountain lake is now present only in winter and early spring. The area provides a spring migration area for Canada geese and

ducks, (mainly mallards and pintails) and wintering use for tundra swans, Canada geese, ducks, and bald eagles. Additionally, one of three known nesting areas for sandhill cranes in Washington is located on the NWR, as is one of two known populations of Oregon spotted frogs (www.r1.fws.gov/visitor/washington.html).

Wild and Scenic Rivers

The Wild and Scenic Rivers Act was created by Congress to preserve in a free-flowing condition selected rivers of the nation which, with their immediate environments, possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historical, cultural, or other similar values. On November 17, 1986, the lower 11.1 miles of the Klickitat River (from its confluence with Wheeler Creek, near the town of Pitt, to its confluence with the Columbia River) were designated as a National Recreation River under this legislation. The "recreational" designation is for those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past. The segment is administered by the Secretary of Agriculture (Wild and Scenic Rivers Act. http://www.nps.gov/rivers/wsract.html). The Act restricts the construction of any dam or other water resource project on or directly affecting a designated river, or that which would have a direct and adverse effect on the values for which such a river was established, such as its free-flowing nature. The Act directed the Forest Service to develop management plans for these portions. In addition, the Act calls for completion of Wild and Scenic River Suitability Studies on other segments of the Klickitat. The Wild and Scenic Rivers Act on the Klickitat River does not supersede local Shoreline Management Plans.

Appendix IV. Estimates of Abundance Provided by Yakama Nation Fisheries

The following information is provided by Yakama Nation Fisheries. The information contained in this appendix represents the best available information prior to the installation of the adult fishway trap near Lyle. Monitoring of adult passage through the Lyle Fishway trap is provided better estimates of population size in 2005 and 2006 (Gray 2007) and will continue to provide better estimates of population size in the future.

Prior to the run year of 2005-06, total abundance and escapement estimates of wild Klickitat steelhead are highly uncertain. Run reconstruction and escapement has relied upon estimated number of spawners expanded from redd surveys. In some years, High flow and turbidity have precluded survey ability and effectiveness resulting in low and/or conservative spawner escapement estimates. Beginning in 2005-06, a Mark-recapture procedure used for population estimates has been implemented for estimating abundance at the mouth of the Klickitat for both wild and hatchery steelhead.

In the most recent ten years between 1997-98 and 2006-07, tribal harvest of wild steelhead in the Klickitat has ranged from 0 to 363 with an average of 107 fish annually (Table 1). Estimated harvest rates derived for years prior to 2005-06 are likely biased high as result of underestimated spawner escapement and total run size to the mouth of the Klickitat. For the return years of 2005-06 and 2006-07, estimated harvest rates on wild steelhead were 5.8 percent and 3.5 percent respectively (Table 1). Expansion of the spawner escapement estimates for harvest prior to these two years would suggest a much higher rate upward around 15 percent for the period of record of 1986-2007. Considering the recent two year average of 4.7 percent expanded from the mark recapture abundance estimates, actual harvest over the recent ten year period of record has probably ranged from 3.5 percent – 10 percent of the wild run to the mouth of the Klickitat.

Table IV-1. Estimated Klickitat River Steelhead Returns, Harvest and Escapement (Source Yakama Nation Fisheries).

Klickitat River Steelhead

		Sport			Tribal						
Year	Run[1]	Hatchery	Wild	Total	Hatchery[2]	Wild[2]	Total	Escapement[3]	Redds[4]	Wild run to mouth[7]	Wild Harvest rate[8]

2005-06[6]		1,115	0	1,115	368	98	466	520	12	1675	5.8%
2006-07[6]						61			74	1730	3.5%
Avg:	3,305	1,378	20	1,398	968	178	1,146	701	188	1,702	4.7%

Note: Data for this table are from YN and WDFW databases and US v. Oregon TAC reports
[1]Sum of harvest and escapement
[2]Hatchery and wild proportions of tribal harvest are estimated as follows: For 1999-00 through 2005-06 percentages estimated from sampling of ceremonial and subsistence harvest were applied to total tribal harvest. For 1986-87 through 1998-99 the average percentages from the 1999-2005 sampling were applied to total tribal harvest.
[3]Assumes 2.5 fish per redd. For years when redd counts were unavailable or unreliable, assumes average escapement-to-total-harvest ratio from years when reasonably accurate redd counts were available
[4]Actual redd counts expanded for mileage surveyed
[5]Sport Harvest numbers include data from May 1 - April 30 except for 2003-04, which does not include April data
[6]High flows and turbidity limited survey ability and effectiveness, probably biasing the redd count low.
[7]Wild run to mouth includes Lyle Falls Mark-recapture expansions and tribal fisheries below Falls
[8] Estimated terminal harvest rate for wild steelhead

Recovery Plan for the Rock Creek Population of the Middle Columbia River Steelhead Distinct Population Segment

October 2009

Prepared by
National Marine Fisheries Service
Northwest Region

DISCLAIMER

Endangered Species Act (ESA) recovery plans delineate reasonable actions which the best available information indicates are necessary for the conservation and survival of listed species. Plans are published by the National Marine Fisheries Service (NMFS), usually with the assistance of recovery teams, state agencies, local governments, salmon recovery boards, non-governmental organizations, interested citizens of the affected area, contractors, and others. ESA recovery plans do not necessarily represent the views, official positions, or approval of any individuals or agencies involved in the plan formulation, other than NMFS. They represent the official position of NMFS only after they have been signed by the Northwest Regional Administrator. ESA recovery plans are guidance and planning documents only; identification of an action to be implemented by any public or private party does not create a legal obligation beyond existing legal requirements. Nothing in this plan should be construed as a commitment or requirement that any Federal agency obligate or pay funds in any one fiscal year in excess of appropriations made by Congress for that fiscal year in contravention of the Anti-Deficiency Act, 31 U.S.C. 1341, or any other law or regulation. Approved recovery plans are subject to modification as dictated by new information, changes in species status, and the completion of recovery actions.

With respect to the Middle Columbia Steelhead Recovery Plan, where areas of disagreement arose between a management unit plan and the species level, distinct population segment (DPS) plan, NMFS worked with the relevant parties to resolve the differences and in a few cases, identified in the DPS plan, decided not to incorporate the disputed material into the DPS plan.

ESA recovery plans provide important context for NMFS's determinations pursuant to section 7(a)(2) of the Endangered Species Act. However, recovery plans do not place any additional legal burden on NMFS or the action agency when determining whether an action would jeopardize the continued existence of a listed species or adversely modify critical habitat. The procedures for the section 7 consultation process are described in 50 CFR 402 and are applicable regardless of whether or not the actions are described in a recovery plan.

Recovery Planning Glossary

abundance: In the context of salmon recovery, unless otherwise qualified, abundance refers to the number of adult fish returning to spawn.

adaptive management: Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. A plan for monitoring, evaluation, and feedback is incorporated into an overall implementation plan so that the results of actions can become feedback on design and implementation of future actions.

anadromous fish: Species that are hatched in freshwater, migrate to and mature in salt water, and return to freshwater to spawn.

baseline monitoring: In the context of recovery planning, baseline monitoring is done before implementation, in order to establish historical and/or current conditions against which progress (or lack of progress) can be measured.

biogeographical region: an area defined in terms of physical and habitat features, including topography and ecological variations, where groups of organisms (in this case, salmonids) have evolved in common.

broad-sense recovery goals: Goals defined in the recovery planning process, generally by local recovery planning groups, that go beyond the requirements for delisting, to address, for example, other legislative mandates or social, economic, and ecological values.

compliance monitoring: Monitoring to determine whether a specific performance standard, environmental standard, regulation, or law is met.

delisting criteria: Criteria incorporated into ESA recovery plans that define both biological viability (biological criteria) and alleviation of the causes for decline (threats criteria based on the five listing factors in ESA section 4[a][1]), and that, when met, would result in a determination that a species is no longer threatened or endangered and can be proposed for removal from the Federal list of threatened and endangered species. These criteria are a NMFS determination and may include both technical and policy considerations.

distinct population segment (DPS): A listable entity under the ESA that meets tests of discreteness and significance according to USFWS and NMFS policy. A population is considered distinct (and hence a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics, it occupies an unusual or unique ecological setting, or its loss would represent a significant gap in the species' range.

diversity: All the genetic and phenotypic (life history, behavioral, and morphological) variation within a population. Variations could include anadromy vs. lifelong residence in

freshwater, fecundity, run timing, spawn timing, juvenile behavior, age at smolting, age at maturity, egg size, developmental rate, ocean distribution patterns, male and female spawning behavior, physiology, molecular genetic characteristics, etc.

endangered species: A species in danger of extinction throughout all or a significant portion of its range.

effectiveness monitoring: Monitoring set up to test cause-and-effect hypotheses about recovery actions: Did the management actions achieve their direct effect or goal? For example, did fencing a riparian area to exclude livestock result in recovery of riparian vegetation?

ESA recovery plan: A plan to recover a species listed as threatened or endangered under the U.S. Endangered Species Act (ESA). The ESA requires that recovery plans, to the extent practicable, incorporate (1) objective, measurable criteria that, when met, would result in a determination that the species is no longer threatened or endangered; (2) site-specific management actions that may be necessary to achieve the plan's goals; and (3) estimates of the time required and costs to implement recovery actions.

evolutionarily significant unit (ESU): A group of Pacific salmon or steelhead trout that is (1) substantially reproductively isolated from other conspecific units and (2) represents an important component of the evolutionary legacy of the species.

extinct: No longer in existence. No individuals of this species can be found.

extirpated: Locally extinct. Other populations of this species exist elsewhere. The ICTRT considers extirpated steelhead populations to be those that are entirely cut off from anadromy, such as the Crooked River population. Functionally extirpated populations are those of which there are so few remaining numbers that there are not enough fish or habitat in suitable condition to support a fully functional population.

factors for decline: Five general categories of causes for decline of a species, listed in the Endangered Species Act section 4(a)(1)(b): (A) the present or threatened destruction, modification, or curtailment of its habitat or range; (B) overutilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; or (E) other natural or manmade factors affecting its continued existence.

functionally extirpated: Describes a species that has been extirpated from an area; although a few individuals may occasionally be found, there are not enough fish or habitat in suitable condition to support a fully functional population.

hyporheic zone: Area of saturated gravel and other sediment beneath and beside streams and rivers where groundwater and surface water mix.

implementation monitoring: Monitoring to determine whether an activity was performed and/or completed as planned.

independent population: Any collection of one or more local breeding units whose population dynamics or extinction risk over a 100-year time period is not substantially altered by exchanges of individuals with other populations.

indicator: A variable used to forecast the value or change in the value of another variable.

interim regional recovery plan: A recovery plan that is intended to lead to an ESA recovery plan but that is not yet complete. These plans might address only a portion of an ESU or lack other key components of an ESA recovery plan.

intrinsic potential: The estimated relative suitability of a habitat for spawning and rearing of anadromous salmonid species under historical conditions inferred from stream characteristics including channel size, gradient, and valley width.

intrinsic productivity: The expected ratio of natural-origin offspring to parent spawners at levels of abundance below carrying capacity.

kelts: Steelhead that are returning to the ocean after spawning and have the potential to spawn again in subsequent years (unlike most salmon, steelhead do not necessarily die shortly after spawning).

large woody debris (LWD): A general term for wood naturally occurring or artificially placed in streams, including branches, stumps, logs, and logjams. Streams with adequate LWD tend to have greater habitat diversity, a natural meandering shape, and greater resistance to flooding.

legacy effects: Impacts from past activities that continue to affect a stream or watershed in the present day.

limiting factor: Physical, biological, or chemical features (e.g., inadequate spawning habitat, high water temperature, insufficient prey resources) experienced by the fish that result in reductions in viable salmonid population (VSP) parameters (abundance, productivity, spatial structure, and diversity). Key limiting factors are those with the greatest impacts on a population's ability to reach a desired status.

locally developed recovery plan: A plan developed by state, tribal, regional, or local planning entities to address recovery of a species. These plans are being developed by a number of entities throughout the region to address ESA as well as state, tribal, and local mandates and recovery needs.

maintained status: Population status in which the population does not meet the criteria for a viable population but does support ecological functions and preserve options for ESU/DPS recovery.

major population group (MPG): A group of salmonid populations that are geographically and genetically cohesive. The MPG is a level of organization between demographically independent populations and the ESU or DPS.

management unit: A geographic area defined for recovery planning purposes on the basis of state, tribal or local jurisdictional boundaries that encompass all or a portion of the range of a listed species, ESU, or DPS.

metrics: A metric is something that quantifies a characteristic of a situation or process; for example, the number of natural-origin salmon returning to spawn to a specific location is a metric for population abundance.

morphology: The form and structure of an organism, with special emphasis on external features.

natural-origin fish: Fish that were spawned and reared in the wild, regardless of parental origin.

parr: The stage in anadromous salmonid development between absorption of the yolk sac and transformation to smolt before migration seaward.

phenotype: Any observable characteristic of an organism, such as its external appearance, development, biochemical or physiological properties, or behavior.

piscivorous: (Adj.) Describes fish that eat other fish.

productivity: The average number of surviving offspring per parent. Productivity is used as an indicator of a population's ability to sustain itself or its ability to rebound from low numbers. The terms "population growth rate" and "population productivity" are interchangeable when referring to measures of population production over an entire life cycle. Can be expressed as the number of recruits (adults) per spawner or the number of smolts per spawner.

recovery domain: An administrative unit for recovery planning defined by NMFS based on ESU boundaries, ecosystem boundaries, and existing local planning processes. Recovery domains may contain one or more listed ESUs.

recovery goals: Goals incorporated into a locally developed recovery plan, which may include delisting (i.e. no longer considered endangered or threatened), reclassification (e.g., from endangered to threatened), and/or other goals. Broad-sense goals are a subset of recovery goals (see glossary entry above).

recovery plan supplement: A NMFS supplement to a locally developed recovery plan that describes how the plan addresses ESA requirements for recovery plans. The supplement also proposes ESA delisting criteria for the ESUs addressed by the plan, since a determination of these criteria is a NMFS decision.

recovery scenarios: Alternative combinations of target status for the populations in an ESU that would be generally consistent with TRT recommendations for ESU viability.

recovery strategy: Statements that identify the assumptions and logic – the rationale – for the species' recovery program.

redd: A nest constructed by female salmonids in streambed gravels where eggs are fertilized and deposited.

riparian area: Area with distinctive soils and vegetation between a stream or other body of water and the adjacent upland.

salmonid: Fish of the family *Salmonidae*, including salmon, trout, chars, grayling, and whitefish. In general usage, the term usually refers to salmon, trout, and chars.

smolt: A juvenile salmonid that is undergoing physiological and behavioral changes to adapt from freshwater to saltwater as it migrates toward the ocean.

spatial structure: Characteristics of a fish population's geographic distribution. Current spatial structure depends upon the presence of fish, not merely the potential for fish to occupy an area.

stakeholders: Agencies, groups, or private citizens with an interest in recovery planning, or who will be affected by recovery planning and actions.

Technical Recovery Team (TRT): Teams convened by NMFS to develop technical products related to recovery planning. TRTs are complemented by planning forums unique to specific states, tribes, or regions, which use TRT and other technical products to identify recovery actions.

threatened species: A species likely to become endangered within the foreseeable future throughout all or a significant portion of its range.

threats: Human activities or natural events (e.g., road building, floodplain development, fish harvest, hatchery influences, volcanoes) that cause or contribute to limiting factors. Threats may exist in the present or be likely to occur in the future.

viability criteria: Criteria defined by NMFS-appointed Technical Recovery Teams to describe a viable salmonid population, based on the biological parameters of abundance, productivity, spatial structure, and diversity. These criteria are used as technical input

into the recovery planning process and provide a technical foundation for development of biological delisting criteria.

viability curve: A curve describing combinations of abundance and productivity that yield a particular risk of extinction at a given level of variation over a specified time frame.

viable salmonid population (VSP): an independent population of Pacific salmon or steelhead trout that has a negligible risk of extinction over a 100-year time frame.

VSP parameters: Abundance, productivity, spatial structure, and diversity. These describe characteristics of salmonid populations that are useful in evaluating population viability. See NOAA Technical Memorandum NMFS-NWFSC-42, *Viable salmonid populations and the recovery of evolutionarily significant units* (McElhany et al. 2000).

Executive Summary

The Endangered Species Act of 1973 (ESA) requires NOAA's National Marine Fisheries Service (NMFS) to develop recovery plans for species listed under the Act. The purpose of recovery plans is to identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA.

This plan focuses on the conservation and survival of Middle Columbia River steelhead (*Oncorhynchus mykiss*) in the Rock Creek subbasin. Rock Creek drains an area of 223.2 sq. miles (578.1 sq. km) in southeastern Washington State. It joins the Columbia River at RM 230, approximately 12 miles upstream of John Day Dam (Figure ES-1). This is one of several recovery plans developed for independent populations of the Middle Columbia River steelhead distinct population segment (DPS), which was listed as threatened under the ESA on March 25, 1999 and reconfirmed on January 5, 2006 (71 FR 834). Similar plans have been prepared for Middle Columbia steelhead populations in the White Salmon River, Klickitat River, and Yakima River, as well as in areas of southeast Washington and the State of Oregon. These separate plans are part of a DPS-level plan that integrates recovery actions across the DPS.

Purpose of Plan

A recovery plan is a guidance document, not regulatory. This plan provides a roadmap for restoring the Rock Creek steelhead population and its habitats to a level that supports recovery of the Middle Columbia River steelhead DPS and allows the population to become a viable component of its ecosystem.

The plan describes the current status of the Rock Creek population and proposes a strategy for its conservation and recovery. The recovery strategy builds on past and current recovery efforts. A key component of the strategy is collaborative development of a research, monitoring, and evaluation plan to further characterize population and habitat characteristics. Finally, the plan provides guidelines for implementation and an adaptive management framework for making appropriate adjustments as new information becomes available.

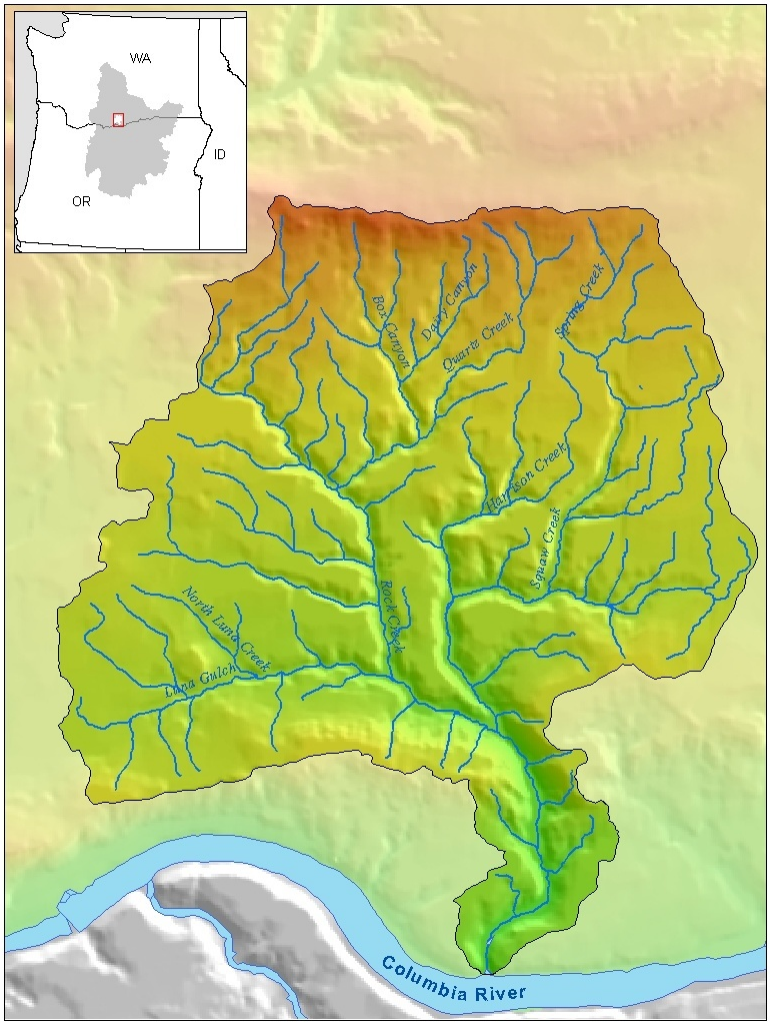

Figure ES-1. Rock Creek Subbasin.

Context of Plan Development

The plan is the product of a process initiated by NMFS; it incorporates information from the Yakama Nation (YN), Washington Department of Fish and Wildlife (WDFW), Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal agencies, state agencies, local governments, and the public.

Currently, there are 19 ESA-listed ESUs/DPSs of Pacific salmon and steelhead in the Pacific Northwest. For the purpose of recovery planning for these species, NMFS Northwest Region designated five geographically based "recovery domains" (Figure ES-2). The range of the Middle Columbia River steelhead DPS is located in the Middle Columbia sub-domain of the Interior Columbia domain.

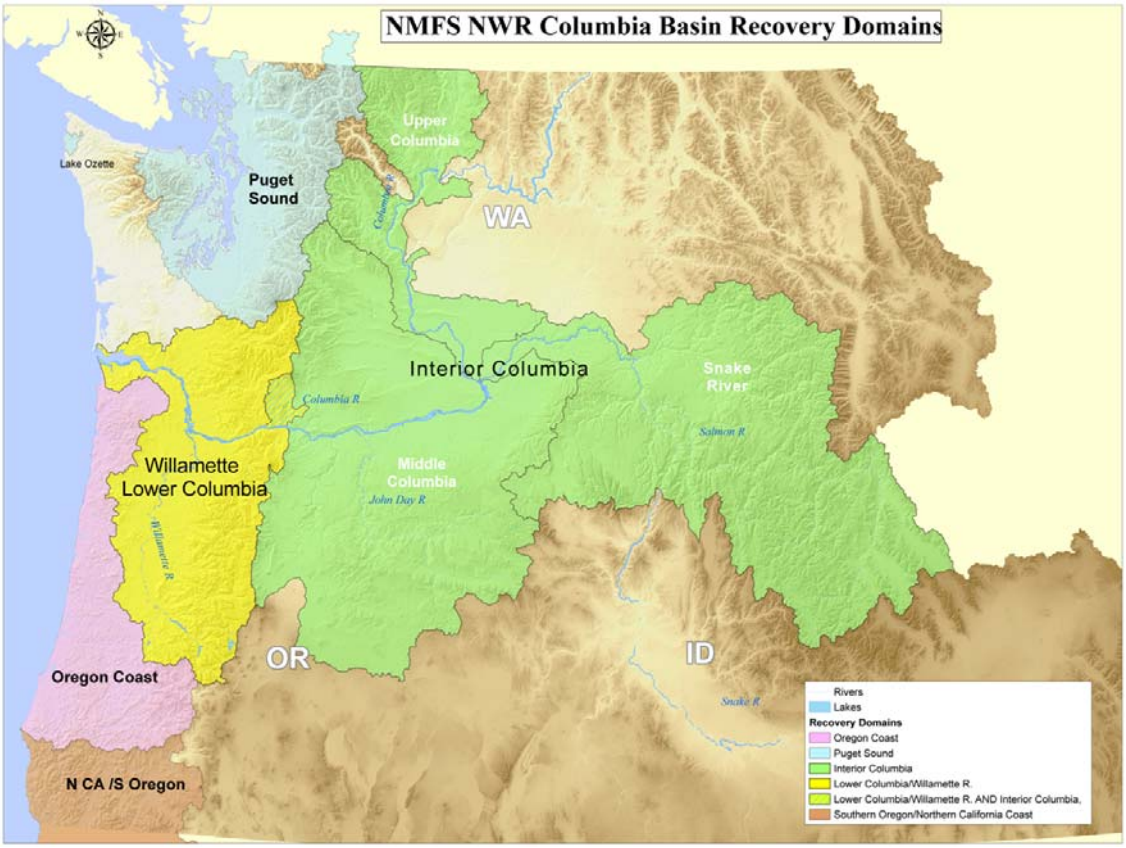

Figure ES-2. Columbia Basin Recovery Domains for NMFS Northwest Region.

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each Technical Recovery Team (TRT) was to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. The Interior Columbia TRT (ICTRT) includes biologists from NMFS, states, tribes, and academic institutions.

All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population viability criteria – criteria that may be used, along with criteria based on mitigation of the factors for decline, in determining whether a species has recovered sufficiently to be downlisted or delisted. These principles are described in a NMFS technical memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000).

Viable salmonid populations (VSP) are defined in terms of four parameters: abundance, productivity (growth rate), spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework, based on data availability, the

unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective experience and expertise. Although NMFS has encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs are working from a common scientific foundation. Viability criteria are an important part of recovery goals, as described later in this summary.

The Rock Creek Plan reflects direction for Rock Creek steelhead adopted into the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program subbasin plan (NPCC 2004). The subbasin plan was produced through a collaborative process involving the Yakama Nation, Washington Department of Fish and Wildlife, and NPCC. In addition, the plan reflects technical data drawn from the following sources:

- Watershed Resource Inventory Area (WRIA) 31 Watershed Assessment (Aspect and WPN 2004) and WRIA 31 Instream Habitat Assessment (Glass 2009)
- The Interior Columbia Technical Recovery Team (ICTRT) viability criteria and current status assessment for the Middle Columbia River steelhead DPS (ICTRT 2007a, 2007b, and 2009)

Biological Background

Salmonid species' homing propensity (their tendency to return to the locations where they originated) creates unique patterns of genetic variation and connectivity that mirror the distribution of their spawning areas across the landscape. Diverse genetic, life history, and morphological characteristics have evolved over generations, creating runs highly adapted to diverse environments. It is this variation that gives the species as a whole the resilience to persist over time.

Historically, a salmon ESU or steelhead DPS typically contained multiple populations connected by some small degree of genetic exchange that resulted from some spawners "straying" into neighboring streams. Thus, the overall biological structure of the ESU/DPS is hierarchical; spawners in the same area of the same stream will share more characteristics than those in the next stream over. Fish whose natal streams are separated by hundreds of miles will have less genetic similarity.

Definition of Evolutionarily Significant Units/Distinct Population Segments
An ESU is defined as a group of Pacific salmon that is "substantially reproductively isolated from other conspecific units and represents an important component of the evolutionary legacy of the species" (Waples 1991). A "population segment" is considered distinct (a DPS and hence a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics; or if it occupies an unusual or unique ecological setting; or if its loss would represent a significant gap in the species' range (71 FR 834).

ESUs/DPSs may contain multiple populations that are connected by some degree of genetic exchange through straying, and hence may have a broad geographic range across watersheds and river basins.

Major Population Groups
Within an ESU/DPS, independent populations can be grouped into larger populations that share similar genetic, geographic, and/or habitat characteristics (McClure et al. 2003). These "major groupings" of populations (MPGs) are isolated from one another over a longer time scale than that defining the individual populations, but retain some degree of connectivity greater than that between ESUs/DPSs.

Independent Populations
McElhany et al. (2000) defined an independent population as follows:

"…a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season."

The Rock Creek population is one of 17 extant independent populations that make up the Middle Columbia River steelhead DPS, and one of the five extant populations (Klickitat River, Fifteenmile Creek, Rock Creek, Deschutes River Eastside, and Deschutes River Westside) and two extirpated populations (White Salmon River and Deschutes Crooked River) that make up the major population group (MPG) of the Cascades Eastern Slope Tributaries (Figure ES-3). Steelhead in this MPG occupy diverse habitats, generally those draining the eastern slopes of the Cascades and the Columbia Plateau.

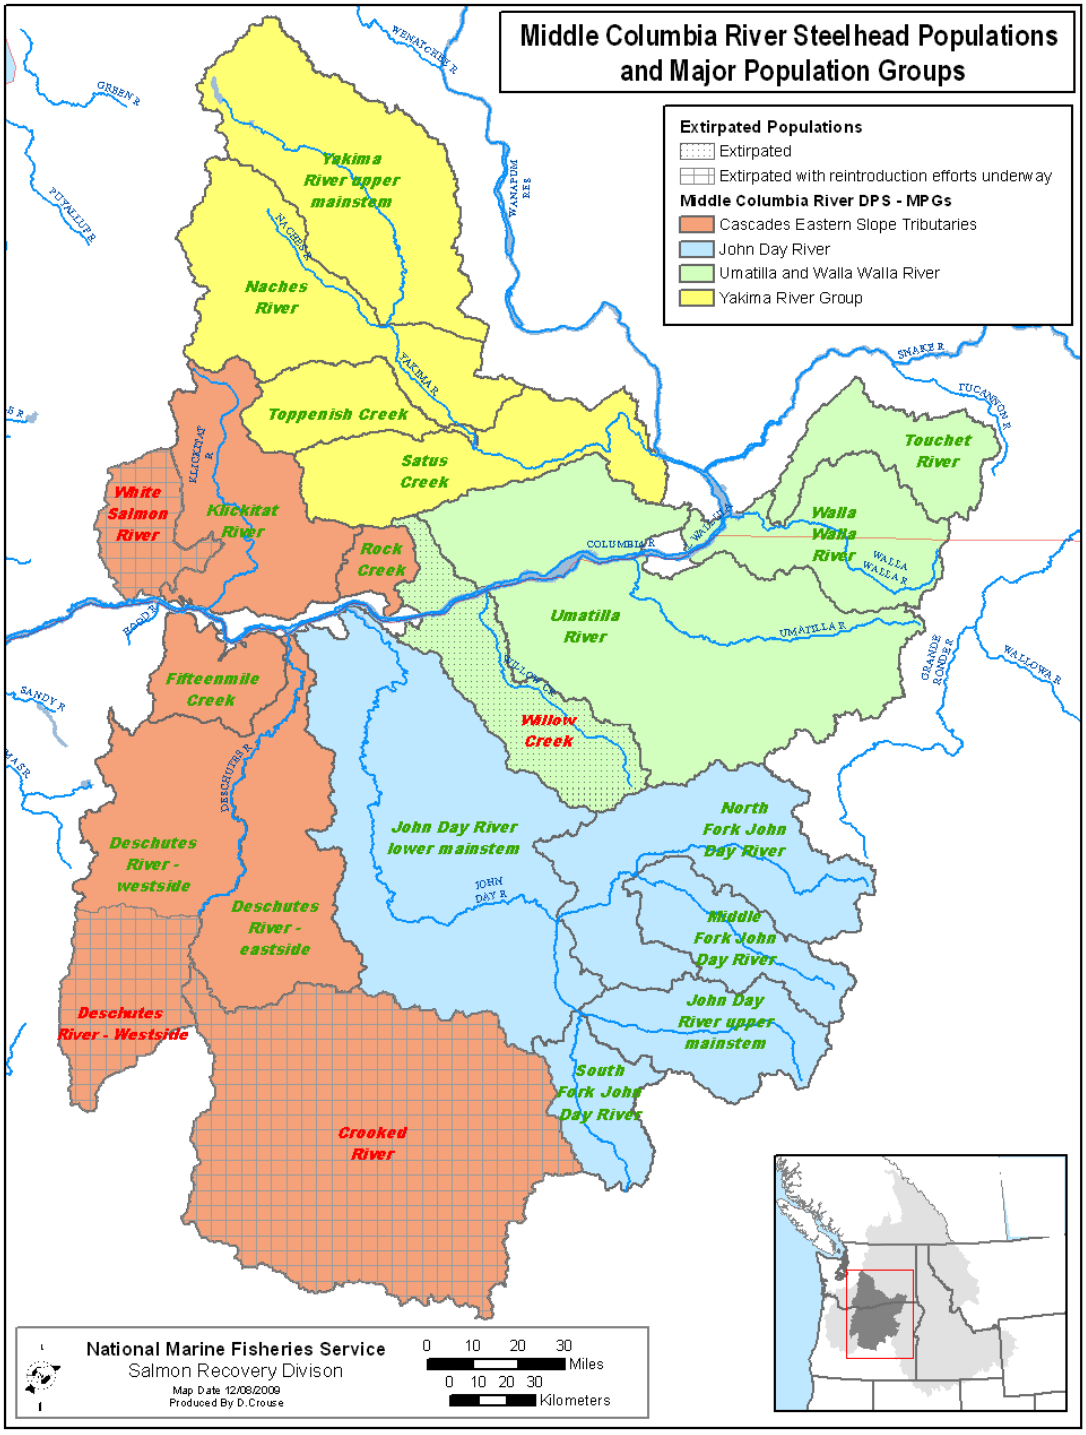

Figure ES-3 Middle Columbia River Steelhead Populations and Major Population Groups.

Physical Setting

Rock Creek begins in the Simcoe Mountains, which form the subbasin's northern border and the southern edge of the Yakama Indian Reservation. Major tributaries to Rock Creek include Badger Gulch, Harrison Creek, Luna Gulch, Quartz Creek and Squaw Creek. Lake Umatilla, the reservoir behind John Day Dam on the Columbia River, inundates the lower mile of Rock Creek.

The drainage has a high basalt plateau and deeply incised canyons that reflect its underlying basalt geology. Headwater streams cross a relatively flat basalt plateau that is primarily forested and above known anadromous use, and then drop into steep-walled canyons where gradients increase to 2 to 4 percent or more. Flows in the subbasin's canyon and alluvial reaches are considered flashy, rising and falling rapidly in response to precipitation and snowmelt. Snowmelt runoff from higher elevations appears to help sustain flows into early spring. Numerous springs also exist in the subbasin, most of which are located in the headwaters (Brown 1979). No flow regulation occurs in the drainage, although small amounts are diverted for stock watering.

Lands in the Rock Creek subbasin remain generally undeveloped, with nearly 47 percent rangeland, 26 percent forestland, and 4 percent dry land agriculture. Forests cover the upper elevations, and the middle and lower watershed supports range and agricultural uses. No irrigated land was estimated to exist as of 2001 (Aspect Consulting and WPN 2004). Developed land accounts for less than one percent of the subbasin area (Aspect Consulting and WPN 2004).

Rock Creek Steelhead Population

Steelhead in Rock Creek are considered indigenous. Rock Creek is a natural production area, with no hatcheries located in the subbasin, although it is possible that some strays from outside hatchery sources enter Rock Creek. The stock is considered distinct from other mid-Columbia stocks based on geographic isolation of the spawning population (ICTRT 2003).

Limited information exists on steelhead abundance in the Rock Creek drainage; however, some observations suggest that a significant number of steelhead may utilize the Rock Creek watershed in good water and ocean condition years. Surveys conducted by the Yakama Nation in lower Rock Creek in 2002, 2003 and 2004 show as many as 35 to 45 steelhead redds per mile in the lower five miles, and extensive distribution of redds throughout the watershed. Steelhead spawner surveys conducted in 2008 found 2 to 3 redds per mile (Glass 2009). More surveys are needed to determine steelhead abundance in the drainage. Efforts are underway to model the abundance and capacity within the watershed (J. Spencer, pers. comm. 2006).

Historically, steelhead likely utilized virtually all of the major streams and tributaries of Rock Creek for some part of their life history. Spawning distribution probably included all accessible portions of the Rock Creek watershed. As now, the highest spawning densities likely occurred in the more complex, braided reaches of the lower mainstem of

Rock Creek, and in third- and fourth-order tributaries with moderate (1-4 percent) gradients (NPCC 2004). The headwaters of the mainstem and Box Canyon are generally above known anadromous fish use (NPCC 2004); however, live steelhead, redds and *O. mykiss* fry have been observed up to the falls in Box Canyon.

All steelhead in the Columbia River Basin upstream of The Dalles Dam, including the Rock Creek population, are classified as summer-run fish (Chapman et al. 1994; ICTRT 2009); however, Yakama Nation biologists suspect that a portion of the steelhead population in Rock Creek consists of winter-run fish.

Recovery Goals and Criteria

The primary goal of ESA recovery plans is for the species to reach the point that it no longer needs the protection of the Act – i.e. to be delisted. Delisting criteria are applied at the DPS level, and are based on determinations of the viability of the independent populations that make up the DPS. Criteria for delisting the Middle Columbia steelhead DPS are described in the Middle Columbia River Steelhead ESA Recovery Plan, to which this plan is an appendix. The primary goal of this plan is for the Rock Creek steelhead population to be restored to moderate risk, also called "maintained," status and thus to support recovery of the Mid-Columbia steelhead DPS.

Two kinds of criteria enter into a delisting decision: population or demographic parameters (the biological viability criteria) and "threats" criteria related to the five listing factors detailed in the ESA (see Section 1.1). The threats criteria define the conditions under which the listing factors, or threats, can be considered to be addressed or mitigated. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B). Both kinds of criteria are discussed in Chapter 3.

Biological Criteria

The ICTRT developed biologically based viability criteria for ESA-listed salmon and steelhead in the Interior Columbia domain. The ICTRT based its approach to recovery on guidance from the NMFS Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). This memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels.

A viable salmonid population is defined as an independent population that has negligible (less than 5 percent) risk of extinction over a 100-year period (McElhany et al. 2000). The ICTRT criterion for a viable ESU/DPS is that all extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS should be at low risk. The ICTRT provided additional criteria for determining MPG viability (Section 3.2.1). The risk levels of the populations within the DPS collectively determine MPG viability and, in turn, the likely persistence of the DPS. However, it may not be necessary for all of the populations to attain the lowest risk level. There may be more than one way for a DPS to meet the viability criteria. The ICTRT called alternative combinations of population risk status that would meet the MPG and DPS-level criteria "recovery scenarios."

According to the ICTRT's recovery scenario for the Cascades Eastern Slope Tributaries MPG, the Rock Creek steelhead population should reach "moderate" risk status in order to support overall DPS viability. Moderate risk is defined as between 25 and 5 percent risk of extinction over a 100-year time period.

The ICTRT classified the Rock Creek steelhead population as a "Basic" sized population, based on historical habitat potential (ICTRT 2007b) and provided viability criteria for a Basic population, as follows (ICTRT 2007b):

Abundance
For a Basic population, viable status, i.e. a 5 percent or less risk of extinction over a 100-year timeframe, would require a mean minimum abundance threshold of 500 naturally produced spawners. Maintained status or moderate (6 to 25 percent) risk would also require a mean minimum abundance of 500 naturally produced spawners because populations with fewer than 500 individuals are at higher risk for inbreeding depression and a variety of other genetic concerns (ICTRT 2007b).

Productivity
Productivity rates at relatively low numbers of spawners should, on average, be sufficiently greater than 1.0 to allow the population to rapidly return to abundance target levels. For a maintained/moderate risk Basic population at 500 naturally produced spawners, productivity should be at about 1.3. For the population to reach viable status (the 5 percent risk level), productivity should be >1.56.

Spatial Structure and Diversity
In general, the ICTRT defined two goals, or biological or ecological objectives, that spatial structure and diversity criteria should achieve (ICTRT 2007b):

- Natural rates and levels of spatially mediated processes should be maintained.
- Natural patterns of variation should be maintained.

Threats Criteria and Approach

Section 3.2.2 of the Plan describes the listing factors and listing/threats criteria that must also be addressed to de-list the DPS. These listing factors are the features that were evaluated under section 4(a)(1) when the initial determination was made to list the species for protection under the ESA.

At the time of a delisting decision, NMFS will use the listing factors/threats criteria to review the status of the section 4(a)(1) listing factors and determine if the affected DPS is recovered to the point that it no longer requires protections of the ESA. NMFS expects that if the proposed actions described in this and other Middle Columbia River steelhead recovery plans are implemented, they will make substantial progress toward meeting the listing factor/threats criteria. These criteria are identified in Section 3.3 and address the five listing factors that were evaluated under section 4(a)(1): 1) the present or threatened destruction, modification, or curtailment of its habitat or range; 2) over-utilization for

commercial, recreational, scientific or educational purposes; 3) disease or predation; 4) the inadequacy of existing regulatory mechanisms; and 5) other natural or manmade factors affecting its continued existence.

Current Status Assessment

Chapter 4 summarizes the ICTRT's viability assessment results for Rock Creek's Middle Columbia River steelhead population. The ICTRT identified the Rock Creek steelhead population as a summer run within the Cascades Eastern Slope Tributaries MPG. It classified the population as a "basic" population based on historical habitat potential (ICTRT 2007b).

- *Abundance/Productivity:* The ICTRT determined that, at present, no direct estimates of abundance and productivity are available for Rock Creek steelhead. There have been no systematic redd surveys in this population area; however, the general presence of steelhead has been documented. Because of the lack of direct information on current or indirect assessments of abundance and productivity, the ICTRT assigned the Rock Creek steelhead population High risk.

- *Spatial Structure and Diversity:* The ICTRT gave the Rock Creek population a combined integrated Spatial Structure/Diversity rating of Moderate risk. Based on the ICTRT historical potential analysis, the team found that the Rock Creek population has a relatively simple population structure, containing a single major spawning area (MaSA). It determined that although observations indicate that steelhead spawning may occur across much of the historical range, the relatively simple population structure results in a moderate risk rating for complexity. It noted that there have likely been minor reductions in life history diversity and phenotypic variation, but these changes are not severe enough to raise risk levels above low for this parameter.

- *Overall Risk Rating*: The ICTRT concluded that the Rock Creek steelhead population does not currently meet viability criteria because the abundance/productivity parameter is assigned a High risk rating and the overall spatial structure/diversity parameter, Moderate risk. The lack of direct estimates of abundance and productivity for this population was a factor in assigning a high risk rating (ICTRT 2009).

Limiting Factors and Threats

The reasons for a species' decline are generally described in terms of limiting factors and threats. Analysis of limiting factors and threats across the entire species' life cycle forms the basis for designing recovery strategies and actions. NMFS defines limiting factors as the biological and physical conditions limiting DPS and population status (e.g. elevated water temperature), and defines threats as those human activities or naturally induced actions that cause the limiting factors (e.g. removal of riparian vegetation for agricultural or residential purposes, which causes loss of shade and, consequently, elevated water temperature).

While the term "threats" carries a negative connotation, it does not mean that activities identified as threats are inherently undesirable. They are typically legitimate human activities that may at times have unintended negative consequences on fish populations—and that can also be managed in a way that minimizes or eliminates the negative impacts.

For steelhead and other salmonids, survival to reproduce depends on a complex, interacting system of environmental conditions, with different conditions needed for each life stage. Optimal water temperature, for example, varies (within limits) for adult migration vs. egg incubation or juvenile rearing. In addition, the particular factors limiting production may vary across different sections of the tributary drainage used by a particular population. Data on a full range of potential limiting factors is rarely available at the reach level.

The list of potential limiting factors for the Rock Creek steelhead population, as for the other populations that make up the Middle Columbia steelhead DPS, is based on a substantial body of research on salmonids, local field data and field observations, and the considered opinions of regional experts. These are implicitly hypothetical statements to be tested, made with the expectation that by taking action in the face of some degree of scientific uncertainty, monitoring the results, continuing to conduct research to further characterize the factors limiting the population, and adapting our management actions in response, the state of our knowledge will improve and so will the survival of these fish, although not necessarily in a directly parallel process.

Freshwater Habitat

Habitat factors (e.g. temperature) may limit steelhead production in the Rock Creek watershed and, to some extent past and/or current land use practices may constitute threats that stress naturally occurring conditions. For example, anthropogenic changes in the subbasin may have reduced stream shade in some reaches and thereby increased the intensity of low summer flows and high summer water temperatures that likely occur naturally in some parts of the watershed because of aspect, low precipitation and high width-to-depth ratios.

The factors potentially limiting freshwater steelhead productivity within the Rock Creek watershed include degraded channel structure and complexity (lack of key habitat quantity and habitat diversity), riparian function and condition, and floodplain function and channel migration processes; low summer flows, high summer water temperatures, increased fine sediment, altered food web, predation, and competition with exotic species such as smallmouth bass. Section 5 provides more detail on limiting factors.

- *Hydrograph*: Seasonally low to intermittent and/or subsurface stream flows are potentially a primary factor that limits steelhead production in the Rock Creek. The hydrograph in the Rock Creek system is naturally flashy, with high intensity, short duration flow. Currently, low to nonexistent flows in the mainstem and many tributaries during late summer, fall and early winter might limit juvenile steelhead production and mobility. In 2008, sufficient pool volume was available

to support an estimated population of 38,300 to 95,700 age-0 steelhead (Glass 2009).

- *Stream temperature:* Seasonally high water temperature is potentially a primary factor limiting steelhead production in the Rock Creek watershed (Glass 2009). Average daily summer water temperatures in the lower Rock Creek subbasin sometimes rise above 63.5°F (17.5°C), and in some reaches rise above 73.4°F (23.9°C) (Aspect Consulting 2005), a level considered potentially lethal for steelhead and other salmonids (Glass 2009). One headwater reach of Rock Creek is listed on the Washington State Department of Ecology's 2008 water quality assessment (303(d) list as impaired, Category 5 (Washington Department of Ecology 2008).

- *Riparian function and condition*: Rock Creek's rocky substrate and steep topography inhibit riparian forest stand development along many reaches. However, current riparian condition and function in some sections of Rock Creek have been disturbed due to wildfires, recent major flood events, past and current grazing, historical timber practices, road construction, and/or other land uses. Despite these influences, the amount of vegetation in the valley bottom has been increasing steadily since 1938, presumably due to fire suppression (Aspect Consulting 2005).

- *Channel structure and complexity:* Findings from a reconnaissance survey of portions of Rock Creek indicate that the creek's general channel characteristics may be similar to those noted in a 1860s survey (e.g., broad rocky reaches), with the exception that the lowermost reach may be somewhat wider today than historically (Aspect Consulting and WPN 2004). In-channel and riparian habitats in some stream reaches may be degraded because of disturbance from grazing, historic timber harvest, road construction, and other anthropogenic changes, and from major flood events. Inundation of the one-mile reach above Rock Creek's mouth by the pool behind John Day Dam (Columbia River) has altered key habitat quantity and complexity.

- *Floodplain function and channel migration processes*: The effects from several threats locally influence channel migration processes and morphology. Bridges on the Bickleton Highway (scheduled for replacement) and Old Highway 8 locally constrain flow and channel migration processes. The stream channel in lower Rock Creek is highly dynamic and moves across the valley bottom with regularity, often switching channels during flood flows (Aspect Consulting 2005). One of the more dynamic sections of the stream channel is upstream of the Old Highway 8 Bridge, where the channel changed courses many times over the period of photo record, and has distinctly different courses in 1938, 1969, 1996, and 2002 (Aspect Consulting 2005). This section of the creek also is one of the least densely vegetated along the mainstem of Rock Creek (Aspect Consulting 2005), reflecting the dynamic nature of the channel.

- *Sediment routing:* Sediment loads (the percentage of fines in spawning gravel, embeddedness and turbidity) in the Rock Creek subbasin may have increased over historical conditions; however, recent data indicates that the percent fines in spawning gravels is within a range that is unlikely to significantly affect survival of eggs and alevins in redds (Glass 2009).

- *Competition for food sources:* Changes in the hydrologic regime and riparian conditions could potentially affect the food web. No data are available regarding food sources in Rock Creek.

- *Predation and competition*: The building of the John Day Dam and subsequent inundation of the bottom mile of Rock Creek introduced exotic piscivorous fish such as smallmouth bass and channel catfish to the lower mile and reservoir and made it possible for these fish to travel up Rock Creek. Exotic piscivorous species have been observed in Rock Creek up to approximately one mile above the Old Hwy. 8 bridge (RM 3.5-4) (G. Morris, pers. comm. 2006). However, no exotic fish were observed upstream of the inundated area of the creek during snorkel surveys conducted in 2008 (Glass 2009).

Harvest

Without more data on Rock Creek steelhead abundance, and without targeted tagging of Rock Creek fish, the percentage of Rock Creek steelhead that are harvested in the Columbia River cannot be specifically calculated. However, it may be inferred that Rock Creek steelhead are subject to the same relatively low overall harvest rate estimated for other Middle Columbia steelhead. Washington Department of Fish and Wildlife (2008) estimates that in 2002, tributary fisheries in the Rock Creek area affected about 1 percent of the adult steelhead and less than 1 percent of the juvenile steelhead. Mainstem non-treaty commercial and recreational fisheries have an estimated impact of 1.6 percent of the A-run Middle Columbia steelhead (NMFS 2008a), and mainstem treaty fisheries have an estimate 6.64 percent impact (NMFS 2008a) for an overall estimated harvest impact of less than 10.24 percent.

Hatcheries

Steelhead are not stocked in Rock Creek, and very few fin-clipped steelhead have been seen in the subbasin. Hatchery strays of upriver origin may enter and spawn in Rock Creek, but the effects of out-of-subbasin hatchery programs on the Rock Creek steelhead population are unknown. Nevertheless straying, especially by non-indigenous hatchery steelhead, remains a concern.

Out-of-Subbasin Limiting Factors and Threats

Out-of-subbasin factors are discussed briefly in Section 5.3 and provide information on the influences from harvest, the Columbia River hydrosystem, and ocean conditions. The 2008 FCRPS Biological Opinion (NMFS 2008b) details the influences from the Columbia River hydrosystem on Middle Columbia steelhead populations. The Columbia River Estuary Module http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-

Recovery -Plans/upload/Estuary-Module.pdf discusses factors that limit viability of Rock Creek steelhead in the Columbia River Estuary.

Recovery Strategy and Actions

In Chapter 6, a recovery strategy is described to address the significant data gaps and uncertainties regarding the status of the Rock Creek steelhead population and to address the potential limiting factors based on the existing, best available science. In addition, Appendix II details the many efforts already underway to improve and protect watershed conditions in the Rock Creek subbasin—efforts that will benefit salmonids as well as other wildlife and human communities.

The overall aim of the recovery strategy is to gather needed data on the Rock Creek steelhead population and the watershed, while also addressing the potential limiting factors in a manner that is most likely to contribute to improved viability. The strategies and actions were defined through review and analysis of currently available information. They are consistent with actions identified in the Lower Mid-Columbia Mainstem Subbasin (including Rock Creek) Management Plan (NPCC 2004), and address risks identified in the ICTRT's viability assessment for the population. A collaboratively designed implementation program that includes a research, monitoring, and evaluation (RM&E) plan to support adaptive management will allow managers the flexibility to continue or change course in response to new information.

Gather Information on VSP Parameters

Information on population abundance, productivity, spatial structure, and diversity is needed to set priorities and determine the actions that will make the greatest contribution to steelhead recovery. Needed actions include initiating systematic surveys to calculate abundance and productivity, completing a gap analysis, characterizing spatial distribution and genetic variation, and evaluating hatchery contribution to naturally spawning steelhead in the Rock Creek subbasin.

Protect and Conserve Existing Good Quality Habitat

Protecting existing good quality habitat is a high priority. Many objectives are likely to be met through habitat protection and the associated natural recovery of upland and riparian areas. Protection and maintenance includes compliance with existing rules and regulations, such as the State Forest Practices Act, the State Shorelines Act, and other State, County, and local regulations designed to protect aquatic habitat. Protection may also incorporate a wide range of voluntary actions such as fencing riparian areas, participation in the various agricultural land reserve programs, and voluntarily implementing programs that help to avoid impacts to aquatic resources. Land acquisitions, easements, cooperative agreements, and protective land designations can also be used to facilitate high quality habitat protection.

Restore and Enhance Habitat and Gather Information

Restoration and enhancement of habitat conditions for salmon and steelhead populations should improve population production. The value of these actions to the viability of the population will depend on whether or not they address the factors currently limiting the population or threats associated with factors that are now, or are trending toward, becoming limiting, e.g. climate change. The success of these strategies is further enhanced when actions build from existing restoration efforts and incorporate a range of project types.

- Conduct research to further evaluate factors and threats limiting habitat diversity in the Rock Creek watershed. This information is needed to prioritize and focus restoration and enhancement activities.

- Improve instream flow during critical periods. The seasonally low to intermittent stream flow in the area of steelhead distribution upstream of the Columbia River backwater is a likely limiting factor on abundance, productivity, spatial structure, and diversity. Low flow can result in stranding and mortality to eggs or juvenile steelhead. Further study is required to determine causes of low flow, whether anthropogenic or natural, and options to enhance stream flow.

- Improve water quality, reduce summer high temperatures. Water temperature is directly related to riparian vegetative cover and other watershed characteristics such as channel complexity, floodplain function, and upland processes. Hence, many types of habitat actions are likely to function together to improve water quality, particularly water temperature. The more directly related actions to improve water quality include the following:
    - Restore riparian vegetative cover with appropriate native vegetation to increase shading.
    - Develop sediment control basins.
    - Manage livestock grazing in the riparian areas.
    - Increase deep pool habitat.

- Improve/restore riparian function and condition. Actions to address this potential limiting factor include the following:
    - Restore riparian vegetative cover with appropriate native vegetation.
    - Manage livestock grazing in riparian areas.
    - Eradicate invasive plant species from riparian areas.
    - Relocate beaver to suitable areas.

- Increase key habitat by improving or restoring channel structure and complexity. Key habitat, as described in Chapter 5, refers to characteristics such as riffles, pools, suitably aerated gravel, etc. that are essential to each steelhead life stage. The following actions would increase key habitat:
    - Introduce large woody debris (LWD) and other structures in stream as appropriate.
    - Improve riparian vegetation to provide future source of LWD.
    - Stabilize and protect stream banks.

- Fertilize streams with fish carcasses.

- Improve and/or restore floodplain function and channel migration processes. Reconnecting floodplain habitats and side channels would provide additional sheltered rearing areas. Increasing LWD and other actions such as relocating floodplain infrastructure where feasible, implementing road management BMPs or decommissioning roads as appropriate, could restore floodplain function, moderate the "flashiness" of the stream, and moderate peak flows.

- Improve or restore optimal sediment processes. Watershed processes of runoff and sediment production can be improved through restoring native upland plant communities, implementing appropriate upland management practices, managing off-road vehicle usage to reduce erosion and fine sediment, and managing roads to reduce fine sediment inputs to the stream.

- Conduct research to determine status of food web and presence or absence of competition from other species for food resources.

- Conduct research to determine presence and extent of predation on steelhead by non-native species such as piscivorous fish.

Review and Reduce Effects of Harvest

As described in Chapter 5, only adipose fin-clipped steelhead are allowed to be retained in sport or recreational fisheries in Rock Creek and throughout the Columbia River, but wild steelhead may be accidentally caught and/or retained. Poaching is also considered a problem. Actions to address harvest effects include better review of current practices, enforcement of regulations, and considering whether any modifications are needed. Outreach and education to reduce retention or handling mortality is also recommended.

Research Effects of Hatchery Fish (If Any)

As described in Chapter 5, hatchery strays of upriver origin may enter and spawn in Rock Creek, but no data are available on this issue. Monitoring for hatchery fish should be included in the RM & E program to be developed collaboratively after this plan is adopted.

Address Out-of-Subbasin Limiting Factors

Out-of-subbasin limiting factors for Rock Creek steelhead may include hydroelectric operations, harvest, interactions with hatchery fish, predation, food, disease, competition, and ocean conditions. Actions to address these factors for all Middle Columbia steelhead are presented in the Columbia River Estuary Module (NMFS 2007b) and the 2008 FCRPS Biological Opinion (NMFS 2008b), summarized in the Hydro Module (NMFS 2008c). Table ES-1 summarizes the recovery strategy designed to improve the viability of Rock Creek steelhead. The table links strategies and actions to the factors and threats potentially limiting steelhead viability in the subbasin, and the viability parameters and life stages that would be most affected. Priority locations are provided for some

strategies, with stream reaches or areas where actions should be applied first to gain the greatest benefit.

Table ES-1. Recovery Strategy and Actions for the Rock Creek Population of Middle Columbia Steelhead.

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
Gather information on population size and productivity	• Gather information to calculate abundance and productivity estimates	Entire Watershed	Addresses a primary risk factor	N/A	N/A	abundance and productivity	N/A
Gather information on population spatial structure and diversity	• Conduct surveys to determine steelhead distribution. • Identify major life history strategies • Conduct studies to address genetic variation in the population • Assess the contribution of hatchery-origin steelhead to the natural spawning population	Entire Watershed	Addresses a primary risk factor	N/A	N/A	spatial structure and diversity	N/A
Gather information to further evaluate habitat limiting factors and threats in the basin	• Conduct surveys to evaluate factors affecting habitat quantity. • Conduct surveys to evaluate factors affecting habitat quality. • Conduct surveys to evaluate factors affecting habitat function.	Entire Watershed	Addresses a primary risk factor	N/A	All life stages	All VSP parameters	N/A
Protect and conserve natural ecological processes that support steelhead viability throughout the life cycle	• Apply BMPs to livestock grazing practices • Apply BMPs to road system management • Apply BMPs to agricultural practices to control erosion and runoff • Manage stream corridor through conservation easements and/or land acquisition from willing sellers • Adopt and manage cooperative agreements	Throughout watershed	Key habitat quality and diversity, sediment inputs, water quality, stream flow	Road and grazing management activities	All life stages	abundance, productivity, spatial structure and diversity	Immediate for sediment, other parameters 5-15 years

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
Improve instream flow during critical periods	• Most of the actions listed in other categories are likely to improve stream flow. • Protect springs	Rock Creek downstream of RM 19.2, lower Squaw Creek, upper watershed	Channel morphology, habitat diversity, key habitat quantity, fine sediment, flow, water tempera-ture, thermal refugia, altered food web	Road and grazing management, channelization	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve water quality, reduce summer water temperatures	• Restore riparian vegetative cover with suitable native vegetation to increase shading • Restore natural habitat functions and processes through actions previously identified • Develop sediment control basins • Management livestock grazing in the riparian areas • Increase deep pool habitat	Rock Creek downstream of RM 19.2, lower Squaw Creek, upper watershed	Channel morphology, habitat diversity, key habitat quantity, fine sediment, flow, water temperature, thermal refugia	Road and grazing management,, particularly in riparian areas, channelization	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve and/or restore riparian function and condition	• Restore riparian vegetation cover with appropriate native vegetation • Manage grazing in riparian areas • Eradicate invasive plant species from riparian areas • Relocate beaver to suitable areas	Rock Cr. Below unnamed trib. at RM 19.2, Luna Gulch, lower Squaw Cr.	Hydrology, channel stability, fine sediment, water quality, key habitat quantity, habitat diversity, riparian vegetation	Road and grazing management activities	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve and/or restore channel structure and complexity	• Introduce LWD and other structure in stream as appropriate • Improve riparian vegetation to provide future source of LWD • Stabilize and protect stream banks • Fertilize streams with fish carcasses	Rock Creek downstream of RM 19.2, lower Squaw Creek, headwater streams	Channel morphology, habitat diversity, key habitat quantity, fine sediment, flow, water temperature, thermal refugia, altered food web	Road and grazing management, channelization	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve and/or restore floodplain function and	• Reconnect floodplain habitats • Reconnect side channels	Rock Cr. Below	Channel morphology,	Road and grazing	Juvenile rearing stage	abundance and productivity	0-10 years

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
channel migration processes	• Increase role and abundance of wood and large organic debris in streambeds • Relocate floodplain infrastructure, roads; improve maintenance, rehabilitate, decommission as appropriate • Remove dikes • Relocate beaver to suitable areas	unnamed trib. at RM 19.2, Luna Gulch, lower Squaw Cr.	habitat diversity, key habitat quantity, riparian vegetation, fine sediments, flow, water temperature	management activities			
Address upland processes to minimize unnatural rates of erosion and runoff	• Restore native upland plant communities • Implement upland management practices to restore natural runoff and sediment production • Implement off-road vehicle management actions that reduce erosion and fine sediment • Implement road management actions that reduce fine sediment inputs	Upper watershed	Hydrology, channel stability, fine sediment, water quality, key habitat quantity, habitat diversity, riparian vegetation	Road and grazing management activities and off-road vehicles	Egg, fry	abundance and productivity	0-50 years
Review and reduce effects of harvest on the Rock Creek steelhead population	• Review the need for modifications to sport, tribal, and commercial harvest practices on direct catch and by-catch • Increase outreach efforts to reduce the number of steelhead caught in recreational fisheries near the mouth of Rock Creek	All fishing areas in the basin, the Columbia River, and off-shore	Direct mortality	Harvest	Adult migrants	abundance	0-10 years
Research and reduce hatchery effects on the Rock Creek steelhead population	• Reduce the uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish • Monitor the potential for hatchery strays entering Rock Creek • Increase the proportion of Columbia River Basin hatchery steelhead marked with coded-wire	Columbia River and anadromous reaches of Rock Creek	Competition, genetic introgression	Hatchery releases	Juvenile and adult	abundance, spatial structure, diversity	2-10 years

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
	tags, especially in programs shown to stray at high rates in the past, and support the mass marking of all hatchery steelhead releases with, at a minimum, an adipose fin-clip						
Reduce competition with and predation by non-native piscivores	• Reduce the number of non-native predators	Columbia River and mouth of Rock Creek	Predation	Non-native species	fry and juvenile	abundance and productivity	2-20 years
Reduce mortality and/or improve passage at hydroelectric facilities	• Implement strategies and actions in the FCRPS Biological Opinion (NMFS 2008b)	Columbia River	Passage, predation, direct mortality	Hydroelectric plants	juvenile and adult	abundance	0-20 years

Implementation

Implementation of this plan depends on the voluntary actions and cooperation of local entities and citizen groups. An important part of implementation will be working cooperatively to develop an implementation schedule that includes site-specific actions and a detailed research, monitoring, and evaluation (RM&E) plan addressing the information needs described in Chapter 8. A detailed RM&E plan should be developed collaboratively after the Rock Creek recovery plan is adopted.

NMFS has worked independently with the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, and local entities to develop the recovery plan for the Rock Creek steelhead population. NMFS encourages the formation of a planning group for the Washington Gorge Management Unit, a forum or entity that would take responsibility for coordinating implementation of the plan. Implementing the proposed recovery actions for steelhead in the Washington Gorge Management Unit, including the Rock Creek subbasin, would be a primary task for a Washington Gorge Area Regional Board, subject to concurrence by state, tribal, and local governments and the opportunity for involvement and comment by the public.

In addition to their co-management responsibility and key role on a Gorge recovery board (if one is formed), the Yakama Nation will play an important role during implementation because of their funding agreement under the Columbia Basin Fish Accords, which are three Memorandums of Agreement (MOAs) entered into between the Federal Columbia River Power System (FCRPS) action agencies (Bonneville Power Administration, U.S. Army Corps of Engineers and the Bureau of Reclamation), four tribes, and one state. The most relevant MOA to the Middle Columbia River steelhead is with the Columbia River Inter-Tribal Fish Commission and the three treaty fishing tribes—Confederated Tribes of the Umatilla Indian Reservation; Confederated Tribes of the Warm Springs Reservation; and Confederated Tribes and Bands of the Yakama Nation. The MOAs are 10-year action agency commitments for projects to benefit fish affected by the FCRPS, with a focus on ESA-listed fish. The projects will be reviewed through the Northwest Power Act processes for implementing the Fish and Wildlife Program, administered by the Northwest Power and Conservation Council. The agreement secures approximately $200,000 per year for habitat actions, including project management, in the Rock Creek subbasin. Some of the projects listed in Table 7.1 will be implemented with these funds.

Cost Estimates

There are existing Federal, tribal, state, county, and other local programs that are being carried out in the Rock Creek subbasin. Many of those programs are described in Appendix II. This plan assumes that those existing programs are funded, and will continue to be. At this time, this plan provides only additional incremental costs that would be incurred with implementation of this recovery plan. Total time and cost of recovery is estimated for the DPS as a whole and is iincorporated into Chapter 8 of the Middle Columbia River Steelhead DPS Recovery Plan. As implementation proceeds and implementation schedules are developed, the costs of both existing programs and new incremental costs of this recovery plan will be included in those schedules. If existing

programs are not funded, funding will be identified as a need in the implementation schedule and the cost estimates for the recovery plan adjusted accordingly.

In this chapter, cost estimates are provided for an extensive and reach-specific set of potential habitat actions that will be refined and prioritized in the implementation process. NMFS, in coordination with the Yakama Nation, developed these cost estimates for a range of habitat improvement/restoration actions that may be necessary to address limiting factors and improve viability of the Rock Creek steelhead population. These costs, presented in Table 7-1 (in Chapter 7), are general range summaries. Habitat action costs for recovery over a 10-year time period are estimated to be up to $1.8 million ($0.9 million for years 1-5). The actions listed in Table 7-1 do not include or account for RM&E (Section 6.1.1), because those costs will be developed as part of implementation planning, nor do they account for tributary fishery harvest management and enforcement activities (Section 6.1.4), which are considered existing programs, nor for costs of out-of-subbasin effects, which are addressed through other programs (Section 6.1.6).

RM&E and Adaptive Management Framework

Comprehensive, empirical monitoring data on fish populations and habitat are needed to identify appropriate projects and locations, populate habitat/production capacity modeling efforts (such as EDT, AHA, or other appropriate models), and inform adaptive management for the salmonid recovery plan. Information on fish distribution, abundance, productivity, habitat conditions, genetic diversity, pathogen levels, and other population parameters, as well as on population limiting factors, is necessary to help direct and evaluate these efforts. A coordinated monitoring program is needed to ensure that these various needs, including salmonid recovery planning, are met.

As part of implementing the Rock Creek steelhead recovery plan, a detailed monitoring and evaluation program will be collaboratively designed and incorporated into an adaptive management framework based on the principles and concepts laid out in the NMFS' guidance document, Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance (NMFS 2007a) http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf. The Rock Creek subbasin monitoring and evaluation program will build on existing programs designed for monitoring tributary habitat in the Rock Creek subbasin and will emphasize regional coordination.

1. Introduction

The Endangered Species Act of 1973 (ESA) requires NOAA's National Marine Fisheries Service (NMFS) to develop recovery plans for species listed under the Act. The purpose of recovery plans is to identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA.

This plan focuses on the conservation and survival of Middle Columbia River steelhead (*Oncorhynchus mykiss*) in the Rock Creek subbasin, which encompasses an area of 223.2 sq. miles (578.1 sq. km) in southeastern Washington and joins the Columbia River at RM 230, about 12 miles upstream of John Day Dam (Figure 1-1). Lake Umatilla, the reservoir behind the dam, inundates the lower mile of Rock Creek.

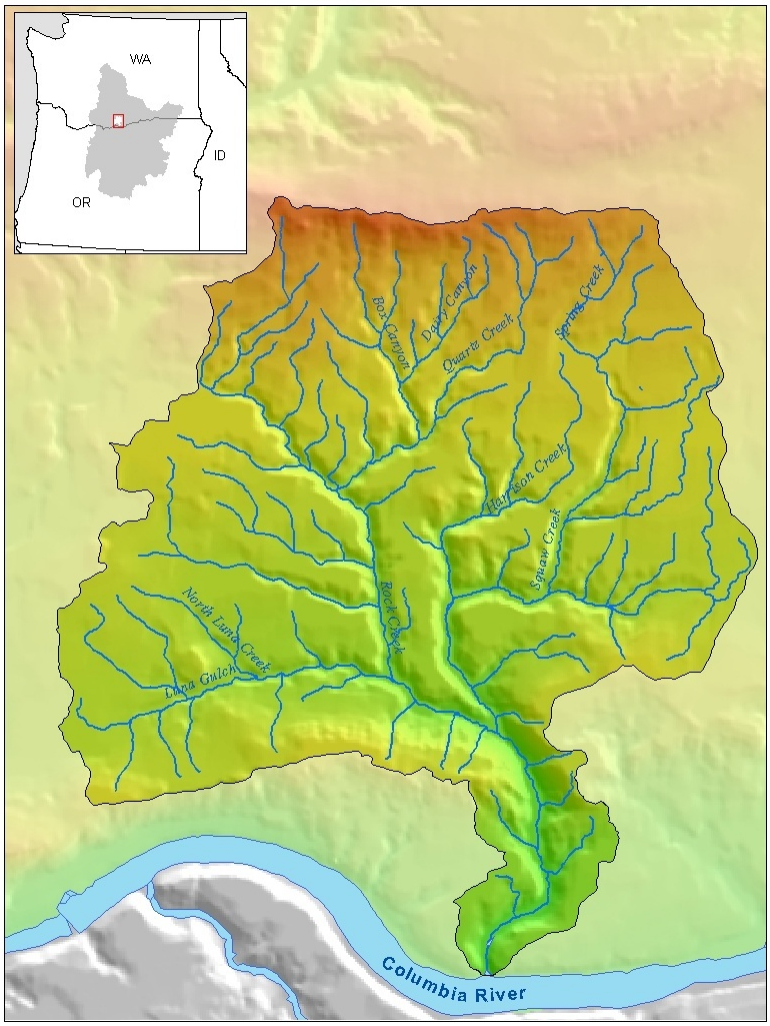

Figure 1-1 Rock Creek Subbasin.

"Steelhead" is the name commonly applied to the anadromous form of the biological species Oncorhynchus mykiss. The common name of the non-anadromous, or resident, form is rainbow trout. When NMFS originally listed the species as threatened on March 25, 1999 (64 FR 14517), it was classified as an "evolutionarily significant unit" (ESU) of salmonids that included both forms. Recently, NMFS revised its species determinations for West Coast steelhead under the ESA, delineating anadromous, steelhead-only "distinct population segments" (DPS) (Good et al. 2005). NMFS listed the Middle Columbia River steelhead DPS as threatened on January 5, 2006 (71 FR 834). Rainbow trout are under the jurisdiction of the U.S. Fish and Wildlife Service (USFWS). The DPS is made up of steelhead populations in Oregon and Washington tributaries of the Columbia River upstream of the Hood and Wind River systems, up to and including the Yakima River. Reasons for listing the Middle Columbia River steelhead DPS included low returns to the Yakima River, poor abundance estimates for Klickitat River and Fifteenmile Creek winter steelhead, and an overall decline of naturally producing "stocks" within the DPS.

NMFS developed this recovery plan with involvement and input from the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal agencies, state agencies, local governments, and the public. While NMFS is directly responsible for ESA recovery planning for salmon and steelhead, NMFS believes that ESA recovery plans for salmon and steelhead should be based on the many state, regional, tribal, local, and private conservation efforts already underway throughout the region. Local support of recovery plans by those whose activities directly affect the listed species, and whose actions will be most affected by recovery efforts, is essential. NMFS therefore supports and participates in locally led collaborative efforts to develop recovery plans that involve local communities, state, tribal, and Federal entities, and other stakeholders.

1.1 Purpose of Plan

This Plan provides a roadmap for restoring the Rock Creek steelhead population and its habitats to a level that supports recovery of the Middle Columbia River steelhead DPS and allows the population to become a viable component of its ecosystem. The Plan is a guidance document. It describes the current status of the Rock Creek population and its habitat, and summarizes the results of a technical assessment of the population's viability. The Plan also identifies the factors and threats potentially affecting the population and proposes strategies and actions designed to aid in the population's recovery. Finally, the Plan provides an implementation and adaptive management framework for making needed future adjustments on the road to recovery.

1.1.1 ESA Requirements

Section 4(f) of the ESA requires that a recovery plan be developed and implemented for species listed as endangered or threatened under the statute.

ESA section 4(a)(1) lists factors for re-classification or delisting that are to be addressed in recovery plans:

A. The present or threatened destruction, modification, or curtailment of [the species'] habitat or range
B. Over-utilization for commercial, recreational, scientific or educational purposes
C. Disease or predation
D. The inadequacy of existing regulatory mechanisms
E. Other natural or human-made factors affecting its continued existence

ESA section 4(f)(1)(B) directs that recovery plans, to the extent practicable, incorporate:

1. a description of such site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species;
2. objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this chapter, that the species be removed from the list; and;
3. estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal.

In addition, it is important for recovery plans to provide the public and decision makers with a clear understanding of the goals and strategies needed to recover a listed species and the science underlying those conclusions (NMFS Interim Recovery Planning Guidance, 2007).

Once a species is deemed recovered and therefore removed from a listed status, section 4(g) of the ESA requires the monitoring of the species for a period of not less than five years to ensure that it retains its recovered status.

1.1.2 Coordination with Others

The Plan aims to provide consistency among related recovery planning and management efforts, including NMFS' Federal treaty and trust responsibilities and the many state and local entities involved in salmon recovery.

Federal Treaty and Trust Responsibilities

Northwest Indian tribes have legally enforceable rights reserving to them a share of the harvestable salmon and steelhead. Achieving the basic purposes of the ESA such that the species no longer needs the protection of the Act may not by itself fully meet these rights and expectations, although it will lead to major improvements in the current situation. Ensuring a sufficient abundance of salmon to sustain harvest can be an important element in fulfilling trust and treaty rights as well as garnering public support for these plans.

It is NMFS policy that recovery of salmonid populations must achieve two goals: (1) the recovery and delisting of salmonids listed under the provisions of the ESA, and (2) the restoration of the meaningful exercise of tribal fishing rights. "It is the agency's view that there is no conflict between the statutory goals of the ESA and Federal trust responsibility to Indian tribes" (Letter from Terry Garcia, Assistant Secretary for Oceans and

Atmosphere, to Ted Strong, Executive Director, Columbia Inter-Tribal Fish Commission, July 21, 1998). Additionally, NMFS "will continue to join with states and tribes to develop a comprehensive approach to the restoration of fish and wildlife resources in a manner that fulfills all obligations under Federal law, including trust obligations to Indian tribes" (ibid.).

Thus, it is appropriate for recovery plans to take these considerations into account and plan for a recovery strategy that includes harvest. In some cases, the desired abundances for harvest may come about through increases in the naturally spawning population. In others, the recovery strategy may include appropriate use of hatcheries to support a portion of the harvest. So long as the overall plan is likely to achieve the biological recovery of the listed ESU, it will be acceptable as a recovery plan.

Treaty Indian fishing rights in the Columbia basin are under the continuing jurisdiction of the U.S. District Court for the District of Oregon in the case of *United States v. Oregon*, No. 68-513 (filed in 1968). The parties to *U.S. v. Oregon* are the United States acting through the Department of Interior (USFWS and Bureau of Indian Affairs) and Department of Commerce (National Marine Fisheries Service), the Warm Springs, Umatilla, Nez Perce, Yakama, and Shoshone-Bannock Tribes, and the states of Oregon, Washington, and Idaho. In *U.S. v. Oregon*, the Court affirmed that the treaties reserved for the tribes 50 percent of the harvestable surplus of fish destined to pass through their usual and accustomed fishing areas.

The Rock Creek subbasin is part of the Yakama Nation's ceded area, and home to the Rock Creek Band of the Confederated Bands and Tribes of the Yakama Nation. Yakama Nation staff developed much of the data on the Rock Creek population. The Yakama Nation is voluntarily participating in recovery planning and implementation in the Rock Creek subbasin and throughout its ceded area as a sovereign with treaty-reserved rights on and off the reservation, and as a fish and wildlife co-manager. In so doing, Yakama Nation does not waive or in any way alter its treaty-reserved rights.

Other Federal, State and Local Responsibilities

To ensure consistency in goals, strategies, and actions and to eliminate needless duplication of effort, the process aims to provide consistency between planning for ESA recovery, the Northwest Power and Conservation Council (NPCC) fish and wildlife program, the State of Washington watershed management and salmon recovery programs, and local planning and regulatory efforts.

The Plan follows ESA guidelines and builds upon direction for Rock Creek in the Lower Mid-Columbia Mainstem Subbasin Plan (NPCC 2004), which included information provided by Yakama Nation, Washington Department of Fish and Wildlife, and other Federal, state, and local entities. The NPCC adopted the subbasin plan into its Fish and Wildlife Program. Additional scientific data are drawn from other more recent sources, including technical products for WRIA 31 and those developed by the technical recovery team appointed by NMFS for the Interior Columbia recovery domain.

1.2 Context of Plan Development

Currently there are 19 ESA-listed ESUs /DPSs of Pacific salmon and steelhead in the Pacific Northwest. For the purpose of recovery planning for these species, NMFS Northwest Region designated five geographically based "recovery domains": Interior Columbia; Willamette-Lower Columbia; Puget Sound and Washington Coast; the Oregon Coast; and the Southern Oregon/Northern California Coast. The range of the Middle Columbia River steelhead DPS is located in the Middle Columbia sub-domain of the Interior Columbia domain (the other Interior Columbia sub-domains are the Snake River and Upper Columbia). Similar opportunities for technical and stakeholder involvement exist in each domain.

1.2.1 Technical Recovery Teams

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each Technical Recovery Team (TRT) is to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. The Interior Columbia TRT (ICTRT) included biologists from NMFS, states, tribes, and academic institutions.

All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population viability criteria – criteria to be used, along with criteria based on mitigation of the factors for decline, to determine whether a species has recovered sufficiently to be downlisted or delisted. These principles are described in a NMFS technical memorandum, Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units (McElhany et al. 2000). Viable salmonid populations (VSP) are defined in terms of four parameters: abundance, population productivity or growth rate, population spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework, based on data availability, the unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective experience and expertise. Although NMFS encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs worked from a common scientific foundation.

1.2.2 Planning Forums

In each domain, NMFS has worked with state, tribal, local and other Federal entities to develop planning forums that build to the extent possible on ongoing, locally led recovery efforts. NMFS defined "management units" based on jurisdictional boundaries as well as areas where citizen planning efforts were underway. The Mid-Columbia management units are (1) Oregon; (2) Washington Gorge, which, in turn, is subdivided into three planning areas, White Salmon, Klickitat, and Rock Creek; (3) Yakima subbasin; and (4) Southeast Washington. These management units have active planning and implementation forums, with the exception of the Washington Gorge Management.

In the Washington Gorge Management Unit, NMFS has worked independently with the Yakama Nation, Washington Department of Fish and Wildlife (WDFW), Klickitat County, and local entities to develop the recovery plan for the Rock Creek steelhead population. NMFS encourages the formation of a planning forum for the Washington Gorge Management Unit.

Several small tributaries to the Columbia River drain areas in eastern Washington State upstream of Rock Creek. These tributaries are included in the Washington Gorge Management Unit. There is evidence of steelhead spawning in some of them, but very little data are available. Appendix I summarizes the available information about these tributaries as it relates to recovery of Middle Columbia steelhead. NMFS considers investigating these areas lower priority than restoring the core populations of the DPS, but includes a description of the areas because they are in the management unit and may be of interest to scientists and stakeholders at some future date.

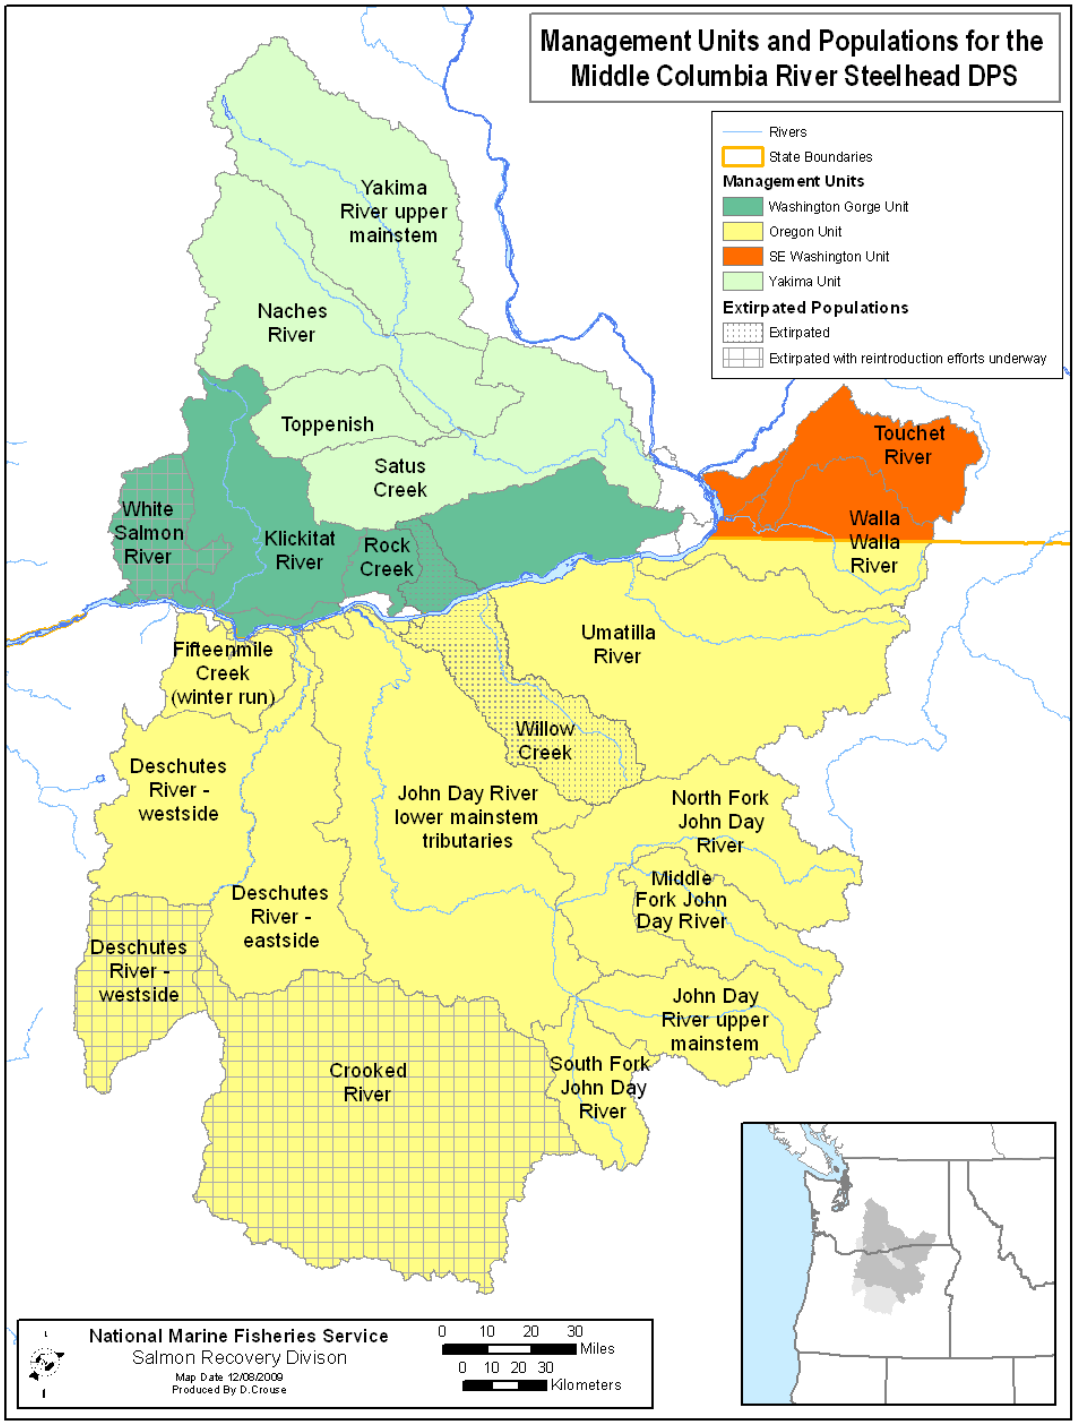

Figure 1-2 NMFS Management Units for the Middle Columbia Steelhead DPS.

1.3 How NMFS Intends to Use this Plan

Although recovery plans are not regulatory and their implementation is voluntary, they are important tools that help to do the following:

- Provide context for regulatory decisions.
- Guide decision making by Federal, state, Tribal, and local jurisdictions.
- Provide criteria for status reporting and delisting decisions.
- Organize, prioritize, and sequence recovery actions.
- Organize research, monitoring, and evaluation efforts.

NMFS will encourage Federal agencies and non-Federal jurisdictions to take recovery plans under serious consideration as they make the following sorts of decisions and allocate their resources:

- Actions carried out to meet section 7(a)(1) obligations to use their programs in furtherance of the purposes of the ESA and to carry out programs for the conservation of threatened and endangered species
- Actions that are subject to ESA sections 4d, 7(a)(2), or 10
- Hatchery and Genetic Management Plans and permit requests
- Harvest plans and permits
- Selection and prioritization of subbasin planning actions
- Development of research, monitoring, and evaluation programs
- Revision of land use and resource management plans
- Other natural resource decisions at the state, Tribal, and local levels

NMFS will emphasize recovery plan information in ESA section 7(a)(2) consultations, section 10 permit development, and application of the section 4(d) rule by considering:

- The importance of affected populations to listed species viability
- The importance of the action area to affected populations and species viability
- The relation of the action to recovery strategies and management actions
- The relation of the action to the research, monitoring, and evaluation plan for the affected species

In implementing these programs, recovery plans will be used as a reference and a source of context, expectations, and goals. NMFS staff will encourage the Federal "action agencies" to describe in their biological assessments how, within the action area, their proposed actions will affect individuals of specific populations and limiting factors identified in the recovery plans, and to describe any mitigating measures and voluntary recovery activities in the action area.

2. Biological Background

This chapter describes habitat and population characteristics for Middle Columbia River steelhead in the Rock Creek subbasin, and also fills in some important background on salmonid biological structure.

2.1 Physical Setting

Rock Creek joins the Columbia River at RM 230, about 12 miles upstream of John Day Dam. The watershed encompasses an area of 223.2 sq. miles (578.1 sq. km). Lake Umatilla, the reservoir behind the dam, inundates the lower mile of Rock Creek. Headwater tributaries of Rock Creek flow out of the Simcoe Mountains, which form the subbasin's northern border and the southern edge of the Yakama Indian Reservation. Major tributaries to Rock Creek include Badger Gulch, Harrison Creek, Luna Gulch, Quartz Creek, White Creek and Squaw Creek (Figure 2-1).

Figure 2-1. Geology and Stream Location of Rock Creek Subbasin (Aspect Consulting and WPN 2004).

The entirety of the Rock Creek subbasin is located within Klickitat County, and the subbasin's population, as of the 2000 census, was 503 persons. It is also part of the area the Yakama Nation ceded to the United States in the Treaty of 1855, while reserving fishing, hunting and gathering rights, among other rights and responsibilities. In the lower and eastern portions of the watershed, the Yakama Nation and its members own a significant amount of trust allotments.

Lands in the Rock Creek subbasin remain largely undeveloped, with nearly 47 percent rangeland, 26 percent forestland, and 4 percent dry land agriculture (Figure 2-2). Most forestland exists at upper elevations; range and agricultural lands generally cover the middle and lower watershed. No irrigated land was estimated to exist as of 2001 (Aspect Consulting and WPN 2004). Developed land accounts for less than one percent of the subbasin area (Aspect Consulting and WPN 2004), little of which is in the floodplain (http://klickitatcounty.org/Road/ContentROne.asp?fContentIdSelected=455695186&fCategoryIdSelected=948111261). Deeply incised canyons with narrow valley floors make up most of the upper portions of the fish-bearing tributaries.

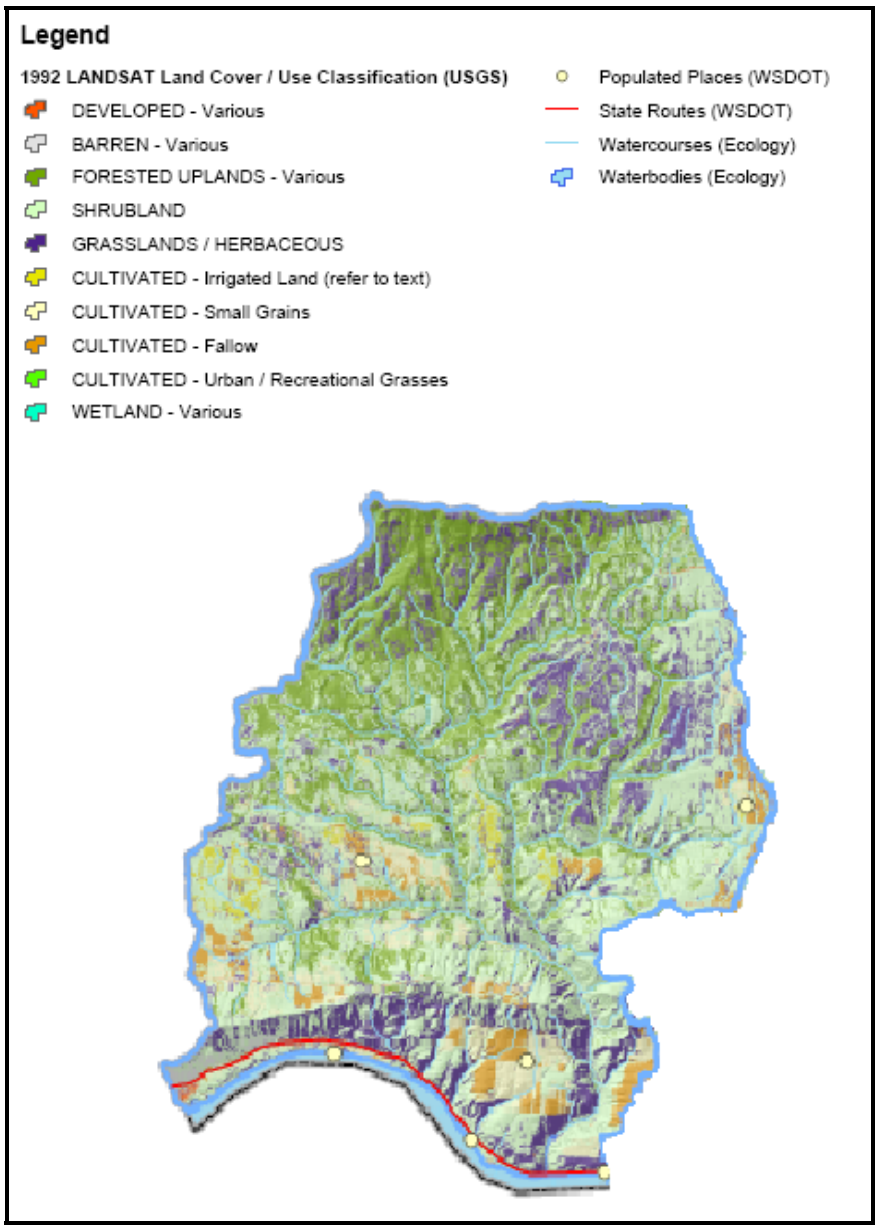

Figure 2-2. Land Use in the Rock Creek subbasin (Adapted from Aspect Consulting and WPN 2004).

2.1.1 Topography

The Rock Creek drainage has a steep topography; approximately 20 percent of the area has side slopes greater than 100 percent (Aspect Consulting and WPN 2004). This is reflected in the subbasin's great stream velocities and erosion potential. The underlying basalt geology also creates several potential barriers to upstream movement of adult anadromous fish, including partial barriers on Quartz Creek (RM 2.4) and upper mainstem Rock Creek (RM 19.4, RM 20.7, RM 22.7), as well as barriers on the upper Rock Creek mainstem (RM 23.1). A falls in Box Canyon (RM 0.3) is likely the only currently impassable barrier under most flow conditions (Greg Morris, pers. comm. 2006). No complete barriers (natural or manmade) to steelhead passage were identified

during a habitat survey conducted in 2008 within the area delineated as steelhead distribution (Glass 2009); however, not all of the area was surveyed, and barriers could exist in the unsurveyed portions of the basin. The average Rock Creek basin elevation is 2,162 feet (maximum 4,728 feet, minimum 266 feet) (Aspect Consulting and WPN 2004).

Streams in the Rock Creek subbasin share many similar geomorphic characteristics. From the headwaters, the streams cross a relatively flat basalt plateau at gradients of generally less than 1 percent. Headwater and plateau areas are primarily forested and presumed to be above most anadromous use. Coming off the plateau, streams enter steep-walled canyons where gradients increase to 2-4 percent or more, and substrates consist of gravel, cobbles, and boulders. Although limited by narrow floodplains, riparian vegetation in the canyon reaches is often of relatively good quality (Glass 2009). Suitable spawning gravel and rearing areas (pools) are intermittent and limited by geomorphic conditions. Downstream of the canyon reaches, streams flow through alluvial valleys that support agriculture and range uses. Gradients in these reaches generally drop from between 1 percent and 2 percent near the upper end to less than 1 percent as streams approach the Columbia River (Lautz 2000).

In several reaches of the lower river, large quantities of rock have been deposited where the grade breaks (Glass 2009). Through these avulsed areas, the channel is not well defined and often changes course during major flood events. The riparian vegetation along the creek in the avulsed area is sparse, largely due to the naturally unstable condition of the channel in those reaches. In the rest of the lower Rock Creek basin, riparian vegetation is highly variable (Aspect Consulting 2005). Substrate in alluvial reaches is dominated by gravel and cobble (Glass 2009).

2.1.2 Hydrology

Average annual precipitation in Rock Creek is 16.2 inches (Aspect Consulting and WPN 2004). Flows in the subbasin's canyon and alluvial reaches are considered flashy, rising and falling rapidly in response to precipitation and snowmelt. Snowmelt runoff from higher elevations appears to help sustain flows into early spring. Aspect Consulting and WPN 2004 report that the streams have eroded into and dissected the underlying basalt unit, which has resulted in truncated basalt interflow zones, such that the aquifer units are discontinuous and disconnected from recharge sources. The water flowing in these discontinuous aquifer zones discharges along seepage faces in the canyons (Aspect Consulting and WPN 2004). Numerous springs in the subbasin also discharge groundwater through the incised underlying basalt. These springwater releases may provide important cool water refuges for juvenile salmonids during the summer and early fall when stream flows are at their lowest and stream temperatures are high (NPCC 2004). The releases, however, are generally insufficient to sustain continuous stream flows in the lower subbasin during the dry season (Aspect Consulting and WPN 2004). No flow regulation occurs in the drainage, although small amounts of water are diverted for stock watering.

Stream flow data are very limited for the subbasin and consist of historical information (presence or absence of flow) collected by the General Land Office in the 1860s (reported in Aspect Consulting and WPN 2004), USGS recorded flows from 1962 to 1968, incomplete staff gauge data being collected by the Yakama Nation since 2005, a continuous flow gauge operated by the Washington Department of Ecology since November 2007 (https://fortress.wa.gov/ecy/wrx/wrx/flows/station.asp?wria=31), and spot measurements of flow taken by Eastern Klickitat Conservation District since 1995 (data for years 1995 to 2003 reported in Aspect Consulting and WPN 2004).

Flows in Rock Creek are typically seasonal, with no measured surface flow at the monitoring station in the summer months (Figure 2-3). The exception in the period of record is the summer of 1965, when flows were maintained as a result of an exceptionally wet winter and spring (Figure 2-4). Monthly median (50 percent exceedance) and low (90 percent exceedance) during August, September, and October are zero cfs (Figure 2-5; Aspect Consulting and WPN 2004). Pools are abundant in the basin even when stream flow is apparently zero. In late fall of 2008, no flow was apparent at the Department of Ecology flow gauge, yet at least 4,229 cubic meters of pool habitat were present. Pool volume in the reach inundated by Lake Umatilla and reaches on Tribal Trust lands were not included in the estimate (Glass 2009).

Historical information, coupled with observed intermittent conditions based on USGS stream gauge data in the 1960s, suggest that the streamflow in Rock Creek is naturally intermittent rather than a condition created by human development (Aspect Consulting and WPN 2004). Much of the runoff generally occurs in two or three discrete events (Figure 2-5). For example, in water year 2008-2009, much of the total runoff occurred during two major events in December, and the balance occurred at much lower levels in spring.

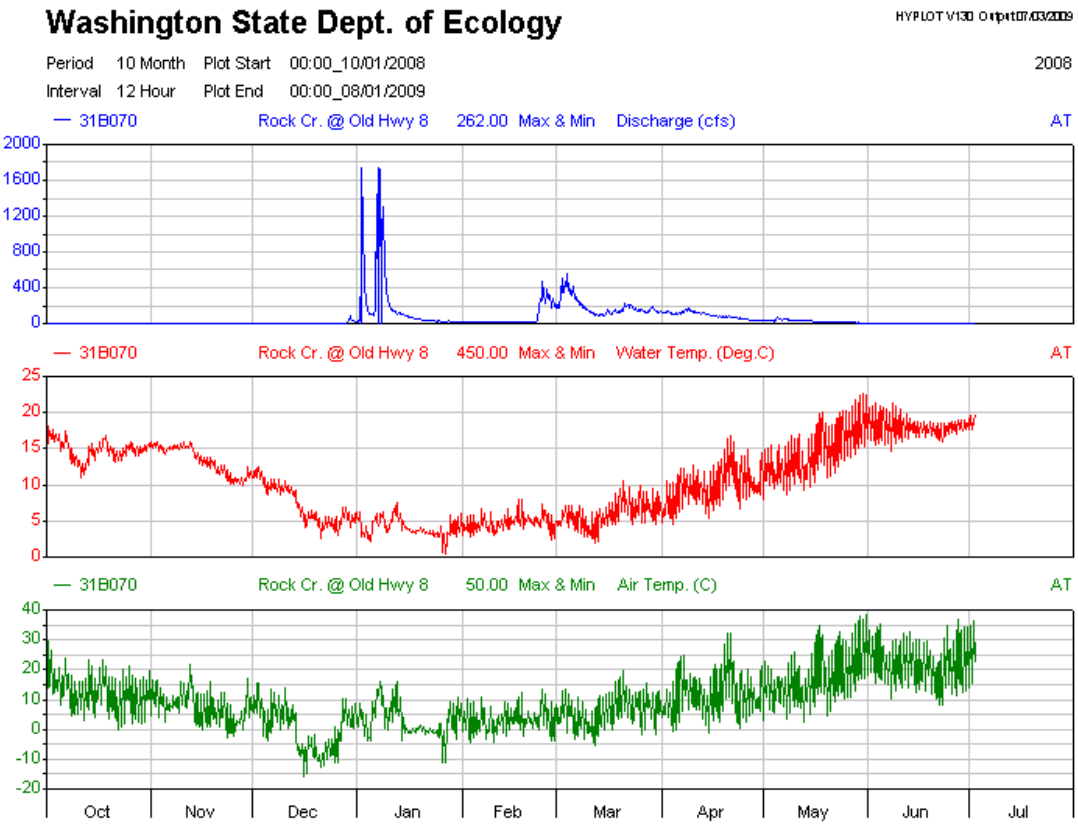

Figure 2-3. Stream flow, water temperature, and air temperature at the Washington Department of Ecology gage near the mouth of the Rock Creek. from October, 2008 to June 2009 (https://fortress.wa.gov/ecy/wrx/wrx/flows/station.asp?sta=31B070).

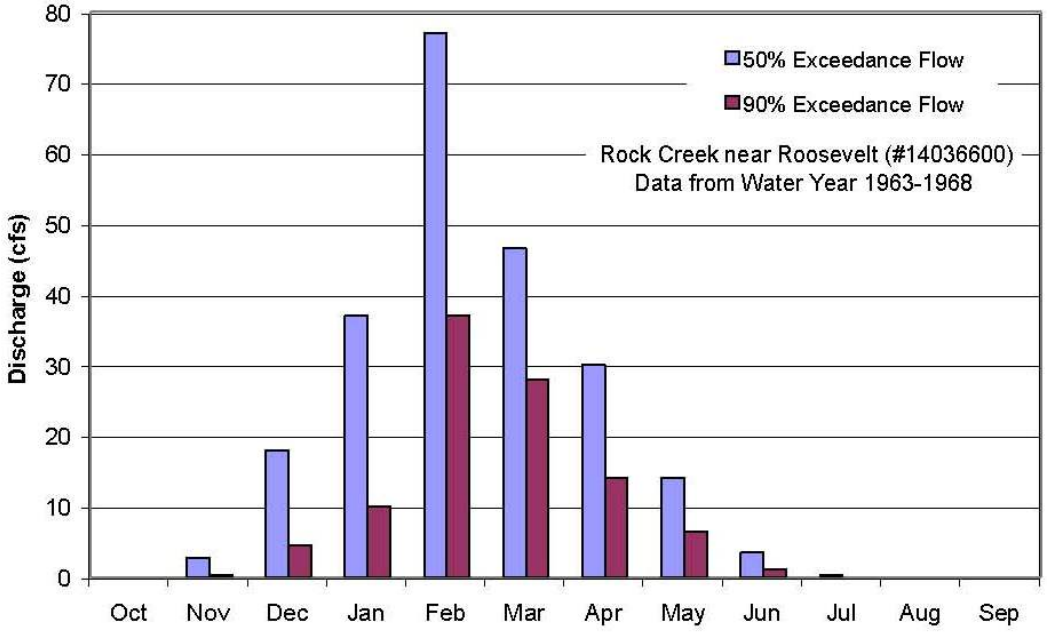

Figure 2-5. Monthly Exceedance Flows for Historical USGS Flow Gage near Mouth of Rock Creek. (Aspect Consulting and WPN 2004).

2.1.3 Water Quality

One headwater reach of Rock Creek is listed for temperature on the Washington Department of Ecology's (Ecology) 2008 water quality assessment list (often referred to as the "303(d) list") as Category 5, a water body that requires a TMDL (Ecology 2008). This headwater reach of Rock Creek was changed from Category 4B (designation for water bodies that have a pollution control program) to Category 5 on 3/24/05 because Ecology had not been able to confirm the results of implementation of items contained within the Memorandum of Agreement (MOA) between Ecology and the Eastern Klickitat Conservation District (EKCD) (http://apps.ecy.wa.gov/wats08/ViewListing.aspx?LISTING_ID=7967).

While only one reach in Rock Creek Basin is designated Category 5, published data suggest that many areas in Rock Creek and some of its tributaries (i.e., Quartz Creek, Squaw Creek, and Luna Gulch) frequently exceeded the applicable temperature criterion (7-DADMax of 17.5°C [63.5° F]) over the period of 1995 to 2004 (Aspect 2005) (Figure 2-6). A supplemental temperature standard (7-DADMax 13°C (55.4°F) for salmonid spawning and incubation is applicable to some areas of Rock Creek and several of its tributaries from February 1 to June 1 (http://www.ecy.wa.gov/pubs/0610038/start.pdf). Conformance with this supplemental standard has not been assessed, but available data suggest that it is exceeded in many areas of Rock Creek (Figure 2-6).

Approximately 73 percent of all O. mykiss observed in the basin during the single pass snorkel surveys conducted in late fall 2008 were found in the mainstem of Rock Creek between water temperature monitoring stations identified in Figure 2-6 as RC-09 and RC-06 (Glass 2009).

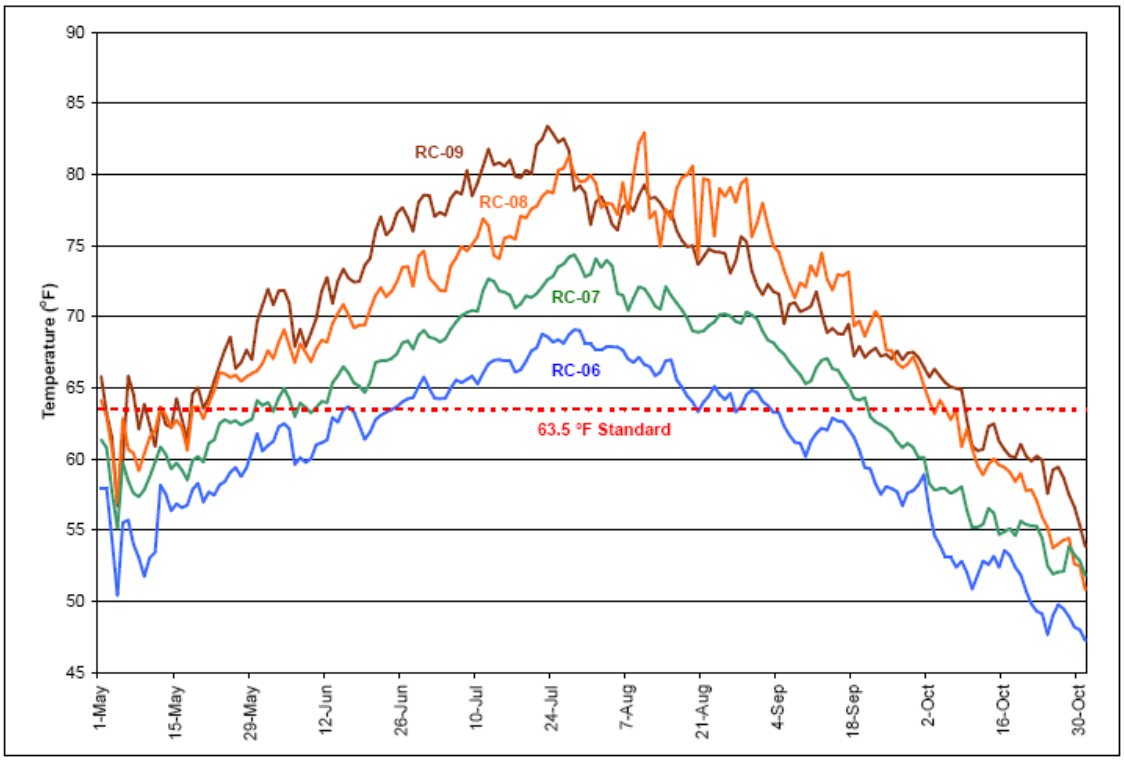

Figure 2-6. Daily maximum water temperature at four stations in Rock Creek based on 1999 to 2004 data (Aspect 2005). (RC-09 is located near the mouth of Rock Creek, RC-8 is located just downstream of the confluence with Squaw Creek, RC-7 is located in Squaw Creek near the confluence with the mainstem Rock Creek, and RC-6 is located upstream in the basin near the confluence with Badger Gulch.)

In 1995-1996, Ecology, in cooperation with the EKCD and the Natural Resources Conservation Service (NRCS), completed an evaluation of water temperature, including the influence of riparian canopy cover, on Rock Creek (Ehinger 1996). For the study, EKCD and the NRCS deployed continuous water temperature loggers at ten stations within Rock Creek during summer 1995. They also conducted a stream habitat evaluation at each station. During the study period, the loggers recorded daily maximum stream temperatures above the current default water temperature standard of 63.5°F (17.5°C) throughout the 1995 summer months at most stations monitored (Aspect Consulting and WPN 2004). In addition, stream habitat evaluation results showed that six of the ten stations had riparian canopy (vegetative) cover more than 10 percent below state target goals for eastern Washington Class A streams (Aspect Consulting and WPN 2004).

However, an analysis of historical aerial photographs revealed that the aerial extent of vegetation in the valley bottom of the mainstem of Rock Creek (lower 15 miles of the creek, excluding the area inundated by Lake Umatilla) increased 10 percent between 1996 and 2002, presumably due to fire exclusion (Aspect 2005). Ehinger (1996) inferred that the high water temperatures in upper Rock Creek "may be natural for a small creek in a hot, sunny summer climate." It was inferred that the lack of riparian shading and

rocky substrate contribute to elevated water temperatures in the lower stream reaches (Aspect Consulting and WPN 2004).

Aspect Consulting (2005) arrived at much the same conclusion in an assessment of water temperature in Rock Creek conducted for the WRIA 31 Planning Unit. Namely, "*The Rock Creek subbasin is sparsely populated with minimal water use, and geological conditions limit the quantities of groundwater discharge (springs) to support summer stream flows. This lack of late-season baseflow, in conjunction with the braided and highly dynamic stream channel and limited riparian vegetation in the lower reaches, combine to create a situation in which the water that is present is subject to abundant solar heating, and thus elevated water temperatures, throughout the summer. In this case, ongoing water temperature monitoring by EKCD is serving to establish a baseline condition for the watershed. Although it is difficult to definitively attribute the observed high water temperatures to natural causes versus anthropogenic causes, we are not aware of any evidence indicating it is the result of anthropogenic causes*" (Aspect 2005).

2.2 Life History Characteristics

Based on their level of sexual maturity at the time they enter freshwater and the duration of the spawning migration, steelhead populations in the Mid-Columbia DPS can be classified into one of three major life history patterns: summer run, winter run or a summer/winter run arrangement (ICTRT 2009). All steelhead in the Columbia River Basin upstream of The Dalles Dam, including the Rock Creek population, are classified as summer-run fish (Chapman et al. 1994; ICTRT 2009); however, Yakama Nation biologists suspect that a portion of the steelhead population in Rock Creek consists of winter-run fish.

Generally, winter-run fish enter freshwater streams between November and April, while summer-run fish enter rivers between May and October. Summer steelhead are of the stream-maturing type and enter freshwater in a sexually immature condition, requiring several months in freshwater to mature and spawn. Winter steelhead mature in the ocean and enter freshwater with well-developed gonads and spawn relatively shortly after river entry (Bambrick et al. 2004).

A combination of environmental cues, including flow and temperature, triggers spawn timing throughout the Rock Creek watershed. Spawning begins in the middle of March and peaks in early April. Upper watershed steelhead appear to spawn about three weeks later. Steelhead generally spawn in clear, cool streams with suitable gravel size, depth and flow velocity (Bjornn and Reiser 1991).

The range of temperatures steelhead can tolerate varies with life stage and other characteristics. Temperatures above 13.3ºC (56ºF) can result in egg mortality (McEwan and Jackson 1996), and sufficient oxygen may not be available above 21.1ºC (70ºF) (ibid.). Steelhead are considered to do best at a range of 12.8-15.6º C (55.0-60.1º F) (Rich 1987). Temperatures above 22^{o} C (72^{o} F) are highly stressful for steelhead.

Data regarding the average age, sex ratio, etc. of steelhead spawners in Rock Creek are unavailable. Further research is needed. Spawners include an unknown number of kelts (repeat spawners). Some steelhead are *iteroparous* (do not die after spawning), and may return to the ocean for a short period and repeat the spawning migration, a life history adaptation that may be fundamental to ensuring population stability. Respawning rates may be affected by environmental conditions, location of the natal stream, sex, size at maturity, and differences in the energy investment of spawning among different stocks and species (Fleming 1998). Reduced genetic contributions from populations formerly supplemented by repeat spawners may contribute to the decline of steelhead stocks in the Columbia River basin (NMFS 2000).

Iteroparity for Mid-Columbia steelhead ranges from reported rates of 2-4 percent above McNary Dam (at RM 292 measured from the mouth of the Columbia) (Busby et al. 1996) to 17 percent in the unimpounded tributaries below Bonneville Dam (at RM 146.1) (Leider et al. 1986). Iteroparity rates for Rock Creek River steelhead are unknown.

Steelhead eggs incubate at the same time that temperatures are increasing. In the lower mainstem Rock Creek where densities are highest, fry emerge very rapidly. Densities from electro-shocking suggest that emergence occurs in approximately 60 days (NPCC 2004). Because the lower mainstem becomes intermittent from July to late October, juvenile steelhead in the reach must use a number of life history strategies. While juveniles likely continue to rear in upper watershed areas during these months, juveniles reared in the lower watershed may either move out of the system, take advantage of pools, risking encounter with smallmouth bass and other predators in the lower 3.5-4.0 miles, or move higher in the watershed (NPCC 2004). No predators were observed during snorkel surveys conducted in mid-October/early-November 2008 above the area inundated by Lake Umatilla excluding reaches on Tribal Trust lands (Glass 2009). Approximately 94 percent of the juveniles observed in the Rock Creek mainstem during these snorkel surveys were in the lower sections of the river, downstream of the Bickleton Bridge, suggesting that few, if any, move upstream to rear (Glass 2009). It is unknown if juveniles rearing anywhere in the watershed move into the Columbia River to rear.

While limited information exists on steelhead abundance in the Rock Creek drainage, some observations suggest that a significant number of steelhead may use the Rock Creek watershed in years of good water and ocean conditions. Surveys conducted by the Yakama Nation in lower Rock Creek in 2002, 2003, and 2004 found as many as 35 to 45 steelhead redds per mile in the lower 5 miles, and extensive distribution of redds throughout the watershed (NPCC 2004). These surveys, however, were intermittent and were not conducted across all potential habitat. Spawner surveys conducted in April of 2009 found 20 redds and 6 additional features that might have been redds between the Bickleton Bridge and River Mile 4 (Glass 2009), the equivalent of roughly 2 redds per mile. Survey crews estimated that 30 to 40 percent of that area could not be adequately surveyed due to limitation on visibility, so the actual number of redds may have been 30 to 40 percent higher than reported. More surveys are needed to determine steelhead abundance and distribution in the drainage. Further research is needed.

Steelhead are believed historically to have utilized virtually all of the accessible major streams and tributaries of Rock Creek for some aspect of their life history. Spawning distribution probably included all accessible portions of the Rock Creek watershed. Then as now, the highest spawning densities likely occurred in the more complex, braided reaches of the lower mainstem of Rock Creek, and in third- and fourth-order tributaries with moderate (1-4 percent) gradients (NPCC 2004). The headwaters of the mainstem are generally above known anadromous fish use (NPCC 2004), although spawning has been observed up to the falls in Box Canyon (RM 0.3).

The current steelhead range in the Rock Creek watershed likely resembles the historical condition. During single pass snorkel surveys conducted in early October to mid-November 2008, no O. Mykiss were observed in the Rock Creek mainstem between the upper extent of the Lake Umatilla backwater and approximately RM 2, where the survey stopped because of private land ownership. The snorkel survey resumed at approximately RM 5. Approximately 78 percent of the O. mykiss observed in the Rock Creek subbasin were between RM 5 and the confluence with Quartz Creek and a few more fish (5 fish total) were observed upstream of Quartz Creek. O. mykiss were also observed in Squaw Creek to a point roughly 5 miles upstream of the confluence with White Creek. The majority of O. mykiss in Squaw Creek were found downstream of the confluence with Harrison Creek. No O. mykiss were observed in the lower reaches of Quartz Creek. Since anadromous and resident forms cannot be visually distinguished, the proportion of the O. mykiss observed in 2008 that were of anadromous form is unknown (Glass 2009).

Yakama Nation biologists observed live steelhead adults, redds, and *O. mykiss* fry in Rock Creek above the confluence of Quartz Creek; in Quartz Creek above the Box Canyon confluence; and in lower Box Canyon up to the falls at RM 0.3 (from the Quartz Cr. confluence). Live steelhead and redds have also been confirmed 0.5 RM up an unnamed tributary located below the confluence of Rock and Quartz creeks (RM 19.2). Additionally, steelhead adults and *O. mykiss* fry have been observed in Badger Gulch. Landowners report having seen steelhead adults, redds, and *O. mykiss* fry up Luna Gulch, from the confluence with Rock Creek, and into Squaw Creek, as well as catching steelhead in White and lower Harrison creeks (up to RM 2.5). Yakama Nation staff also noted 'anecdotal' evidence of steelhead being observed in mainstem Squaw Creek 2.0 miles upstream of the confluence with White Creek. In the Rock Creek mainstem, BLM staff recorded seeing steelhead above the confluence with Quartz Creek as well as in lower Quartz Creek (BLM 1985; BLM 1986). Figure 2-7 shows the current distribution of Rock Creek steelhead as observed by Yakama Nation biologists.

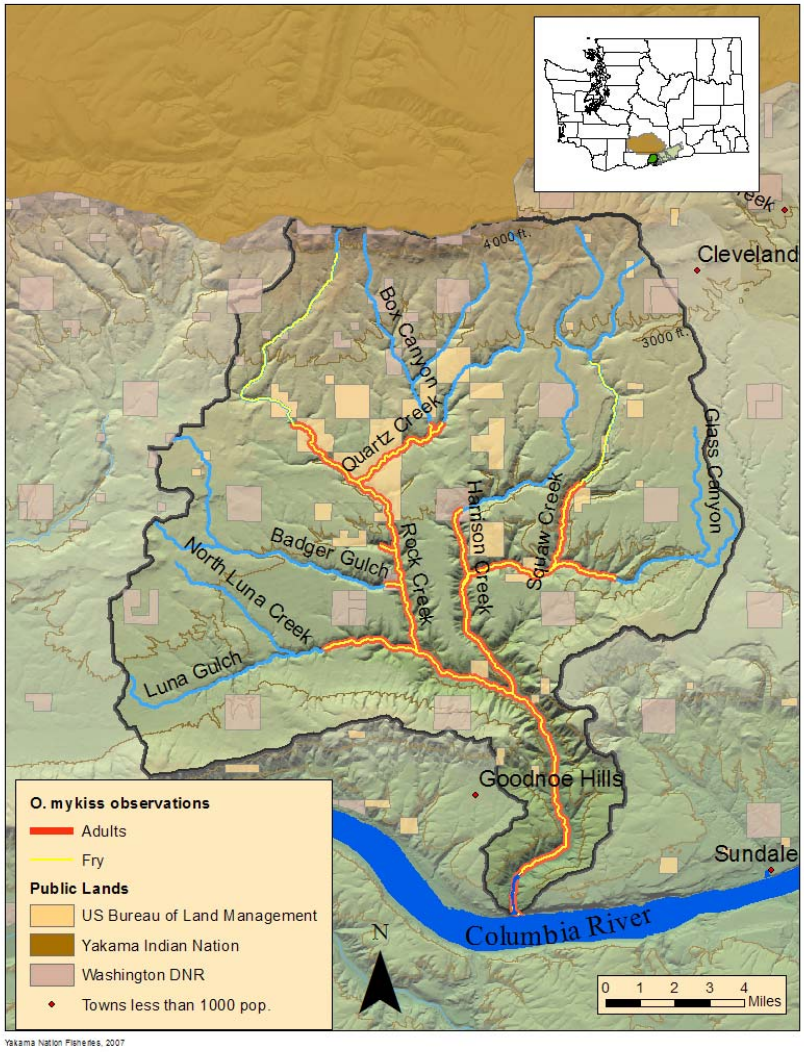

Figure 2-7. Rock Creek subbasin major streams and steelhead distribution as observed by Yakama Nation Fisheries Staff.

2.3 Major Spawning Area

The ICTRT identified potential intrinsic habitat in the Rock Creek subbasin as a major spawning aggregation (MaSA) for Middle Columbia River steelhead (Figure 2-8). The ICTRT delineated this MaSA using model results that estimated the historical amount of potentially accessible spawning and rearing habitat available to a specific population based on stream width, gradient, and valley width from GIS-based analysis of tributary habitat associated with each population (ICTRT 2005).

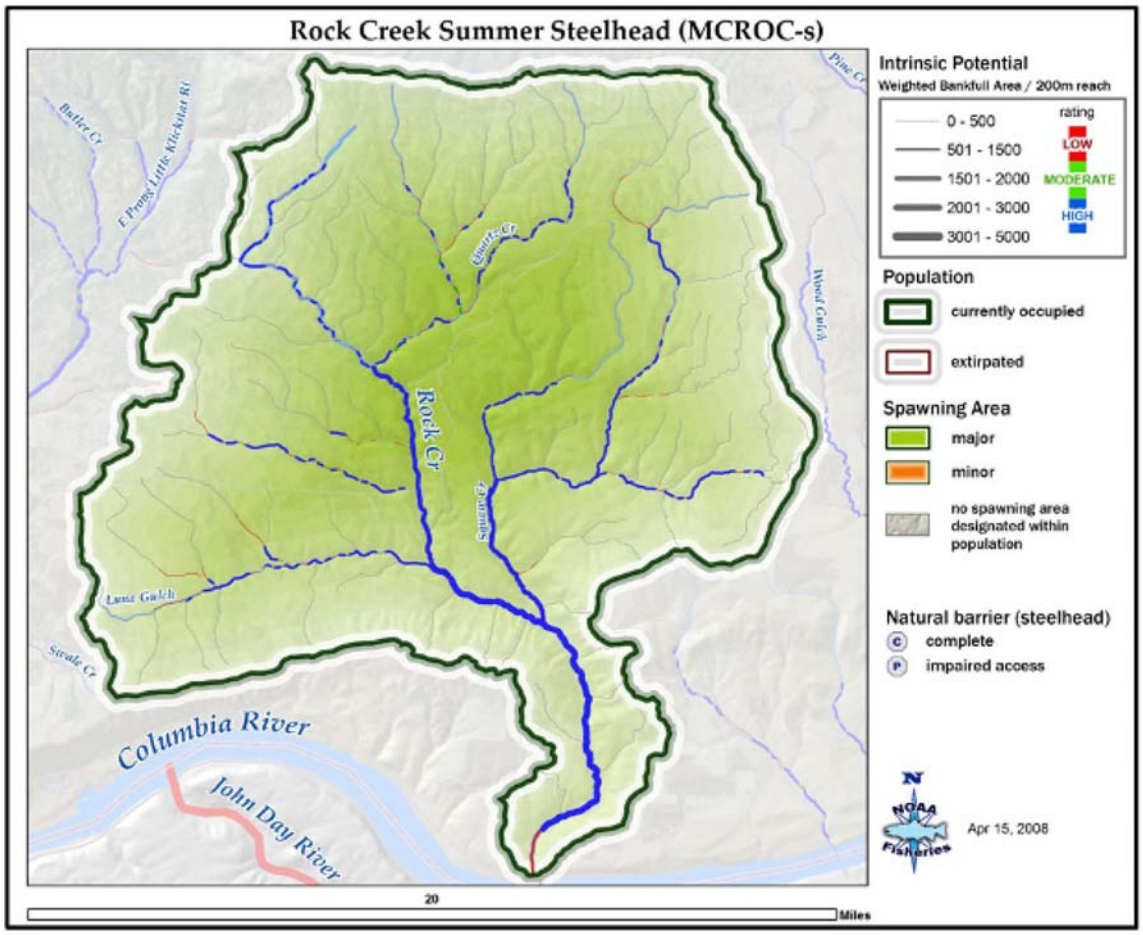

Figure 2-8. Rock Creek summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas (ICTRT 2009).

2.4 Salmonid Biological Structure

Salmonid species' homing propensity (their tendency to return to the locations where they originated) creates unique patterns of genetic variation and connectivity that mirror the distribution of their spawning areas across the landscape. Diverse genetic, life history, and morphological characteristics have evolved over generations, creating runs highly adapted to diverse environments. It is this variation that gives the species as a whole the resilience to persist over time.

Historically, a salmon ESU or, as in this case, steelhead DPS typically contained multiple populations connected by some small degree of genetic exchange by straying spawners. Thus, the overall biological structure of the ESU/DPS is hierarchical; spawners in the same area of the same stream will share more characteristics than those in the next stream over. Fish whose natal streams are separated by hundreds of miles will have less genetic similarity. The ESU or DPS is a metapopulation defined by the common characteristics of populations within a geographic range. Recovery planning efforts focus on this biologically based hierarchy (Figure 2-9).

McElhany et al. (2000) formally identified two levels in this hierarchy for recovery planning purposes: the evolutionarily significant unit (ESU) or distinct population segment (DPS) and the independent population. The ICTRT identified an additional level between the population and ESU/DPS levels, which they call a major population group (MPG) (McClure et al. 2003).

2.4.1 Distinct Population Segments

An ESU or DPS is a distinctive group of Pacific salmon or steelhead that is uniquely adapted to a particular area or environment. Because of the hierarchical structure of salmonid populations, the concept of "distinctive group" has received considerable attention and refinement. An ESU is defined as a group of Pacific salmon that is "substantially reproductively isolated from other conspecific units and represents an important component of the evolutionary legacy of the species" (Waples 1991). A "population segment" is considered distinct (a DPS and hence, like ESUs, considered a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics, or if it occupies an unusual or unique ecological setting, or if its loss would represent a significant gap in the species' range. ESUs/DPSs may contain multiple populations that are connected by some degree of migration, and hence may have a broad geographic range across watersheds and river basins.

2.4.2 Major Population Groups

Within an ESU/DPS, independent populations can be grouped into larger populations that share similar genetic, geographic, and/or habitat characteristics (McClure et al. 2003). These "major groupings" of populations (MPGs) are isolated from one another over a longer time scale than that defining the individual populations, but retain some degree of connectivity greater than that between ESUs/DPSs. The relationship between ESU/DPS, MPG, and independent populations is depicted in Figure 2-9.

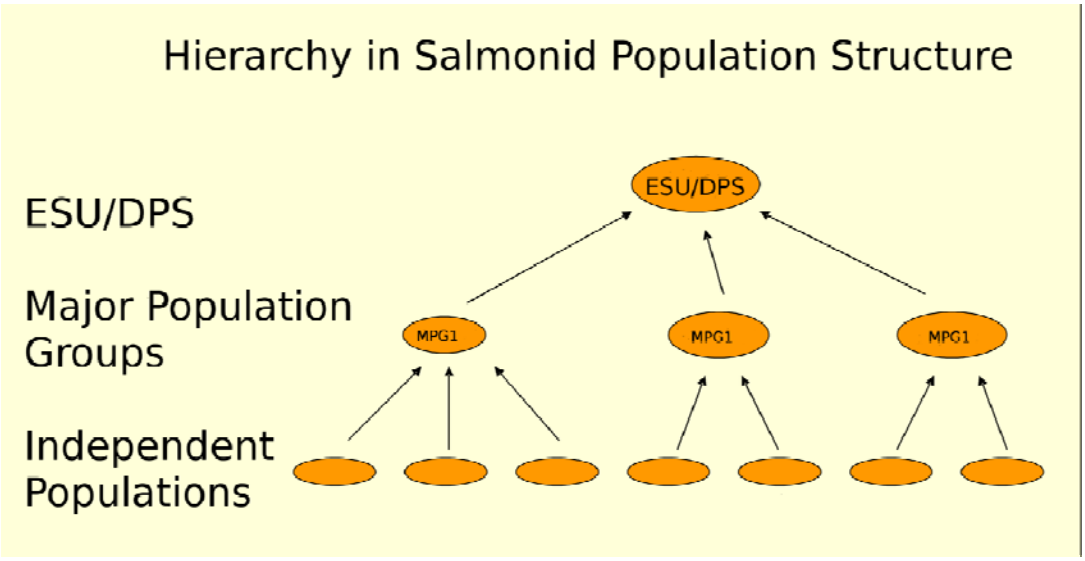

Figure 2-9 Hierarchical levels of salmonid species structure as defined by the TRTs for ESU/DPS recovery planning.

2.4.3 Independent Populations

McElhany et al. (2000) defined an independent population as follows:

"…a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season. For our purposes, not interbreeding to a 'substantial degree' means that two groups are considered to be independent populations if they are isolated to such an extent that exchanges of individuals among the populations do not substantially affect the population dynamics or extinction risk of the independent populations over a 100-year time frame."

2.5 Middle Columbia Steelhead Populations and MPGs

The ICTRT identified 17 extant and 3 extirpated independent steelhead populations in the Middle Columbia River steelhead DPS (McClure et al. 2003). These populations are shown in Figure 2-10. The ICTRT delineated the populations based on genetic information, geography, life-history traits, morphological traits, and population dynamics.

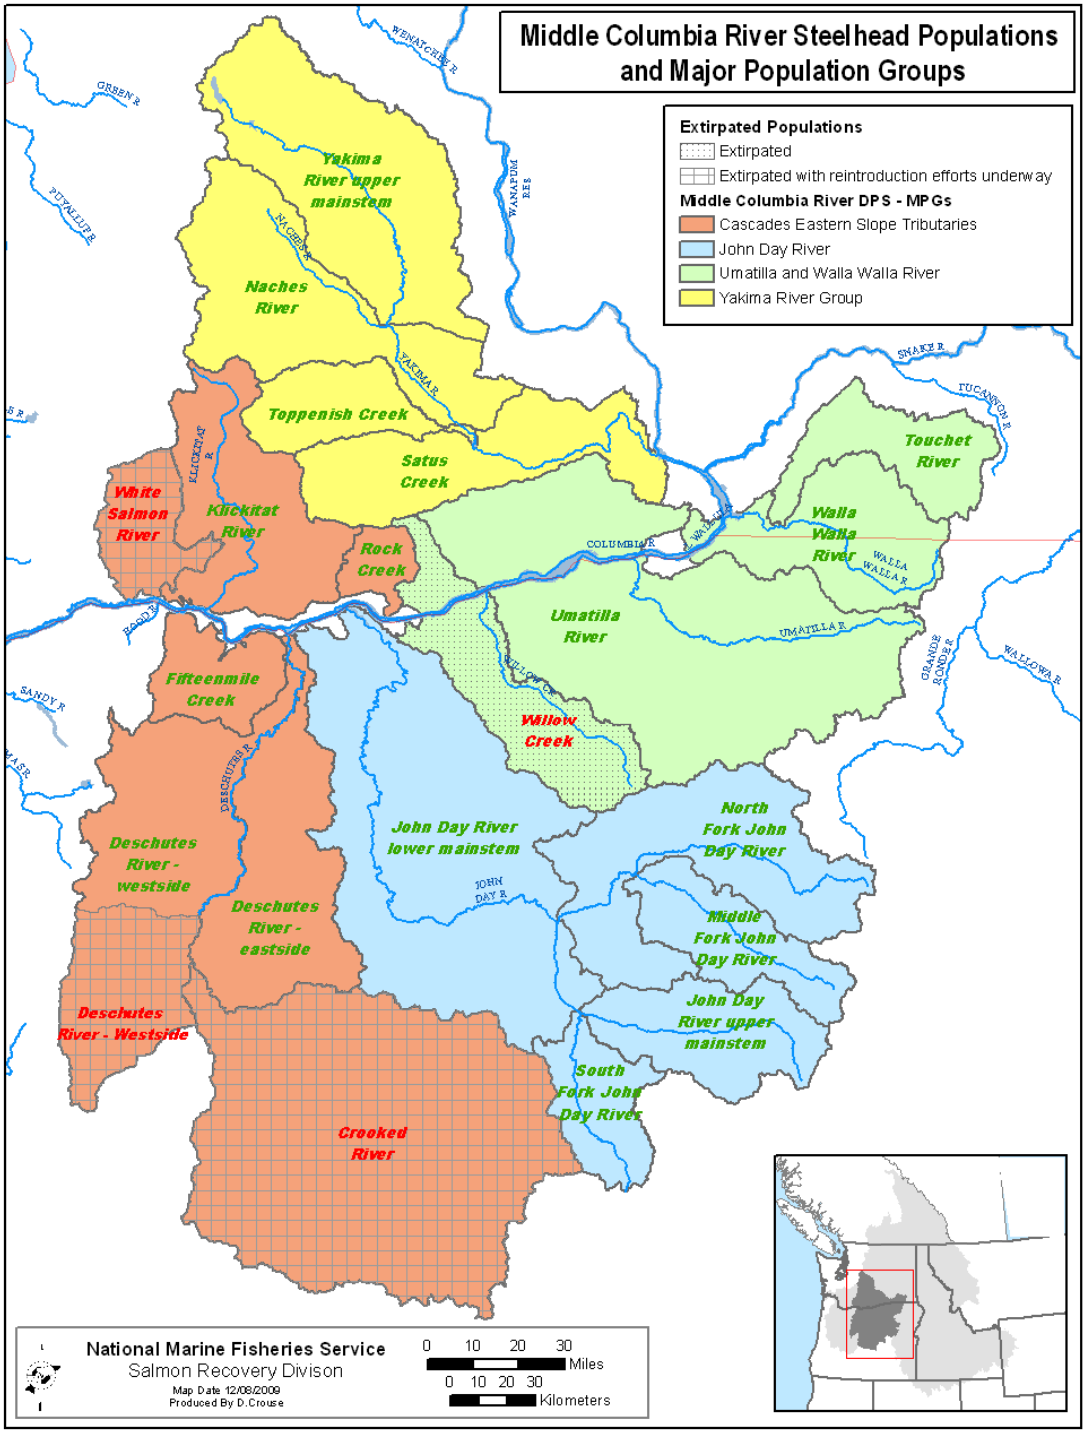

Figure 2-10 Middle Columbia River Steelhead Independent Populations and Major Population Groups.

The ICTRT grouped these independent populations into four major population groups (MPGs) within the DPS: the Cascades Eastern Slope Tributaries MPG, Yakima River

MPG, John Day River MPG, and Umatilla/Walla Walla MPG. The Rock Creek population is one of five extant populations (Klickitat River, Fifteenmile Creek, Rock Creek, Deschutes River Eastside, and Deschutes River Westside) and two extirpated populations (White Salmon River and Deschutes Crooked River) comprising the Cascades Eastern Slope Tributaries MPG (Figure 2-10). Populations in the group are united primarily by proximity and occupy diverse habitats, generally those draining the eastern slopes of the Cascades and the Columbia Plateau.

The ICTRT classified the Rock Creek population as Basic in size, based on intrinsic habitat potential (Table 2-1)

Table 2-1 Rock Creek Summer Steelhead Basin Statistics (ICTRT 2009).

Drainage area (km^2)	586
Stream lengths km (total) [a]	169
Stream lengths km (below natural barriers) [a]	166
Branched stream area weighted by intrinsic potential (km^2)	0.665
Branched stream area km^2 (weighted and temp. limited) [b]	0.411
Total stream area weighted by intrinsic potential (km^2)	0.683
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	0.419
Size / Complexity category	Basic
Number of Major Spawning Areas (MaSAs)	1
Number of Minor Spawning Areas (MiSAs)	0

a. All stream segments greater than or equal to 3.8m bankfull width were included
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was greater than 22°C.

3. Recovery Goals and Delisting Criteria

The primary goal of ESA recovery plans is for the species to reach the point that it no longer needs the protection of the Act – i.e. to be delisted. Recovery plans may also contain "broad-sense goals," defined in the recovery planning process, that go beyond the requirements for delisting to address, for example, other legislative mandates or social, economic, and ecological values.

Delisting criteria are applied at the DPS level, and are based on determinations of the viability of the independent populations that make up the DPS. Criteria for delisting the Middle Columbia steelhead DPS are described in the Middle Columbia Steelhead ESA Recovery Plan, to which this plan is an appendix. This chapter provides recovery goals for the Rock Creek steelhead population, describes the criteria to be used to assess progress toward those goals, and describes the role of the Rock Creek steelhead population in overall DPS viability.

There are two kinds of criteria that enter into a delisting decision: population, or demographic parameters (the biological recovery criteria) and "threats" criteria related to the five listing factors detailed in the ESA. The threats criteria define the conditions under which the listing factors, or threats, can be considered to be addressed or mitigated. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B) of the ESA. Both kinds of criteria are discussed in this chapter.

3.1 Recovery Goals

The primary goal of this plan is for the Rock Creek steelhead population to be restored to a sufficiently robust condition to support recovery of the Mid-Columbia steelhead DPS. If a local, collaborative Washington Gorge Area Regional Board is formed, it may choose to define broad-sense goals for the Rock Creek subbasin and other areas within the Washington Gorge Management Unit. The Board's broad-sense goals for the area would likely build upon direction from, and respond to interests identified by various stakeholders in the area. These goals would then guide the Board as it defines and implements future recovery actions for the Rock Creek subbasin.

For DPS delisting, the Rock Creek population should attain at least "moderate" risk status, also called "maintained" status by the ICTRT (described in more detail in Section 3.2.2). Achieving moderate risk status would be consistent with putting the population on a trajectory toward achieving viability. The ICTRT cautioned against closing off the options for any population prematurely, because of the many uncertainties in predicting the biological response to recovery actions (ICTRT 2007a).

3.2 Biological Viability Criteria

The ICTRT developed biologically based viability criteria for ESA-listed salmon and steelhead in the Interior Columbia domain. The ICTRT based its approach to recovery on guidance from the NMFS Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). This memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels. A viable population is defined as an independent population that has negligible risk of extinction due to threats from demographic variation, local environmental variation, and genetic diversity changes over a 100-year timeframe (McElhany et al. 2000).

Viability criteria at the population level address four VSP parameters (McElhany et al. 2000):

- *Abundance* – the average number of spawners in a population over a generation or more,
- *Productivity* – the performance of a population over time in terms of recruits produced per spawner,
- *Spatial Structure* – a population's geographic distribution and the processes that affect that distribution, and
- *Diversity* – the distribution of genetic, life history and phenotypic variation within and among populations.

The ICTRT grouped specific population level criteria into two categories to assess viability at the independent population level: measures addressing abundance and productivity, and measures addressing spatial structure and diversity. The viability of an independent population is determined by integrating risks across the four parameters. Additionally, the VSP guidelines (McElhany et al. 2000) recommend that a viable DPS population should be large enough to:

1. have a high probability of surviving variation observed in the past and expected future;
2. be resilient to environmental and anthropogenic disturbances;
3. maintain genetic diversity; and
4. support/provide ecosystem functions.

They also recommend that viable populations demonstrate sufficient productivity to support a net replacement rate of 1:1 or higher at abundance levels established as long-term targets. Productivity rates at relatively low numbers of spawners should, on average, be sufficiently greater than 1.0 to allow the population to rapidly return to abundance target levels.

3.2.1 DPS and MPG Viability Criteria

The major objectives of the ICTRT's viability criteria are to ensure preservation of basic historical metapopulation processes including 1) genetic exchange across populations within an ESU/DPS over a long time frame; 2) the opportunity for neighboring populations to serve as source areas in the event of local population extirpations; 3) population distribution within an ESU/DPS so that they are not all susceptible to a specific localized catastrophic event (ICTRT 2007b).

Since MPGs are geographically and genetically cohesive groups of populations, they are critical components of ESU/DPS spatial structure and diversity. Having all MPGs within an ESU/DPS at low risk provides the greatest probability of persistence for the ESU/DPS. Thus, the ICTRT criterion for a viable ESU/DPS is that all extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS should be at low risk.

The population level assessments provide the basis for evaluation viability at the MPG level and, in turn, for the DPS as a whole. The combined effects of requiring each MPG to sustain a minimum number of viable populations, representation of larger size classes of populations, major life history patterns and the maintenance requirement provide for a network of populations that would sustain the DPS.

Further, the following five criteria should be met for an MPG to be regarded as low risk (viable) (ICTRT 2007b):

1. At least one-half of the populations historically within the MPG (with a minimum of two populations) should meet viability standards. This equals to four for this MPG.

2. At least one population should be classified as "Highly Viable."

3. Viable populations within an MPG must include some populations classified (based on historical intrinsic potential) as "Very Large," "Large" or "Intermediate" generally reflecting the proportions historically present within the MPG. In particular, Very and Large populations should be at or above composite historical fraction within the MPG.

4. All major life history strategies (e.g. spring and summer run timing) that were present historically within the MPG should be represented in populations meeting viability requirements.

5. Remaining MPG populations should be maintained with sufficient abundance, productivity, spatial structure, and diversity to provide for ecological functions and to preserve options for DPS recovery.

The DPS criterion requiring viable populations in each of the extant MPGs would result in sustainable production across a substantial range of environmental conditions. The presence of viable populations across MPGs would preserve a high level of diversity

within the DPS, thereby promoting long-term evolutionary potential for adaptation to changing conditions. The presence of multiple, relatively nearby, viable and maintained populations acts as protection against long-term impacts of localized catastrophic loss by serving as a source of re-colonization (ICTRT 2007a).

3.2.2 Application of Biological Viability Criteria to Rock Creek Population

Although the risk levels of the populations within the DPS collectively determine MPG viability and, in turn, the likely persistence of the DPS, it may not be necessary for all of the populations to attain the lowest risk level. There may be more than one way for a DPS to meet the viability criteria. The ICTRT called alternative combinations of population risk status that would meet the MPG and DPS-level criteria "recovery scenarios." In a January 8, 2007 technical memorandum (ICTRT 2007a), the ICTRT offered a detailed discussion of possible recovery scenarios for each MPG.

For the Eastern Cascades Slope Tributaries MPG to be viable, four populations representing historical types of diversity in terms of life history, size category, etc., should meet criteria for a low extinction risk, i.e. less than 5 percent risk of extinction (alternatively, more than 95 percent probability of persistence). The Klickitat River, Fifteenmile Creek, and Deschutes West and East populations need to meet low risk criteria because of their life history types and other characteristics. In this recovery scenario, the biological recovery goal for the Rock Creek steelhead population is to contribute to recovery for the Middle Columbia River Steelhead DPS by reaching a "maintained" or moderate risk status (ICTRT 2007a). A maintained or moderate risk is defined as having between 25 and 6 percent risk of extinction within 100 years. To achieve low risk the population would need to meet the 5 percent criterion, and for very low risk, 1 percent. Low and very low risk targets would be consistent with broad-sense goals that have been adopted for populations elsewhere.

The ICTRT classified the Rock Creek steelhead population as a "Basic" sized population, based on historical habitat potential (ICTRT 2007b) and provided viability criteria for a Basic population, as follows (ICTRT 2007b):

Abundance
For a Basic population, viable status, i.e. a 5 percent or less risk of extinction over a 100-year timeframe, would require a mean minimum abundance threshold of 500 naturally produced spawners. Maintained status or moderate (6 to 25 percent) risk would also require a mean minimum abundance of 500 naturally produced spawners because "populations with fewer than 500 individuals are at higher risk for inbreeding depression and a variety of other genetic concerns" (ICTRT 2007b).

Productivity
Productivity rates at relatively low numbers of spawners should, on average, be sufficiently greater than 1.0 to allow the population to rapidly return to abundance target levels. For a Basic population at 500 naturally produced spawners to meet the moderate risk criterion, productivity should be at about 1.3 (ICTRT 2007b, Figure 4a). To meet the 5 percent risk criterion (viable status), productivity should be >1.56.

Spatial Structure and Diversity
In general, the ICTRT defined two goals, or biological or ecological objectives, that spatial structure and diversity criteria should achieve (ICTRT 2007b):

- *Maintaining natural rates and levels of spatially mediated processes*. This goal serves to minimize the likelihood that populations will be lost due to local catastrophe, to maintain natural rates of recolonization within the population and between populations, and to maintain other population functions that depend on the spatial arrangement of the population.

- *Maintaining natural patterns of variation*. This goal serves to ensure that populations can withstand environmental variation in the short and long-terms.

Based on historical potential analysis, the ICTRT gave the Rock Creek population a combined integrated spatial structure/diversity rating of Moderate risk. The Rock Creek population has a relatively simple population structure, containing a single major spawning area (MaSA). Although observations indicate that steelhead spawning may occur across much of the historical range, the relatively simple population structure results in a moderate rating for complexity. There have likely been minor reductions in life history diversity and phenotypic variation, but these changes are not severe enough to raise risk levels above low for this parameter.

3.3 Threats Criteria

Listing factors are those features that were evaluated under section 4(a)(1) when the initial determination was made to list the species for protection under the ESA. These may or may not still be limiting recovery when in the future NMFS reevaluates the status of the species to determine whether the protections of the ESA are no longer warranted and the species could be delisted.

At the time of a delisting decision, NMFS will examine whether the section 4(a)(1) listing factors have been addressed. To assist in this examination, NMFS will use the listing factors (or threats) criteria described below in addition to evaluation of biological recovery criteria and other relevant data and policy considerations.

To determine that the affected DPS is recovered to the point that it no longer requires the protections of the ESA, NMFS will review the status of the listing factors according to the specific criteria identified for each of them (see below). The threats need to have been addressed to the point that delisting is not likely to result in their re-emergence. It is possible that current perceived threats will become insignificant in the future due to changes in the natural environment or changes in the way threats affect the entire life-cycle of salmon. Consequently, NMFS expects that the ranking of threats will change over time and that new threats may be identified. During the status reviews, NMFS will evaluate and review the listing factor criteria under conditions at the time.

The specific criteria listed below for each of the relevant listing/delisting factors helps to ensure that underlying causes of decline have been addressed and mitigated before considering a species for delisting. NMFS expects that if the proposed actions described in this plan are implemented, they will make substantial progress toward meeting the following listing factor (threats) criteria.

Factor A: The present or threatened destruction, modification, or curtailment of its habitat or range.

To determine that the DPS is recovered, threats to habitat should be addressed to a degree sufficient to support a viable Middle Columbia River steelhead DPS as outlined below:

1. Passage obstructions (e.g., dams and culverts) are removed or modified to improve survival and restore access to historically accessible habitat where necessary to support recovery goals.
2. Flow conditions that support adequate steelhead rearing, spawning, and migration of a viable DPS are achieved where possible through management of mainstem and tributary irrigation and hydropower operations, and through the improvement of other water user efficiencies and conservation, including for municipal supply and other consumptive purposes.
3. Forest management practices that protect watershed and stream functions are implemented on Federal, state, tribal, and private lands.
4. Agricultural practices, including grazing, are implemented to protect and restore riparian areas, floodplains, and stream channels, and to protect water quality from sediment, pesticide, herbicide, and fertilizer.
5. Urban and rural development, including land use conversion from agriculture and forestland to residential uses, avoids impairment of water quality or natural stream conditions.
6. The effects of toxic contaminants on salmonid fitness and survival in the mainstem and tributaries are sufficiently limited so as not to affect recovery.
7. Channel function, including vegetated riparian areas, canopy cover, stream-bank stability, off-channel and side-channel habitats, natural substrate and sediment processes, and channel complexity is restored to provide adequate rearing and spawning.
8. Floodplain function and the availability of floodplain habitats for salmon are restored to a degree sufficient to support a viable DPS. This restoration should include connectedness between river and floodplain and the restoration of impaired sediment delivery processes.

Factor B: Over-utilization for commercial, recreational, scientific or educational purposes

To determine that the DPS is recovered, any utilization for commercial, recreational, scientific, or educational purposes should be managed as outlined below:

1. Fishery management plans for steelhead are in place that (a) accurately account for total fishery mortality (i.e., both landed catch and non-landed mortalities) and constrain mortality rates to levels that are consistent with achieving population viability (i.e., provide for adequate spawning escapement given their productivity); and (b) are implemented in such a way as to avoid deleterious genetic effects on populations or negatively affect the distribution of populations.

2. Federal, state, and local fishing rules and regulations are effectively enforced.

3. Technical tools accurately assess the effects of the harvest regimes so that harvest objectives are met but not exceeded.

4. Handling of fish is minimized to reduce indirect mortalities associated with education or scientific programs, while recognizing that monitoring, research, and education are key actions for conservation of the species.

5. To the degree necessary to support a viable DPS, routine instream construction and maintenance practices are implemented in a manner to reduce or eliminate mortality of listed species.

Factor C: Disease or predation

To determine that the DPS is recovered, any disease or predation that threatens its continued existence should be addressed as outlined below:

1. Hatchery operations do not subject steelhead populations to deleterious diseases and parasites and do not result in increased predation rates of wild steelhead;

2. Predation by avian predators is managed in a way that promotes recovery of salmon and steelhead populations;

3. The northern pikeminnow and other exotic piscivorous species are managed to reduce predation on steelhead to a degree sufficient to meet recovery goals;

4. Populations of introduced smallmouth bass, walleye, channel catfish and other exotic piscivorous species are managed such that competition or predation does not impede steelhead recovery.

5. Predation of steelhead runs below Bonneville Dam by marine mammals is managed within the framework of applicable statutes and to the degree necessary to protect upstream migration of steelhead.

6. Physiological stress and physical injury that may cause disease or increase susceptibility to pathogens during rearing or migration should be reduced during critical low flow periods (e.g. low water years) or poor passage conditions (e.g. at diversion dams or bypasses).

Factor D: The inadequacy of existing regulatory mechanisms

To determine that the DPS is recovered, any inadequacy of existing regulatory mechanisms that threatens its continued existence should be addressed to the degree necessary to support a viable DPS, as outlined below:

1. Sufficient resources, priorities, regulatory frameworks, and coordination mechanisms are established and/or maintained for effective enforcement of land and water use regulations that protect and restore habitats and for the effective management of fisheries.

2. Habitat conditions and watershed functions are protected through land-use planning that guides human population growth and development.

3. Habitat conditions and watershed function are protected through regulations that govern resource extraction such as timber harvest and gravel mining.

4. Habitat conditions and watershed functions are protected through land protection agreements as appropriate, where existing policy or regulations do not provide adequate protection.

5. Regulatory, control, and education measures to prevent additional exotic plant and animal species invasions are in place.

Factor E: Other natural or manmade factors affecting its continued existence

To determine that the DPS is recovered, other natural and man-made threats to its continued existence should be addressed as outlined below:

1. Hatchery programs are being operated in a manner that is consistent with individual watershed and region-wide recovery approaches; appropriate criteria should be used for the integration of hatchery steelhead populations and extant natural populations inhabiting watersheds where the hatchery fish return.
2. Hatcheries operate using appropriate ecological, genetic, and demographic risk containment measures for (1) hatchery-origin adults returning to natural spawning areas, (2) release of hatchery juveniles, (3) handling of natural-origin adults at hatchery facilities, (4) withdrawal of water for hatchery use, (5) discharge of hatchery effluent, and (6) maintenance of fish health during their propagation in the hatchery.
3. Mechanisms are in place to reduce the incidence of, and impacts from, introduced, invasive, or exotic plant and animal species.

4. Nutrient enrichment programs should be evaluated to determine where additional nutrient inputs can provide significant benefits.

4. Current Status Assessment

This chapter summarizes the ICTRT's viability assessment results for Middle Columbia River steelhead in the Rock Creek watershed. The assessment reflects existing data, previous assessment findings and GIS analysis.

4.1 Abundance and Productivity

At present, no direct estimates of abundance and productivity are available for Rock Creek steelhead. There have been no systematic redd surveys in this population area. The general presence of steelhead has been documented (NPCC 2004). The ICTRT assigned the Rock Creek steelhead population High risk based on the lack of information on current abundance and productivity (ICTRT 2009).

4.2 Spatial Structure and Diversity

The Rock Creek population has a single major spawning area (MaSA) (a system of one or more branches capable of supporting 500 spawners). Steelhead are known to occur in Rock Creek up to a point ¼ mile above the confluence with Quartz Creek (BLM 1985, 1986), and possibly above it. Steelhead have also been located in lower Quartz Creek (BLM 1985, 1986). Steelhead are known to occur in Squaw Creek up to the confluence with Harrison Creek, and have occurred historically as far as the confluence with Spring Creek (C. Dugger, WDFW, pers. comm., 1999). Known utilization includes the lower and middle portions of Rock Creek, lower Quartz Creek and Squaw Creek.

The ICTRT rated the Rock Creek population at Moderate risk for spatial structure/diversity (Table 4-1). Based on the ICTRT historical potential analysis, the Rock Creek population had a relatively simple population structure, containing a single MaSA. Although observations indicate that steelhead spawning may occur across much of the historical range, the relatively simple population structure results in a moderate rating for complexity. There have likely been minor reductions in life history diversity and phenotypic variation, but these changes are not severe enough to raise risk levels above low for the diversity parameter.

Table 4-1 Rock Creek Summer Steelhead Population Spatial Structure and Diversity Risk Rating Summary (ICTRT 2009).

Metric	Risk Assessment Scores				
	Metric	Factor	Mechanism	Goal	Population
A.1.a	H (-1)	H (-1)	(Mean = 0.33) Moderate Risk	Moderate Risk	**Moderate Risk**
A.1.b	L (1)	L (1)			
A.1.c	L (1)	L (1)			
B.1.a	M (0)	M (0)	Moderate Risk (0)	(Mean=0.25) Moderate Risk	
B.1.b	M (0)	M (0)			
B.1.c	M (0)	M (0)			
B.2.a(1)	M (0)	M (0)	Moderate Risk (0)		
B.2.a(2)	L (1)				
B.2.a(3)	L (1)				
B.2.a(4)	VL (2)				
B.3.a	M (0)	M (0)	M (0)		
B.4.a	L (1)	L (1)	L (1)		

4.3 Overall Risk Rating

The Rock Creek steelhead population does not currently meet viability criteria because it is assigned High risk for abundance/productivity (Figure 4-1). The overall spatial structure/diversity rating is Moderate risk. The lack of direct estimates of abundance and productivity for this population was a factor in assigning it High risk.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V**	**V**	**M**
	Moderate (6 – 25%)	**M**	**M**	**M**	**HR**
	High (>25%)	**HR**	**HR**	**HR Rock Creek***	**HR**

Figure 4-1. Integrated Risk Rating for the Rock Creek Steelhead Population (ICTRT 2009). ***Viability Key: HV – Highly Viable; V – Viable; M – Moderate/Maintained; HR – High Risk; * = Candidate for Maintained; Shaded cells – does not meet viability criteria (darkest cells are at greatest risk).***

5. Limiting Factors and Threats

The reasons for a species' decline are generally described in terms of limiting factors and threats. Analysis of limiting factors and threats across the entire species' life cycle forms the basis for designing recovery strategies and actions. NMFS defines limiting factors as the biological and physical conditions limiting DPS and population status (e.g. elevated water temperature), and defines threats as those human activities or naturally induced actions that cause the limiting factors (e.g. removal of riparian vegetation for agricultural or residential purposes, which causes loss of shade and, consequently, elevated water temperature).

While the term "threats" carries a negative connotation, it does not mean that activities identified as threats are inherently undesirable. They are typically legitimate human activities that may at times have unintended negative consequences on fish populations—and that can also be managed in a manner that minimizes or eliminates the negative impacts.

For steelhead and other salmonids, survival to reproduce depends on a complex, interacting system of environmental conditions, with different conditions needed for each life stage. Optimal water temperature, for example, varies (within limits) for adult migration vs. egg incubation or juvenile rearing. In addition, the particular factors limiting production may vary across different sections of the tributary drainage used by a particular population. Data on a full range of potential limiting factors is rarely available at the reach level.

The list of potential limiting factors for the Rock Creek steelhead population, as for the other populations that make up the Middle Columbia steelhead DPS, is based on a substantial body of research on salmonids, local field data and field observations, and the considered opinions of regional experts. These are implicitly hypothetical statements to be tested, made with the expectation that by taking action in the face of some degree of scientific uncertainty, monitoring the results, continuing to conduct research to further characterize the factors limiting the population, and adapting our management actions in response, the state of our knowledge will improve and so will the survival of these fish, although not necessarily in a directly parallel process. This chapter describes factors that may be limiting Middle Columbia River steelhead production in the Rock Creek subbasin.

5.1 Freshwater Habitat

Low summer flows and high summer water temperatures occur naturally in some parts of the Rock Creek watershed because of bedrock terrain and steep slopes. The intensity of some of these factors may have increased because of anthropogenic changes in the subbasin. For example, historical forest practices, including logging and road construction, adversely impacted functional quality of riparian areas in some portions of the headwaters and canyon reaches (e.g., upper Rock Creek, Box Canyon and Quartz

Creek) (NPCC 2004). In addition, channel widening and incision, such as along lower Rock Creek, could cause a reduction or loss of summer base flows.

While the Rock Creek watershed is sparsely populated, anthropogenic influences occur throughout the subbasin. Much of the watershed has been grazed or logged, and primitive roads extend from near the Columbia River to the headwaters of most streams in the subbasin. Beaver were once likely abundant and are now less common. Still, while grazing, roads, and other uses may contribute to habitat problems in some parts of the watershed, considerable forest canopy remains and most stream reaches support at least shrub-dominated riparian areas.

The major factors and associated threats that potentially limit abundance, productivity, spatial structure and diversity of Middle Columbia River steelhead in the Rock Creek watershed are discussed briefly below. The factors were identified based on information in the Northwest Power and Conservation Council's subbasin plan for the Lower Mid-Columbia Mainstem, including Rock Creek (NPCC 2004) and the Watershed Assessment for Rock Creek, part of WRIA 31 (Aspect Consulting and WPN 2004). They also reflect the input data for an Ecosystem Diagnosis and Treatment (EDT) model for Rock Creek (available at: http://edt.jonesandstokes.com/).

The stakeholders in the Rock Creek–Glade Creek watershed completed and approved in April 2009 the WRIA 31 Watershed Management Plan (WRIA 31 Planning Unit et al. 2008), with the help of the State of Washington under the Watershed Management Act pursuant to chapter 90.82 Revised Code of Washington. The watershed plan includes identification of prioritized fish habitat issues and actions in the Rock Creek–Glade Creek watershed. In the fall of 2008 through spring of 2009, a quantitative instream habitat assessment and fish survey was conducted on non-Tribal lands in the Rock Creek watershed (Glass 2009). Fish habitat was assessed with a stratified random sample design incorporating the entire area indicated as potentially containing steelhead (Figure 2-7 of this document). The total stream length assessed was 11,700 meters, or 14.5 percent of a study area (Glass 2009). Potential limiting factors and threats identified in Glass 2009 and WRIA 31 Planning Unit et al. 2008 are incorporated in this summary.

- ***Hydrograph.*** Seasonally low to non-existent stream flows might be a primary factor limiting steelhead production in the Rock Creek watershed. Low to intermittent and/or subterranean flows in all streams during late summer, fall and early winter can limit juvenile mobility and cause mortality due to stranding. The historical information, coupled with documented intermittent conditions (USGS 1989; Ecology's gaging station, https://fortress.wa.gov/ecy/wrx/wrx/flows/station.asp?sta=31B070), which occur under minimal human water use (Aspect Consulting and WPN 2004), suggest that the streamflow in Rock Creek is naturally intermittent rather than a condition created by human development (Aspect Consulting and WPN 2004). However, the loss of riparian vegetation, instream habitat complexity and diversity, and floodplain connectivity in some reaches because of grazing, roads, and/or other land uses can increase the intensity of flows in some parts of the drainage. In the

Rock Creek subbasin, roads are at low density (Coe 2004, Harr et al. 1975, Aspect Consulting and WPN 2004). The amount of vegetation in the valley bottom has been increasing since 1938, presumably due to fire suppression (Aspect 2005). Most of the land in the basin is lightly grazed. Low summer stream flows occur in the lower part of the subbasin ─ lower Rock Creek mainstem, lower Squaw Creek, and lower Luna Gulch ─ but also occur in some headwater and canyon reaches (NPCC 2004, Ecology's stream gage https://fortress.wa.gov/ecy/wrx/wrx/flows/station.asp?sta=31B070). None of the stream length of the Rock Creek mainstem above the Bickleton Bridge to the upper extent of steelhead distribution (Figure 2-7) was dry in mid-October/early November 2008, although measured flow in the lower mainstem was zero (Glass 2009). Flow in some of lower Rock Creek is below the surface because of the high proportion of alluvial material in the substrate. Approximately 14 percent of the stream length was dry in the reaches of the Rock Creek subbasin surveyed in mid-October/early November 2008 when measured flow in the lower mainstem was zero. Spring outflows feed some reaches and pools, and may provide important refugia during periods of low flow.

- ***Water quality, high stream temperatures.*** Seasonally high water temperature is potentially a primary factor limiting steelhead production in the Rock Creek watershed (Glass 2009). As noted in Chapter 2, the range of temperatures steelhead can tolerate varies with life stage and other characteristics. Temperatures above 13.3ºC (56ºF) can result in egg mortality (McEwan and Jackson 1996), and sufficient oxygen may not be available above 21.1ºC (70ºF) (ibid.). Steelhead are considered to do best at a range of 12.8-15.6ºC (55.0-60.1ºF) (Rich 1987). Temperatures above 22ºC (72ºF) are highly stressful for steelhead. The Washington State water quality criteria for aquatic life list 63.5º F as the maximum for salmonid spawning, rearing, and migration; temperatures above 63.5º F can be lethal to developing fish embryos (WAC 173-201A-200).

  Summer water temperatures in the lower Rock Creek subbasin frequently rise above 63.5°F (Aspect 2005). With respect to steelhead incubation, some lower reaches of Rock Creek and Squaw Creek start exceeding 63.5°F in mid- to late-May and in some reaches rise above 73.4°F (23.9°C) (Aspect Consulting 2005), a level considered potentially lethal for salmon and steelhead (Glass 2009). One reach of Rock Creek is listed twice on the Washington State Department of Ecology's 2008 water quality assessment (known as the 303(d) list) as being impaired for water temperature (Category 5), and requiring a TMDL (http://apps.ecy.wa.gov/wats08/ViewListing.aspx?LISTING_ID=7967). Loss of habitat quantity and diversity, channel degradation due to flooding and other factors, low summer flows, and loss of riparian vegetation can contribute to this potential limiting factor. High stream temperatures during summer and early fall, especially in the lower watershed, limit juvenile mobility and may result in stranding or mortality because of thermal stress (NPCC 2004). Potential anthropogenic effects on stream temperature have not been quantitatively evaluated; however, the evidence suggests that high water temperatures in Rock

Creek are a natural condition (Ehinger 1996, Aspect Consulting and WPN 2004, Aspect Consulting 2005). The amount of vegetation in the valley bottom has been increasing steadily since 1938, presumably due to fire suppression (Aspect Consulting 2005). Fine sediment levels in the basin tend to be low (Glass 2009), which suggests that filling of pools or widening of the stream, which would contribute to warm temperature, is unlikely.

- ***Riparian function and condition.*** While the stream system's rocky substrate and steep topography naturally inhibit riparian forest stand development along many reaches, riparian function and condition have been affected by major flood events, grazing, historical timber practices, road construction, and other land uses. Since 2006, commercial forestry in the Rock Creek watershed is managed under a NMFS-approved Habitat Conservation Plan (HCP): the Forest Practices HCP, or FPHCP, which applies to private commercial timberlands regulated by State Forest Practice Rules. Tribal harvest is managed under the Yakama Nation Forest Management Plan. Glass (2009) concluded that the magnitude of the anthropogenic effects is likely minor, because roads are sparse, largely located upslope of streams, and likely input little sediment (Aspect Consulting and WPN 2004); harvest in riparian areas is highly regulated; and there is little development in the basin (Klickitat County Assessor's Office http://www.klickitatcounty.org/Road/ContentROne.asp?fContentIdSelected=455695186&fCategoryIdSelected=-342308583&fX=X). Grazing affects portions of the Rock Creek watershed; its impacts can be directly observed in the lower mainstem. A 1995 stream habitat evaluation along Rock Creek showed that six of ten sites examined during the evaluation had riparian vegetative cover more than 10 percent below the target for eastern Washington Class A streams (Aspect Consulting and WPN 2004; Ehinger 1996).

- ***Channel structure and complexity.*** Degraded channel structure and complexity in the subbasin may reduce key habitat quantity and habitat diversity for steelhead. Key habitat quantity refers to the amount of key habitat, such as riffles, that is present in the stream for each life stage. If key habitat is limited, fewer steelhead can be supported by the stream. Habitat diversity refers to the extent of habitat complexity, such as large wood, boulders, undercut banks and pools, and the processes that form pools and cover within a stream reach. Greater complexity increases survival and provides better habitat. Large wood in the stream plays a major role. Instream wood in the basin is low relative to streams of the Cascade Mountains (Glass 2009); however, riparian density has been increasing for at least 70 years (Aspect Consulting and WPN 2004), and increases in recruitment of instream wood are expected as the riparian stands mature.

  Glass 2009 estimated the area of spawning habitat in the Rock Creek subbasin at 59,506 square meters and the volume of pools at low flow at 4,229 cubic meters (Glass 2009). Findings from a reconnaissance survey of portions of Rock Creek indicate that the creek's general channel characteristics may be similar to those noted in an 1860s survey (e.g., broad rocky reaches), with the exception that the

lowermost reach may be wider today than historically (Aspect and WPN 2004). Over the years, however, key habitat quantity and habitat diversity have declined in some reaches due to disturbance of channel and riparian habitats from grazing, historical timber harvest, road construction, other anthropogenic changes and from major flood events. These factors could potentially have contributed cumulatively to changes in the hydrograph, altering available perennial wet habitat as well as decreasing riparian quality and function and instream habitat and function. In addition, key habitat quantity and habitat diversity have been lost in the one-mile reach above Rock Creek's mouth as a result of inundation by Lake Umatilla behind John Day Dam on the Columbia River.

- ***Floodplain function and channel migration processes.*** The stream channel in lower Rock Creek is highly dynamic and moves across the valley bottom with regularity, likely switching channels during flood flows. One of the more dynamic sections of the stream channel is upstream of the Old Highway 8 Bridge, where the channel changed courses many times over the period of photo record, and has distinctly different courses in 1938, 1969, 1996, and 2002 (Aspect Consulting 2005). Bridges for the Bickleton Highway and Old Highway 8 have locally increased hydro confinement, constricting flow and channel migration processes. The Bickleton Bridge is scheduled for replacement with a longer spanned bridge. A series of dikes also exists in a middle mainstem Rock Creek reach that limit the stream's ability to meander. Extensive grazing, historically and currently, could potentially diminish riparian health and affect channel plain form in some reaches of the lower watershed, decreasing channel stability. However, most of the basin is lightly grazed, and grazing effects tend to be localized (Glass 2009). Although beavers have been observed near Luna Gulch (Glass 2009) and likely are present elsewhere in the basin, their abundance is likely lower than the historical population level.

- ***Sediment routing.*** Sediment loads (the percentage of fines in spawning gravel, embeddedness and turbidity) in the Rock Creek subbasin may have increased over historical conditions. Actions potentially contributing to increased sediment delivery include historical forest practices (skidding and road building, clearing of upland forests and stream banks), agricultural and grazing practices (rill irrigation, streamside grazing), and road building and maintenance activities.

  However, there is no commercial irrigation in Rock Creek, most of the basin lands are lightly grazed, and roads are sparse and largely located upslope from streams (Aspect Consulting and WPN 2004). These would tend to minimize the anthropogenic effects on sediment routing. A recent study that evaluated sediment loads in 278 riffles located throughout the basin found that only two of the riffles, both located in backwater areas, had fine sediment levels that exceeded 20 percent fines (Glass 2009). All other riffles had less than 20 percent fines and the majority of the riffles had less than 15 percent fines (Glass 2009). Previous studies have found these levels to have little effect on survival of eggs and alevins (Tappel and Bjornn, 1983, Chapman 1988).

- ***Competition for food sources.*** Changes in the hydrological regime and riparian conditions affect the food web and thus increase competition among species. Macroinvertebrates can be produced in reduced quantities where there are poorly functioning hyporheic zones, diminished pool and riparian presence, and a lack of stream structure. To date, there has been no assessment of food production or competition for food in the basin.

- ***Predation and competition.*** Inundation of the lower one mile of Rock Creek by the waters of Lake Umatilla behind John Day Dam may have increased access of piscivorous fish such as smallmouth bass, channel catfish, and northern pikeminnow to the lower mile of Rock Creek and the reservoir through which the steelhead must travel. However, no exotic piscivorous species were observed above the inundated area during snorkel surveys conducted in Rock Creek, Luna Gulch, and Squaw Creek during October and November of 2008 (Glass 2009). No evaluation has been done on the effects of predation and competition on the Rock Creek steelhead population.

  The ISAB (2007 and 2008) concluded that the Columbia River impoundments have created sloughs and backwater habitats where water exchange is very low and summer water temperatures are often several degrees warmer than the nearby main-channel habitats. As a consequence, introduced resident fish such as smallmouth bass and channel catfish are expanding into these habitats. The ISAB 2007 also commented that increases in water temperature would favor further expansion of warm-water piscivores. Hence, the potential for predation could increase over time.

5.2 Hatchery Effects

Anadromous fish production within the subbasin is almost exclusively natural. Steelhead are not stocked in Rock Creek, and very few fin-clipped steelhead have been observed in the subbasin. Hatchery strays of upriver origin may enter and spawn in Rock Creek, but the effects of out-of-subbasin hatchery programs on the Rock Creek steelhead population are unknown.

5.3 Tributary Harvest

Rock Creek and its tributaries are open to steelhead and trout fishing from June 1 to October 31 annually (trout over 20 inches are considered steelhead), and the area inundated by the John Day Pool (up to the Army Corps of Engineers Park at river mile 1) is open year around to allow for warm water fisheries and for trout over 12 inches (trout over 20 inches are considered steelhead) from June 16 to March 31. Only adipose fin-clipped steelhead may be retained (WDFW 2008a). Adult steelhead are not present in Rock Creek during the summer because of low or non-existent flows. They enter the creek after flows resume and temperatures drop, generally after the season is closed. Some minor tribal catches for ceremonial purposes are reported, but they are currently considered insignificant (Bill Sharp, Pers. comm. 2008). Poaching has been observed in

the subbasin, however, and is considered a problem. While increased patrols are desired, funding levels are mostly inadequate to provide for such services.

The fishery targeting other species at the mouth of Rock Creek is quite active at times and it is expected that some steelhead are unintentionally caught by recreational anglers, of which only marked hatchery fish are permitted to be retained. Better educational opportunities at the Army Corps of Engineers Park may assist in preventing accidental catch and retention of wild steelhead.

The overall mortality rate for catch-and-release adult steelhead fisheries depends on the encounter rate of naturally produced fish (percentage of run actually caught and released) in the fisheries, and the mortality rate associated with being caught and released (hook-and-release mortality). In winter steelhead fisheries, WDFW (2008b) estimates that catch-and-release mortality is less than 5 percent, while mortality in summer steelhead fisheries is estimated to be higher, less than 10 percent of the wild fish handled, reflecting high temperatures. The catch and release mortality only affects that proportion of the wild run encountered in the fishery. WDFW (2008b) estimates that in the Rock Creek tributary fisheries less than 5 percent of the steelhead are handled, due to the closure of Rock Creek during the period adult steelhead would be present, and the limited effort during the time that steelhead may be present below the Army Corps of Engineers Park. Multiplying the catch and release mortality rate by the encounter rate provides the estimate of tributary fisheries impacts of less than one percent wild steelhead (WDFW 2008b). For further evaluation of the harvest rate, please see the Middle Columbia River Steelhead DPS Recovery Plan.

Steelhead occupy many waters that are also occupied by resident trout species. It is not possible to visually separate juvenile steelhead from similarly sized stream-resident rainbow trout. Because juvenile steelhead and resident rainbow trout are the same species, are similar in size, and have the same food habits and habitat preferences, it is reasonable to assume that catch-and-release mortality studies on stream-resident trout also apply to juvenile steelhead. WDFW has implemented a number of regulation changes to limit impacts on juvenile steelhead in Rock Creek. These include increasing the minimum size limit for rainbow trout fisheries from 6 inches to the current size limit of 8 inches in the tributary and 12 inches below the Army Corps of Engineers Park. The daily bag limit was also reduced from 6 fish to 2 fish. Trout angling is only open from June 1 to October 31 in the tributary, and June 16 to March 31 in the area below the Army Corps of Engineers Park. These changes have reduced impacts on naturally produced juvenile steelhead/trout to less than 1 percent of the population, a substantial reduction from historical impacts of tributary fisheries that were estimated to be over 50 percent in some Middle Columbia River steelhead basins (WDFW 2008b). Rainbow trout are not released into Rock Creek, and this also reduces harvest impacts. Fisheries that target non-resident warm water species can affect juvenile steelhead, but these fisheries are limited to the area below the Army Corps of Engineers Park (WDFW 2008a). WDFW has submitted to NMFS a Fisheries Management and Evaluation Plan (FMEP) for tributary fisheries in the Middle Columbia steelhead DPS to cover impacts from these fisheries under the 4(d) rule limit 4 of the ESA (WDFW 2008b). This FMEP,

when finalized, will have all the site-specific actions for the tributary fisheries. NMFS expects the FMEP to be completed in 2010.

5.4 Out-of-Subbasin Limiting Factors and Threats

The Middle Columbia River Steelhead DPS Recovery Plan uses information from two "modules" developed by NMFS to address conditions in the Columbia River mainstem and estuary that affect all Middle Columbia steelhead: the Hydro Module, based on the NMFS 2008 Biological Opinion on the Federal Columbia River Power System (NMFS 2008b), and the Estuary Module (NMFS 2007b). In addition to proposed actions in the management unit plans, the DPS Plan relies upon Hatchery and Genetic Management Plans and Artificial Production for Pacific Salmon (Appendix C of the Supplemental Comprehensive Analysis, NMFS 2008 Biological Opinion) to address hatchery effects. For harvest effects, the Plan refers to fishery management planning through the 2008 U.S. v. Oregon agreement for mainstem fisheries, and Fisheries Management Evaluation Plans for tributary fisheries. The reader is referred to the DPS plan for this information. The following is a summary of the information most relevant to the Rock Creek plan.

5.4.1 Harvest

Without more data on Rock Creek steelhead abundance, and without targeted tagging of Rock Creek fish, the percentage of Rock Creek steelhead that are harvested in the Columbia River cannot be specifically calculated. However, it may be inferred that Rock Creek steelhead are subject to the same relatively low overall harvest rate estimated for other Middle Columbia steelhead. Washington Department of Fish and Wildlife (2008) estimates that in 2002, tributary fisheries in the Rock Creek area affected about 1 percent of the adult steelhead and less than 1 percent of the juvenile steelhead. Mainstem non-treaty commercial and recreational fisheries have an estimated impact of 1.6 percent of the A-run Middle Columbia steelhead (NMFS 2008a), and mainstem treaty fisheries have an estimate 6.64 percent impact (NMFS 2008a) for an overall estimated harvest impact of less than 10.24 percent.

The various fisheries that may harvest Rock Creek steelhead as they migrate through the Columbia River and Pacific Ocean are the following.

Ocean Fisheries

Since steelhead are rarely caught in ocean fisheries, these fisheries are not considered a significant source of mortality to Middle Columbia River steelhead (NMFS 2000). Ocean fishing mortality on Middle Columbia River steelhead is assumed to be zero.

Columbia River Mainstem Non-Tribal Fisheries

There has been no direct freshwater non-tribal harvest on wild steelhead from the Mid-Columbia DPS since 1992, when the last wild fish catch-and-release regulations on these populations became effective. Therefore, all current non-tribal harvest impacts on Mid-Columbia DPS steelhead are due to incidental bycatch in commercial or recreational fisheries that target hatchery steelhead or other species, and monitoring these impacts is complex. Released fish experience a mortality rate, possibly delayed and difficult to

measure, that is highly variable and depends on what gear is used, how the fish is caught by the gear, how the fish are handled during capture and release, and environmental conditions. Release mortality is estimated to be very low (below 1 percent of encounters), with an unknown range of error. Recreational fisheries are monitored by creel surveys (fisheries technicians interview anglers about their catch, gear, and wild steelhead releases); the total recreational impact on winter and summer steelhead as they move through the mainstem to the tributaries is estimated to be less than 2.5 percent (Carmichael 2009).

There are three stocks of summer steelhead used for management of treaty and non-treaty mainstem fisheries, including the lower Columbia River Skamania stock, upriver A-run stock, and upriver B-run stock. All MCR steelhead populations are designated A-run, except the two winter-run populations. In NMFS' Biological Opinion for the 2008-2017 *U.S. v. Oregon* Fisheries Agreement (NMFS 2008a), the wild MCR steelhead DPS in the non-treaty winter, spring, and summer mainstem fisheries are subject to a 2 percent harvest rate limit. Non-treaty fall fisheries are also limited to a 2 percent harvest rate limit for A-run summer steelhead. The total annual harvest rate limit for A-run steelhead in non-treaty fisheries is 4 percent and 2 percent for the summer-run and winter-run of the MCR steelhead DPS, respectively. The expected harvest impacts from non-treaty fisheries are less than the limits proposed in the *U.S. v. Oregon* fisheries Agreement. The yearly incidental catch of A-run steelhead in non-treaty fisheries has averaged 1.6 percent since 1999, and are not expected to change over the course of the Agreement (NMFS 2008a).

Treaty Native American Fisheries

Tribal fishers in Zone 6 of the Columbia mainstem (between Bonneville Dam and McNary Dam) continue to retain wild steelhead for commercial sale or for personal use. Impacts on MCR steelhead from treaty-Native American fall fisheries that affect summer-run steelhead populations including Rock Creek are limited by harvest rate limits for B-run steelhead and Upper Columbia River bright fall Chinook (NMFS 2008a). The harvest rate on MCR summer-run steelhead in spring, summer, and fall Zone 6 treaty-Native American fisheries combined averaged 11.7 percent since 1985 and 6.64 percent since 1998 (NMFS 2008b, Table 8.8.5.5-1). The impacts resulting from the treaty-Native American fisheries are expected to be similar to the 1998-2006 average of 6.64 percent. The harvest rate is less for populations that pass fewer dams in Zone 6 and are therefore subject to fewer non-Native American and treaty-Native American fisheries.

5.4.2 Columbia River Hydropower Operations

Hydrosystem construction and operation (flow regulation) in the Columbia River Basin has been a major cause of changes to the Columbia River and estuary from historical conditions. The effects of Columbia River hydro operations on salmonids are reviewed briefly here and described in detail in two NMFS documents: the 2008 FCRPS Biological Opinion (NMFS 2008b) and the Hydro Module (NMFS 2008c).

Within the Rock Creek subbasin, steelhead and salmon were directly affected by the creation of the John Day Dam on the mainstem Columbia River, which effectively inundated the lowest reach of Rock Creek, reducing riparian habitat and increasing predation by native and non-native fish in the lower river. A lack of historical data inhibits quantitative evaluation of the impacts of John Day pool inundation on native fish, plant, and wildlife species.

In the mainstem Columbia River, changes in river flow, circulation, water quality, contaminants, channel alterations, and predation have negative impacts on adult and juvenile fish. Hydro operations have changed flow conditions in the Columbia River and through the estuary. Before the development of the hydrosystem, Columbia River flows were characterized by high spring-runoff from snowmelt and regular winter and spring floods. Dam construction and operation have altered Columbia River flow patterns substantially throughout its basin. Historical flow records at The Dalles and Bonneville Dam demonstrate that annual peak flows have been reduced by about 50 percent, as water is stored for power generation and irrigation, and winter flows have increased approximately 30 percent.

The Columbia River Estuary Module http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery -Plans/upload/Estuary-Module.pdf, provides more information on factors that limit viability of Rock Creek steelhead in the Columbia River estuary.

5.4.3 Ocean Conditions

The effects of ocean conditions on abundance of Pacific salmon and steelhead vary among species and populations within species. Migration patterns in the ocean may differ dramatically and expose different stocks to different conditions in different parts of the ocean. Some species have broad, offshore migration patterns that may extend as far as the Gulf of Alaska (steelhead, chum, some Chinook). Others have migration patterns along the Washington, British Columbia, Oregon and California coasts (Chinook, coho, cutthroat). Thus, ocean conditions do not have coincident effects on survival across species or populations.

Ocean survival of steelhead has been dramatically affected by widespread changes in ocean conditions. Cooper and Johnson (1992) showed that variation in steelhead run sizes and smolt-to-adult survival was highly correlated between runs up and down the West Coast. Smolt-to-adult survival rates generally varied 10-fold between good and bad years. Ocean survival rates for three West Coast steelhead populations where good annual index data were available showed high variability and a generally declining trend since the late 1970s.

5.4.4 Climate Change

Climate change represents a potentially significant threat to recovery of Rock Creek steelhead, as well as Mid-Columbia steelhead DPS. The Independent Scientific Advisory Board (ISAB) for the Northwest Power and Conservation Council, Columbia River Basin Indian Tribes, and NMFS reviewed the potential effects of climate change on salmonids

in the Columbia River basin (ISAB 2007). The ISAB report shows that changes in climate may adversely affect steelhead in freshwater habitats across the DPS by exacerbating existing problems with water quantity (lower summer streamflows) and water quality (higher summer water temperatures). Consistently identified types of impacts on snow pack, stream flow, and water quality in the Columbia Basin are the following (ISAB 2007):

- Warmer temperatures will result in more precipitation falling as rain rather than snow.
- Snow pack will diminish, and the timing of stream flow will be altered.
- Peak river flows will likely increase.
- Water temperatures will continue to rise.

These changes may affect steelhead more than other salmonids because of their long rearing period in freshwater and sensitivity to water temperature.

Changing conditions could also affect salmonid health and survival in the ocean through a variety of mechanisms, including increased ocean temperatures, increased stratification of some waters, changes in the upwelling season, shifts in the distribution of salmonids, long term variability in winds and ocean temperatures, increased acidity, and increased atmospheric and oceanic variability. (NMFS 2007b, 2008a; ISAB 2007)

All other threats and conditions remaining equal, future deterioration of water quality, water quantity, and/or physical habitat can be expected to cause a reduction in the number of naturally produced adult steelhead returning to these populations across the DPS. This possibility further reinforces the importance of achieving survival improvements throughout the entire steelhead life cycle. Recent research also indicates that neighboring populations with differences in habitat may show different responses to climate changes (Crozier and Zabel 2006; Crozier et al. 2008). This research reinforces the importance of maintaining habitat diversity.

5.4.5 Other Large-Scale Threats

- Projected continued population growth will increase pressures for conversion of forestry and agricultural land uses to residential uses, with potential impacts on habitat and water conditions.
- Increase in exotic invasive species that potentially compete with native flora and fauna, and provide food and/or cover to species that potentially compete with, prey on or carry diseases which could affect native species.
- New disease and/or pathogen introductions (e.g. from marine aquaculture operations on steelhead ocean migration routes, illegal stocking of out-of-subbasin species).
- Natural catastrophic events (e.g. earthquake, volcanic eruption and related effects).

6. Recovery Strategy and Actions

The preceding chapters summarize recovery goals, biological criteria and threats criteria, current status assessment, and the limiting factors and threats identified for the Rock Creek steelhead population. How will we reach recovery? In this chapter, a recovery strategy is described to address the significant data gaps and uncertainties regarding the status of the Rock Creek steelhead population and to address the potential limiting factors based on the existing, best available science. In addition, Appendix II details the many efforts already underway to improve and protect watershed conditions in the Rock Creek subbasin—efforts that will benefit salmonids as well as other wildlife and human communities.

Lack of information about the Rock Creek steelhead population is a major problem for recovery planning for the Middle Columbia River steelhead DPS. Using the ICTRT criteria for DPS viability, this population needs to achieve "maintained" or moderate risk status for the DPS to be considered viable. The Rock Creek population's high risk rating was assigned primarily on the basis of uncertainty and lack of information on current abundance and productivity. Thus, research and monitoring to resolve the uncertainties and address data gaps is a top priority. Although some published and unpublished data are available, some disagreement also exists among regional experts concerning limiting factors and threats for the Rock Creek steelhead population. Further research will help to resolve these disagreements.

NMFS believes existing information and analyses are adequate to suggest a recovery trajectory and a scale of effort that can reasonably be expected to achieve the goal. A collaboratively designed implementation program that includes a research, monitoring, and evaluation (RM&E) plan to support adaptive management will allow managers the flexibility to continue or change course in response to new information.

The overall aim of the recovery strategy is to gather needed data on the Rock Creek steelhead population and the watershed, while also addressing the potential limiting factors in a manner that is most likely to contribute to improved viability. The strategies and actions were defined through review and analysis of currently available information. They are consistent with actions identified in the Lower Mid-Columbia Mainstem Subbasin (including Rock Creek) Management Plan (NPCC 2004), and address risks identified in the ICTRT's viability assessment for the population.

6.1 Strategies and Actions

The Plan proposes a number of strategies and actions to address data gaps and potentially limiting factors, assess anthropogenic effects, and implement actions to rebuild the Rock Creek steelhead population to the desired level of viability.

6.1.1 Gather Information on VSP Parameters

Information on population abundance, productivity, spatial structure, and diversity is needed to set priorities and determine the actions that will make the greatest contribution to steelhead recovery. Needed actions include initiating systematic surveys to calculate

abundance and productivity, completing a gap analysis, characterizing spatial distribution and genetic variation, and evaluating hatchery contribution to naturally spawning steelhead in the Rock Creek subbasin.

6.1.2 Protect and Conserve Existing Good Quality Habitat

Protecting existing good quality habitat is a high priority. Many objectives are likely to be met through habitat protection and the associated natural recovery of upland and riparian areas. Protection and maintenance includes compliance with existing rules and regulations, such as the State Forest Practices Act, the State Shorelines Act, and other State, County, and local regulations designed to protect aquatic habitat. Protection may also incorporate a wide range of voluntary actions such as fencing riparian areas, participation in the various agricultural land reserve programs, and voluntarily implementing programs that help to avoid impacts to aquatic resources. Land acquisitions, easements, cooperative agreements, and protective land designations can also be used to facilitate high quality habitat protection.

6.1.3 Restore and Enhance Habitat and Gather Information

Restoration and enhancement of habitat conditions for salmon and steelhead populations should improve population production. The value of these actions to the viability of the population will depend on whether or not they address the factors currently limiting the population or threats associated with factors that are now, or are trending toward, becoming limiting, e.g. climate change. The success of these strategies is further enhanced when actions build from existing restoration efforts and incorporate a range of project types.

- Conduct research to further evaluate factors and threats limiting habitat diversity in the Rock Creek watershed.

- Improve instream flow during critical periods. The seasonally low to intermittent stream flow in the area of steelhead distribution upstream of the Columbia River backwater is a likely limiting factor on abundance, productivity, spatial structure, and diversity. Low flow can result in stranding and mortality to eggs or juvenile steelhead. Further study is required to determine causes of low flow, whether anthropogenic or natural, and options to enhance stream flow.

- Improve water quality, reduce summer high temperatures. Water temperature is directly related to riparian vegetative cover and other watershed characteristics such as channel complexity, floodplain function, and upland processes. Hence, many types of habitat actions are likely to function together to improve water quality, particularly water temperature. The more directly related actions to improve water quality include the following:
    - Restore riparian vegetative cover with appropriate native vegetation to increase shading.
    - Develop sediment control basins.
    - Manage livestock grazing in the riparian areas.

  - Increase deep pool habitat.

- Improve/restore riparian function and condition. Actions to address this potential limiting factor include the following:
  - Restore riparian vegetative cover with appropriate native vegetation.
  - Manage livestock grazing in riparian areas.
  - Eradicate invasive plant species from riparian areas.
  - Relocate beaver to suitable areas.

- Increase key habitat by improving or restoring channel structure and complexity. Key habitat, as described in Chapter 5, refers to characteristics such as riffles, pools, suitably aerated gravel, etc. that are essential to each steelhead life stage. The following actions would increase key habitat:
    - Introduce large woody debris (LWD) and other structures in stream as appropriate.
    - Improve riparian vegetation to provide future source of LWD.
    - Stabilize and protect stream banks.
    - Fertilize streams with fish carcasses.

- Improve and/or restore floodplain function and channel migration processes. Reconnecting floodplain habitats and side channels would provide additional sheltered rearing areas. Increasing LWD and other actions such as relocating floodplain infrastructure where feasible, implementing road management BMPs or decommissioning roads as appropriate, could restore floodplain function, moderate the "flashiness" of the stream, and moderate peak flows.

- Improve or restore optimal sediment processes. Watershed processes of runoff and sediment production can be improved through restoring native upland plant communities, implementing appropriate upland management practices, managing off-road vehicle usage to reduce erosion and fine sediment, and managing roads to reduce fine sediment inputs to the stream.

- Conduct research to determine status of food web and presence or absence of competition from other species for food resources.

- Conduct research to determine presence and extent of predation on steelhead by non-native species such as piscivorous fish.

6.1.4 Review and Reduce Effects of Harvest

As described in Chapter 5, only adipose fin-clipped steelhead are allowed to be retained in sport or recreational fisheries in Rock Creek and throughout the Columbia River, but wild steelhead may be accidentally caught and/or retained. Poaching is also considered a problem. Actions to address harvest effects include better review of current practices, enforcement of regulations, and considering whether any modifications are needed. Outreach and education to reduce retention or handling mortality is also recommended.

6.1.5 Research Effects of Hatchery Fish (If Any)

As described in Chapter 5, hatchery strays of upriver origin may enter and spawn in Rock Creek, but no data are available on this issue. Monitoring for hatchery fish should be included in the RM & E program to be developed collaboratively after this plan is adopted.

6.1.6 Address Out-of-subbasin Limiting Factors

Out-of-subbasin limiting factors for Rock Creek steelhead may include hydroelectric operations, harvest, interactions with hatchery fish, predation, food, disease, competition, and ocean conditions. Actions to address these factors for all Middle Columbia steelhead are presented in the Columbia River Estuary Module (NMFS 2007b) and the 2008 FCRPS Biological Opinion (NMFS 2008b), summarized in the Hydro Module (NMFS 2008c).

6.2 Summary of Recovery Strategy

Table 6-1 summarizes the recovery strategy designed to improve the viability of Rock Creek steelhead. The table links strategies and actions to the factors and threats potentially limiting steelhead viability in the subbasin, and the viability parameters and life stages that would be most affected. Priority locations are provided for some strategies, with stream reaches or areas where actions should be applied first to gain the greatest benefit.

Table 6-1. Recovery Strategy and Actions for the Rock Creek Population of Middle Columbia Steelhead.

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
Gather information on population size and productivity	• Gather information to calculate abundance and productivity estimates	Entire Watershed	Addresses a primary risk factor	N/A	N/A	abundance and productivity	N/A
Gather information on population spatial structure and diversity	• Conduct surveys to determine steelhead distribution. • Identify major life history strategies • Conduct studies to address genetic variation in the population • Assess the contribution of hatchery-origin steelhead to the natural spawning population	Entire Watershed	Addresses a primary risk factor	N/A	N/A	spatial structure and diversity	N/A
Gather information to further evaluate habitat limiting factors and threats in the basin	• Conduct surveys to evaluate factors affecting habitat quantity. • Conduct surveys to evaluate factors affecting habitat quality. • Conduct surveys to evaluate factors affecting habitat function.	Entire Watershed	Addresses a primary risk factor	N/A	All life stages	All VSP parameters	N/A
Protect and conserve natural ecological processes that support steelhead viability throughout the life cycle	• Apply BMPs to livestock grazing practices • Apply BMPs to road system management • Apply BMPs to agricultural practices to control erosion and runoff • Manage stream corridor through conservation easements and/or land acquisition from willing sellers • Adopt and manage cooperative agreements	Throughout watershed	Key habitat quality and diversity, sediment inputs, water quality, stream flow	Road and grazing management activities	All life stages	abundance, productivity, spatial structure and diversity	Immediate for sediment, other parameters 5-15 years

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
Improve instream flow during critical periods	• Most of the actions listed in other categories are likely to improve stream flow. • Protect springs	Rock Creek downstream of RM 19.2, lower Squaw Creek, upper watershed	Channel morphology, habitat diversity, key habitat quantity, fine sediment, flow, water tempera-ture, thermal refugia, altered food web	Road and grazing management, channelization	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve water quality, reduce summer water temperatures	• Restore riparian vegetative cover with suitable native vegetation to increase shading • Restore natural habitat functions and processes through actions previously identified • Develop sediment control basins • Management livestock grazing in the riparian areas • Increase deep pool habitat	Rock Creek downstream of RM 19.2, lower Squaw Creek, upper watershed	Channel morphology, habitat diversity, key habitat quantity, fine sediment, flow, water temperature, thermal refugia	Road and grazing management,, particularly in riparian areas, channelization	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve and/or restore riparian function and condition	• Restore riparian vegetation cover with appropriate native vegetation • Manage grazing in riparian areas • Eradicate invasive plant species from riparian areas • Relocate beaver to suitable areas	Rock Cr. Below unnamed trib. at RM 19.2, Luna Gulch, lower Squaw Cr.	Hydrology, channel stability, fine sediment, water quality, key habitat quantity, habitat diversity, riparian vegetation	Road and grazing management activities	All life stages	abundance, productivity, spatial structure and diversity	0-50 years
Improve and/or restore channel structure and complexity	• Introduce LWD and other structure in stream as appropriate • Improve riparian vegetation to provide future source of LWD • Stabilize and protect stream banks • Fertilize streams with fish carcasses	Rock Creek downstream of RM 19.2, lower Squaw Creek, headwater streams	Channel morphology, habitat diversity, key habitat quantity, fine sediment, flow, water temperature, thermal refugia, altered food web	Road and grazing management, channelization	All life stages	abundance, productivity, spatial structure and diversity	0-50 years

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
Improve and/or restore floodplain function and channel migration processes	• Reconnect floodplain habitats • Reconnect side channels • Increase role and abundance of wood and large organic debris in streambeds • Relocate floodplain infrastructure, roads; improve maintenance, rehabilitate, decommission as appropriate • Remove dikes • Relocate beaver to suitable areas	Rock Cr. Below unnamed trib. at RM 19.2, Luna Gulch, lower Squaw Cr.	Channel morphology, habitat diversity, key habitat quantity, riparian vegetation, fine sediments, flow, water temperature	Road and grazing management activities	Juvenile rearing stage	abundance and productivity	0-10 years
Address upland processes to minimize unnatural rates of erosion and runoff	• Restore native upland plant communities • Implement upland management practices to restore natural runoff and sediment production • Implement off-road vehicle management actions that reduce erosion and fine sediment • Implement road management actions that reduce fine sediment inputs	Upper watershed	Hydrology, channel stability, fine sediment, water quality, key habitat quantity, habitat diversity, riparian vegetation	Road and grazing management activities and off-road vehicles	Egg, fry	abundance and productivity	0-50 years
Review and reduce effects of harvest on the Rock Creek steelhead population	• Review the need for modifications to sport, tribal, and commercial harvest practices on direct catch and by-catch • Increase outreach efforts to reduce the number of steelhead caught in recreational fisheries near the mouth of Rock Creek	All fishing areas in the basin, the Columbia River, and off-shore	Direct mortality	Harvest	Adult migrants	abundance	0-10 years
Research and reduce hatchery effects on the Rock Creek steelhead population	• Reduce the uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish • Monitor the potential for hatchery strays entering Rock Creek • Increase the proportion of	Columbia River and anadromous reaches of Rock Creek	Competition, genetic introgression	Hatchery releases	Juvenile and adult	abundance, spatial structure, diversity	2-10 years

Strategy	Actions	Action Area	Potential Limiting Factors Addressed	Threats Addressed	Life Stages Potentially Affected	VSP Parameters Addressed	Expected Biophysical Response[1]
	Columbia River Basin hatchery steelhead marked with coded-wire tags, especially in programs shown to stray at high rates in the past, and support the mass marking of all hatchery steelhead releases with, at a minimum, an adipose fin-clip						
Reduce competition with and predation by non-native piscivores	• Reduce the number of non-native predators	Columbia River and mouth of Rock Creek	Predation	Non-native species	fry and juvenile	abundance and productivity	2-20 years
Reduce mortality and/or improve passage at hydroelectric facilities	• Implement strategies and actions in the FCRPS Biological Opinion (NMFS 2008b)	Columbia River	Passage, predation, direct mortality	Hydroelectric plants	juvenile and adult	abundance	0-20 years

7. Implementation and Cost Estimates

Implementation of this plan depends on the voluntary actions and cooperation of local entities and citizen groups. An important part of implementation will be working cooperatively to develop an implementation schedule that includes site-specific actions and a detailed research, monitoring, and evaluation plan addressing the information needs described in Chapter 8. As a regional collaborative structure begins to take shape, it has become clear that a detailed RM&E plan should be developed collaboratively after the Rock Creek recovery plan is adopted.

7.1 Implementation

NMFS has worked independently with the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, and local entities to develop the recovery plan for the Rock Creek steelhead population. NMFS encourages the formation of a planning group for the Washington Gorge Management Unit, a forum or entity that would take responsibility for coordinating implementation of the plan. Implementing the proposed recovery actions for steelhead in the Washington Gorge Management Unit, including the Rock Creek subbasin, would be a primary task for a Washington Gorge Area Regional Board, subject to concurrence by state, tribal, and local governments and the opportunity for involvement and comment by the public.

The Board could consist of representatives from Klickitat, Yakima, and Benton counties, local landowners, and the Yakama Nation. The Washington Gorge Area Regional Board could also provide an opportunity for coordination with the Lower Columbia River Fish Recovery Board (LCFRB), since the Washington Gorge Management Unit encompasses both the Middle Columbia River Steelhead DPS, and the Willamette/Lower Columbia ESUs for Chinook, coho, and chum ESA-listed populations, which are covered by the LCFRB. The Board could prioritize recovery actions in the Rock Creek subbasin and other areas within the Washington Gorge Management Unit by developing one- and three-year implementation schedules that would build upon and respond to the interests of stakeholders in the area.

Setting priorities for projects for funding and developing an implementation schedule should be based on a balance between the biological benefit of the project, its cost, and feasibility of implementation. Projects that address primary limiting factors, have high biological benefit, are relatively inexpensive, and are feasible should receive highest funding priority. Projects that are costly, have low biological benefit to listed fish species, and have relatively low feasibility should receive lowest funding priority.

In addition to their co-management responsibility and key role on a Gorge recovery board (if one is formed), the Yakama Nation will play an important role during implementation because of their funding agreement under the Columbia Basin Fish Accords (Columbia Basin Accords 2008), which are three Memorandums of Agreement (MOAs) entered into between the Federal Columbia River Power System (FCRPS) action agencies (Bonneville Power Administration, U.S. Army Corps of Engineers and the Bureau of Reclamation),

four tribes, and one state. The most relevant MOA to the Middle Columbia River steelhead is with the Columbia River Inter-Tribal Fish Commission and the three treaty fishing tribes—Confederated Tribes of the Umatilla Indian Reservation; Confederated Tribes of the Warm Springs Reservation; and Confederated Tribes and Bands of the Yakama Nation. The MOAs are 10-year action agency commitments for projects to benefit fish affected by the FCRPS, with a focus on ESA-listed fish. The projects will be reviewed through the Northwest Power Act processes for implementing the Fish and Wildlife Program, administered by the Northwest Power and Conservation Council. The agreement secures approximately $200,000 per year for habitat actions, including project management, in the Rock Creek subbasin. Some of the projects listed in Table 7-1 will be implemented with these funds.

7.2 Costs

There are existing Federal, tribal, state, county and other local programs that are being carried out in the Rock Creek subbasin. Many of those programs, for example the USDA NRCS Conservation Reserve Enhancement Program, the Washington State Forest Practices regulations and county plans and ordinances are described in Appendix II. This plan assumes that those existing programs are funded, and will continue to be. At this time, this plan provides only additional incremental costs that would be incurred with implementation of this recovery plan. Total time and cost of recovery is estimated for the DPS as a whole and is iincorporated into Chapter 8 of the Middle Columbia River Steelhead DPS Recovery Plan. As implementation proceeds and implementation schedules are developed, the costs of both existing programs and new incremental costs of this recovery plan will be included in those schedules. If existing programs are not funded, funding will be identified as a need in the implementation schedule and the cost estimates for the recovery plan adjusted accordingly.

In an earlier iteration of this recovery plan, rough, preliminary estimates were also made for the data gathering actions described in Chapter 8 as part of the recovery strategy. The preliminary estimate for RM&E was reported at that time as $3,350,000 over 10 years. As described above, NMFS is not going to incorporate this cost estimate at this time; rather, we expect those costs to be developed as part of a collaborative effort to design an RM&E plan.

In this chapter, cost estimates are provided for an extensive and reach-specific set of potential habitat actions that will be refined and prioritized in the implementation process. NMFS, in coordination with the Yakama Nation, developed these cost estimates for a range of habitat improvement/restoration actions that may be necessary to address limiting factors and improve viability of the Rock Creek steelhead population. These costs, presented in Table 7-1, are general range summaries. Habitat action costs for recovery over a 10-year time period are estimated to be up to $1.8 million ($0.9 million for years 1-5). The actions listed in Table 7-1 do not include or account for RM&E (Section 6.1.1), because those costs will be developed as part of implementation planning, nor do they account for tributary fishery harvest management and enforcement activities (Section 6.1.4), which are considered existing programs, nor for costs of out-of-subbasin effects, which are addressed through other programs (Section 6.1.6).

The list of actions in Table 7-1 was developed primarily to address habitat limitations in each major reach of Rock Creek. The actions are a primary component of the restoration and habitat enhancement strategy discussed in Section 6.1.3 of this plan. Costs were assigned to key actions such as riparian plantings with native vegetation, removal of exotic vegetation, fencing exclosures, and the installation of root wads and other instream structures. These labor-intensive actions will increase shading, resulting in an improvement to water quality and a restoration of riparian function and channel structure and complexity. Several water and sediment control basins will also be installed to assist in the removal of cattle from sections of the stream with an anticipated improvement of riparian condition. An additional major strategy is to protect and conserve existing good quality habitat (Section 6.1.2), through such actions as purchase of conservation easements or land acquisition from willing sellers. Table 7-1 includes costs for acquisition and easement estimates provided by personnel of The Nature Conservancy who have been involved with easements and acquisitions in the Rock Creek watershed. Although each easement and acquisition negotiation is unique, NMFS believes these values to be the best available estimate for such actions within the Rock Creek subbasin.

Table 7-1 Costs Associated with Proposed Reach-Specific Actions for Rock Creek Provided by Yakama Nation Fisheries.

	Rock Creek Actions and Costs

8. Monitoring, Research, and Adaptive Management

Comprehensive, empirical monitoring data on fish populations and habitat are needed to identify appropriate projects and locations, populate habitat/production capacity modeling efforts (such as EDT, AHA, or other appropriate models), and inform adaptive management for the salmonid recovery plan. Information on fish distribution, abundance, productivity, habitat conditions, genetic diversity, pathogen levels, and other population parameters, as well as on population limiting factors, is necessary to help direct and evaluate these efforts. A coordinated monitoring program is needed to ensure that these various needs, including salmonid recovery planning, are met.

As part of implementing the Rock Creek steelhead recovery plan, a detailed monitoring and evaluation program will be collaboratively designed and incorporated into an adaptive management framework based on the principles and concepts laid out in the NMFS' guidance document, Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance (NMFS 2007a) http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf.

8.1 Adaptive Management

Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. It is a process of adjusting management actions and/or directions based on new information. It means taking an experimental approach to a complex task, making one's assumptions clear, and continuously evaluating them in light of new information. It works best when the collection of performance data and methods of evaluation are designed to get the information managers need to make sound decisions.

As outlined in the NMFS Adaptive Management guidance document, several types of monitoring are needed to support adaptive management: (1) implementation and compliance monitoring, which is used to evaluate whether the recovery plan is being implemented; (2) status and trend monitoring, which assesses changes in the status of an ESU and its component populations, as well as changes in status or significance of the threats to the ESU; and (3) effectiveness monitoring, which tests hypotheses and determines (via research) whether an action is effective and should be continued. (These three types of monitoring are discussed in more detail below.)

In addition, it is important to build in some research to illuminate the many unknowns in salmon recovery—the "critical uncertainties" that make management decisions all the harder. Critical uncertainty research may seem expensive or unnecessary in light of basic information needs; however, in the long run, it may reduce monitoring and implementation costs.

NMFS' guidance document presents a decision framework that can guide the design of a research, monitoring, and evaluation plan. The framework (Figure 8-1) contains two basic sorts of questions: (1) questions regarding ESU status (biological viability criteria)

and (2) questions regarding statutory listing factors and factors limiting recovery (limiting factor and threats criteria). Evaluating a species for potential delisting requires an explicit analysis of both types of criteria.

The guidance document contains a more detailed discussion of the framework and identifies the specific questions that should be answered to evaluate ESU status. These specific questions take the form of a series of decision-question sets that address the status and change in status of a salmonid ESU and the risks posed by threats to the ESU. The decision-question sets are designed to elicit the information NMFS needs to make delisting decisions. For recovery planners, the framework can guide future decisions about strategies and actions aimed at achieving recovery goals.

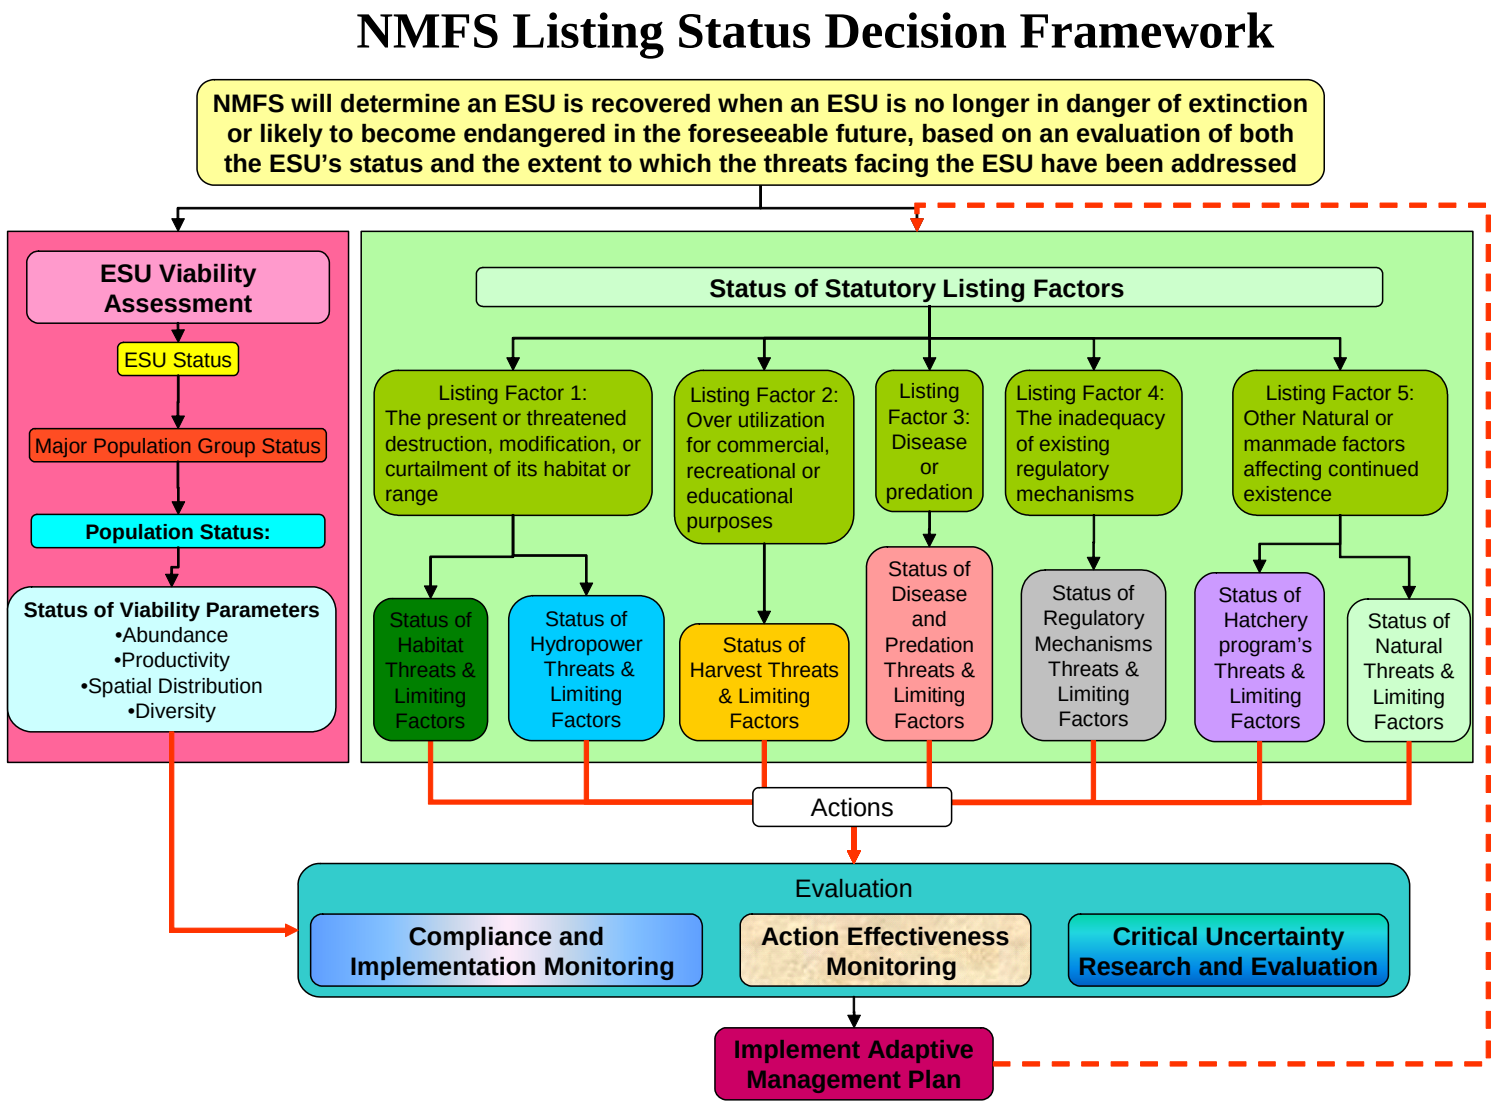

Figure 8-1 NMFS Listing Status Decision Framework.

8.2 Designing a Monitoring and Evaluation Program to Support Adaptive Management

Because of the length and complexity of the salmonid life cycle, there are many uncertainties involved in improving salmonid survival. Simply identifying cause-and-effect relationships between any given management action and characteristics of salmon populations can be a scientific challenge. It is essential to design a monitoring and evaluation program that will answer these basic questions: How will we know we are making progress? How will we get the information we need? And how will we use the information in decision making?

Designing an effective monitoring program for salmon recovery involves the following initial steps:

1. Clarify the questions that need to be answered for policy and management decision making. Include the full ESU and the full salmonid life cycle.
2. Identify entity or entities responsible for coordinating development of this program.
3. Identify:
    - Which populations and associated limiting factors to monitor
    - Metrics and indicators
    - Frequency, distribution, and intensity of monitoring
    - Tradeoffs and consequences of these choices
4. Assess the degree to which existing monitoring programs are consistent with NMFS guidance.
5. Identify needed adjustments in existing programs, additional monitoring needs, and strategy for filling those needs.
6. Develop a data management plan (See Appendix B of *Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance (May 1, 2007)* http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf
7. Prioritize research needs for critical uncertainties, testing assumptions, etc.
8. Identify entities responsible for implementation.

The Rock Creek subbasin monitoring and evaluation program will build on existing programs designed for monitoring tributary habitat in the Rock Creek subbasin, hydropower actions in the Mid-Columbia, Mid-Columbia hatchery programs, and other actions outside of the Mid-Columbia tributary subbasins (e.g., Columbia mainstem hydropower, estuary and ocean conditions and salmon use, mainstem and ocean harvest). The Rock Creek monitoring and evaluation program will provide (1) a clear statement of the metrics and indicators by which progress toward achieving goals can be assessed, (2) a plan for tracking such metrics and indicators, and (3) a decision framework through which new information from monitoring and evaluation can be used to adjust strategies or actions aimed at achieving the Plan's goals.

8.2.1 Implementation and Compliance Monitoring

Recovery actions implemented within the Rock Creek subbasin will be monitored to assess whether the actions were carried out as planned. This will be carried out as an administrative review and will not require environmental or biological measurements.

Implementation and compliance monitoring simply check on whether activities were carried out as planned, and whether specified criteria are being met as a direct result of an implemented action.

Implementation monitoring will address the types of actions implemented, how many were implemented, where they were implemented, and how much area or stream length was affected by the action. Indicators for implementation monitoring may include visual inspections, photographs, and field notes on numbers, location, quality, and area affected by the action. For example, if a fence is planned for 20 miles of stream corridor to keep livestock off the stream-banks so that riparian vegetation will rebound, implementation monitoring would verify the presence of the fence. Compliance monitoring would take note of the presence or absence of livestock in the fenced-off area.

Success will be determined by comparing field notes with what was specified in the plans or proposals (detailed descriptions of engineering and design criteria). Thus, design plans and/or proposals will serve as the benchmark for implementation monitoring. Any deviations from specified engineering and design criteria will be described in detail.

8.2.2 Status and Trend Monitoring

Status and trend monitoring is a simple compilation of data-based descriptions of existing conditions. To be useful in decision making, the raw data, or metrics, should be reduced to a more directly applicable form or indicator. For example, if the question is "What is the annual spawning population size of steelhead in Rock Creek?" the indicator would be total spawning numbers of steelhead over one season for the entire river basin; however, the metric, or directly measured thing, would be something quite different, perhaps steelhead redds sighted on weekly passes over known spawning grounds. Thus, the metric should be processed to translate it from the metric data type (e.g., redds) into the indicator data type (e.g., spawners), and then reduced to generate the indicator required (e.g., list of weekly counts on spawning grounds to annual total for watershed).

A future collaborative Washington Gorge Area Regional Board could direct implementation and develop a program to monitor the status and trend of steelhead population viability attributes, their habitats and their associated limiting factors throughout the Rock Creek subbasin. In the event that a collaborative Board cannot be established, co-managers along with participating local entities and individuals would establish such a program to utilize and comport with the guidelines developed in the NMFS, "Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance", the Pacific Northwest Aquatic Monitoring Partnership (PNAMP) and the Collaborative, and the Systemwide Monitoring and Evaluation Project (CSMEP).

8.2.3 Effectiveness Monitoring

Effectiveness monitoring specifically addresses cause-and-effect questions. Demonstrating the direct and indirect impact of management actions requires supporting all steps in the logical chain that connects the action to its expected impact. This chain is rarely short and usually contains several hypotheses. For this reason, it's better to build the effectiveness monitoring into the recovery action strategies, with, for example, pilot-scale tests or other methods carefully thought out beforehand.

Effectiveness monitoring, tests hypotheses and determines (via research) whether an action is effective and should be continued. Effectiveness monitoring should be coordinated with implementation monitoring. Not all recovery actions recommended in this plan need to be monitored for effectiveness. However, it is important that a sufficient number of replicates of each "type" of action be assessed for effectiveness. To the extent possible, effectiveness monitoring of recovery actions should be coordinated with the Washington's effectiveness monitoring program and should be monitored using the Before-After-Control-Impact (BACI) design with stratified random sampling, as described in the Comprehensive Statewide Monitoring Strategy (Monitoring Oversight Committee 2002). This strategy describes in detail the approach, indicators, and protocols needed to assess effectiveness of habitat restoration classes.

Monitoring and evaluation will only provide the answers to the questions they were designed to address; they do not provide the framework for revising these questions if they are ill-posed, evaluating the assumptions upon which the strategy was built, or incorporating learning into future decisions on actions and strategies—this is the role of adaptive management. Further guidance on effectiveness monitoring and validation monitoring/research can be found in NOAA's "Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance."

8.3 Research and Critical Uncertainties

Critical uncertainties, the unknown aspects of environmental conditions vital to salmonid survival, are a major focus of the research, monitoring, and evaluation program. Critical uncertainties fall into several categories policy, legislation, and science. The RM&E will focus primarily on the scientific uncertainties.

8.3.1 Out-of-Subbasin Uncertainties

There are numerous uncertainties regarding out-of-subbasin factors affecting the Rock Creek steelhead population. Successful recovery of steelhead as defined by the regional recovery plan requires achieving specific levels of productivity for populations within the entire DPS, not only acceptable productivity within any single basin that is a part of the DPS. This means that local communities in different watersheds/basins across local and state boundaries are dependent upon each other for successful delisting of these species. Results of actions, monitoring and research associated with NOAA's Estuary Module and 2008 FCRPS Biological Opinion should be coordinated with an appropriate local collaborative Board.

8.3.2 In-Subbasin Uncertainties

Monitoring is needed to establish linkages between specific actions and resultant environmental effects. Those linkages are complex and often not well understood. Understanding them requires input from experts from various fields. It is important that the actions recommended in the Plan to benefit listed fish species in the Rock Creek subbasin be reviewed by fish ecologists, geologists, hydrologists, and other experts familiar with the recovery region to determine how uncertainties may affect the interpretation of results.

Specific benchmark values for the VSP parameters will likely be refined during plan implementation based on new information. The following are examples of questions/research that would significantly enhance the ability to answer the information gaps or other relevant questions by providing new information to reduce uncertainty. These ideas and concerns could be discussed and prioritized during collaborative development of an RM& E plan.

- Conduct surveys to determine steelhead distribution.
- Gather information to calculate abundance and productivity estimates.
- Evaluate population phenotypic and genetic variation.
- Identify major life history strategies.
- Conduct studies to address genetic variation in the population.
- Assess the contribution of hatchery-origin steelhead to the natural spawning opulation.
- Document the 'spawner' contribution/distribution throughout the subbasin.
- Determine the number of Rock Creek steelhead caught in various fisheries.
- Evaluate the importance of 'straying' as a mechanism of maintaining the population.
- Determine survival from egg to fry.
- Further evaluate limiting factors and their causes.
- Evaluate what can be done to reduce stream temperature (Aspect Consulting 2005; Glass 2009).
- Evaluate what can be done to enhance stream flow (Aspect Consulting 2005; Glass 2009).
- Implement genetic research to identify genotypic variation, help establish presence of winter and summer runs in Rock Creek.
- Increase understanding of linkages between physical and biological processes so that managers can predict changes in survival and productivity in response to selected recovery actions.
- Validate the EDT model for Rock Creek with up-to date information, conduct sensitivity analyses for the model, and test assumptions built into the Rock Creek model runs.
- Determine relative performance (survival and productivity) and reproductive success of naturally produced steelhead in the wild.
- Assess population structure.

- Assess steelhead distribution in neighboring subbasins and determine genetic relationship to Rock Creek steelhead population
- Determine the effects of exotic species on recovery of steelhead and the feasibility of actions to eradicate or control numbers of exotic species.
- Evaluate increased predation risks from native and non-native fish and birds.
- Assess eutrophication and aquatic vegetation impacts and determine ecologically sound solutions to address the problems near the mouth of Rock Creek.
- Assess potential of conserving and rehabilitating springs.
- Identify what current water temperatures in the lower river are, and whether fish can survive with higher average mainstem temperatures if in-stream and side channel/floodplain habitats are intact, diverse and provide thermal refugia.

8.4 Existing Monitoring and Research

Many entities have been or will be implementing recovery actions within and downstream from the Rock Creek subbasin. Monitoring programs with which to coordinate include:

- WRIA 31 Watershed Monitoring Program (Klickitat County, EKCD, and the Washington Department of Ecology).
- Yakima Klickitat Fisheries Project,
- Yakama Nation Monitoring,
- NOAA Fisheries RME Program,
- Washington Salmon Recovery Funding Board Program,
- PACFISH/INFISH Monitoring Program,
- Pacific Northwest Interagency Regional Monitoring Program,
- USFWS, USGS, and BOR Monitoring Programs,
- WDFW and Department of Ecology monitoring programs, and
- Local Conservation District monitoring.

It is critical that these programs be consulted to emphasize utility, reduce redundancy, increase efficiency, and minimize costs.

8.5 Additional Needs

Additional monitoring needs may be identified in the future and should be incorporated into the RM&E plan during development or through the implementation of the adaptive management process.

8.6 Data Management

A formal and documented approach to data management is essential to adaptive management. A well-designed data management plan can help to ensure that data of a specified quality and quantity is available, at a specified time, to meet specified data analysis needs. Protocols, metrics, and other data standardization tools such as common data entry methods are a top priority for recovery plans. Coordination across existing monitoring programs and projects will be underpinned by an integrated monitoring and

data management framework. The framework would, for example, require the use of common methodologies for sample design, data collection, data validation, and data sharing in order to address common questions. Data management systems should be developed and coordinated with national and regional efforts for consistency with regional and national data standards. Project implementation data management should be consistent with PCSRF protocols where appropriate and guidance from PNAMP's effectiveness work group. Further guidance on data management is provided in the NMFS Guidance document Adaptive Management for Salmon Recovery.

It may be appropriate to incorporate data management with the Yakima Klickitat Fisheries Project, the WRIA 31 Watershed Management Plan implementation (and the WRIA 31 initiating governments), and other regional programs to provide easy comparison with existing large datasets within the DPS. There may be some administrative obstacles to this, but efficiency would dictate that this is likely the most appropriate resource. Storage of new monitoring information and access to existing information will be under contract with the local implementation body of this plan.

8.7 Consistency with Other Monitoring Programs

This recovery plan will utilize existing monitoring programs to evaluate the status/trend and effectiveness of recovery actions within the Rock Creek Basin. Specifically, this approach should incorporate strategies, indicators, and protocols described in the WRIA 31 Watershed Management Plan, the Upper Columbia Monitoring Strategy, the Comprehensive Statewide Monitoring Strategy, and Collaborative Systemwide Monitoring and Evaluation Project (CSMEP). The development of other regional monitoring programs may result in modifications to the monitoring programs used in the Rock Creek basin. These other programs, in various states of development, include such approaches as Pacific Northwest Aquatic Monitoring Partnership (PNAMP). As these programs develop more fully, they will provide guidance on valid sampling and statistical designs, measuring protocols, and data management. This information may be used to refine and improve the existing monitoring and evaluation programs in the Rock Creek basin. The intent is to make monitoring and evaluation programs in Rock Creek consistent with programs throughout the ESUs/DPSs and Columbia Basin.

8.8 Coordination

Many entities have been or will be implementing recovery actions within and downstream from the Rock Creek Basin. Monitoring programs to coordinate with include:

- NOAA Fisheries RME Program,
- Washington Salmon Recovery Funding Board Program,
- PACFISH/INFISH Monitoring Program,
- Pacific Northwest Interagency Regional Monitoring Program,
- USFWS, USGS, and BOR Monitoring Programs,
- WDFW and WDOE Monitoring Programs,
- Local Underwood Conservation District Monitoring, and
- WRIA 31 Implementing Governments.

It is critical that these programs be consulted to emphasize utility, reduce redundancy, increase efficiency, and minimize costs.

8.9 Evaluation Schedule

The Rock Creek subbasin currently has no collaborative regional Board guiding and coordinating recovery implementation. Tracking progress or needs for adaptive management in the Rock Creek subbasin by evaluating information from the recovery plan's research and monitoring programs would be one of the roles of a Washington Gorge Area Regional Board. Appropriate time intervals and triggers/goals need to be established to evaluate project implementation, compliance and effectiveness; the status (and change in status) of a population's viability attributes; the status of a population's limiting factors; and the research needs identified in the recovery plan.

On an annual basis, the Washington Gorge Area Regional Board would review efforts within the Rock Creek subbasin to determine whether funding has been obtained and actions initiated. Further evaluations should occur at intervals coordinated with other subbasin in the DPS. Reviews at this time should start with funding and implementation effectiveness. If funding and implementation have taken place previously, their effectiveness should be reviewed and progress toward the overall implementation of projects within Rock Creek should be measured. Status reviews should be coordinated with NOAA Fisheries five-year status reviews. Progress, or the lack thereof, should be evaluated within context of the entire DPS. In the absence of a Washington Gorge Area Regional board, monitoring efforts would probably continue to be coordinated/implemented through two programs -- Yakama Nation Fisheries, and, WRIA 31 Watershed Planning under Chapter 90.82 RCW, which coordinates state and local efforts.

Appendix I. Eastern Tributaries in the Washington Gorge Management Unit

Appendix I describes steelhead distribution and current conditions in several small tributaries to the Columbia River that drain areas in eastern Washington State upstream of Rock Creek. These tributaries are included in the Washington Gorge Management Unit of the Middle Columbia River steelhead DPS, which also contains the Rock Creek subbasin. There is very little information available about these small eastern Washington tributaries. NMFS considers them lower priority at this time than restoring the core populations of the Middle Columbia steelhead DPS. These drainages do not have enough historical habitat potential to sustain minimum numbers of spawners over a long time. If there are steelhead present, which has not been established in all cases, the ICTRT believes that the long-term occupancy of these small, relatively isolated streams probably depends on straying from a variety of areas, with the nearest upstream populations likely being the largest contributors of strays.

A summary of the available information is included as an Appendix to the Rock Creek Plan simply to acknowledge that these tributaries are part of the Washington Gorge Management Unit and that some insight into these areas might be useful to scientists and stakeholders in the future.

Introduction

NMFS defined "management units" for salmon and steelhead recovery planning based on jurisdictional boundaries as well as areas where local recovery planning efforts were underway. Several small eastern Washington tributaries of the Columbia River that drain lands to the east of the Rock Creek watershed are included in the Washington Gorge Management Unit and are considered part of the Middle Columbia River steelhead DPS. The management unit includes the White Salmon, Klickitat, and Rock Creek subbasins as well as the following small tributaries to the east: Chapman Creek, Wood Gulch, Pine Creek, Alder Creek, Glade Creek, and Fourmile Canyon (Figure ApI-1).

The Interior Columbia Technical Recovery Team (ICTRT) included these small eastern Washington State tributaries in the independent population boundaries of the Willow Creek and Umatilla populations of the Middle Columbia River steelhead DPS, which were historically the closest upstream independent populations (Figure ApI-1). The Willow Creek population is now considered extirpated (ICTRT 2009).

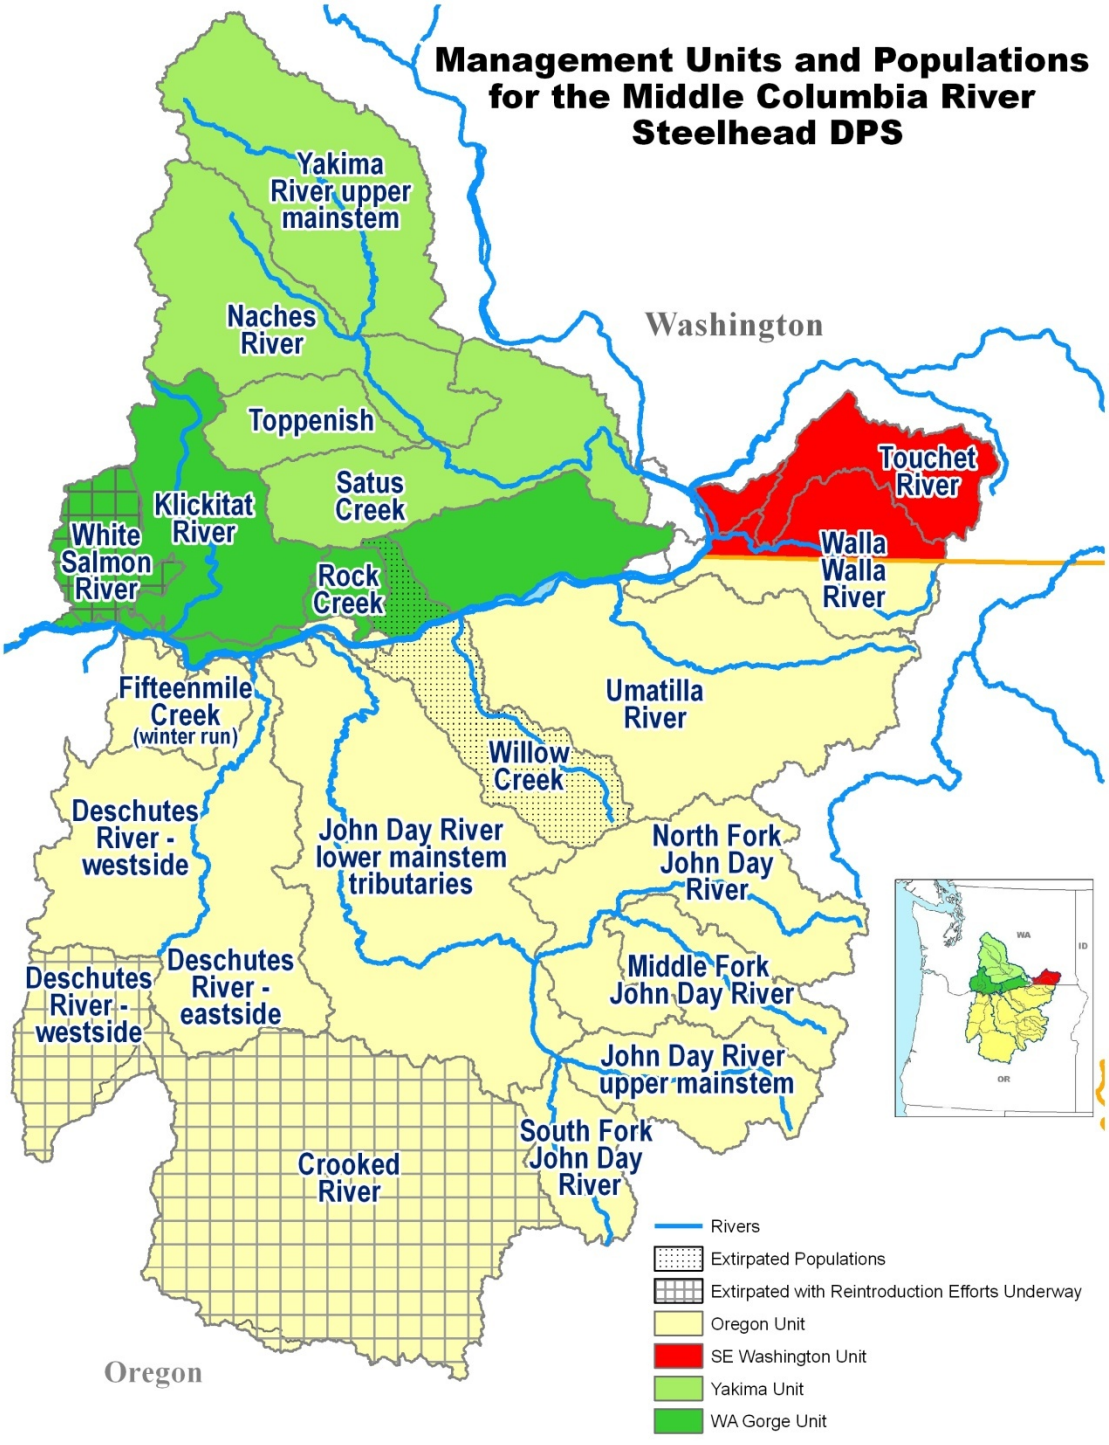

Figure ApI-1 NMFS Management Units for the Middle Columbia Steelhead DPS

The Umatilla and Willow Creek populations are part of the Oregon-Washington bi-state Umatilla/Walla Walla major population group (MPG) of the Middle Columbia River steelhead DPS. The Umatilla/Walla MPG includes three extant populations and one extirpated population. The Umatilla population is classified as a large population, and the other two, the Walla Walla and the Touchet, are classified as intermediate in size. The Umatilla population spawns primarily in Oregon, the Walla Walla population in both Oregon and Washington, and the Touchet population entirely in Washington. The Middle Columbia Steelhead DPS Recovery Plan (NMFS 2009) and the Oregon Middle Columbia River Steelhead Recovery Plan (Carmichael 2009) target the Umatilla population for viability and provide viability criteria, status assessment, limiting factors and threats, strategies and actions for recovery of the Umatilla population. The Willow Creek population is extirpated, and it is not considered to be a potential contributor to recovery of the DPS (NMFS 2009).

The small eastern Washington tributaries do not have enough historical habitat potential to sustain minimum numbers of spawners over a long time. If there are steelhead present, which has not been established in all cases, the ICTRT believes that the long-term occupancy of these small, relatively isolated streams probably depends on straying from a variety of areas, with the nearest upstream population likely being the largest contributor of strays. For that reason, the ICTRT included Alder Creek, Glade Creek, and Fourmile Canyon in the Umatilla population, and by the same logic inferred that steelhead (if any) in Chapman Creek, Wood Gulch, Pine Creek, and Old Lady Canyon historically could have been related to the now-extirpated Willow Creek population. It is unlikely that any current production in those small tributaries on the Washington side reflects Willow Creek. It is much more likely that any current production in those streams is either ephemeral, or linked with a currently producing upstream tributary (e.g., the Umatilla), or the result of straying from other extant steelhead populations/hatchery programs (ICTRT 2003, ICTRT 2009, and Tom Cooney, pers. comm. 2009).

Recovery Goal

NMFS' goal is for the Middle Columbia River Steelhead DPS to be recovered and removed from listed status under the ESA. Biological goals and criteria for the recovery of steelhead populations and MPGs in the Middle Columbia River steelhead DPS were developed by the ICTRT (2009) and described in the Middle Columbia Steelhead DPS Recovery Plan.

According to ICTRT viability criteria (ICTRT 2005, ICTRT 2007a, ICTRT 2007b), the Umatilla/Walla Walla MPG and other MPGs in the DPS should be at low risk (viable) for the Middle Columbia River steelhead DPS to be considered viable. ICTRT criteria recommend, and the Middle Columbia River Steelhead DPS Recovery Plan provides, that for the Umatilla/Walla Walla MPG to be regarded as viable:

1. Two of the historical populations in the MPG should meet at least minimum viability standards.
2. Viable populations within the MPG should include one large and one intermediate sized populations.
3. All major life history strategies present historically should be represented.
4. One population should be highly viable.

5. All populations that do not meet viable status should be maintained.

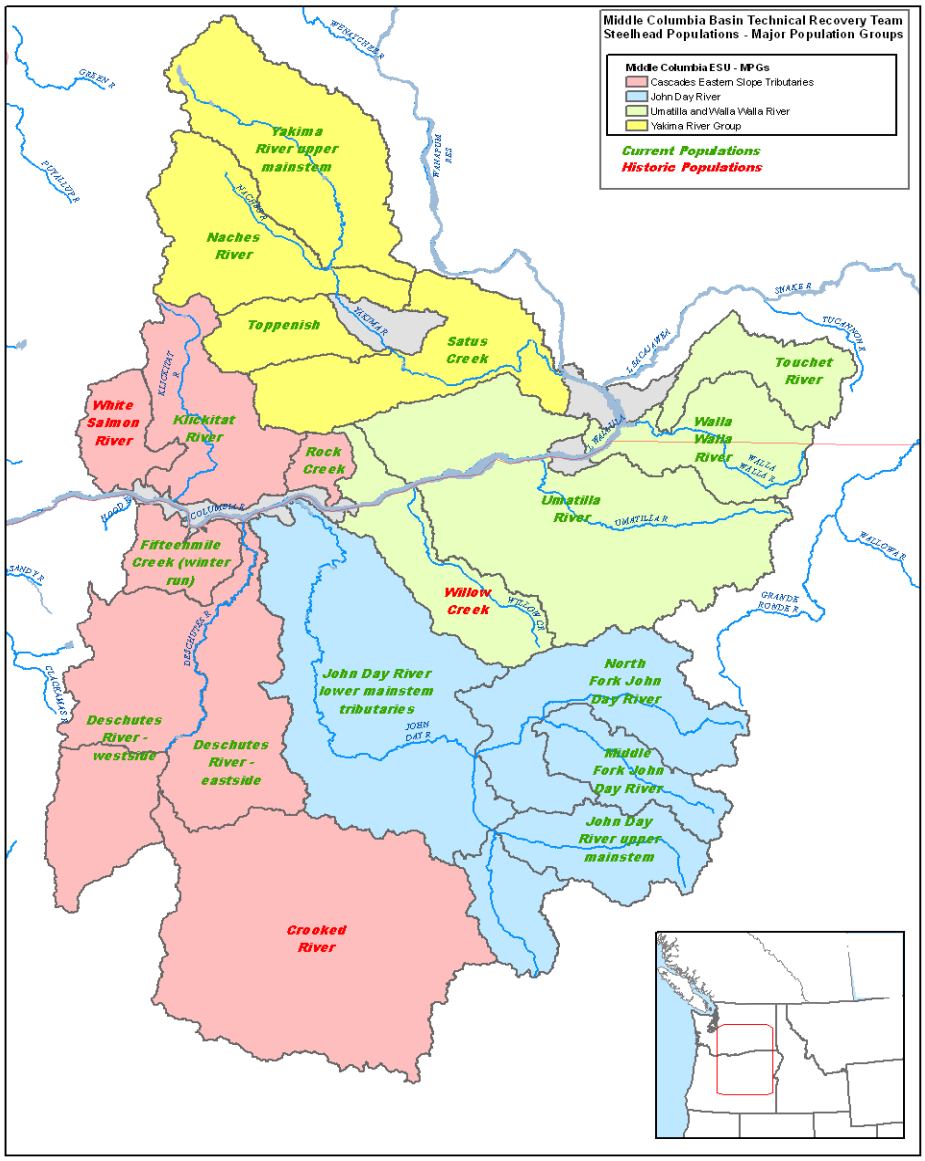

Figure ApI-2 NMFS Populations and Major Population Groups for the Middle Columbia River Steelhead DPS.

To meet the MPG-level viability criteria for the ESA, the Umatilla population should be at least viable (less than 5 percent extinction risk), or highly viable (less than 1 percent extinction risk). Either one of the intermediate populations, the Touchet or Walla Walla, should also reach viable or highly viable status. The remaining extant population should have no more than a 25 percent extinction risk. The Willow Creek population is considered extirpated and is not currently included in the ICTRT's recommended recovery scenario for the Umatilla/Walla Walla MPG (ICTRT 2005, ICTRT 2007a).

Because the Umatilla is a large population, the ICTRT recommended that to be viable, it should reach a minimum abundance threshold of 1,500 naturally produced spawners with a sufficient intrinsic productivity to achieve a 5 percent or less risk of extinction over a 100-year timeframe (ICTRT 2009).

The ICTRT considered Alder Creek, Glade Creek, and Fourmile Canyon to be spawning areas for the Umatilla River steelhead population, and included them in the assessment of spatial structure/diversity for that population (Section 6.1.9 in Carmichael 2009, and ICTRT 2009). However, these small tributaries were not included in the abundance/productivity rating because the Umatilla River drainage contains sufficient intrinsic potential habitat by itself to meet the definition of a large population. The Umatilla drainage is the core production area for the population (ICTRT 2009).

The Umatilla population does not currently meet the recommended viability criteria because its abundance/productivity and spatial structure/diversity risk ratings are both moderate. It does meet criteria for a "maintained" (moderate risk) population.

Recovery strategies and actions for the Umatilla population aim to improve viability by implementing actions to:

- Coordinate between planners, scientists and those implementing recovery actions in Washington and Oregon for sequencing, monitoring and adaptive management.
- Protect and improve freshwater habitat conditions and access for steelhead production. Improvements to freshwater habitat should be targeted to address specific factors in specific areas as described in the Southeast Washington Plan (SE Washington Management Unit Plan) and the Oregon Steelhead Recovery Plan (Oregon Management Unit Plan).
- Improve hatchery management to reduce straying from out-of-DPS hatchery fish onto natural spawning grounds within the Umatilla/Walla Walla subbasins.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007) and FCRPS Biological Opinion (NMFS 2008).

Summary of Existing Information on the Eastern Washington Tributaries

The eastern tributaries that are part of the Umatilla/Walla Walla MPG fall within Washington's Middle Columbia River Salmon Recovery Region, which comprises salmon-bearing streams in Benton, Kittitas, Yakima, and parts of Chelan and Klickitat counties. They are in the state's Rock-Glade Water Resource Inventory Area (WRIA) 31, which is bounded on the south and east by the Columbia River, on the west by the Klickitat River subbasin, and on the north by the Simcoe Mountains and a basalt ridge of the Horse Heaven Hills. They flow in a southerly to southeasterly direction to Lake Umatilla, the portion of the Columbia River impounded by the John Day Lock and Dam. Elevations range from 200 feet at the confluence of Rock Creek and the Columbia River to over 4,000 feet in the Horse Heaven Hills (WSCC 2005).

Wood Gulch and Pine Creek drain an area of Washington State that is dominated by extensive basalt flows having a total thickness of up to 5,000 feet. The erosion-resistant nature of these flows has resulted in the creation of deep (500 to 800 feet), steep-walled canyons and has severely constrained floodplain development along substantial portions of the streams within this area (Aspect Consulting and WPN 2004). Chapman, Alder, Glade, and Fourmile Creeks flow over deep deposits of loess (Aspect Consulting and WPN 2004). Steep-walled canyons are common in these creeks as well because the underlying loess is highly erosive.

The streams appear to have similar geomorphic characteristics. Headwater tributaries flow out of the mountains and across the relatively flat basalt plateau at gradients of generally less than 1 percent; this area is above known anadromous use. Coming off the plateau, streams enter steep-walled canyons; gradients increase to 2 – 4 percent or more. Below the canyon reaches, most of the streams enter alluvial valleys; gradients range between 1 percent and 2 percent near the upper end, dropping to less than 1 percent as streams approach the Columbia.

Climate over the area is typical of that found on the east side of the Cascades; average daily temperatures range from 70°F in the summer (with maximums commonly above 90° F) to 37° F in the winter. Annual precipitation ranges from 14 to 16 inches in the eastern portion of upper Wood Gulch to less than 10 inches over the eastern two-thirds of the area. Most of the precipitation in the area falls between October and April (Aspect Consulting and WPN 2004). Cultivated agriculture is a more dominant land use in those subbasins with deep deposits of loess, including the lower halves of Alder, Glade, and Fourmile Creeks. A large portion of the cultivated land is irrigated in the southern halves of Glade Creek and Fourmile Creek, and to a lesser extent in the Alder Creek tributaries (Aspect Consulting and WPN 2004).

All these streams may have temperature problems: high water temperatures are recorded during summer months. Data suggest that water temperatures in Chapman Creek, Alder Creek, Wood Gulch and Pine Creek have been found to exceed the Washington Department of Ecology standard (17.5°C/63.5°F) (BLM 1986, EKCD 1997, Lautz 2000).

The ICTRT (2007) used regression models based on available stream temperature-elevation data to characterize reach-specific temperature regimes. The ICTRT cautioned that those projections reflect the factors driving stream temperatures during the periods of observation and are not necessarily representative of historical conditions. However, they used temperature mapping, based on those relationships, to identify populations and areas that are subject to relatively high stream temperatures during key rearing (and spawning) periods. Glade Creek and Fourmile Canyon are temperature-limited areas that could potentially have had temperature limitations historically. Alder Creek appears to be only partially temperature limited (ICTRT 2009).

Land use in Wood Gulch and Pine Creek subbasins is largely rangeland. While there is some dryland farming in these subbasins, the subbasins have shallow soils overlying aged basalts and are not well suited for cultivation. Cultivated agriculture is a more dominant land use in those subbasins with deep deposits of loess, including the lower halves of Chapman, Alder, Glade, and Fourmile Creeks. A large portion of the cultivated land is irrigated in the southern halves of

Glade Creek and Fourmile Creek, and to a lesser extent Alder Creek, subbasins (Aspect Consulting and WPN 2004).

Alder Creek

Alder Creek encompasses an area of 199.09 sq. miles (127,418.3 acres). Very little information is available regarding habitat conditions or steelhead distribution in the basin. The lower portion of Alder Creek is perennial as a result of spring water inputs and, in the lower half of the subbasin, irrigation return flow. Despite relatively dense riparian vegetation along the narrow creek, stream temperatures in the summer tend to be warm, with seven-day average temperatures possibly exceeding the state standard. Hill slopes of Sixprong Creek, a tributary to Alder Creek, were found to be up to 50 feet in height, nearly vertical, and of highly erosive material. The stream channel is well-defined in much of the Sixprong Creek, except in the lowest reaches, which contain broad wetlands. Government Land Office (GLO) land survey notes of the late 1800s indicate the steep canyon slopes were present at the time of early settlement (Aspect Consulting and WPN 2004).

Steelhead distribution: No surveys of fish distribution have been completed in the basin. Steelhead adults have reportedly been observed in the lower 1.5 mi. of Alder Creek (Yakama Nation Fisheries, unpublished information).

Habitat Conditions: Geology in the basin is dominated by flood deposits and loess (Aspect Consulting and WPN 2004). The loess is derived from wind-blown sediments and does not contain the gravels and cobbles necessary to form spawning habitat; therefore, there may be little spawning gravel present in the basin.

Glade Creek

The Glade Creek watershed covers 432.7 square miles on a wide, open, largely treeless, gently south-sloping plateau in southeastern Washington known as the Horse Heaven Hills. The majority of the watershed, including the lower half of mainstem Glade Creek, the eastern tributaries of Moore Canyon, East Branch Glade Creek, and Carter Canyon, lies in western Benton County, while the main branch of Glade Creek and Coyote Canyon extend across the northeastern corner of Klickitat County and into the southeast corner of Yakima County. Glade Creek's headwaters drain the east-west trending crest of the Horse Heaven Hills at elevations that range from 3,560 feet at the western end to 1,420 feet. East Branch joins the main branch of Glade Creek at an elevation of 365 feet; the confluence of Glade Creek at the Columbia River is at 266 feet above sea level (Garrigues 1996).

Annual precipitation is typically under 10 inches (Aspect Consulting and WPN 2004). About 90 percent of the precipitation falls between November and April, primarily as snow (Packard et al. 1994).

The Glade Creek watershed is underlain by at least 5,000 feet of basaltic flows forming three basalt formations, each composed of numerous, layered basalt flows with many potential fractured, water-bearing zones. Loess, alluvial, glaciofluvial and lacustrine deposits overlie the basalt and range from less than 5 feet to about 200 feet thick (Packard et al. 1994). Groundwater

flow direction in the watershed is determined to a large extent by geologic structure and topography, which combine to funnel groundwater flow toward the lower reaches of Glade Creek (Garrigues 1996). Groundwater recharge in the subbasin is estimated to be roughly 300 percent of pre-development conditions due to irrigation return flows (Aspect Consulting and WPN 2004).

Glade Creek and its tributaries are intermittent streams that, historically, have often been dry in the summer and autumn (Molenaar 1982; Davis 1993). Flow typically only occurs in the precipitation and snow-melt period, based on six crest-stage gauges on central Glade Creek and various tributaries and at a discharge measurement site at the creek's mouth (Molenaar 1982). Under normal precipitation conditions, nearly 100 percent of the flow in Glade Creek comes from baseflow (groundwater discharge), except during spring runoff and peak stream discharges after storm events (Garrigues 1996).

Crop production is the basis of the economy in the Glade Creek watershed. Dryland wheat occupies the greatest crop area, but irrigated lands have increased dramatically since the early 1970s (Packard et al. 1994) The principal groundwater use is for crop irrigation; however, the primary source of water used in the subbasin is surface water imported from the Columbia River (Aspect Consulting and WPN 2004).

Steelhead distribution: During a study conducted in spring of 2009, single pass snorkel surveys were conducted in Glade Creek. *O. mykiss* were not observed in Glade Creek (Glass 2009). Dace were the only species occupying the basin.

Habitat Condition: No suitable spawning habitat was found in the lower 2.5 miles of the stream (Glass 2009). The loess that dominates most of the basin is derived from wind-blown sediments and does not contain the gravels and cobbles necessary to form spawning habitat; therefore, it appears that the lack of spawning habitat is a natural condition. The available information regarding the naturally occurring lack of spawning habitat (Glass 2009) and absence of surface water flow throughout much of the basin (Garringues 1996) suggests that Glade Creek cannot support salmonid populations under naturally occurring conditions.

Fourmile Canyon

No information is available for Fourmile Canyon. A review of available aerial photographs indicate that Fourmile Canyon does not have an outfall into the Columbia or a tributary to the Columbia, suggesting that the canyon cannot support anadromous species (Glass 2009).

Chapman Creek

The Chapman Creek watershed encompasses 24.15 sq. miles (15,453.5 acres). The headwaters and other stream sections are dry for much of the year.

Steelhead distribution: No *O. mykiss* were observed in the one pass snorkel surveys conducted in Chapman Creek in October and November of 2008 (Glass 2009). Speckled dace were the only species observed utilizing habitats in the basin during the survey.

Habitat Condition: No suitable spawning habitat was found in the lower 4.5 miles of the stream, which includes the majority of the wetted area in late summer and fall. The loess which dominates most of the basin is derived from wind-blown sediments and does not contain the gravels and cobbles necessary to form spawning habitat; therefore, it appears that the lack of spawning habitat is a natural condition (Glass 2009). Due to the naturally occurring lack of spawning habitat, it is unlikely that Chapman Creek can support salmonid populations.

Wood Gulch Creek

Wood Gulch encompasses an area of 64.39 sq. miles (41,207.9 acres). The creek runs through a steep, arid canyon, with slopes that extend 500-800 feet up from the valley bottom. Precipitation in the basin ranges from 8 to 16 inches per year, falling primarily from October through April (Aspect Consulting and WPN 2004). The Wood Gulch fire burned 11,640 acres 2007, (www.wsp.wa.gov/fire/docs/mobilization/mobe_history_for_2008.pdf) including several stretches of riparian vegetation.

Human population is sparse in the subbasin. The primary land use in the subbasin is rangeland. Commercial-scale wind energy facilities are also present in the subbasin on the plateaus. Few roads traverse the basin, and most existing jeep trails are located at a distance from the stream, except a few which reach the valley bottom.

***O. Mykiss* distribution:** Single pass snorkel surveys were conducted in Wood Gulch in October and November of 2008 (Glass 2009). *O. Mykiss* were observed between river mile 1 and river mile 9. The majority (58 percent) of these fish were observed between river mile 1 and river mile 5. The proportion of the population that is anadromous is unknown. The size distribution of the *O. Mykiss* in the lower 5 miles of the stream is consistent with sizes expected of juvenile anadromous fish; however, the size distribution of the fish in the upper 4 miles of the fish distribution suggests that those fish may be part of a resident population because there were numerous larger fish (Glass 2009).

Habitat Condition: Twenty-four percent of the stream length surveyed in October and November of 2008 was dry. Dry segments were concentrated in the lower 1 mile of the stream (58.4 percent dry) and in segments upstream of approximately river mile 9 (68.7 percent dry) (Glass 2009). Based on GLO Land Survey notes from June 1867, Wood Gulch Creek was dry at the mouth and intermittent from there to the confluence of Big Horn Canyon, upstream of which perennial water seemed to return and extend to four miles upstream of the confluence with Big Horn Canyon, as well as 2-3 miles upstream into Big Horn Canyon (Aspect Consulting and WPN 2004).

The majority of the spawning habitat in the Wood Gulch basin is located in the lower 5 miles of the stream. The percent fines in the spawning gravels in fall and early winter of 2008 was less than 20 percent in most of the basin, indicating that the quality of spawning gravel was generally

good. Sixty-nine percent of the pool (rearing) volume identified in the surveys of 2008 was found in a 0.5 mile segment between river miles 8 and 9. Twenty-eight percent of the *O. mykiss* observed in the basin were found in this short stretch. The portion of the creek extending from river mile 1 to river mile 5 also contained numerous pools that represented 21 percent of the total pool volume in the basin. Fifty-eight percent of the *O. mykiss* observed in the basin were found in these pools (Glass 2009).

Pine Creek

Pine Creek is a small stream with a basin area of approximately 62.64 sq. miles (40,086.8 acres). Pine Creek feeds Lake Umatilla on the Columbia River upstream of John Day Dam in WRIA 31. Average subbasin elevation is 1904 feet; average annual precipitation ranges from 8 to 10 inches near the mouth to 14 to 16 inches in the headwaters of the basin (Aspect Consulting and WPN 2004)**.**

A system of five culverts at the SR 14 highway crossing of Pine Creek was included in the WSDOT Fish Passage Barrier Inventory as of March 2006. The intended entrance is fully submerged at approximately 30 feet depth in Lake Umatilla. The upstream invert of the pipes is several feet above the pool water surface much of the year. A large volume of sediment and debris has filled in the previous creek channel nearly 15 feet, and obstructs the entrance to the submerged culvert. Only a small opening clogged with woody debris passes flow from the stream through the road fill. The constricted culvert entrance has created a barrier to fish passage due to physical obstructions and high water velocities (Harbor Consulting Engineers 2007). The culvert was attributed with 0 percent fish passage by WSDOT (2006). The barrier culverts are slated for replacement in 2012.

***O. Mykiss* Distribution**: Due to the passage barrier at the mouth, all fish in Pine Creek are resident fish. They may have some genetic link to a previous anadromous population, but they are not currently an anadromous population.

The one pass snorkel surveys conducted in the lower 7 miles of the creek in November of 2008. Sixty-nine resident *O. mykiss* were observed distributed throughout the surveyed area (Glass 2009). Forty percent of the *O. mykiss* were observed in a single pool at roughly river mile 1 and thirty-two percent of the fish were observed in a single pool at roughly river mile 8.3. The remaining 19 percent of the fish were scattered throughout the lower 7 miles of the creek. Since *O. mykiss* were found throughout the survey area, additional fish may be present upstream of the surveyed area.

Habitat Condition: Within the area surveyed in November of 2008, 41.6 percent of the survey area was dry. Fifty-nine percent of the lower 5 miles of the stream was dry, but flow was more consistent further upstream where less than 10 percent of the channel length was dry (Glass 2009).

The majority of the spawning habitat in the surveyed portions of the Pine Creek basin is located between river mile 4 and river mile 8 (Glass 2009). The percent fines in the spawning gravels in November of 2008 was less than 20 percent in most of the basin, indicating that the quality of

spawning gravel was generally good. The total pool volume in the surveyed area was 182.1 cubic meters. Pool habitat was distributed throughout the survey area. Many of the pools in the lower 5 miles were isolated between dry stretches of channel.

Old Lady Creek

A brief reconnaissance of Old Lady Canyon was completed on 12/16/08, four days after a period of heavy rain (Glass 2009). The basin has several emergent wetlands. Despite the heavy rains, the stream was not flowing. The culverts under Highway 14 near the mouth of the basin is well positioned to carry any flow but were dry and clean suggesting flow occurs rarely, if at all.

Two vertical drops (no water) are along the apparent channel in the first reach of the basin; one is 17 feet high and the second is 16 feet high. There is a 21-foot interval between the two drops where a small depression 0.5 foot deep is present. Both drops would be upstream barriers to fish movement if flow were present in the canyon (Glass 2009).

Appendix II. Current Efforts to Improve the Watershed

Many positive steps have already been taken or are currently underway that will improve steelhead habitat and overall watershed function in the Rock Creek drainage, and thus improve the viability of Rock Creek steelhead. The breadth of these efforts illustrates how natural resource managers, local governments, tribes, soil and water conservation districts, non-profit organizations, local land owners and many others are working together to improve watershed conditions that will support a viable Rock Creek steelhead population throughout its freshwater life stage. This appendix describes many of these efforts.

Conservation Efforts

- The Eastern Klickitat Conservation District (EKCD), under a 1996 Memorandum of Agreement with the Washington Department of Ecology, implemented actions to contribute to the protection of water quality, speed riparian recovery, and potentially prevent future flood-related damage in the Rock Creek drainage. In accordance with the MOA, the EKCD monitors water temperatures other water quality parameters (e.g., dissolved oxygen, pH, nitrates). This MOA, however, lapsed in 2004 and has not been renewed, but the EKCD continues to implement its provisions. The EKCD monitors water temperatures other water quality parameters (e.g., dissolved oxygen, pH, nitrates) as well as plant vegetation throughout the watershed. Under a grant from the Washington Conservation Commission (WCC), the EKCD "cost-shares" with landowners for grassland/permanent cover plantings and for no-till seeding throughout the Rock Creek drainage. Under a different grant from the WCC, the EKCD is working with livestock growers throughout the basin to develop and implement BMPs (Best Management Practices) which target restoration and protection of riparian areas (Jim Hill, EKCD District Manager, pers. comm. 2006).

- County governments, state and local agencies and other stakeholders/water resource interests developed a watershed plan under chapter 90.82 RCW for the Rock Creek Basin and elsewhere in Water Resource Inventory Area 31 (WRIA 31). WRIA 31 encompasses the Rock Creek subbasin and other Columbia River tributary systems between the John Day Dam and Kennewick in Washington State. A watershed assessment (http://klickitatcounty.org/NaturalR/Content.asp?fC=29&fD=3) was completed in support of the planning process (Glass 2009). The watershed management plan (http://klickitatcounty.org/NaturalR/Content.asp?fC=31&fD=3), which was approved in April 2009, will guide water resource and habitat management (WRIA 31 Planning Unit 2008). Chapter 90.82 RCW provides for plan implementation in the amounts of $100,000 for each of the first three years, and $50,000 for two additional optional years. The watershed management plan includes a list of prioritized habitat and water resource issues and a suite of

strategies to address those issues. Actions undertaken to date to implement the plan include ongoing stream flow monitoring by Washington Department of Ecology and completion of a quantitative instream habitat assessment for Rock Creek and several other streams in the WRIA.

- Washington's water quality and other water resource related funding programs administered by Washington Department of Ecology take local priorities and consistency with WRIA watershed plans into consideration when determining whether to fund proposed projects through grants and/or low interest loans. The WRIA 31 watershed planning unit serves as the body that develops the local statement of agreed priority for projects proposed within Rock Creek and other areas of WRIA 31.

- The U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS) works with landowners to conserve natural resources on private lands. The NRCS accomplishes this through various programs including, but not limited to, the Conservation Technical Assistance Program, Soil Survey Program, Conservation Reserve Enhancement Program, and the Wetlands Reserve Program. The NRCS works closely with local Conservation Districts; providing technical assistance and support.

- The Nature Conservancy has acquired land and conservations easements within the watershed. The Conservancy is working with Federal, state and private adjoining landowners to protect native habitats and significant plant and animal species, and to restore sites as functional ecosystems within the watershed.

- The Yakama Nation has provided basic monitoring and recently received a small grant to perform fencing and riparian plantings in lower Rock Creek. These actions will begin to address at a small scale the following limiting factors: loss of riparian vegetation, altered food web, altered channel morphology. A small grant was recently awarded the YN to conduct water quality/quantity measures, habitat surveys, and Ecosystem Diagnosis and Treatment (EDT) modeling in Rock Creek. Complementing this effort, the YN has proposed assessing Rock Creek's current and potential steelhead production by assessing the juvenile salmonid abundance, growth, life histories, and genetics. Data collected through assessment activities to determine steelhead distribution, diversity, relative abundance, and movement within or out of the watershed will help feed modeling efforts, which in turn will help prioritize restoration activities.

Regulatory Protection

Various state, tribal and county regulatory mechanisms are in place to protect riparian areas from current and future threats posed to listed species through habitat loss and degradation caused by human land uses and development. These mechanisms include Washington State forest and fish regulations, state and county shoreline development regulations and the Yakama Nation Forest Management Plan. In addition, some areas

receive special protection through designation, such as Wild and Scenic River reaches, primitive areas, and wildlife refuges.

Washington State Forest Practices Regulations

The Washington Forests & Fish Law (ESHB 2091) was signed into law in 1999 as part of The Washington State Forest Practices Act (Title 76.09 RCW), passed in 1974. The Forests & Fish Law, based on the Forests & Fish Report, resulted in changes to forest practices rules to protect riparian and aquatic resources on more than eight million acres of private forestland. It is intended to meet the provisions of the Federal Clean Water Act concerning nonpoint source silvicultural practices. Changes to the law included:

- Updates of the stream typing system in the state to improve mapping of fish-bearing waters,
- Increases in buffer widths along fish bearing and non fish bearing streams,
- Changes in forest practices to protect against landslides
- Mandatory requirements to update the forest road system to hydrologically disconnect roads from streams and minimize sediment delivered to streams,
- New regulations on pesticide applications to prevent or avoid drift of chemicals into streams,
- Increased protection of wetlands
- Changes in enforcement,
- Establishment of a scientifically based adaptive management and monitoring process for evaluating the impact of forest practices on aquatic resources,
- Establishment of a process for amending the forest practices rules to incorporate new information as it becomes available, and
- Establishment of a small landowner office to assist non-industrial landowners.

The Forest Practices Rules prescribe how forest practices such as logging, road building, and applying chemicals are to be conducted in ways that protect public resources. When operators or landowners do not follow the rules, the WDNR issues enforcement orders and may also issue a civil (monetary) penalty. A civil penalty is most often issued when the violation caused significant environmental damage, when an operator or landowner does not comply with the department's enforcement orders, or when the operator or landowner has a history of repeated violations. All civil penalties become final orders of the department unless appealed. Although violators are notified and/or fined, the infractions are usually addressed after they have already been committed, and the fines are often relatively insignificant compared to the value of the timber harvested.

Additional information regarding the Forest Practices rules can be found at: http://www.dnr.wa.gov/forestpractices.

The Washington Department of Natural Resources, on behalf of the State of Washington, submitted applications to NMFS and the U.S. Fish and Wildlife Service for incidental take permits under section 10 of the Endangered Species Act. Issuance of these permits would provide assurances that all forest practices activities in compliance with the state

forest practices rules and administrative program will satisfy ESA requirements for aquatic species. The two services released the final HCP, environmental impact statement (FEIS), and implementing agreement in a *Federal Register* notice on Jan. 27, 2006. This notice provides an opportunity for the public to review the final documents and the responses to public comments on the draft documents.

Klickitat County Shorelines Master Plan

The Klickitat County's Shorelines Master Plan (SMP) regulates "development" within the "shorelines" of Rock Creek and other water bodies in Klickitat County's jurisdiction. "Development" is broadly defined as: construction or exterior alteration of existing structures; dredging; drilling; dumping; filling; removal of any sand, gravel or minerals; bulkheading; driving of piling; placing of obstructions; or any project of a permanent or temporary nature which interferes with the normal public use of the surface of the waters overlying lands subject to the SMP regulations at any state of water level. "Shorelines" are those lands extending landward for 200 feet in all directions as measured from the ordinary high water mark, floodways and contiguous floodplain areas landward 200 feet from such floodways, and all wetlands and river deltas associated with the streams and lakes. The SMP applies to the shorelines of the main stem of the Klickitat River as well as the shorelines of all tributaries with a mean annual flow of 20 cfs or more.

The SMP designates various shorelines as "environments", which determine the level of protection that is warranted. Rock Creek is designated "Conservancy Environment", which allows a limited scope of development, subject to conditions (i.e. shoreline conditional use permit).

Each development proposal is subject to review pursuant to the shoreline environment within which it is to be located. One or more shoreline permits must be secured prior to implementation: Substantial Development Permits (SDPs) are required for any development for which the total cost or fair market value exceeds $5,000, or any development which materially interferes with the normal public use of the water or shorelines; Shoreline Conditional Use Permits (CUPs) are required for development types that warrant conditions to ensure consistency with the SMP; and Variances (VARs) are issued to grant relief from specific bulk, dimensional, or performance standards of the SMP in order to avoid unnecessary hardship, provided that extraordinary circumstances are shown to exist and the public interest shall suffer no substantial detrimental effect. Some types of development, such as a single-family residence, normal maintenance and repair, or construction of a normal protective bulkhead for a single family residence, are exempt from the requirement of a substantial development permit, but are still subject to all other provisions of the SMP.

Klickitat County's SMP was first adopted in the mid-1970s pursuant to the Washington State Shoreline Management Act of 1971, and has been updated periodically since then. Existing structures and developments that were established prior to adoption of the SMP are considered legally established "nonconforming" uses. Since adoption of the SMP, all developments within shorelines, including modifications to nonconforming uses, have

been reviewed by the County and Washington Department of Ecology (Ecology) to ensure compliance with the goals and requirements of the SMP.

The Department of Ecology reviews County permit decisions and has final authority to approve or deny conditional use permits and variances. Persons may appeal the final decision to the Shorelines Hearings Board.

Klickitat County Critical Areas Ordinance

Klickitat County adopted a Critical Areas Ordinance (CAO) in 2001 and, with the concurrence of Washington Departments of Fish and Wildlife, Community Trade and Economic Development, and Ecology, amended it in 2004. The CAO extends beyond the geographical scope of the County's SMP to protect wetlands, critical fish/wildlife habitat, geologically hazardous areas, aquifer recharge areas, and frequently flooded areas. The CAO is, in effect, an overlay on existing land use regulations. The CAO provides for standard setbacks of 300' from Category I wetlands; 200' from Category II; and 75' from Category III and IV. The CAO provides for standard buffers of 200' from Type 1 & 2 waters; 150' from Type 3 waters; 50' from Type 4 waters; and 25' from Type 5 waters. A wildlife habitat management plan is required for new development that will likely impair habitat functions and values. As with the SMP, developments and uses that existed prior to the adoption of the CAO are considered legally established "nonconforming" uses.

Klickitat County Floodplain Management Ordinance

The Klickitat County Floodplain Management Ordinance (FPO) regulates all development and activities that may increase flood hazards. A permit is required for development within areas of special flood hazard (with at least 1 percent chance of flooding). The applicant for a non-residential structure must include a certification and flood analysis conducted by a professional engineer. In general, development that will does not meet the specific criteria in the ordinance for development in these areas, to protect public health and safety, will be denied.

Klickitat County Zoning Ordinance

The Klickitat County Zoning Ordinance (CZO) was adopted in 1979 and has been amended over time. Much of the Rock Creek watershed is zoned by the CZO as "extensive agriculture" which requires a 20-acre minimum lot size for the purpose of dividing properties, and new development/uses are restricted to resource management uses/activities and other compatible uses. One permanent residential dwelling is allowed per lot. Some areas of the watershed are zoned for residential development. The allowable minimum lot size for new lots is either 1 or 2 acres; and one residential dwelling is allowed per lot. Other than residential development, most new development/uses in these zones is either prohibited or allowed per a zoning conditional use permit.

Klickitat County Environmental Ordinance (CEO)

The Klickitat County Environmental Ordinance (CEO) was adopted pursuant to the State Environmental Policy Act (SEPA). The CEO and SEPA require an analysis of probable significant adverse environmental impacts that may result from a proposed development. The CEO and SEPA require a threshold determination for each proposed development that is not exempt. The threshold determination is a determination that a project will or will not have probable significant adverse environmental impacts. If a project has probable significant adverse impacts, and environmental impact statement (EIS) is prepared. Any proposed development/use that is not specifically exempt in SEPA, chapter 43.21C RCW, or the SEPA rules adopted by the Department of Ecology, chapter 197-11 WAC, is required to comply with SEPA. Klickitat County provides applicable state agencies and tribes, as well as the public, the opportunity to review threshold determinations and EISs.

Washington State Water Pollution Control Act (Chapter 90.48 RCW)

This act gives Ecology the authority to protect water quality in the state and to promulgate regulations as needed to achieve this goal. The Act makes discharges of pollutants into waters of the state unlawful and has provisions for enforcement of violations, including the authority and process for issuing compliance orders and civil penalties, and for seeking criminal penalties. The Act also provides for permitting processes, cooperation with other entities, water quality monitoring, grants, and numerous other subjects regarding management of water quality issues in the state.

Washington's Statewide Monitoring Program

In 2001, Substitute Senate Bill (SSB) 5637 was signed into law. This act related to monitoring of watershed health and salmon recovery. The Monitoring Oversight Committee developed a comprehensive statewide strategy that addresses the actions identified in SSB 5637 (Monitoring Oversight Committee 2002). Among other things, the Plan is intended to provide information regarding trends in fish, water, and habitat conditions and assess effectiveness of actions taken to improve watershed health and provide for salmon recovery. The strategy includes documentation of fish population trends in some areas of the state; however, the Rock Creek Subbasin is not one of the areas included to date in that monitoring effort. The strategy is also monitoring the effectiveness of habitat restoration efforts funded by the State. The monitoring of project effectiveness follows the Monitoring and Evaluation Strategy that was developed by the Washington Salmon Recovery Funding Board in support of the Comprehensive Statewide Strategy. The Monitoring and Evaluation Strategy specified methods to assess a wide range of restoration and protection projects.

On-Site Sewage Systems

Chapter 246-272 of the Washington Administrative Code (WAC) regulates the on site disposal of sewage in the state. The law is applicable to septic systems as well as larger on-site systems. The rule addresses location of systems, site evaluations, design,

installation, inspection, operation and maintenance, repair, abandonment, and other areas of concern. The rule helps to prevent the discharge of sewage into fish-bearing streams.

Hydraulic Code

Chapter 75.20 RCW governs construction projects within the waters of the state. The law requires hydraulic project approvals from the Department of Fish and Wildlife for wharves, bulkheads, bridges, culverts, fish habitat restoration projects, and other construction activities within the ordinary high water mark. This regulation helps to protect fish and fish habitat during construction.

Regulation of Dairy Farms

Chapter 90.64 RCW, the Dairy Nutrient Management Act, includes a number of requirements designed to protect water quality from dairy operations. These are in addition to NPDES requirements in the Federal and State Clear Water Acts for concentrated animal feeding operations. The Act requires inspection of all dairy farms, implementation of dairy nutrient management plans, technical assistance and enforcement (including civil penalties) against significant polluters. The intent of the regulation is to protect water quality and, subsequently, fish habitat. Ecology is the primary regulatory authority under this Act.

Other Rules and Regulations

There are over 100 additional rules and regulations applicable to the protection of water quality and fish habitat in the State of Washington. These rules cover a broad range of subjects such as groundwater quality standards, application of pesticides, well construction, motor oil disposal, utilities, solid waste disposal and recycling, water supply facilities, mining, energy facilities, dikes and levies, aquiculture, etcetera. Lists of applicable laws and rules and links to the specific requirements of those laws and rules can be found at www.ecy.wa.gov/laws-rules.

Voluntary Programs

A number of voluntary programs have been developed to encourage landowners to implement conservation programs on their lands and to assist landowners with habitat improvement actions. Some of these programs are described below. The list includes only the larger programs. Other programs exist and new programs may be developed in the future that can be used to assist with conservation actions on private lands.

Lead Entity Process

In 1998 the Washington State Legislature enacted chapter 77.85 RCW to empower citizens at the community level to engage in salmon recovery through a locally driven habitat protection and restoration program. The legislation recognized that active local participation is the key to ensuring public participation in, and support for, salmon recovery. Through this legislation, local "Lead Entities" were identified and funded to implement chapter 77.85 RCW. Lead Entities prioritize projects for PCSRF funding administered by Washington State's Salmon Recovery Funding Board. A lead entity has

not been established for the Rock Creek subbasin, therefore PCSRF funds are not accessible at this time for habitat protection or restoration projects in the subbasin.

Conservation Reserve Enhancement Program (CREP)

The Conservation Reserve Enhancement Program is a voluntary program designed to establish forested buffers along streams where riparian habitat is poorly developed. Land enrolled in CREP is removed from production and grazing under 10 to 15-year contracts. In return, landowners receive annual rental, incentive, maintenance and cost share payments. The CREP program is administered by the Farm Service Agency and the State of Washington.

Conservation Reserve Program (CRP)

The Conservation Reserve Program provides technical and financial assistance to eligible farmers and ranchers to address soil, water, and related natural resource concerns on their lands. The program encourages farmers to convert highly erodible cropland or other environmentally sensitive acreage to vegetative cover such as native grasses, wildlife plantings, trees, filter strips, or riparian buffers. Farmers receive an annual rental payment for the term of a multi-year contract. The program is funded by the Farm Service Agency with technical assistance from the National Resource Conservation Service (NRCS).

Continuous Conservation Reserve Program (CCRP)

The Continuous Conservation Reserve Program is a voluntary program that protects soil, improves air and water quality, and enhances fish and wildlife habitat through the use of buffers, filter strips, and wind breaks. Contract periods range from 10 to 15 years. Cost shares and yearly payments are provided as incentives for participation in the program. The program is run by the Farm Services Agency.

The Grassland Reserve Program (GRP)

The Grassland Reserve Program is a voluntary program that helps landowners and operators restore and protect grassland, including rangeland, pastureland, shrubland, and certain other lands, while maintaining the areas as grazing lands. The program includes options for permanent or 30-year easements. Landowners receive payment for the easements. The Natural Resources Conservation Service (NRCS) administers the program in cooperation with the Forest Service.

Environmental Quality Incentives Program (EQIP)

The Environmental Quality Incentives Program was re-authorized by the 2002 Farm Bill to promote agricultural production and environmental quality as compatible national goals. The program is administered by NRCS. Management incentive payments and cost share benefits are available to support implementation of practices directly affecting the health of soils, water, animals, plants, and air.

The Conservation Security Program (CSP)

The Conservation Security Program is a voluntary program that provides financial and technical assistance to producers who practice good stewardship on their agricultural lands and incentive to those that want to improve or expand their conservation measures. Lands that can be placed into the program include cropland, pastureland, prairie, rangeland, and incidental forested land. The contract period and cost-share payments are based on a three-tier approach, with increasing compensation associated with increased natural resource protection. The program is run by the NRCS.

Wildlife Habitat Incentive Program (WHIP)

The Wildlife Habitat Incentive Program is a voluntary program that encourages creation of high quality wildlife habitats that support populations of National, State, tribal, and local significance. Through WHIP, the NRCS provides technical and financial assistance to landowners to develop upland, wetland, riparian, and aquatic habitat areas on their properties. Participants voluntarily limit future use of the land for a period of time, but retain private ownership. Agreements are usually five to ten years in duration.

The Healthy Forest Reserve Program (HFRP)

The Healthy Forest Reserve Program is a voluntary program established for the purpose of restoring and enhancing forest ecosystems to promote the recovery of threatened and endangered species, improve biodiversity, and enhance carbon sequestrations. The program offers three enrollment options including a 10-year agreement, a 30-year easement, and a longer term easement. The compensation to landowners increases with the term of the easement agreement. The program is administered by the U.S. Department of Agriculture and through the Conservation District.

Wetlands Reserve Program (WRP)

The Wetlands Reserve Program is a voluntary program that provides technical and financial assistance to landowners to address wetland, wildlife habitat, soil, water, and related natural resource concerns on private lands. The landowner receives financial incentives to restore, protect, and enhance wetlands or lands that have been historically modified for agricultural production in exchange for retiring marginal land from agriculture. Easements are either permanent or 30-year agreements. The NRCS administers the program.

Forestry Riparian Easement Program (FREP)

The Forestry Riparian Easement Program was developed to partially compensate eligible small forest landowners in exchange for a 50-year easement on timber that is required to be left under the forest practices rules. The landowner still owns the property and retains full access, but has “leased” the trees and their associated riparian function to the State. WDNR administers this program.

Yakama Nation Forest Management Plan

The Yakama Nation has voluntarily adopted the Yakama Nation Forest Management Plan, which is used to guide management of timber harvest and road construction and maintenance on tribal land.

Conservation Designations

Badger Gulch Natural Area Preserve

The Washington Department of Natural Resources (WDNR) established the 180-acre Badger Gulch Natural Area Preserve in 1982 to protect four important native plant communities and three rare plants. The Natural Area Preserve lies within Klickitat County about 6.8 miles north of the Columbia River and 13 miles east of Goldendale on the Goldendale-Bickleton road. The preserve includes a 2-mile long portion of Badger Gulch, a narrow, steep-walled canyon that contains Badger Creek, which empties into Rock Creek near RM 15. The four protected native plant communities (Idaho fescue, houndstongue hawkweed, Oregon white oak-ponderosa pine, bluebunch wheatgrass-Sandberg's bluegrass and white alder riparian) and three rare plant species (porcupine sedge, shining flatsedge, and beaked cryptantha) play an important ecological role in protecting the subbasin's water quality and many vertebrate and invertebrate species (WDNR 1998).

In 1998, Washington Department of Natural Resources' Southeast Region developed the "Badger Gulch Natural Area Preserve Management Plan." The purpose of the management plan is "to permit natural ecological and physical processes to predominate, while controlling activities that directly or indirectly modify these processes" on the preserve. The WDNR 1998 'Plan' defines all aspects of management for the site from public use to monitoring and research activities (WDNR 1998).

Klickitat Oaks Preserve

Adjoining the Badger Gulch Natural Area Preserve is The Nature Conservancy (TNC) of Washington's Klickitat Oaks Preserve. The current TNC Klickitat Oaks Preserve 414-acre site conserves/preserves native habitats and significant plant and animal species as a functional ecosystem within the upper Rock Creek watershed. This area has been a major conservation site for the TNC since the ecological significance of the area was identified in the 1980s. The Conservancy is currently negotiating the purchase of an additional 120-acre plot and, with another private landowner, a 1,500-acre limited development conservation easement. Working with Federal, state and private adjoining landowners, the TNC's purpose is to protect all of the native habitats and significant plant and animal species of the site as a functional ecosystem within the upper Rock Creek watershed.

The Nature Conservancy has developed an initial preserve design and an in-depth Site Conservation Plan for the area. The Nature Conservancy's conservation plan is a cooperative management strategy for the upper Rock Creek watershed involving the U.S. Bureau of Land Management, WDNR, and resident private landowners. The Nature

Conservancy has made a long-term commitment to the site and is currently involved in restoration and management work on the ground, including exotic species control, plant and animal inventory and assessment, and long-term restoration planning.

EXECUTIVE SUMMARY

Introduction

The federal Endangered Species Act (ESA) requires listing species that have declined to the point that they are threatened with extinction and sets up regulations to protect these species. Recovering a listed species to the point that it no longer needs protection under the ESA is an important goal, both for people with a direct interest in the health of that species and for the individuals and groups who may be negatively affected by regulations put into place to protect a listed species. The ESA requires development of recovery plans that review a listed species' status, set recovery goals, and identify actions required to recover it and remove it from the list. Recovery plans are non-regulatory documents that provide guidance on how to recover a species; they do not create any binding commitments or legal mandates.

In 1999, the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NOAA Fisheries) classified Middle Columbia River Steelhead as a threatened species under the ESA. In 2006, NOAA Fisheries revised its listing to apply only to the anadromous (ocean-going) form *of Oncorhynchus mykiss,* commonly known as steelhead.[1] This listing applies to steelhead that spawn in a large portion of central and eastern Washington and Oregon (See Figure 1.1). This document, the Yakima Steelhead Recovery Plan, is a recovery plan for those listed Middle Columbia Steelhead that spawn in the Yakima Basin and are collectively referred to as the Yakima Major Population Group (MPG).

This document is an updated version of the steelhead portion of the 2005 Yakima Subbasin Salmon Recovery Plan, which NOAA Fisheries approved as an interim recovery plan for Yakima Basin populations of the Middle Columbia Steelhead River Distinct Population Segment (DPS) in May 2006. This 2007 Yakima Steelhead Recovery Plan will be incorporated into NOAA Fisheries' Middle Columbia Steelhead Recovery Plan, which will be released in final form in the fall of 2009.

The Yakima Basin Fish & Wildlife Recovery Board developed this plan to guide steelhead recovery efforts in the Yakima Basin. The Board is a locally based organization governed by representatives of Yakima, Benton, and Kittitas counties, the Yakama Nation, and cities in the basin. The Board's mission is to "to restore sustainable and harvestable populations of salmon, steelhead, bull trout, and other at-risk fish and wildlife species through the collaborative, economically sensitive efforts, combined resources, and wise resource management of the Yakima River Basin." It is recognized by the State of Washington as one of the regional organizations at the heart of the state's salmon recovery efforts.

The Board and its partners followed guidance from NOAA Fisheries, Washington Department of Fish and Wildlife (WDFW) and the Washington Governor's Salmon

---

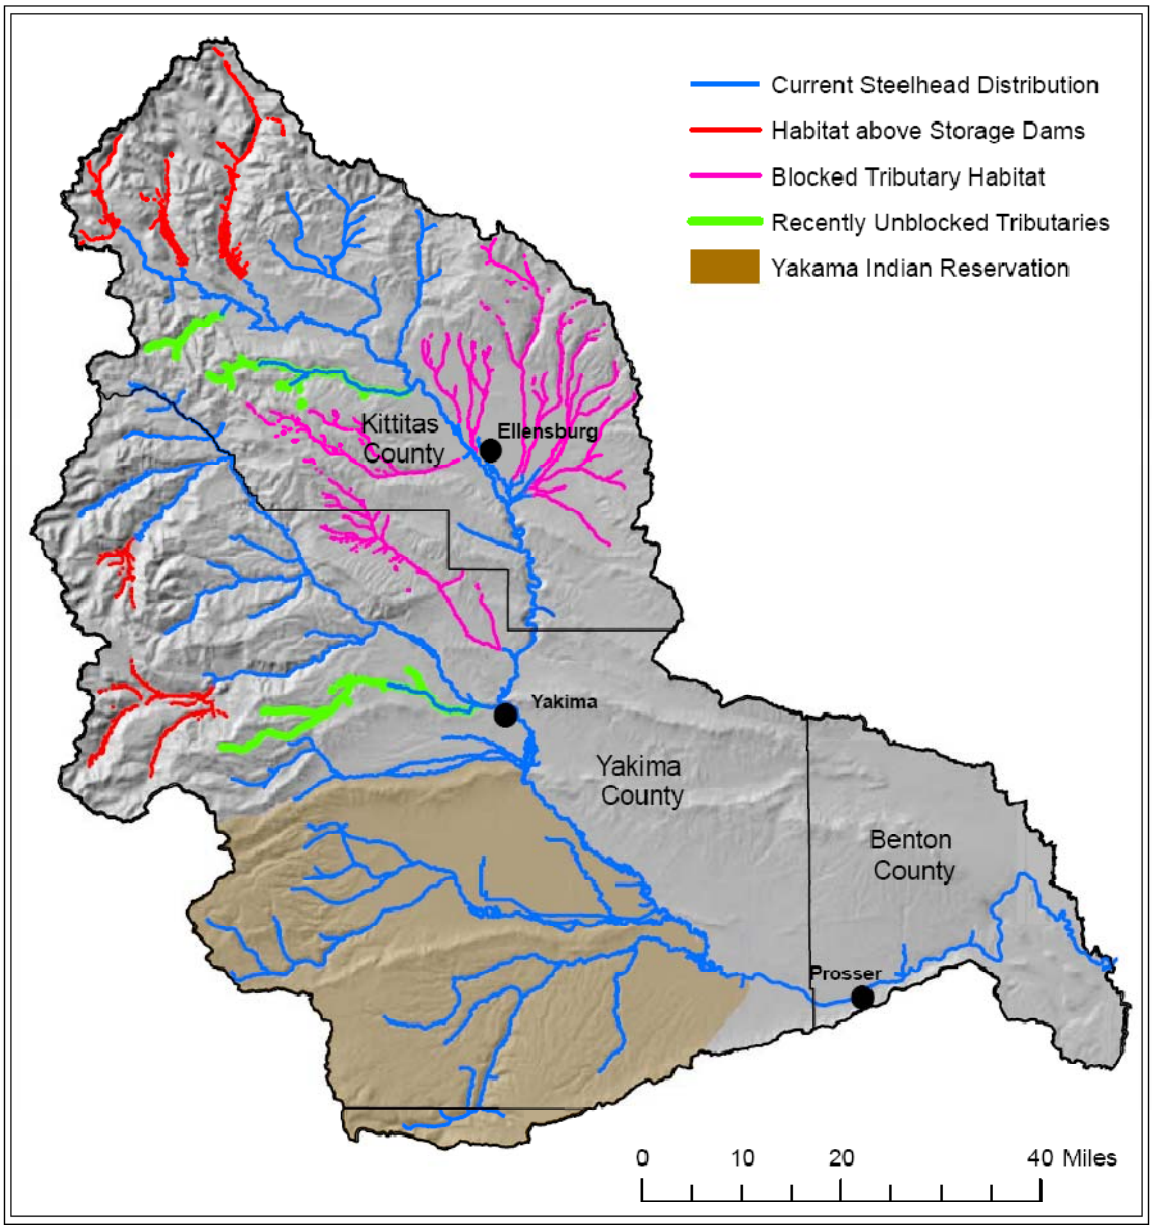
[1] The freshwater-resident form of *O. mykiss* (commonly known as rainbow trout) is not listed, and falls under the jurisdiction of the U.S. Fish and Wildlife Service.

Recovery Office (GSRO) in developing this plan. Local planners also provided information and feedback to the Interior Columbia Technical Recovery Team (ICTRT) that NOAA Fisheries convened to develop science-based viability criteria and assessments of the status of steelhead populations. The ICTRT stock status assessments for Yakima Basin steelhead populations are incorporated into this document by reference.

This plan is built on the belief that healthy steelhead populations can be rebuilt in a manner that coexists with vibrant human communities and the local economies that support them. This plan emphasizes that steelhead recovery should build on existing fish and wildlife recovery programs and should rely on voluntary, non-regulatory approaches to habitat improvement. While this plan focuses on recovery efforts in the Yakima Basin, it acknowledges the need for ongoing recovery actions in the Columbia River, its estuary, and the Pacific Ocean. These are further addressed in NOAA Fisheries' Middle Columbia Steelhead Recovery Plan.

Recovery of steelhead in the Yakima Basin will not occur in a vacuum. In addition to steelhead, the basin once supported large populations of Chinook, coho, and sockeye salmon, oceangoing lamprey, and migratory bull trout. While only bull trout and steelhead are listed under the ESA, all of these species have declined significantly over the last 150 years. Recovering steelhead is just one objective of ongoing efforts to restore conditions that allow all of these species to thrive.

Chapter 1 provides more detail on the planning process and its broader context.



Species Status

Chapter 2 presents detailed empirical data about the status, distribution, characteristics, and life histories of Yakima Basin steelhead. Steelhead in the Yakima Basin are divided into four populations: the Satus Creek, Toppenish Creek, Naches River, and Upper Yakima River populations. The NOAA ICTRT identifies the Satus Creek population as steelhead that spawn in the Satus Creek drainage on the Yakama Indian Reservation, the mainstem Yakima River below Satus Creek, and tributaries to the lower mainstem. For management purposes, local planners have subdivided the Satus population into the Satus block, which spawns in the Satus Creek drainage, and a mainstem block, whose current and historic status is uncertain. The Toppenish population consists of steelhead that spawn in Toppenish Creek, its tributaries and the short stretch of the mainstem between Toppenish and Satus creeks, and is entirely on the Yakama Reservation. The Naches population includes steelhead spawning in the Naches River and its tributaries (including the Tieton, Little Naches, American, and Bumping rivers and Cowiche, Rattlesnake and Nile creeks), the mainstem Yakima from the Naches confluence to the Toppenish Creek confluence and the tributaries to that reach of the Yakima, including Ahtanum Creek. The Upper Yakima population consists of all steelhead that spawn in the Yakima River and its tributaries upstream of the Naches confluence. Together these four populations make up the Yakima MPG.

Estimates of the number of adult steelhead returning to the Yakima Basin prior to European settlement range from 20,800 to 100,000. In contrast, the number of adults passing fish counting facilities at Prosser Dam (on the mainstem Yakima downstream of virtually all current spawning locations) between 1985 and 2006 has ranged from 450 to

4,491 with an average of 1,764. The ICTRT estimated the 10-year (1996-2005) geometric average by population as 379 for the Satus population, 322 for the Toppenish population, 472 for the Naches population, and 85 for the Upper Yakima.

Map A: Basin overview and status of steelhead habitat

The ICTRT modeled the extent of historically available steelhead habitat. This plan reviews that model, presents local planners revisions to the model, and compares that to current steelhead distribution (see Map A). Steelhead spawning is widely distributed throughout the areas accessible to them, except in the lower Yakima River and its tributaries (below the Satus Creek confluence). The extent and distribution of spawning

in the mainstem from the Columbia to Roza Dam is uncertain. Steelhead currently cannot access the watersheds above Tieton, Bumping, Cle Elum, Kachess, and Keechelus dams[2] and a number of significant tributaries (e.g., Wenas, Manastash, and Naneum creeks in the Upper Yakima population area, and until just last year, Cowiche Creek in the Naches population area).

The Yakama Nation and WDFW have emphasized maintaining the natural genetic composition of Yakima Basin steelhead stocks. The last release of hatchery-origin juvenile steelhead in the Yakima Basin occurred in 1993. Stray hatchery-origin fish from other basins made up only 3% of the run from 1999 to 2005.

Instead of dying immediately after spawning like most salmon, steelhead can survive, return to the ocean, and spawn again. The Yakama Nation is currently capturing post-spawning steelhead at Prosser Dam and reconditioning them in hatchery facilities to increase the number that survive to spawn again.

Our knowledge of steelhead status in the upper portions of the basin is complicated by the fact that steelhead and rainbow trout are different forms of the same biological species that can interbreed. Better understanding the historic, current, and future potential for steelhead production in these areas will require determining how habitat conditions, genetics, and survival rates for oceangoing smolts interact to affect the balance between resident and anadromous life histories.

The ICTRT assessed the viability of Yakima Basin steelhead populations and concluded that none currently meet its standards for viability. The Satus population comes nearest to meeting the ICTRT's standard, while the Upper Yakima population is farthest from the standard. The ICTRT analysis is based on NOAA Fisheries' Viable Salmonid Population (VSP) framework, which calls for managing salmon and steelhead populations based on an understanding of their abundance, productivity, spatial structure, and diversity.

Factors for Decline

Chapter 3 reviews the factors that led to the order of magnitude decline in abundance of steelhead in the Yakima Basin over the last 150 years. This decline parallels that of salmon throughout the Columbia Basin and is a function of both in-basin habitat changes, major impacts in the Columbia River and the Pacific Ocean associated with extensive harvest in fisheries, development of the Columbia River hydropower dams—Yakima steelhead must pass four on migrations to and from the sea—and management of hatchery programs in a manner that adversely affected wild populations.

Major in-basin factors for decline include:

1) Alteration of stream flows due to development of irrigation systems, including both the dewatering of lower reaches in many tributaries and the high and low flows in the mainstem Yakima and Naches rivers associated with water storage and delivery from upstream reservoirs

[2] The Bureau of Reclamation is currently evaluating passage options at the five storage dams.

2) Creation of passage barriers associated with both small and large diversion dams, road crossings, and Bureau of Reclamation (BOR) storage dams

3) Reductions in floodplain function due to diking, channel simplification, and floodplain development for agricultural and urban uses

4) Impacts to riparian areas and upland hydrology due to past and, to a lesser extent, current, grazing, and forestry practices

5) Changed ecological dynamics, including reduction in beaver populations, reductions in delivery of oceanic nutrients to headwaters by salmon, introduction of exotic species, and increased predation by native species

Significant progress has been made to address many of these threats, even as other threats have intensified because of changes in socio-economic conditions. Chapter 3 details the past and current status of these factors for each of the four populations (Satus, Toppenish, Naches, and Upper Yakima) and links them to the limiting factors framework used by NOAA Fisheries in the Middle Columbia Steelhead Recovery Plan.

Recovery Goals, Criteria, and Strategies

Chapter 4 identifies three different recovery thresholds for the Yakima MPG:

- An ESA de-listing threshold based on the ICTRT's framework that calls for one population to be viable, one to be highly viable, and two to be at "maintained status" or better

- A short-term recovery threshold that is based on the ICTRT framework, but emphasizes bringing all four Yakima populations to viable status

- A long-term recovery threshold that calls for restoring access to all historic habitat that can be restored consistent with the Board's commitment to sustaining local traditions and economies and improving abundance to levels that support broad ecological and harvest goals

The Board sees these three thresholds as points on a continuum. The Board concurs with NOAA Fisheries and the ICTRT that when the delisting threshold is met for the Yakima MPG and all other MPGs in the Middle Columbia River Steelhead DPS, it will be appropriate to consider removing the ESA listing. The Board expects recovery actions to continue after that point, even without the immediate motivation of the ESA. The long-term goals are less definite, but are meant to affirm that the Board and its partners believe that long-term recovery to significantly higher abundance levels is both feasible and desirable.

The abundance and productivity criteria associated with each of these thresholds are presented below. The delisting and short-term recovery criteria are drawn from the ICTRT viability analysis. Chapter 4 also sets out specific criteria for spatial distribution and diversity.

Abundance and Productivity Criteria

	Delisting Threshold		Short-Term Recovery		Long-term Recovery	
Population	**Avg. #**	**Prod.**	**Avg. #**	**Prod.**	**Avg. #**	**Prod.**
Satus: Satus Watershed Mainstem Block*	 500 500	 2.00 1.56	 500 500	 1.56 1.56	2,000	1.2 1.2
Toppenish	250	1.2	500	1.56	1,500	1.2
Naches	1,500	1.26	1,500	1.26	5,400	1.2
Upper Yakima	500	1.2	1,500	1.26	7,700	1.2
Total	***3,250***		***4,500***		***16,600***	

*Either spawners in the lower mainstem, or additional spawners above targets in other population areas, as described in Chapter 4

Achieving recovery goals for the Satus Population will require implementing these strategies:

1) Continuing efforts to protect existing functional habitat
2) Continuing ongoing efforts by the Yakama Nation to improve watershed and riparian conditions within the Satus drainage
3) Restoring floodplain function and channel complexity in lower Satus Creek
4) Improving migration conditions in the mainstem Yakima River

Achieving recovery goals for the Toppenish Population will require implementing these strategies:

1) Continuing efforts to protect existing functional habitat
2) Significantly improving passage, flows, and riparian conditions in Toppenish Creek and its tributaries
3) Restoring floodplain function in lower Toppenish Creek
4) Improving migration conditions in the mainstem Yakima River

Achieving recovery goals for the Naches Population will require implementing these strategies:

1) Continuing efforts to protect existing functional habitat
2) Significantly protecting and improving passage, flows, and instream and riparian conditions in tributaries (Ahtanum, Bumping, Cowiche, Rattlesnake, Nile, and Little Naches watersheds)

3) Addressing the effects on steelhead of reservoir operations and irrigation withdrawals in the Tieton, lower Bumping, and lower Naches rivers

4) Improving floodplain function and conditions in the mainstem Naches River

5) Improving migration conditions in the mainstem Yakima River

Achieving recovery goals for the Upper Yakima Population will require implementing these strategies:

1) Continuing efforts to protect existing functional habitat

2) Providing unimpeded passage for steelhead in key tributaries (Manastash, Taneum and, if feasible, Naneum and Cle Elum)

3) Improving outmigration conditions at Roza Dam

4) Addressing the effects of reservoir and irrigation system operations on winter/spring/fall low flows and summer high flows in the lower Cle Elum and mainstem Yakima rivers

5) Protecting and enhancing floodplain conditions along the mainstem Yakima

6) Improving flows and instream and riparian conditions in tributaries and side channels

7) Improving migration conditions in the lower mainstem Yakima River

Recovery Actions

Chapter 5 identifies 94 steelhead recovery actions. These are broken into basinwide actions (16), Lower Mainstem Yakima actions (9), Satus Creek actions (8), Toppenish Creek actions (10), Naches actions (32), and Upper Yakima actions (21). These actions implement the strategies described above.

Implementing some or all of the set of actions presented here should significantly improve the abundance, productivity, spatial structure, and diversity of steelhead in the Yakima Basin. Recovery planners anticipate that the full suite of actions presented here, if combined with expected improvements outside of the Yakima Basin, will be more than sufficient to meet de-listing and short-term recovery goals, but that additional actions may be needed to reach long-term broad sense recovery goals.

The scope and level of detail of specific actions varies considerably. The Yakima Basin Fish & Wildlife Recovery Board is committed to working with partners who will implement recovery actions to refine action descriptions and develop a more specific implementation schedule.

Initial cost estimates for implementing all of the actions identified in this plan over 15 years total $1,168.3 million, with $269.3 million of that cost directly attributed to steelhead recovery. The remaining portion of the total cost is attributed to other sources based on anticipated benefits to agricultural producers (e.g. irrigation system improvements), flood control, open space, other fish and wildlife species, etc. This is a

simple and very preliminary estimate of actual implementation costs for actions. It is not a cost-benefit analysis of the proposed actions and does not include indirect costs such as opportunity and compliance costs associated with recovery efforts. It should not be taken as the total cost of recovery, as achieving delisting goals may require only implementing some of the actions included in this plan, while long-term recovery may require additional actions not included in the plan.

Plan Implementation

This plan is a beginning, not an end. Chapter 6 describes how this plan will be implemented. Achieving recovery goals will require sustained long-term efforts by a wide range of stakeholders. Salmon recovery is not a new pursuit in the Yakima Basin. Fish screening efforts began in the early 20th century, and intensive recovery efforts have been ongoing since the 1980s. The steelhead recovery actions proposed in this plan are a natural extension of this work.

Key recovery partners include the Yakama Nation, WDFW, BOR, USFS, NOAA Fisheries, USFWS, the Washington Department of Ecology, county and municipal governments, local Conservation Districts, non-profit organizations, and other landowners and managers throughout the basin. Developing collaborative partnerships between existing organizations should take precedence over the creation of new organizations and programs unless there is a clear need for a new structure.

This plan focuses on voluntary, non-regulatory approaches to implementing recovery actions. While it does call on decision-makers to effectively implement existing regulatory programs, it does not mandate specific regulatory actions or call for new regulatory programs.

Coordinating diverse recovery efforts and ensuring that limited funding is used effectively requires ongoing collaboration between in-basin stakeholders and state and federal agencies. The Yakima Basin Fish & Wildlife Recovery Board has committed to working with recovery partners to 1) develop a regularly updated implementation schedule that prioritizes future recovery actions, 2) track completion of recovery actions, 3) promote effective use of existing funding[3], 4) work with partners to develop new sources of support for recovery actions, and 5) ensure Yakima Basin recovery efforts are coordinated with recovery efforts across the range of the Middle Columbia River Steelhead DPS.

---

[3] Current funding sources include the Washington Salmon Recovery Funding Board (which distributes both federal Pacific Coast Salmon Recovery Fund dollars and state funds), the BPA/NPCC Fish and Wildlife Program, the Bureau of Reclamation's Yakima River Basin Water Enhancement Project, and the Washington Department of Ecology's Columbia River Initiative.

Research Monitoring and Evaluation

Our understanding of steelhead biology and the factors that affect steelhead habitat and survival is continually improving. Chapter 7 reviews key uncertainties and the research, monitoring, and evaluation actions that will answer them. While the extent of empirical data about Yakima Basin steelhead populations is much greater than for most other populations of the Middle Columbia River Steelhead DPS, successfully implementing this plan will require additional data collection and analyses. Targeted empirical research is needed to increase our ability to effectively and efficiently implement recovery actions. Tracking the response of steelhead to specific actions and broad habitat trends and evaluating progress towards meeting quantifiable recovery goals will require a robust monitoring and evaluation program. This research and monitoring will build on the extensive research capacity built by the Yakima/Klickitat Fisheries Program and others. Chapter 7 reviews the need for research and monitoring and identifies key uncertainties that will need to be addressed as part of implementing this recovery plan. The Yakima Basin Fish & Wildlife Recovery Board will develop a Research, Monitoring and Evaluation Plan that builds on Chapter 7 of this plan to identify critical research and monitoring needs and assess how they can be incorporated into an effective and practical adaptive management framework.

Public Education and Outreach

Chapter 8 reviews outreach and education needs and presents some initial proposals for future actions. Effectively implementing the recovery actions identified in this plan will require outreach and education activities that: 1) build support for steelhead recovery actions among decision makers, land managers, and the public at large, and 2) increase public understanding of how individual actions affect steelhead and their habitat. Outreach activities are often forgotten in the push to implement on-the-ground recovery actions, yet they are vital to sustaining the political and financial support that achieving recovery will require. The Yakima Basin Fish & Wildlife Recovery Board is committed to working with partners throughout the basin to support and expand education and outreach programs.

TABLE OF CONTENTS

1 Introduction 1

1.1 Overview of Recovery Planning 1

1.1.1 Listing of Yakima Basin Steelhead 1

1.1.2 Requirements for a Recovery Plan 3

1.1.3 Development of the Yakima Subbasin Salmon Recovery Plan 3

1.2 Vision and Guiding Principles for Local Planning 5

1.2.1 Vision 5

1.2.2 Guiding Principles 5

1.2.3 Non-Regulatory Nature of Recovery Plans 6

1.3 Process Used to Develop the Plan 7

1.3.1 Drafting of the Plan 7

1.3.2 Public Involvement 8

1.3.3 Incorporating the Local Plan into NOAA's Recovery Plan 8

1.4 Relationship to Other Recovery Activities 9

1.4.1 Relationship to Other Planning Efforts 9

1.4.2 Relationship to Ongoing On-the-Ground Recovery Efforts 10

2 Species Status 12

2.1 Regional Setting 12

2.1.1 Geographic Setting 12

2.1.2 Ecological Setting 18

2.2 Identification of Populations 19

2.3 Steelhead Distribution 20

2.3.1 Satus Population 26

2.3.2 Toppenish Population 26

2.3.3 Naches Population 27

2.3.4 Upper Yakima Population 27

2.4 Steelhead Abundance 28

2.4.1 Estimates of Historic Abundance 28

2.4.2 Current Abundance and Productivity 30

2.5 Population Characteristics and Life Histories 35

2.5.2 Spawning 42

2.5.3 Role of Kelts 46

2.5.4 Incubation and Emergence 47

2.5.5 Juvenile Rearing 48

2.5.6 Resident/Anadromous Interactions 49

2.5.7 Smolt Outmigration 50

2.5.8 Ocean Residence 54

2.6 Viability Assessments for Yakima Basin Steelhead 54

2.6.1 Satus Creek 56

2.6.2 Toppenish Population 59

2.6.3 Naches Population *61*
2.6.4 Upper Yakima Population *64*
3 Factors for Decline **68**
3.1 Introduction 68
3.1.1 General Overview of Steelhead Population Decline *68*
3.1.2 Ongoing Efforts to Address the Decline of Steelhead *70*
3.2 Definition of Threats and Limiting Factors 70
3.2.1 Threats *70*
3.2.2 Limiting Factors *71*
3.2.3 Relationships of Threats to Limiting Factors *93*
3.3 In-Basin Threats and Limiting Factors 93
3.3.1 Basinwide Threats and Limiting Factors *93*
3.3.2 Lower Mainstem Threats and Limiting Factors *106*
3.3.3 Satus Population Threats and Limiting Factors *108*
3.3.4 Toppenish Population Threats and Limiting Factors *109*
3.3.5 Naches Population Threats and Limiting Factors *111*
3.3.6 Upper Yakima Population Threats and Limiting Factors *114*
3.4 Out-of-Basin Threats and Limiting Factors 117
3.4.1 Out-of-Basin Effects on the Lower Yakima Basin *118*
3.4.2 Columbia River Dams *118*
3.4.3 Columbia River Estuary *119*
3.4.4 Ocean Conditions *119*
3.4.5 Out-of-Basin Harvest *120*
3.4.6 Predation *120*
3.4.7 Competition with Non-Native Species *121*
4 Recovery Goals and Criteria **122**
4.1 Recovery Goals 122
4.1.1 Delisting Threshold *122*
4.1.2 Short-term Recovery Threshold *124*
4.1.3 Delisting & Short-term Recovery Threshold Differences *124*
4.1.4 Long-term Recovery Threshold *125*
4.1.5 Relationship of Recovery Thresholds to NOAA Delisting Decisions *125*
4.2 Recovery Objectives and Criteria 125
4.2.1 Abundance *126*
4.2.2 Productivity *127*
4.2.3 Spatial Structure *128*
4.2.4 Diversity *129*
4.3 Recovery Strategies 130
4.3.1 Habitat Strategies *130*
4.3.2 Predation Strategies *130*
4.3.3 Harvest Strategies *130*
4.3.4 Hatchery Strategies *130*
4.3.5 Recovery Strategies Outside of the Yakima Basin *131*
4.3.6 Recovery Strategies Affecting All Yakima Populations *131*

4.3.7 Role of Areas Above Storage Dams in Steelhead Recovery 131
4.3.8 Toppenish Population Recovery Strategies 132
4.3.9 Satus Population Recovery Strategies 132
4.3.10 Naches Population Recovery Strategies 134
4.3.11 Upper Yakima Population Recovery Strategies 135
5 Recovery Actions 139
5.1 Identifying and Describing Recovery Actions 139
5.2 Timeframe for Implementing of Actions 141
5.3 Necessity and Sufficiency of Proposed Actions 142
5.4 Overall Cost of Recovery 143
5.5 Recovery Action Descriptions 143
6 Plan Implementation 204
6.1 Approach to Implementation 204
6.1.1 Voluntary and Non-Regulatory Nature of Plan 204
6.1.2 Coordination of Existing Recovery Programs 205
6.1.3 Coordination with Bureau of Reclamation Yakima Project 205
6.1.4 Coordination with Land Management Agencies 206
6.1.5 Coordination with Other Planning Efforts 207
6.1.6 Coordination with Local Land Use Planning 207
6.1.7 Role of Yakima Basin Fish & Wildlife Recovery Board 207

1 Introduction

1.1 Overview of Recovery Planning	1.3 Process Used to Develop the Plan
1.2 Vision and Guiding Principles	1.4 Relationship to Other Recovery Activities

1.1 Overview of Recovery Planning

1.1.1 Listing of Yakima Basin Steelhead

Anadromous steelhead (*Oncorhynchus mykiss*) have declined significantly in abundance and geographic extent in the last one and a half centuries, but are still found across a broad geographic area. The National Oceanographic and Atmospheric Administration's National Marine Fisheries Service (NOAA Fisheries) is responsible for applying the Endangered Species Act (ESA) to anadromous salmon and steelhead. NOAA Fisheries has divided habitat areas with salmon in Washington, Oregon, Idaho, and California into Evolutionarily Significant Units (ESUs), while dividing habitat areas with steelhead in those states into Distinct Population Segments (DPSs). Yakima Basin steelhead were first listed under the ESA as part of the Middle Columbia River Steelhead ESU, which NOAA Fisheries first designated as threatened on March 25, 1999 [4]. The Middle Columbia River Steelhead ESU (later DPS) included the Columbia River and its tributaries from above the Wind River in Washington and the Hood River in Oregon, upstream to, and including, the Yakima River, in Washington. Snake River basin steelhead are not included (see Figure 1.1).

In 2005-6, NOAA Fisheries revised its species determinations for West Coast steelhead under the ESA, delineating steelhead-only "distinct population segments" (DPS) in place of the earlier ESUs. NMFS listed the Middle Columbia River Steelhead DPS as threatened on January 5, 2006 [5]. The area occupied by the Middle Columbia River Steelhead DPS remained the same as the area originally designated as an ESU. The steelhead DPS does not include rainbow trout, the non-anadromous freshwater form of *Oncorhynchus mykiss*, which are under the jurisdiction of the U.S. Fish and Wildlife Service (USFWS).[6]

[4] See the Federal Register, Volume 64, p. 14517.
[5] See the Federal Register, Volume 71, p. 834.
[6] For a good overview of the history of the listing and the reasoning underlying NOAA's decision to list only the anadromous form of *O. mykiss* as a DPS, see the January 5, 2006 Federal Register notice (Volume 71, p. 834).

Figure 1.1: Location of Yakima MPG within Middle Columbia River DPS

1.1.2 Requirements for a Recovery Plan

Section 4(f) of the ESA calls for the development of recovery plans. The following are the key provisions:

- 4(f)(1) – Recovery plans shall be developed and implemented for listed species unless the Secretary "…finds that such a plan will not promote the conservation of the species."
- 4(f)(1)(A) – Priority is to be given, to the maximum extent practicable, to "…species, without regard to taxonomic classification, that are most likely to benefit from such plans, particularly those species that are, or may be, in conflict with construction or other forms of economic activity."
- 4(f)(1)(B) – Each plan must include, to the maximum extent practicable, "(i) a description of site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species; (ii) objective, measurable criteria which, when met, would result in a determination…that the species be removed from the list; and, (iii) estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal."

A recovery plan is a guidance document, or "road map" that describes the current status of a species and the actions that the federal agencies administering the ESA (NOAA Fisheries and the USFWS) have determined will lead to recovery of the listed species and its associated habitats. Recovery requires reversing the decline of a listed species and removing the threats to the long-term survival of a species that led to its listing under the ESA. When this is accomplished a species may be removed from the ESA list, or "delisted." Recovery, as defined by NOAA Fisheries, requires restoring listed species so that they become viable components of their ecosystem.[7] This document addresses the status and recovery needs of the portion of the Middle Columbia River Steelhead DPS that utilize the Yakima Basin. The Yakima Basin Fish & Wildlife Recovery Board is providing it to NOAA Fisheries in order to assist in its efforts to develop a federal recovery plan for the Middle Columbia River Steelhead DPS.

1.1.3 Development of the Yakima Subbasin Salmon Recovery Plan

This document is builds upon the Yakima Subbasin Salmon Recovery Plan, which was prepared by the Yakima Basin Fish & Wildlife Recovery Board (YBFWRB, also the Board), and its predecessor organization, the Yakima Subbasin Fish and Wildlife Planning Board (YSPB). These Boards developed this plan in response to the Washington State Salmon Recovery Act (RCW 77.85), which encourages the creation of regional recovery plans that address the needs of ESA-listed salmonid species. The

---

[7] A "viable" population is defined by NOAA Fisheries as an independent population that has negligible risk of extinction due to threats from demographic variation, local environmental variation, and genetic diversity changes over a 100-year timeframe (ICTRT 2004b).

Yakima Subbasin Salmon Recovery Plan addressed the recovery needs of both of the ESA-listed fish species found in the Yakima Basin: steelhead and bull trout. The Salmon Recovery Act states that the fish and wildlife resources of the state are currently managed by state resource agencies, and that it is in the interest of the citizens of the State of Washington to retain management responsibility for these resources. Accordingly, local organizations, in cooperation with state, tribal, and federal governments, are developing recovery plans. This approach accelerates the required recovery planning process and ensures that NOAA Fisheries and USFWS consider local expertise and concerns in the preparation and approval of recovery plans.

In order to implement the Salmon Recovery Act, the Washington Salmon Recovery Funding Board and the Office of the Interagency Committee (known as the Recreation and Conservation Office) contracted with the Yakima Subbasin Fish and Wildlife Planning Board to develop a local salmon recovery plan based on guidance from the Washington Department of Fish and Wildlife (WDFW) and the Governor's Salmon Recovery Office (GSRO). The YSPB was originally convened to develop the Yakima Subbasin Plan for the Northwest Power and Conservation Council, and consisted of representatives from local governments in the Yakima Basin.[8] The YSPB worked with local partners and stakeholders to develop and review the initial draft of Yakima Subbasin Salmon Recovery Plan.

The draft plan was approved by the state and forwarded to NOAA Fisheries and the USFWS on October 26th, 2005. NOAA Fisheries subsequently reviewed the draft plan and developed a response entitled "Supplement to the Draft Yakima Subbasin Salmon Recovery Plan" (NMFS Northwest Region 2006). NOAA Fisheries announced the availability of the draft plan and the agency's supplement in the Federal Register on May 3, 2006 [9], with a formal comment period that extended until July 3, 2006.

In April 2006, in an effort to consolidate salmon recovery efforts, the Planning Board was dissolved and its duties taken on by a new organization, the Yakima Basin Fish & Wildlife Recovery Board. The new Board also took on the role of Lead Entity from the Yakima River Salmon Recovery Board, a separate Board that was also dissolved. The YBFWRB assumed responsibility for the Yakima Subbasin Salmon Recovery Plan.[10]

Since the formation of the Yakima Basin Fish & Wildlife Recovery Board, the original October 2005 draft has been revised to incorporate new information, improve clarity, and address issues identified in the NOAA Fisheries' supplement and comments received in response to publication in the Federal Register. In order to ensure clarity and facilitate incorporation into NOAA Fisheries' Middle Columbia River Steelhead Recovery Plan,

---

[8] Membership in the Yakima Subbasin Planning Board included the Yakama Nation, Benton County, Yakima County, the cities of Benton, Ellensburg, Granger, Kennewick, Prosser, Richland, Roslyn, Selah, Sunnyside, West Richland, Union Gap, and Yakima, and WDFW.
[9] See the Federal Register, Volume 71, p. 26052.
[10] Membership in the Yakima Basin Fish & Wildlife Recovery Board includes the Yakama Nation, Benton, Kittitas, and Yakima counties and 18 of the 24 municipalities in the Yakima Basin. Its work is overseen by a Board of Directors and conducted through a non-profit organization that reports to the Board. For more information see http://www.ybfwrb.org.

this steelhead-specific plan was compiled from the Yakima Subbasin Salmon Recovery Plan. The Yakima Basin Fish & Wildlife Recovery Board has followed existing statutory and policy guidance to develop what we believe is an effective and practical recovery plan for steelhead in the Yakima Basin.

1.2 Vision and Guiding Principles for Local Planning

1.2.1 Vision

The recovery plan built upon the Yakima Subbasin Fish and Wildlife Planning Board's (YSPB) Vision 2020 (Yakima Subbasin Fish and Wildlife Planning Board 2005). Vision 2020 describes in general terms the desired future conditions of fish and wildlife habitats and populations in the Yakima Basin. It states:

> Yakima River basin communities have restored the Yakima River basin sufficiently to support self-sustaining and harvestable populations of indigenous fish and wildlife while enhancing the existing customs, cultures, and economies in the basin. Decisions that continuously improve the river basin ecosystem are made in an open and cooperative process that respects different points of view and varied statutory responsibilities and benefits current and future generations.

1.2.2 Guiding Principles

The Guiding Principles set the direction for the recovery plan by taking into account local economic and social conditions and concerns, generally accepted biological assumptions, treaty rights, and other applicable laws and policies. The Guiding Principles developed by the YSPB for the subbasin planning process are:

- The natural environment, including its fish and wildlife resources, is the common heritage of our diverse human community. The underlying premise of the Vision is to prepare and implement a balanced plan of action that plays a key role in the long-term sustainability of this common cultural and biological heritage in the Yakima Basin.
- The quality of water and a near natural timing and quantity of water flow (normative hydrograph) are principal indicators of a healthy river ecosystem. These indicators must be improved and monitored.
- The continued exercise of the Yakama Nation treaty-reserved and aboriginal rights to religious, subsistence, commercial, and recreational use of natural resources is recognized.
- Planning and implementation is based on voluntary actions and incentives.
- The processes of plan preparation, implementation, and amendment are open and equitable.

- The costs of plan actions are estimated in relation to benefits. Alternatives that achieve the highest benefit relative to costs are preferred. Costs of habitat and species restoration should be mitigated and distributed equitably.
- Programs and actions must be monitored and evaluated for effectiveness and may be altered as necessary.
- Balanced sustainable resource management recognizes these basic precepts:
  - The physical and biological environments are functionally interdependent relative to productivity.
  - At any level of function, productivity is finite.
  - Without actions to restore degraded functions, and to protect, avoid, and mitigate impacts to the physical and biological environment, the increasing demands of human population growth could reduce productivity to zero, with unacceptable costs to the cultures and economies of the Yakima subbasin.

The primary focus of this plan is "recovery" of listed species to levels that no longer require those species to be listed under the Endangered Species Act. However, both the mission of the Yakima Basin Fish & Wildlife Recovery Board and the specific goals identified in Chapter 4 go beyond just delisting of these species, and include maintaining population levels that support sustained harvest and diverse ecological functions. In order to reach these goals, recovery to the point where delisting is possible is a necessary first step, but not the end point. Meeting the long-term population and harvest goals of the Board will require ongoing actions even after the initial goal of delisting is met.

1.2.3 Non-Regulatory Nature of Recovery Plans

The NOAA Fisheries Recovery Plan for Middle Columbia River Steelhead and the Yakima Subbasin Salmon Recovery Plan are not regulatory documents. They lay out recommended actions, but do not require anyone to implement those actions. The intent of the plans is to provide information and guidance to those looking for ways to recover listed species. The recommendations made in the plans can only become binding commitments if decision makers subsequently incorporate them into requirements established by other governmental entities or programs according to their regular processes. The plans themselves create no obligations.

Both local and NOAA Fisheries recovery planners have repeatedly assured basin citizens and stakeholders that these recovery plans are not a regulatory mechanism, and that their implementation will not usurp or diminish the existing authority under state law or federal treaty, of any government or special district. The Board envisions that implementation of the plan will be inclusive, transparent, collaborative, cooperative, and voluntary. This approach is essential in order to build the long-term social and political support required for successful steelhead recovery. While the science, metrics and overall recovery strategy of the Yakima Subbasin Salmon Recovery Plan must guide what actions should be taken to increase steelhead productivity, there will often be additional considerations that will determine the sequence of actions that are taken, and how the actions should best be implemented so that recovery goals can be achieved in an

atmosphere of trust and cooperation. The organizations that promote implementation of these recovery plans must be flexible and innovative in using their resources so that broad understanding, support, involvement, and enthusiasm for salmon recovery is nurtured.

1.3 Process Used to Develop the Plan

1.3.1 Drafting of the Plan

In the initial 2005 draft of the Yakima Subbasin Salmon Recovery Plan, the limiting factors and actions were developed based on consideration of both bull trout and steelhead. The plan took a watershed-based approach that focused on protecting existing habitat and supporting natural habitat-forming processes. In this updated steelhead version, we have extracted the steelhead-specific information for ease of reference and incorporation into NOAA Fisheries' Middle Columbia River Steelhead Recovery Plan. We will update the bull trout section of the 2005 plan in conjunction with the USFWS's development of a bull trout recovery plan.

This plan was developed as follows:

- The Interior Columbia Technical Recovery Team (ICTRT) identified "Independent" populations for steelhead (ICTRT 2003; ICTRT 2005c). See Section 2.2 for definition of these populations.
- Current and historical conditions of each population were described, with emphasis on four general Viable Salmonid Population (VSP) parameters: abundance, productivity, spatial structure, and diversity (McElhany et al. 2000).
- Limiting factors that led to the decline of each population in the Yakima Basin were identified. Limiting factors were identified in the Yakima Subbasin Plan based on Ecosystem Diagnosis and Treatment (EDT) model runs specific to steelhead, other watershed assessment documents and plans, the species management programs by the Yakama Nation (YN) and WDFW, NOAA Fisheries' Draft Guidelines for Limiting Factors and Threats Assessments, and recent research on habitat conditions and populations.
- Specific recovery actions were selected from those listed in the subbasin plan, and additional actions were identified consistent with "An Outline for Salmon Recovery Plans" (WDFW 2003). The plan also includes actions to respond to extinction risks consistent with the Interior Columbia Technical Recovery Team's guidelines (ICTRT 2004a; ICTRT 2004b), actions based on threats identified by stakeholders, and actions stakeholders identified for the first time during this planning process.
- The benefits, practicability, and relative cost of actions for each population were assessed.
- A suite of actions that could be implemented, were reasonable, and should provide the greatest benefit to the listed and other species was selected.

Planners believe that the proposed actions are sound. The actions identified in the plan address the range of threats to steelhead as they are understood at this time. However, outcomes are uncertain because of the lack of comprehensive knowledge about the ecological and social processes that affect fish. Unpredictable events will continue to affect recovery efforts. In order to ensure that the recovery strategy effectively incorporates improved knowledge and changing conditions, the plan calls for monitoring and evaluation efforts that assess the outcomes of recovery efforts and the response of target fish populations. Participants will take this information and updated cost estimates and use them to re-evaluate proposed actions and their priorities and update the plan.

1.3.2 Public Involvement

The public participation process for the preparation of Yakima Subbasin Salmon Recovery Plan was a continuation of the process carried out for the Yakima Subbasin Fish and Wildlife Plan. The contact list developed during the subbasin planning process was used and updated to keep interested parties informed and involved in the progression of the draft salmon recovery plan. The Yakima Subbasin Fish and Wildlife Planning Board's website remained active and updated, the media were kept informed, and there was a public comment period on each agenda of the advertised Board meetings. Board staff continued to give presentations and updates to various interested groups. During the preparation of the Salmon Recovery Plan, however, public participation activities emphasized involving stakeholders—the agencies, special districts, non-profits, economic interests, local government departments, and others that are daily engaged in consumptive use, management, or acquisition of resources that directly or indirectly affect salmon and salmon habitat. These entities include irrigation districts, conservation districts, state and federal agencies (e.g., BOR, USFS, and Washington Department of Transportation), greenways and land trusts, and local government planning and public works departments. These stakeholders funding, abilities, constraints, legal authorities, constituent interests, and internal policies will determine whether or not they can commit to the changes in their operations and programs identified in the draft Recovery Plan as necessary to restore salmon habitat.

Within the salmon recovery planning process, the interaction with stakeholders is called the Policy Forum. Board staff consulted with stakeholders during the months of March, April, and early May, beginning with a well-attended workshop held at the Yakima Convention Center on March 2, 2005. The list of Policy Forum stakeholders is shown in Appendix D. Additional outreach efforts were made throughout the planning process, as described in Appendix D, and changes were made in response to comments made during the September to December 2008 NOAA Fisheries comment period on the Middle Columbia River Steelhead Recovery Plan.

Chapter 8 of this document discusses information and outreach needs associated with recovery efforts.

1.3.3 Incorporating the Local Plan into NOAA's Recovery Plan

NOAA Fisheries is currently preparing its recovery plan for the Middle Columbia River Steelhead DPS, as mandated by the ESA. The geographic area of the DPS encompasses

much of north-central Oregon and south-central Washington. The Yakima MPG is one of four MPGs in the Middle Columbia River Steelhead DPS. It contains 20% of the acreage and four of the 18 extant steelhead populations in the DPS (see Figure 1.1). It is the intent of both NOAA Fisheries and the YBFWRB that the Yakima Subbasin Salmon Recovery Plan be the basis for the Yakima MPG portion of NOAA Fisheries' Mid-Columbia Steelhead Recovery Plan.

This excerpt includes the portion of the updated version of the Yakima Subbasin Salmon Recovery Plan that address the recovery needs of the Middle Columbia Steelhead DPS. It has been prepared specifically for reference by NOAA Fisheries in preparation of the formal federal recovery plan for Middle Columbia River Steelhead, and this excerpt is expected to be included by NOAA Fisheries as an Appendix in its final recovery plan. For the sake of brevity and clarity, this excerpt does not include those portions of the Yakima Subbasin Salmon Recovery Plan that focus solely on bull trout. Where bull trout recovery needs influence and/or overlap recovery needs for steelhead, this is noted in the excerpt.

The steelhead that spawn in the Yakima Basin spend their first years in the basins streams and rivers, and then migrate out the Columbia to the Pacific ocean before turning around and, as adult fish, migrating up the Columbia and Yakima rivers to their spawning grounds. Recovering Yakima steelhead will require taking actions that improve survival rates for steelhead in the Yakima Basin, the Columbia River, its estuary, and the ocean. The Yakima Subbasin Salmon Recovery Plan and this steelhead excerpt focus on the factors that affect steelhead during the portions of their lives spent in the Yakima Basin. The NOAA Fisheries Recovery Plan for the Middle Columbia River Steelhead DPS will combine this within-basin information with an assessment of the many factors that affect steelhead during their time outside of the Yakima Basin. These include passage through the mainstem Columbia hydropower system, conditions in the Columbia River and its estuary, harvest by both fisheries and predators, and ocean conditions. The NOAA Fisheries recovery plan will incorporate proposed actions that address these out of basin impacts.

1.4 Relationship to Other Recovery Activities

1.4.1 Relationship to Other Planning Efforts

The Yakima Subbasin Salmon Recovery Plan draws from several related planning efforts undertaken in the basin in recent years. In 2000, the Northwest Power and Conservation Council (formerly the Northwest Power Planning Council) adopted a revised Columbia River Basin Fish and Wildlife Program with the intent that the program will be more comprehensive than, but complementary to, regional, state, county, and tribal efforts. Their revised program called for an ecosystem-based approach for planning and implementing mitigation of impacts to fish and wildlife from the Columbia Basin hydroelectric system. To provide specific recommendations for the Yakima Basin, the Northwest Power and Conservation Council (NPCC) contracted with the Yakima Subbasin Fish & Wildlife Planning Board to develop the Yakima Subbasin Plan (Yakima Subbasin Fish and Wildlife Planning Board 2005), which was completed in 2004 and is

the basis of much of the information contained in this recovery plan. While the Yakima Subbasin Salmon Recovery Plan focuses more narrowly on steelhead and bull trout, other resident and anadromous fish species should also benefit from the actions it identifies.

The Washington State Conservation Commission drafted a Limiting Factors Analysis of fish habitat in the Yakima Basin (Haring 2001) as part the Washington State Salmon Recovery Strategy laid out in House Bill 2496 in 1998. It provides a detailed stream-by-stream discussion of habitat conditions in the basin.

The Yakima River Basin Watershed Management Plan was developed as part of the state-wide watershed planning process under House Bill 2514. The draft plan was completed in November 2005, and addresses water supply, water quality, and fish habitat issues. Yakima, Benton, and Klickitat counties have adopted the plan, but neither Kittitas County nor the Yakima Nation have approved it. The Yakima Basin Water Resources Agency has developed a Detailed Implementation Plan for the Watershed Plan and is coordinating its implementation. It is our hope that implementation of the Yakima Subbasin Salmon Recovery Plan can be closely coordinated with efforts to implement the Watershed Plan.

1.4.2 Relationship to Ongoing On-the-Ground Recovery Efforts

WDFW and the Yakama Nation work together as co-managers to manage the basin's fish resources. These co-managers and numerous partners (including federal agencies, local governments, non-profit organizations, Conservation Districts, and local landowners and managers) have a strong history of working together to improve habitat and recovery salmon and steelhead in the Yakima Basin. Fish management programs in the basin are described in Appendix A and include fisheries enhancement projects funded by the Bonneville Power Administration's Fish & Wildlife Program, salmon restoration projects funded by the Washington Salmon Recovery Funding Board via the Lead Entity system developed by HB 2496, the Bureau of Reclamation's Yakima River Basin Water Enhancement Project, restoration projects conducted by the Wenatchee National Forest, local comprehensive and shoreline management plans and their respective regulatory programs, and numerous voluntary efforts by private individuals and organizations. The recovery strategy described in the Yakima Subbasin Salmon Recovery Plan is built on continuing and enhancing these fish restoration efforts. Meeting the recovery goals for ESA-listed fish populations within the Yakima Basin will likely require sustained efforts over the course of several decades. The estimated cost attributed to steelhead recovery for all actions identified in this plan is $269.3 million. Local budgets and economies within the basin cannot fund such expenditures on their own, and success in salmon recovery will depend on the ongoing support of state and federal governments. This support needs to be sufficient, reliable, and consistent over time.

Successfully delisting steelhead in the Yakima Basin will also require coordinating efforts with other areas within the Middle Columbia River DPS. NOAA Fisheries will only delist the Yakima steelhead Major Population Group (MPG) if delisting is deemed to be appropriate for the entire DPS. This is dependent on progress towards recovery in other MPGs in the DPS (the John Day, Walla Walla/Umatilla, and East Cascades Major Population Groups). This means that local communities in different basins that cross

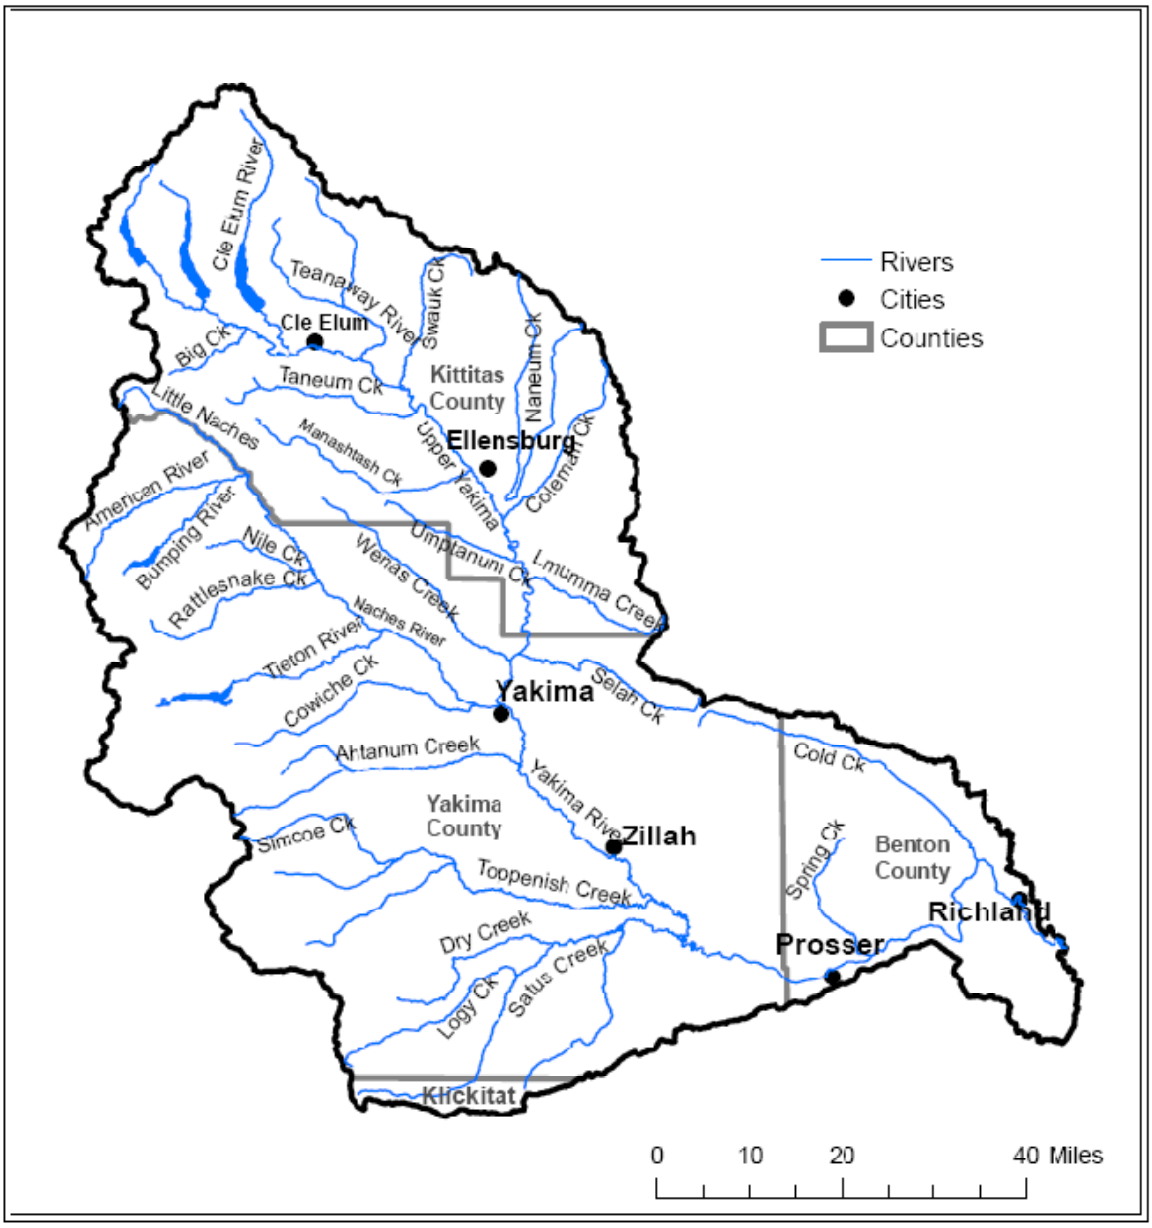
local and state boundaries are dependent upon each other for success in meeting de-listing goals, and will need to work together to insure that their shared goals are met.

2 Species Status

2.1 Regional Setting	**2.4 Abundance**
2.2 Identification of Populations	**2.5 Population Characteristics & Life Histories**
2.3 Distribution	**2.6 Viability Assessments for Yakima Steelhead**

This section describes the Yakima Basin, its steelhead populations, and their population structure, distribution, abundance, characteristics, and life histories. It then reviews existing viability assessments of Yakima Basin steelhead populations. In this document, steelhead refers to the anadromous component of *O. mykiss* in the Yakima Basin, as described in Chapter 1, the Introduction.

2.1 Regional Setting



2.1.1 Geographic Setting[11]

The 214-mile Yakima River and its tributaries drain a 6,150 square mile watershed that runs from the crest of the Cascade Mountains (over 8,000 feet in elevation) to the Columbia River 333 miles upstream of the Pacific Ocean (340 feet in elevation). The Yakima River and its tributaries run through landscapes that range from the forested, mountainous terrain of the Cascades to the dry, shrub-steppe hills of the Columbia Basin. The Yakima Basin occupies two physiographic provinces (the Columbia Plateau and Cascade Mountains), and three major ecoregions, Cascades, Eastern Cascades Slopes and Foothills, and Columbia Basin (Omernik 1987). Climate, topography, precipitation, and vegetative cover are highly variable across the basin. Precipitation in the basin ranges from over 120 inches in the mountains to 7 inches in the lower Yakima Valley. Figure 2.1 shows the major rivers and streams in the Yakima Basin discussed in this recovery plan.

Basin geology dictates the form of the river valleys in the Yakima Basin. At the highest elevations of the Naches and Upper Yakima systems, streams flow through wide glacially carved valleys and glacial lakes that have been converted to serve as storage reservoirs. At lower elevations, and in other tributaries, stream channels have incised narrow canyons into the basalt and other bedrock. Valley floors near the towns of Ellensburg, Selah, Yakima, and Wapato contain deep alluvial floodplains composed of glacial outwash materials separated by geologic nickpoints consisting of bedrock outcroppings or anticlinal basalt ridges (e.g., Manastash, Umtanum, Yakima, and Ahtanum ridges). In the lower Yakima Valley, the Yakima River assumes a meandering planform atop broad floodplains composed of wind-blown soils and lacustrine silts from the Missoula Floods of the late Pleistocene (Bretz 1969).

[11] Unless otherwise noted, information for this section comes from the Yakima Subbasin Plan (Yakima Subbasin Fish and Wildlife Planning Board 2005).

Figure 2.1: Yakima Basin

The longitudinal profiles of anadromous salmonid streams in the Yakima Basin respond to these physiographic and geologic factors, with stream gradients ranging from greater than 15% in the upper reaches of tributaries to the Naches River to less than 0.1% in meandering reaches of the Lower Yakima River. In many areas, the floodplains that once contained a complex network of braided channels covered by dense riparian forests have been reduced to simplified channels confined by transportation infrastructure and levees.

The basin includes parts of four counties (Kittitas, Yakima, Klickitat, and Benton) and has a population of about 300,000 people. The largest towns in the basin are Ellensburg,

Yakima, and part of two of the Tri-Cities (Richland and Kennewick). Table 2.1 and Figure 2.2 summarize land ownership in the basin.

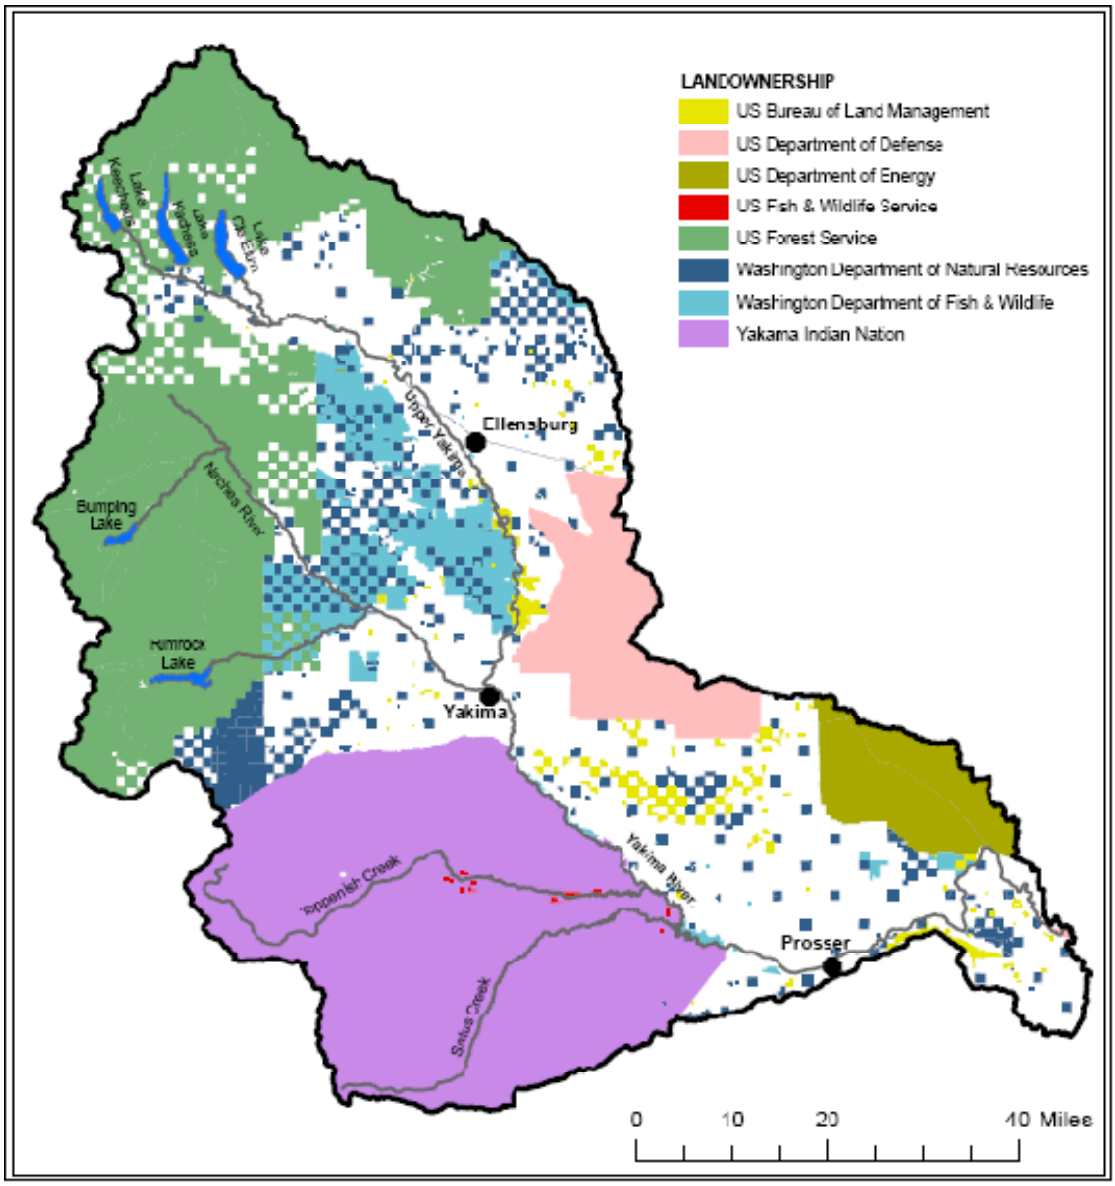
Table 2.1: Land ownership in the Yakima Basin

OWNERSHIP	ACRES	%
Private	**1,246,818**	**31%**
Yakama Nation	**889,786**	**22%**
Federal	**1,303,297**	**33%**
Forest Service	892,509	22%
Bureau of Land Management	48,893	1%
Department of Defense	199,099	5%
Department of Energy	160,098	4%
Other Federal	2,698	0%
State	**361,403**	**9%**
Department of Fish & Wildlife	156,712	4%
Department of Natural Resources	203,085	5%
Other State	1,606	0%
Other/Unknown	**168,870**	**4%**
TOTAL	**3,970,174**	

Compiled from the Yakima Subbasin Plan (YSPB 2005)

Forests and rangelands each cover 40% of the basin. From an economic perspective, the primary land uses in the basin include irrigated agriculture (1,000 square miles or 16% of land area), commercial and residential development (60 square miles or 1% of land area), and transportation. Figure 2.3 shows irrigated acreage and major dams in the basin. Secondary land uses include recreation, forestry, floodplain gravel mining, and grazing. For a more detailed description of the Yakima Subbasin, see Chapter 1 of the Yakima Subbasin Salmon Recovery Plan (Yakima Subbasin Fish and Wildlife Planning Board 2005). Overviews of each population area's geography are given below; population area boundaries are shown in Figure 2.4.

Figure 2.2: Yakima Basin land ownership



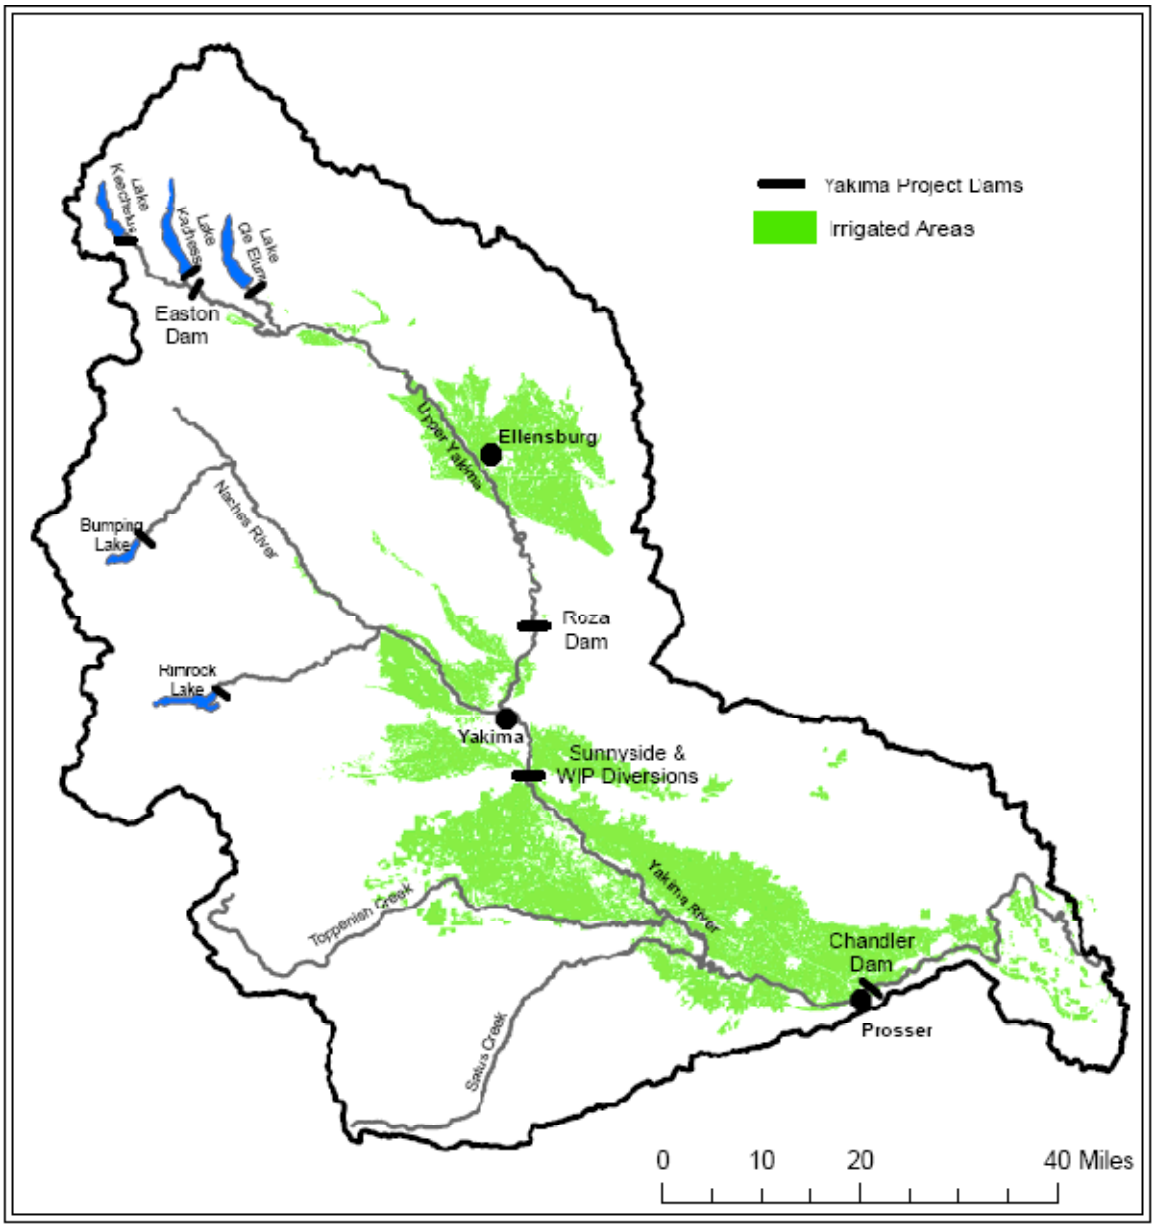


Figure 2.3: Irrigated areas and major storage & diversion dams

Satus Creek

With a drainage area of 612 square miles, Satus Creek comprises 10% of the Yakima Basin area. Many of the headwater streams in the Satus Creek watershed flow across plateaus bordered by wet meadows. As they flow generally eastward the headwater streams cascade through narrow canyons toward the relatively broad Satus Creek canyon. Satus Creek exits the canyon at RM 12.5 and flows eastward across the Yakima River floodplain to the confluence with the Yakima River. Most of the Satus Creek watershed is undeveloped and is not exposed to agricultural, industrial, or domestic effluents, but because of riparian conditions and low flow, maximum weekly average temperatures can

exceed 26^{o} C in the reach of Satus Creek between Logy Creek and Wilson Charley Creek (RM 39.3). Logy Creek cools Satus Creek for a few miles downstream from their confluence. Water quality suffers, although water quantity increases as Satus Creek flows through the Wapato Irrigation Project (WIP) in its lower eight miles. The relatively young and rapid steelhead out-migration from Satus Creek appears to be a population response to harsh historic and current summer conditions.

Toppenish Creek

The Toppenish Creek watershed, at 625 square miles, is similar in size to the Satus Creek watershed. Upper Toppenish Creek consists of three forks along with several smaller tributaries draining the Cascade foothills between Toppenish and Ahtanum ridges. These are all high gradient streams in narrow basalt canyons. Anadromous access is limited by steadily increasing gradient and coarsening substrates, not the distinct waterfalls typical in the Satus Creek system. Agency and Wahtum creeks flow into Simcoe Creek, which joins Toppenish Creek at low elevation. A few miles downstream of the Simcoe Creek confluence, the Toppenish Creek channel historically assumed a branched appearance and flowed through an extensive network of wetlands for nearly 30 miles to the Yakima River. This network has a gradient of less than 0.1%. The complexity of this network has been significantly reduced.

Naches River

The Naches River drains some of the highest and wettest terrain in the Yakima Basin. The Naches and Tieton rivers are considerably steeper and naturally more confined than the most of the Upper Yakima River. Nevertheless, the predevelopment floodplain reaches of the mainstem Naches River and its tributaries provided a labyrinth of channels surrounded by extensive riparian forests that maintained cool summer temperatures and habitat complexity for all life stages of salmon and steelhead (Kinnison and Sceva 1963; Snyder and Stanford 2001; Stanford et al. 2002). In an unregulated condition, the flow of the Naches River would be characteristic of snowmelt-dominated systems where discharge peaks between May and June concurrent with melting snow and reaches base flow in August and September. Late autumn rainfall and minor snowmelt would augment summer base flow, with occasional winter high water events under the influence of Chinook winds. Above the confluence with the highly regulated Tieton River, the Naches River and its tributaries have some of the most natural flow regimes in the Yakima Basin. Below the Tieton confluence, the Naches River floodplain widens, although a highway and other structures have isolated the river from part of the active floodplain. Rimrock Reservoir blocks passage to upstream habitat and has a major effect on flows in the Tieton River and lower Naches mainstem.

Upper Yakima River

The Yakima River above the Naches confluence is nearly 100 miles long and drains nearly twice as much area as the Naches drainage. Much of the mainstem of the Upper Yakima has relatively low gradient with extensive floodplains that once contained multiple channels and large areas of spawning and rearing habitat for salmonids, as around the towns of Easton, Cle Elum, Ellensburg, and Selah. Other reaches run through

large bedrock canyons between Cle Elum and Ellensburg and Ellensburg and Selah. The mainstem Yakima, Teanaway River, and Swauk Creek support most of the current steelhead use in the Upper Yakima population area. A number of other tributaries to the Upper Yakima River (e.g., Wilson, Naneum, Big, Little, Taneum, Manastash, Tucker, Cooke, Caribou, Coleman, and Reecer creeks) are likely to have historically supported steelhead, but impassable dams, dry reaches below dams and unscreened diversions have greatly reduced or eliminated steelhead use of these tributaries. The upper watershed contains three natural glacial lakes that now serve as storage reservoirs; historically accessible habitat above Cle Elum, Kachess, and Keechelus dams has been unavailable to steelhead since the early 20th century.

2.1.2 Ecological Setting

Steelhead use a wide range of aquatic habitats in the Yakima Basin, ranging from small intermittent streams to large multi-channel floodplains. Steelhead share the aquatic environment with at least 46 other fish species in the Yakima Basin (Fast and Berg 2001). Other species of importance include spring and fall Chinook salmon, reintroduced coho salmon, bull trout, Pacific lamprey (*Lampetra tridentata*), and westslope cutthroat trout (*O. clarki lewisi*). Sockeye are extinct in the basin, but kokanee (*O. nerka*) exist in five upper-basin storage reservoirs, and four of the populations may be descended in part from sockeye salmon present before dam construction. Summer Chinook were historically present but are now extinct in the basin. Anadromous salmon runs are thought to have once reached half a million fish or more; in recent decades combined numbers for all anadromous species have ranged from less than 3,000 in the early 1990s to more than 40,000 in 2001.[12]

Active conservation-oriented hatchery programs exist for Chinook and coho salmon. Bull trout are listed as threatened under the ESA and are under the jurisdiction of the USFWS; they are addressed in detail in the Yakima Subbasin Salmon Recovery Plan. Bull trout and steelhead distributions in the Yakima Basin currently overlap in the Naches, Ahtanum, and Upper Yakima systems. Historically bull trout would have been present across much of the current steelhead distribution, and steelhead would have been present in areas now blocked by storage dams. Currently, Pacific lamprey, and westslope cutthroat are designated as species of concern by USFWS. Steelhead recovery actions identified in this plan should benefit all these species.

There are also potential negative interactions between steelhead and other fish species. Three salmonid species (brook trout, *Salvelinus fontinalis*; lake trout *S. namaycush*; brown trout, *Salmo trutta*) have been introduced in the basin and may compete with or prey on juvenile steelhead, along with a variety of exotic sunfish, perch, catfish, and minnow species. Smallmouth bass are established in the lower river. Before the introduction of exotics, northern pikeminnow (*Ptychocheilus oregonensis*), sculpin

[12] Data compiled from Prosser Dam fish counts available online at http://www.cbr.washington.edu/dart/

(*Cottus* spp.), bull trout, rainbow trout, cutthroat trout, and burbot (*Lota lota*) were the primary piscivores in the basin.

2.2 Identification of Populations

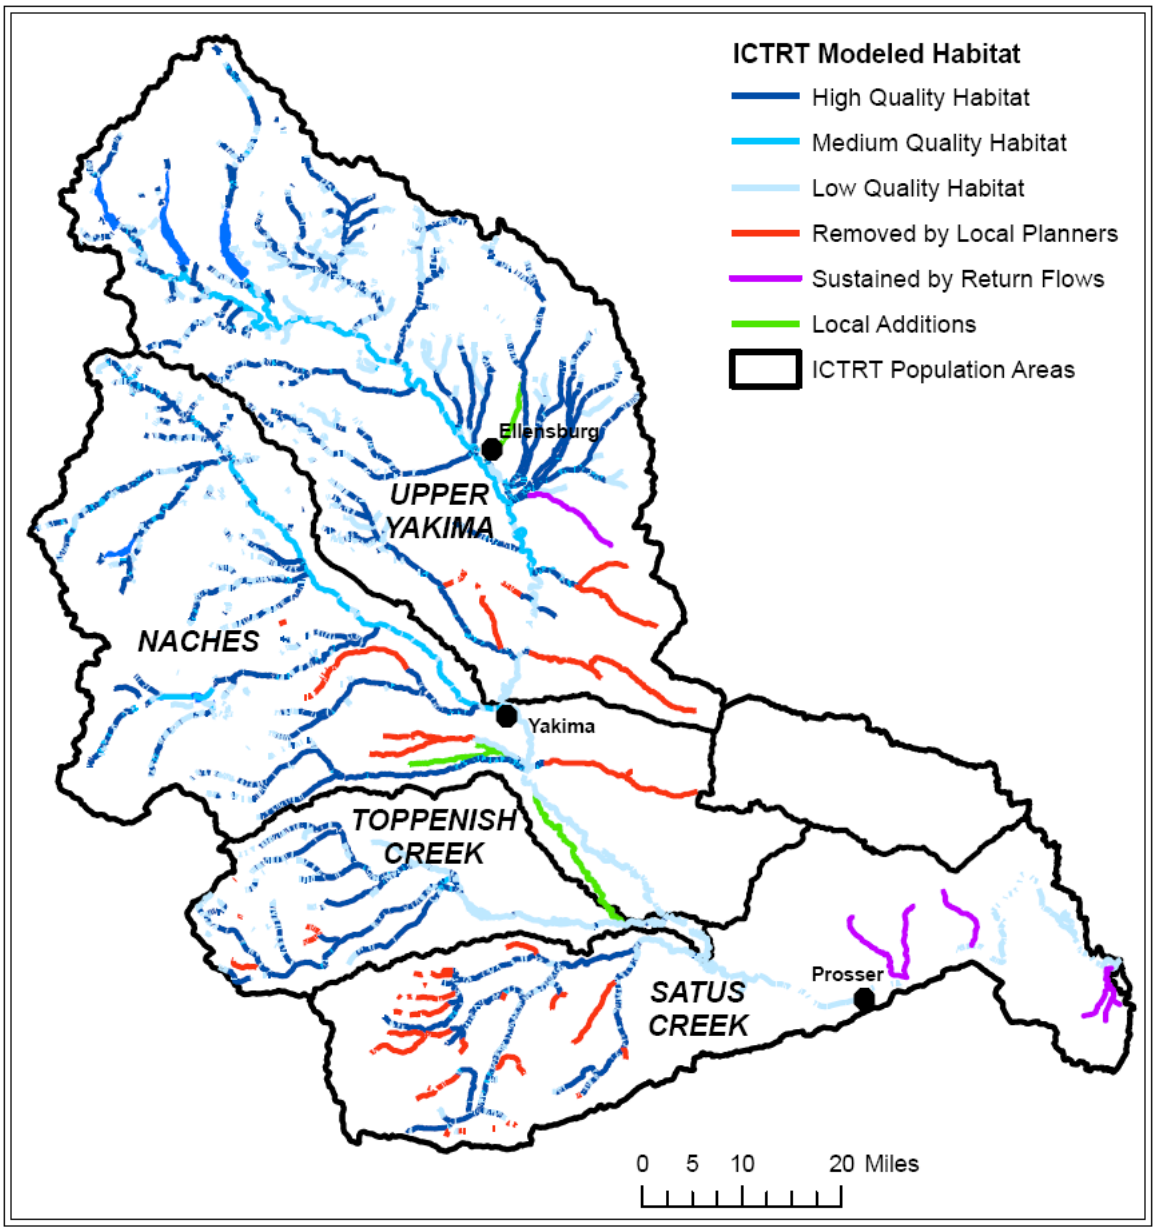
NOAA Fisheries classified Yakima Basin steelhead as summer run steelhead within the Middle Columbia River ESU when the 1999 Endangered Species Act listing was completed.[13] Yakima Basin steelhead are the upstream-most part of the Middle Columbia River DPS. NOAA Fisheries considered including them as part of the Upper Columbia ESU but they were ultimately included in the Middle Columbia ESU due to their genetic similarity to Klickitat steelhead and the similarity of their life histories and habitat types to other Middle Columbia populations (Busby et al. 1996). Genetic analyses of Yakima Steelhead include Loxterman et al. (2003) and Phelps (2000). The ICTRT has classified Yakima Basin steelhead as one of the four Major Population Groups (MPGs) within what is now the Middle Columbia River Steelhead DPS. (The others are the East Cascades, Umatilla/Walla Walla, and John Day MPGs.) The ICTRT has further subdivided the Yakima MPG into the Satus Creek, Toppenish Creek, Naches River, and Upper Yakima River populations (ICTRT 2003; ICTRT 2005c). The population level is the basic unit used in this plan for developing recovery goals, strategies, and actions. Figure 2.4 shows the ICTRT's boundaries for the spawning areas for each of the four populations.

The Toppenish and Upper Yakima population boundaries correspond well to the informal population designations used by fish managers in the basin. The ICTRT has included the Yakima River and its tributaries from the confluence of Satus Creek to the Columbia River in the Satus Creek Population area, while fish managers in the basin generally consider the Satus Creek steelhead to include only steelhead that spawn in the Satus Creek drainage. While currently almost all the spawning in the ICTRT Satus population area occurs within the Satus drainage itself, the large extent and uncertain historic habitat value of the lower mainstem and its tributaries do affect assessments of historic potential and current viability of this ICTRT population area. Local planners have addressed this by dividing the Satus population into two parts: the Satus Creek block, which spawns within the Satus Creek watershed, and the mainstem block, which spawns in the lower mainstem and its tributaries below Satus Creek. While the Satus Creek block represents an area with known and wide spread spawning, the current and historic status of the mainstem block is uncertain. This issue is addressed in more detail in Sections 2.3.1 and 4.1.1.

The ICTRT has also included the Yakima River from Selah Gap to the mouth of Toppenish Creek and the Ahtanum Creek drainage in the Naches River population area, while fish managers in the basin have generally considered the Naches population to include only steelhead that spawn in the Naches River and its tributaries. The current and historic level of steelhead use of this portion of the mainstem Yakima is not well understood. While Ahtanum Creek steelhead may be genetically distinct from other Naches Basin populations (Small et al. 2006), the similarity in habitat and geographic

[13] See the Federal Register, Volume 64, p.14517.

proximity of Ahtanum Creek makes its inclusion as part of the ICTRT Naches population appropriate. The Naches population would still rank as a large population even if mainstem area were excluded, so no there is no separate “mainstem block.”



2.3 Steelhead Distribution

Steelhead are the most widespread anadromous fish in the Yakima Basin. They range from intermittent streams in semi-arid watersheds to headwaters high in the Cascades. A consensus of local managers on the current distribution of steelhead for the Yakima Basin is represented in WDFW’s SalmonScape online mapping system (included as orange symbol in Figure 2.4).[14] The USFS and the Yakama Nation maintain more detailed estimates of distribution for specific areas. The overlap between anadromous and resident forms of *O. mykiss* can make determining the exact distribution of steelhead in the Naches and Upper Yakima populations challenging. Redd surveys and radio-tracking data (Hockersmith et al. 1995; Karp et al. 2003; Karp et al. 2005) provide the most definitive information on areas used by anadromous spawners in recent years.

Numerous qualitative efforts have been made to estimate the historic and/or potential distribution of steelhead in the Yakima Basin (Haring 2001; Tuck 1995; Yakima Subbasin Fish and Wildlife Planning Board 2005). The ICTRT developed its Historic Intrinsic Potential Analysis to enable comparisons between modeled estimates of historic steelhead distribution and abundance and current steelhead distribution and abundance. These comparisons play a key role in the ICTRT’s efforts to assess the current status and potential viability thresholds for individual steelhead populations. The ICTRT has described its viability assessment procedure (ICTRT 2007b) and the Historic Intrinsic Potential Analysis (Cooney and Holzer 2006). The model estimates the amount of historically available steelhead habitat using defined decision rules and quantitative data captured in a Geographic Information System (GIS). The model focuses on identification of spawning and early rearing habitat within the Columbia Basin. It uses stream widths to calculate habitat areas in addition to simple linear stream lengths. The ICTRT model also gives a relative habitat value (high, medium, or low) to all areas identified as potential habitat, which is used to develop estimates of habitat area weighted by relative value. Model results are intended to estimate the potential habitat accessible to steelhead in the Yakima Basin using readily available measurements and consistent rules. They should not be used to classify specific areas and their current habitat values and/or potential.

[14] http://wdfw.wa.gov/mapping/salmonscape

Figure 2.4: ICTRT Intrinsic Potential Analysis & population areas in the Yakima

Local recovery planners worked closely with the ICTRT to review the results of the preliminary ICTRT Intrinsic Potential Analysis, provide additional information for inclusion into the GIS (e.g., locations of natural barriers to steelhead access), note discrepancies between results of the ICTRT analysis and previous historic/potential analyses, and propose adjustments to the decision rules that would reduce the discrepancies. To assure the integrity of their model, the ICTRT did not adjust specific model outputs to correspond with local reviews. The ICTRT adjusted the model by making changes to decision rules based on documented rationales and then applying the revised rules to the entire regional database. In general, the most current iteration of the ICTRT model takes into account these local assessments of habitat potential, but

continues to overestimate the extent of potential habitat in arid areas. Figure 2.4 shows the potential habitat identified by the model and the locations where local planners did not concur with the model results.

The model consistently assigned habitat potential to streams in semi-arid portions of the Basin that the review team identified as not generating enough flow to support steelhead. Correcting this may require refining the model's approach to predicating flow in semi-arid (under 16") precipitation regimes. The ICTRT has acknowledged this limitation and is exploring ways to build a decision rule that would better model arid watersheds. Inclusion of streams with watersheds that do not have the precipitation and/or watershed area to generate any sustained base flows was primarily an issue in the Satus Creek watershed and the lowest elevations in the Upper Yakima and Naches watersheds. These areas are marked in red in Figure 2.4. In a few cases, streams that are unlikely to have had sufficient flow to support steelhead under historic conditions now have flows that are enhanced by surface and subsurface irrigation return flows (purple on Figure 2.4) (Smith et al. 2006).

In areas with over 16" annual precipitation, model results largely matched local surveys and expert opinion. The model consistently extended lower quality habitat higher up small tributaries and headwater reaches than locally derived maps, but these differences do not make significant differences in overall population-level weighted habitat area and were considered as feasibly within historic potential by local reviewers.

The model also failed to include a few streams considered by the review team to be potential/historic habitat. In all of these cases, the streams were either distributary channels connected to other streams at both upstream and downstream ends or small spring-fed creeks in floodplains. The ICTRT has acknowledged that their model either does not recognize these streams as having sufficient watershed area to generate flow or routes flows down a single channel where channels diverged. These streams are colored green in Figure 2.4. For a more detailed description of remaining divergences between the ICTRT model and recovery planners' assessments, see Appendix A. In this plan, the locally corrected model results are used as the basis for determining potential steelhead distribution. The weighted habitat areas identified by the ICTRT model and the locally adjusted model output are listed in Table 2.2. The table shows the habitat area cited in the most recent draft of the ICTRT stock status reports; the area indicated in the updated GIS coverage of the model results provided by NOAA Fisheries; and the area remaining after local edits to the model were made. In general, the ICTRT reports include more estimated habitat area than either the updated GIS-data or the locally edited model results.

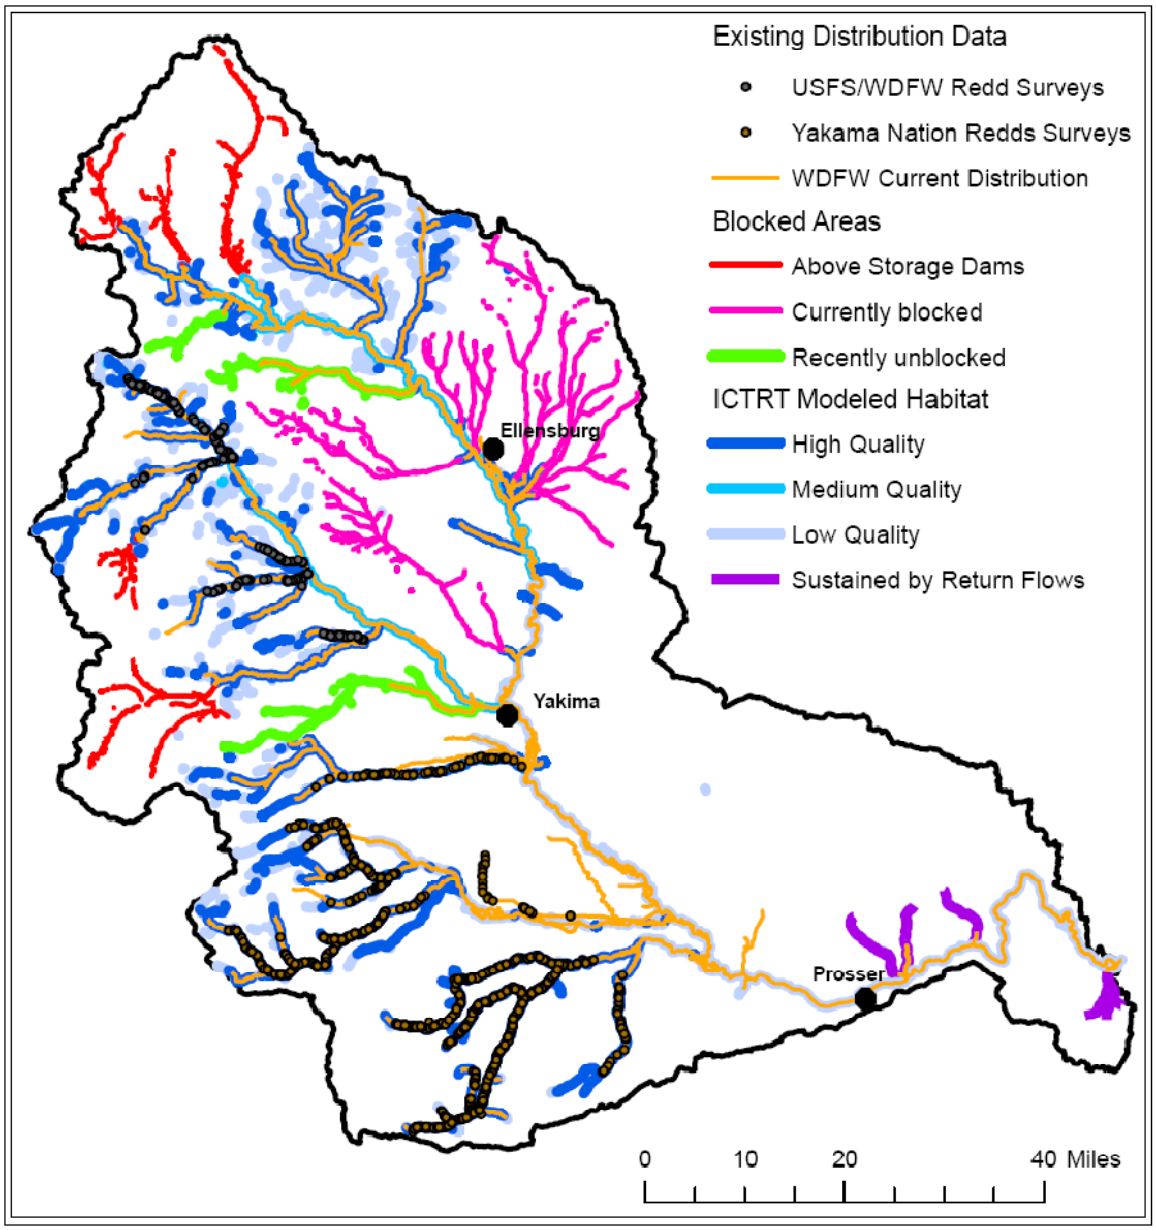


Table 2.2: Intrinsic Potential Analysis modeled habitat areas

Figure 2.5 shows current spawning and distribution data from Yakama Nation redd surveys in the Satus, Toppenish, and Ahtanum watersheds, USFS/WDFW redd surveys in selected Naches Population tributaries, and the WDFW SalmonScape database. Redd survey data are for varying spans of years and survey intensities; they show areas where spawning is confirmed to occur but should not be used as indicators of relative spawning densities. Redd surveys have not been done in most of the mainstem Naches and Tieton

rivers[15] or in the Upper Yakima population area. Radio-tracked fish have been located in and are presumed to have spawned in all the habitat areas above Roza identified in the WDFW SalmonScape distribution (orange line) except for the Upper Yakima River above Easton Dam (Karp et al. 2003; Karp et al. 2005). Figure 2.5 also shows currently accessible habitat, blocked habitat, and recently re-opened habitat. It indicates that the locally adjusted Intrinsic Habitat Potential map of high quality habitat corresponds well with current distribution and spawning for accessible areas.

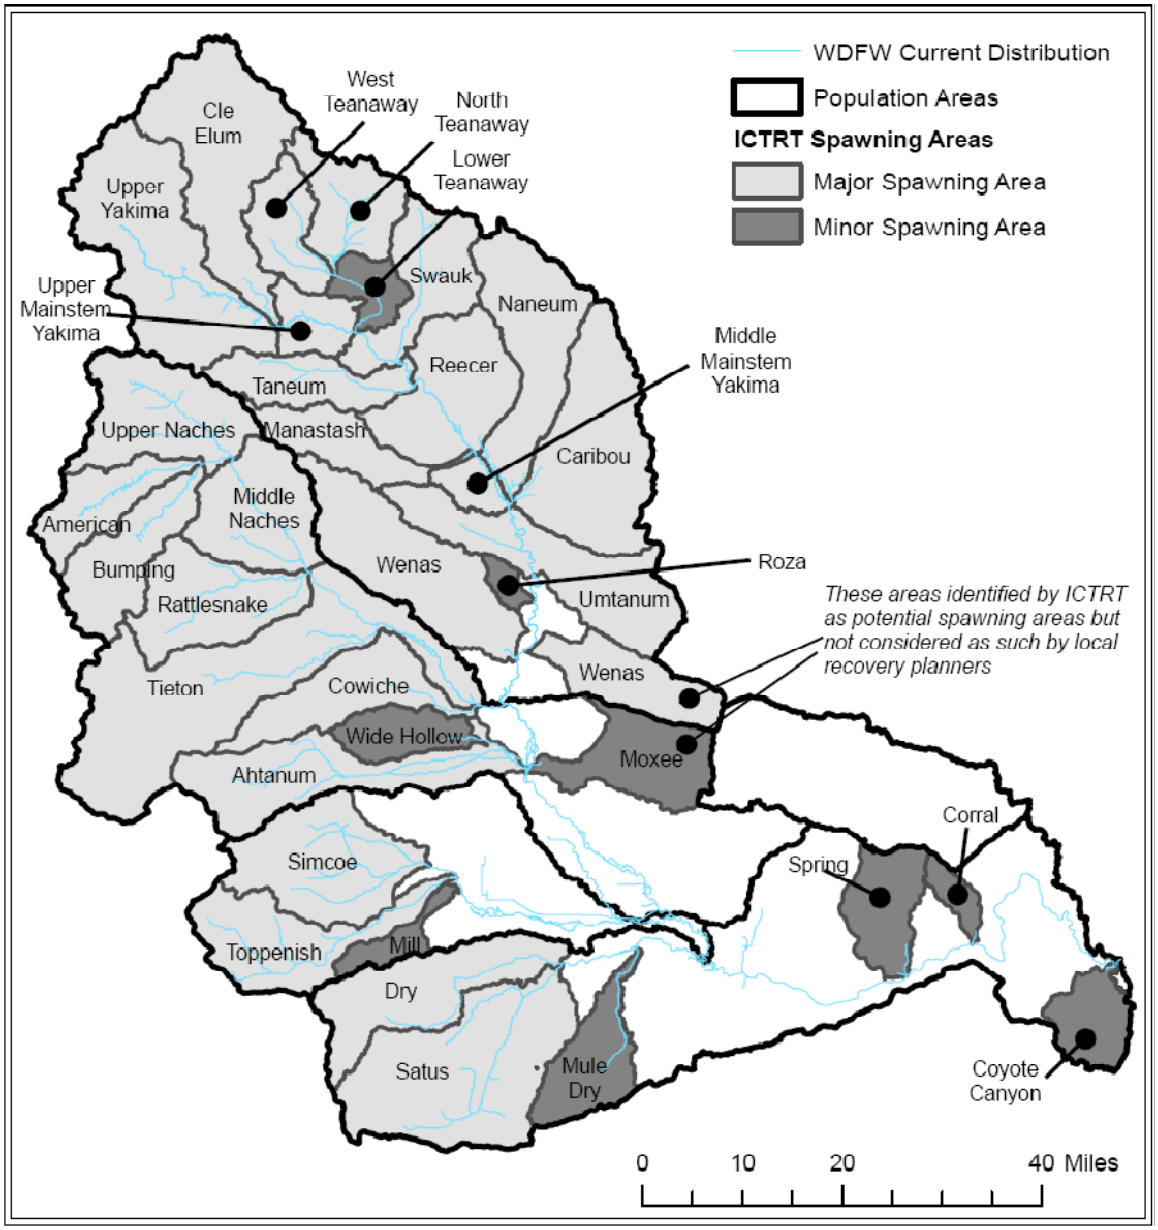

Figure 2.5: Available habitat, current distribution, and blocked areas

15 A redd survey was conducted from RM 38 to RM 27 on the Naches River by Pat Monk on 4/20/05. No redds were observed.

The ICTRT Intrinsic Potential Model (Cooney and Holzer 2006; ICTRT 2007b; ICTRT 2008) was used to designate major spawning areas (MSAs) and minor spawning areas (MiSAs) within each population area. Local recovery planners have used this as the basic unit for assessing spatial distribution in this plan. Figure 2.6 shows the ICTRT's MSAs and MiSAs overlaid with WDFW's current steelhead distribution map.

Figure 2.6: ICTRT spawning areas and WDFW steelhead distribution

2.3.1 Satus Population

The ICTRT assigned two MSAs and four MiSAs to the Satus Creek steelhead population, based on historical intrinsic potential analysis (Figure 2.6). Both MSAs and one of the MiSAs are within the Satus Creek drainage itself. The remaining three minor spawning concentrations are associated with small tributary drainages of the mainstem Yakima River.

Spawning is known to occur throughout the Satus and Dry Creek MSAs, as well as in Mule-Dry Creek MiSA. Spawning is also attributed to the Corral Creek MiSAs in WDFW's SalmonScape online mapping system. Surveys of Snipes Creek and its tributary Spring Creek have revealed small numbers of *O. mykiss* (Monk 2001) and an adult steelhead was identified 0.5 miles up Spring Creek by WDFW in 2007 (Bartand, communication, 2007). Habitat surveys in 2001 revealed that, of the left-bank drains with suitable spawning substrate, only Spring Creek had sufficient flow in the non-irrigation season to provide adult steelhead access (Romey and Cramer 2001). *O. mykiss* presence during the summer was documented in Amon Wasteway (in the Coyote Canyon MiSA) during WDFW electroshock sampling by Paul Hoffarth in 2005 and during snorkel surveys by Dr. David Smith of the University of Idaho in 2002. A planned 2007 steelhead spawning ground survey was thwarted by high flow (P. LaRiviere, WDFW, communication, 2007).[16]

For the Satus Population, the local review team was generally agreed with the ICTRT model results for the Satus Creek watershed itself, with the exception of a few tributaries indicated on Figure 2.5 that were not believed to have the flows needed to support steelhead. The habitat area within the Satus Creek drainage itself would (both with and without the tributaries in question) classify as a Basic population under the ICTRT framework, with a minimum viable abundance target of 500 returning adults. When the mainstem and tributaries to the lower mainstem were included in the Satus population, it was classified as an Intermediate population, with an abundance threshold of 1,000 spawners. The local review team felt most comfortable addressing management of these two portions of the Satus population area separately, with a threshold of 500 fish for Satus Creek watershed and another 500 for the mainstem component of the ICTRT population area; this is discussed in more detail in Section 4.3.9.

2.3.2 Toppenish Population

The ICTRT assigned two MSAs and one MiSA to the Toppenish Creek steelhead population, based on historical intrinsic potential analysis (Figure 2.6). All are within the Toppenish Creek drainage itself. Spawning is known to occur throughout the Simcoe

[16] Spring, Corral, and Snipes creeks, and Amon Wasteway are referred to by the names used on the USGS 7.5 minute topographic maps. The first three are referred to as drainageways by local irrigation districts, while Amon Wasteway is often referred to as Amon Creek. The use of these names in this document is in no way meant to indicate any conclusions regarding ongoing disputes about the legal status of these waterways.

Creek and Toppenish Creek MSAs but WDFW's SalmonScape online mapping system does not include the Mill Creek MiSA in its spawning or rearing databases. Resident *O. mykiss* were recently found in a perennial upper reach of Mill Creek (T. Resseguie, YN, communication, 2007), indicating that steelhead have used the intermittent Toppenish Creek tributary. Conversely, steelhead are shown to be present in Medicine Creek, a channel tributary to Simcoe Creek, in SalmonScape, but the ICTRT does not designate Medicine Creek as a spawning area. Medicine Creek is an abandoned distributary channel of Simcoe Creek that carried irrigation returns prior to 2003 (B. Rogers, YN, communication, 2007).

Steelhead spawning has also been documented in Marion and Harrah drains, which join near the confluence of Toppenish and Simcoe creeks. Marion Drain then flows east and enters the Yakima River 3 km upstream of Toppenish Creek (B. Rogers, YN, communication, 2007). Both drains were excavated in the 1920s to carry return flows from the Wapato Irrigation Project to the Yakima River.

2.3.3 Naches Population

The ICTRT has identified eight major historical MSAs and two MiSAs associated with the Naches River steelhead population (Figure 2.6). Seven of the MSAs are in the Naches River drainage. The remaining MSA, Ahtanum Creek, is a major tributary to the Yakima River mainstem, entering just downstream of the Naches River confluence. Impassable storage dams block the upper portions of the Tieton and Bumping watersheds. Their MSA sizes are based on modeled historic (pre-dam) habitat area. The MSA identified by the ICTRT as "Upper Naches" is actually the Little Naches River and its tributaries. The two MiSAs are small tributaries to the Yakima River between the Naches River and Ahtanum Creek. Wide Hollow Creek begins in the dry foothills west of Yakima and becomes perennial upon reaching the irrigated agricultural area surrounding Yakima. Before irrigation development, springs may have kept lower reaches of the creek perennial. Because of significant groundwater inputs, Wide Hollow Creek has received some passage and habitat funding during the past 20 years. Moxee Drain is an excavated channel draining the Roza and Selah-Moxee irrigation districts east of Yakima and receives ephemeral runoff from the arid upper Moxee Valley. Monk (2001), along with Romey and Cramer (2001), concluded that Moxee Drain was not suitable for spawning or rearing salmonids. The lower reach of Moxee drain in the Yakima River floodplain has perennial flows and provides suitable juvenile habitat. Steelhead spawning is known to occur in all eight MSAs. WDFW's SalmonScape online mapping system also includes Wide Hollow Creek and the lower end of Moxee Drain in its "documented presence" database.

2.3.4 Upper Yakima Population

The ICTRT has identified fourteen major historical MSAs and two MiSAs associated with the Upper Yakima River steelhead population (Figure 2.6). Of these, the ICTRT identifies seven as currently occupied (in both upper and lower portions) and another four

as occupied in their lower extent only (See Figure 2.6).[17] Impassable storage dams block the Cle Elum and Kachess rivers and the uppermost reach of the Yakima River. The Upper Yakima and Cle Elum MSA sizes are based on modeled historic (pre-dam) habitat area. The lower Teanaway River is designated a MiSA, probably because of the ICTRT model's branching algorithm that separated the North and West Teanaway MSAs from this lower section. The Roza Creek MiSA includes Burbank Creek which is on the other side of the Yakima River; Roza and Burbank creeks drain small, semi-arid watersheds.

2.4 Steelhead Abundance

2.4.1 Estimates of Historic Abundance

Published estimates of the size of the annual return of adult steelhead to the Yakima Basin prior to European settlement range from 20,800 (Kreeger and McNeil 1993) to "less than 50,000" (Cramer et al. 2003) to 80,000 (Howell et al. 1985) to 100,000 (Smoker 1956, as cited in WDF(1993, Appendix 3); although Cramer et al. (2003) note this is a misinterpretation of Smoker's assessment).

Table 2.3 shows estimates of "historic" abundance of anadromous spawners identified by EDT model runs conducted in development of the Yakima Subbasin Plan (see Appendix B). This estimate is based on historic conditions in the Yakima Basin coupled with current Columbia River and ocean conditions, and is not equivalent to a true historic scenario; it also does not fully address the interactions between resident and anadromous *O. mykiss* presumed to occur in the Upper Yakima and parts of the Naches basin. The population boundaries referenced here are similar, but not identical, to the updated ICTRT population designations used in this plan.

Table 2.3: EDT estimates of "historic" abundance

Population	EDT Abundance
Satus	5,761
Toppenish	4,639
Naches	14,542
Upper Yakima	21,152
TOTAL	46,094

The ICTRT used the Historic Intrinsic Potential analysis described in Section 2.4 to classify populations according to relative historic size, with Toppenish classified as a Basic population, Satus Creek as an Intermediate, and the Naches and Upper Yakima as Large populations (ICTRT In press). Table 2.4 goes a step further and uses the results of the Intrinsic Potential Analysis to extrapolate historic spawner abundance based on two calculations.

[17] See Section 4.2.3 for the ICTRT definition of "occupancy."

Table 2.4: Historic abundance estimates derived from Intrinsic Potential Analysis

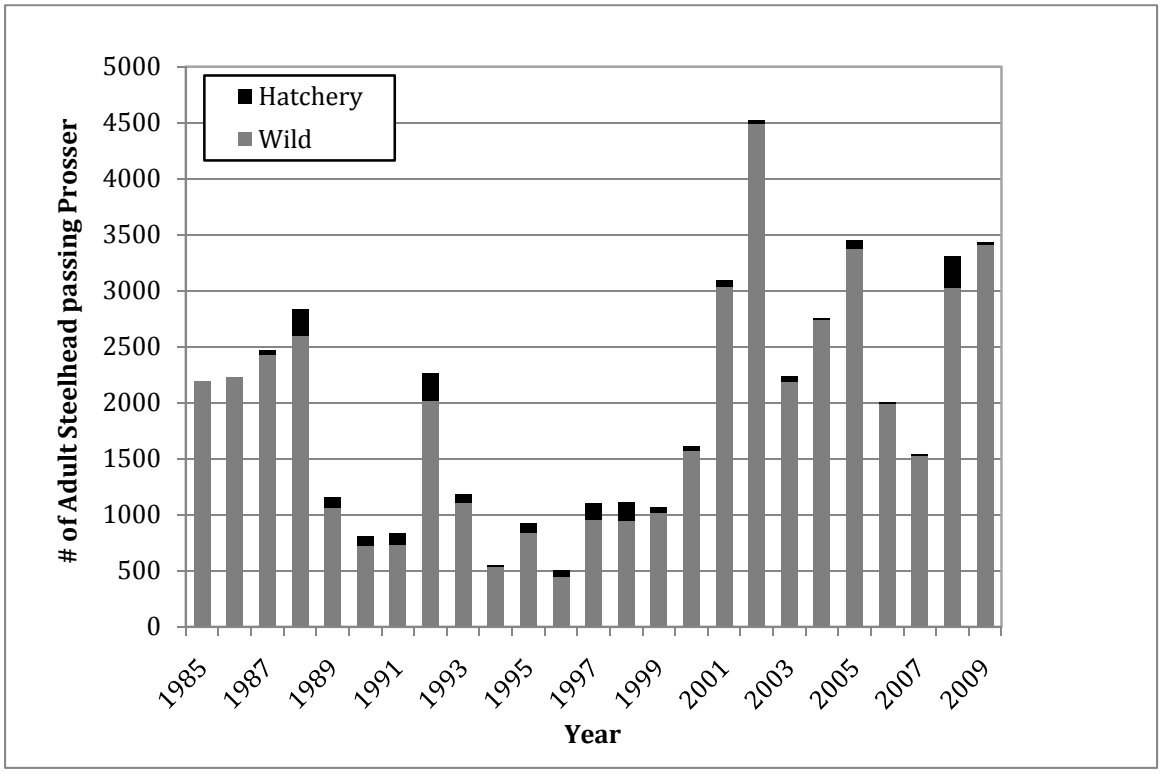
		Spawner Abundance	
Population	**Locally Adjusted ICTRT Weighted & Branched Area in km2**	**at 2000/km2**	**at 0.1 smolt/m2 and 4% SAR**
Satus	1.06	2,120	4,240
Toppenish	1.120	2,240	4,480
Naches	4.661	9,322	18,644
Upper Yakima	6.851	13,702	27,404
Total	**13.692**	**27,384**	**54,768**

The first calculation is based on densities of spawning adults and multiples the estimated branched and weighted habitat area (see Figure 2.4 and Table 2.2) by an estimate of spawners per unit area. The value of 2000 spawners per km^2 is equivalent to 500 spawners per 250,000 m^2, which is the potential density of spawners used by the ICTRT to designate Major Spawning Areas based on branched habitat area (Cooney and Holzer 2006). This corresponds to 20 spawners in a hypothetical high quality stream reach 1 km long and 10m wide, or, using conversions of 1.75 spawners/redd and 1.609 km/mile, 18 redds per mile. This compares to rates of 5-10 redds per mile observed in portions of Satus Creek after an average or better steelhead run and up to 30 to 100 spawners per mile in some other areas (Rock Creek in Klickitat County at 34 to 45 redds per mile (NPPC 2004) and a range of 33 to 109 on the Middle Rogue River (ODFW 2005, p. 325). At the 2000/km^2 rate, the basin would produce about 31,000 spawners. Using 540 spawners/km^2 (which converts as above to about five redds/mile) results in approximately 8,400 fish. The second calculation is based on smolt production per unit area set at 0.1/m^2 and a smolt to adult survival rate of 4% (versus 2% generally assumed under current conditions) and results in ~62,000 spawners. Neither calculation models the impacts of resident/anadromous interactions on anadromous abundance. Note that when run with a smolt density of 0.01 smolts/m^2 and a SAR of 2% and limited to currently utilized habitat (both estimates based on empirical data from the Yakima Basin under current conditions), this simple model gives estimated abundances in line with current abundances. This admittedly simple model may serve as a useful thought tool with results that correspond with other estimates of historic abundance; its results should not be treated as definitive.

While precise estimates of historic abundance are impossible to generate, it seems reasonable to conclude that historic spawners abundances were between 25,000 and 75,000 per year. Major areas of uncertainty that affect our estimates of historic spawner abundance include:

- The extent of historic use by steelhead of the mainstem Yakima and its side channels
- The outcomes of interactions between steelhead and other salmonid species also estimated to be far more numerous under pre-European conditions, including positive relationships (enhanced supply of nutrients in headwaters) and negative relationships (increased interspecific competition)
- The nature of interaction between resident and anadromous *O. mykiss*
- The range of year-to-year variability in run size under pre-European conditions

2.4.2 Current Abundance and Productivity



Overall Abundance in the Yakima Basin

Returning adult steelhead are counted and classified as wild or hatchery as they pass the fish ladders at Prosser Dam downstream from all major spawning areas.[18] Since records began in 1985, estimated returns have ranged from a low of 450 in 1996 to a high of 4,491 in 2002, with an average of 1,764. The run is dominated by wild fish, with a hatchery component of 8% over the period of record and 3% between 1999 and 2007.

Figure 2.7 gives an indication of the variability of recent steelhead returns. At the time of listing (1999), the 10-year average abundance for wild steelhead was 933, the majority of which was being produced in a single tributary drainage (Satus Creek). Since then abundance has increased, with the current 10-year average at 2,269. Upstream dam, redd, and smolt trap counts have also revealed a somewhat wider distribution of steelhead in the Yakima Basin than was recognized in 1999. However, even the more recent estimates of steelhead abundance are at least an order of magnitude less than even the low to middle range of estimates of historic abundance.

[18] Very limited spawning has been observed in the Yakima River and its tributaries below Prosser, but whether or not offspring survive is unknown.

Figure 2.7: Yakima Basin steelhead abundance

Abundance by Population

While the Prosser Dam counts provide excellent abundance estimates for the Yakima Basin MPG as a whole, determining the abundance of each of the four component populations is more challenging. The ICTRT's current approach apportions the total Prosser count based on a combination of 1990-92 radio-tracking data (Hockersmith et al. 1995), redd counts from Satus and Toppenish creeks and counts at the Roza Dam fish ladder. Table 2.5 summarizes available data from Yakima/Klickitat Fisheries Project dam counts, Yakama Nation Fisheries redd counts for Satus, Toppenish, and Ahtanum watersheds, and USFS/WDFW led redd counts for selected Naches tributaries.

* No survey; ** Partial survey; *** Survey affected by poor redd visibility; (#) Interpolation used by ICTRT
Dam count data from www.ykfp.org; redd data from Yakama Nation staff except for USFS data for Naches data from USFS.

Given that we do not have direct counts for all populations, the best existing population-specific abundance estimates are from the ICTRT stock status reviews (ICTRT In press) and are summarized in Table 2.6; Table 2.7 shows how Prosser counts were apportioned to derive these estimates. The ICTRT adjusted aggregate annual Prosser counts to account for estimated losses between Prosser Dam and tributary spawning by applying 11% average loss rates from the 1990 to 1991 radio-tracking studies (losses directly associated with tagging were excluded). Prior to 1995, an additional 2% of the returns passing Prosser were attributed to harvest (directed harvest was closed after 1994). Population-specific abundance estimates for return years 1985-1989 were generated by applying the average distribution from the 1990 to 1992 radio tagging studies to the Prosser Dam count adjusted for pre-spawning mortality (Table 2.13). For those return years where radio tag-based distribution estimates were available (1990-92), the aggregate count over Prosser Dam was allocated among populations based on the relative distribution of radio tagged steelhead during the spring spawning time window.

For each of the return years, 1993-2004, an estimate of the aggregate number of spawners in Satus and Toppenish creeks was generated by subtracting the Roza Dam count and the

Naches River abundance estimates from the Prosser count adjusted for prespawning losses. The resulting composite estimate was allocated to Satus Creek and Toppenish Creek based on the annual ratios of expanded redd counts for the two populations. Redd counts provide the only current index to adult abundance, and redd counting conditions are more favorable in these two watersheds than in the upper basin. Redd counts in the Naches River and its higher-elevation tributaries are not a reliable index of spawner abundance, and the lower Naches River lacks an impassable dam and counting facility similar to Roza Dam in the Yakima River above the Naches confluence. This leaves managers with 15-year-old radio-tracking data for allocating Prosser adults, after subtracting upper Yakima River returns, to the Naches River and a Satus-Toppenish composite. Genetic sampling of adults at Prosser and/or new radio-tracking studies would greatly improve population specific abundance and productivity estimates.

For run years 1993-2004, Roza Dam counts were incorporated into abundance estimates for the Upper Yakima population. During the Hockersmith study, some radio tagged steelhead were tracked to the mainstem Yakima River below Roza Dam but above the confluence with the Naches River. To account for possible spawning below Roza Dam, the year-specific counts at Roza Dam were averaged with corresponding estimates based on the 1990-92 radio telemetry proportion returning to the Upper Yakima.

Hatchery releases of steelhead into the Yakima system ceased after 1993 (Fast and Berg 2001); the proportion of returning spawners at Prosser Dam that are of natural origin has averaged 94% since 1985 (99% for the most recent five years). The ICTRT assumed that hatchery strays were not disproportionately present in any specific populations.

Table 2.6: Natural-origin spawner abundance by population, 1995-2004

Population	Low (year)	High (year)	1995 to 2004 Geomean

Prosser # = Prosser wild plus Prosser Hatchery from Table 2.5
Presumed 11% mortality from Prosser to spawning from Hockersmith plus 2% in-basin harvest prior to 1994
1990 to 1992 run approtionment done using Hockersmith data for those years;
1985 to 1989 done using average run portion data from the Hockersmith study;
1993 on:
Hockersmith average used for Naches (36%)
Avg of Hockersmith average & annual proportion of Roza to Prosser count used for Upper Yakima;
Remainder of Prosser count attributed to Satus and Toppenish; divided between the two based on the relative redd numbers (gaps in redd data interpolated linearly)

Productivity by Population

The ICTRT used the adult age structure from the 1990-92 radio tagging study to calculate returns per spawner. To estimate intrinsic productivity (the rate at which the population rebuilds when depressed to low numbers), the ICTRT calculated geometric means of spawner/return ratios for those data pairs where parent spawner abundance was less than 75% of the abundance target for the population. This approach is designed to minimize density dependant effects that may influence the average productivity value. The ICTRT then applied a further adjustment to compensate for annual basinwide fluctuations in marine survival. Table 2.8 shows the results.

Table 2.8: Spawner/return ratios for the brood years 1985-1999

Population	Low (year)	High (year)	15-yr Adjusted*
Satus	0.19 (1992)	2.36 (1996)	1.40
Toppenish	0.30 (1985)	14.48 (1996)	1.60
Naches	0.37 (1986)	5.03 (1996)	1.12
Upper Yakima	0.35 (1988)	4.87 (1997)	1.12

*Median delimited and adjusted based on marine survival, as per text and ICTRT (2007b)

2.5 Population Characteristics and Life Histories

2.5.1 Adult Upstream Migration

Timing of Upstream Migration

All Yakima Basin steelhead are classified as summer steelhead based on the timing of their return from the ocean to the Columbia River. Table 2.9 shows the seasonal progression of upstream migrants from Bonneville into the Yakima. Adult steelhead that were tagged with passive integrated transponders (PIT tags) in Satus, Toppenish, and Ahtanum creeks as juveniles have migrated upstream past Bonneville Dam from May through October, with 90% passing Bonneville in July (62%) and August (28%). About a third of the run then moves relatively rapidly up the Columbia past McNary in July (19%) and Aug (9%). The majority of the run holds in the Columbia between Bonneville and McNary into the fall, with Yakima steelhead presumably forming part of the large concentrations of steelhead found holding in the cool waters at the mouths of tributaries such as the White Salmon and Klickitat rivers. In September and October, 64% of the run continues past McNary, while in November and December the last 8% passes. Timing of movements through the Columbia may differ for steelhead from other parts of the Yakima Basin. Assessing this requires additional PIT-tag data from the Naches and Upper Yakima populations.

Table 2.9: Timing of dam passage by adult steelheads

	Bonneville	McNary	Prosser	Roza
	n=58	n=47	n=19332	n=1088
June	3%	0%	0%	0%
July	62%	19%	0%	0%

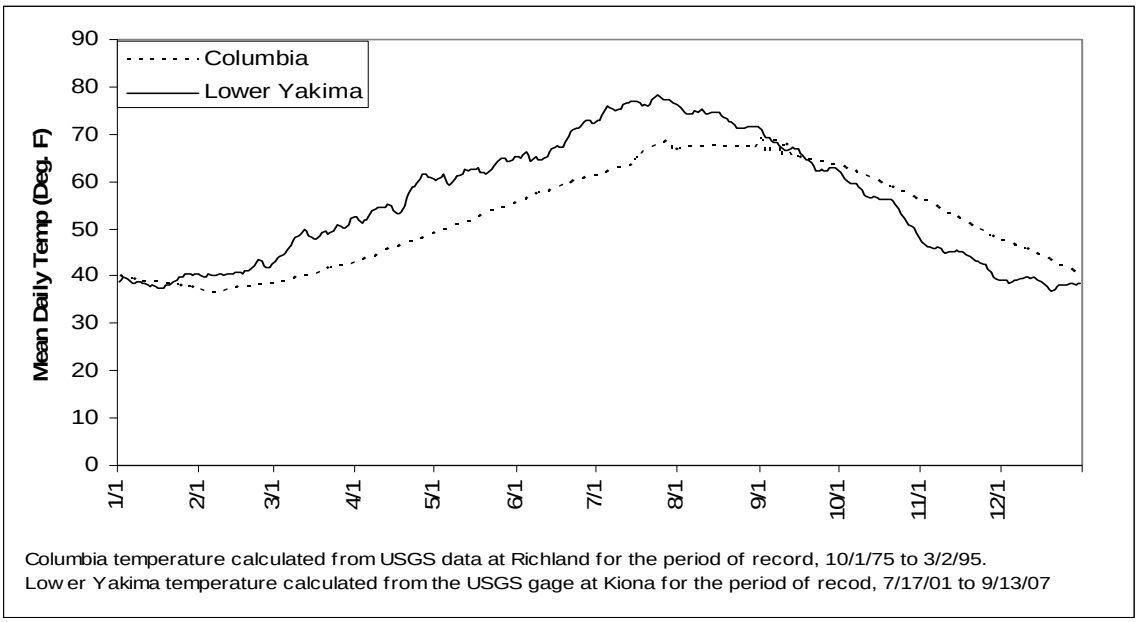
Bonneville & McNary data from PIT-tagged adults tagged as juveniles in Satus, Toppenish, and Ahtanum creeks, 2004 to 2006				
Prosser and Roza data from dam counts of adults, 2000 to 2006				



Most (63% of dam counts from 2000 to 2006) of the run continues from McNary relatively rapidly past Prosser in September, October and November. However about one third of the run holds between McNary and Prosser until December through April before passing Prosser. These fish may be using habitat in both the McNary Pool of the Columbia (where temperatures are lower through the summer) and the lower Yakima River, which cools off faster than the McNary Pool after September 1 (Figure 2.8). Where and how fish use the McNary Pool and the Lower Yakima and how that is affected by habitat conditions is noted as a key knowledge gap in Chapter 7.

While limited numbers of PIT tags make any conclusions preliminary, existing data suggest that a significant percentage of Yakima-origin steelhead overshoot the mouth of the Yakima and continue up the Columbia, with some ascending as many as four more dams on the Columbia before turning downstream to return to the Yakima. The main source of evidence is from adult steelhead tagged in the trap at Priest Rapids dam. Of the 3,890 adult steelhead tagged there between 7/12/06 and 10/16/08, 72 were subsequently detected at Prosser, with no returns from Prosser to the Upper Columbia noted so far. Of the 72 tagged steelhead, 2 were also detected at Ice Harbor after release from Priest Rapids: 1 before detection at Prosser and 1 after detection at Prosser. There were 6 Priest Rapids-tagged adults that reached Wells Dam before falling back and ascending Prosser Dam. One of them later ascended Roza Dam.

Returns of adult steelhead PIT tagged as juveniles in the Yakima Basin also indicate some Yakima steelhead pass the Yakima to ascend farther up the Columbia. Fifty-one adult steelhead tagged as juveniles in the 2006-07 outmigration and earlier were detected ascending Prosser ladders from 5/28/05 through the 2008-9 adult migration. The nine adults that were tagged as juveniles in the Yakima Basin during the 2006-07 outmigration

have been detected as adults at Priest Rapids Dam as of October 2008. Of these nine Priest Rapids detections of Yakima steelhead, four returned to Prosser. The need to better understand the rates of overshot by returning adults, its causes, and the implications for survival and condition of returning spawners is highlighted as a key uncertainty in Section 7.2.5.

Figure 2.8: Lower Yakima River and McNary Pool temperatures

While at least some adult steelhead movement into the Yakima Basin and past Prosser Dam has been documented in every month of the year, the main migration past Prosser Dam occurs from September through April. Passage from the McNary Pool and/or Lower Yakima River past Prosser Dam appears to be driven by flow and temperature cues, with fish generally moving rapidly following increased flow and moderating water temperatures.

In the two years between 1999 and 2007 when spring high flows (>2000 cfs) and lower river temperatures (< 68 ºF at Kiona) continued into July, a portion of the run passed Prosser in July (28 in 1999 and 10 in 2002). In the only other year (2004) where mean daily temperatures in July were below 68ºF at Kiona, flows remained lower (<1000 cfs) and no steelhead passed Prosser.[19] Prior to regulation of flows in the Yakima and Columbia rivers, the high flows and lower temperatures of spring runoff would have prevailed longer into the summer. It is likely that historically, some portion of the steelhead run would have traveled rapidly from the ocean into the Yakima system during the summer, but that high temperatures in the Columbia and lower Yakima rivers now limit that run timing.

[19] Analyses based on passage data accessed via DART http://www.cbr.washington.edu/dart/dart.html; Prosser flow and temperature data at http://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html.

In those years when more than two steelhead passed Prosser in August (2000, 2003, 2004 and 2007), there appears to be a significant correlation between fish movements and periods when flows increase and temperatures drop below 70ºF. The typical September beginning of the upstream run past Prosser occurs when river temperatures at Kiona consistently drop below 70ºF (in 2001, when low flows and high temperatures persisted through most of September, steelhead movement past Prosser began in late September). Throughout the fall and winter run, fish tend to move in response to increased flows, though low water temperatures can limit the influence of a midwinter flow increase, and a midwinter rise in temperature can stimulate movement even when flow remains relatively constant.

Most steelhead that pass Prosser in the fall overwinter in the Yakima River between Prosser and Sunnyside dams in reaches with deep pools and low velocity (Hockersmith et al. 1995). The final migration from holding areas to the spawning grounds begins between January and May, with fish that will spawn in lower elevation tributaries generally beginning to move earlier. Eighty-eight % of steelhead passage past Roza into the Upper Yakima occurs in March, April and May with the remaining 12% scattered from September through February. Radio tracking in 2002 through 2004 found that upstream movements above Roza towards spawning areas peaked in mid-March, but could occur anytime between November and late June (Karp et al. 2003; Karp et al. 2005).

Currently the range of run timings for specific populations cannot be accurately determined; all information presented here (except for Roza passage) is for the Yakima MPG as a whole. Developing the ability to identify steelhead to population at Prosser and increasing the number of PIT tags for the Naches and Upper Yakima populations would facilitate determining if there are significant differences in run timing between the four populations.

Age and Sex Distribution of Upstream Migrants

From 2000 to 2006, an average of 75% of the returning adult steelhead handled at the Prosser Denil and Roza Trap were females, as shown in Table 2.10 over the three years of the Hockersmith study (1990-92), radio-tagged fish were 73%, 78%, and 64% female (Hockersmith et al. 1995). Currently the only population-specific sex ratio that can be determined is for the Upper Yakima Population, which is slightly higher than the aggregate rate. With improvements to our ability to assign fish to population at Prosser, we will be able to determine if sex ratios are similar across all four populations and their subpopulations, or if they differ (perhaps based on degree of overlap with resident fish).

Table 2.10: Sex ratios of returning steelhead

		Prosser				Roza	
	Total	Female	%		Total	Female	%
2001-2	472	329	70%		210	153	73%
2002-3	169	143	85%		126	110	87%
2003-4	575	389	68%		207	154	74%
2004-5	985	629	64%		201	167	83%
Totals	2201	1490	68%		744	584	78%

Yakima Basin steelhead cover a wide range of combinations of freshwater and ocean ages with residence in freshwater ages ranging from one to four years followed by one to three years of saltwater residence (the saltwater age does not include the winter spent by adults in freshwater prior to spawning).

Table 2.11 shows the combinations of fresh and saltwater ages determined through scale analysis of steelhead handled in the Prosser Denil for the 2002-3 to 2004-5 return years (this sample is representative of steelhead passing Prosser in September to December, but does not include fish passing after December).[20] The bulk of the run consists of age 2.1 and 2.2 fish (with a combined total of between 63% and 80% all years). The age structure of the run can vary significantly from year to year, as indicated by the range separating minimum and maximum percentages for each age class. On average, males return at younger freshwater and ocean ages (1.1 fish make up 15% of males, versus 8% of females, and for fish of freshwater age two, males return proportionally more often as one ocean fish). Based on summary tables in Hockersmith et al. (1995), there is also a weak inverse correlation between freshwater age and saltwater age for the sample as a whole (i.e., younger smolts returned at slightly older average ocean age).

Table 2.11: Prosser Denil age structures, 2002-3 to 2004-5 return years

Ages from scale analysis; n = 1729

Age	Min %	Max %	Total %	% Males	% Females
1.1	1.2%	25.5%	9.4%	14.6%	7.8%
1.2	0.5%	11.2%	4.4%	3.7%	5.0%
2.1	36.7%	77.0%	53.3%	64.0%	51.9%
2.2	3.1%	28.4%	16.8%	8.7%	21.2%
2.3	0.0%	0.2%	0.1%	0.2%	0.1%
3.1	1.2%	15.5%	7.5%	7.5%	7.9%
3.2	0.2%	3.0%	1.5%	0.4%	2.1%
4.1	0.0%	1.2%	0.5%	0.1%	0.6%
Rs	2.3%	17.2%	6.5%	0.8%	3.4%

[20] Ages are given as (# of freshwater winters) and (# of saltwater winters), so a 2.3 age fish would have had two winters in freshwater as a juvenile followed by three winters at sea. Rs = repeat spawner.

Age distribution appeared to differ somewhat among populations. Table 2.12 shows the age distribution of the steelhead sampled at Roza Dam, which comprise most of the Upper Yakima population for the 2002-3 to 2004-5 returns. When compared to the aggregate run at Prosser, Upper Yakima fish are weighted towards older fish freshwater and ocean ages: one freshwater fish represent 4% of returns vs. 14% for the aggregate sample, while two ocean fish represent 52% of the Roza return vs. only 23% at Prosser.

Table 2.12: Roza Dam age structures, 2002-3 to 2004-5 return years

Ages from scale analysis; n = 534

Age	Min %	Max %	Total %	% of males	% of females
1.1	0.0%	3.3%	1.1%	2.3%	0.8%

4.1	0.0%	0.5%	0.1%	0.0%	0.1%
4.2	0.0%	0.8%	0.3%	0.0%	0.4%
Rs	2.0%	7.1%	4.2%	1.6%	4.9%

In contrast, data on the 70 of the 99 known-age adults that were tracked to spawning locations in the Hockersmith (1995) radio-tracking study (Table 2.13) found that known-age Satus spawners had younger freshwater ages than the other three groups and younger saltwater ages than the Naches and Toppenish groups.

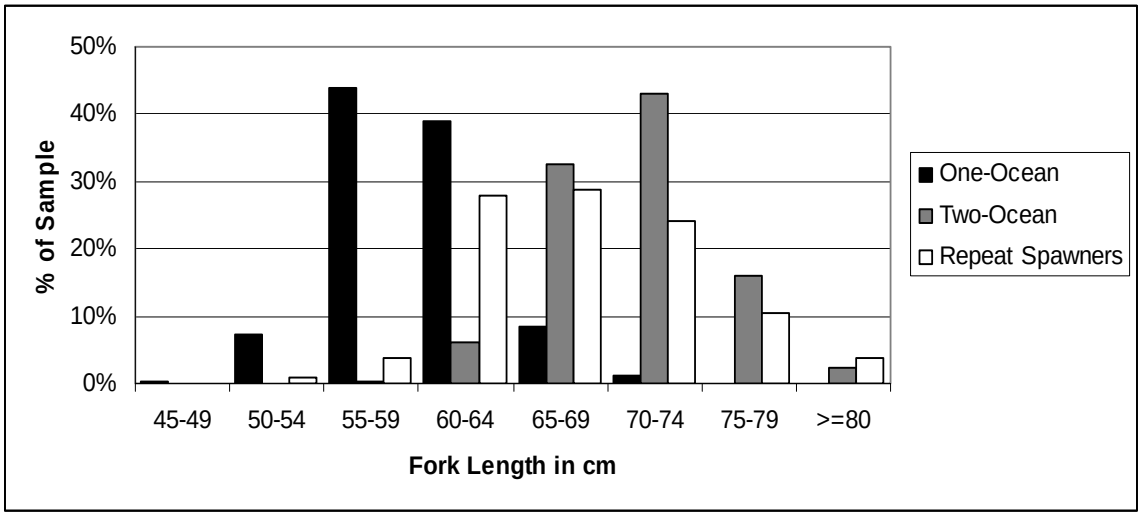

Table 2.13: Spawning locations of known-age steelhead by population, 1990-92

Total Age	Satus Spawners		Naches Spawners		Toppenish Spawners		Yakima Spawners		Total Aged Fish	
	No.	%	No.	%	No.	%	No.	%	No.	%

Size of Returning Adults

Fork lengths of returning steelhead measured at the Prosser Denil and Roza Trap from 2001 to 2006 ranged from 49 cm to 88 cm. Length is associated with ocean age, with an average of 60 cm for fish that have passed one winter at sea, 71 cm for fish that have passed two winters at sea, and 68 cm for repeat spawners. Figure 2.9 shows the distribution of spawners by ocean age.

Figure 2.9: Size class by ocean age

Survival Rates of Upstream Migrants

The only Yakima-population specific data on survival during the upstream migration comes from a very limited number of PIT tag detections.[21] For the period spanning the 2003-04 to 2006-07 return years, 60 of 75 Yakima-origin PIT-tagged adult steelhead (80%) that were detected moving upstream past Bonneville were subsequently detected at McNary Dam. Three of those 60 strayed to the Snake or Upper Columbia, for a total of 57 of the 75 (76%) known to have survived from Bonneville to above McNary and presumed to have entered the Yakima River.

PIT tag detectors have been in place on all three fish ladders at Prosser Dam since August 30, 2005. Of the 16 Yakima-origin adults detected at McNary between August 2005 and June 2007, 13 (81%) were detected at Prosser and 1 at Priest Rapids (6%). Two (12%) were not detected again above McNary.

According to this very preliminary analysis, 80% of tagged fish passing Bonneville are known to have survived to above McNary and 20% died, strayed into other tributaries between Bonneville and McNary, or passed upstream or back downstream undetected. Of those PIT-tagged Yakima origin fish passing McNary, 81% passed Prosser into the Yakima Basin, 6% are known to have strayed into upstream areas, and 12% died, strayed into other tributaries to the McNary Pool, passed upstream undetected, or entered the Lower Yakima River but did not pass Prosser. Multiplying the 80% confirmed passage from Bonneville to McNary by the 81% confirmed passage from McNary to Prosser gives an estimated rate of confirmed passage from Bonneville to Prosser of 65%.

A portion of the losses is attributable to harvest in tribal fisheries and incidental mortality in recreational fisheries in the Columbia River above Bonneville. NOAA Fisheries estimates that overall harvest rates of Middle Columbia steelhead in tribal fisheries average of 4.8% of the run (NMFS 2008, Sec. 6.3.7). Detection failure may account for

[21] Analysis based on data from the DART database http://www.cbr.washington.edu/dart/dart.html

some, but not all, of the remaining loss between Bonneville and McNary. Of 57 fish detected at McNary in all return years, 4 had not been detected at Bonneville, a 7% detection failure. However, all of the 19 adults detected at Prosser since the first ladder went on line had been detected at McNary, indicating that detection rates at McNary are high.

These preliminary survival estimates differ significantly from the estimate of 90% survival from Bonneville to tributaries commonly used. While the analysis presented here relies on a small and short-term dataset and should be considered preliminary at best, the results highlight the need for empirical population-specific estimates of survival rates for the upstream migration of both specific populations and the Middle Columbia River Steelhead DPS as a whole.

Our only estimates of pre-spawning mortality of returning adults within the Yakima Basin come from radio-tracking studies. Of the 194 fish tracked by Hockersmith, 3.6% were confirmed to have died during migration and winter holding, 4% were harvested, and 9% were lost due to either harvest or failed transmitters prior to spawning (Hockersmith et al. 1995). Karp notes that 5 of 93 fish (5%) tagged at Roza in 2002-3 were lost to anglers and 7 of 105 fish (7%) tagged at Roza in 2003-4 were presumed lost to anglers or otters (Karp et al. 2003; Karp et al. 2005). Yakama Nation redd survey teams have also observed otter kills on Satus Creek. These studies support manager's estimates of approximately 10% mortality between passage at Prosser and spawning.

2.5.2 Spawning

Distribution of Spawning

Steelhead spawn across a broad seasonal and geographic range in the Yakima Basin, although based on intrinsic potential analysis and on planners' professional judgments, the current spatial distribution is significantly decreased from historic conditions. Spawning locations include intermittent streams, mainstems, and side-channels of larger rivers, and perennial streams up to relatively steep gradients (Hockersmith et al. 1995; Pearsons et al. 1996). Most Yakima steelhead are tributary spawners, although the distribution of redds throughout the basin is highly variable from year to year and significant amounts of mainstem spawning are known to occur.

Table 2.14 shows spawning locations identified in the Hockersmith radio-tracking study in the early 1990s. At that time 10 spawning areas (Satus Creek, Toppenish Creek, Marion Drain, Naches River, the mainstem Yakima River below Roza Dam, the mainstem Yakima River in the Roza Canyon, Taneum Creek, Swauk Creek, the upper Yakima River [above Ellensburg], and the Teanaway River) were identified.

Table 2.14: Known spawning locations from 1990 to 1992 radio tracking

Location			Number	Percent
Satus Creek				
	Satus Creek		30	28%
	Logy Creek		8	7%
	Dry Creek		11	10%

	Toppenish Mainstem		12	11%
		Total	*14*	13%
Naches				
	Naches Mainstem		29	27%
	Little Naches		1	1%
	Bumping River		3	3%
	Rattlesnake Creek		1	1%
	Mainstem Yakima		5	5%
		Total	*39*	36%
Upper Yakima				
	Mainstem in Roza Canyon		3	3%
	Teanaway		2	2%
	Upper Yakima Mainstem		1	1%
		Total	*6*	6%
		TOTAL	109	100%

Population-specific spawning location information comes from a variety of sources. For the Satus Creek watershed, the Yakama Nation has surveyed accessible reaches since 1988. No surveys of mainstem spawning outside of the Satus Creek drainage have been conducted; there are anecdotal accounts of limited spawning in mainstem and lower

sections of Spring and Corral creeks and Amon Wasteway.[22] For the Toppenish Creek Population, redd counts initiated in 1989 by the Yakama Nation give a detailed picture of spawning distribution.

For the Naches Population, the Yakama Nation has conducted redd surveys in Ahtanum Creek since 2000. Since 2004, the USFS, WDFW, USFWS, the Yakama Nation, and others have worked together to survey portions of the Naches drainage (Table 2.15). This information has greatly improved our understanding of spawning distribution in the Naches basin, but inconsistent survey conditions due to high flows and poor visibilities (especially in 2006) limit their use in estimating abundance. No surveys have been conducted in the lower mainstem of the Naches and the associated reaches of the mainstem Yakima. Figure 2.5 shows surveyed redd locations for recent years.

Table 2.15: Naches redd survey results

	2004	2005	2006*	2007	2008	2009

Total	**94**	**138**	**19**	**44**	**11**	**29**

*Poor survey conditions

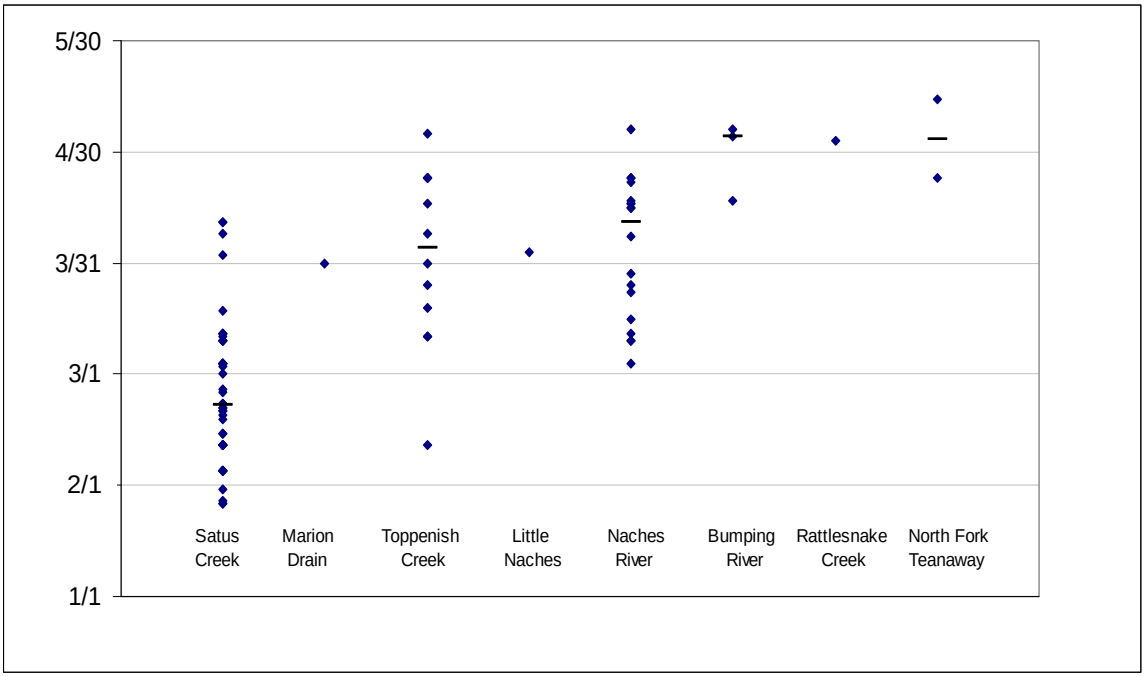
Our primary source of information on spawning locations for the Upper Yakima population comes from 2002 to 2006 radio-tracking surveys (Karp et al. 2003; Karp et al. 2005; Karp et al. 2009). Spawning locations are given in Table 2.16. The high proportion of mainstem spawners (87 of 183 spawners, or 48% for 2002-2004) is striking. The Teanaway system and Swauk Creek are the most consistently used tributary spawning areas.

[22] Spring, Corral, and Snipes creeks and Amon Wasteway are referred to by the names used on the USGS 7.5 minute topographic maps. The first three are referred to as drainageways by local irrigation districts, while Amon Wasteway is often referred to as Amon Creek. The use of these names in this document is in no way meant to indicate any conclusions regarding ongoing disputes about the legal status of these waterways.

Table 2.16: Presumed spawning locations of steelhead tracked by Karp et al. (2009)

Location of Presumed Spawning	Number of Radio-tagged Steelhead
Mainstem Yakima River[1]	133 (37.7%)
Teanaway River	137 (38.8%)
Swauk Creek	46 (13.0%)
Taneum Creek	17 (4.8%)
Cle Elum River	12 (3.4%)
Lower Naches River, Umtanum, Cherry, Naneum, and Wilson creeks	8 (2.3%)
Total tributary	220 (62.3%)
Total	353

Timing of Spawning



Based on radio tagging and redd surveys, most spawning is completed between late January and mid-May. Figure 2.10 shows spawning dates by tributary for the 86 steelhead tracked to spawning in 1990-1992 (Hockersmith et al. 1995). In Satus Creek and its tributaries, the median spawning date was more than a month earlier than in any of the other tributaries, with spawning beginning in late January and predominantly occurring in February and March. In Toppenish Creek and the Naches spawning occurred mostly in March and April, while spawning in higher elevation tributaries occurred in late April and May.

Fecundity

Yakima steelhead have a relatively high fecundity in spite of their small size. Broodstock collected for species interaction experiments in brood years from 1986 to 1993 carried an average of 5,100 eggs (Fast and Berg 2001).[23]

[23] A length/fecundity relationship of # eggs = 189.28 x Fork Length in cm—6449 was calculated based on data from broodstock collected from the 1988-89 return (Chris Fredrickson, Yakama Nation, personal communication).

Figure 2.10: Individual and median dates for spawning initiation 1990-1992

2.5.3 Role of Kelts

Steelhead can return to the ocean after spawning and return to spawn again. During their return to the ocean they are called kelts. In spawning areas near the ocean, rates of repeat spawning can be as high as 79%. Natural rates of repeat spawning for Interior Columbia steelhead populations are unknown. Recent rates range include 17% for the Kalama River, 4.6% for the Hood River, 2-9% in the Walla Walla, and 1.5% in the Upper Columbia River (Branstetter et al. 2005). Natural repeat spawning by Yakima Basin steelhead is extremely limited; scale analysis in 1990-1992 indicated that 1.6% of returning adults were repeat spawners in the 1990-1992 brood years (Hockersmith et al. 1995). It is hypothesized that the development of the mainstem Columbia hydropower system and the associated passage impediments, reduced spring flows, and increased temperatures have reduced kelt survival rates.

Kelts typically migrate downstream from spawning areas in March through June. Kelts have been observed at the Chandler Juvenile Enumeration Facility (RM 47.1) into the middle of July, but water temperature approaches lethal levels by that time even in normal water years. Temperatures do not return to safe levels until early autumn (Fast and Berg 2001). Out-migration of kelts from the upper basin may be especially hazardous because later spawning dates combine with increased travel distance as the Yakima and Columbia rivers warm and their flow declines.

To increase the contribution of repeat spawners to steelhead productivity in the basin, the Yakima-Klickitat Fisheries Project initiated kelt reconditioning experiments in 2000 with funding from BPA. Post-spawning steelhead are captured as they pass through the Chandler Juvenile Facility at Prosser Dam on their downstream migration. From 2000 to 2006, between 15 and 37% of the upstream adult count were captured (the remaining fish

either pass over Prosser Dam or it ladders without entering the juvenile facility or do not migrate downstream) (Table 2.17). Over 90% of collected kelts are female.

Table 2.17: Numbers of kelts[24]

Year	Collected	% of run	In-river	No-term	Reconditioned	Short-term	Long-term	Mortalities
2000	512	37%	0	0	512	0	91	421
2001	551	19%	0	0	551	0	108	443
2002	1113	25%	0	0	899	334	140	425
2003	826	37%	0	0	690	187	298	205
2004	966	35%	0	64	779	83	216	480
2005	808	23%	67	96	541	96	65	380
2006	520	26%	53	49	348	50	85	213
2007	567	37%	53	38	465	38	221	206
2008	855	26%	88	100	600	100	266	234

Captured kelts are put into one of four groups: in-river, no-term, short-term, and long-term. In-river kelts are tagged and returned directly to the Yakima River to continue their downstream voyage. This treatment was established in 2005 to develop better estimates of current rates of natural repeat spawning (Branstetter et al. 2005). No-term kelts are tagged and immediately transported to release sites below Bonneville Dam. Short-term kelts are held and fed in the hatchery for three to five weeks prior to being released below Bonneville, while long-term kelts are held and fed for six to nine months prior to being released in the lower Yakima River prior to the next spawning season.

The program is currently the only hatchery program for Yakima steelhead stocks. It is estimated to have increased the number of spawning steelhead in the Yakima Basin by 7% (David Lind, Yakama Nation, personal communication, 2008.). The basin's most famous kelt was captured and PIT-tagged as an adult headed above Roza Dam in 2002, then recaptured in 2003 and radio tracked to spawning in Swauk Creek. She then traveled downstream to Chandler where she was reconditioned, and after release, was tracked back to the same reach of Swauk Creek (Karp et al. 2003; Karp et al. 2005). That is over 1,500 miles of in-river migration by a single fish!

Efforts to evaluate the reproductive success of reconditioned kelts began in 2004 (Branstetter et al. 2005). The effects of the kelt reconditioning program on the steelhead populations' genetic and life history diversity are unknown, but thought to be minor due to the natural origin of the fish themselves and the volitional release strategy that allows the reconditioned kelts to naturally select spawning sites. This issue is being investigated using genetic sampling and radio tracking of reconditioned adults.

2.5.4 Incubation and Emergence

Unlike other species in the *Oncorhynchus* genus, steelhead eggs incubate as temperatures increase. Hatching time varies with water temperature, region, habitat, and season (Bjornn and Reiser 1991). The timing of steelhead fry emergence in the Yakima Basin is poorly understood. Field studies indicate that 50% of steelhead trout in a redd will have

[24] Based on annual reports from BPA Project # 200001700 (Branstetter et al. 2005)

emerged when roughly 1,300 cumulative temperature units have been acquired. [25] Based on this relationship, fry emergence would occurs as follows (Yakima Subbasin Fish and Wildlife Planning Board 2005):

- Satus Creek: early May to early June
- Toppenish Creek: late May through early July
- Lower Naches and Cowiche: early June through mid-July
- Upper Naches: mid June through mid-July
- Upper Naches tributaries: late June through late July
- Middle Yakima and tributaries: early June through early July
- Mainstem in Yakima Canyon (including tributaries): early June through early July
- Upper Yakima mainstem above the Yakima Canyon: mid June through late July
- Upper Yakima tributaries: late June through early August

2.5.5 Juvenile Rearing

Juvenile steelhead spend from one to three years in fresh water before migrating to the Pacific Ocean. Juveniles use tributary and mainstem reaches throughout the Yakima Basin as rearing habitat, until they begin to smolt and leave the basin. Some juveniles leave their natal areas and may spend considerable time from fall to spring rearing in areas that may have been inhospitable in the summer.

Juvenile rearing conditions significantly affect the size and condition of outmigrating smolts. For example, Yakama Nation smolt trap data indicate that steelhead from Ahtanum Creek were substantially larger than those in Satus and Toppenish creeks in each age class in both seasons sampled. This higher growth rate may be related to lower rearing density and more favorable discharge and temperature for growth in late summer.

Data from Toppenish Creek smolt traps demonstrate the value of seasonal rearing habitat. Five juveniles that were tagged prior to March 1 in a section of Toppenish Creek not hospitable to summer rearing were recaptured an average of 85 days later only 28 km downstream, and had tripled their average weight, indicating the potential significance of lower Toppenish Creek for pre-smolt rearing, despite substrate too fine for spawning and water temperatures that preclude summer use.

Cramer et al. (2003; 2004) have used stock-recruit relationships to argue that Yakima Basin steelhead production is limited by juvenile capacity, assuming habitat capacity above Roza Dam is naturally predisposed to produce resident *O. mykiss*. (See below.)

---

[25] Cumulative temperature units are calculated by summing the daily average degrees Celsius over the number of days from spawning to emergence.

2.5.6 Resident/Anadromous Interactions

Offspring of steelhead can residualize in tributaries and never migrate to sea, thereby becoming resident rainbow trout. Conversely, progeny of resident rainbow trout can migrate to the sea and thereby become steelhead. This dynamic expression of life-history characteristic makes *O. mykiss* very challenging to understand and manage. For an overview of the current understanding of the range of interactions between resident and anadromous *O. mykiss*, see Chapter 2 of WDFW's recent draft assessment of steelhead status (Scott and Gill 2006) and NOAA Fisheries' Salmon Recovery Science Review Panel Report on the topic (Salmon Recovery Science Review Panel 2004). Generally, the anadromous form of *O. mykiss* dominates the Satus and Toppenish populations, while the resident form currently dominates the Upper Yakima. In the Naches population, both anadromous and resident forms are geographically widespread.

Steelhead/resident pairing during spawning has not been noted at any significant levels during Satus and Toppenish Creek redd surveys (Tim Resseguie, Yakama Nation Fisheries, personal communication, 2007) but has been observed repeatedly during redd surveys in the Naches drainage (Gary Torretta, USFS, personal communication, 2007). Pearsons et al. (1998) concluded that ecological and genetic evidence indicated that rainbow and steelhead trout in the upper Yakima interbreed when in sympatry, and document several cases of observed resident/steelhead matings. However during 2004 radio tracking in the Upper Yakima, no resident/anadromous pairs were observed; all 15 observed pairings were between male and female steelhead, and occurred in tributaries (Teanaway, Taneum, and Swauk creeks) (Karp et al. 2005).

Cramer et al. (2003; 2004) assert that the Upper Yakima and portions of the Naches drainage would naturally primarily support the resident form of *O. mykiss*. Many others have asserted that the Upper Yakima would once have been a major producer of anadromous steelhead, and that changes in habitat conditions and introduction of non-native hatchery rainbow trout have greatly reduced the expression of anadromy. Factors hypothesized to contribute to this shift include:

- Reduction in survival rates for outmigrating smolts and returning adults associated with changed flow, predation, and passage conditions in the mainstem Yakima and Columbia that reduces the fitness of the anadromous life history relative to residents
- Reduction in temperatures and increases in flow in mainstem habitat reaches associated with irrigation delivery flows increasing the relative benefits of residency
- Loss of access to tributary habitat with conditions that promote anadromy
- Reduction of mainstem habitat quality for year-0 juveniles due to simplified channels, high summer velocities associated with irrigation delivery flows and rapid changes in flows associated with flip-flop
- Possible introgression of genes from non-anadromous hatchery trout and steelhead introductions

Genetic analysis indicates that in specific Upper Yakima tributaries, the anadromous and resident forms of *O. mykiss* are genetically more similar to each other than to the same life history in other tributaries, while the trout population in the mainstem is both genetically distinct from tributary *O. mykiss* and shows signs of introgression from hatchery stocks (Pearsons et al. 2007).

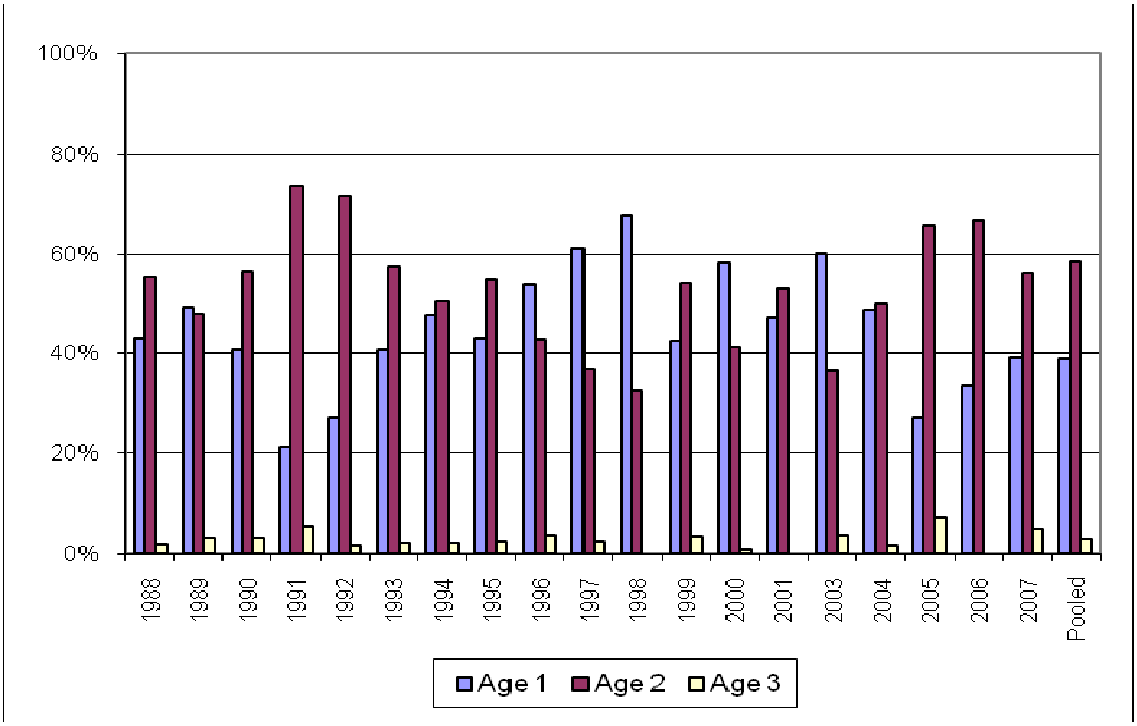
Based on the goal built into NOAA Fisheries' policy of conserving the anadromous component of *O. mykiss* as a Distinct Population Segment, interactions between resident and anadromous *O. mykiss* can have both positive and negative outcomes. The ICTRT viability framework identifies a significant shift by a predominantly anadromous population to increased residency as a factor that increases the extinction risk of the anadromous portion of the population.

The ability of resident males to successfully breed with anadromous females and produce anadromous offspring can significantly increase the effective population size of the anadromous population, especially when spawner abundance is low, and can increase the resilience and persistence of the population.

The ability of resident-resident pairings to produce anadromous offspring can also allow for re-establishment of an anadromous run in the absence of anadromous spawners. While this is known to occur, and may be an important survival mechanism for temporarily isolated populations, the persistence of this trait after many generations without anadromous returns contributing to the gene pool is unknown (Salmon Recovery Science Review Panel 2004; Scott and Gill 2006). Thrower (2004) found, however, that a resident population continued to produce smolts despite 70 years of isolation from anadromous adults. Thrower's results indicate that the correlation between smoltification and other traits associated with fitness in the freshwater environment provide a mechanism to explain how a low level of smoltification could persist despite the loss of all smolts from the isolated population. However, this example is only 70 years old, which is fairly short from an evolutionary perspective. If the ability is retained, it is likely that interim absence of selection for traits favorable to anadromy may result in loss of these traits (Thrower 2004).

The impacts of competitive interactions between larger resident individuals and juvenile anadromous *O. mykiss* may also reduce the production of smolts, especially where habitat conditions have shifted to promote residency.

The nature of the relationship between resident and anadromous forms is inherently complex. Setting realistic goals for steelhead production in different parts of the Upper Yakima and Naches systems will require an improved understanding of the range of interactions between resident and anadromous life histories. This is identified as a key knowledge gap in Chapter 7.



2.5.7 Smolt Outmigration

Age and Size at Outmigration

Steelhead smolt ages at Prosser Dam are shown in Figure 2.11 below, which is derived from more than 9,000 age determinations from 1988 through 2004. Overall, 39% of the

sample was age one, 58% was age two and 3% was age three. The percentage of age one steelhead smolts passing Prosser Dam (Fig. 2.1) is unusually high for an interior population (Peven et al. 1994). The age distribution of outmigrating smolts differs from the freshwater age distribution of returning adults (15% age one, 75% age two and 10% age three (calculated from Figure 2.11 and excluding repeat spawners), indicating significantly better survival from smolt to returning adult for older smolts. (Some of the difference could also be explained by smolts spending another winter in freshwater below Prosser Dam; however, this is not a known life history for Yakima Basin steelhead.)

Figure 2.11: Steelhead smolt ages at Prosser Dam

Very little data exist to estimate age at outmigration for specific populations. Based on scale samples from juvenile steelhead trapped by the Yakama Nation in Satus, Toppenish, and Ahtanum creeks during the 2001-02 and 2003-04 out-migration seasons, age one smolts appeared to be more prevalent than age two in Satus and Toppenish creeks, and age three smolts were uncommon in all three creeks. Table 2.18 shows the average size by smolt age for outgoing smolts sampled at the Chandler juvenile facility at Prosser.

Average	**147**	**186**	**223**	

Abundance of Outmigrants

Prosser Dam is located downstream of almost all steelhead spawning areas in the Yakima Basin. A juvenile fish counting facility is built into the fish screen bypass system, enabling both PIT tag detections and manual counts of entrained fish. Steelhead mark-and-recapture studies have not been conducted at Prosser Dam since before the June 23, 1999 listing of Middle Columbia River steelhead. Instead, steelhead passage is estimated by applying entrainment, canal mortality, and sampling rate coefficients established for spring Chinook to manual counts of steelhead at the Prosser Juvenile Facility. The degree of bias introduced by this substitution is not known, but may be significant. For this reason, annual steelhead smolt counts are not considered reliable enough for year-to-year comparisons of the number of outmigrants. Estimates of the number of steelhead smolts passing Prosser Dam have ranged between 25,000 and 50,000 smolts between 1999 and 2005 (2006 counts were hampered by high flows).

Timing of Outmigration

As noted in Section 2.5.4, some juveniles leave their natal areas and may spend considerable amounts in the fall through spring rearing in areas that may have been inhospitable in the summer. Others move fairly rapidly from their initial rearing areas towards the Columbia. Juvenile outmigration through the lower Yakima River and past Prosser Dam begins in November and peaks between mid-April and May. The timing of

the overall steelhead outmigration at McNary and Bonneville dams parallels the timing at Prosser, and runs from early April through the end of June. Steelhead smolts have been observed passing Prosser into the middle of July, but the Lower Yakima has warmed to lethal temperatures by that time even in normal water years and typically does not cool again to safe levels until early autumn (Fast and Berg 2001). Little information is currently available to determine if the timing of outmigration differs by population. Steelhead tagged in Satus Creek in the 2003-04 and 2004-05 seasons arrived earlier at Prosser Dam than smolts tagged in Toppenish Creek or Ahtanum Creek (Table 2.19).

Table 2.19: Steelhead travel times from tributary tagging locations to Prosser Dam

		Mean Dates	
Release Year	Trap Location	Release	Prosser
2003-04	Toppenish	2/10/04	4/24/04
2003-04	Ahtanum	4/8/04	5/8/04
2003-04	Satus	3/25/04	4/20/04
2004-05	Toppenish	3/12/05	4/25/05
2004-05	Ahtanum	3/25/05	5/5/05
2004-05	Satus	2/27/05	4/7/05

Survival Rates for Outmigrants

A series of PIT tag groups used for entrainment rate studies at Prosser Dam in the relatively high-flow year of 1999 were used to estimate juvenile steelhead survival rate of 0.798 to McNary Dam by Williams et al. (2005). Subsequent years' survival estimates to McNary Dam by the authors were lower, (0.314 in 2002 and 0.394 in 2003), and were likely derived from the 2001-02 and 2002-03 Toppenish Creek releases described below, thus having a point of origin well upstream from Prosser Dam.

The Yakama Nation operates screw traps in Satus, Toppenish, and Ahtanum creeks, but widely fluctuating flows and heavy debris loads during the out-migration period hamper passage estimation at these locations. Toppenish Creek steelhead have been PIT tagged since the 2001-02 out-migration season, giving an opportunity to estimate downstream survival and return rates of tag groups. PIT tagging at the Ahtanum and Satus creek traps began in the 2003-04 season.

Downstream survival rate of PIT-tagged juvenile steelhead to Prosser Dam can be estimated by dividing Prosser detections by Prosser entrainment rate on the date of each detection (using the aforementioned diversion-entrainment relationship) and also by using PIT tag detections at the McNary Dam juvenile bypass to calculate the Prosser entrainment rate. Table 2.20 shows tagging data and estimated survival rates. Calculated survival rates from tributaries to Prosser range from 14% to 74%.

Table 2.20 supports the hypothesis that steelhead smolt survival rate to Prosser is related to travel distance. Fish from the Satus Creek trap, which is closest to Prosser Dam, survived best, while estimated survival rates from the Toppenish and Ahtanum creek traps were both lower, and much lower from Toppenish Creek in the drought year of 2005. Within Toppenish Creek, survival rates were lower for upstream releases, especially in the 2001-02 outmigration period. There is a strong tendency for later out-

migrants to travel faster downriver. Better understanding of the relationship between flows, habitat conditions, and outmigration timing and survival is identified as a key knowledge gap in Chapter 7.

Table 2.20: Survival rates of steelhead smolts from selected tributaries

2.5.8 Ocean Residence

Yakima Basin steelhead typically spend between one and three years in the ocean before returning to natal streams to spawn, as detailed in the discussion of age structures in Section 2.5.1.2. Variability in estuary and ocean conditions is a major driver of year-to-year survival and growth of adult steelhead. Variation occurs because of changing climatic conditions, fisheries impacts (presumed minimal for the Middle Columbia Steelhead DPS), possible density-dependant competitive interactions with other salmon species and hatchery fish, and variability of prey and predator abundance. NOAA Fisheries' Middle Columbia Steelhead Recovery Plan will address ocean and estuary effects on the Middle Columbia River Steelhead DPS as a whole. The only specific data about ocean survival rates of Yakima Basin steelhead comes from analysis of return rates of PIT-tagged smolts detected during their downstream and subsequent upstream migrations. Preliminary estimates show McNary smolt to McNary adult return rates of 2.5% to 6.3%; general experience with PIT tag returns shows that they typically underestimate smolt to adult survival rates for the untagged portion of the run (FPC (Fish Passage Center) and Comparative Survival Study Oversight Committee 2006). Future efforts to assess the impacts of size, age, and condition of outmigrating smolts on ocean survival rates will help guide efforts to manage conditions within the Yakima Basin in a manner that improves ocean survival of outgoing smolts.

2.6 Viability Assessments for Yakima Basin Steelhead

Several efforts have been made to assess the current status of steelhead in both the Yakima Basin and the Middle Columbia DPS as a whole. At the time of the initial listing under the ESA in 1999 (64FR14517 and Busby (1996)), habitat degradation, low

abundance, declining productivity, and the threat of hatchery practices to genetics of native stocks were identified as the primary factors justifying listing.

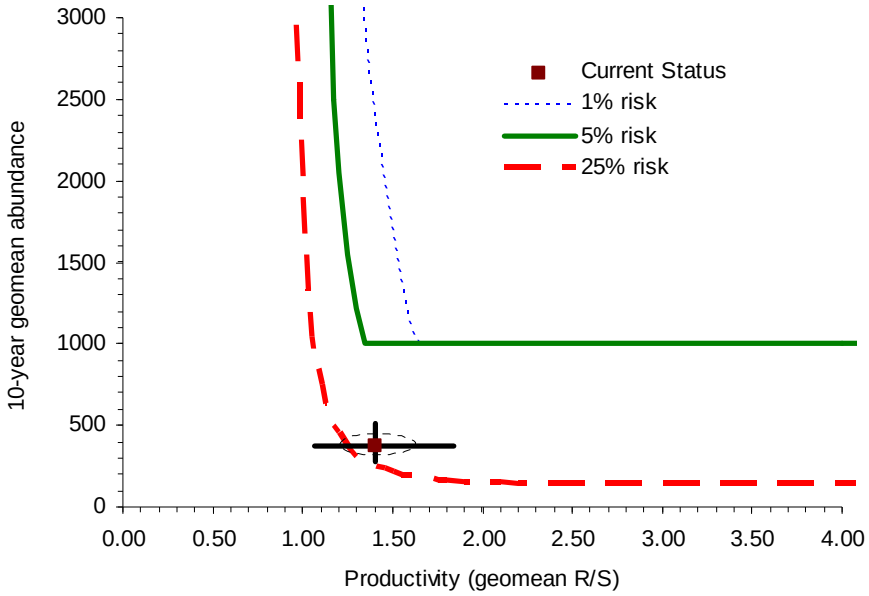
Cramer et al. (2003; 2004) have emphasized that Yakima Basin steelhead are minimally affected by intermixing with hatchery spawners, that abundance and productivity trends improved significantly between the mid-1990s and 2004, and that steelhead production from parts of the basin may be limited by conditions that promote residency. They assert that steelhead are fully seeding currently available habitat and that the availability of rearing habitat is limits production. They do not address the degree to which improvements in existing habitat and increased access to currently inaccessible habitat could increase juvenile habitat capacity nor do they address how improvements in survival rates in migratory life stages (smolt and adult) could change the adult abundance supported by a given smolt production capacity.

This plan incorporates the viability assessments developed by the ICTRT in 2004 through 2007 based on the Viable Salmonid Population conceptual framework (McElhany et al. 2000). The ICTRT Stock Status Assessments for the Yakima Basin (ICTRT In press) were prepared in accordance with ICTRT guidelines (ICTRT 2004a; 2004b; 2005a; 2005b; 2007b). Supporting data were drawn from multiple sources, including previous drafts of this recovery plan. These analyses are based on the best information available. While this information is at times limited, the stock status assessments represent a solid effort to utilize existing data to evaluate viability. As noted in Chapter 7, these assessments should be updated as our ability to determine population-specific VSP parameter improves.

Table 2.21 shows the results of the ICTRT analysis: the Satus and Toppenish populations were each assigned an abundance/productivity risk of moderate and a Spatial Structure/Diversity risk of moderate. The Naches population was assigned a high abundance/productivity risk and a Spatial Structure/Diversity risk of moderate. The Upper Yakima was ranked high for both risk classes. The rest of this section reviews the ICTRT’s basis for these assignments.

Table 2.21: ICTRT risk ratings for Yakima steelhead populations

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1–5%)	**V**	**V**	**V**	**M**
	Moderate (6–25%)	M	M	M **Satus/ Toppenish**	
	High (>25%)			**Naches**	**Upper Yakima**



Viability Key: HV = Highly Viable; V = Viable; M = Not Viable, Candidate for Maintained Status

2.6.1 Satus Creek

Abundance and Productivity

The ICTRT classified the Satus Creek steelhead population as “Intermediate” in size based on historical habitat potential analysis (ICTRT 2007). This classification requires a minimum abundance threshold of 1,000 wild spawners with sufficient productivity (greater than 1.35 returns per spawner at the abundance threshold) to avoid a 5% extinction risk on the ICTRT’s viability curve. With a 10-year (1996-2005) geomean abundance of 379 and a delimited/adjusted productivity value of 1.40 returns per spawner, the Satus Creek steelhead population is deemed to be at moderate risk of extinction, i.e., between the 5% and 25% risk lines for an intermediate-size population (Figure 2.12).

Figure 2.12: Satus abundance & productivity compared to the viability curve

Curve is for an intermediate-sized population. The point estimate includes a 1 standard error ellipse and 95% confidence intervals (1.81 x SE for both productivity and abundance estimates).

Spatial Structure and Diversity

Both MSAs and the MiSA in the Satus Creek drainage are rated as occupied.[26] Table 2.22 summarizes spatial structure and diversity risk assessment scores. The ICTRT placed the Satus Creek steelhead population at low risk for Goal A, which covers spatial structure factors, and moderate risk for Goal B, which covers genetic and phenotypic diversity. The three metrics contributing to the risk rating under Goal B were phenotypic variation due to constraints on migration timing, distribution across habitat types because of habitat loss in lower Satus Creek, and selective impacts related to migration timing constraints. Using the lower score for the two goals gives the population an overall spatial structure and diversity risk rating of moderate.

According to the ICTRT the population status relative to Goal B could be improved by addressing B.1.b (phenotypic variation). The first step in addressing this component should be a more detailed evaluation of spawning and rearing timing. That assessment should be designed to evaluate the relative change in phenotypic characteristics for the population and the factors driving the shifts. If further analysis confirms a significant shift in phenotypic characteristics relative to the assumed historical condition or with unaltered reference populations in a similar habitat, geologic, and hydrologic setting, restoration actions should be initiated. Based on this scoring system, this metric must be addressed in order for the status of goal B to improve to low risk.

[26] See Section 4.2.3 for the ICTRT definition of “occupancy.”

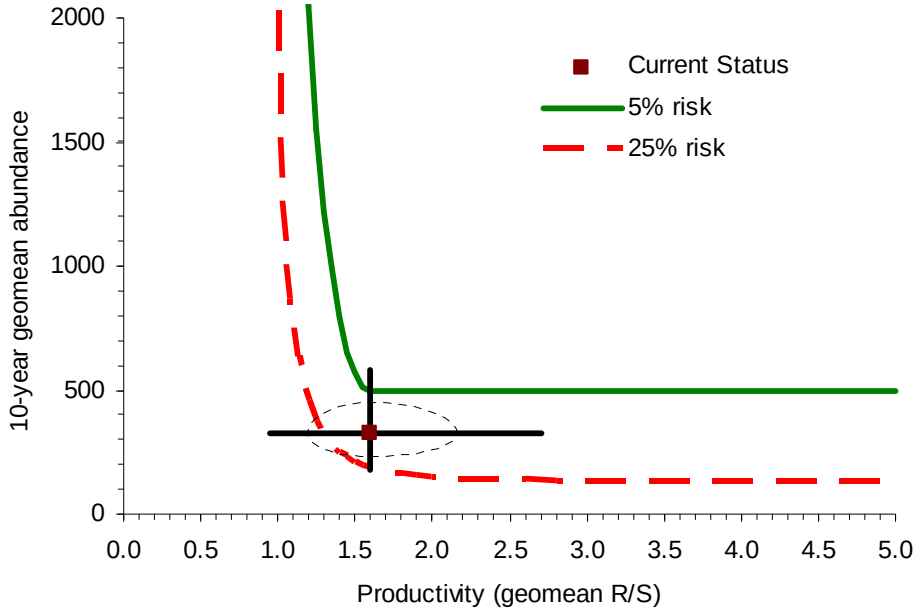
</table>

Overall, the Satus Creek steelhead population is not considered viable under the ICTRT guidelines—both abundance/productivity and spatial structure/diversity elements indicate



moderate risk. To achieve viable status, the Satus Creek population must exceed the minimum threshold escapement of 1,000. To achieve very low risk status (high viability) the improvement in abundance would need to be accompanied by an increase in productivity and the changes in spatial structure and diversity described above.

2.6.2 Toppenish Population

Abundance and Productivity

The ICTRT classified the Toppenish Creek steelhead population as "Basic" in size based on historical habitat potential analysis (ICTRT 2007). This classification requires a minimum abundance threshold of 500 wild spawners with sufficient productivity (greater than 1.56 returns per spawner) to avoid a 5% extinction risk on the ICTRT's viability curve. With a 10-year (1996-2005) geomean abundance of 322 and a delimited/adjusted productivity value of 1.60 returns per spawner, the Toppenish Creek steelhead population is deemed to be at moderate risk of extinction, i.e., between the 5% and 25% risk lines for a basic-size population (Figure 2.13).

Figure 2.13: Toppenish abundance & productivity compared to the viability curve

Curve is for a basic-sized population. The point estimate includes a one standard error ellipse and 95% confidence intervals (1.81 x SE for both parameters).

Spatial Structure and Diversity

The ICTRT classifies both MSAs as occupied. Table 2.23 summarizes spatial structure and diversity risk assessment scores. The ICTRT placed the Toppenish Creek steelhead population at low risk for Goal A, which covers spatial structure factors and moderate risk for Goal B, which covers genetic and phenotypic diversity. Using the lower score for the two goals gives the population an overall spatial structure and diversity risk rating of moderate.

Table 2.23: ICTRT spatial structure & diversity ratings for the Toppenish population

Metric	Risk Assessment Scores				
	Metric	Factor	Mechanism	Goal	Population
A.1.a Number and spatial arrangement of spawning areas	L (1)	L (1)	Low Risk Mean = 0.66	Low Risk

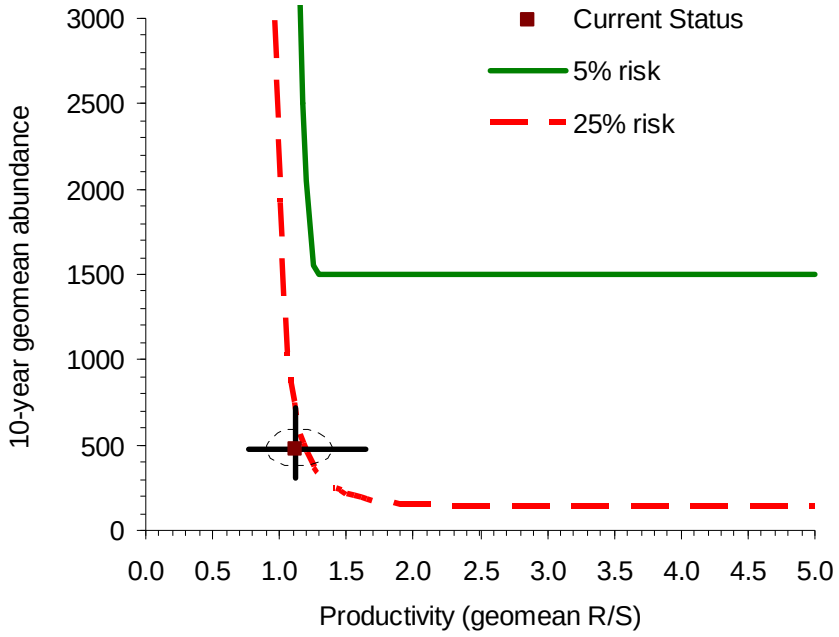
B.1.b. Phenotypic variation	M (0)	M (0)			
B.1.c. Genetic variation	M (0)	M (0)			
B.2.a. (1) Out-of-DPS spawners	L (1)	Low Risk (1)	Low Risk (1)		
B.2.a. (2) Out-of-MPG spawners	L (1)				
B.2.a. (3) Out-of-Population spawners	VL (2)				
B.2.a. (4) Within-population hatchery spawners	L (1)				
B.3.a. Distribution of population across habitat types	L (1)	L (1)	L (1)		
B.4.a. Selective change in natural processes or selective impacts	M (0)	M (0)	M (0)		

Since listing of the DPS in 1999, problems with adult passage, juvenile entrainment, and instream flow have been addressed in part through several restoration projects and flow regulation in the agricultural portion of the Toppenish Creek watershed. However, seepage losses (which may be partly of human origin) combine in dry years with agricultural diversions to restrict passage to and from the most important spawning and rearing areas. Summer rearing is also precluded in lower Toppenish and Simcoe creeks. Eggs and fry in Marion and Harrah drains, a new spawning area, are unlikely to survive due to poor habitat and to irrigation spills during the emergence period. This ostensible increase in range may actually increase extinction risk, hence the moderate risk rating under the spatial extent metric.

Under Goal B, risk is elevated with respect to life history strategies given rearing conditions in the lower creek, phenotypic variation because of constraints on adult migration timing, and in genetic variation due to low levels of heterozygosity that may be related to earlier passage bottlenecks. Migration timing constraints and loss of rearing habitat in the lower creek result in moderate risk with respect to the selective impacts metric.

According to the ICTRT, at least two major components of the spatial structure/diversity criteria must be addressed to move this population to a low risk rating. Expansion of the current range into historically utilized rearing areas in the lower reaches of Toppenish Creek would increase the range of life history patterns towards historical levels. The status relative to goal B could be improved by addressing B.1.b (phenotypic variation). The first step in addressing this component should be a more detailed evaluation of spawning and rearing timing. That assessment should be designed to evaluate the relative change in phenotypic characteristics for the population and the factors driving the shifts. If further analysis confirms a significant shift in phenotypic characteristics relative to the assumed historical condition or with unaltered reference populations in a similar habitat, geologic, and hydrologic setting, restorations actions should be initiated. Based on the ICTRT scoring system, this metric must be addressed in order for the status of goal B to improve to low risk.

Overall, the Toppenish Creek steelhead population is not considered viable under the ICTRT guidelines—both abundance/productivity and spatial structure/diversity elements indicate moderate risk. To achieve viable status, the abundance of the population must be increased sufficiently to maintain the population above the minimum threshold escapement of 500 spawners. To achieve very low risk status (high viability) those improvements in abundance would need to be accompanied by the changes in spatial structure and diversity described above.



2.6.3 Naches Population

Abundance and Productivity

The ICTRT classified the Naches River steelhead population as “Large” in size based on historical habitat potential analysis (ICTRT 2007). This classification requires a minimum abundance threshold of 1500 wild spawners with sufficient productivity (greater than 1.26 returns per spawner at the abundance threshold) to avoid a 5%

extinction risk on the ICTRT's viability curve. With a 10-year (1996 to 2005) geomean abundance of 472 and a delimited/adjusted productivity value of 1.12 returns per spawner, the Naches River steelhead population is deemed to be at high risk of extinction, i.e., below the 25% risk line for a large-size population (Figure 2.14).

Figure 2.14: Naches abundance & productivity compared to the viability curve

Curve is for a large-sized population. The point estimate includes a 1 standard error ellipse and 95% confidence intervals (1.81 x SE for both productivity and abundance estimates).

Spatial Structure and Diversity

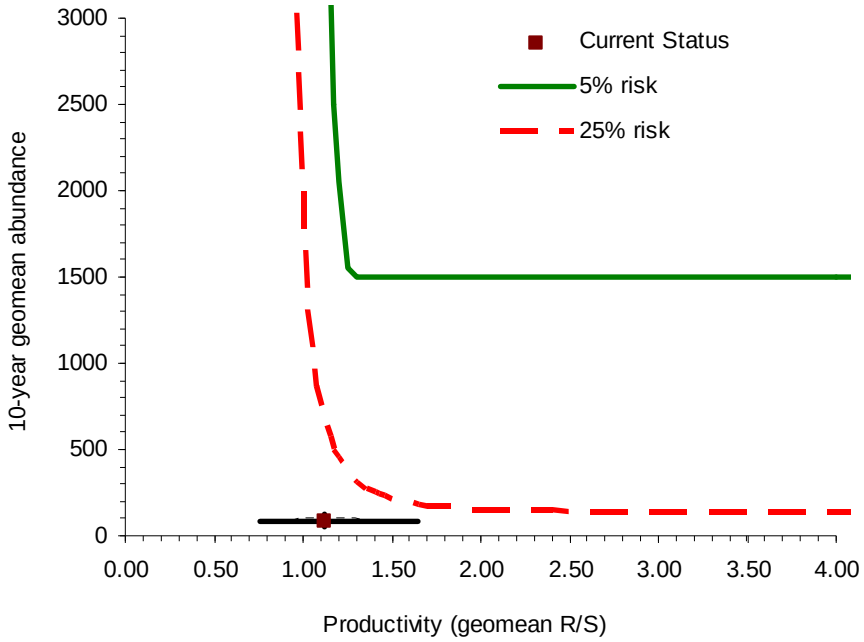
The ICTRT classified seven of eight MSAs in the Naches Population area as occupied (the Cowiche MSA was rated as unoccupied). Table 2.24 summarizes spatial structure and diversity risk assessment scores. The ICTRT placed the Naches River steelhead population at low risk for Goal A, which covers spatial structure factors, and moderate risk for Goal B, which covers genetic and phenotypic diversity. Using the lower score for the two goals gives the population an overall spatial structure and diversity risk rating of moderate.

Table 2.24: ICTRT spatial structure & diversity ratings for the Naches population

Metric	Risk Assessment Scores				
	Metric	Factor	Mechanism	Goal	Population
A.1.a Number and spatial arrangement of spawning areas	VL (2)	L (2)	Low Risk Mean = 1.33		
A.l.b. Spatial extent or range of population	L (1)	L (1)			
A.1.c. Increase or decrease in gaps or continuities between spawning areas	L (1)	L (1)			
B.1.a. Major life history strategies	M (0)	M (0)	Moderate Risk		
B.1.b. Phenotypic variation	M (0)	M (0)			
B.1.c. Genetic variation	L (1)	L (1)			
B.2.a. (1) Out-of-DPS spawners	L (1)	Low Risk (1)	Low Risk (1)		
B.2.a. (2) Out-of-MPG spawners	L (1)				
B.2.a. (3) Out-of-Population spawners	VL (2)				
B.2.a. (4) Within-population hatchery spawners	L (1)				
B.3.a. Distribution of population across habitat types	L (1)	L (1)	L (1)		
B.4.a. Selective change in natural processes or selective impacts	H (-1)	H (-1)	H (-1)		

Under Goal B, risk is elevated with respect to life history strategies and phenotypic variation, because of flow regulation, including the “flip-flop” water management strategy, affecting rearing conditions in the main stem below the Tieton River. Migration timing constraints in the lower Naches and the lower Yakima, and the aforementioned loss of rearing habitat in the lower Naches, both hamper mainstem rearing strategies and result in high risk with respect to the selective impacts metric.

The status relative to goal B could be improved by addressing phenotypic variation, beginning with a more detailed evaluation of spawning and rearing timing to evaluate the relative change in phenotypic characteristics for the population and the factors driving the shifts. If further analysis confirms a significant shift in phenotypic characteristics relative to the assumed historical condition or with comparable unaltered reference populations, restoration actions should be initiated. The status rating could also be improved by evaluating detrimental selective impacts of activities affecting within-basin passage, and reducing those impacts if warranted. Based on the ICTRT scoring system, this metric must be addressed in order for the status of goal B to improve to low risk.



Overall, the Naches River steelhead population is not considered viable under the ICTRT guidelines—both abundance/productivity and spatial structure/diversity elements indicate moderate risk. To achieve viable status, the abundance of the population must be increased sufficiently to maintain the population above the minimum threshold escapement of 1500 spawners. To achieve very low risk status (high viability) those improvements in abundance would need to be accompanied by the changes in spatial structure and diversity described above.

2.6.4 Upper Yakima Population

Abundance and Productivity

The ICTRT classified the Upper Yakima River steelhead population as “Large” in size based on historical habitat potential analysis (ICTRT 2007). This classification requires a minimum abundance threshold of 1500 wild spawners with sufficient productivity (greater than 1.26 returns per spawner at the abundance threshold) to avoid a 5% extinction risk on the ICTRT’s viability curve. With a 10-year (1996 to 2005) geomean abundance of 85 and a delimited/adjusted productivity value of 1.12 returns per spawner, the Upper Yakima River steelhead population is deemed to be at high risk of extinction, i.e., below the 25% risk line for a large-size population (Figure 2.15).

Figure 2.15: Upper Yakima abundance & productivity compared to viability curve

Curve is for a large-sized population. The point estimate includes a 1 standard error ellipse and 95% confidence intervals (1.81 x SE for both productivity and abundance estimates).

Spatial Structure and Diversity

Table 2.25 summarizes spatial structure and diversity risk assessment scores. The ICTRT placed the Upper Yakima River steelhead population at moderate risk for Goal A, which covers spatial structure factors, and high risk for Goal B, which covers genetic and phenotypic diversity. Using the lower score for the two goals gives the population an overall spatial structure and diversity risk rating of high.

Table 2.25: ICTRT spatial structure & diversity ratings for Upper Yakima population

Metric	Risk Assessment Scores				
	Metric	Factor	Mechanism	Goal	Population
A.1.a Number and spatial arrangement of spawning areas	L (1)	L (1)	Moderate Risk (Mean = 0)	Moderate Risk	**High Risk**
A.l.b. Spatial extent or range of population	M (0)	M (0)			
A.1.c. Increase or decrease in gaps or continuities between spawning areas	H (-1)	H (-1)			
B.1.a. Major life history strategies	H (-1)	H (-1)	High Risk	High Risk	
B.1.b. Phenotypic variation	M (0)	M (0)			
B.1.c. Genetic variation	H (-1)	H (-1)			
B.2.a. (1) Out-of-DPS spawners	NA	Low Risk	Low Risk		
B.2.a. (2) Out-of-MPG spawners	NA				
B.2.a. (3) Out-of-Population spawners	NA				
B.2.a. (4) Within-population hatchery spawners	VL (2)				
B.3.a. Distribution of population across habitat types	L (1)	L (1)	L (1)		
B.4.a. Selective change in natural processes or selective impacts	H (-1)	H (-1)	H (-1)		

Under Goal A, extinction risk is elevated with respect to spatial extent or range and increase in gaps between spawning areas. Of the 14 MSAs, only seven are judged to have steelhead spawning in both their upper and lower portions (the ICTRT standard for occupancy). Another four MSAs are occupied in their lower portions only, and significant gaps exist between spawning areas.

Under Goal B, risk is elevated with respect to life history strategies and phenotypic variation, because of flow regulation, including the “flip-flop” water management strategy, affecting rearing conditions in the mainstem and because of curtailment of presmolt migration within and between tributaries. Migration timing constraints in the lower Yakima, long migration distances coupled with past and present constraints on passage at Roza Dam, and the aforementioned loss of rearing habitat in the mainstem both hamper mainstem rearing strategies and result in high risk with respect to the selective impacts metric.

Overall, the Upper Yakima River steelhead population is not considered viable under the ICTRT guidelines—both abundance/productivity and spatial structure/diversity elements indicate high risk of extinction. The ICTRT concludes that improving the overall rating to Viable will require substantial improvements in current abundance and productivity relative to the recent base period. Improved passage at Roza Dam and into Taneum and Big creeks was only recently restored (post 1988), and further improvements in survival and in habitat availability (including provision of access into currently blocked areas) will likely be required to meet overall abundance and productivity objectives for this population. Key improvements in spatial/structure and diversity (described above) will also be required.

3 Factors for Decline

3.1 Introduction	3.4 Relationship of Threats to Limiting Factors
3.2 Definition of Threats	3.5 In-Basin Threats and Limiting Factors
3.3 Definition of Limiting Factors	3.6 Out-of-Basin Threats and Limiting Factors

3.1 Introduction

This chapter gives an overview of the factors that have contributed to the decline in steelhead populations identified in Chapter 2. To provide a context for the actions presented in Chapter 5, this chapter discusses the threats and limiting factors currently affecting the four steelhead populations in the Yakima Basin. Chapter 3 does not give a reach-by-reach assessment of habitat conditions and limiting factors for Yakima Basin steelhead habitat. More detailed reach-specific assessments can be found in the habitat assessment portions of the Yakima Subbasin Plan (Yakima Subbasin Fish and Wildlife Planning Board 2005) and the Limiting Factors Analysis conducted for the Washington State Conservation Commission (Haring 2001); numerous other watershed assessments give information for specific geographic areas. These more detailed assessments will be incorporated into the implementation scheduling process described in Chapter 6.

3.1.1 General Overview of Steelhead Population Decline

Salmon, and trout recolonized and expanded their range in the Columbia River Basin after the most recent Ice Age (10,000-15,000 years ago). Native Americans had access to an abundant fish resource comprised of coho, chum, and sockeye salmon, spring, summer, and fall runs of Chinook, steelhead, bull trout, cutthroat trout, Pacific lamprey, and white sturgeon. Their cultures were formed around the availability of anadromous fish (Craig and Hacker 1940), with catches increasing as their populations rose and fishing techniques developed. Estimates of pre-development (late 1700s) abundance of Columbia River salmon and steelhead ranged from about 8 million (Chapman 1986) to 14 million (NPPC 1986) fish.[27] While questions exist about the degree of cyclic variations in freshwater and ocean habitat conditions, it is quite certain that salmon and steelhead have declined to a small fraction of their former abundance and distribution (NRC 1996, Figure 3-2). In recent decades, the total run of all salmon and steelhead has ranged from one to two million fish, with about three-quarters of the recent spring Chinook and summer steelhead runs consisting of fish cultured to smolt size in hatcheries. The overall decline of anadromous fish runs in the Columbia Basin has been reviewed extensively (Busby et al. 1996; Lichatowich 1999; Nehlsen et al. 1991; NPPC 1986; NRC 1996).

[27] Estimates of pre-development salmon and steelhead numbers are based on multiplying the maximum catches in the latter part of the 1800s (which reached 3-4 million salmon and steelhead) with the assumed catch rates by all fishing gear.

The decline of salmon and steelhead in the Yakima Basin occurred in two major phases. During the first phase, between 1850 and roughly 1900, Yakima runs declined about 90% from historical values (Davidson 1953; Lichatowich 1999; Tuck 1995). Initial causes of decline include diversion of instream flows into unscreened watercourses for irrigation (Lichatowich 1999; Tuck 1995) and over-harvest in early mainstem fisheries. In the second phase, covering the years 1900 to the present, native sockeye (*O. nerka*), coho (*O. kisutch*), and summer Chinook were extirpated and the abundance of the other stocks fell to small fractions of historical values. The construction of dams to convert natural glacial lakes into storage reservoirs early in the twentieth century blocked off many miles of spawning and rearing habitat and, along with reduced flows and increased temperatures in the lower Yakima, led to the extinction of native sockeye salmon. Reservoir and diversion operations cut off access to headwater streams and significantly changed flow and temperature regimes downstream, resulting in reductions in spawning, rearing, and migratory habitat quality and quantity. Unscreened diversions are known to have stranded large numbers of fish. While a long history of fish screening programs has greatly reduced extent of such stranding, many unscreened diversions remain. Irrigation diversions reduced flows, sometimes to the point of drying out specific stream reaches. Irrigation drains have severely impacted water quality in some tributaries and in the lower Yakima River, (although recently many components of some irrigation effluents have been reduced).

Development of the Columbia River dams also had a large impact on anadromous fish runs by reducing survival rates for upstream and downstream migrants. Steelhead are able to return to the sea after spawning and then travel upstream to spawn again. The degree to which repeat spawners contributed to the productivity of Yakima Basin steelhead populations prior to European settlement is unknown, but is presumed depressed from historic levels due to general changes in habitat and the development and operation of the Columbia River hydropower system. Early hatcheries constructed to mitigate for fish loss at mainstem dams were operated without a clear understanding of population genetics. Although hatcheries were increasing the abundance of depleted stocks, they were probably also decreasing the diversity of the native populations with which they overlapped.

Human population growth and associated land uses within the basin (agriculture, mining, timber harvest, transportation systems, and urban and rural development) have significantly affected salmon and trout spawning and rearing habitat. The National Research Council Committee on Protection and Management of Pacific Northwest Anadromous Salmonids identified habitat problems as a primary cause of declines in wild salmon runs (ISAB 1996; ISAB 2000; NRC 1996). They identified the fragmentation and loss of available spawning and rearing habitat, migration delays, degradation of water quality, removal of riparian vegetation, decline of habitat complexity, alteration of stream flows and stream bank and channel morphology, alteration of ambient stream water temperatures, sedimentation, and loss of spawning gravel, pool habitat and large woody debris.

Floodplain development has degraded floodplain and channel function. Portions of the Yakima River and its tributaries have been detached from their historical floodplains, impairing floodplain function, reducing access to off-channel habitats, and reducing flow

and elevating temperatures. Urbanization (especially in alluvial floodplains) and livestock grazing practices have altered riparian habitat (Busby et al. 1996; NMFS 1996; Washington Department of Fisheries et al. 1993; West Coast Steelhead Biological Review Team 1999). Exotic species introductions have directly and indirectly affected steelhead. All these activities (harvest, hydropower, hatcheries, and habitat, both within and outside of the Yakima Basin) acted in concert to decrease the abundance, productivity, spatial structure, and diversity of steelhead populations in the Yakima Basin.

The 2004 Yakima Subbasin Plan (Yakima Subbasin Fish and Wildlife Planning Board 2005) and the Yakima River Habitat Limiting Factors Analysis for the Yakima (Haring 2001) describe, in some detail, the array of habitat modifications that currently affect the quantity and quality of salmonid habitat within the Yakima Basin. Although land and water management practices have typically improved in recent decades, factors such as storage dams, diversions, roads and railways, agriculture (including livestock grazing), residential development, and forest management all continue to affect steelhead and their habitat in the Yakima Basin.

3.1.2 Ongoing Efforts to Address the Decline of Steelhead

Changing land-use practices have reduced some threats to steelhead and increased others. Many activities that address threats and reverse the long-term decline of steelhead in the Yakima Basin have been initiated at the federal, state, and local levels (e.g., restrictive harvest regulations, habitat improvement projects, adoption of various land management rules, and development of conservation strategies and plans). Appendix C gives an overview of some of the major fish restoration programs in the Yakima Basin. While these efforts are important to the conservation and recovery of ESA-listed species, additional work is needed to minimize current threats to recovery. Chapter 5 proposes specific actions to be taken to recover steelhead populations. The remainder of Chapter 3 addresses the threats and limiting factors that currently affect steelhead populations in the Yakima Basin. This provides a context for understanding the purpose for actions proposed in Chapter 5.

3.2 Definition of Threats and Limiting Factors

3.2.1 Threats

Section 4(a) (1) of the Endangered Species Act of 1973 lists five sets of threats to consider when determining species status under the ESA. These listing factors are: (A) the present or threatened destruction, modification, or curtailment of its habitat or range; (B) over-utilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; or (E) other natural or manmade factors affecting its continued existence. Historical and current human activities associated with these five factors—especially habitat-related factors—have negatively affected steelhead in the Yakima Basin to the point that they were listed under the ESA, as described in Chapter 1. The National Marine Fisheries Service (1996) listed a number of habitat-related factors affecting the Middle Columbia River Steelhead

ESU and the Yakima Basin that led to the 1999 listing. They included water withdrawal, conveyance, and storage, flood control, logging, agriculture, mining, road building, and urbanization. Their list closely corresponds to the definition of threats used in this document.

The ESA describes the human and naturally induced actions that have resulted in the decline of steelhead populations as threats. According to NMFS' Draft Guidelines for Limiting Factors and Threats Assessment (2005):

> Threats are the human actions or natural events (e.g., road building, floodplain development, fish harvest, hatchery influences, and volcanoes) that cause or contribute to limiting factors. Threats may be caused by the continuing results of past events and actions as well as by present and anticipated future events and actions.

While the term "threats" carries a negative connotation, it does not mean that activities identified as threats are inherently undesirable. They are typically legitimate and necessary human activities that may at times have unintended negative consequences on fish populations—and that can also be managed in a manner that minimizes or eliminates these negative impacts.

3.2.2 Limiting Factors

Limiting factors are the specific changes in conditions through which threats affect the abundance, productivity, spatial distribution, and diversity of the species of concern (NMFS 2005). Limiting factors are characterized in relation to the biological needs of the species. According to NMFS' Draft Guidelines for Limiting Factors and Threats Assessment (2005):

> Limiting factors are the physical, biological, or chemical features (e.g., inadequate spawning habitat, high water temperature, insufficient prey resources) experienced by the fish at the population, intermediate (e.g., stratum or major population grouping), or ESU-levels that result in reductions in VSP parameters (abundance, productivity, spatial structure, and diversity) at any life stage. Key limiting factors are those with the greatest impacts on a population's ability to reach its desired status.

Table 3.1, Table 3.2, Table 3.3, Table 3.4, Table 3.5 and Table 3.6 list the threats and associated limiting factors identified by recovery planners in the Yakima Basin. Sections 3.3.1 thru 3.3.6 describe these in more detail for each population area. NOAA Fisheries has identified 12 basic limiting factors that affect the viability of Middle Columbia Steelhead populations, as described below:

1) **Degraded floodplain connectivity and function:** The loss, impairment, or degradation of floodplain connectivity; access to previously available habitats (seasonal wetlands, off-channel habitat, side channels); and a connected and functional hyporheic zone.

2) **Degraded channel structure and complexity:** The loss, impairment, or degradation of channels; a suitable distribution of riffles and functional pools; functional amounts and sizes of large woody debris or other channel structure.

3) **Degraded riparian areas and LWD recruitment:** Factor includes loss, degradation or impairment of riparian conditions important for production of food organisms and organic material, shading, bank stabilizing by roots, nutrient and chemical mediation, control of surface erosion, and production of large-sized woody material.

4) **Altered hydrology:** Changes in the hydrograph that alter the natural pattern of flows over the seasons, causing inadequate flow, scouring flow, or other flow conditions that inhibit the development and survival of salmonids.

5) **Degraded water quality:** Degraded or impaired water quality due to abnormal temperature, or levels of suspended fine sediment, dissolved oxygen, nutrients, heavy metals, pesticides, herbicides and other contaminants (toxics).

6) **Altered sediment routing:** Altered sediment routing leading to an overabundance of fine-grained sediments, excess of course-grained sediments, inadequate course-grained sediments, and/or contaminated sediment.

7) **Impaired fish passage:** The total or partial human-caused blockage to previously accessible habitat that eliminates or decreases migration ability or alters the range of conditions under which migration is possible. This may include seasonal or periodic total migration blockage.

8) **Hatchery-related adverse effects:** Any hatchery-related adverse effects on natural-origin salmonid population survival and productivity.

9) **Harvest-related adverse effects:** Any harvest-related adverse effects on survival.

10) **Predation/Competition/Disease:** Predation or competition levels that have been elevated above likely rates in a normative system due to human actions.

11) **Degraded estuarine and nearshore marine habitat:** The loss, impairment or degradation of intertidal, salt marsh, and other functional estuarine and marine vegetation; altered amounts, quality, distribution, and timing of freshwater inflows; loss of estuary complexity; access to previously available habitats; and inadequate large woody debris.

12) **Mainstem Columbia River hydropower-related adverse effects:** Any adverse effects caused by the operation of hydroelectric dams in the mainstem Columbia and Snake rivers.

Table 3.1, Table 3.2, Table 3.3, Table 3.4, Table 3.5 and Table 3.6 show the correspondence between the limiting factors used in this plan and these more general limiting factors from NOAA Fisheries. For more details on NOAA Fisheries' limiting factors and their application to the Middle Columbia River Steelhead DPS, see the Middle Columbia Steelhead Recovery Plan (to be released in 2009).

Table 3.1: Basinwide threats and limiting factors

Basinwide Threats and Limiting Factors					
Threat	**#**	**Limiting Factor**	**Level 3 EDT Survival Factors**	**NOAA Limiting Factors**	**Actions**
Regulation of stream flow for irrigation storage and flood control	1	Inadequate migration flow because of irrigation storage or flood control headspace targets	Flow	4) Altered hydrology	BW1,3,4,5
	2	Altered hydrograph affects riparian and submerged vegetation	Flow	4) Altered hydrology 3) Degraded riparian area & LWD recruitment	BW1,3,4, 5,12
Water storage and diversion structures	3	Entrainment, injury or delay of downstream migrants at diversions	Withdrawals (entrainment), Obstructions	7) Impaired fish passage	BW2,6
Forest harvest practices, road construction and fire suppression	4	Increased risk and severity of forest disease, pests and land-scape scale fire	Sediment load, Flow	4) Altered hydrology 6) Altered sediment routing	BW13
Climate variation and trends	5	Drought worsens effects of other threats on adult spawning success and juvenile survival	Flow, Temperature, Key habitat quantity	4) Altered hydrology 5) Degraded water quality	
In-basin Harvest	6	Incidental take in legal fisheries	Harassment	9) Harvest-related adverse effects	BW14
	7	Illegal harvest of steelhead	Harassment	9) Harvest-related adverse effects	BW14

Basinwide Threats and Limiting Factors					
Threat	**#**	**Limiting Factor**	**Level 3 EDT Survival Factors**	**NOAA Limiting Factors**	**Actions**
Ecological Legacy	8	Slow recolonization of reopened habitats by small populations	NONE	NONE	BW6,7
	9	Lack of nutrients in rearing areas	Food	5) Degraded water quality	BW8,15
	10	Reduction of beaver activity	Channel stability, Flow	4) Altered hydrology 2) Degraded channel structure & complexity	BW11

Table 3.2: Lower mainstem Yakima threats and limiting factors

Lower Mainstem Threats and Limiting Factors					
Threat	**#**	**Limiting Factor**	**Level 3 EDT Survival Factors**	**NOAA Limited Factors**	**Actions**
Withdrawal of stream flow for irrigation and hydropower	1	Inadequate migration flow below diversions	Flow	Altered hydrology	LM2,5,7
	2	Loss of habitat quantity and diversity below diversions	Flow	Altered hydrology	LM2,5,7
	3	Increased summer water temperature below diversions	Temperature	Degraded water quality	LM7
Conveyance of irrigation deliveries and return flow in streams	4	High temperature, sediment and other pollutants in summer flow	Temperature, Sediment load, Chemicals	Degraded water quality Altered sediment routing	LM2,9
	5	False attraction due to high flow and/or mixing of sources	Flow	Altered hydrology	LM2,9
Water storage and diversion structures	6	Entrainment, injury or delay of downstream migrants at diversions	Withdrawals (entrainment), Obstructions	Impaired fish passage	LM3
Floodplain constriction and development	7	High water temperature, low flow in summer due to floodplain storage loss	Temperature, Flow	Altered hydrology Degraded water quality	LM7
	8	Degraded riparian vegetation needed for shade, bank stability and food	Habitat diversity	Degraded riparian area & LWD recruitment	LM6,7

Lower Mainstem Threats and Limiting Factors					
Threat	**#**	**Limiting Factor**	**Level 3 EDT Survival Factors**	**NOAA Limited Factors**	**Actions**
	9	Reduced availability of woody debris in the channel and floodplain	Key habitat quantity	Degraded riparian area & LWD recruitment	LM6,7
	10	Simplified, degraded, and/or unstable stream channels	Channel stability, Key habitat quantity	Degraded channel structure & complexity	LM6
	11	Reduced quantity and/or quality of side channel habitat	Habitat diversity, Key habitat quantity	Degraded floodplain connectivity & function	LM6,7
Management of Gravel Pits	12	Increased habitat for predatory and exotic fish	Predation, Competition (with other species)	Predation/Competition/Disease	BW10
	13	River capture creating channel instability and raising water temperature	Channel stability, Temperature	Degraded channel structure & complexity Degraded water quality Altered sediment routing	BW10
Non-native fish species	14	Predation by bass and catfish	Predation	Predation/Competition/Disease	LM3,7, BW16
Native predatory fish species	15	Increased predation by northern pikeminnow	Predation	Predation/Competition/Disease	LM3,7, BW16
Predatory birds and mammals	16	Increased predation by gulls and pelicans, especially at inriver structures	Predation	Predation/Competition/Disease	LM3,7

Table 3.3: Satus population area threats and limiting factors

Satus Threats and Limiting Factors					
Threat	**#**	**Limiting Factor**	**Level 3 EDT Survival Factors**	**NOAA Limiting Factors**	**Actions**
Conveyance of irrigation deliveries and return flow in streams	1	High temperature, sediment and other pollutants in summer flow	Temperature, Sediment load, Chemicals	Degraded water quality Altered sediment routing	S3,4
Water storage and diversion structures	2	Upstream migration blockages or delays at diversions	Obstructions	Impaired fish passage	S5
Floodplain constriction and development	3	High water temperature, low flow in summer due to floodplain storage loss	Temperature, Flow	Altered hydrology Degraded water quality	S1
	4	Simplified, degraded, and/or unstable stream channels	Channel stability, Key habitat quantity	Degraded channel structure & complexity	S1
	5	Reduced quantity and/or quality of side channel habitat	Habitat diversity, Key habitat quantity	Degraded floodplain connectivity & function	S1
Forest harvest practices, road construction and fire suppression	6	Impassable and/or unstable stream crossings	Obstructions, Channel stability	Impaired fish passage Degraded channel structure & complexity	S6

Satus Threats and Limiting Factors					
Threat	**#**	**Limiting Factor**	**Level 3 EDT Survival Factors**	**NOAA Limiting Factors**	**Actions**
	7	Loss of riparian, floodplain and wetland function due to tree harvest and road building	Habitat diversity, Flow	Altered hydrology Degraded riparian area & LWD recruitment	S7
	8	Acceleration and degradation of runoff (sediment, high summer temperature) by road and skid trail drainage	Sediment load, Temperature	Altered sediment routing Degraded water quality	S7
Grazing Impacts	9	Damage to stream channels, banks and riparian zones	Channel stability, Habitat diversity	Degraded channel structure & complexity Degraded riparian area & LWD recruitment	S2
	10	Sedimentation of streams	Sediment load	Altered sediment routing	S2
	11	High water temperature, low flow in summer due to wet meadow storage loss	Temperature, Flow	Altered hydrology Degraded water quality	S8

3.2.3 Relationships of Threats to Limiting Factors

The relationship between threats and limiting factors can be complex, with a single threat affecting many limiting factors, and a single limiting factor being a function of many interacting threats. Sections 3.5.1 to 3.5.6 describe the interaction of threats and limiting factors that affect the basin as a whole, the shared migration corridor of the lower mainstem and the four population areas. Section 3.6 gives a brief overview of threats and limiting factors acting on Yakima Basin steelhead during their time outside of the Yakima Basin.

3.3 In-Basin Threats and Limiting Factors

The following sections describe the threats and limiting factors that occur throughout the basin, in the Lower Yakima River, and in the four population areas—Satus Creek, Toppenish Creek, Naches River and Upper Yakima.

3.3.1 Basinwide Threats and Limiting Factors

See Table 3.1. for a compilation of basinwide threats and limiting factors, which are also linked to the recovery actions described in Chapter 5, Recovery Actions.

Basinwide Effects of Changed Flow Regimes

In the Yakima Basin, water is an essential resource. Since the 1850s, extensive water supply systems have been developed to store and deliver water to irrigated agriculture and, to a lesser degree, to industrial, domestic, and hydropower users. This has made the Yakima Basin one of the most productive agricultural regions in the United States and the world. The federal government authorized the Yakima Irrigation Project in 1905. This brought a number of private irrigation projects under the jurisdiction of the BOR and resulted in construction of five storage reservoirs that enabled expansion of irrigated acreage to 464,000 acres in six divisions. Lands irrigated under the Project extend from Cle Elum to the Tri-Cities. There are six major diversion dams (Easton, Roza, Tieton, Wapato, Sunnyside, and Prosser), 420 miles of canals, 1,697 miles of laterals, 30 pumping plants, and 144 miles of drains. Generators served by Roza and Chandler canals produce hydroelectric power ((BOR 2002), and a generator was installed at Tieton Dam in 2006. The Wapato Irrigation Project diverts its water from the river just below Union Gap to serve 136,000 acres of irrigated lands on the Yakama Reservation. Water delivery and storage systems in the basin range from these larger systems to small ditches on tributaries owned and managed by one or two private landowners. Many tributaries have been converted into irrigation distribution systems, such as the Wilson/Naneum Creek system in the Kittitas Valley, or drainage systems such as lower Toppenish Creek and Marion Drain.

These diverse systems are an essential part of the basin’s economy, past, and present. They have also had significant impacts on fish populations in the basin. Managing water supply and delivery systems in a manner that meets economic needs while minimizing negative impacts on fish populations is one of the principal challenges faced in

recovering steelhead populations. There have been many efforts to lessen the impact of this infrastructure on fish—improved screening, improvements in water use efficiency, reconstruction for improved or restored passage—but the infrastructure itself has remained in place and expanded over time. Additional changes in the configuration of infrastructure—the function and location of storage dams, delivery and return points for irrigation water conveyance, delivery, and routing of water—are required to address the impacts of the altered flow regimes (see Chapter 5).

Adequate flows are necessary for migrating adult steelhead to pass upstream to spawning areas, provide rearing habitat, and facilitate smolt emigration to marine environments. Flows also affect other habitat parameters like temperature, riparian vegetation, and food supply. In an unregulated condition, the flows in the Yakima Basin would be dominated by snowmelt-driven discharge peaks in May or June that then decline to ground-water driven base flows in August and September. Late autumn rainfall and minor snowmelt would augment summer base flow, with Chinook winds causing occasional winter high water events. Steelhead are adapted to these natural seasonal flow patterns, which maintained a variety of habitats and facilitated migratory behavior.

Management of water storage and delivery systems in the Yakima Basin has significantly altered this flow pattern. Now winter and spring runoff from the upper Yakima, Kachess, Cle Elum, Tieton and Bumping rivers is captured in storage reservoirs and is utilized to meet summer irrigation needs in accordance with yearly entitlements. These operations result in streamflows across the basin that are often out of phase with the life-history requirements of native salmonids (Fast et al. 1991; Stanford et al. 2002) and riparian species such as cottonwoods (Jamieson and Braatne 2001). The most significant changes in flow regimes are the creation of: 1) unnaturally low flows, 2) unnaturally high flows, 3) rapidly changing flow levels, 4) return flows, and 5) altered sediment and wood transport. Issues associated with each of these are described below. The most significant area in which a largely natural flow regime has been maintained is the Naches River above its confluence with the Tieton.

Reduced Flows

Low flows arise under two basic situations. From April through October, irrigation diversions and other water withdrawals reduce streamflows in tributaries throughout the basin (examples include Manastash, Ahtanum, and Cowiche creeks and the Teanaway River), in the lower mainstem Naches, and in the mainstem Yakima below Sunnyside Dam.[28] These low flows and associated increased temperatures limit the availability of summer and early fall rearing habitat in affected tributary and lower mainstem reaches and create passage barriers for migrating and rearing steelhead. As discussed in section 2.5.1.1, the timing of the start of upstream migration into the Yakima River by adult steelhead is driven by flow and temperature conditions. Decreased flows and increased temperatures generally prevent adults from entering the Yakima River prior to September. Since fish are holding in either the Columbia or Yakima rivers from mid-

[28] Winter diversions for power generation and, in some tributaries, for stock water, can also decrease stream flows. These instances are addressed in the area-specific discussions.

summer until spawning begins in late winter, the effect that this delay in in-migration has on survival and reproductive success is unknown.

Low flows also occur in the Tieton River below Tieton dam and the Upper Yakima and Cle Elum rivers when releases from Cle Elum, Kachess, and Keechelus dams are minimized to store water for irrigation. The effects of these low winter and spring flows on rearing juveniles are not well understood. Lowered flows also occur in the bypass reaches associated with the Roza and Chandler Hydro power plants.

These low flows and associated increases in water temperature are hypothesized to increase travel times for migrating smolts, expose smolts to increased predation rates, and reduce the extent and variety of off-channel habitat available for use during the out-migration period. In many years, these low flows truncate the out-migration window for smolts migrating downstream and may alter the emigration cues that trigger smolts to emigrate towards the ocean. It is also likely that reduced streamflow and longer travel time in the lower Yakima River decrease survival of kelts during their downstream migration. The need for a better understanding of the relationship between flows, temperature and other habitat conditions and survival of outmigrating smolts is highlighted in Chapter 7.

Overall, decreased flows and associated temperature regimes have a selective effect on Yakima Basin steelhead for both in-migration (delaying entry to the system) and out-migration (truncating the smolt run and kelt out-migration in late spring). EDT model results based on spawn timing and flow in the tributaries show that these effects probably are most severe on the Naches and Upper Yakima populations. The potential for viable steelhead life histories that included both short- and long-term juvenile rearing in mainstem habitats has been reduced by the loss of summer rearing habitat extent (low flow) and suitability (temperature) in the lower Naches River and the Yakima River below Sunnyside diversion dams.

Increased Flows

The mainstem Yakima, Cle Elum, Tieton, and lower Naches rivers are all used to deliver water stored in large headwater reservoirs to downstream users. This results in unseasonably high flows (Bumping Reservoir has a much more limited effect on the Bumping and Naches rivers due to its small size). Flows are increased further due to the “flip-flop” flow management strategy, which was established in 1981 in response to a suit brought against BOR by the Yakama Nation in order to protect spring Chinook redds in the Upper Yakima and Cle Elum rivers. Flip-flop consists of delivering water primarily via the Upper Yakima in the spring and summer while conserving water in Rimrock reservoir for use in August through October, when flows in the Upper Yakima are dropped to the levels that will be sustained through the winter in order to protect redds.

Water deliveries in general and flip-flop operations in particular result in high summer flow through the Cle Elum/Yakima arm until September when the water supply is switched to the Rimrock and Bumping reservoirs in the Tieton/Naches arm, which then experiences high flow until the irrigation season ends in October. While flip-flop has helped to protect upper Yakima spring Chinook, associated high flows have significantly impacted steelhead habitat. The most drastic impacts are in the Tieton River, where the

unnaturally high and sustained flows in late summer and fall are posited to have greatly reduced available habitat for rearing steelhead, both through the immediate influence of high velocities and the reduction in mid-to small sized sediment and woody debris (currently Oak Creek, a small tributary with unregulated flows, is the only part of the Tieton River watershed consistently used by spawning steelhead).

Fry emergence in the Upper Yakima occurs from mid-June through the end of July, when natural flows would begin to drop. The sustained high flows associated with irrigation water deliveries are hypothesized to reduce growth and potentially survival. Pearsons et al. (1993) studied at *O. mykiss* in regulated reaches of the Yakima Basin and hypothesized that such flow fluctuations during the month following swim-up were responsible for the scarcity of young-of-the-year observed during subsequent snorkeling and electro-fishing surveys in areas with highest redd densities. They also found that *O. mykiss* in the Yakima River grow slower than trout in other regional rivers, and attributed these slow growth rates to degraded growing conditions produced by reservoir releases throughout the summer rearing period. Flow manipulation may also affect steelhead through competition for food, which becomes scarcer under fluctuating or artificially high flows (James et al. 1999). The increases in summer flows and associated decreases in summer temperatures in the Upper Yakima are hypothesized to favor resident life histories in the mainstem, potentially reducing the number of anadromous smolts produced. Chapter 7 identifies better understanding the impacts of delivery flows and flip-flop on juvenile steelhead as a key knowledge gap.

In tributary settings, high flows associated with use for irrigation conveyance and operation spill from canals can have mixed effects on habitat conditions. This is primarily an issue in the lower reaches of tributaries to the Upper Yakima, which are used to convey irrigation delivery and return flows.

Rapid Changes in Flow

Flow oscillations during the irrigation season may also reduce habitat quality for juvenile steelhead. While a seasonal range of flows is vital, stable base flows support high salmonid growth rates during periods of high ecosystem production from late spring through early fall (Poff and Ward 1989; Stanford et al. 1996). Rapid reductions in flow associated with flip-flop operations in the Upper Yakima and Naches and the initiation of storage control below Parker can reduce macroinvertebrate populations that serve as food source (Arango 2001), and limit growth of riparian vegetation, especially cottonwood seedlings. Power plant operation and screen maintenance activities in the Chandler and Roza canals can also combine to produce large flow fluctuations in the Yakima River when the canals are dropped for maintenance and rewatered to generate power.

Return Flows

Return flows associated with irrigation use can increase stream temperatures and transport sediment and associated contaminants into natural waterways. Return flows can also create false attraction when water diverted upstream is released well downstream and attracts returning adults that gravitate towards the characteristics of the upper basin water

source. Note that subsurface return flows can also reduce water temperatures and provide habitat benefits. Specific return flow issues are addressed in subsequent sections.

Affects of Altered Flows on Sediment and Wood Transport

River systems naturally transport large amounts of sediment downstream. The continuous removal and deposition of sediment plays a key role in the formation of complex floodplains and associated fish habitat. These changes also affect fish through the availability of appropriately sized spawning gravels and the productivity of macro-invertebrate populations and other prey species. Both instream structures and changed flow regimes associated with water delivery and use can change sediment transport.

Large dams may prevent movement of sediment, resulting in reduced availability of sediment downstream. Smaller diversion dams and other instream structures can dramatically change sediment dynamics in upstream and downstream reaches. Changes in flow regimes change the ability of stream systems to transport and deposit sediments. Reaches regularly exposed to artificially high flows may show scouring, loss of spawning gravels, channel simplification, and loss of habitat diversity; inversely, areas with reduced flows may show increased deposition of fine sediments.

Dams, diversions, other structures, and changes in flow regimes can also significantly change the distribution of large woody debris in a river system by blocking its downstream movement in some areas and by washing it out of other areas. Woody debris has also frequently been removed as part of system operations and maintenance.

Flow-induced Changes in Vegetation

Altered flow regimes in most mainstem reaches are incompatible with the flow characteristics required for black cottonwood to successfully regenerate from seed (Jamieson and Braatne 2001). Cottonwood is dependent on a gradual reduction in the spring snowmelt runoff and on exposed sediments on gravel bars for seed establishment. Too rapid a drop in spring flows exceeds new seedlings' root growth ability, resulting in loss of root contact with the local water table and seedling death. Constant of increasing streamflow from spring into summer (as occurs in the Upper Yakima) limits the exposure of suitable substrates. High streamflow during the fall months (as occurs in the Tieton and lower Naches rivers) scours and "drowns" newly established seedlings. The effects are most notable in the Naches and Wapato reaches, where the number of exposed gravel bars and the channel width/depth ratio has increased over time. In the Upper Yakima, higher flows allow replacement of cottonwood stands by other shrub and grass dominated riparian vegetation (typically dominated by Russian olive, Pacific willow, reed canary grass, or European silver willow). It is currently unknown how the loss of cottonwood recruitment will affect steelhead. Cottonwood is a keystone species to interior Columbia riparian zones. Loss of this species will affect shade, large wood input, temperature, width/depth ratios, availability of riparian prey items for salmonids, and other ecosystem scale effects. Natural high spring flows may also play a role in limiting the extent of aquatic vegetation in the lower mainstem Yakima River.

Unscreened Diversions

Diversion structures and other water delivery infrastructure and practices (such as running irrigation ditches across natural streams) can also funnel fish into water delivery systems that are not managed as fish habitat. This can result in significant mortality when fish enter pumped systems or are stranded in irrigation ditches. It may also cause delay and injury for fish that are able to return to natural stream systems. Screening of diversions has been a priority in the Yakima Basin since the 1920s, when some of the first self-cleaning fish screen designs were developed in the basin. Many diversions, especially larger ones, have had effective fish screens installed, but there are also still many unscreened diversions in the basin.

Floodplain Development

The floodplain reaches of the Naches and Yakima rivers once consisted of complex networks of braided channels covered by dense riparian forests. In many areas, river channels have been leveed, armored, realigned, and shortened, severely diminishing natural river-floodplain interactions. Floodplains have always been favored sites for agricultural fields, industrial areas, residential and commercial structures, railways and roads, and extensive systems of dikes and drains have been built to protect these areas. Overall, floodplain development has resulted in profound alterations in fish habitat in the Yakima Basin, including:

- Reduced connectivity between streams and adjacent riparian areas, floodplains, and uplands
- Elevated fine sediment yields and water temperatures
- Reduced large woody debris to trap sediment, stabilize banks and form pools
- Reduced vegetative canopy to minimize solar heating of streams and provide bank stability and food
- Modified streams channels with reducing rearing habitat and increasing water temperature fluctuations
- Altered peak flow volume and timing, leading to channel changes and potentially altering fish migration behavior
- Altered floodplain function, water tables, and base flows
- Reduced flows in summer due to floodplain storage loss

For more general background on the impacts of floodplain development, see Henjum et al. (1994), McIntosh et al. (1994), Rhodes et al. (1994), Wissmar et al. (1994), National Research Council (1996), Spence et al. (1996), and Lee et al. (Lee et al. 1997). The best references on floodplain conditions on the Yakima are Snyder and Stanford (2001), Sanford et al. (2002), and Eitemiller et al. (2002).

Gravel Mines

Floodplain gravel mining has had significant impacts on floodplains throughout the basin, including along I-90 in Kittitas County, near the cities of Yakima and Selah and in the Wapato reach downstream. Dikes associated with gravel mines constrict the floodplain, and when they burst, gravel pits can cause avulsion of the river channel and act as sediment sinks that increase stream power and erosion downstream. Ponds in abandoned gravel pits can warm adjacent river temperatures and act as reservoirs for bass, catfish and other potential introduced species that prey on and/or compete with steelhead. Management of past, current and future gravel pit operations should strive to minimize these impacts (Yakima River Floodplain Mining Impact Study Team 2004).

Upland Watershed Development

While the effect of floodplain development on fish habitat is generally far more dramatic, upland development for commercial, residential, and agricultural use can also impact steelhead habitat. Increases in impervious area associated with buildings and pavement, reductions in vegetative cover, and the presence of roads, drainage ditches and storm water systems all facilitate rapid drainage of surface water, increasing streamflows and sediment inputs immediately after precipitation events, and reducing groundwater recharge and associated base flows in streams. Both overland flows and contamination of groundwater can result in transport of pollutants from upland areas to stream systems. Development pressure in the Yakima Basin is focused in the Naches and Upper Yakima population areas, in the greater Yakima area and in the corridor from Easton to Ellensburg.

Population Growth and Associated Development

While many of the impacts to fish habitat addressed in this plan are a function of past land use patterns, it must also address future development impacts. Human population growth in the Yakima Basin will continue, both from relatively high birth rates in the valley, and immigration into the valley. A review of the Comprehensive Plan Land Use maps of communities within the basin clearly indicate that whether urban or rural, the bulk of land use and development for future population growth will occur along the Yakima River main-stem and major tributary corridors where there is water, an existing core of rail and road transportation infrastructure, major concentrations of urban services, and high value shoreline property. Additionally, large numbers of eastern Washington residents recreate along the basin waterways. Population growth may increase camping, hiking, fishing, and off-road-vehicle activities, especially on the publicly owned lands of the upper watersheds. Numerous programs within local government, land use planning, and development regulations are designed to manage the impacts of population growth; applying these in a balanced manner that protects steelhead habitat while supporting economic growth and private property rights will require a strong commitment from local governments, landowners and the public at large.

Increased Forest Disease, Pests, and Landscape-scale Fire

The health and stability of many forest stands in the basin are declining, especially in the managed forests at lower and middle elevations on the Yakama Reservation, on state and

private lands, and on USFS lands in the Naches, Swauk, Teanaway, and Cle Elum drainages. A legacy of fire suppression has increased the density of less fire- and pest-resistant tree species, and consequently catastrophic fire or pest outbreaks are increasingly likely to occur. While periodic, low-level disturbance contributes to overall forest health, landscape-scale fires would likely result in increased peak flows, lower summer flows, and increased sediment delivery for several decades, increasing the risk of extinction for steelhead. The relationship between wildland fire to aquatic ecosystems is reviewed by Dunham et al. (2003) and Riemann et al. (2003) Current low funding levels for efforts to improve forest health suggest that the risk may continue to increase.

Forestry Practices

Habitat conditions in the forested areas of the basin are generally better than in lowlands, but past forest harvest practices, road construction and maintenance, and fire suppression have all had impacts of steelhead habitat. These activities can lead to road encroachment on streams and floodplains, riparian damage, impassable and/or unstable stream crossings, acceleration of runoff, increased landslides and sediment loading, elevated water temperatures, and increased streamflows or flood frequency due to loss of forest cover, especially on south facing watersheds. Numerous programs are underway to improve habitat conditions on federal, state, and private lands, but it will take several decades for the full benefits of these actions to accrue.

The Forest Service manages habitat for listed fish species on federal forestlands through several programs, including the Northwest Forest Plan and PACFISH/INFISH[29] Biological Opinions. The State of Washington's Forest Practice Rules address forest habitat conditions and functions needed for listed fish on non-federal lands, but there is some uncertainty as to the long-term adequacy of these rules to address all major ecological processes that maintain properly functioning habitat for all life stages of listed fish species. These efforts to regulate forestry activity will need to be reviewed to ensure that they adequately protect listed species and their habitats.

Managing the existing networks of forest roads so as to minimize watershed impacts will continue to be a priority. Timber companies are disposing of large blocks of private forestland in the Yakima Basin. Efforts to work with landowners to maintain economically viable working forests that also sustain steelhead habitat will be an important part of larger efforts to reduce fragmentation of the landscape.

Climate Change

The regional climate in the Northwest may be changing in response to global atmospheric changes. Scientists predict reduced winter snow pack, increased winter rainfall and increased summer drought. These changes affect fish populations when changes in precipitation and snow pack patterns directly affect streamflows and when higher

---

[29] PACFISH is the Interim Strategy for Managing Anadromous Fish-producing Watersheds in Eastern Oregon and Washington, and Portions of California. INFISH is the Interim Strategy for Managing Fish-producing Watersheds in Eastern Oregon and Washington, Idaho, Western Montana, and Portions of Nevada.

summer temperatures result in more evapotranspiration and increased water temperatures. Actions in this plan, including maintenance of habitats in high elevation areas, restoration of hydrology and passage, and improvement of riparian zones may reduce the effects of global warming. Climate change may also make colder habitats that are currently unsuitable for steelhead more suitable. The potential impacts of global climate change are recognized at national and international levels. The risks of global climate change are potentially great for Yakima Basin stocks because of the sensitivity of salmon stocks to climate-related shifts in the position of the sub-arctic boundary, the strength of the California Current, the intensity of coastal upwelling, and the frequency and intensity of El Nino events (Yakima Subbasin Fish and Wildlife Planning Board 2005). These changes could have significant effects on the success of recovery actions and the status of listed fish populations in the Yakima Basin (Climate Impacts Group 2009; Mastin 2008). Understanding and responding to changes in climate will be an important part of long-term recovery actions.

In-basin Harvest

Impacts of current fisheries in the basin are of two sorts: 1) incidental take during legal fisheries, and 2) illegal take and harassment. Both occur, but neither is considered a primary limiting factor for steelhead at this time. Past recreational steelhead fisheries had significant impacts on the run, with harvest levels ranging from 14% to 68% of the run between 1983 and 1988 (Yakima Subbasin Fish and Wildlife Planning Board 2005, p. 2-193). The harvest rate dropped in the late 80s and early 1990s, and the Yakima River and its tributaries were closed to steelhead fishing in 1994.

Current legal fisheries in the basin are highly regulated to reduce negative impacts on steelhead. Selective gear rules (no bait, single barbless hooks) for trout fishing are in effect in other tributaries known to support bull trout and steelhead spawning and rearing (e.g., Yakima River upstream of Roza Dam, Taneum, Swauk, Teanaway, Naches, Little Naches, Bumping, Rattlesnake, and American rivers). In some areas, including the Yakima River upstream of Roza Dam, the lower Cle Elum River, part of the Naches River and Rattlesnake Creek, trout fishing is limited to catch and release only. In remaining areas there are low catch limits for trout (generally two trout, minimum length 8 or 12 inches). Areas near the mouths of Toppenish and Satus creeks are closed for coho and fall Chinook during fall salmon fisheries to protect pre-spawning steelhead that hold in these areas during upstream migration. These regulations are designed to protect adult and juvenile steelhead and bull trout populations, while allowing economically important recreational fisheries for resident trout.

Despite these regulations, both incidental take and illegal harvest of steelhead occur. Angler interviews conducted by WDFW in the lower Yakima River during sport fisheries indicate that steelhead are incidentally hooked and released during Chinook and coho fisheries. Interviews suggest that there were between 13 and 146 steelhead caught and released each year during legal salmon seasons. Based on a 5% hooking mortality rate, this activity would kill up to seven steelhead in a given year. Both incidental take and poaching of steelhead during the winter fishery for whitefish pose a risk to steelhead adults holding prior to spawning. Starting in 2008, the winter whitefish fishery below

Granger was closed to protect holding steelhead, which are known to concentrate near the mouth of Satus Creek.

Loss of Nutrients from Anadromous Species

At the watershed scale, the loss of major contributors to the basin nutrient base, such as coho, sockeye, summer Chinook and components of the remaining steelhead and spring and fall Chinook populations, negatively affects the productivity of the ecosystem as a whole. Martin et al. (1994) suggested that low biomass in the Upper Yakima River may be related to low dissolved solids as expressed in conductivity measurements, but the correlation is not strong when certain other rivers are considered. Specific nutrients may correlate better with productivity, and salmon carcasses have been found in a number of studies to be a major source of these nutrients. Lowered ecosystem productivity has selective effects on steelhead life history (by reducing the tributary food base and selecting for shorter tributary residence), further reducing the potential for longer-term juvenile rearing within the basin. The lack of understanding about the actual effects of reduced nutrient transport by anadromous fish is a key knowledge gap identified in Chapter 7.

Reduction in Beaver Activity

In the Yakima Basin, the abundance and distribution of American Beaver (*Castor canadensis*) have been greatly reduced. Beaver have a tremendous influence on salmonid habitat quantity and quality. Loss of beaver dams has reduced the number of pools and straightened, widened, and incised channels. Streams have become disconnected from their floodplains and LWD supplies to streams have been diminished. The loss of beaver activity also alters sediment routing, stream temperature and hydrograph, and riparian zone composition and productivity. The loss of the ecological functions that beavers provide directly diminishes salmon productivity (Lichatowich 1999). These effects occur in both the upper watershed and in side channels along downstream river reaches.

Increased Predation

Fish, mammals, and birds are the primary natural predators of steelhead in the Yakima Basin. Although the behavior of steelhead precludes any single predator from focusing exclusively on steelhead, predation by certain species can be seasonally and locally significant. Recent changes in predator and prey populations along with major changes in habitat conditions have reshaped the role of predation (Li et al. 1987). Better understanding predation dynamics is identified as a knowledge gap in Chapter 7.

Non-native salmonids with the potential to prey on steelhead include hatchery-strains of rainbow, brook trout, and brown trout, all of which are found in upper parts of the Basin.[30] In the lower mainstem Yakima, introduced bass and catfish prey on steelhead, although the smolt out-migration occurs during periods that are cooler than optimal for

[30] WDFW ended stocking of brook trout and brown trout in the Yakima Basin in 2006 and now only stocks rainbow trout in lakes.

bass and catfish, and multiple years of bass diet data from the lower Yakima showed that bass generally do not prey on yearling-sized salmonids (Fritts 2004; Fritts 2006).

Changes in ecological dynamics caused by habitat changes have also increased predation by native species. Northern pikeminnow (a native fish whose abundance has increased due to more favorable habitat conditions under current river management) has the greatest potential to negatively affect the abundance of juvenile salmonids in the Yakima Basin. The pikeminnow is a large, opportunistic predator that readily adjusts feeding patterns to prey availability. Most adult salmonids within the Yakima Basin are opportunistic feeders and are therefore capable of preying on juvenile steelhead and bull trout. Native salmonids likely to have some effect on the survival of juvenile salmonids include adult bull trout, rainbow/steelhead trout, and cutthroat trout. Native species such as sculpins also prey on salmonid eggs and juveniles (Hunter 1959; Patten 1962; Patten 1971a; Patten 1971b).

Predation risk is also linked to water temperature. Studies have indicated predation rates increase at higher temperatures (Collis et al. 2000a; Gray and Rondorf 1986; NMFS 2000). Predation and high temperature may be acting synergistically to increase selection pressure on juvenile outmigration, although steelhead are considered less vulnerable than other salmonid species to piscine predators.

Avian predation on fish contributes to the loss of migrating juvenile salmonids in the Yakima River Basin. Fish-eating birds that occur in the Yakima Basin include great blue herons (*Ardea herodias*), gulls (*Larus spp*.), osprey (*Pandion haliaetu*s), common mergansers (*Mergus merganser*), American white pelicans (*Pelecanus erythrorhynchos*), double-crested cormorants (*Phalacrocorax spp*.), Caspian terns (*Sterna caspia*), belted kingfishers (*Ceryle alcyon*), black-crowned night herons (*Nycticorax nycticorax*), Forster's terns (*Sterna forsteri*), hooded mergansers (*Lophodytes cucullatus*) and bald eagles (*Haliaeetus leucocephalus*) (Stephenson and Fast 2005). These birds have high metabolic rates and require large quantities of food relative to their body size.

Yakama Nation data (J. Siegel, personal communication, 2006) point to common mergansers as the primary avian fish predator in the Yakima River from Keechelus Dam downstream to Roza Dam, and white pelicans as the primary avian predator from Roza Dam to the Columbia River, with a significant gull population at Wanawish (Horn Rapids) Dam. These estimates are based primarily on census data multiplied by consumption rates from the literature and are not prey species-specific. However, *O. mykiss* is only a significant component of the fish biomass in the Yakima River upstream of Roza Dam (G. Temple,WDFW, communication 2006).

Mammals may be an important agent of mortality to steelhead in the Yakima Basin. Predators such as river otters (*Lutra canadensis*), raccoons (*Procyon lotor*), mink (*Mustela vison*), and black bears (*Ursus americanus*) are common. These animals, especially river otters, are capable of removing large numbers of salmon and trout (Dolloff 1993). Otter-killed adult steelhead are frequently found along Satus Creek during spawner surveys (B. Rogers, YN, communication 2006). Black bears generally scavenge spawned-out salmon.

Increased Competition with Native Species

Increased competition can occur not only between steelhead and introduced species that did not co-evolve, but also between steelhead and other native species. This happens when anthropomorphic induced habitat change alters competitive relationships. For example, Reeves et al. (1987) found that redside shiners dominated juvenile steelhead at warmer temperatures. Thus, where habitat changes result in increased water temperature, increased competition with shiners may affect steelhead.

Human-caused changes in the relative abundance of native species can also change competitive interactions. For example, although coho salmon were native to the basin, the species was extirpated by the early 1980s. Recent efforts to re-establish coho (Hubble et al. 2004) and the ongoing supplementation of Chinook populations in the Yakima Basin are providing an opportunity for research on possible human-induced changes in competitive interactions. As noted in Section 3.5.1.11, however, these reintroduced coho and supplemented Chinook may also have the beneficial effect of importing oceanic nutrients into the basin.

Recent analyses (Pearsons et al. 2004) of the potential effects of reintroduced species on steelhead and bull trout have found some depression of rainbow and steelhead mean size at age since coho reintroduction and spring Chinook supplementation began in the Yakima Basin. However, preliminary results of Yakima/Klickitat Fisheries Project (YKFP) research indicate that this trend was not related to supplementation activities. This YKFP research continues.

Increased Disease

A variety of bacterial, viral, fungal, and microparasitic pathogens can infect steelhead. Numerous diseases may result from pathogens that occur naturally in the wild or are transmitted to wild fish by infected hatchery fish. Infectious hematopoietic necrosis virus, bacterial kidney disease (BKD) (*Renibacterium salmoninarum*), coldwater disease (*Flavobacterium psychrophilum*), and columnaris (*F. columnare*) have all been identified in salmonids in the Yakima River (BPA Division of Fish and Wildlife 1990; Pearsons and Thomas 2003; Yakima Indian Nation et al. 1990). Beginning as early as mid-April in water-short years, water temperatures in the lower Yakima River are in the range favorable for the development and serious progression of infectious salmonid diseases (Fryer and Sanders 1981; Jobling 1981). Steelhead are more resistant to BKD than are other salmon species, although Foott (1992) found high incidence of BKD in wild steelhead populations in the Trinity River.

Sublethal chronic infections can impair the performance of steelhead in the wild, thereby contributing to mortality or reduced reproductive success. Fish weakened by disease are more sensitive to other environmental stresses and may become more vulnerable to predation (Hoffman and Bauer 1971) or less able to compete with other species. When Reeves et al. (1987) found that water temperature affected competitive interactions between redside shiners and steelhead, they determined that the outcomes of interactions were, in part, related to infection with *F. columnare*. In their study, most steelhead were infected at warmer temperatures, whereas shiners showed a higher incidence of infection at cooler temperatures.

Increased Gaps Between Populations

Gaps between steelhead populations are assumed to have increased with the advent of irrigation, water storage, and floodplain development. Disproportionate decreases in abundance and productivity in lower tributaries of the Naches and Yakima rivers, (e.g., Cowiche Creek on the Naches; and Wenas and Umtanum creeks on the Yakima), along with increased mortality of the progeny of mainstem spawners due to flow manipulation and habitat damage, are believed to have widened the gaps between the Upper Yakima, Naches, and Satus steelhead populations. However, spawning in the Toppenish Creek watershed was probably limited to upper reaches throughout the Holocene epoch; also, spawning appears to be more prevalent today in the upper Yakima River mainstem than previously assumed (Karp et al. 2003; Karp et al. 2005). Whether successful spawning occurs in the Yakima below the Naches confluence is unknown and is identified as a knowledge gap in Chapter 7.

Genetic Impacts of Past Hatchery Management

Introduction of hatchery-origin rainbow trout or non-local steelhead from mixed Columbia Basin or Skamania stocks subjected all steelhead populations to some degree of genetic risk. During the 20th century, steelhead from several sources were introduced into the Yakima Basin; the predominant one was the Skamania stock from the Washougal River. In the mid-1980s, the Yakama Nation and WDFW agreed to produce fish from wild Yakima broodstock. Between 1985 and 1989, the Yakama Nation trapped broodstock at Prosser Dam for spawning, egg incubation, and rearing at the WDFW Yakima hatchery, with assistance from the Northwest Steelheaders and Trout Unlimited. The co-managers agreed to discontinue wild broodstock collection after 1989 because of the low smolt-to-adult survival rate and the inability to select population-specific broodstock at Prosser Dam. From 1990 through 1992, a small number of adult Yakima Basin steelhead were trapped and their progeny reared by YKFP researchers to evaluate species interactions in the upper Yakima River. Hatchery-produced steelhead smolts were last released in the Yakima Basin in 1993 (Fast and Berg 2001). Although these practices no longer occur, interbreeding with hatchery fish may have reduced the genetic fitness of some steelhead populations.

Introductions of resident rainbow trout are believed to have contributed to the decline of the anadromous form of *O. mykiss* in the upper Yakima. Genetic introgression from non-indigenous hatchery trout populations into the rainbow trout population of the upper Yakima is believed to have occurred (Phelps et al. 2000). Because interbreeding of resident rainbow and steelhead has been observed in the field (Pearsons et al. 1998), this introgression likely has also occurred in what remains of the upper Yakima steelhead stock. There is less evidence of introgression into the Naches stock (Phelps et al. 2000). While planting of hatchery trout has ceased, the continued presence of non-native genes in the rainbow population presents genetic risks to steelhead.

3.3.2 Lower Mainstem Threats and Limiting Factors

For an overview of the threats and limiting factors that occur in the lower mainstem Yakima (from the mouth to the Naches confluence), see Table 3.2. These threats are discussed in more detail below.

Altered Streamflows

Low flows in much of the lower Yakima River combine with high air temperatures, degraded riparian vegetation, and reduced floodplain function to create extended river reaches with water temperatures that exceed the physiological tolerances of native salmonids. Native and non-native predatory fish tolerate these conditions well and may be more efficient predators under these conditions. Additionally, poor water quality conditions in the lower Yakima River can lead to increased mortality rates in steelhead and other native anadromous smolts from water-borne pathogens (BPA Division of Fish and Wildlife 1990; Pearsons and Thomas 2003). High water temperatures persist in the lower Yakima River throughout the irrigation season. Migrating adult steelhead must hold on the Columbia River near the mouth of the Yakima River until the river cools in late summer or fall.

Changes in flow and associated temperature regimes may have had a strong selection effect on all populations of steelhead during both upstream migration (delaying adult entry to the system) and the downstream migration (truncating the smolt run and kelt outmigration in late spring/early summer). Steelhead life histories that include both short- and long-term juvenile rearing in the lower mainstem are no longer viable due to high temperatures, reduced water quality, and the resulting loss of summer rearing habitats in the lower mainstem Yakima.

Floodplain Alteration

The lower mainstem Yakima River flows through extensive floodplains in the Union Gap and Wapato reaches. Highways, railroads, and dike systems have cut off significant portions of the floodplain, reducing floodplain function and the availability of side-channel habitat. Stanford et al. (2002) identified the Union Gap reach as having the greatest potential for floodplain restoration. The Bureau of Reclamation's YRBWEP program has acquired significant amounts of floodplain property and is working with the county, the city of Yakima, gravel mine operators, and others to significantly improve floodplain function in this reach. In lower reaches of the Yakima, residential development along the river and associated alterations to natural riparian vegetation are becoming increasingly common. Little attention has been given to the floodplain reaches in the Tri-Cities area near the mouth of the Yakima River.

Creation of False Attraction Flows

Hydropower wasteways, such as Roza Power Plant Wasteway, irrigation drains, and spillways, including Sulphur Creek Wasteway and Marion Drain, discharge flow that can entrain or confuse adult steelhead during the upstream migration period. This can result in stranding of fish in unsuitable habitat and/or delays in upstream migration.

Reduced Water Quality

Degraded water quality (especially pH, dissolved oxygen [DO], and temperature conditions) significantly reduces habitat quality in the lower Yakima. Intensive agricultural production, including drainage improvements, and the use of fertilizers and pesticides have left a legacy of contamination (i.e., DDT and DDE in aquatic sediments and arsenic and lead in the soil profile), and residual concentrations of nutrients (i.e., phosphorus in lower river sediments), which may diminish only slowly over time.

Throughout the irrigation season, the lower Yakima River (downstream from Granger, RM 82) receives large volumes of irrigation return flows (Johnson et al. 1986; Rinella et al. 1999; Rinella et al. 1992). In 1997, the Roza Sunnyside Board of Joint Control initiated a water quality improvement program for drains and wasteways in the lower Yakima River, making significant strides at improving water quality in the lower river. In particular, fine sediment discharge has been reduced, although not eliminated.

The recent explosive growth of water star-grass in the lower Yakima River has led to concerns about its effect on water quality (especially dissolved oxygen), habitat, and migration conditions for salmonids. Growth of this native plant may have been augmented by advances in controlling suspended sediments, which increased light-penetration into the water column, and by long periods without bed-scouring high flows.

The Washington Department of Ecology (WDOE) has placed 72 watercourse segments throughout the Yakima Basin on the most recent 303(d) list (in 1998) of threatened and impaired water bodies (WDOE 1998). Primary impairments leading to these listings included increased temperatures, high agricultural pollutant concentrations (e.g., 4,4'-DDE, DDT, dieldrin, 4,4'-DDD, chlorpyrifos, endosulfan, and PCB), dissolved oxygen deficits, and a host of other water quality constituents (e.g., arsenic, mercury, silver, fecal coliform, pH, ammonia, chlorine, turbidity, and phosphorous) that are generally detrimental to fish health and persistence (Johnson et al. 1986; Morace et al. 1999; Rinella et al. 1999; Rinella et al. 1992). Current agricultural trends may result in reduced water use (e.g., conversion of large areas to wine grapes), but also increased nutrient loading and waste (e.g., from expansion of the dairy industry and other confined animal feeding operations). Recent dramatic improvements in water quality in the lower river have shown that concerted efforts by all parties can reduce agriculture’s impacts on water quality.

Predation by Introduced Species

Non-native fish species can prey on juvenile salmonids. Smallmouth bass have the greatest potential to negatively affect the abundance of juvenile steelhead in the lower mainstem of the Yakima. They are large, opportunistic predators that readily adjust their feeding patterns to prey availability. Abundant channel catfish also have the potential to prey on juvenile salmonids. WDFW currently has no catch limits on bass in the Yakima River, although only bass less than 12" or greater than 17" may be retained, of which no more than one may be over 17". There are no catch limits for channel catfish. Smolt outmigration generally occurs in conditions that are cooler than optimal for bass, as noted under predation in Section 3.3.1, but some overlap occurs. Better estimating the impacts of predation by bass is identified as a research need in Chapter 7.

Impaired Fish Passage

Significant work has been done to ensure fish passage at major irrigation diversions in the mainstem Yakima River. However specific seasonal operations and flow conditions at some diversions with fish ladders can still hinder adult upstream migrations. There is also significant uncertainty over the impacts of diversion structures on the survival of downstream migrating smolts, with some structures known to cause physical injury and/or concentrate predation (e.g., Horn Rapids (Wanawish) Dam and the Chandler Canal screen entrance and bypass outfall).

3.3.3 Satus Population Threats and Limiting Factors

For an overview of the threats and limiting factors that occur in the Satus Creek Watershed, see Table 3.3. Loss of floodplain habitats, reduced riparian zone health caused by intrusive roads and poor grazing management practice, and increased peak flow and sediment loads from forestry activities, including an extensive network of forest roads, have all diminished habitat productivity in this system. The Yakama Nation has had an active watershed restoration program in this basin since the 1980s.

Floodplain Alteration

The lowest eight miles of Satus Creek (below Mule-Dry Creek) have been simplified and confined to increase agricultural acreage. Although excavation and filling essentially ceased in the late 1980s, impacts to channel morphology and function remain (Ringer and McCoy 1998). Farther upstream, State Route 97 crosses Satus Creek five times and confines it for several miles. Riparian roads parallel several tributaries, confining stream channels and acting as alternative drainage systems.

Grazing Impacts

Fencing, off-stream water development, and conservation leasing of key riparian parcels have largely addressed negative impacts from cattle grazing, but wild horses have a heavy impact on wide areas of the watershed. Tributary wet meadow systems have become incised through loss of stabilizing vegetation, woody debris, and reduced lower beaver activity.

Forestry Impacts

Increased peak flows and sediment loads from forestry activities and the associated network of forest roads negatively affect Satus Creek. Work is ongoing to address road-related issues in the watershed.

Altered Streamflows

Streamflow in Satus Creek is essentially unregulated. The four irrigation diversions present on Satus Creek in 1980 were all shut down by 1991 to protect instream flows. In dry summers, the creek can still dry up for several miles within the alluvial reach upstream of the Logy Creek confluence (mile 23.6). Past grazing practices and extensive flooding in the early 1970s and 1990s have degraded floodplain conditions; ongoing

efforts to improve floodplain and upland function will be required to improve flow conditions.

Impaired Passage

The Wapato Irrigation Project's abandoned Satus diversion dam may act as a partial barrier to steelhead passage. A complete passage barrier exists where Highway 97 crosses Shinando Creek. Other barriers may exist on small tributaries in association with forest road networks.

Reduced Water Quality

Most of the Satus Creek watershed is undeveloped and is not exposed to agricultural, industrial, or domestic effluents, but because of degraded riparian habitats and low flows, maximum weekly average temperatures can exceed 26^{o}C in the Satus Creek reach between Logy Creek and Wilson Charley Creek (RM 39.3). Logy Creek may cool Satus Creek for a few miles downstream from their confluence. Water quality suffers (although water quantity increases) as Satus Creek flows through the Wapato Irrigation Project (WIP) in its lower eight miles. Improved management of return flows would increase conditions in the lower eight miles of Satus Creek. The relatively young and rapid steelhead outmigration from Satus Creek described in an earlier section appears to be a population response to harsh summer conditions.

3.3.4 Toppenish Population Threats and Limiting Factors

For an overview of the threats and limiting factors that occur in the Toppenish population area, see Table 3.4. Reduction in habitat productivity in this system is related to loss and alteration of floodplain habitats in lower Toppenish Creek, altered surface water/groundwater interactions in lower Toppenish Creek, altered flow characteristics on the alluvial fan of Toppenish Creek, reduction in flow and passage barriers in the Simcoe/Wahtum/Agency creek systems, and increased peak flow and sediment loads from forestry activities.

Floodplain Alteration

The Toppenish Creek channel historically assumed an anabranched appearance downstream of the Simcoe Creek confluence and flowed through an extensive network of wetlands for nearly 30 miles to the Yakima River. This system has been simplified to facilitate agriculture, grazing, and management of waterfowl habitat. Between RM 45 and the Simcoe Creek confluence (RM 32.7), diking, channel straightening, installation of drains, and low-capacity crossings have caused alternating deep incision and heavy deposition as the creek traverses its alluvial fan, reduced riparian vegetation, and compromised floodplain function.

Channel conditions upstream of the mouth of Toppenish Canyon are considered to be significantly better than in the downstream reaches. Riparian roads associated with timber harvest and the loss of beaver dams have straightened, widened, and incised the channel upstream of the mouth of Toppenish Canyon and degraded riparian conditions in the canyon portion of the watershed. Rapid deposition of gravel behind new channel grade

controls just below the canyon indicates more rapid erosion upstream than managers had assumed.

Altered Streamflows

The Toppenish Lateral Canal (TLC) at RM 44.2 historically diverted all flow in the creek from mid-June to mid-October. Despite recent adherence to a 10-cfs minimum flow requirement below the TLC diversion, natural seepage of up to 18 cfs into the expansive Toppenish Creek/Mill Creek alluvial fan results in a dry reach by late summer for several miles downstream from the three-way diversion. Most of the seepage does not reappear downstream before WIP return flows enter Toppenish Creek. A portion of the loss appears to seep into Simcoe Creek, which wraps around the toe of the fan, although seepage from the creek and from the TLC cannot be easily distinguished at this location. Other possible sinks are Harrah and Marion drains and large irrigation wells in the underlying basalt, which may be in communication with the fan. Despite this loss, the perennial section of stream downstream from the dam provides summer habitat for approximately 2,000 juvenile steelhead.

Two irrigation diversions downstream from the TLC supply Unit 2 and the Satus area of the WIP, primarily using return flows routed into Toppenish Creek via Mud Lake and Marion drains. Marion Drain, which is much deeper than Toppenish Creek for much of its length, intercepts subsurface flows that once entered the creek from the north.

The North Fork of Simcoe Creek provides the majority of flow in the Simcoe Creek watershed. Four private diversions and a WIP diversion (Simcoe Feeder Canal) historically took most of the base flow of Simcoe Creek. Since 2002, the Yakama Nation has worked to maintain minimum instream flows below all five Simcoe Creek diversions.

Reduced Water Quality

High water temperatures in lower Toppenish, Simcoe, and Agency creeks have resulted from diversion of annual spring flooding, draining of wetlands, riparian degradation, and the large volume of warm water irrigation returns routed from WIP down Simcoe and Toppenish creeks. As in Satus Creek, stream temperatures increase with proximity to the mouth of Toppenish Creek, with the highest weekly average temperature among four stations in 2004 approaching 24 degrees Celsius at a point 10 miles above the mouth. Data from the summer of 2007 indicate some cooling below stream mile 10 that may be related to upwelling. Temperatures in Marion Drain are about 6°C cooler in the summer and 5°C warmer in the winter than temperatures in the mainstem. This thermal moderation is attributable to the large proportion of groundwater in the drain; before the drain was constructed much of this groundwater presumably flowed into nearby Toppenish Creek.

Impaired Passage

In February 2006, Yakama Nation personnel confirmed that a private road crossing of Toppenish Creek just upstream from the Simcoe Creek confluence was impeding adult steelhead passage at moderately high streamflows of several hundred cfs. This crossing has the potential to hinder passage into the entire Toppenish Creek spawning population.

Several other passage barriers and unscreened diversions exist in Simcoe Creek and other tributaries.

Grazing Impacts

Fencing, off-stream water development, and conservation leasing of key riparian parcels have largely addressed negative impacts from cattle grazing, but wild horses have a heavy impact on wide areas of the watershed. Tributary wet meadow systems have become incised through loss of stabilizing vegetation and woody debris and lower beaver population size and activity.

Forestry Impacts

Increased peak flows and sediment loads from forestry activities and the associated network of forest roads affect the Toppenish Creek system. Work is ongoing to address road related issues in the watershed.

3.3.5 Naches Population Threats and Limiting Factors

For an overview of the threats and limiting factors that occur in the Naches population area, see Table 3.5. These threats are discussed in more detail below:

Floodplain Alteration

Most of the braided, alluvial floodplain reaches in the Naches system have been altered by highways, gravel pits, levees, local roads, agriculture, irrigation diversions, and rural and urban development, with the most severe impacts on the lower Naches below the Tieton confluence. The diversity of channel types in the Naches River upstream from the Tieton River confluence (RM 17.5) has been greatly reduced. Basalt canyon walls, riprapped dikes, road embankments, and revetments confine the upper channel. Bedload movement is apparent in some of the more narrowly confined reaches of the upper Naches River, and right-bank revetments, which protect homes, have cut off historic side channels and spring brooks.

Downstream from the Tieton confluence, the Naches River floodplain widens, although a highway and other structures have isolated the river from part of the active floodplain. Floodplain activities and structures (e.g., highways, gravel pits, levees, local roads, agriculture, irrigation diversions, rural and urban development) have degraded, removed, or altered the functional condition of the river-floodplain ecosystem.

The lower Little Naches River and the lower Bumping River are confined by highways and associated levees, which constrict floodplains and cut off historic side channels and meanders.

Channel Simplification

As noted earlier, changed flow regimes in the Tieton River combine with its natural confinement to simplify its channel. Tieton Dam captures the river’s main source of gravel, and the remaining gravel supply is readily transported by high flow. Because of unsuitable conditions in the mainstem Tieton, Oak Creek is the only portion of the Tieton

River watershed currently occupied by steelhead. Sections of the Little Naches have also been simplified by a highway that runs alongside the river for much of its length.

Impaired Passage

Tieton Dam has inundated or blocked the most productive habitats in the Tieton River drainage, which comprises a fourth of the entire Naches watershed, and Bumping Dam blocks six miles of upstream habitat. Telemetry data and spawning ground surveys suggest that only a small number of adult steelhead now reach the base of these dams, probably because upstream migration coincides with reservoir filling and low river discharge, which is most pronounced in the Tieton River, Migration efforts are further compounded by poor passage at the Yakima-Tieton diversion dam (RM 14.2). Modifications to the fish passage facilities at the Yakima-Tieton Diversion Dam are scheduled for completion in 2008. Passage into Cowiche Creek was eliminated or greatly reduced through the 20th century, but recent diversion improvements have reopened that watershed. Partial passage barriers have also been removed from the Ahtanum Creek watershed, and similar work is ongoing in Rattlesnake, Nile, and Wide Hollow creeks. Passage into other Naches tributaries is generally unimpaired.

Grazing Impacts

In the middle and upper portions of Cowiche Creek, Ahtanum Creek, and other mid-elevation tributaries, livestock have negatively impacted riparian zones by grazing and trampling streambanks. Cooperative projects with livestock managers have reduced grazing impacts in many of these areas. Extensive sheep grazing in the late 19th and early 20th centuries also significantly affected upland and riparian conditions throughout the Naches population area.

Forestry Impacts

Past forest practices and road networks have been affected Ahtanum and Cowiche creeks; ongoing efforts to manage and improve road systems will be needed. The upper watershed of the Little Naches River has been heavily logged. Spawning gravel is abundant in the Little Naches River and tributaries, although deposition of fine sediments increased after the initiation of large-scale clear-cutting. The lower 4.4 miles of the Little Naches River now afford the poorest spawning and rearing habitat in the drainage due sedimentation and confinement by roads and levees. Fine sediment in spawning substrates may be declining since an apparent peak in 1993 (Muir 2003).

Streamside Recreation

The upper Naches River watershed is a popular recreation area. Activities, which include recreational mining, establishment of dispersed camp sites, and off-road vehicle use, have had major impacts on various streams, streamside habitats and species, increased sedimentation, reduced riparian and floodplain function, and reduced abundance and spatial structure of listed species. Impacts have been greatest in the Little Naches and American River watersheds, but recent efforts by the USFS and others are significantly moderating these impacts.

Altered Streamflows

Flow regimes in the Naches Basin and associated tributaries can be put into three groups: 1) the highly modified flows of the Tieton and Lower Naches rivers; 2) the relatively natural flow regimes of the Naches and its tributaries above the Tieton River and of tributaries above Rimrock and Clear lakes; and 3) the lower tributaries subject to irrigation withdrawals, such as Cowiche, Ahtanum, and Rattlesnake creeks.

The Tieton River has the most skewed hydrograph of all Naches River tributaries, varying from less than 100 cfs, while the Rimrock Lake reservoir is filled from late October through March to nearly 2,000 cfs when the reservoir supplies most of the Yakima Project's irrigation demand each September as part of flip-flop operations. These flow effects persist downstream, with Naches River discharge rapidly quadrupling in late summer as the Tieton Dam gates are opened. This rapid increase in flow in the Tieton and lower Naches during a time of year when natural flow fluctuations would be uncommon is likely to displace and even injure or kill early juvenile steelhead, which are not large enough to maintain position in high river flow. Although flip-flop flows in the lower Naches may open access to side- and off-channel areas that could be used by juvenile steelhead, the rapid increase and decrease in flow can cause dewatering and stranding. Monitoring is needed to understand what happens when these conditions occur. From October through early summer, the Naches, Tieton, and Bumping rivers are flowing below estimated unregulated stream flow levels, which also affect salmonid habitat values.

During the summer months, irrigation withdrawals reduce flows in the lower Naches River, decreasing the availability of rearing habitat. Recently, the BOR and WDOE acquired the Wapatox hydropower site and its water right. Flows that formerly were diverted for power generation at this site are now remaining in-stream in a critical low-flow reach of the Naches River. However, the Wapatox Canal also serves irrigators, and their requirement for conveyance water limits the quantity of water that can be placed instream.

In contrast to the Tieton and the lower Naches, the Naches River and its tributaries upstream from the Tieton River still exhibit a largely normative flow regime, regulated only by the relatively small Bumping Lake reservoir.

Cowiche, Ahtanum, lower Nile, and Rattlesnake creeks have numerous irrigation diversions, which significantly reduce summer and fall flows, and at times have dried up portions of the creek beds. In recent years, significant efforts have been made to secure instream flows in Cowiche and Ahtanum creeks. The small steelhead subpopulation in Ahtanum Creek was mostly ignored through a century of over-appropriation and dewatering of the lower reaches, but appears to be responding to recent efforts to maintain a summer flow of 10 cfs throughout the mainstem.

Rattlesnake Creek provides good to excellent habitats in its middle and upper reaches. In the lower reaches of Rattlesnake Creek, irrigation diversions, low flow associated with floodplain loss, and the accumulation of coarse sediments limit habitat availability and diversity.

Impacts from Increased Development

Rapid population growth and development is occurring in Yakima County (including the cities of Yakima, Union Gap, Selah, Moxee, and outlying rural areas). In the Ahtanum Creek watershed, along the Naches River above the Tieton, and parts of the Cowiche Creek watershed, residential or recreational home development is often located adjacent to streambanks. Near the cities of Yakima and Union Gap, agricultural lands, many with shallow groundwater, are being converted to residential, commercial, and industrial uses. Conversion of agricultural lands to other uses will be accompanied by fragmentation of ownerships and land uses, each with different management goals. The probability of conflict between new land owners/land uses and floodplain/stream channel functions (which sustain fish habitat and conveyance of water and sediment) is high.

3.3.6 Upper Yakima Population Threats and Limiting Factors

For an overview of the threats and limiting factors that occur in the Upper Yakima population area, see Table 3.6. These threats are discussed in more detail below:

Floodplain Alteration

The once extensive floodplains of the Upper Yakima in the Easton, Cle Elum, Ellensburg, and Selah reaches contained multiple channels and large areas of spawning and rearing habitat for steelhead. Roads, including I-90, railroads, and dikes associated with agriculture, development, and gravel mining have constricted these floodplains. Near Ellensburg significant efforts are being made to reopen access to side channel habitat that has been incorporated into irrigation systems.

Impaired Passage

Passage barriers have significantly reduced the habitat available to anadromous steelhead in the Upper Yakima population area. Cle Elum, Kachess, and Keechelus dams block all upstream movements and allow only limited downstream movements. Cle Elum Dam has inundated or blocked an important component of Yakima River tributary steelhead habitat, the BOR estimating that 29.4 miles of potentially useable anadromous habitat are located upstream of Lake Cle Elum ((BOR 2005).

A number of tributaries to the Upper Yakima River (e.g., Swauk, Wilson, Naneum, Big, Little, Taneum, Manastash, Tucker, Cooke, Caribou, Coleman, and Reecer creeks and the Teanaway River) are likely to have historically supported steelhead, but impassable dams, dry reaches below dams and unscreened and inadequately screened diversions have eliminated steelhead from many of these tributaries. Diversion structures at Tucker, Naneum, Manastash, Cooke, and Caribou creeks were built without passage facilities. In many cases (e.g., Manastash, Taneum and Naneum creeks), the forested watersheds above the agricultural zone support very good habitat. Low flows and unstable channel conditions, including the construction of recreational dams during the summer migration season, also inhibit movement of steelhead in the Teanaway River.

Roza Dam is a potential bottleneck for outmigrating smolts. When runoff is low, the design of the Roza spillway gates hinders downstream passage for fish that miss the

bypass, as the only available passage is a narrow slot underneath the gates. Under these conditions, significant concentrations of smolts have been observed in the pool above the dam. Delays can result in immediate mortality, residualization, or delaying arrival in the lower Yakima River until periods when low flow, high temperature, and increased predator activity reduce survival.[31] BOR has recently been "tucking" a spillway gate at Roza Dam to allow surface spill when river flow permits and is evaluating options for modify the spillway gates so that surface spill can take place at lower river flow.

Historically Roza Dam was also a seasonal barrier to migrating adults moving upstream. Every year between 1939 and 1958 when winter power diversions were first begun, the Roza Dam forebay was kept at minimum elevation for significant periods between mid-October and mid-March. The fish ladder was operational only at full pool, while the spillway was and is impassable at all pool levels. Based on the University of Washington's DART database, between 1999 and 2009, 20% of the steelhead passing Roza was counted between November 1 and March 15. These data, collected since power diversions and associated winter ladder operations were initiated, suggest that a significant proportion of the steelhead bound for the Upper Yakima prior to 1958 may have been delayed or prevented from reaching their destination due to the seasonal ladder closures.

The original Roza Dam fish ladder only operated at full pool levels. A new ladder was installed at Roza Dam in 1989 that allows passage at minimum pool and full pool levels, but there is no passage at levels between these extremes, which occur while the pool, is being drained or filled (a period of days a few times a year). There is also the possibility of reduced passage at Easton Dam in dry years when BOR guidelines call for closing the dam's fish ladder in the spring to prevent spring Chinook from spawning in sections of the Upper Yakima that will not have sufficient winter flows to protect the redds. Closure of the Easton Dam fish ladder has not occurred since 1996.

Although major water diversions are screened, numerous unscreened diversions exist on tributaries. These are being addressed in conjunction with efforts to remove passage barriers and improve riparian conditions in the lower reaches of tributaries in the Ellensburg area.

Altered Streamflows

Unnaturally low flows in the Upper Yakima and Cle Elum rivers when reservoirs are being filled may inhibit steelhead migration and spawning. An emphasis on reservoir refill in water-short years may also result in low winter and spring streamflows that affect the extent and quality of juvenile rearing habitat. More data are needed on the impact of reservoir fill timing and associated low flows on adult and juvenile migrations and juvenile steelhead rearing environments.

---

[31] While empirical data on the constraints to juvenile passage at Roza are primarily available for hatchery Chinook smolts, the same conditions are expected to be encountered by outmigrating steelhead.

There are large releases of water into the Upper Yakima and Cle Elum rivers during the summer irrigation season. As discussed in Section 3.5.1.3, this may both reduce growth and survival of young-of-the-year steelhead and promote residency for older juveniles. Due to the flip-flop regimes, significant portions of streambed along the Upper Yakima and Cle Elum rivers are dewatered within a week in early September, with likely adverse effects on benthic macroinvertebrates and juvenile native and anadromous fish (Arango 2001; James et al. 1999; Pearsons et al. 1996). Pearsons et al. (1996) surveyed juvenile salmonid (including steelhead) use of side channel habitat in the Cle Elum and Upper Yakima rivers, and determined that 3 of the 21 monitored side channels and sloughs were totally dewatered and another was disconnected from the main channel after flip-flop. The authors concluded from this indirect evidence that nearly all juvenile salmonids they found in these side channels before flip-flop were likely killed because of rapid dewatering (83% flow reduction in two weeks). Monitoring is needed to understand what happens when these conditions occur.

Irrigation diversions have dewatered the lower reaches of many tributaries (e.g., Swauk, Teanaway, Taneum, Manastash and Big creeks), creating flow and temperature conditions that reduce juvenile rearing capacity. Efforts to secure instream flows in these reaches are ongoing. Other tributaries (e.g., the Reecer and Wilson creek systems) have flows that have been significantly increased in summer due to their use for irrigation water conveyance.

Simplification of Natural Waterways Used for Conveyance

In the Wilson/Naneum and Currier/Reecer creek systems in the Kittitas Valley, tributaries and side channels have been highly modified to facilitate use as part of irrigation distribution systems. This has resulted in simplification of channel structure due to 'ditch' cleaning, diking, and removal of vegetation. These areas are also typically subject to passage barriers by numerous diversions and to degraded water quality. Habitat that was once suitable for rearing and, in some cases, for spawning has often been rendered inaccessible and/or inhospitable. The Kittitas County Conservation District, Yakama Nation, Kittitas Conservation Trust, and others are working to open up many of these areas.

Reduced Water Quality

Although water quality in the Upper Yakima Basin is generally much better than in the lower basin, irrigation effluents and flow regulation have adversely affected some areas (Joy 2002; Joy and Patterson 1997). The Upper Yakima and Cle Elum rivers, as well as tributaries to the Yakima River in the Kittitas Valley (e.g., Cherry, Cooke, Wilson, Taneum, and Manastash creeks), are 303(d)-listed for numerous water quality problems.[32] Seasonal decreases in natural flow, along with added irrigation effluents expose regulated reaches to high late-summer ambient temperatures, suspended sediments, agricultural pollutants, and other adverse water quality constituents, including

[32] For more information on 303-d listings see the Department of Ecology's State Water Quality Assessments at http://www.ecy.wa.gov/programs/wq/303d/index.html

fecal coliform bacteria, low dissolved oxygen, and elevated nutrients. These issues are most pronounced in the Wilson Creek system.

Forestry Impacts

Past forest practices and road networks have affected many parts of the Upper Yakima; ongoing efforts to manage and improve road systems will be needed. Because of its south-facing aspect and its steep, confined tributaries, the Teanaway watershed is especially prone to increases in peak flow resulting from changes in watershed condition associated with forest road networks and timber harvest activities. Recovery planners consider the Teanaway River to be the highest priority in the basin for identifying and reducing impacts from forest practices.

Grazing Impacts

Past and current grazing practices have negatively affected riparian conditions in many of the mid-elevation tributaries to the Upper Yakima River. Cooperative efforts to work with livestock managers to address remaining impacts are ongoing.

Streamside Recreation

The Upper Yakima Population Area contains a number of popular streamside recreation areas. Recreational mining, establishment of dispersed campsites, and off-road vehicle use have increased sedimentation and reduced riparian and floodplain function on various streams, streamside habitats, and species within the basin. These conditions have contributed to the reduced abundance and productivity of listed fish species.

Impacts from Increased Development

Kittitas County and cities within the county, such as Ellensburg, Cle Elum, Ronald, Roslyn, and others, are experiencing rapid population growth and associated development. In many areas, forest and agricultural lands are being converted to residential development. Development immediately adjacent to the mainstem river and to tributaries can result in reduction or elimination of riparian zones and increase flood hazard. Adjacent to the city of Ellensburg, agricultural lands (many with shallow groundwater) are being converted to residential, commercial, and industrial uses. Conversion of agricultural lands to other uses will be accompanied by fragmentation of ownership and land use. The probability of conflict between new land owners/land uses and floodplain/stream channel functions (which sustain fish habitat and conveyance of water and sediment) is high.

3.4 Out-of-Basin Threats and Limiting Factors

Conditions in the Columbia River, its estuary, and the Pacific Ocean significantly affect the productivity, abundance, and life history diversity of Yakima Basin steelhead. In its All-H analysis, NOAA Fisheries is estimating the survival rates for the Middle Columbia Steelhead DPS from the mainstem Columbia to the ocean and back. There are currently no estimates of the effect of out of basin factors on the other VSP metrics for Yakima steelhead populations. The BPA, the Corps of Engineers, the BOR, NOAA Fisheries,

WDFW, Tribes, and others are implementing actions to improve survival of anadromous fish in the Columbia and the ocean. Current and proposed actions are being assessed as part of development of a new Biological Opinion for the Federal Columbia River Power System.

This plan focuses on conditions within the Yakima Basin, but understanding how in-basin actions interact with these out-of-basin factors is crucial to understanding the potential effectiveness of our in-basin actions. This requires monitoring out-of-basin survival rates for Yakima Basin steelhead populations (see Chapter 7).

While this plan does not address out-of-basin impacts on Middle Columbia River Steelhead in detail, a brief overview of significant issues is given below. Areas where impacts on Yakima Basin steelhead may be different from impacts on Middle Columbia River Steelhead as a whole are highlighted.

3.4.1 Out-of-Basin Effects on the Lower Yakima Basin

Conditions immediately beyond the mouth of the Yakima River influence conditions for steelhead in the lowest part of the Yakima River. The mainstem Columbia now provides excellent habitats for exotic species such as smallmouth bass and catfish, which migrate into the lower Yakima and may increase in-basin predation risk. The diverse habitat of the Yakima River delta, which once included an extensive forested riparian zone and numerous side channels, has been degraded and partially submerged by McNary Pool, an adjacent portion of the Columbia River upstream of McNary Dam. Changes to the Columbia River hydrograph may also affect the shared groundwater/surface water system of the Yakima River downstream of Wanawish Dam, where temperature extremes currently limit salmonid survival and diversity. These potential out-of-basin impacts on the Lower Yakima need to be studied to determine if they are negatively affecting listed species, and if so, how their effects can be reduced.

3.4.2 Columbia River Dams

Steelhead migrating to and from the Yakima Basin pass four Columbia River hydroelectric dams: Bonneville, The Dalles, John Day, and McNary. These dams are maintained for primarily hydroelectric production, navigation, and irrigation. They affect survival rates, migratory patterns, and timing of Yakima steelhead populations. Access and passage through these dams results in the direct mortality of both adults and juveniles at each dam. These dams have also significantly changed the nature of fish habitat in the Columbia above Bonneville Dam, replacing former rapids, pools, and riffles with wide, deep, slow-moving reservoir habitat. These impoundments affect the temperatures and travel times faced by migrating fish and result in increased exposure to predation. Extensive efforts are being made to improve the survival of anadromous fish through the Columbia River hydrosystem. The future of these actions is being negotiated as part of development of the revised Biological Opinion for the Federal Columbia River Power System.

3.4.3 Columbia River Estuary

The Columbia River estuary is a key habitat where juvenile and adult fish make the physiological transition from fresh to saltwater and vice versa. Pearcy et al. (1992) found that environmental conditions encountered by juveniles in the ocean, which includes the estuary and the river plume, are important predictors of the success of a brood year and the overall adult return rates.

The Columbia River estuary has been extensively modified. Estuary habitat has been lost due to dredging of a shipping lane, diking and the sedimentation and active filling of side channels (Weitkamp 1994). Dredge spoils have been used to create artificial islands in the estuary, which fish eating birds (e.g., Caspian terns, Double-crested Cormorants and gulls) use as nesting, resting, and foraging grounds. Upriver dams have created reservoirs that act as settling ponds, reducing the delivery of sediment and organic matter to the estuary (Sherwood et al. 1990). The cumulative effects of urbanization, industrialization, agricultural practices, and dams have degraded water quality in the estuary.

Prior to flow regulation, spring freshets created an immense freshwater plume at the mouth of the Columbia during the time that smolts were entering the ocean. Conditions within the plume may protect juvenile salmon making the transition to the ocean. The freshwater-saltwater margins of the plume provide key feeding areas. Reduction in the spring flows from the Columbia River has greatly reduced the size of the plume and its influence on nearshore marine conditions (Sherwood et al. 1990) and is believed to reduce survival conditions for emigrating juvenile salmonids (Pearcy 1992).

3.4.4 Ocean Conditions

Listed steelhead from the Yakima Basin spend a significant portion of their lives and accumulate most of their body mass in the marine environment. About half the mortality to salmonids occurs in the ocean (Bradford 1995). Conditions in the ocean affecting survival are subject to short-and long-term variation and are a source of significant variation in salmon returns to freshwater (Beamish and Bouillon 1993). Specific understanding of the marine ecosystem inhabited by Columbia Basin salmon and steelhead is limited. However, it is clear that short- and long-term cycles drive marine productivity and salmon survival. These cycles are the result of forces acting across the Pacific Ocean that affect currents, temperature, upwelling, and nutrients in coastal areas inhabited by Yakima Basin steelhead. Short- and long-term changes in marine productivity cascade through the food chain and affect salmonid abundance. Annual fluctuations in ocean survival make the potentially positive effects of freshwater restoration actions difficult to detect. At the same time, the negative effects of habitat degradation may be masked by improving marine conditions, leading to deeper reductions when the ocean subsequently shifts to a regime of poorer conditions (Lawson 1993).[33] The need to evaluate smolt-to-adult and adult-to-smolt ratios to separate out the influences of in- and out-of-basin conditions is highlighted in section 7.2.2. The effects of

[33] Much of the background information on lower river, estuary, and ocean effects is taken from the Snake River Salmon Recovery Plan (2005).

ocean conditions on Yakima Basin steelhead will be incorporated into NOAA Fisheries' all-H analysis for the Middle Columbia River Steelhead DPS as a whole. We are not aware of any aspects of ocean survival that are distinct for Yakima steelhead stocks when compared to Middle Columbia River Steelhead as a whole.

3.4.5 Out-of-Basin Harvest

Harvest in the Columbia River, estuary, and ocean fisheries has historically been a major limiting factor for anadromous fish in the Yakima Basin. Current commercial, recreational and subsistence fisheries are managed to minimize impacts on listed stocks, but some level of incidental mortality in mixed-stock fisheries is known to occur. Better estimating the impacts of fisheries in the Columbia will help us understand the degree to which harvest affects in-basin returns.

3.4.6 Predation

The altered environments of the mainstem Columbia and its estuary support a variety of both native and non-native predators. Changed river conditions have increased predation by native northern pikeminnow, while introduced species like walleye and bass also prey on migrating smolts. Avian predators such as Caspian terns, Double-crested Cormorants and gulls also have significant impacts (NMFS 2000). The creation of artificial islands in the Columbia River estuary from dredge spoils attracts opportunistic fish-eating birds, which feed on juvenile salmonids migrating from the Columbia River to marine habitats (Antolos et al. 2005). In the Columbia River estuary, avian predators are estimated to have consumed 18% (range, 11-30%) of smolts (all species) reaching the estuary in 1998 (Collis et al. 2000b). Relocation of nesting terns from Rice Island to East Sand Island has resulted in a reduction of the percentage composition of salmonids in their diet (Collis et al. 2002).

Yakima steelhead populations are exposed to out-of-basin avian predation that other Middle Columbia River Steelhead major population groups bypass because of the Yakima River's location. Bird populations on islands in the Columbia near the mouth of the Yakima are known to consume steelhead migrating out of the Yakima River. In 2005, an estimated 1% (22) of PIT tags from outmigrating Yakima River steelhead were subsequently recovered on the Crescent Island Caspian tern colony. In 2004, the figure was 2% (A. Evans, Real Time Research Inc., communication 2006). In 2005, only 0.1% (3 PIT tags) of PIT-tagged Yakima River steelhead were recovered on the Badger Island pelican colony (located just downstream from the mouth of the Yakima with >1057 adult birds present). PIT tag recoveries from the Foundation Island colony of double-crested cormorants, situated 8 km upstream of Crescent and Badger islands indicated an overall steelhead predation rate about 1/5 as great as for the tern colony, though this is changing as tern numbers drop and cormorant numbers increase (Collis and Roby 2006). These rates do not account for ingested PIT tags deposited off the colonies or for mortality of tagged fish (at least 50% for Yakima steelhead) between release sites and the Yakima River mouth.

Pinnipeds, including harbor seals (*Phoca vitulina*), California sea lions (*Zalophus californianus*), and Steller's sea lions (*Eumetopia jubatus*) are the primary marine

mammals preying on steelhead originating from the Yakima Basin (Spence et al. 1996). Pacific striped dolphin (*Lagenorhynchus obliquidens*) and killer whale (*Orcinus orca*) may also prey on adult steelhead. Seal and sea lion predation is primarily in saltwater and estuarine environments, although they are known to travel well into freshwater terrain in pursuit of migrating fish. While in recent years, significant numbers of sea lions have entered the Columbia River below Bonneville during the spring, they are not generally present during the July-August migration window for Yakima steelhead. All of these predators are opportunists, searching out locations where juveniles and adults are most vulnerable. Although marine mammals and salmon coexisted long before man interfered ecologically, human alterations and management practices throughout the species' ranges have resulted in a reduction in salmon and steelhead abundance to the point that increased or targeted predation can have more significant effects on population viability.

3.4.7 Competition with Non-Native Species

A potentially important source of exploitative competition occurring outside the basin may be between the exotic American shad (*Alosa sapidissima*) and juvenile steelhead. Palmisano et al. (1993) concluded that increased numbers of shad likely compete with juvenile salmon and steelhead, resulting in reduced abundance and production of salmon and steelhead. It is also hypothesized that the large numbers of shad in the Columbia contribute to the growth of northern pikeminnow, smallmouth bass, and walleye, which are important predators of salmon and steelhead. Shad may be sustaining large populations of predators during periods when salmon and steelhead are not available to the predators, and, as a result, more and larger predators are present during periods when salmon and steelhead are moving through the Columbia River. Research is needed to assess the direct and indirect effects of American shad on the abundance and survival of Yakima Basin steelhead.

4 Recovery Goals and Criteria

4.1 Recovery Goals
4.2 Recovery Objectives & Criteria
4.3 Recovery Strategies

Recovering listed species requires reducing or eliminating threats to the long-term persistence of populations, maintaining widely distributed populations across the diversity of habitats in their native ranges, and preserving genetic diversity and life-history characteristics. According to current guidance from NOAA Fisheries, demonstrating recovery of the Middle Columbia River Steelhead will require showing that populations, MPGs and the DPS, have met certain measurable and objective criteria based on the Viable Salmonid Populations (VSP) framework (ICTRT 2004) and the threats criteria identified in the listing.[34] This chapter presents measurable goals, objectives, and criteria based on the four VSP parameters of abundance, productivity, spatial structure, and diversity and then describes general strategies for achieving these criteria. Specific actions that implement the general strategies are described in Chapter 5.

4.1 Recovery Goals

The overall goal of this plan is to ensure long-term persistence of viable populations of naturally produced steelhead distributed across their native range in the Yakima Basin. A "viable" population is defined as an independent population that has negligible risk of extinction due to threats from demographic variation, local environmental variation, and genetic diversity changes over a 100-year timeframe. This recovery plan is build around three separate but linked sets of thresholds for assessing progress towards recovery: a delisting threshold, a short-term recovery threshold, and a long-term recovery threshold.

4.1.1 Delisting Threshold

The delisting threshold is based on the recovery scenarios identified by the ICTRT (2007a; 2007b) with minor modifications based on discussions between local recovery planners and the ICTRT. When these criteria and similar criteria for other MPGs within the Middle Columbia DPS are met, a proposal to delist the DPS is considered appropriate by the ICTRT. According to the ICTRT (2007b, p. 8), an MPG meeting the following five criteria would be at low risk:

1) At least one-half of the populations historically within the MPG (with a minimum of two populations) should meet viability standards.

2) At least one population should be classified as "Highly Viable."

3) Viable populations within an MPG should include some populations classified (based on historical intrinsic potential) as "Very Large," "Large," or "Intermediate," generally reflecting the proportions historically present within the

[34] See the Federal Register, Volume 71, p. 834.

MPG. In particular, Very Large and Large populations should be at or above their composite historical fraction within each MPG.

4) All major life history strategies that were present historically within the MPG should be represented in populations meeting viability requirements.

5) Populations not meeting viability standards should meet or exceed the maintenance standard[35] with (a) sufficient productivity so the overall MPG productivity does not fall below replacement (i.e., these areas should not serve as significant population sinks) and (b) sufficient spatial structure and diversity demonstrated by achieving such maintenance standards.

Choices made by the Yakima Basin Fish & Wildlife Recovery Board in applying the ICTRT standards include presuming that 1) the Naches would achieve at least the Viable standard (meeting the ICTRT requirement for one of the large populations to be classed as Viable), 2) the Satus population is the most likely candidate for Highly Viable status, and that 3) the Toppenish and Upper Yakima populations would meet or exceed the maintenance standard for remaining populations. Other combinations that also meet ICTRT guidelines are possible, and if during implementation these seem more appropriate to pursue, the delisting strategy should be revised accordingly.

The Yakima Basin Fish & Wildlife Recovery Board also split the Satus Population into the Satus Creek and Mainstem blocks, as described in section 2.2. The Satus Creek block is attributed the number of spawners the ICTRT would have identified for a population based just on the habitat available in the Satus Creek watershed itself; planners believe that achieving “high viability” status for this block, using the criteria for a basic population, is likely. The “mainstem block” represents steelhead identified by the ICTRT as being potentially produced in the lower Yakima River portion of the Satus Population Area (from the Satus Creek confluence to the Columbia River). Given the uncertainties about both historic and future potential for significant amounts of spawning in this portion of the basin, the Board chose to treat that portion of the Satus population as a block of spawners that can be produced in the lower mainstem Yakima and its tributaries or in the portion of the mainstem Yakima upstream of Satus Creek and below the Naches River. If mainstem spawning in these reaches is not found to be viable, additional fish produced beyond the abundance thresholds in one or more of the other population areas can make up for the “mainstem block.”

---

[35] The ICTRT calls for a “maintained” population to have an abundance/productivity combination above the 25% extinction risk on their viability curves and a spatial structure/diversity risk rating as per Figure 4.1, with the qualification that the minimum abundance threshold for a basic population should be 250 spawners and the minimum for intermediate through very large populations should be at least 500 spawners (ICTRT 2007b, p. 79).

4.1.2 Short-term Recovery Threshold

The short-term recovery threshold calls for recovering all four steelhead populations in the Yakima Basin to the ICTRT's Viable status (a 5% or less risk of extinction over a 100 year period). This threshold differs from the delisting threshold in that all populations must exceed maintained status and be classified as viable, and no population is singled out for Highly Viable status. This threshold was the one originally developed by the Yakima Subbasin Planning Board prior to development of the final ICTRT recommendations. It was retained in order to emphasize the Yakima Basin Fish & Wildlife Recovery Board's commitment to achieving viability across all four populations in order to minimize long-term extinction risks. The Board recognizes the delisting threshold as an appropriate point at which to consider delisting, but holds that continuing on beyond delisting to achieve the short-term recovery goal is both important and feasible in the 15-30 years needed to implement actions from this plan and see a population-level response by steelhead.

4.1.3 Delisting & Short-term Recovery Threshold Differences

The matrix presented in Figure 4.1 helps clarify the difference between the delisting and short-term recovery thresholds. The figure is adapted from the ICTRT's stock status reports (ICTRT In press); a full description of the ICTRT approach to determining Viability can be found in ICTRT (2007b).

Figure 4.1: VSP parameter risk ratings for Yakima steelhead populations

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/Productivity Risk	**Very Low (<1%)**	**HV**	**HV**	**V**	M
	Low (1-5%)	**V**	**V**	**V**	M
	Moderate (6-25%)	M	M	M Toppenish Satus	
	High (>25%)			Naches	Upper Yakima

HV = Highly Viable; V = Viable; M = Maintained; Shaded cells do not meet viability criteria

The short-term recovery threshold calls for moving all four of the Yakima Basin populations to a 5% viability level. Looking at the figure, this would require moving them from the lower right portion of the diagram to one of the boxes marked with a V in the second row. The ICTRT's viability criteria for the Yakima Basin Major Population Group (MPG) calls for two of the populations (including one of the large populations) to move to Viable status or better, with one of the Viable populations then moving on to Highly Viable status. The remaining two populations must reach or exceed Maintained status. The most likely scenario addressing these criteria was described in Section 4.1.1.

4.1.4 Long-term Recovery Threshold

Achieving the delisting and short-term recovery goals described above are only the first steps towards increasing the abundance and productivity of Yakima Basin steelhead populations to levels that allow for harvest for recreational, commercial, and ceremonial purposes in keeping with the Vision 2020 statement in Section 1.2. The specific long-term recovery targets identified in this plan are far from definitive determinations of what may be possible. They do serve to remind us that while the short-term goals of recovering steelhead to the point that they no longer require the protective measures of the Endangered Species Act is an immediate priority, the long-term recovery vision of the Yakima Basin Fish & Wildlife Recovery Board will require building on that initial success and continuing recovery efforts long after delisting is achieved. No time frame is set for achieving long-term recovery.

4.1.5 Relationship of Recovery Thresholds to NOAA Delisting Decisions

NOAA Fisheries' decision whether or not to delist Middle Columbia River Steelhead should be guided by the Board and ICTRT recovery thresholds, but is not required to be strictly determined by them. NOAA has the discretion to determine when it considers the MPG sufficiently recovered to be labeled as Viable. NOAA Fisheries also has the ability to proceed with delisting even if neither threshold is met, based on the determination that substantial progress towards recovery is being made. Because steelhead populations within the Yakima Basin make up only a portion of the total Middle Columbia River DPS, it is also possible that Yakima Basin steelhead meet their recovery criteria but are not delisted, based on concerns over the status of other steelhead MPGs in the DPS.

4.2 Recovery Objectives and Criteria

This section describes recovery objectives and criteria developed in accordance with NOAA Fisheries guidance (NMFS 2004) and the ICTRT Yakima Stock Status Assessments described in Chapter 2 (ICTRT In press). The purpose of these objectives and criteria is to provide concrete measures of progress towards meeting the recovery goals. These objectives and criteria are based on quantitative and qualitative measurements of abundance, productivity, and spatial structure/diversity on a population basis. Criteria for the delisting and short-term recovery thresholds are drawn directly from the ICTRT's Stock Status Assessments, with the delisting threshold based on the most likely application of the maintenance standard to one large population (Upper

Yakima) and one other population (Toppenish), and the short-term recovery threshold based on achieving Viability for each of the four populations. Productivity and diversity criteria for the long-term recovery threshold are the same as for the short-term threshold. Long-term recovery threshold abundance and spatial structure criteria are based on restoring full access to historically accessible stream reaches throughout the basin that that can be restored consistent with the Board's commitment to sustaining local customs and economies.

4.2.1 Abundance

The abundance objective is to maintain the number of steelhead within each population in the Yakima Basin at levels consistent with viability. The abundance criteria call for maintaining the 10-year geometric mean for spawner abundance at levels equal to or exceeding the values given in Table 4.1.

Table 4.1: Minimum abundance criteria for recovery thresholds

Population	Delisting Threshold	Short-Term Recovery	Long-term Recovery
Satus: Satus Watershed Mainstem Block[36]	 500 500	 500 500	 2,000
Toppenish	250	500	1,500
Naches	1,500	1,500	5,400
Upper Yakima	500	1,500	7,700
Total for MPG	3,250	4,500	16,600

The long-term recovery targets presented here were calculated by averaging and rounding the results of the 2005 subbasin planning EDT restoration threshold for steelhead and an extrapolation to spawner abundance from the ICTRT total weighted and temperature limited habitat area for the Yakima Basin (discussed in Sections 2.3 and 2.4.1) times an average of 10 spawners per 10,000 m^2 of high-quality habitat (a rate currently seen in good habitat in the Yakima Basin) as shown in Table 4.2.

[36] As noted in Section 4.1.1, the "mainstem block" represents spawners attributed to the Satus population by the ICTRT that local recovery planners call for producing either in the portion of the mainstem Yakima below the Naches River, or if mainstem spawning in these reaches is not found to be viable, as additional fish produced beyond the abundance thresholds in any of the population areas.

Table 4.2: Sources for long-term recovery abundance targets

Population	EDT Restoration Scenario	ICTRT Expansion	Average of EDT & ICTRT
Satus	2,733	1,280	2,007
Toppenish	1,784	1,171	1,478
Naches	4,911	5,849	5,380
Upper Yakima	6,533	8,795	7,664
Total	***15,961***	***17,095***	***16,528***

Note that these numbers do not take into account interactions with resident rainbow

Although the total abundance target for the long-term recovery threshold is approximately an order of magnitude greater than recent 10-year average abundance, it is still only one third of the estimated historic abundance levels discussed in Section 2.4.1. Both methods assume that the anadromous form of *O. mykiss* dominates the entire Upper Yakima population area. Reviewing this assumption is identified as a key research need in Chapter 7. These long-term abundance targets should not be interpreted as definitive goals. They are meant to encourage discussion and ongoing research about the potential size of fully recovered steelhead populations in the Yakima Basin.

4.2.2 Productivity

The productivity goal is to increase the number of reproductive offspring per spawner within each population to levels that, together with increased abundance, result in low risk of extinction. All thresholds call for the Yakima major population group to maintain a long-term average spawner:spawner ratio greater than or equal to 1.0, indicating stable or increasing long-term population size. Productivity criteria are based on intrinsic productivities calculated using the ICTRT's methods[37] in order to assess the ability of populations to rebound when reduced to below average abundances. Criteria for minimum 10-yr geometric means for intrinsic productivity at the size threshold for each population and threshold are indicated in Table 4.3. Criteria are based on the ICTRT Viability Curves (ICTRT 2007b).

[37] See explanation of ICTRT intrinsic productivity calculations in Section 2.4.2.3.

Table 4.3: Spawners and spawner:spawner ratio

Population	Delisting Threshold	Short-Term Recovery	Long-term Recovery
Satus: Satus Watershed Mainstem Block	 2.00 (High Viable) 1.56 (Viable)	 1.56 (Viable) 1.56 (Viable)	 1.2 1.2
Toppenish	1.20 (Maintained +)	1.56 (Viable)	1.2
Naches	1.26 (Viable)	1.26 (Viable)	1.2
Upper Yakima	1.20 (Maintained +)	1.26 (Viable)	1.2

4.2.3 Spatial Structure

The spatial structure goal is to restore the distribution of steelhead across a broad range of habitats in historically occupied areas in order to maintain resilience and life history diversity. Distribution of steelhead spawning across the ICTRT designated spawning areas for each population is used to assess spatial distribution. Distribution is assessed based on the ICTRT's definition of occupancy:

> Occupied areas are those in which two or more redds from natural origin spawners have been observed in all years of the most recent brood cycle (i.e., the most recent generation) and have been observed for at least half of the most recent three brood cycles (approximately 15 years for steelhead and Chinook). A Minor Spawning Area (MiSA) is regarded as occupied when it has two or more redds present over the previously defined time periods. A MSA is regarded as occupied when it has two or more redds within BOTH the upper and lower half of the weighted spawning area within that MSA over the previously defined time periods. (ICTRT 2007b, p. 50).

Satus Population

Naturally produced steelhead should occupy both major spawning areas in the Satus watershed (Satus and Dry Creek MSAs) and the Mule-Dry minor spawning areas. Consistent spawning must occur in both major spawning areas.

Toppenish Population

Naturally produced steelhead spawning should occupy both of the major spawning areas in the Toppenish watershed (upper Toppenish and Simcoe MSAs). Consistent spawning must occur in both major spawning areas.

Naches Population

Naturally produced steelhead should occupy at least seven of the eight major spawning areas for the delisting and short-term recovery thresholds. For the long-term recovery threshold all eight will be occupied. Consistent spawning must occur within the Naches

mainstem and Ahtanum, and Rattlesnake creeks to maintain distribution across habitat types and life histories.

Upper Yakima Population

Naturally produced steelhead should occupy at least 10 of the 14 major spawning areas for the delisting and short-term recovery thresholds. For the long-term recovery threshold 12 of 14 MSAs should be occupied. Spawning should consistently occur within at least the Yakima mainstem; Umtanum, Swauk, Manastash, and Taneum creeks; and the Teanaway River (West and North Teanaway MSAa and Lower Teanaway minor spawning area). While this threshold does not specifically require passage at Cle Elum, Kachess, and/or Keechelus dams, it recognizes that providing passage can play an important role in meeting these criteria. Table 4.4 summarizes the options for meeting the spatial structure criteria in the Upper Yakima.

Table 4.4: Possible combinations of spawning areas for the Upper Yakima

Required MSAs	Plus at least three of these:	Recovery not required
Umtanum Swauk North Teanaway West Teanaway Taneum Manastash Upper Mainstem	Cle Elum Naneum Reecer MSA Caribou MSA Middle Mainstem	Wenas Roza/Burbank

4.2.4 Diversity

The diversity goal for all thresholds is to maintain and enhance both phenotypic (morphology, behavior, and life-history traits) and genotypic diversity while limiting introgression of non-local genes. This will be accomplished by continuing to carefully manage and/or minimize factors that alter the distribution of traits such as timing of spawning and upstream and downstream migrations, age structure, size, fecundity, morphology, behavior, and genetic characteristics.

Population-specific criteria based on measurable traits, including body length, run timing, age structure, sex ratio, and genetic composition have not been developed at this time. As noted in Chapter 2, data is available on these traits for the MPG as a whole, but only the Upper Yakima population can be characterized in any detail at this time (based on samples at Roza Dam). Developing methods to identify fish by population at Prosser Dam fish ladders will play an important role in developing the information base needed to develop population specific diversity criteria. Additional information on the research needed to develop detailed population-specific diversity criteria is given in Chapter 7. The hatchery stray rate into the basin should be maintained at less than 5% of the total spawner abundance in the MPG (based on Prosser counts). Monitoring of genetic composition to detect the presence of non-indigenous genetic markers should be established.

4.3 Recovery Strategies

This section describes the geographic priorities and action strategies that will need to be applied to successfully meet the recovery goals, objectives, and thresholds described above. It provides an overview and framework for the more detailed discussion of specific recovery actions in Chapter 5. The action strategies were chosen to serve as a linkage between the specific action descriptions in this plan and the more general summary in the draft NOAA Fisheries recovery plan for the Middle Columbia River Steelhead DPS. These strategies are specific to the Yakima Basin; additional strategies to address factors affecting Yakima steelhead in the Columbia River and the ocean will be addressed in the NOAA Middle Columbia River Steelhead Recovery Plan.

Recovery strategies for the Yakima Basin are:

4.3.1 Habitat Strategies

1) Protect existing functional habitats
2) Restore unimpeded upstream and downstream fish passage (includes screening diversions)
3) Restore floodplain connectivity and function
4) Restore channel structure and complexity
5) Restore riparian condition and future LWD recruitment
6) Improve flow conditions
7) Improve water quality
8) Improve upland watershed conditions
9) Enhance upstream nutrient supplies

4.3.2 Predation Strategies

1) Reconfigure infrastructure to reduce predation
2) Evaluate and modify predator management options

4.3.3 Harvest Strategies

1) Maintain in-basin fishing regulations that protect steelhead, including regulations of other fisheries aimed at eliminating by-catch of steelhead and reducing negative impacts of introduced species

4.3.4 Hatchery Strategies

1) Use small-scale supplementation to accelerate recovery
2) Promote repeat spawning of kelts

All of the actions in Chapter 5 are classified according to the action strategies they implement and the limiting factors they address.

4.3.5 Recovery Strategies Outside of the Yakima Basin

Recovery actions in the mainstem Columbia, estuary, and ocean are identified and implemented through a complex framework of federal and state programs and policies over which Yakima Basin stakeholders have little control. The choice of which out-of-basin recovery actions to implement and the rate that they are completed will significantly affect the survival of Yakima steelhead during their upstream, downstream, and oceanic migrations. This plan focuses on recovery strategies within the Yakima Basin, but assumes that significant improvements will also be made out-side of the basin. Out-of-basin strategies and actions are to be addressed in detail as part of NOAA's Middle Columbia Steelhead Recovery Plan.

4.3.6 Recovery Strategies Affecting All Yakima Populations

All four Yakima populations will benefit significantly from efforts to improve conditions for upstream adult and downstream smolt migrations in the mainstem Yakima River. This will require:

1) Altering irrigation delivery and storage operations in the Yakima Basin to improve flows and temperatures in migration periods (Habitat Strategy 6) and utilize managed high flows to maintain floodplain habitat

2) Improving channel and floodplain conditions and reducing predation through the shared migratory reach (Habitat Strategies 3, 4 & 5 and Predation Strategy 1)

All four Yakima populations also benefit from the kelt-reconditioning program (Hatchery Strategy 2), protective fisheries regulations (Harvest Strategy 1), and ongoing efforts to protect existing functional habitat (Habitat Strategy 1). The Upper Yakima and Naches populations would also benefit from the conservation-oriented supplementation programs under consideration (Hatchery Strategy 1).

4.3.7 Role of Areas Above Storage Dams in Steelhead Recovery

When the five major Yakima Basin storage dams were constructed early in the 20th century, steelhead access to streams above the dams was blocked. The BOR has assessed the amount of anadromous fish habitat potentially available if passage facilities are built as 13.8 miles above Keechelus Dam, 2.4 miles above Kachess Dam, 29.4 miles above Cle Elum Dam, 6.0 miles above Bumping Lake Dam, and 36.8 miles above Tieton Dam ((BOR 2005). There is some uncertainty over the degree of productivity and past use of these areas by steelhead (Yakima Subbasin Fish and Wildlife Planning Board 2005, p. 2-335), but this may be offset by the prospect that these colder waters could become more important refugia for steelhead if climate change leads to decrease flows and increased water temperatures at lower elevations. Even limited use of these areas would increase the viability of the populations through improvements in spatial structure and life history

diversity. If Chinook, sockeye, or coho also recolonize these habitats, the resulting marine-derived nutrients would benefit steelhead.

The costs of providing passage at the storage dams are substantial when compared solely to their potential benefit to steelhead. It is the contention of the Yakima Basin Fish & Wildlife Recovery Board that 1) recovery of steelhead to levels of viability sufficient to warrant delisting under the ESA may be feasible without restoration of access to habitat above the storage dams, but that 2) access at some or all of the storage dams would greatly facilitate the process of steelhead recovery. Accordingly, our recovery criteria for steelhead do not require establishment of spawning populations above the passage dams, but do recognize that passage at the storage dams can help in reaching steelhead recovery goals. Fish passage at some or all of the storage dams is a key component for both bull trout recovery and re-establishment of sockeye salmon in the Yakima Basin, and offers significant benefits to non-listed Chinook and coho. When the benefits for all salmonid species are considered, passage at the storage dams becomes a much higher priority than it would be for steelhead on their own. Construction of Lake Cle Elum and Bumping Lake passage facilities are identified as specific actions in Chapter 5. Passage at all five storage dams should continue to be assessed based on the full range of benefits it would provide.

4.3.8 Toppenish Population Recovery Strategies

Geographic Focus

Recovery efforts should focus equally on both MSAs and their shared migration corridor. No specific actions are identified for the Mill Creek minor spawning area, but it should benefit from the general watershed-wide and lower Toppenish Creek actions.

Key Strategies

Achieving recovery goals for the Toppenish Population will require:

1) Continuing efforts to protect existing functional habitat (Habitat Strategy 1)

2) Significant efforts to improve passage, flows, and riparian conditions in Toppenish Creek and its tributaries (Habitat Strategies 2, 5, 6, 7 & 8)

3) Restoration of floodplain function in lower Toppenish Creek (Habitat Strategies 3 & 4)

4) Improving migration conditions in the mainstem Yakima River as detailed in Section 4.3.6

4.3.9 Satus Population Recovery Strategies

Geographic Focus

Within the Satus Creek watershed itself, recovery efforts should focus equally on both MSAs and their shared migration corridor. No specific actions are identified for the Mule-Dry minor spawning area, but it should benefit from the general watershed-wide

and lower Satus Creek actions. Within the mainstem Yakima portion of the ICTRT Satus Population Area, recovery efforts should focus on improving habitat and survival for upstream and downstream migration by all populations. Specific efforts to restore spawning aggregations in the lower mainstem and its tributaries should only occur if there is evidence that successful life history strategies based in the lower river and its tributaries currently exist or can be re-established.

Recovery actions in tributary drainages to the lower Yakima River are not identified in this plan. Portions of Snipes, Spring, and Corral creeks and Amon Wasteway[38] may have potential to produce steelhead (Romey and Cramer 2001), and some level of use by salmon and *O. mykiss* is known to occur (Monk 2001). These waterways were identified as parts of minor spawning areas in the ICTRT intrinsic potential analysis. However, as discussed in Chapter 2, flows in these waterways are dominated by return flows from irrigation systems. Evidence that they would not have sustained significant year-round flows prior to the establishment of irrigation is presented by Smith et al. (2006). The Kennewick Irrigation District provided the Yakima Basin Fish & Wildlife Recovery Board with aerial photographs of Amon Wasteway from 1948 and 1955 that show a dry channel prior to irrigation development in the surrounding area (letter sent 12/26/07). This plan does not require these areas to be managed for steelhead in order to meet recovery objectives; and local recovery planners have indicated to the ICTRT that these areas should not be included as part of modeled historic habitat (See Appendix A).

Management of these waterways for fish habitat values has been limited. The irrigation districts manage these waterways as part of their drainage infrastructure and are concerned about potential regulatory burdens. WDFW notes that maintenance of the drainage networks need not prevent the protection and management of these waterways as fish-bearing waters. If these interests can be reconciled in a mutually acceptable manner, maintaining and enhancing fish habitat in the lower ends of these waterways should be encouraged as part of improving migratory habitat in the lower river.

Amon Wasteway is currently the focus of significant conservation efforts by the Tapteal Greenway Association. If habitat conditions that sustain steelhead production can be maintained and mutually acceptable agreements regarding future management reached by the Kennewick Irrigation District, WDFW, and other key stakeholders, management of this area as steelhead spawning habitat may be possible. However maintenance of steelhead spawning in this area is not a prerequisite for recovery and delisting of Yakima Basin steelhead.

Key Strategies

Achieving recovery goals for the Satus Population will require:

---

[38] Spring, Corral, and Snipes creeks and Amon Wasteway are referred to by the names used on the USGS 7.5 minute topographic maps. The first three are referred to as drainageways by local irrigation districts, while Amon Wasteway is often referred to as Amon Creek. The use of these names in this document is in no way meant to indicate any conclusions regarding ongoing disputes about the legal status of these waterways.

1) Continuing efforts to protect existing functional habitat (Habitat Strategy 1)

2) Continuing ongoing efforts by the Yakama Nation to improve watershed and riparian conditions within the Satus drainage ((Habitat Strategies 5, 7 & 8)

3) Restoring floodplain function and channel complexity in lower Satus Creek (Habitat Strategies 3 & 4)

4) Improving migration conditions in the mainstem Yakima River as detailed Section 4.3.6

4.3.10 Naches Population Recovery Strategies

Geographic Focus

The recovery threshold presented in this plan requires steelhead occupancy in seven of the eight major spawning areas. Currently there is at least some level of use in all eight MSAs, though steelhead spawning in the Tieton MSA is only confirmed from Oak Creek and the portion of the mainstem Naches associated with this MSA. Re-establishment of steelhead spawning in the Tieton River would make a valuable contribution to long-term recovery, but is not required by the de-listing threshold described in this plan. Efforts to increase steelhead use of the lower Tieton will only become feasible if fall high flows associated with flip-flop can be addressed; restoring use of the Tieton and its tributaries above Tieton Dam would require providing both upstream and downstream fish passage at the dam (see discussion of storage dams in Section 4.3.1).

The location of the Ahtanum and Cowiche MSAs between the Satus and Toppenish populations and the remainder of the Naches population make them important components of the spatial diversity of the population and the Yakima MPG as a whole.

The ICTRT has identified two minor spawning areas, Wide Hollow and Moxie, in the Naches population area. The Wide Hollow spawning area may have the ability to support limited steelhead spawning, but irrigation conveyance, return flows, and surrounding urban development hinder spawning activity. Establishment of steelhead in Wide Hollow is not a required part of recovery thresholds presented in this plan. The Moxee spawning area identified by the ICTRT is not considered to have had sufficient flows to support steelhead spawning, as noted in Section 2.3.3. The recovery thresholds presented in this plan do not require the establishment of steelhead in the Moxie area. Managing the lower reaches of Wide Hollow Creek and Moxee Drain to provide rearing habitat for fish moving to and from the mainstem Yakima, however, would be beneficial to Naches steelhead recovery.

The Naches River upstream from the Tieton confluence is the only mainstem reach in the basin with flows that are currently in a nearly normative state. Increasing the availability and quality of habitat in this portion of the basin will help offset the loss or alteration of mainstem habitats in other portions of the basin.

EDT model results indicate that conditions in the Naches River for the 17.5 miles below the Tieton confluence have a steelhead mortality rate—compared to the predevelopment estimate—of more than five times that for the 27.1 miles of the Naches upstream from

the confluence. Most of the modeled impact is due to daily maximum river temperatures during the summer period before the flow spike associated with flip-flop. According to BOR flow data for water years 1995-1999, average regulated flow in the lower Naches was significantly lower than modeled average unregulated flow in July and the first half of August. Improving conditions in this reach will benefit all upstream MSAs. The purchase of the Wapatox water right by BOR (Sec. 3.3.5.7) is a significant step towards improving flows in this reach.

The 47-mile section of the mainstem Yakima included by the ICTRT in the Naches Population is a critical part of migratory and rearing habitat for both Naches and Upper Yakima steelhead. The degree to which it currently supports spawning that results in successful production of smolts is unknown. If successful life histories based on spawning in this area exist or can be established, the reach will be a candidate for meeting the "mainstem spawner" abundance objective identified in Section 4.1.1. The extent and viability of spawning in this mainstem reach is identified as a key knowledge gap.

Key Strategies

Achieving recovery goals for the Naches Population will require:

1) Continuing efforts to protect existing functional habitat (Habitat Strategy 1)
2) Making significant efforts to protect and improve passage, flows, and instream and riparian conditions in tributaries (Ahtanum, Bumping, Cowiche, Rattlesnake, Nile and Little Naches watersheds) (Habitat Strategies 2, 5, 6, 7 & 8)
3) Addressing the effects on steelhead of reservoir operations and irrigation withdrawals that create winter/spring/early summer low flows and late summer/fall high flows in the Tieton, lower Bumping and lower Naches River (Habitat Strategy 6)
4) Improve floodplain function and habitat conditions in the mainstem Naches River
5) Improving migration conditions in the mainstem Yakima River as detailed in Section 4.3.6

4.3.11 Upper Yakima Population Recovery Strategies

Recovery planners recognize that the Upper Yakima River steelhead population has the highest risk of extinction of the four populations in the MPG and will likely require more time and effort to recover than the Satus, Toppenish, and Naches populations. Just achieving "maintained" status in accordance with ICTRT maintenance guidelines will require a significant commitment to recovery actions in the Upper Yakima.

Geographic Focus

The Upper Yakima has the largest, most complex and diverse spatial structure of the four population areas, with 14 major and 2 minor spawning areas spread across a wide range

of ecological settings. It is also the population with the most limited current distribution relative to the estimated historic distribution.

Lower Upper Yakima Tributaries

The ICTRT's Wenas Creek MSA is not required in the recovery thresholds identified in this plan. If passage and appropriate migratory conditions in lower Wenas Creek could be assured, the upper watershed could potentially support a significant amount of steelhead spawning. The significant challenges associated with restoring passage and migratory conditions mean that it is not considered a short-term priority in this plan. If conditions change such that restoring Wenas Creek becomes feasible (e.g., major changes to irrigation systems and Wenas Dam), or if it is clear that production from the higher priority areas identified in this plan will not be sufficient to meet recovery objectives, restoration of steelhead spawning in Wenas Creek should be given higher priority. Efforts to maintain the lowest reaches of Wenas Creek as off-channel habitat for fish in the mainstem Yakima should be continued. The Selah Creek portion of the ICTRT's Wenas Creek MSA is not considered by local recovery planners to have ever maintained the streamflow needed to support steelhead and is not considered a recovery priority.

The Umtanum Creek portion of the Umtanum MSA is a mandatory element of the recovery threshold. Umtanum Creek itself is the only tributary with near-natural flow and habitat conditions that supports steelhead in the lower portion of the Upper Yakima population (it is managed as part of WDFW's LT Murray Wildlife Area). Potential contributions of Umtanum Creek to overall abundance and productivity of the Upper Yakima population as a whole are minor, but its role in improving gene flow between steelhead populations and as an island of relatively intact habitat in the Upper Yakima make it an important component of the spatial structure and diversity of the Upper Yakima population. While no specific actions are proposed for Umtanum Creek (the last significant passage barrier was removed in 2005-6), maintaining current management and protections is a high priority. While Lmuma Creek (also included in the ICTRT's Umtanum MSA) has the potential to support limited steelhead spawning, priority should be on restoring conditions in the lower end for use as an off-channel refuge by steelhead in the mainstem Yakima. Roza and Burbank creeks were also identified as potential habitat by the ICTRT, but have intermittent flows and limited access because of alluvial fans at their mouths. Neither is required as part of this recovery threshold. Work by the Department of Defense and other landowners aimed at improving watershed conditions in these areas should continue based on the benefits to downstream areas.

Ellensburg Area Tributaries

The Reecer and Caribou MSAs both contain complex networks of small creeks, including Dry, Reecer, and Currier (Reecer MSA) and Cherry, Cooke, Coleman, Park, and others (Caribou MSA). These creeks have been managed for a century as part of a complex network of irrigation ditches and drains. The lower ends of these tributaries have high value as off-channel rearing habitat for the adjoining reach of the mainstem Yakima and are being restored to serve as such through YTHAP restoration efforts. These creeks have only limited spawning potential due to their low gradients and highly altered hydrographs.

The Naneum MSA includes the Naneum and Wilson creek systems. The upper Naneum Creek watershed includes significant amounts of potential habitat and is thought to have sustained steelhead spawning prior to development of the irrigation infrastructure that now blocks passage into the upper watershed. Several possible routes exist for opening up passage through the interconnected network of streams and irrigation ditches east of Ellensburg. Identifying the most effective route and prioritizing barrier removal and habitat actions through this route is a significant but feasible challenge. Ongoing efforts to restore passage in Wilson Creek upstream to the city of Ellensburg are opening access to valuable rearing habitat; however, the high cost and logistical challenges of opening Wilson Creek through the city make working further up on Wilson Creek a low priority.

Other Upper Yakima Area Tributaries

The Swauk Creek, North Teanaway and West Teanaway MSAs and the Lower Teanaway minor spawning area are the current tributary strongholds for steelhead production in the Upper Yakima (the Middle Fork Teanaway is a portion of the West Teanaway MSA). Maintaining these spawning areas is required to meet the Upper Yakima recovery threshold. Taneum Creek has high quality habitat that is currently partially accessible. Projects to assure unimpeded fish passage are underway. Manastash Creek is currently inaccessible to steelhead due to passage barriers at irrigation dams; cooperative efforts to remove these barriers and improve instream flows are underway. Both of these MSAs are anticipated to be consistent producers of the anadromous form of *O. mykiss* and are required components of this recovery scenario.

Mainstem Spawning Areas

The Middle Mainstem MSA between the Teanaway and Cle Elum rivers is currently accessible. The Upper Mainstem MSA includes the accessible reaches of the mainstem Yakima River upstream from the Cle Elum River, tributaries such as Big Creek, and up to 15 miles of currently blocked habitat above Kachess and Keechelus dams. The Cle Elum MSA is split into the accessible section below Cle Elum Dam and up to 30 miles of blocked habitat above the dam. All are candidates for recovery.

Key Strategies

The complex interactions between habitat conditions and anadromous and resident life histories of *O. mykiss* in the Upper Yakima will require ongoing monitoring and research aimed at understanding what conditions promote anadromy, and specifically, whether residency is more a reflection of favorable local habitat or unfavorable migration conditions. Research outcomes will guide restoration in addition to the obvious needs for improved passage. For example, if flow manipulation has a disproportionate effect on early juveniles, moderating its effects may shift the current balance toward anadromy.

Actions that are expected to benefit the Upper Yakima steelhead population include:

1) Continuing efforts to protect existing functional habitat (Habitat Strategy 1)
2) Providing unimpeded passage for steelhead in key tributaries (Manastash, Taneum and if feasible, Naneum and Cle Elum) (Habitat Strategy 2)

3) Improving outmigration conditions at Roza Dam (Habitat Strategies 2 & 6)

4) Addressing the effects of reservoir and irrigation system operations that create winter/spring/fall low flows and summer high flows in the lower Cle Elum and mainstem Yakima rivers (Habitat Strategy 6)

5) Protecting and enhancing floodplain conditions along the mainstem Yakima (Habitat Strategy 3)

6) Improving flows and instream and riparian conditions in tributaries and side channels (Habitat Strategy 4, 5, 6 & 9)

7) Improving migration conditions in the lower mainstem Yakima River as detailed in Section 4.3.6

5 Recovery Actions

5.1 Identifying & Describing Recovery Actions
5.2 Timeframe for Implementing Actions
5.3 Necessity/Sufficiency of Proposed Actions
5.4 Overall Cost of Recovery
5.5 Recovery Action Descriptions

5.1 Identifying and Describing Recovery Actions

This chapter of the recovery plan recommends specific recovery actions that will contribute directly to restoring steelhead in the Yakima Basin to viable levels. Research and monitoring actions are described in Chapter 7, and outreach and education actions are described in Chapter 8. Both of these sets of actions do not directly alleviate threats to steelhead viability, but are essential to improving our ability to design and implement actions that do. Implementation of the recovery actions identified in this chapter should restore steelhead populations to viable levels. These actions will also benefit other fish species and some wildlife and lessen the chance for additional listings in the Yakima Basin.

Some of the actions identified in this plan were developed in other forums or processes (e.g., the Yakima Subbasin Plan and the HB 2514 Watershed Planning process) and are incorporated with little or no modification. Specific restoration actions that have been completed and are not ongoing in nature are not listed here; an inventory of past restoration actions was included in the Yakima Subbasin Plan (Yakima Subbasin Fish and Wildlife Planning Board 2005); and the Yakima Basin Fish & Wildlife Recovery Board anticipates maintaining a continually updated database of completed recovery actions. Intensive fish restoration work has occurred in the Yakima Basin for over three decades and continuing, refining, and expanding these existing efforts will be a key component of steelhead recovery in the Yakima Basin. Recovery will also require a significant commitment to new actions. Both new and ongoing actions are detailed in this plan. The following NOAA Fisheries recovery planning guidelines were applied when selecting and describing recovery actions (NMFS 2004):

- Recovery actions should be discrete and action-oriented.
- Whenever possible, recovery actions should be site-specific, as per ESA Section 4(f)(1)(B)(i).
- Recovery actions should be feasible and fundable.
- The plan should include both near-term (completed in less than 15 years) and long-term (taking longer than 15 years) actions.
- Recovery actions should be described with sensitivity and discretion.

Actions identified in this plan are classified into six groups, Basinwide, Lower Mainstem, Naches, Status, Toppenish, and Upper Yakima. Basinwide actions are those that can be applied throughout the basin. Most are programmatic in nature, though a few key

basinwide actions involve specific proposals for river and hatchery operations. Lower Mainstem actions are site-specific actions in the shared migratory corridor from the mouth of the Yakima upstream to the confluence of the Naches. Actions below the Toppenish Creek confluence are noted as benefiting all population areas, while those above are noted as benefiting the Naches and Upper Yakima populations.

All other actions are population-specific; where actions occur in and/or specifically benefit individual Major Spawning Areas (MSAs), these areas are indicated in the action description. Note that while MSAs are often named after a single creek, they typically include a complex of nearby creeks. For example, the Caribou Creek MSA also includes Coleman, Parke, Cooke, Cherry, and other creeks (see figure 2.5 for clarification).

As noted in Chapter 4, for local planning purposes we have broken the ICTRT's Satus population area into two components. The Satus Creek actions listed here are specific to the Satus Creek Watershed, while actions in the lower mainstem Yakima (technically part of the ICTRT's Satus population) are listed separately due to their broad benefits to all populations. Similarly, while the ICTRT Naches population area includes the Yakima mainstem from the mouth of Toppenish Creek upstream to the Naches confluence, we have included actions in this area under the mainstem actions category.

Additional information provided for each recovery action includes:

- Key partners
- Focal area
- Strategies implemented by the action
- Likelihood of implementation
- Time to implement
- Time to realize benefits
- Cost estimates

Key partners are entities likely to play a significant role in implementing the action.

Focal area is the location of the action itself.

For strategies implemented by the action, see Chapter 4.

Likelihood of implementation was scored in one of three categories. Only actions in the first two categories were retained:

- High (action is technically feasible, support is likely and there is little or no opposition)
- Moderate (action is technically feasible, there is some support, and opposition could likely be resolved)
- Low (action involves substantial technical issues and/or has little apparent or likely support or would likely encounter opposition)

Time to implement indicates the time required to implement the action on the ground. Categories were:

- Ongoing (action is in place and needs to be continued at roughly current levels)
- Expand ongoing effort (action is in place but needs to be expanded)
- 0-3 years required to implement
- 4-6 years
- 6-10 years
- Greater than 10 years

Time to realize benefits indicates the time needed following implementation for benefits of the action to be fully realized. This time ranges from instantaneous (e.g., improved passage is available the day after a dam is removed) to decades long (e.g., for plantings to generate new woody debris).

Cost estimates given in this plan are preliminary estimates based on the best information on hand. The accuracy of estimates varies greatly from action to action, and the estimates should not be taken as definitive. Each estimate represents the total cost of implementing the action, but does not include either the value of resulting benefits or opportunity costs incurred as a result of the action. The cost proportions indicate the percentage of the project costs attributed to benefiting fish in general and steelhead in particular. These are general estimates meant to indicate if a project would be done specifically to benefit steelhead (e.g., 100% fish, 100% steelhead), benefit steelhead and other fish species (e.g., 100% fish, 50% steelhead), or benefit fish indirectly (e.g., water conservation efforts that directly benefit irrigators in addition to their fish benefits).

Each action description is meant to give an overview of the proposed action and its key components. As part of the development of a recovery implementation schedule, action descriptions will be refined and expanded, and more detailed descriptions of specific components of the actions will be developed. This implementation schedule will be maintained in a tiered structure, with general strategies identified in this plan at Tier I (e.g., “Restore unimpeded fish passage”) and the actions described in this plan at Tier II (e.g., “Restore passage in lower Taneum Creek”). Tier III will include detailed descriptions of specific projects that implement the Tier II actions (e.g., “Install rock-weir fishway at the Bruton Diversion”). All of the actions described in this plan have been compiled into a simple database that will be regularly updated in response. See Chapter 6 for more information about how this will be integrated into the recovery implementation process.

5.2 Timeframe for Implementing of Actions

Actions in this recovery plan are intended to be implemented in the next 15 years. Recovery of the species themselves may take considerably longer (up to several decades) because of delayed environmental response (e.g., the time required for a planted riparian zone to reach maturity and full function) and subsequent population response (e.g., the

time required for a population to incorporate restored portions of its range into its life history). Actions are assigned to one of three time frames:

1) Actions classified as Ongoing are generally currently being undertaken by existing entities that have a history successfully implementing similar actions. In most cases ongoing actions will need to be continuously implemented in the future.

2) Short-term Actions are one-time or unique actions that can be implemented within the next six years.

3) Long-term Actions generally require additional technical study, policy review, and public comment prior to implementation. Implementation of these actions should begin within the 15-year time frame and continue thereafter. This requires that studies, policy review, and public involvement begin early in the implementation process. Specific timeframes for implementation of these long-term actions will be developed during the implementation scheduling process described in Chapter 6.

5.3 Necessity and Sufficiency of Proposed Actions

Given 1) natural variability in climate and ocean conditions, 2) uncertainty about the implementation and survival benefits of recovery actions in the ocean, estuary and mainstem Columbia, and 3) uncertainties about the rates and types of biological responses to within-basin recovery actions described in this plan, it is impossible to predict exactly which subset of the recovery actions described in the plan will be required to meet each of the separate goals of delisting, short-term, and long-term recovery. Implementing some or all of the actions presented here should significantly improve the abundance, productivity, spatial structure, and diversity of steelhead in the Yakima Basin. Recovery planners anticipate that the full suite of actions presented here, if combined with expected improvements outside of the Yakima Basin, will be more than sufficient to meet de-listing and short term recovery goals, but that additional actions may need to reach long-term broad sense recovery goals.

The Yakima Basin Fish & Wildlife Recovery Board is working with recovery stakeholders to refine the actions presented in this plan and developing a detailed Implementation Schedule that will be regularly updated to indicate the status of actions and identify priorities for future action based on their biological benefit and socio-economic feasibility. More detail on this process is given in Chapter 6.

Chapter 7 describes the monitoring and research efforts needed to track progress towards recovery goals and help us understand which recovery actions will be required to meet those goals. Evaluating the effectiveness of implemented recovery actions will require a rigorous and quantitative approach to adaptive management as priority actions are being implemented. Actual implementation efforts will have to be adjusted over time based on monitoring results. Detailed recommendations on implementing a strong adaptive management process will be included in the Research, Monitoring and Evaluation (RME) supplement to the Yakima Steelhead Recovery Plan that is currently being developed by the Yakima Basin Fish & Wildlife Recovery Board. Local recovery planners encourage

interested parties to participate in the development of the RME supplement and the ongoing adaptive management and implementation scheduling process.

This plan does not include a quantitative effort to analyze the sufficiency of the recovery actions recommended in this plan. At this time we do not have the level of detailed information needed to make quantitative predictions about the benefits of specific actions and the exact suite of actions that will be required to meet recovery goals. The Yakima Basin Fish & Wildlife Recovery Board and its partners will develop some of this detail as part of a regularly updated implementation schedule that identifies and prioritizes specific steps needed to implement the recovery actions in the Yakima Steelhead Recovery Plan. This process will focus on identifying specific habitat goals and tracking progress towards meeting them.

As part of development of NOAA Fisheries' Middle Columbia DPS Recovery Plan, the broad recovery scenario developed using the EDT model as part of the 2005 Yakima Subbasin Plan is being integrated into an all-H model that predicts steelhead response to recovery actions across the basin, the Columbia River, and the ocean. This EDT recovery scenario is described in Appendix B. More information about the integrated modeling effort will be available in the NOAA Fisheries' Mid-Columbia Steelhead Recovery Plan.

5.4 Overall Cost of Recovery

The cost identified for each action in this plan is a preliminary estimate of the cost of implementing the actions and was developed in accordance with NOAA Fisheries' guidelines for recovery plans. Costs are all in current dollars; they have not been adjusted for inflation or discounted to account for opportunity costs. Because these costs are preliminary and the specific set of actions that will be required to meet de-listing goals is not yet known, the sum of the costs presented here should not be presumed to be the cost of achieving de-listing. No attempt has been made to quantify either opportunity costs or economic benefits associated with proposed actions. While some actions described here will be implemented specifically to benefit steelhead and will be paid for by funds devoted to that purpose, many others will be implemented to achieve a wide range of benefits and will be paid for using an accordingly wide range of funding sources (e.g., floodplain enhancement projects that will improve habitat but also reduce infrastructure maintenance costs, improve flood protection for developable lands, and meet open space and recreation needs). Other actions (e.g., improving on-farm irrigation efficiency) will only occur when justified by direct benefits to the implementer, with benefits to fish as an incidental benefit. Section 5.1 described our attempt to address this complexity by assigning cost proportions, but to truly understand the economic impacts of specific actions requires a level of cost-benefit analysis not included in this plan.

5.5 Recovery Action Descriptions

This section provides detail on the 94 separate actions identified in this planning process. The action descriptions are given in a standardized format generated by the actions database maintained by the Yakima Basin Fish & Wildlife Recovery Board. This database will continue to be developed and will be linked with the implementation

schedules that will guide on-the-ground implementation and prioritization of recovery actions. Actions are presented in six groups: 1) Basinwide actions (16 total), which apply equally to all population areas, 2) Lower Mainstem Actions (9 total), which occur in the mainstem Yakima in areas shared by multiple populations (from the Columbia River to Roza Dam), and then 3) Naches (31 total), Satus (8 total), Toppenish (10 total) and Upper Yakima population area-specific actions (21 total), in that order. The sequence of actions does not indicate any priority; prioritization of actions will be specified in the implementation schedules under development. The references listed under limiting factors are the numbers of the related limiting factors in Tables 3.1 through 3.6.

Basinwide Action #1 **Modify reservoir operations to improve out-migration flows**

Key Partners:
Bureau of Reclamation

Affected MSAs:
All Spawning Areas

Focal Area: Mainstem Yakima and Naches Rivers **Implementation Likelihood:** Moderate

Time to Implement: 0-3 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions
Improve flow conditions
Improve flow conditions

Limiting Factors:
BW1,2,3

Cost Derivation: Operational change; no specific cost identified.

Total Cost: **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:**

Sufficient spring outmigration flows are essential for steelhead survival. Low spring flows increase smolt travel times and exposure to high temperatures and predators in the mainstem Yakima. In spring, BOR reservoir operations balance the need to refill storage with flood control. Flood control rule curves call for maintaining reservoirs at less than full levels in the early spring to provide capacity capture rapid runoff that would otherwise cause flooding. Later in spring, outflows are minimized to ensure refilling of reservoirs. This reduction in flows typically coincides with the smolt out-migration period. BOR has committed to studying alteration of rule curves themselves and is already altering operations to fill reservoirs sooner and spill in spring; other options include making releases during the outmigration period based on runoff predicitions, rather than spilling after reservoirs fill, and managing pulse flows. Evaluating the effects of changes in reservoir operations on water supply, flood hazard, and ecological functions should be facilitated by the work underway through the Storage Study. The potential of these changes to return the river to a more normative hydrograph without significantly impacting water supplies should be evaluated. Changes in spring/early summer reservoir operations may increase frequency of short-term overbank flooding, but would decrease the extent of long duration high water events, decreasing flood hazard, and increasing channel stability. Increased cottonwood regeneration and reductions in aquatic plant densities in the lower river are other potential benefits.

Basinwide Action #2 **Adequately screen all water diversions**

Key Partners:

Yakima Tributary Access and Habitat Program
Yakama Reservation Watersheds Project
Irrigation Districts
Individual irrigators
Conservation Districts
Bureau of Reclamation
Washington Department of Fish & Wildlife
Bonneville Power Administration

Affected MSAs:

All Spawning Areas

Focal Area: Basinwide **Implementation Likelihood:** High

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**

Time to Benefit: 0-3 years Restore unimpeded fish passage BW3

Cost Derivation: $300,000/year for 15 years based on current efforts.

Total Cost: $4,500,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $2,250,000

In the 1980s and 1990s, WDFW and the BOR updated fish screens on the larger diversions in the basin. These screens need ongoing maintenance and upgrading. Smaller diversions are being screened via the WDFW screen shop and the YTAHP program. Many smaller surface water and pump diversions need screening throughout the basin. Programs for these actions are in place, but limited by funding. Existing screens need to be operated and updated in a manner that ensures that they meet current criteria. Where fish are present in canals, fish salvage operations should continue. Entrainment in unscreened diversions is an issue for kelts as well as juveniles.

Basinwide Action #3 **Increase on-farm irrigation efficiency**

Key Partners:
- Irrigation Districts
- Department of Ecology
- Bureau of Reclamation
- Individual irrigators
- USDA Natural Resource Conservation Service
- Conservation Districts

Affected MSAs:
All Spawning Areas

Focal Area: Irrigated lands throughout the basin **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 0-3 years

Strategies:
Improve flow conditions
Improve water quality

Limiting Factors:
BW1,2

Cost Derivation: Work on 30% of 474,000 irrigated acres at a cost of $3,500/acre.

Total Cost: $497,700,000 **Fisheries:** 25% **Steelhead:** 50% **Steelhead Cost:** $62,212,500

Increases in on-farm irrigation efficiency can reduce the amount of water diverted from the river and reduce return flows and associated water quality issues. Benefits often also include increased agricultural productivity and reduced labor needs. Significant improvements have been made in recent decades by individual irrigators and NRCS, conservation districts, WSU extension and other programs. These efforts should be continued and expanded. Programs should ensure that reductions in on-farm water use can be tracked and utilized in a manner that directly contributes to instream flows at key locations and times (see actions that identify priority areas for flow improvement).

Basinwide Action #4 **Increase irrigation water delivery efficiency**

Key Partners:
- Bureau of Reclamation
- Irrigation Districts
- Department of Ecology
- Bureau of Reclamation
- Washington Department of Agriculture

Affected MSAs:
All Spawning Areas

Focal Area: Irrigation systems throughout the basin **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 0-3 years

Strategies:
Improve flow conditions

Limiting Factors:
BW1,2

Cost Derivation: Specific costs for high priority systems listed under specific actions.

Total Cost: **Fisheries:** 30% **Steelhead:** 50% **Steelhead Cost:**

Many of the irrigation systems in the basin could be upgraded. Where older systems have been converted to pressurized systems (e.g. the Yakima-Tieton) water consumption has been reduced, crop production has become more efficient, and susceptibility to drought has decreased. Even with increased irrigation assessments to maintain new systems, total cost of irrigation water has been reduced via reduced power demand and on-farm pumping. Delivery efficiency should be broadly promoted throughout the basin to reduce overall water demand and increase flexibility in reservoir operations. Power conservation programs, such as BPA's, should be used to support system improvements. Fisheries benefits are greatest where low flows are limiting during irrigation season; specific actions that address these areas are listed separately.

Basinwide Action #5 **Utilize Trust Water Rights Program to improve instream flows**

Key Partners:
Department of Ecology Water Trust Program
Washington Department of Fish & Wildlife
Bureau of Reclamation
Water Trust & Conservancies

Affected MSAs:
All Spawning Areas

Focal Area: Basinwide as opportunities arise **Implementation Likelihood:** Moderate

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**
Time to Benefit: 0-3 years Improve flow conditions BW1,2

Cost Derivation: $200,000/year plus 1 FTE & expenses at $75,000/year for 15 years.

Total Cost: $4,125,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $1,546,875

The Department of Ecology, BOR, Washington Water Trust, Washington Rivers Conservancy, Columbia Basin Water Transactions Program, and others have developed programs to lease and purchase water rights for instream use. Use of these programs could be significantly enhanced through education and outreach. This action is associated with the need for better water rights enforcement to ensure that once water is put into trust, it remains in-stream and is not diverted by down stream users. Benefits will be greatest in specific tributary locations; these are identified as separate actions in this plan.

Basinwide Action #6 **Continue kelt reconditioning**

Key Partners:
Columbia River Inter-Tribal Fisheries Commission
Yakima Klickitat Fisheries Project

Affected MSAs:
All Spawning Areas

Focal Area: Prosser Hatchery Facility **Implementation Likelihood:** High

Time to Implement: Ongoing **Strategies:** **Limiting Factors:**
Time to Benefit: 0-3 years Promote repeat spawning of kelts BW3,8

Cost Derivation: Existing program cost of $446,000/year (1/3 of BPA# 200306200 & 2/3 of BPA #200001700 as Yakima basin portion plus $50,000/yr YKFP contributions) for 15 years.

Total Cost: $6,690,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $6,690,000

The Yakima kelt reconditioning program directly increases the abundance of spawning adult steelhead with a relatively low risk of altering population characteristics. The kelt reconditioning program could play a role in reintroduction of populations to newly re-opened suitable habitats and in directed efforts to increase the numbers of spawning adults in specific steelhead populations in the subbasin. Monitoring of kelt reproductive success and genetic impacts should be expanded to ensure the kelt program is successful contributing to meeting recovery goals.

Basinwide Action #7 **Use artificial production techniques to restore steelhead to underutilized habitats**

Key Partners:
National Marine Fisheries Service
Yakama Nation
Washington Department of Fish & Wildlife
Yakima Klickitat Fisheries Project

Affected MSAs:
All Naches
All Upper Yakima

Focal Area: Targeted spawning areas in Naches and Upper Yakima Populations

Implementation Likelihood: Moderate

Time to Implement: 6-10 years

Time to Benefit: 6-10 years

Strategies:
Use small-scale supplementation

Limiting Factors:
BW8

Cost Derivation: $500,000 startup costs plus $200,000/year for 15 years based on use/expansion of existing facilities.

Total Cost: $3,500,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $3,500,000

Small-scale targeted supplementation that is designed to enhance steelhead VSP parameters may play an important role in accelerating recovery of the Upper Yakima and Naches populations. Focal areas would be watersheds with good habitat conditions where steelhead are not present or severely reduced due to historic passage barriers that have been or are being removed. Leading candidates include Cowiche, Manashtash, and Taneum watersheds. If passage into Naneum Creek and above Cle Elum and/or Bumping Dam is secured, these areas would also be strong candidates. Metrics should be developed to evaluate desired recolonization rates and population characteristics and the range of cultural actions that would be appropriate if these rates or populations characteristics are not met. The rate of colonization, productivity, life-history form (anadromous versus resident), and genetic structure of new populations should be closely monitored. The Yakima-Klickitat Fisheries Program is currently developing a Master Plan that will assess supplementation options.

Basinwide Action #8 **Continue coho, sockeye and summer Chinook reintroduction efforts**

Key Partners:
Yakima Klickitat Fisheries Project

Affected MSAs:
All Spawning Areas

Focal Area: Basinwide

Implementation Likelihood: High

Time to Implement: Ongoing

Time to Benefit: 6-10 years

Strategies:
Enhance upstream nutrient supplies

Limiting Factors:
BW9

Cost Derivation: Costs not directly attributable to steelhead recovery.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

The Yakima/Klickitat Fisheries Project is currently working to reintroduce coho to the subbasin and is evaluating the possibility of reintroducing sockeye and summer Chinook. These efforts have the potential to benefit steelhead by increasing the flow of ocean-derived nutrients into rearing areas in the Yakima Basin. Possibilities for competetive interactions also exist and should continue to be monitored by YKFP.

Basinwide Action #9 **Maintain a local policy and informational entity for steelhead recovery**

Key Partners:
Yakima Basin Fish & Wildlife Recovery Board

Affected MSAs:
All Spawning Areas

Focal Area: Basinwide

Implementation Likelihood: High

Time to Implement: Ongoing

Strategies:

Limiting Factors:

Time to Benefit: 0-3 years

Cost Derivation: $200,000/year over 15 years for steelhead portion.

Total Cost: $3,000,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $3,000,000

The Yakima Basin Fish & Widllife Recovery Board was established in 2006 to act as the regional recovery organization for the Yakima Basin under the State of Washington's salmon recovery framework. The Board plays an important role in 1) updating the local and federal steelhead recovery plans, 2) coordinating recovery actions both in the basin and with other recovery entities in the Mid-Columbia steelhead DPS, 3) tracking and reporting on the status of recovery efforts, and 4) building local and regional support for recovery efforts.

Basinwide Action #10 **Promote land and resource use decisions that protect and enhance fisheries resource values**

Key Partners:
Natural Resource Management Agencies
Local governments

Affected MSAs:
All Spawning Areas

Focal Area: Basinwide

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Strategies:
Protect existing functional habitat

Limiting Factors:
All

Time to Benefit: 0-3 years

Cost Derivation: Costs not directly attributable to steelhead recovery.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

Existing regulations and management programs that govern natural resource use need to be implemented in a manner that protects steelhead habitat and the upland and watershed functions that sustain it. These actions need to be coordinated with efforts to protect open space, wildlife habitat, and working landscapes; reduce flood damage; and support development that enhances the quality of life of local communities and meets the needs of private landowners. This plan identifies a number of specific non-regulatory protection actions that should be coordinated with ongoing work to build an effective and balanced system of land use management and zoning.

Basinwide Action #11 **Restore beaver populations**

Key Partners:
- Yakama Reservation Watersheds Project
- Local governments
- Washington Department of Fish & Wildlife

Affected MSAs:
- All Spawning Areas

Focal Area: Basinwide

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Time to Benefit: 3-10 years

Strategies:	Limiting Factors:
Restore floodplain connectivity/function	BW10
Restore channel structure/complexity	

Cost Derivation: Policy aspect not costed; Relocation & habitat management priced at $150,000/year for 15 years.

Total Cost: $2,250,000 **Fisheries:** 50% **Steelhead:** 75% **Steelhead Cost:** $843,750

Beaver played an important role in the pre-European hydrology of the Yakima Basin. Beaver dams and associated meadows can provide complex habitat and increase floodplain storage and the volume and quality of stream baseflows. Where beaver presence is compatible with land uses, it should be encouraged, via reductions in trapping and development of food sources (e.g. riparian plantings). Beaver dams that are potential nusiances can be managed to reduce flood risks or beavers can be relocated to more appropriate locations.

Basinwide Action #12 **Improve recruitment of cottonwoods**

Key Partners:
- Bureau of Reclamation
- USDA Natural Resource Conservation Service
- Private landowners and lessees
- Regional Fisheries Enhancement Group or other volunteer groups
- Conservation Districts
- Local governments
- Washington Department of Fish & Wildlife

Affected MSAs:
- All Spawning Areas

Focal Area: Floodplain reaches of the mainstem Yakima and Naches Rivers

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Time to Benefit: 6-10 years

Strategies:	Limiting Factors:
Restore riparian condition/future LWD	BW2

Cost Derivation: Undetermined.

Total Cost: **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:**

Natural black cottonwood germination generally requires overbank flow in late spring when seeds are dispersing and then a gradual reduction in flows as seedlings establish. This requirement is often at odds with current river operations. The regulated hydrograph could be altered in some years to increase the cottonwood regeneration rate in some reaches; identifying how to do so will require additional analysis. Many floodplain reaches have been heavily grazed and cottonwood regeneration has occurred in places where grazing pressure is relaxed, even under current flow regimes. This highlights the value of ongoing efforts to improve grazing management in riparian areas and floodplains. In the short term, planting programs for cottonwood, especially in the Wapato Reach, would benefit salmonids and the ecosystem as a whole.

Basinwide Action #13 **Address forest health issues**

Key Partners:
US Forest Service
Washington Department of Natural Resources
Private landowners
Bureau of Indian Affairs, Yakama Agency

Affected MSAs:
All Spawning Areas

Focal Area: Forested areas throughout Yakima Basin

Implementation Likelihood: Moderate

Time to Implement: Expand ongoing

Time to Benefit: 6-10 years

Strategies:
Restore riparian condition/future LWD
Improve upland watershed conditions

Limiting Factors:
BW4

Cost Derivation: Costs not directly attributable to steelhead recovery.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

The condition of forest stands directly affects watershed processes, and current increases in disease, pest and fire damage all threaten steelhead habitat. The U.S. Forest Service, the Bureau of Indian Affairs (which manages forests on the Yakama Reservation) and the Washington Department of Natural Resources all have programs to address forest health issues, but the need for treatment greatly exceeds the resources available to perform these tasks. Local interests such as the Yakima Basin Fish & Widllife Recovery Board, the Joint Board of Irrigators, Chambers of Commerce, the Farm Bureau, and federal agencies such as NOAA Fisheries, the BOR and BPA should make federal, state and local decision makers aware of the central role that healthy forests play in fish and wildlife conservation, cultural and recreational activities, management of the public and private water supplies and the health of the entire subbasin economy.

Basinwide Action #14 **Maintain and enforce in-basin fisheries regulations that protect steelhead**

Key Partners:
Washington Department of Fish & Wildlife
Yakama Nation

Affected MSAs:
All Spawning Areas

Focal Area: Basinwide

Implementation Likelihood: High

Time to Implement: Ongoing

Time to Benefit: 0-3 years

Strategies:
Maintain protective fishing regulations

Limiting Factors:
BW6,7

Cost Derivation: Policy action & use of existing enforcement capacity; no new cost charged to recovery.

Total Cost: **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:**

There is no directed recreational steelhead fishing allowed in the basin, and other fisheries are regulated to minimize impacts on steelhead. WDFW and the Yakama Nation should maintain protective regulations and ensure that they are adequately enforced.

Basinwide Action #15 **Evaluate and implement nutrient enhancement in steelhead streams**

Key Partners:
Yakima Klickitat Fisheries Project

Affected MSAs:
All Naches
All Upper Yakima

Focal Area: Selected tributary subwatersheds **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Enhance upstream nutrient supplies BW9

Cost Derivation: $0.50 (0.35/ft plus 0.15/ft program overhead based on NOAA fisheries estimates) per foot per year for 5 five mile reaches for 15 years.

Total Cost: $198,000 **Fisheries:** 100% **Steelhead:** 75% **Steelhead Cost:** $148,500

Historically, higher salmon runs transported significantly more oceanic-derived nutrients to Yakima Basin headwaters. There is interest in launching pilot nutrient enhancement projects in selected tributaries using salmon carcasses and/or carcass analogues. Potential sites include Taneum Creek and the Little Naches River, where carcass placement would occur following large woody debris enhancement (to facilitate retention of carcasses in headwaters). Nutrient enhancement should be coordinated with monitoring of steelhead response.

Basinwide Action #16 **Explore fisheries management options that reduce predation**

Key Partners:
Washington Department of Fish & Wildlife

Affected MSAs:
All Spawning Areas

Focal Area: mainstem Yakima River **Implementation Likelihood:** Moderate

Time to Implement: 0-3 years **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Maintain protective fishing regulations LM9

Cost Derivation: Policy decisions without specific cost to implement.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

Management of existing recreational fisheries for species that prey on steelhead could be implemented in a manner that reduces predation on steelhead, particularly during the outmigration of smolts. Changing recreational fishing rules for bass and catfish in the lower river to reduce number and/or change age structures so as to reduce predation on salmonids and establishing a pikeminnow bounty program have been identified as possible actions. Any efforts to adjust fisheries to reduce predation should be coordinated with ongoing monitoring designed to evaluate the impacts of these adjustments.

Lower Mainstem Action #1 **Increase flows in Chandler bypass reach to improve juvenile out-migration conditions**

Key Partners:
Bureau of Reclamation

Affected MSAs:
All Spawning Areas

Focal Area: Yakima mainstem below Prosser Dam **Implementation Likelihood:** Moderate

Time to Implement: 0-3 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions

Limiting Factors:
LM1

Cost Derivation: No cost to implement, but lost revenue due to reduced power sales (amount not specified at this time).

Total Cost: **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:**

Flows diverted to run the Chandler power plant reduce flows in the Yakima River from Prosser Dam to the powerplant return 12 miles downstream. During the spring, BOR currently reduces generation at the Chandler plant whenever flows would otherwise drop below the 1000 cfs subordination target during the spring. Increasing this minimum flow level when steelhead smolts are moving through the lower Yakima would improve passage conditions for smolts at Chandler Dam and in the bypass reach downstream. It would also reduce the proportion of juvenile entrainment in the Chandler powerhouse diversion and thereby reduce mortality rates in the Chandler canal and at the Chandler outfall. BOR has not committed to this action at this time; implementation would be facilitated by proposed changes to the KID irrigation system.

Lower Mainstem Action #2 **Improve flows below Parker through irrigation system improvements**

Key Partners:
Bureau of Reclamation
Roza-Sunnyside Board of Joint Control
Irrigation Districts
Bureau of Reclamation
BIA/Wapato Irrigation Project

Affected MSAs:
All Spawning Areas

Focal Area: Irrigation Districts in lower Yakima Valley **Implementation Likelihood:** Moderate

Time to Implement: > 10 years
Time to Benefit: 10-25 years

Strategies:
Improve flow conditions

Limiting Factors:
LM2,4,5

Cost Derivation: Roza ID, $40 million; Benton ID, $16 million; SVID, $50 million; KID, $35 million; WIP, $150 million; all very preliminary figures.

Total Cost: $291,000,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $72,750,000

The Sunnyside Irrigation District is nearing completion of a canal improvement project that will result in the dedication of about 20,000 acre/ft of water to instream use. The Wapato Irrigation Project is working with YRBWEP to move diversions for the Satus diversion from Wapato Dam to a new pump station near Granger, which would leave the water to be diverted instream for an additional 25 miles. The Kennewick Irrigation District is working with YRBWEP on several proposals to move some or all of their diversions downstream, potentially as far as the Columbia mainstem, and the Benton Irrigation District has also proposed moving diversions downstream. These proposal (and similar future proposals) would result in significant improvements in mainstem flows during the irrigation season while also resulting in improved water delivery for irrigators.

Lower Mainstem Action #3 Reconfigure infrastructure to improve smolt survival rates

Key Partners:
Bureau of Reclamation
Irrigation Districts

Affected MSAs:
All Spawning Areas

Focal Area: Chandler outfall, Wanawish/Horn Rapids Dam, WIP and SVID bypasses

Implementation Likelihood: High

Time to Implement: 0-3 years

Time to Benefit: 3-10 years

Strategies:
Change structures to reduce predation

Limiting Factors:
LM6,14,15,16

Cost Derivation: BOR cost estimate for outfall structure & a grade control in the river below the Chandler outfall.

Total Cost: $500,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $250,000

The current configuration of the Chandler juvenile bypass outfall and the condition of fish as they exit the bypass result in high concentrations of avian and aquatic predators and high predation rates at that site. Migrating smolts may also be subject to physiological stress and mortality in the bypass system. A more diffuse outfall, improved instream passage routes, bird deterrents and/or provision of additional cover or safe recovery areas for juveniles that transit the bypass would improve survival. Other potential bypass reaches and predation hotspots that should be assessed include Wanawish (Horn Rapids) Dam and the WIP and SVID screen bypass outfalls.

Lower Mainstem Action #5 Improve hydrograph through artificial storage and/or Columbia River water transfer

Key Partners:
Bureau of Reclamation
Department of Ecology

Affected MSAs:
All Spawning Areas

Focal Area: Lower basin (Parker and below)

Implementation Likelihood: Moderate

Time to Implement: > 10 years

Time to Benefit: 10-25 years

Strategies:
Improve flow conditions

Limiting Factors:
LM1,2

Cost Derivation: Cost as proposed is up to $6.5 billion; cost not attributed to steelhead recovery at this time.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

The Yakima Basin Storage Study is assessing proposals to increase water storage capacity through construction of the Black Rock and/or Wymer reservoirs and the possible transfer of water from the Columbia Basin to Yakima Basin irrigation use. As proposed, Black Rock Reservoir would eliminate the most severe effects of the flip-flop flow regime, improve flow and temperature in the Wapato reach, and potentially further delay the onset of lethal temperature regimes. There is still considerable uncertainty about the technical and economic feasibility of the Black Rock project; these questions should be resolved in the EIS to be released by the BOR in 2008. Any efforts to use water from outside the basin will need to ensure that imported water does not negatively affect homing of salmon and steelhead.

Lower Mainstem Action #6 **Restore mainstem and side channel habitats in the Union Gap reach**

Key Partners:

US Army Corps of Engineers
Yakima County
Bureau of Reclamation
Yakima Basin Side Channels Project

Affected MSAs:

All Naches
All Upper Yakima

Focal Area: Mainstem near City of Yakima

Implementation Likelihood: High

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:

Restore floodplain connectivity/function
Restore channel structure/complexity

Limiting Factors:

LM8,9,10,11

Cost Derivation: Based on preliminary estimate by Yakima County.

Total Cost: $13,500,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $3,375,000

The Union Gap reach of the Yakima River between Naches River and Wapato Dam is considered to have very high restoration potential. It is one of the only mainstem reaches that is not currently limited by severely altered flow and temperature regimes. YRBWEP has purchased large areas of floodplain habitat to the east of the river. The majority of this area is currently isolated by levees and passage barriers. Yakima County Flood Control Zone District is proposing to set back the levees in this reach to significantly increase the size of the active floodplain, including on the YRBWEP properties. WSDOT has constructed a new bridge at SR 24 which is much longer than the old bridge to allow the levee setback to proceed. Floodplain restoration work is being coordinated with Central Pre-mix's gravel mining operation.

Lower Mainstem Action #7 **Protect and restore mainstem and floodplain habitats below Sunnyside Dam**

Key Partners:

US Army Corps of Engineers
Yakima County
Bureau of Reclamation
Yakima Basin Side Channels Project
Land Conservancies
Yakama Nation Riparian/Wetlands Restoration Project

Affected MSAs:

All Spawning Areas

Focal Area: Floodplain reaches below Parker **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 0-3 years

Strategies:

Protect existing functional habitat
Restore floodplain connectivity/function
Restore channel structure/complexity
Restore riparian condition/future LWD

Limiting Factors:

LM1,3,7,8,9,11,14,15,16

Cost Derivation: 500 acres floodplain restoration (dike setback/reveg) at $10,000/acre, CREP/easement costs for 636 acres (5% of 1000' x 105 miles) at $3000/ac.

Total Cost: $6,908,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $2,590,500

Lower river conditions play a major role in migration timing for adults and survival of out-migrating smolts. Protecting and restorating mainstem and off-channel habitats (especially those that provide thermal refugia) is critical for these life stages. The best opportunities for restoration lie in the Wapato Reach (especially between the Toppenish/Satus confluences);additional opportunities exist in the very lower river at the Barker Ranch and adjacent to the City of West Richland. Work may include protecting habitat through acquisition, easements or cooperative agreements (including the CREP program), and activities like riparian plantings, reactivation of side channels, and winter irrigation to saturate floodplains. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Lower Mainstem Action #8 Reduce adult attraction to Sulphur Creek & Roza Wasteways

Key Partners:
Roza-Sunnyside Board of Joint Control
Irrigation Districts

Affected MSAs:
All Spawning Areas

Focal Area: Sulfur Drain (by Sunnyside)

Implementation Likelihood: High

Time to Implement: 0-3 years

Time to Benefit: 0-3 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:

Cost Derivation: $400,000 cost for barrier estimated by SVID; reducing flows costed in other actions. No cost available for Roza action.

Total Cost: $400,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $200,000

Sulphur Creek Wasteway (RM 61.0) receives return flows from the Roza and Sunnyside irrigation districts, and has attracted steelhead and salmon that can be stranded in the drain system when irrigation delivery ceases. To avoid this, fish are trapped and removed from the drain each fall. Even if stranding does not occur, passage delays associated with false attraction expose fish to predators and harassment by humans, and exposure to warm water can lessen their reproductive success. Measures to prevent or minimize such attraction are likely to increase steelhead spawning success. The Roza-Sunnyside Joint Board of Control is currently pursuing installation of a fish barrier in Sulfur Creek Wasteway 3/4 of a mile above the Yakima River [note: the fish barrier was completed in 2008 whiloe this plan was under review]. Reducing or eliminating return flows through the drain through improved irrigation system management is also a key part of long-term resolution of this issue (see Basinwide Action #3 and Lower Mainstem Action #2). Roza Wasteway near the City of Yakima is also known to have attract adult salmonids; Reclamation is currently looking at methods to improve the effectiveness of the barrier at the mouth of the wasteway.

Lower Mainstem Action #9 Improve quality of irrigation return flows

Key Partners:
BIA/Wapato Irrigation Project
Roza-Sunnyside Board of Joint Control
Department of Ecology
Irrigation Districts
Individual irrigators
USDA Natural Resource Conservation Service

Affected MSAs:
All Spawning Areas

Focal Area: Irrigation drains entering the lower Yakima River

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Time to Benefit: 0-3 years

Strategies:
Improve water quality

Limiting Factors:
LM4,5

Cost Derivation: Costs of Clean Water Act programs not attributed to specifically to steelhead recovery.

Total Cost: **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:**

In the last decade, the quality of return flows in the lower Yakima River has improved dramatically, with an ~90% decrease in turbidity due to improved irrigation management and implemention of the sediment TMDL for the lower Yakima River. The improved water quality is believed to be contributing to the rapid expansion of water star grass in the lower river. Work to continue water quality improvements should continue and should be accompanied by ongoing research to understand and respond to the ecological changes it is causing.

Naches Action #1 **Improve Wapatox Canal conveyance efficiency**

Key Partners:

Irrigation Districts
Bureau of Reclamation

Affected MSAs:

American
Bumping
Middle Naches
Rattlesnake
Tieton
Upper Naches

Focal Area: Wapatox by-pass reach of the lower Naches

Implementation Likelihood: Moderate

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:

Improve flow conditions

Limiting Factors:

N3,4

Cost Derivation: Based on preliminary discussions with BOR.

Total Cost: $3,000,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $1,500,000

BOR acquired the Wapatox power plant and diversion in 2002 in order to use the associated 300-450 cfs water right to augment instream flows in 7.4 miles of the lower Naches River. The Wapatox diversion also supplies 50 cfs of water to irrigators so the diversion remains active. The conveyance system was designed for 400 cfs and needs a minimum of approximately 130 cfs to provide sufficient head to run the system. This has reduced the amount of water BOR has been able to put to instream use. Improving the efficiency of the conveyance system would allow irrigators access to their full water rights while allowing all of the BOR's water right to be left instream. Consolidating the Wapatox and Naches-Selah diversions has been proposed, which would address this issue, increase instream flows between the Naches-Selah and Wapatox diversions, and reduce constraints on Bumping Reservoir operations.

Naches Action #2	**Improve water use efficiency and habitat in South Naches Irrigation District**

Key Partners:

Irrigation Districts
Bureau of Reclamation

Affected MSAs:

American
Bumping
Middle Naches
Rattlesnake
Tieton
Upper Naches

Focal Area: Lower mainstem Naches

Implementation Likelihood: Moderate

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:

Improve flow conditions

Limiting Factors:

N3,4

Cost Derivation: $1,000,000 estimate in Daily Journal of Commerce article (www.djc.com/news/en/11170266.html).

Total Cost: $1,000,000 **Fisheries:** 33% **Steelhead:** 50% **Steelhead Cost:** $165,000

The South Naches Irrigation District is currently examining means of improving efficiency of the irrigation system and habitat quality in the South Naches Channel. The South Naches Channel is composed of a mixture of natural and artificial channels that parallels the lower Naches for four miles and is used to conveys irrigation water. If appropriate habitat conditions and screening can be assured, the channel can provide increased steelhead rearing habitat. Water savings from efficiency improvements could be allocated to improve instream flows in the South Naches Channel and/or mainstem Naches.

Naches Action #3	**Improve water use efficiency in lower Naches irrrigation districts**

Key Partners:

Irrigation Districts
Bureau of Reclamation

Affected MSAs:

American
Bumping
Cowiche
Middle Naches
Rattlesnake
Tieton
Upper Naches

Focal Area: Lower mainstem Naches River **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years **Strategies:** **Limiting Factors:**

Time to Benefit: 3-10 years Improve flow conditions N3,4

Cost Derivation: $13 million City of Yakima system improvements; $5 million to move Fruitvale diversion to Nelson Dam;$5 million for other Districts.

Total Cost: $23,000,000 **Fisheries:** 33% **Steelhead:** 50% **Steelhead Cost:** $3,795,000

Irrigation system improvements that would increase instream flows have been proposed for the Naches-Selah Irrigation District, Naches Cowiche Canal Company, City of Yakima General Irrigation District (Nelson Dam), Fruitvale (City of Yakima), New Schanno Company, Fruitvale Schanno Company, Yakima Valley Canal Company (Congden Ditch), and Old Union Irrigation Company. These diversions reduce summer flows in steelhead rearing habitat between the diversion points and return flow locations. Increasing conveyance and on-farm efficiencies in these systems and using a portion of the water savings to increase instream flows will improve conditions for the Naches steelhead populations.

Naches Action #4 **Modify flip-flop flow regime**

Key Partners:

Bureau of Reclamation

Affected MSAs:

American
Bumping
Cowiche
Middle Naches
Rattlesnake
Tieton
Upper Naches

Focal Area: Tieton and Lower Naches Rivers **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions

Limiting Factors:
N2,3,4

Cost Derivation: Not estimated at this time; reservoir operation alternatives would have no direct cost, while major structural improvements would have high costs.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

The majority of the streams within the Naches watershed have a relatively unregulated flow regime that is nearer to natural conditions than the rest of the basin. However, flows in the Tieton and the Naches below the confluence with the Tieton are driven by Rimrock Reservoir operations. The flip-flop regime results in low flows in the Tieton through most of the irrigation season and then high (essentially bankfull) flows in the fall. Modifications to the flip-flop flow regime that improve habitat, flow, and temperature conditions for steelhead and other salmonid species in the Tieton and Lower Naches subbasin would have broad benefits for the Naches steelhead population. The negative effects of flip-flop could be addressed through alteration of reservoir operations, conservation, additional storage, or a combination of these and other measures. The Bureau of Reclamation, in collaboration with other subbasin resource managers and stakeholders, should determine if and how flip-flop can be modified to achieve these goals, make the necessary changes, and monitor habitat and fish population response.

Naches Action #5 **Restore lower Naches River floodplain**

Key Partners:

Lower Naches River Partnership Group
Yakima County
Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:

American
Bumping
Cowiche
Middle Naches
Rattlesnake
Tieton
Upper Naches

Focal Area: Lower Naches from Powerhouse Bridge area to confluence

Implementation Likelihood: High

Time to Implement: 6-10 years

Time to Benefit: 10-25 years

Strategies:

Restore floodplain connectivity/function

Limiting Factors:

N9,11

Cost Derivation: 1.2 mile dike removed & reconfigured at $5,000,000/mile.

Total Cost: $6,000,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $1,500,000

A cooperative project between the City of Yakima, Yakima County and WSDOT is seeking to restore floodplain functions in conjunction with planned capital projects for water conservation, elimination of irrigation diversions, reconstruction of Power House Road, and actions to protect US 12 from erosion. Wetland habitats with relatively cool water sources are found at several places along the river: across from Naches Wonderland, within and downstream of Eschbach Park, and the Buckskin Slough in the lower Naches. All of these areas could support increased rearing for salmonids and should be the focus of restoration activities. Proposals are described in the Upper Yakima Comprehensive Flood Management Plan.

Naches Action #6 **Improve sediment transport in lower Naches River**

Key Partners:

Irrigation Districts
Bureau of Reclamation
Yakima County
US Army Corps of Engineers

Affected MSAs:

American
Bumping
Cowiche
Middle Naches
Rattlesnake
Tieton
Upper Naches

Focal Area: Lower mainstem Naches **Implementation Likelihood:** Moderate

Time to Implement: > 10 years **Strategies:** **Limiting Factors:**

Time to Benefit: 10-25 years Restore channel structure/complexity N12

Cost Derivation: Diversion at Gleed (Naches Union) at $300,000, Naches-Cowiche diversion at $5,000,000, City of Yakima diversion at $100,00

Total Cost: $5,400,000 **Fisheries:** 33% **Steelhead:** 50% **Steelhead Cost:** $891,000

Confinement of the lower Naches has reduced sediment transport efficiency, causing aggradation upstream and channel incision or avulsion downstream. Where these facilities are located in the lower end of the alluvial valleys, such as near Eschbach Park/Yakima Water Treatment Plant, and at Rambler's Park/Cowiche (Nelson) Dam, their effects further reduce the amount of rearing habitat (i.e., side channels fed by groundwater return), which should be available in these locations. Improving sediment transport by modification of dam structure and levee reconfiguration will improve habitat availability over the long term. The Upper Yakima Comprehensive Flood Hazard Management Plan contains more detail regarding proposed reworking of Naches-Cowiche, Yakima Water Treatment Plant and Gleed (Naches Union) diversion dams to facilitate sediment movement (efforts will also benefit fish passage at the Naches-Cowiche diversion).

Naches Action #7 **Protect habitats in Naches River mainstem above Tieton confluence**

Key Partners:
- Private landowners
- Land Conservancies
- Washington Department of Fish & Wildlife
- Yakima County

Affected MSAs:
- American
- Bumping
- Middle Naches
- Rattlesnake
- Upper Naches

Focal Area: Nile and Oak Flats areas **Implementation Likelihood:** Moderate

Time to Implement: > 10 years **Time to Benefit:** 10-25 years

Strategies: Protect existing functional habitat

Limiting Factors: N10,14

Cost Derivation: Nile area side channels (60 acres @ $3,500/ac) & Oak Flats in progress ($600,000).

Total Cost: $816,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $204,000

Above the confluence with the Tieton, the Naches River is the least regulated of all Yakima Basin large rivers. Protecting functional habitat in the mainstem Naches and its floodplain above the Tieton confluence should be a priority and may involve a combination of acquisitions, conservation easements, and cooperative agreements. Priority areas include Oak Flats and the Nile area. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Naches Action #8 **Maintain, upgrade or abandon forest roads**

Key Partners:
- Private landowners
- Washington Department of Natural Resources
- US Forest Service
- Washington Department of Fish & Wildlife

Affected MSAs:
- All Naches
- Cowiche
- Upper Naches

Focal Area: Forested areas throughout population area **Implementation Likelihood:** Moderate

Time to Implement: Expand ongoing **Time to Benefit:** 3-10 years

Strategies:
- Improve water quality
- Improve upland watershed conditions

Limiting Factors: N14,15

Cost Derivation: 25 miles /year at $10,000/mile for fifteen years.

Total Cost: $3,750,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $937,500

Programs to address watershed impacts of forest roads exist for US Forest Service and WDNR lands, but are currently limited by funding/staffing and need to be expanded. The Forests and Fish Law applies on private lands. The Cowiche Creek and Little Naches watersheds should be a priority for development and implementation of Road Maintenance and Abandonment Plans under the Forests and Fish agreement. On Forest Service lands, a public scoping process, analysis, and a NEPA decision must be completed before a road can removed from the system.

Naches Action #9 **Provide passage at Bumping Lake Dam**

Key Partners:
Bureau of Reclamation

Affected MSAs:
Bumping

Focal Area: Upper Bumping River watershed **Implementation Likelihood:** Moderate

Time to Implement: 6-10 years
Time to Benefit: 10-25 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
N6

Cost Derivation: BOR has estimated costs of between $8.7 & $31 million; cost given here is for new spillway & fish ladder options.

Total Cost: $15,600,000 **Fisheries:** 100% **Steelhead:** 25% **Steelhead Cost:** $3,900,000

Bumping Lake is a natural glacial lake that supported a run of sockeye salmon. When a dam was constructed to raise the lake to store irrigation water, fish passage was not provided. Providing upstream and downstream fish passage at Bumping Lake would open up 6.6 miles of high quality habitat for steelhead. The BOR Fish Passage Study gives a detailed description (BOR 2005).

Naches Action #10 **Improve habitat in Lower Bumping**

Key Partners:
US Forest Service
Washington State Department of Transportation
Yakima County

Affected MSAs:
Bumping

Focal Area: Lower Bumping River **Implementation Likelihood:** High

Time to Implement: 0-3 years
Time to Benefit: 3-10 years

Strategies:
Restore floodplain connectivity/function
Restore channel structure/complexity

Limiting Factors:
N9,10,11

Cost Derivation: Based on USFS Naches Ranger District estimates.

Total Cost: $370,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $185,000

Redesign of the Bumping Road by the Federal Highways Administration is currently under way. The current design calls for road relocation and expansion to improve safety and reduce travel time. Habitat improvement work has been proposed as part of this road project, and would include: 1) strategically placing about 350 LWD pieces as engineered log jams and small clumps into wood deficient stream reaches (1, 3-4, 6) and along rip rap locations; and 2) Improving riparian conditions and streambank stability at 20-30 dispersed and developed camping areas (about 30 acres) in the Bumping River drainage through motor vehicle barriers, soil decompaction, road obliteration, campsite closures, replanting native vegetation, interpretive signing, and public education.

Naches Action #11 **Restore side channels and floodplain of Little Naches River**

Key Partners:
US Forest Service
Kittitas County
Yakama Nation

Affected MSAs:
Upper Naches

Focal Area: Little Naches mainstem **Implementation Likelihood:** Moderate

Time to Implement: 6-10 years **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Restore floodplain connectivity/function N9,10,11

Cost Derivation: Preliminary costs estimates by USFS & YN staff.

Total Cost: $950,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $356,250

After floods in the 1970s and 1980s, the main road accessing the Little Naches drainage was reconstructed as a levee and and over 6,000 tons of large wood debris were removed from the channel. Over time, this has led to aggradation and degredation of the main channel and isolation of the main channel from side channel and wetland habitats. Restoration of the Little Naches floodplain and reconfiguration of the road/levee system is a major undertaking and will require significant funding and technical support from the US Forest Service and/or the Federal Highway Administration via Kittitas County road department.

Naches Action #12 **Place large woody debris in Little Naches**

Key Partners:
US Forest Service
Yakama Nation
Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:
Upper Naches

Focal Area: Lower mainstem Little Naches **Implementation Likelihood:** Moderate

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**
Time to Benefit: 0-3 years Restore channel structure/complexity N9,10,11

Cost Derivation: 10 engineered log jams at $25,000 each.

Total Cost: $250,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $125,000

Lower reaches of the Little Naches lack large woody debris (LWD), in part due to large-scale wood removal efforts following flooding in the 1970s. This has contributed to downcutting of the stream channel, isolation or dewatering of off-channel habitats, channel instability and habitat simplification. LWD installation projects have been implemented in this watershed with the intent of improving fish habitat and reducing threats to developed campgrounds. Additional projects should be focus on improving fish habitat.

Naches Action #13 **Reduce dispersed recreation impacts in key tributaries**

Key Partners:
- Private landowners
- Regional Fisheries Enhancement Group or other volunteer groups
- US Forest Service
- Washington Department of Fish & Wildlife

Affected MSAs:
- Upper Naches
- Rattlesnake
- Middle Naches

Focal Area: Little Naches, American & Bumping rivers; Oak Creek

Implementation Likelihood: Moderate

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:
- Restore riparian condition/future LWD
- Improve water quality
- Improve upland watershed conditions

Limiting Factors: N20,21

Cost Derivation: $80,000/year for 4 months of 5 person crew & $50,000/year for equipment & supplies for 15 years.

Total Cost: $1,950,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $731,250

Impacts of recreational activities including dispersed camping and off-road vehicle (ORV) use can be significant in sensitive riparian areas. Over the last five years, the US Forest Service and partners have implemented successful programs to reduce these impacts. Coordinated education, enforcement, and on-the-ground restoration and protection efforts should be maintained and/or expanded in areas with high recreational use. The Little Naches will continue to be a focal area due to the high use by ORVs and the expected growth of this activity. These tasks will require additional funding for the US Forest Service and private forest landowners. ORV groups and the US Forest Service have developed a good working relationship, and the opportunity to partner with these organizations is high.

Naches Action #14 **Protect habitats in Little Naches River**

Key Partners:
- Private landowners
- Forest managers and partners
- Land Conservancies
- US Forest Service

Affected MSAs:
- Upper Naches

Focal Area: Private timberland in Little Naches drainage

Implementation Likelihood: Moderate

Time to Implement: > 10 years

Time to Benefit: 10-25 years

Strategies:
- Protect existing functional habitat

Limiting Factors: N10,14

Cost Derivation: 960 acres at $2,000/acre.

Total Cost: $1,920,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $1,080,000

The upper Little Naches passes through a checkerboard of US Forest Service and private timber company land. Ensuring long term protection of the fisheries habitat on private lands can be done through purchases, easements and cooperative agreements; acquisition of the 960 areas along the Little Naches could be integrated into significantly larger landscape-scale protection efforts in the Little Naches watershed. Land is currently protected through the Plum Creek Habitat Conservation Plan. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Naches Action #15 **Improve Nile Creek flows through improved irrigation management**

Key Partners:
Yakima County
Yakima Tributary Access and Habitat Program
North Yakima Conservation District

Affected MSAs:
Middle Naches

Focal Area: Lower Nile Creek

Implementation Likelihood: Moderate

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:
Improve flow conditions

Limiting Factors:
N3,4

Cost Derivation: $500/acre water conservation costs x 160 acres plus $120,000 infrastructure costs.

Total Cost: $200,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $50,000

Flows in lower Nile Creek are currently limited by irrigation water withdrawals. Improvements to irrigation infrastructure and potential transfer, lease or acquisition of water rights would increase summer and fall stream flows. Cost estimates for water conservation are generic estimates based on possible amounts; any actual amounts will be based on voluntary agreements negotiated with landowners.

Naches Action #16 **Improve channel conditions at the mouth of Nile Creek**

Key Partners:
Yakima County
Yakima Tributary Access and Habitat Program

Affected MSAs:
Middle Naches

Focal Area: Lower 1/4 mile of Nile Creek

Implementation Likelihood: High

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
N7

Cost Derivation: Based on existing designs.

Total Cost: $400,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $200,000

The box culvert across Nile Creek 1/4 mile above the Naches constricts the channel, resulting in sediment deposition and subsurface flows. The installation of a new bridge and channel reconstruction work would dramatically improve passage at this partial barrier. The current culvert is scheduled to be replaced in 2008; the new bridge will have a larger span that allows for improved sediment transport.

Naches Action #17 **Increase instream flows in lower Rattlesnake Creek**

Key Partners:
Department of Ecology
North Yakima Conservation District
Individual irrigators
Washington Department of Fish & Wildlife

Affected MSAs:
Rattlesnake

Focal Area: Lower Rattlesnake Creek

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Time to Benefit: 0-3 years

Strategies:
Improve flow conditions

Limiting Factors:
N3,4

Cost Derivation: Based on cost of $500/acre foot conservation or acquisition for 500 acre feet total.

Total Cost: $250,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $125,000

Irrigation diversions from Rattlesnake Creek can dewater the lower creek, where steelhead spawning has been documented. Improving irrigation and conveyance efficiencies, switching water users to shallow groundwater wells, leasing water rights and ensuring diversions are limited to legal rights can all be used to reduce diversions. Cost estimates for water conservation are generic estimates based on possible amounts; any actual amounts will be based on voluntary agreements negotiated with landowners.

Naches Action #18 **Improve sediment transport at Rattlesnake Creek/Naches confluence**

Key Partners:
Washington State Department of Transportation
Yakima County

Affected MSAs:
Rattlesnake

Focal Area: Confluence of Rattlesnake Creek and Naches River

Implementation Likelihood: Moderate

Time to Implement: > 10 years

Time to Benefit: 10-25 years

Strategies:
Restore floodplain connectivity/function

Limiting Factors:
N12

Cost Derivation: Excavation of 2,500 yds @ $10/yd; non-fish proportion is flood control.

Total Cost: $25,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $6,250

The unstable alluvial fan at the mouth of Rattlesnake Creek creates a pasage barrier in low-flow years. The configuration of the irrigation diversion, the Nile Road bridge, and levees on Rattlesnake Creek and the Naches River combine to reduce sediment transport. Improvement or reduction in the impact of the diversion upstream of the bridge and improvements to floodplain connectivity would improve sediment transport out of the Rattlesnake, improving habitat quality in both systems.

Naches Action #19 **Restore lower Cowiche Creek floodplain**

Key Partners:

Lower Naches River Partnership Group
Yakima County
Washington State Department of Transportation
Irrigation Districts
Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:

Cowiche

Focal Area: Lower Cowiche Creek and confluence with Naches River

Implementation Likelihood: High

Time to Implement: Ongoing

Time to Benefit: 10-25 years

Strategies:

Restore unimpeded fish passage
Restore floodplain connectivity/function

Limiting Factors:

N9,11

Cost Derivation: Acquisition of 32 acres of floodplain (350 ft x 3/4 mile) at $7,000/acre & movement of 30,000 cubic yard of dike materials at $10/yard.

Total Cost: $524,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $294,750

The lower end of Cowiche Creek has been confined by dikes and has been checked up in order to convey Naches River irrigation water (a potential source of false attraction). This action involves seperating delivery of Naches River water from Cowiche Creek, removing the check-structure and associated high-maintenance fish ladder, pulling back and/or removing the levees and improving riparian habitats. Associated infrastructure changes for the City of Yakima (Fruitvale) irrigation diversion are included under Naches Action #3. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Naches Action #20 **Protect Cowiche Creek watershed from increasing development pressure**

Key Partners:

Washington Department of Fish & Wildlife
Yakima (City) Habitat Improvement Project
Yakima County
North Yakima Conservation District
Private landowners
Land Conservancies

Affected MSAs:

Cowiche

Focal Area: Cowiche Creek watershed

Implementation Likelihood: High

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:

Protect existing functional habitat
Improve upland watershed conditions

Limiting Factors:

N9,10,11

Cost Derivation: Purchase of 360 acres of riparian corridor easement at $600/acre & 6 sections (3840 acres) at $800/ac (mix of easement & acquisition).

Total Cost: $3,288,000 **Fisheries:** 50% **Steelhead:** 100% **Steelhead Cost:** $1,644,000

Large parcels of private timber and rangelands in the upper Cowiche Creek watershed and smaller parcels lower in the watershed are all subject to increased development pressure. A mix of conservation easements, land purchases and cooperative agreements should be pursued to ensure that fish habitat and associated uplands are not negatively impacted. The area should be maintained in very low density zoning and regulation of road standards and wildland/urban interface standards for fire protection. This action overlaps with ongoing open space/wildlife habitat protection efforts. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Naches Action #21 **Reduce irrigation diversions from Cowiche Creek**

Key Partners:

Individual irrigators
North Yakima Conservation District
Washington Department of Fish & Wildlife
Irrigation Districts
Water Trust & Conservancies
Bureau of Reclamation

Affected MSAs:

Cowiche

Focal Area: South Fork and Mainstem Cowiche Creek

Implementation Likelihood: Moderate

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:

Improve flow conditions

Limiting Factors:

N3,4

Cost Derivation: Phase I currently being proposed by the Cowiche Water Users Association (7 cfs for $350,000). Phase II still to be defined.

Total Cost: $350,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $350,000

Irrigation diversions significantly reduce summer and falls flows in the lower 12 miles of the Cowiche Creek system. Irrigation system improvements that increase water use efficiencies, cooperative agreements with irrigators, and leases and purchase of water rights can all be used to reduce diversions. Much of the land irrigated from Cowiche Creek could potentially be served by the Yakima Tieton Irrigation District, and the possibility for agreements that provide irrigators with Yakima-Tieton water in exchange for leaving surface flows in Cowiche Creek should continue to be pursued.

Naches Action #22 **Improve riparian, floodplain, and temperature conditions in Cowiche Creek**

Key Partners:
- Washington Department of Fish & Wildlife
- Yakima Tributary Access and Habitat Program
- North Yakima Conservation District
- Private landowners and lessees
- Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:
- Cowiche

Focal Area: Mainstem and South Fork of Cowiche Creek; possibly Reynolds Creek

Implementation Likelihood: High

Time to Implement: > 10 years

Time to Benefit: 10-25 years

Strategies:	Limiting Factors:
Restore floodplain connectivity/function	N14,18,19
Restore channel structure/complexity	
Restore riparian condition/future LWD	

Cost Derivation: Riparian plantings along 10 miles at $15,000/mile, 3 miles of channel/floodplain restoration at $200,000/mile, instream LWD at $500 per installed piece at 50/mile for 5 miles & 6 miles fence at $10,000/mile.

Total Cost: $935,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $935,000

This action involves riparian planting, livestock fencing, grazing system improvements, channel/floodplain reconstruction, and large woody debris placement along numerous sites along Cowiche Creek. The middle reach will involve working with a number of smaller landowners, while the upper and canyon reaches are a mix of WDFW, Cowiche Canyon Conservancy, and large private lands that are suitable for large-scale restoration projects. Implementation of these actions should improve natural floodplain function, reduce flooding, and increase base flows, and water quality. The North Fork Cowiche historically comprised only a small proportion of the available habitat in the watershed and is not proposed for full restoration due to limited opportunities and high costs.

Naches Action #23 **Restore Oak Creek habitat**

Key Partners:
- US Forest Service
- Washington Department of Fish & Wildlife
- Yakima Tributary Access and Habitat Program

Affected MSAs:
- Tieton

Focal Area: Lower Oak Creek

Implementation Likelihood: High

Time to Implement: > 10 years

Time to Benefit: 10-25 years

Strategies:	Limiting Factors:
Restore channel structure/complexity	N14,17
Restore riparian condition/future LWD	

Cost Derivation: Revegetate 100 ft buffer each side of the creek for 3.5 miles for $30,000 & weed control of 3.5 miles for $2,500/mile for 3 years.

Total Cost: $56,250 **Fisheries:** 75% **Steelhead:** 100% **Steelhead Cost:** $42,188

Oak Creek is the only portion of the Tieton system that has been confirmed as supporting steelhead spawning. The entire watershed is owned by WDFW, US Forest Service and The Nature Conservancy. Much of the lower watershed (especially the riparian zone) has burned in recent wildfires and would benefit from replanting and weed control. Possibilities to improve instream and floodplain habitat and address road impacts should also be evaluated.

Naches Action #24 **Protect instream flow improvements in Ahtanum Creek**

Key Partners:
Ahtanum Irrigation District
BIA/Wapato Irrigation Project
Yakama Reservation Watersheds Project

Affected MSAs:
Ahtanum

Focal Area: Mainstem Ahtanum Creek **Implementation Likelihood:** High

Time to Implement: Ongoing
Time to Benefit: 0-3 years

Strategies:
Improve flow conditions

Limiting Factors:
N3,4

Cost Derivation: 1 FTE & expenses at $75,000/year.

Total Cost: $1,125,000 **Fisheries:** 100% **Steelhead:** 75% **Steelhead Cost:** $843,750

Recent improvements in both summer and winter instream flows in Ahtanum Creek are due to agreements between the Yakama Nation, the Wapato Irrigation Project and Ahtanum Irrigation District. A network of wading discharge measurement transects and gauging stations are key to maintaining these agreements. Both the agreements and the supporting monitoring efforts should be continued.

Naches Action #25 **Develop off-channel storage in Ahtanum Creek**

Key Partners:
Ahtanum Irrigation District
BIA/Wapato Irrigation Project
Department of Ecology

Affected MSAs:
Ahtanum

Focal Area: Ahtanum, Bachelor and Hatton Creeks **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions

Limiting Factors:
N3,4

Cost Derivation: Cost as identified in preliminary feasibility study.

Total Cost: $45,000,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $11,250,000

The proposed Pine Hollow Reservoir would increasing the amount of water avaialble to meet and increase instream flows and meet irrigators' water needs. Associated irrigation system and habitat improvements would further increase benefits to steelhead by allowing full access to Bachelor and possibly Hatton Creeks. Implementation of the Pine Hollow project would require significant restructuring of complex water rights, including cooperation with the Yakama Nation, BIA/WIP, the Ahtanum Irrigation District, and private diverters. Funding for the project is not yet secured and environmental analyses have not been completed.

Naches Action #26 **Minimize irrigation conveyance loss in Ahtanum Creek**

Key Partners:
BIA/Wapato Irrigation Project

Affected MSAs:
Ahtanum

Focal Area: WIP Ahtanum Main Canal **Implementation Likelihood:** High

Time to Implement: 4-6 years **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Improve flow conditions N3,4

Cost Derivation: 2005 engineer's estimate was $116,305/mile for 5 miles. Multiplied by 1.2 for cost inflation since 2005.

Total Cost: $697,830 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $392,529

Areas of high seepage loss from the Wapato Irrigation Project's Ahtanum Main Canal have been identified and substantially increase the amount of water that has to be diverted to supply users near the end of the canal. Lining these sections of the canal would help in limiting diversions and increase instream flow.

Naches Action #27 **Ahtanum Creek floodplain and side channel restoration**

Key Partners:
Washington Department of Fish & Wildlife
Yakama Reservation Watersheds Project
Yakima County
North Yakima Conservation District

Affected MSAs:
Ahtanum

Focal Area: Ahtanum Creek and side channels **Implementation Likelihood:** Moderate

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Restore floodplain connectivity/function N10,11

Cost Derivation: Based on $90,000 cost of completed Herke side channel x 150% cost adjustment for 5 projects.

Total Cost: $675,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $379,688

There are several opportunities to reconnect side channels and enhance floodplain function in the Ahtanum Creek system, including the 7-mile spring creek through the airport, smaller channels upstream of major diversions, and, if agreements with irrigators can be developed (see Action #22), the Bachelor/Hatton system. Where there are opportunities to reconnect side channels, especially upstream from major diversions, both fish habitat and flood conveyance can be improved. Habitat restoration in lower Ahtanum will also benefit steelhead from other MSAs by providing rearing habitat adjacent to the Yakima River.

Naches Action #28 **Protect Ahtanum Creek riparian areas to lessen development impacts**

Key Partners:
- Washington Department of Fish & Wildlife
- Yakima County
- Yakama Nation
- Yakima (City) Habitat Improvement Project
- Land Conservancies

Affected MSAs:
- Ahtanum

Focal Area: Lower Ahtanum Creek

Implementation Likelihood: Moderate

Time to Implement: 0-3 years

Time to Benefit: 3-10 years

Strategies:
- Protect existing functional habitat

Limiting Factors:
- N9,10,11

Cost Derivation: 450 deeded riparian acres on south side at $8,000/acre; easements on 300 ft buffer for 50% of 10 miles (~180 acres) on northside at $8,000/acre.

Total Cost: $5,040,000 **Fisheries:** 50% **Steelhead:** 75% **Steelhead Cost:** $1,890,000

The lower part of Ahtanum Creek is affected by urbanization in Union Gap, Yakima, and nearby unincorporated areas, while the middle section is experiencing increased residential development. Residential/retirement/recreational development is also increasing in the upper watershed. Current opportunities to protect riparian areas and key floodplain parcels in lower Ahtanum Creek will disappear over time. Tools include land purchases and leases, conservation agreements, and cooperative agreements with landowners (e.g., incorporating protections into development plans). Development within Urban Growth Areas should be carefully planned to protect floodplains, riparian and instream resources, and private properties in this especially flood-prone watershed. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Naches Action #29 **Reduce livestock impacts on Ahtanum Creek riparian areas**

Key Partners:
- Washington Department of Fish & Wildlife
- Yakama Reservation Watersheds Project
- North Yakima Conservation District

Affected MSAs:
- Ahtanum

Focal Area: Ahtanum Creek and tributaries

Implementation Likelihood: High

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:
- Restore riparian condition/future LWD
- Improve upland watershed conditions

Limiting Factors:
- N18,19

Cost Derivation: Based on 20% of $250,000/year cost of Yakama Nation restoration crew; $20,000/year in riparian fencing materials; 5 stock water wells at $60,000 each; annual lease on 640 acres on reservation at $85/acre/yr for 15 years; 7 miles fencing at $10,000/mile; & 2 miles of riparian plantings at $15,000/mile on Northside.

Total Cost: $2,216,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $1,246,500

Improving the condition of Ahtanum Creek's riparian areas will help realize the maximum benefit from instream flow improvements. The Yakama Reservation Watersheds Program has been active on the south side of the creek, while the North Yakima Conservation District has worked extensively with landowners on the North side in its successful efforts to address screening and passage barriers. The Ahtanum Watershed Restoration EIS includes several specific actions.

Naches Action #30 **Improve winter flows below storage dams**

Key Partners:
Bureau of Reclamation

Affected MSAs:
Tieton
Bumping

Focal Area: Tieton, Bumping and Naches rivers below Rimrock and Bumping Lakes

Implementation Likelihood: Moderate

Time to Implement: 0-3 years

Time to Benefit: 0-3 years

Strategies:
Improve flow conditions

Limiting Factors:
N1

Cost Derivation: Operational change; no specific cost identified.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

Late fall/winter flows below Rimrock and Bumping reservoirs are maintained at low levels relative to the unregulated hydrograph, with occassional large releases made for flood control purposes. Effects on the Bumping River are minimal in most years, but the Tieton is significantly affected. Adjusting reservoir operations to increase winter base flows will improve overwintering habitat. The Bureau increased winter flow in the Tieton in 2008 (to a base of ~100-125 cfs vs earlier targets as low as 30cfs); this commitment should be continued.

Naches Action #31 **Restore side channels and floodplain of Upper Naches River**

Key Partners:
US Forest Service
Washington Department of Fish & Wildlife
Private landowners
Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:

Focal Area: Naches River between Tieton confluence and Little Naches

Implementation Likelihood: Moderate

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:
Restore floodplain connectivity/function
Restore channel structure/complexity

Limiting Factors:
N9,10,11

Cost Derivation: Preliminary cost estimates by US Forest Service staff.

Total Cost: $200,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $100,000

Several historic off channel habitats could be enhanced by increasing water flow into them for longer seasonal periods of the year. These off channel habitats are important rearing and refuge areas for juvenile salmonids. Engineered log jams or other instream hydrologic structures could regulate flows into these low gradient side channels.

Satus Action #1 **Reconnect Satus Creek floodplain**

Key Partners:

Yakama Nation Riparian/Wetlands Restoration Project
Washington State Department of Transportation
Yakama Reservation Watersheds Project

Affected MSAs:

Dry
Satus

Focal Area: Mainstem of Satus Creek (lower 8 miles and along Highway 97)

Implementation Likelihood: Moderate

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:

Restore floodplain connectivity/function

Limiting Factors:

S3,4,5

Cost Derivation: Construction of 50 check structure at $20,000 per structure; purchase of 320 acres floodplain at $4000/acre & $215/yr restoration/maintenance cost; & lease of 5000 acres (Satus Wildlife Area, Mule-Dry Confluence, Hwy 97 corridor) at $50/ac/yr lease plus $30/yr maintenance for 15 yrs. Estimate does not include WSDOT cost such as bridge replacement.

Total Cost: $9,312,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $5,238,000

Lower Satus Creek is entrenched and partly confined by dikes. It may not be possible to elevate the creek to the its original floodplain in this reach, but allowing it to meander at its present level, and introducing appropriate roughness features will restore some of the original channel complexity and floodplain functions. Impacts from US 97 farther uspstream are being addressed through a cooperative consultation process between the Yakama Nation and the WSDOT. Examples include the planned replacement of the US 97 crossing of Logy Creek near its confluence with Satus Creek (RM 23.7), which needs to include floodplain restoration at the previous crossing alignment as well as careful design of the replacement and reactivating the floodplain in the reach immediately downstream from the “High Bridge” (RM 32.4). US 97 also restricts the movement of bedload from tributary streams into Satus Creek at several crossings including Kusshi, Shinando, and a host of unnamed tributaries, contributing to incision of Satus Creek. There are also several large levees that could be removed to promote better stream/floodplain connectivity. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Satus Action #2 **Continue improving management of cattle and improve management of feral horses**

Key Partners:
Yakama Reservation Watersheds Project

Affected MSAs:
Dry
Satus

Focal Area: Entire Satus Creek Watershed **Implementation Likelihood:** Moderate

Time to Implement: Ongoing
Time to Benefit: 3-10 years

Strategies:
Restore riparian condition/future LWD
Improve upland watershed conditions

Limiting Factors:
S9,10

Cost Derivation: 20% of restoration crew cost of $250,000/yr plus materials to build & repair range, riparian, & meadow fencing at $10,000/yr plus lease of critical grazing units at $25,000/yr; all for 15 years & 10 stock water well installations at $60,000 each.

Total Cost: $1,875,000 **Fisheries:** 50% **Steelhead:** 100% **Steelhead Cost:** $937,500

Recent and ongoing improvements in the management of cattle grazing have reduced grazing impacts in the Satus Creek watershed. Impacts from wild horses are ongoing, and the Yakama Nation is developing a wild horse management plan for the Satus and Toppenish Creek watersheds which will focus on limiting riparian zone damage.

Satus Action #3 **Reroute North Drain to address return flow issues in lower Satus Creek**

Key Partners:
Bonneville Power Administration
Yakama Nation Riparian/Wetlands Restoration Project
US Fish & Wildlife Service
US Army Corps of Engineers
USDA
Yakama Reservation Watersheds Project

Affected MSAs:
Dry
Satus

Focal Area: Lower mainstem of Satus Creek **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions
Improve water quality

Limiting Factors:
S1

Cost Derivation: Cost of $3,000,000 based on estimates by US Army Corps of Engineers & Yakama Nation.

Total Cost: $3,000,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $1,125,000

Between 5 and 40 cfs of irrigation return flows from the Wapato Irrigation Project enter lower Satus Creek via the North Drain. Rerouting the North Drain into wetlands on the Satus Wildlife Area would reduce the quantity and increase the quality of return flows into Satus Creek. Initial plans have been developed in cooperation with the US Army Corps of Engineers.

Satus Action #4 **Improve Satus East and West Laterals to address return flow issues**

Key Partners:
BIA/Wapato Irrigation Project
Yakama Reservation Watersheds Project
Bureau of Reclamation

Affected MSAs:
Dry
Satus

Focal Area: Lower mainstem of Satus Creek **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions
Improve water quality

Limiting Factors:
S1

Cost Derivation: $3,380,000 based on 2001 conservation plan (1998 costs).

Total Cost: $3,380,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $845,000

The Satus East and West Laterals empty into Satus Creek. Piping the Satus Area of the Wapato Irrigation Project will allow for better management of return flows to Satus Creek. This is one component of the Yakima River Basin Water Enhancement Program's conservation plan for the Wapato Irrigation District. The Secretary of Interior has approved the infrastructure portion of the WIP Priority Water Conservation Measures Plan and a 1990 authorization of $18 million is allocated to the project, but may need to be supplemented. Implementing the Conservation Measures Plan will also improve instream flow and water quality in the Yakima River (see Lower Mainstem Action #10).

Satus Action #5 **Remove BIA Satus Diversion Dam**

Key Partners:
Yakama Reservation Watersheds Project

Affected MSAs:
Dry
Satus

Focal Area: Lower mainstem of Satus Creek **Implementation Likelihood:** High

Time to Implement: 0-3 years
Time to Benefit: 0-3 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
S2

Cost Derivation: Preliminary engineering estimated at $90,000 & construction at $250,000.

Total Cost: $340,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $340,000

The Satus Diversion Dam is no longer in use. Its rudimetary fish ladder is prone to tampering by recreationists. Removing the existing concrete diversion dam and diversion canal headworks would improve stream channel habitat, eliminate a partial steelhead passage barrier and restore this reach of the creek to a more natural and productive condition.

Satus Action #6 **Restore passage in Shinando Creek at Highway 97 crossing**

Key Partners:
Washington State Department of Transportation
Yakama Reservation Watersheds Project

Affected MSAs:
Satus

Focal Area: Shinando Creek **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Restore unimpeded fish passage S6

Cost Derivation: The project presents challenges (hence the high cost estimate) but pipe boring techniques are improving, which may decrease cost below estimate.

Total Cost: $1,500,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $1,500,000

Fish access to the Shinando drainage is blocked by an impassable structure under Highway 97 that is under deep fill. Preliminary engineering indicates that it may be feasible to restore passage without removal of the fill.

Satus Action #7 **Improve, relocate, or close forest roads**

Key Partners:
Bureau of Indian Affairs, Yakama Agency
Yakama Reservation Watersheds Project

Affected MSAs:
Dry
Satus

Focal Area: Entire Satus Creek Watershed **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years **Strategies:** **Limiting Factors:**
Time to Benefit: 3-10 years Improve upland watershed conditions S7,8

Cost Derivation: 5 miles/yr of road reconstruction, upgrade, or abandonment at $10,000/mi x 15 yrs.

Total Cost: $750,000 **Fisheries:** 50% **Steelhead:** 100% **Steelhead Cost:** $375,000

Overall, forest roads have been built and maintained to a lower standard on the Yakama Reservation than on, for example, US Forest Service land. There is a need to continue and expand road closures, relocations and drainage improvements to reduce sediment and peak flows deliveries to creeks. The Yakama Reservation Watersheds Project and other tribal programs have assessed these needs and will coordinate a road improvement program with BIA, which manages reservation forestlands.

Satus Action #8 **Restore headwater meadows**

Key Partners:
Bureau of Indian Affairs, Yakama Agency
Yakama Reservation Watersheds Project

Affected MSAs:
Dry
Satus

Focal Area: Entire Satus Creek Watershed

Implementation Likelihood: High

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:
Improve flow conditions
Improve water quality

Limiting Factors:
S11

Cost Derivation: 10% of $250,000/yr cost for restoration crew plus $15,000/yr construction costs (most work will be hand work, but several locations will require machinery). Fencing is covered under Action #12. $200,000 is included for possible land purchases.

Total Cost: $800,000 **Fisheries:** 75% **Steelhead:** 100% **Steelhead Cost:** $600,000

Steelhead productivity in the Satus Creek watershed is hampered by rapid runoff and minimal summer streamflow. Some of this problem can be traced to headwater meadows that are dissected by gullies and no longer store runoff efficiently. The Yakama Reservation Watersheds Project has been refining headwater meadow restoration techniques and will coordinate further restoration efforts.

Toppenish Action #1 **Rehabilitate alluvial fan and downstream floodplain of Toppenish Creek**

Key Partners:
- BIA/Wapato Irrigation Project
- Yakama Nation Riparian/Wetlands Restoration Project
- Yakama Reservation Watersheds Project
- Bureau of Reclamation

Affected MSAs:
- Simcoe
- Toppenish

Focal Area: Lower mainstem of Toppenish Creek **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 3-10 years

Strategies:
Restore floodplain connectivity/function

Limiting Factors:
T5,7,9,10,11

Cost Derivation: On the alluvial fan, open 14 swale crossings at $150,000 each & breach/remove 0.5 miles of dike at 60,000 yards/mi & $10/yd. For the downstream floodplain, 10 miles of side channel reconnection & grade control at $150,000/mi, 20 miles of revegetation at $15,000/mi across 2 channels. Seepage study based on 0.5 FTE x $75,000 x 2 yr & $50,000 materials. Maintain 2,000 acreat $35/ac/yr for 15 years.

Total Cost: $5,675,000 **Fisheries:** 50% **Steelhead:** 100% **Steelhead Cost:** $2,837,500

The Yakama Nation plans to restore floodplain functions on the Toppenish Creek alluvial fan and along lower Toppenish Creek. This action builds on 1) BIA-funded rehabilitation of the lower canyon/upper fan reach of Toppenish Creek, 2) the acquisition and rehabilitation of riparian lands on lower Toppenish Creek funded by BPA and other entities, and 3) instream flow improvements mandated by the Yakama Nation below a BIA diversion. Funding for the Toppenish Creek Corridor Enhancement Plan is being pursued via YRBWEP and the continuation of existing funded restoration programs. This action should include studies of seepage loss in the alluvial fan reach of the creek to determine if agricultural drains or deep well pumping are contributing to the loss of instream flows and, if so, identify possible mitigation efforts.

Toppenish Action #2 **Elevate Marion Drain to restore Toppenish Creek flows and water quality**

Key Partners:
- BIA/Wapato Irrigation Project
- Yakama Reservation Watersheds Project
- Bureau of Reclamation

Affected MSAs:
- Simcoe
- Toppenish

Focal Area: Lower mainstem of Toppenish Creek **Implementation Likelihood:** Moderate

Time to Implement: 0-3 years
Time to Benefit: 3-10 years

Strategies:
Restore floodplain connectivity/function
Improve flow conditions

Limiting Factors:
T3,7

Cost Derivation: Yakama Nation Engineering preliminary estimate.

Total Cost: $2,000,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $1,125,000

Marion Drain runs parallel to Toppenish Creek for 18 miles, and is deeper than Toppenish Creek for most of its length. It intercepts groundwater that would otherwise reach Toppenish Creek. The drain is deeper than needed for agricultural drainage. Constructing grade controls to raise the water surface in the drain could improve water quantity and quality throughout a 25-mile reach of Toppenish Creek without reducing the drain's ability to meet agricultural needs.

Toppenish Action #3 **Replace undersized crossing culvert in Toppenish Creek**

Key Partners:
Yakama Reservation Watersheds Project
Private landowners

Affected MSAs:
Toppenish

Focal Area: Mainstem of Toppenish Creek above Simcoe Creek

Implementation Likelihood: High

Time to Implement: 0-3 years

Time to Benefit: 0-3 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
T12

Cost Derivation: Engineering for $40,000. Project construction estimates begin at $150,000 & could be significantly higher.

Total Cost: $230,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $230,000

In February 2006, Yakama Nation personnel found a farm crossing of Toppenish Creek just upstream from the Simcoe Creek confluence that appears to impede adult steelhead passage at moderately high streamflow of several hundred cfs. This structure should be removed or replaced to provide unimpeded fish passage; purchasing 139 acres (appraised at $660k) would make the crossing unnecessary and protect nearly a mile of Toppenish and Simcoe creeks.

Toppenish Action #4 **Complete passage and screening projects in Simcoe Creek**

Key Partners:
Yakama Reservation Watersheds Project
Individual irrigators

Affected MSAs:
Simcoe

Focal Area: Lower Simcoe Creek

Implementation Likelihood: Moderate

Time to Implement: Expand ongoing

Time to Benefit: 0-3 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
T6,12

Cost Derivation: Based on a cost of $20,000/cfs for previous screens in area.

Total Cost: $300,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $300,000

There are three remaining unscreened irrigation diversions on Simcoe Creek (South Fork, Hubbard and Smartlowit), with a total capacity of 15 cfs. Screening is complicated by the dynamic nature of the stream channel. A proposal to supply the Hubbard Diversion from the existing screened Hoptowit Diversion could not be implemented. Other options should be explored to lessen this cost.

Toppenish Action #5 **Further reduce diversions by improved water management.**

Key Partners:
Yakama Reservation Watersheds Project

Affected MSAs:
Simcoe
Toppenish

Focal Area: Lower Simcoe and Toppenish creeks **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions

Limiting Factors:
T12,18

Cost Derivation: Cost based on 1 FTE staff at 75,000/yr for 15 years & 10 stock water wells at $50,000 each.

Total Cost: $1,625,000 **Fisheries:** 75% **Steelhead:** 100% **Steelhead Cost:** $1,218,750

Efforts should be made to increase water use efficiencies, reducing diversions, and increasing instream flow. This could include additional wells to provide stock water during the low-flow period, replacing inefficient surface water delivery. A number of stock water wells are already in operation, which has allowed the Yakama Nation to limit diversions and increase instream flow. Cost includes staff time to monitor flow, calibrate gauges, work with irrigators to implement criteria, and improve water management for fisheries benefits.

Toppenish Action #6 **Remove irrigation spills and returns from Toppenish and Simcoe creeks**

Key Partners:
BIA/Wapato Irrigation Project
Yakama Reservation Watersheds Project
Bureau of Reclamation

Affected MSAs:
Toppenish
Simcoe

Focal Area: Lower Toppenish and Simcoe creeks **Implementation Likelihood:** Moderate

Time to Implement: 6-10 years
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions
Improve water quality

Limiting Factors:
N3,4,5

Cost Derivation: Yakama Nation Engineering preliminary estimate.

Total Cost: $3,750,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $2,109,375

The Wapato Irrigation Project (BIA) routes operational spills and sediment-laden return flows down Toppenish and Simcoe creeks to supply other areas of the project. Studies have been initiated by the Yakama Nation on the feasibility of separating these irrigation flows from the creek system. Elimination of return flow should be combined with efforts to restore groundwater seepage, currently intercepted by Marion Drain, back into Toppenish Creek (see Action #2).

Toppenish Action #7 **Continue leases, purchase, and management of riparian areas**

Key Partners:
- Yakama Nation Riparian/Wetlands Restoration Project
- Yakama Reservation Watersheds Project
- Bureau of Reclamation

Affected MSAs:
- Toppenish
- Simcoe

Focal Area: Lower Toppenish and Simcoe creeks **Implementation Likelihood:** High

Time to Implement: Ongoing
Time to Benefit: 3-10 years

Strategies:
- Protect existing functional habitat
- Restore riparian condition/future LWD

Limiting Factors:
- N8

Cost Derivation: Cost based on current program cost of $1,000,000/year for 15 years.

Total Cost: $15,000,000 **Fisheries:** 50% **Steelhead:** 75% **Steelhead Cost:** $5,625,000

Current efforts to protect riparian and floodplain lands via acquisition of land, easements, and Tribal trust leases need to continue in order to protect and restore lower Toppenish and Simcoe creek adult migration and holding areas and juvenile fall, winter, and spring rearing areas. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Toppenish Action #8 **Improve, relocate, or close forest roads**

Key Partners:
- Bureau of Indian Affairs, Yakama Agency
- Yakama Reservation Watersheds Project

Affected MSAs:
- Simcoe
- Toppenish

Focal Area: Entire Toppenish Creek Watershed **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years
Time to Benefit: 3-10 years

Strategies:
- Improve upland watershed conditions

Limiting Factors:
- N13,14

Cost Derivation: 5 miles/year of road reconstruction, upgrade, or abandonment at $10,000/mi for 15 yrs.

Total Cost: $750,000 **Fisheries:** 50% **Steelhead:** 100% **Steelhead Cost:** $375,000

Overall, forest roads have been built and maintained to a lower standard on the Yakama Reservation than on, for example, US Forest Service land. There is a need to continue and expand road closures, relocations, and drainage improvements to reduce sediment and peak flows deliveries to creeks. The Yakama Reservation Watersheds Project and other tribal programs have assessed these needs and will coordinate a road improvement program with BIA, which manages reservation forestlands.

Toppenish Action #9 **Continue improving management of cattle and improve management of feral horses**

Key Partners:
Yakama Reservation Watersheds Project

Affected MSAs:
Simcoe
Toppenish

Focal Area: Entire Toppenish Creek Watershed **Implementation Likelihood:** Moderate

Time to Implement: Ongoing
Time to Benefit: 3-10 years

Strategies:
Restore riparian condition/future LWD
Improve upland watershed conditions

Limiting Factors:
N15,16

Cost Derivation: 20% of restoration crew cost of $250,000/yr plus materials to build & repair range, riparian, & meadow fencing at $10,000/year; all for 15 years & 5 stock water well installations at $60,000 each.

Total Cost: $1,200,000 **Fisheries:** 50% **Steelhead:** 100% **Steelhead Cost:** $600,000

Recent and ongoing improvements in the management of cattle grazing have reduced impacts in the Toppenish Creek watershed. Impacts from wild horses are ongoing and the Yakama Nation is developing a wild horse management plan for the Satus and Toppenish Creek watersheds, which will focus on limiting riparian zone damage.

Toppenish Action #10 **Restore headwater meadows**

Key Partners:
Bureau of Indian Affairs, Yakama Agency
Yakama Reservation Watersheds Project

Affected MSAs:
Satus
Toppenish

Focal Area: Entire Toppenish Creek Watershed **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 3-10 years

Strategies:
Improve flow conditions
Improve water quality

Limiting Factors:
N17

Cost Derivation: 10% of $250,000/yr cost for restoration crew plus $15,000/yr construction costs (most work will be hand work, but several locations will require machinery). Fencing is covered under Action #9. $200,000 is included for possible land purchases.

Total Cost: $800,000 **Fisheries:** 75% **Steelhead:** 100% **Steelhead Cost:** $600,000

Steelhead productivity in the Toppenish Creek watershed is limited in large part by summer streamflow. Some of this problem can be traced to headwater meadows that are dissected by gullies and no longer store runoff efficiently. The Yakama Reservation Watersheds Project has been refining headwater meadow restoration techniques and will coordinate further restoration efforts.

Upper Yakima Action #1 **Redesign Roza Dam facilities to improve downstream smolt passage**

Key Partners:
Bureau of Reclamation

Affected MSAs:
All Upper Yakima

Focal Area: Roza Dam

Implementation Likelihood: High

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
U9

Cost Derivation: Price noted at BOR presentation at Yakima Basin Science & Management Conference in 2006.

Total Cost: $4,500,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $2,250,000

Roza Dam's spill gates currently hinder smolt outmigration unless "tucked" periodically to allow surface spill. When no surface spill occurs at Roza Dam, downstream migrating fish must either navigate through the fish screen bypass located in slackwater with poor attraction flows or sound deep to pass through a small slot near the bottom of the dam structure. The passage obstacle at Roza is thought to increase overall travel time for migrants, prolong exposure to predation in the dam pool, and physically harm passing fish. Proposed modifications would allow some surface spill to be maintained under all conditions. BOR has completed a preliminary design and is scheduled to begin construction in 2009. Gate modifications that allow for surface spill at lower flows should not be used to justify maintenance of insufficient instream flows below Roza (see Upper Yakima Action #2).

Upper Yakima Action #2 **Improve instream flows below Roza Dam**

Key Partners:
Bureau of Reclamation
Irrigation Districts

Affected MSAs:
All Upper Yakima

Focal Area: Mainstem Yakima River from below Roza to Yakima

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Time to Benefit: 0-3 years

Strategies:
Improve flow conditions

Limiting Factors:
U3

Cost Derivation: Cost of lost power under different scenarios are currently being calculated by BPA. Initial estimates for cost of tucking gates whenever flows during the spring allow are ~$160,000/yr.

Total Cost: $2,400,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $1,200,000

Water diversions used for power generation decrease flows in the Yakima River between Roza Dam and the powerplant outfall 15 miles downstream. Many fish biologists in the basin have recommended provisions of higher outmigration flows below Roza Dam to reduce downstream travel times and increase smolt survival. This requires developing biologically based instream flow targets for this reach for the smolt outmigration (April 1 to May 31st) and then reducing or eliminating power diversions at Roza when needed to meet recommended flows. The Bureau of Reclamation has not yet agreed to this action, and its implementation may have funding consequences for Reclamation and the Roza Irrigation District. The possibility of making up for this loss of revenue through a contract with BPA should be explored in conjunction with this action.

Upper Yakima Action #3 **Modify flip-flop flow regime**

Key Partners:	**Affected MSAs:**
Bureau of Reclamation	All Upper Yakima

Focal Area: **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years	**Strategies:**	**Limiting Factors:**
Time to Benefit: 3-10 years	Improve flow conditions	U1,6

Cost Derivation: Not estimated at this time; reservoir operation alternatives would have no direct cost, while major structural improvements would have high costs.

Total Cost:	**Fisheries:**	**Steelhead:**	**Steelhead Cost:**

The flip-flop flow regime results in high flows in the mainstem Yakima throughout most of the summer as Lake Cle Elum serves as the primary source for lower valley irrigation, and then a significant reduction in flows in the fall as BOR shifts to Rimrock Reservoir. The flip-flop regime was devised in response to a court order to protect spring chinook redds in the upper Yakima and Cle Elum rivers, but it is hypothesized to be significantly reducing rearing capacity for juvenile salmonids. Modifications to the flip-flop flow regime that improve habitat, flow, and temperature conditions for steelhead and other salmonid species in the regulated reaches of the subbasin would have broad benefits. The negative effects of flip-flop could be addressed through alteration of reservoir operations, conservation, additional storage, or a combination of these, and other measures. The Bureau of Reclamation, in collaboration with other subbasin resource managers and stakeholders, should determine if and how flip-flop can be modified to achieve these goals, make the necessary changes, and monitor habitat and fish population response.

Upper Yakima Action #4 **Improve instream flows in Swauk Creek and Teanaway watersheds**

Key Partners:

- Bureau of Reclamation
- Department of Ecology
- Individual irrigators
- Kittitas County Conservation District
- Kittitas Conservation Trust
- Water Trust & Conservancies
- Bonneville Power Administration
- Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:

- Swauk
- North Teanaway
- West Teanaway

Focal Area: Teanaway River, Swauk Creek and tributaries

Implementation Likelihood: Moderate

Time to Implement: Ongoing

Time to Benefit: 0-3 years

Strategies:

Improve flow conditions

Limiting Factors:

U4,5

Cost Derivation: Costs depend on options pursued & could be made part of development conditions; projected cost based on acquisition of 1000 acre feet of water at $500/af.

Total Cost: $500,000 **Fisheries:** 100% **Steelhead:** 100% **Steelhead Cost:** $500,000

The Teanaway River and its forks and Swauk Creek and its tributaries have summer/fall stream flows that are significantly reduced by irrigations withdrawals. Improving instream flows through improved water management, off-stream storage, and water acquisitions and transfers will improve rearing habitats. The Teanaway has been the focus of water conservation projects by YRBWEP, Ecology, and Kittitas County Conservation District; WDFW, the Yakama Nation, and the Kittitas Conservation Trust have been active in Swauk Creek.

Upper Yakima Action #5 **Provide passage and instream flows in lower Manastash Creek**

Key Partners:
- Kittitas County Conservation District
- Individual irrigators
- Yakima Tributary Access and Habitat Program
- Yakama Nation
- Water Trust & Conservancies

Affected MSAs:
- Manastash

Focal Area: Lower 3 miles of Manastash Creek **Implementation Likelihood:** High

Time to Implement: Expand ongoing
Time to Benefit: 3-10 years

Strategies:
Restore unimpeded fish passage
Improve flow conditions

Limiting Factors:
U4,5

Cost Derivation: $5,000,000 estimate by Kiititas County Conserrvation District.

Total Cost: $5,000,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $2,812,500

Manastash Creek has numerous small water diversions across the large alluvial fan in the lower reaches which block fish passage and can dewater the creek. Resolution of flow and passage issues in this watershed is high priority for the basin as a whole due to the quantity of suitable but unoccupied habitat in Manastash Creek and its location in the lower portion of the Upper Yakima. Work is currently underway by a local working group led by the Kittitas County Conservation District with support from the Department of Ecology and BPA.

Upper Yakima Action #6 **Provide unimpeded fish passage in Taneum Creek**

Key Partners:
- Kittitas Conservation Trust
- Yakima Tributary Access and Habitat Program
- Individual irrigators

Affected MSAs:
- Taneum

Focal Area: Lower 3 miles of Taneum Creek **Implementation Likelihood:** High

Time to Implement: > 10 years
Time to Benefit: 0-3 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
U9

Cost Derivation: Preliminary design estimates.

Total Cost: $600,000 **Fisheries:** 100% **Steelhead:** 75% **Steelhead Cost:** $450,000

Taneum Creek has several medium-sized diversions in the lower portions of the creek that partially block fish passage. Concrete fishways were installed in the 1980s but rarely provide full adult passage and do not allow juvenile passage. Above those diversions, flows and habitat conditions are good to excellent. Recent improved flow conditions in Taneum Creek have resulted in steelhead use of the most accessible portions of the creek. The Kittitas Conservation Trust is taking the lead on efforts to install low-maintenance fish passage structures.

Upper Yakima Action #7 **Provide fish passage into Upper Naneum Creek**

Key Partners:

City governments
Individual irrigators
Kittitas County Conservation District
Kittitas County
Yakima Tributary Access and Habitat Program
Irrigation Districts
Bureau of Reclamation

Affected MSAs:

Naneum

Focal Area: Lower and middle reaches of Naneum Creek

Implementation Likelihood: Moderate

Time to Implement: > 10 years

Time to Benefit: 10-25 years

Strategies:

Restore unimpeded fish passage

Limiting Factors:

U9

Cost Derivation: 25 structures at $200,000 each.

Total Cost: $5,000,000 **Fisheries:** 100% **Steelhead:** 75% **Steelhead Cost:** $3,750,000

The upper portions of Naneum Creek are presumed to have been historic spawning and rearing habitat for steelhead. There are multiple stream courses that connect the middle reaches of Naneum to the Yakima River, and coordinated planning will be required to identify the most effective route to restore. This will require the involvement of YTAHPs, the Kittitas County Conservation District, Kittitas County, the City of Ellensburg, Cascade Canal Company, Kittitas Reclamation District, Ellensburg Water Company, and private irrigators. Work will involve removing passage barriers, screening diversions, and improving instream flows.

Upper Yakima Action #8 **Provide passage at Cle Elum Dam**

Key Partners:

Bureau of Reclamation

Affected MSAs:

Cle Elum

Focal Area: Cle Elum Dam

Implementation Likelihood: Moderate

Time to Implement: 6-10 years

Time to Benefit: 10-25 years

Strategies:

Restore unimpeded fish passage

Limiting Factors:

U8

Cost Derivation: 2008 cost estimate of $96,000,000 by Bureau of Reclamation.

Total Cost: $96,000,000 **Fisheries:** 100% **Steelhead:** 20% **Steelhead Cost:** $19,200,000

Lake Cle Elum is a natural glacial lake that supported a run of sockeye salmon. When a dam was constructed to raise the lake to store irrigation water, fish passage was not provided. Providing upstream and downstream fish passage at Cle Elum Dam would open up 30 miles of high quality habitat for steelhead. The BOR Fish Passage Study gives a detailed description (BOR 2005). Actions and evaluation at Cle Elum Dam should precede actions at Keechelus and Kachess dams.

Upper Yakima Action #9 **Continue providing access to the Yakima River above Easton Dam in all years**

Key Partners:
Bureau of Reclamation

Affected MSAs:
Upper Yakima

Focal Area: Easton Dam

Implementation Likelihood: Moderate

Time to Implement: 0-3 years

Time to Benefit: 3-10 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
U9

Cost Derivation: Operational action without a specific cost.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

In projected low-flow years, BOR operating plans allow for closing the Easton fish ladder in the spring to block chinook from spawning in areas that may be subsequently dewatered. This would also block steelhead from the upper 12 miles of the Yakima River and its tributaries during spawning season. Closure of the Easton ladder has not occurred since 1996 due to the successful use of the "little flip-flop" flow regime and improvements to the Kachess outlet works, and closure of the ladder is not anticipated in the future (prior to 1996, closures occurred during the latter part of expected steelhead spawning time windows). Continuing to provide year-round access to and adequate flows in the Yakima River above Easton Dam will enable steelhead to successfully spawn and rear in this highly complex and productive reach of the Yakima River.

Upper Yakima Action #10 **Replace County Road culverts on Jack and Indian Creeks**

Key Partners:
Kittitas County Conservation District
Kittitas County
US Forest Service
Kittitas Conservation Trust

Affected MSAs:
North Teanaway

Focal Area: Lower sections of Jack and Indian Creeks

Implementation Likelihood: High

Time to Implement: 0-3 years

Time to Benefit: 3-10 years

Strategies:
Restore unimpeded fish passage

Limiting Factors:
U20

Cost Derivation: Based on preliminary project budgets.

Total Cost: $750,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $375,000

While the Teanaway system is generally accessible to steelhead, there are passage-limiting culverts where the North Fork Teanaway Road crosses Jack Creek and Indian Creek. These culverts block access to about 8.8 miles of upstream habitat. A project to replace them with fish-friendly structures is being developed by the Kittitas County Conservation District and partners.

Upper Yakima Action #11 **Restore passage, separate irrigation conveyance, and screen diversions in Ellensburg-area tributaries**

Key Partners:

- Kittitas County Conservation District
- Yakima Tributary Access and Habitat Program
- Yakama Nation
- Irrigation Districts
- Kittitas Conservation Trust
- Water Trust & Conservancies

Affected MSAs:

- Reecer
- Naneum
- Caribou

Focal Area: Dry, Reecer, and Wilson creeks and associated tributaries

Implementation Likelihood: High

Time to Implement: Ongoing

Time to Benefit: 0-3 years

Strategies:

Restore unimpeded fish passage

Limiting Factors:

U6,13

Cost Derivation: 30 structures at $200,000 each.

Total Cost: $6,000,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $2,250,000

The complicated network of tributaries in the Ellensburg area has been highly modified as part of the development of irrigation systems, roads, and other infrastructure. The Yakima Tributary Habitat and Access Program is removing passage barriers, screening irrigation diversions, and seperating irrigation water conveyence from natural streams. The lower reaches of these streams are expected to provide a dramatic increase in available rearing habitat in the Kittitas Valley that would offset the reduction in rearing habitat due to confinement of the mainstem. Monitoring should be conducted to confirm value of this habitat for rearing fish. Cost-effective implementation of this action will require careful analysis of options and prioritization of actions; current plans are to focus on resotration of selected creeks up to the Cascade Ditch crossings. Work should be coordinated with riparian restoration under Upper Yakima Action #15.

Upper Yakima Action #12 Reduce confinement of Upper Yakima River

Key Partners:

US Army Corps of Engineers
Gravel mine operators
Kittitas County
Washington State Department of Transportation
Yakama Nation
Yakima County
Bureau of Reclamation
Bureau of Reclamation

Affected MSAs:

All Upper Yakima

Focal Area: Floodplain of the Yakima River **Implementation Likelihood:** Moderate

Time to Implement: Ongoing
Time to Benefit: 10-25 years

Strategies:	Limiting Factors:
Restore floodplain connectivity/function	U10,14,24
Restore channel structure/complexity	

Cost Derivation: Estimated at 1,000 acres at $10,000/acre.

Total Cost: $10,000,000 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $3,750,000

Rearing habitat in the mainstem of the Upper Yakima River is limited by the combination of high flows and confined channels. Efforts to reduce confinement through levee setbacks and other infrastructure changes will both reduce the effect of the altered flow regime in the upper Yakima and increase effective habitat area. Proposed locations include the I-90 ponds at mile 101, the BOR's Schaake levee pullback near Ellensburg, the Selah-area (gravel pits and Taylor ditch) and sites associated the I-90 upgrades above Easton. There is the possibility of actions in other locations through setback of abandoned railroad levees and flood control levees on public lands.

Upper Yakima Action #13 **Protect & restore floodplain, riparian and in-channel habitats in Upper Yakima, Kittitas and Easton/Cle Elum Reaches**

Key Partners:

Land Conservancies
Private landowners
Yakima Tributary Access and Habitat Program
Yakima Basin Side Channels Project

Affected MSAs:

Caribou
Cle Elum
Manastash
Middle Mainstem Yakima
Naneum
North Teanaway
Reecer
Swauk
Taneum
Upper Mainstem Yakima
Upper Yakima
West Teanaway

Focal Area: Upper Yakima River and tributaries **Implementation Likelihood:** High

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**

Time to Benefit: 10-25 years Protect existing functional habitat U12,13,14,19, 21

Cost Derivation: 2,000 acres at $8,000/acre.

Total Cost: $16,000,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $8,000,000

There are several ongoing efforts to protect fisheries habitat in key Upper Yakima reaches through acquisition of land and conservation easements. These include the Yakama Nation's side channels project, the Cascade Conservation Partnership and Mountain-to-Sound Greenway Programs, and YRBWEP's acquisition efforts. Habitat restoration should be integrated with these acquisition programs. Much of this work has been guided by the Reaches Study conducted by Stanford and Snyder, which identified key alluvial floodplain reaches. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Upper Yakima Action #14 **Restore instream and floodplain habitat complexity in Swauk and Taneum creeks and Teanaway and lower Cle Elum rivers**

Key Partners:

- Kittitas Conservation Trust
- Cascade Land Conservancy
- Kittitas County
- Yakama Nation
- Washington Department of Fish & Wildlife
- Kittitas County Conservation District
- Bureau of Reclamation
- Washington State Department of Transportation
- Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:

- Cle Elum
- Taneum
- West Teanaway
- North Teanaway
- Swauk

Focal Area: Key tributraies to the Upper Yakima **Implementation Likelihood:** Moderate

Time to Implement: 4-6 years

Time to Benefit: 10-25 years

Strategies:	**Limiting Factors:**
Restore floodplain connectivity/function	U10,12,13,24
Restore channel structure/complexity	

Cost Derivation: 5 miles on Swauk, 17 on Teanaway, 10 on Taneum, 8 on Cle Elum for 40 miles total; 50% treatment = 20 mi x $100,000/mile treatment co.st

Total Cost: $2,000,000 **Fisheries:** 100% **Steelhead:** 75% **Steelhead Cost:** $1,500,000

Efforts to improve channel/floodplain connectivity and riparian habitat will improve habitat conditions in key tributares in the Upper Yakima. Activities may include placing large woody debris and engineered log jams, bank reshaping, channel reconstruction, and other instream habitat work and addressing confinment created by road beds (including US 97 on Swauk Creek). Any passage barriers in these creeks and fish-bearing portions of tributaries to these creeks should also be addressed. Specific areas in Swauk Creek and its tributaries have been inventoried as being in need of restoration; work is currently underway on the lower Cle Elum and under development for Taneum Creek.

Upper Yakima Action #15 Restore tributary riparian areas

Key Partners:

- Kittitas County Conservation District
- Kittitas Conservation Trust
- Yakama Nation
- Yakima Tributary Access and Habitat Program
- Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:

- Caribou
- Manastash
- Middle Mainstem Yakima
- Naneum
- North Teanaway
- Reecer
- Swauk
- Taneum
- Upper Mainstem Yakima
- West Teanaway

Focal Area: Tributary riparian areas **Implementation Likelihood:** High

Time to Implement: Ongoing **Strategies:** **Limiting Factors:**

Time to Benefit: 3-10 years Restore riparian condition/future LWD U13,14,19,21

Cost Derivation: 13 creeks at 3 miles/creek totals 39 miles; fencing & planting of 50% at $20,000/mile.

Total Cost: $390,000 **Fisheries:** 100% **Steelhead:** 50% **Steelhead Cost:** $195,000

Due to regulation and artificial confinement of the upper Yakima, the best available locations for rearing fish in normative flow and temperature conditions are in the lower ends of tributaries. Restoring riparian conditions will improve rearing conditions. Lower Reecer, Currier, Whiskey, Mercer, Wilson, Naneum, Coleman, Cherry, Manashtash, Taneum, Swauk, and Lmumma Creeks and the Teanaway River are all candidates; some work has been completed. This action should be integrated with the passage restoration efforts identified in other actions.

Upper Yakima Action #16 **Build conservation easements and other habitat protections into development plans**

Key Partners:

Cascade Land Conservancy
City governments
Kittitas Conservation Trust
Kittitas County

Affected MSAs:

All Upper Yakima

Focal Area: Floodplain and riparian areas throughout population area

Implementation Likelihood: Moderate

Time to Implement: 4-6 years

Time to Benefit: 10-25 years

Strategies:

Protect existing functional habitat

Limiting Factors:

U16,17

Cost Derivation: Cost for personnel to coordinate action at 2 FTE x $75,000/FTE/yr for 15 years; other costs subsumed into cost of new developments.

Total Cost: $2,250,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $562,500

Current and expected rapid population growth in Kittitas County has the potential to impact currently functioning habitat and reduce restoration options. Areas where development pressure and steelhead habitat overlap include the Teanaway River, Big and Swauk creek watersheds, the Ellensburg urban growth area and floodplain locations along the mainstem Yakima. Assuring that habitat values of riparian and floodplain habitat on private lands are protected and that development does not impair upland watershed processes are high priorities. This will require community-led efforts to 1) utilize the planning processes required by the Growth Management Act, 2) work with developers to promote incorporation of greenbelts and open space that protect fish habitat and reduce flood damages, and 3) develop innovative approaches that integrate habitat protections with ongoing efforts to protect open space, recreational values, livable communities, and working landscapes while protecting private property rights. The recent Suncadia development provides one example of extensive environmental mitigation being incorporated into a successful development proposal.

Upper Yakima Action #17 **Protect Teanaway watershed from negative impacts of development**

Key Partners:
- Land Conservancies
- Washington Department of Fish & Wildlife
- Kittitas Conservation Trust
- US Forest Service
- Bureau of Reclamation

Affected MSAs:
- North Teanaway
- West Teanaway

Focal Area: Teanaway River watershed **Implementation Likelihood:** High

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**

Time to Benefit: 10-25 years Protect existing functional habitat U16,17

Cost Derivation: $1,004,740 currently allocated to KCT easement proposals; also easements on 365 acres (~600' over 50% of 10 miles at $10,000/acre).

Total Cost: $4,654,740 **Fisheries:** 75% **Steelhead:** 50% **Steelhead Cost:** $1,745,528

The Teanaway watershed is currently subject to intense recreational/residential/retirement development pressure as large forestland holdings are sold off. Assuring that habitat values of riparian and floodplain habitat on private lands are protected and that development does not impair upland watershed processes are high priorities; land acquisitions, conservation easements, and cooperative agreements with developers will be key tools in ensuring these protections. This action will need to be integrated with ongoing efforts to protect open space, recreational values, and working landscapes. Cost estimates for acquisition of land and easements are generic estimates based on possible amounts; any actual acquisitions will be based on voluntary agreements negotiated with landowners.

Upper Yakima Action #18 **Relocate forest roads and campsites and revegetate clearcuts in the Teanaway River watershed**

Key Partners:
- Washington Department of Natural Resources
- Private landowners
- US Forest Service
- Regional Fisheries Enhancement Group or other volunteer groups

Affected MSAs:
- North Teanaway
- West Teanaway

Focal Area: Forestlands in the Teanaway watershed **Implementation Likelihood:** High

Time to Implement: Expand ongoing **Strategies:** **Limiting Factors:**

Time to Benefit: 3-10 years Improve upland watershed conditions U21,22,23

Cost Derivation: 30 miles of road work at $5,000/mile; 500 acres of plantings at $300/acre.

Total Cost: $300,000 **Fisheries:** 50% **Steelhead:** 50% **Steelhead Cost:** $75,000

Because of its south-facing aspect and steep, confined nature of the tributaries, the Teanaway is especially prone to increases in peak flow resulting from changes in watershed condition. Actions that improve forest practices, such as addressing the impacts of roads located next to salmon-bearing streams and revegetating clear cuts south-facing slopes, will help protect and improve watershed function. Efforts to relocate and reduce soil compaction at dispersed campsites will also improve watershed function. Due to the critical nature of all salmonid populations that inhabit the Teanaway, this watershed has the highest priority for identifying and reducing impacts from forest practices in the subbasin.

Upper Yakima Action #19 **Coordinate water quality improvements in Reecer, Wilson, Naneum, Cherry, Coleman, and Dry creeks**

Key Partners:
- Individual irrigators
- Kittitas County Conservation District
- USDA Natural Resource Conservation Service
- Department of Ecology
- City governments
- Irrigation Districts
- Washington Department of Natural Resources

Affected MSAs:
- Caribou
- Naneum
- Reecer

Focal Area: Ellensburg-area watersheds

Implementation Likelihood: Moderate

Time to Implement: Expand ongoing

Time to Benefit: 3-10 years

Strategies:
- Improve water quality

Limiting Factors:
- U17

Cost Derivation: Costs of Clean Water Act programs not attributed to steelhead recovery.

Total Cost: **Fisheries:** **Steelhead:** **Steelhead Cost:**

Water quality in Ellensburg-area tributaries is degraded by agricultural activities, urban stormwater, and forestry activities in the upper watersheds. Agricultural practices are improving, but more work is needed on stormwater and reduction of peak flows from forestry activities. A sediment TMDL is being developed for the Upper Yakima; implementation is currently limited by funding.

Upper Yakima Action #20 **Restore tributary headwater meadows**

Key Partners:
- US Forest Service

Affected MSAs:

Focal Area: Headwaters of key Upper Yakima tributaries

Implementation Likelihood: High

Time to Implement: 4-6 years

Time to Benefit: 3-10 years

Strategies:
- Improve flow conditions
- Improve water quality

Limiting Factors:
- U26

Cost Derivation: Cost for restoration crew time & equiment at 30,000/yr for 15 yrs.

Total Cost: $450,000 **Fisheries:** 75% **Steelhead:** 75% **Steelhead Cost:** $253,125

Protecting and restoring the function of wet meadows in the upper watersheds of Swauk, Taneum, and Manashtash creeks and Cle Elum River and its tributaries (e.g. Thorp and French Cabin creeks) will help maintain and improve the quantity and quality of instream flows in downstream steelhead habitat. For the Cle Elum watershed, this only becomes relevant pending completion of Upper Yakima Action #8: Provide passage at Cle Elum Dam.

Upper Yakima Action #21 **Provide adequate late fall/winter flows below storage dams**

Key Partners:

Bureau of Reclamation

Affected MSAs:

Cle Elum
Upper Yakima

Focal Area: Upper Yakima and Cle Elum rivers **Implementation Likelihood:** Moderate

Time to Implement: 0-3 years
Time to Benefit: 0-3 years

Strategies:

Improve flow conditions

Limiting Factors:

U2

Cost Derivation: Operational change; no specific cost identified.

Total Cost: **Fisheries:** 100% **Steelhead:** 25% **Steelhead Cost:**

Late fall/winter flows below Kachees, Keechelus and Cle Elum reservoirs are maintained at relatively low levels by releases from the storage dams as natural reservoir inflows are used to refill storage capacity. Releases may also vary substantially based on flood control operations and efforts to assure adequate storage in dry years. The primary fisheries emphasis in this area is on maintaining appropriate spawning and incubation flows for spring Chinook. Consideration should also be given to ensuring productive spawning and rearing conditions for juvenile steelhead.

6 Plan Implementation

6.1 Approach to Implementation	**6.4 Adaptive Management**
6.2 Funding Strategies	**6.5 Removing Roadblocks to Implementation**
6.3 Implementation Scheduling	**6.6 Links to Larger Recovery Efforts**

This plan is a beginning, not an end. It identifies proposed recovery actions, lays out a framework for assessing progress towards recovery goals, and identifies issues that will need to be assessed during recovery efforts. Implementing the plan and achieving recovery goals will require sustained long-term efforts by a wide range of stakeholders. Coordinating these efforts and ensuring that limited funding is used effectively will require ongoing collaboration within the basin and between in-basin stakeholders and state, tribal, and federal entities. This chapter gives an overview of what will be required to achieve this coordination.

6.1 Approach to Implementation

6.1.1 Voluntary and Non-Regulatory Nature of Plan

As noted in section 1.2.3, both the NOAA Fisheries' Recovery Plan for the Middle Columbia River Steelhead DPS and the Yakima Subbasin Salmon Recovery Plan are not regulatory documents. Both promote cooperative and voluntary approaches to undertaking recovery actions. For this voluntary approach to work, recovery plan implementation will need to be supported by broad outreach, targeted technical and logistic support to landowners and project proponents, and funding and incentive programs that support recovery actions.

This plan does not make specific recommendations to change existing regulatory programs, but does recognize that how regulatory programs are implemented will affect the progress of steelhead recovery. Elected officials, agency staff, stakeholder groups, and voters should consider the recovery needs of steelhead as these programs are established, revised, and implemented.

Effectively designed and well-implemented regulatory programs that strike an appropriate balance between habitat protection and other legitimate land use goals will be a critical component of salmon recovery. Specific regulatory programs that intersect with steelhead recovery include local land use management such as the Growth Management, Shorelines, and Critical Areas Ordinance programs of local governments; the establishment and enforcement of fisheries regulations by WDFW; the implementation of the ESA by NOAA Fisheries (including issuance of Section 7 Biological Opinions and Section 10 take permits); development and implementation of Total Maximum Daily Loads (TMDLs) in accordance with the Clean Water Act; and the issuance of instream work permits by WDFW, WDOE, the Yakama Nation and the U.S. Army Corps of Engineers. Our hope is that the information and proposed actions in this plan can inform ongoing public dialogues about implementation of these regulatory programs.

6.1.2 Coordination of Existing Recovery Programs

Salmon recovery is not a new pursuit in the Yakima Basin. Fish screening efforts began in the early 20th century, and intensive recovery efforts have been ongoing since the 1980s. The steelhead recovery actions proposed in this plan are a natural extension of this work and should build upon existing programs, relationships, and funding sources whenever possible. Developing collaborative partnerships among existing organizations should take precedence over the creation of new organizations and programs unless there is a clear need for a new structure.

The Yakama Nation and the WDFW have played a central role in salmon recovery work in the Yakima Basin. Much of the funding has come from the BPA with oversight from the Northwest Power and Conservation Council, which was established by the Northwest Power Act of 1980. BPA is currently working with basin stakeholders to target its funding in a manner that meets power planning act requirements and contributes to mitigating the impacts of the Federal Columbia River Power System on ESA-listed species. This is occurring as part of the negotiation of an ESA-mandated Biological Opinion for the Federal Columbia River Power System; a draft Biological Opinion was released in October 2007.

Another significant source of funding for recovery actions is the federal Pacific Coast Salmon Recovery Fund (PCSRF). Washington has used its allocation of PCSRF funding along with state funding to support salmon recovery efforts overseen by the Washington Salmon Recovery Funding Board (SRFB). To date, over $8.7 million has been committed to salmon recovery projects in the Yakima Basin via Salmon Recovery Funding Board (SRFB) programs; this funding has leveraged another $5.5 million in locally secured match from diverse sources.

The BOR has also been a key supporter of salmon recovery efforts in the Basin (see Section 6.1.4 for more detail). Federal, state, tribal, and private land managers have incorporated salmon recovery needs into their land management activities and plans (see Section 6.1.5). Local governments, irrigation districts, the South-Central Washington RC & D, and conservation districts have all become active proponents of salmon recovery projects and have built the organizational capacity needed to plan, fund, and implement these projects.

Most of the recovery actions outlined in this plan can be implemented through these programs. This will require ongoing efforts to coordinate diverse programs and identify joint priorities to ensure that recovery efforts build on existing capacities and are implemented efficiently.

6.1.3 Coordination with Bureau of Reclamation Yakima Project

For the last 20 years, BOR has been improving fish passage and installing protective facilities in the Yakima Basin. They maintain a project list and inventory of pending and proposed projects that conserve fish resources and are actively balancing fish requirements and water production needs in Yakima Project operations.

Congress established the Yakima River Basin Water Enhancement Project (YRBWEP) in 1994. YRBWEP has funded a wide range of salmon recovery actions, including major irrigation system improvements, purchase of water rights for transfer to instream flow, cooperative projects with smaller irrigators, and purchase and management of floodplain habitat in key river reaches. BOR also works closely with the System Operations Advisory Committee (SOAC), which consists of representatives of WDFW, the Yakama Nation, the USFWS, and the Yakima Basin Joint Board and was created by the Yakima Basin watermaster in 1981. SOAC provides recommendations to BOR on how fish needs are incorporated into Yakima Project operations.

BOR is working closely with WDFW and the Yakama Nation to assess the possibility of re-establishing fish passage at the five storage dams (see section 4.3.3) through the Storage Dam Passage Feasibility Study scheduled for completion in 2008. The Yakima Basin Storage Study is a major effort by BOR to identify and assess options for increasing water storage capacity in the Yakima Basin to better meet the long-term water supply needs of agriculture, municipal users, and anadromous fish. The draft EIS for the storage study is also due in 2008.[39] Models and other planning documents that BOR is developing as part of the storage study have great potential for informing broader discussions of recovery needs.

In a meeting on February 28, 2005 and in a subsequent letter, BOR staff identified existing projects that could contribute to a salmon recovery plan. As with all federal agencies interviewed, they identified limited budgets and resources as a concern in assisting with salmon recovery planning efforts.

BOR submitted extensive comments on the October 2005 version of the Yakima Subbasin Salmon Recovery Plan and drafts of this steelhead extract. The Yakima Basin Fish & Wildlife Recovery Board will work with BOR to continue these discussions. Several key actions identified in this plan involve BOR and will only move forward to the degree that BOR supports them. The Board hopes that this plan will be a useful document for BOR as it continues its efforts to protect and enhance Yakima Basin steelhead.

6.1.4 Coordination with Land Management Agencies

The USFS, the Bureau of Land Management, the USFWS, and the Washington Departments of Natural Resources and Fish and Wildlife all manage lands in the Yakima Basin. Their management activities are governed by a range of laws, plans, and agreements, including some that specifically address management needs of listed fish species (e.g., Biological Opinions, Habitat Conservation Plans, and the Forests and Fish Act). In addition to general land management decisions, these agencies have many opportunities to undertake specific recovery projects, but rates of implementation are constrained by staffing and budget limitations. These agencies will be key participants in

[39] The BOR's study is coupled with work by the Washington State Department of Ecology to assess non-storage options for improving basin water supplies.

ongoing efforts to prioritize, coordinate, fund, and implement recovery actions identified in this plan.

6.1.5 Coordination with Other Planning Efforts

Section 1.4.1 discussed the relationship between this plan and the Yakima Subbasin Plan and the Yakima Basin Watershed Plan. Other planning efforts that will inform and guide actions called for in this plan include:

- Flood Hazard Management Plans developed by local counties
- Statewide Steelhead Management Plan currently under development by the WDFW
- Steelhead Master Plan being developed by the Yakima/Klickitat Fisheries Project, Comprehensive Irrigation District Management Plans developed by local irrigation districts
- Land management plans developed by the USFS, the BLM, and the Washington Department of Natural Resources
- Capital facilities improvement plans developed by local, state, tribal, and federal governments to guide work on highway systems, water systems, and other critical infrastructure that influences steelhead habitat

It is our intent that this recovery plan and the ongoing collaborative network on which it is built can help make it easier for these diverse groups of planners to understand and incorporate steelhead recovery needs into these plans. The Yakima Basin Fish & Wildlife Recovery Board is committed to working with all of these partners.

6.1.6 Coordination with Local Land Use Planning

While this plan does not make any specific proposals regarding land use planning or associated regulations, local jurisdictions are encouraged to review local subdivision ordinances to see if they encourage creative approaches that balance habitat protection with site planning (possible examples include density bonuses, transfers of development rights, binding site plans, and tax incentives). Local jurisdictions are also encouraged to use the information in this recovery plan as they review their Critical Areas and Shorelines and Flood Hazard Management ordinances to see if they address habitat protection in a consistent and logical manner that avoids redundancy, uses the best available science, and works with adjacent jurisdictions to assure that ordinances do not conflict across the landscape. Cities and counties are also encouraged to seek funding to monitor adherence to development permit conditions and how effectively they met their intended goals.

6.1.7 Role of Yakima Basin Fish & Wildlife Recovery Board

Early in the recovery planning process, planners realized that existing structures, while adequate for supporting the initial development of subbasin and recovery plans (via the

Yakima Subbasin Fish & Wildlife Planning Board) and allocating SRFB funding through the Lead Entity structure (via the Yakima River Basin Salmon Recovery Board), were not capable of coordinating long-term recovery efforts. In response, the two organizations merged to form the Yakima Basin Fish & Wildlife Recovery Board (YBFWRB) in April of 2006. Since then, the YBFWRB has hired a director and staff, secured funding from WDFW and the SRFB, established offices, acted as the Lead Entity for SRFB programs in the Yakima Basin, and coordinated the recovery plan revision process and development of this steelhead extract. The YBFWRB anticipates a key role coordinating and supporting recovery actions and associated research, monitoring, and evaluation efforts (See Chapter 7). The YBFWRB is also planning a strong outreach program that builds community knowledge of and support for salmon recovery actions (See Chapter 8).

6.2 Funding

6.2.1 Total Time and Cost of Recovery

Initial cost estimates for implementing all of the actions identified in this plan over 15 years total $1,168.3 million, with $269.3 million of that cost attributed to steelhead recovery. The remaining portion of the total cost is attributed to other sources based on anticipated benefits to agricultural producers (e.g. irrigation system improvements), flood control, open space, other fish and wildlife species, etc, according to the percentages identified in the action descriptions. Funding steelhead recovery actions will require working with other interests and entities to ensure that full funding can be secured for actions whose benefits to society extend beyond steelhead recovery.

This is a simple and very preliminary estimate of actual implementation costs for actions. It is not a cost-benefit analysis of the proposed actions and does not include indirect costs such as opportunity and compliance costs associated with recovery efforts. It should not be taken as the total cost of recovery, as achieving delisting goals may require only implementing some of the actions included in this plan, while long-term recovery may require additional actions not included in the plan.

This estimate does not include specific costs for steelhead-related monitoring, which will be an essential component of recovery efforts. An initial placeholder of $300,000/yr for 15 years for steelhead-specific monitoring equals $4.5 million; cost estimates will be refined as a more detailed monitoring plan is developed (see discussion in Chapter 7).

6.2.2 Funding Sources

Significant funding is already available for salmon recovery in the Yakima Basin via the BPA Fish and Wildlife Program, SRFB programs, the Department of Ecology Columbia River Initiative, USDA programs like EQIP and CREP, and others. The Board will work with existing programs and partners to help ensure that funding is targeted to ensure real progress towards recovery. A broadly supported implementation schedule for recovery actions will be a key element in guiding how funding is applied (see Section 6.3).

Where existing funding sources are insufficient or cannot be applied to key recovery actions, the YBFWRB will work with partners to help secure new funding sources for recovery actions. Sources may include local, state, and federal appropriations, special improvement districts, grants from foundations, support from private businesses, and private donations. Many of the proposed actions have multiple benefits that extend far beyond salmon recovery. Funding for these may involve complex packages of funding from multiple sources, each of which focuses on specific sets of benefits, any one of which may or may not include salmon recovery.

Different funding sources have different goals, mandates, and application and contracting procedures. Increasing knowledge of different funding sources and their requirements, and streamlining application and contracting procedures would significantly reduce the transaction costs associated with recovery projects. The Board anticipates working with grantors and implementing organizations to increase efficiencies.

6.3 Implementation Scheduling

The YBFWRB has committed to maintaining an implementation schedule that identifies priority recovery actions and sets a schedule for implementing them. The Board will develop this schedule and update it at least annually in coordination with potential project sponsors, partners, and affected stakeholders. The implementation schedule does not create any formal obligations or commitments; it is will serve as a guide to recovery priorities and an informal record of commitments made in other forums.

The implementation schedule should serve as a menu from which project proponents can chose projects to implement. These choices should be guided by the following considerations:

- The degree to which projects address a priority limiting factor for steelhead
- The technical feasibility of implementing a project
- The level of certainty regarding project outcomes and the long-term response to them by steelhead populations
- The strength of the commitment of the parties involved in a project to implement and maintain it
- The cost-effectiveness of a proposed action
- The presence of a “champion” organization or individual with the interest and ability needed to develop and implement the action
- The presence or absence of general community support for a project
- The availability of funding that can be used for that specific project
- The presence of temporary windows of opportunity for completion of a project

Evaluating the effectiveness of implemented recovery actions and identifying future priorities will require a rigorous and quantitative approach to adaptive management as

priority actions are being implemented. The implementation schedule will have to be adjusted over time based on monitoring results, as noted below under Adaptive Management in Section 6.4. Detailed recommendations on implementing a strong adaptive management process will be included in the RME supplement to the Yakima Steelhead Recovery Plan currently being developed by the YBFWRB. We encourage interested parties to participate in the development of the supplement and the ongoing maintenance of the implementation schedule.

The implementation schedule should become a widely used resource that informs project selection. In some contexts (e.g., SRFB project selection) it may become a driving force. However, given the diversity of project partners, funding sources, and the mandates and goals behind recovery actions, actions that are designated recovery priorities will continue to be funded by a wide range of programs that may be informed or guided by the implementation schedule, but are not specifically directed by it.

6.4 Adaptive Management

A key to effective implementation of this plan will be the use of a rigorous adaptive management framework that identifies and addresses key uncertainties through monitoring and research. This will include:

6.4.1 Tracking Implementation

The Board will work together with partners implementing recovery actions to track project completion, document their outcomes, and evaluate whether they are carried out as planned. Project summaries that describe what project sponsors accomplished, document project outcomes and lessons learned, and include maps and project photos will be assembled and maintained in a publicly accessible format. The YBFWRB will use this information to develop regular reports on the status of plan implementation.

6.4.2 Monitoring Habitat and Population Trends

To assess the effectiveness of recovery efforts and sustain the support of the public and key decision makers, we must be able to track progress towards recovery goals. This requires reliable empirical estimates of population status that can be compared to the recovery criteria identified in this plan. The Yakima Basin currently has an ability to monitor anadromous fish runs that has few equals in the region, thanks largely to the fish research infrastructure established by the Yakima/Klickitat Fisheries Project. However, effectively tracking the full range of VSP parameters (abundance, productivity, spatial structure, and diversity) for each individual population will mean adjusting and supplementing our monitoring programs. Chapter 7 describes current efforts to identify and implement the required steelhead population monitoring.

6.4.3 Designing Recovery Actions to Test Key Assumptions

Adaptive management is a powerful concept that is often misrepresented as simply regularly monitoring and reassessing progress. Effective adaptive management requires the application of the principles of experimental design to management actions so that

they test basic hypotheses that improve our understanding of key uncertainties and help us better understand ecosystem responses to our actions. Chapter 7 describes the role of adaptive management in plan implementation and the key uncertainties identified during this planning process.

6.4.4 Revising the Recovery Plan

This plan should be a living document that is revised to reflect improved understanding of key uncertainties, account for progress towards recovery, and refine assessments of future recovery needs. Annual reports by the YBFWRB will describe progress in plan implementation. Plan revisions will be considered at least every five years in conjunction with the five-year status reviews to be conducted by NOAA Fisheries.

6.5 Removing Roadblocks to Implementation

Once actions have been identified and chosen as priorities, the actual work of implementation begins. This is often a complex process that consumes significant amounts of time and funding. Efforts that increase the efficiency of project implementation and remove known roadblocks will play an important role in speeding up the rate of recovery. Possible areas to focus are described below.

6.5.1 Permit Streamlining

It is ironic that those implementing fish habitat improvement projects often see state, federal, and local regulations as impediments, even though these regulations are designed to protect habitat and listed species. Streamlining permitting processes for recovery actions would greatly reduce the transaction costs associated with implementing recovery actions and increase the rate at which recovery actions are implemented. Recent efforts by the Governor's Salmon Recovery Office to work with NOAA Fisheries, the Corps of Engineers, and the USFWS to incorporate SRFB-approved actions identified in NOAA Fisheries-accepted recovery plans into programmatic permits are an excellent first step.

6.5.2 Providing ESA Assurances

In many cases, potentially valuable projects are not implemented out of participants' fears that they may create future liabilities under the ESA (e.g., refusing to improve fish passage on a creek based on fears that the presence of listed fish in previously blocked areas would create a new regulatory burden). This could be addressed through mechanisms and agreements that support good-faith recovery efforts based on the best scientific information available and limit or absolve any future liabilities that the projects might create. Legally binding mechanisms to discharge responsibility for impacts to steelhead populations based upon the performance of recovery actions could significantly increase voluntary participation in recovery planning. There are some existing programs to accomplish this under the ESA (Habitat Conservation Plans, Safe-harbor agreements, etc.), while other programs may need to be developed to meet specific needs.

6.5.3 Building Technical Capacity

Complex recovery actions require a range of expertise unavailable in local communities and small organizations. Resources can be shared to build the capacity to get these actions on the ground. Examples of new and existing technical capacity that could be shared among multiple recovery partners include engineering, geographic information systems, land transaction (especially regarding structuring, valuation, monitoring, and enforcement of conservation easements), and fund raising for large projects.

6.5.4 Supporting Network of Recovery Practitioners

Most groups implementing recovery actions are either small organizations or small units within large organizations with other areas of focus. Successful recovery actions will be built on effective communication between diverse groups and individuals. It will require networks that help people sustain a global understanding of recovery efforts while maintaining focus on their individual components. Networks of recovery practitioners and stakeholders (be they formal or informal) will be an important way of building capacity, sharing lessons, and sustaining mutual support and momentum.

6.6 Maintaining Links to Larger Recovery Efforts

While this plan focuses on steelhead recovery needs within the Yakima Basin, achieving steelhead recovery goals will also require coordination with actions taken outside of the basin. This will require recovery planners and other local stakeholders to engage in several state and regional processes, as discussed below:

6.6.1 Washington State Salmon Recovery Strategy

The State of Washington's Governor's Salmon Recovery Office (GSRO) recognizes the Yakima Basin Fish & Wildlife Recovery Board as one of six regional recovery organizations in the state. The Yakima Subbasin Salmon Recovery Plan that this extract is based on has been accepted as a regional salmon recovery plan in accordance with the Salmon Recovery Act (RCW 77-85). The GSRO and the SRFB are committed to using regional salmon recovery organizations as a key element in the statewide salmon recovery process, and the Yakima Basin Fish & Wildlife Recovery Board is committed to working with the state in this capacity. The Board is also under contract with WDFW to serve as the Lead Entity for the Yakima Basin. Based on these two commitments, the Board coordinates applications for SRFB funding of projects in the Yakima Basin and intensive local reviews of proposals to the SRFB. The Board is committed to making this plan an integral part of the Yakima Basin SRFB proposal review process. The Board will also work with GSRO on regional sections of the biennial State of the Salmon report produced by GSRO as required by state law. The legislature has designated regional recovery organizations as members of the Washington Forum on Monitoring Salmon Recovery and Watershed Health, which seeks to coordinate salmon recovery monitoring efforts throughout the state.

6.6.2 Middle Columbia DPS-wide Coordination

The Yakima Basin's steelhead make up only one of the four Major Population Groups that together comprise the Middle Columbia River Steelhead DPS. The geographic area of the Middle Columbia River Steelhead DPS encompasses a large part of north-central Oregon and south-central Washington. Under the ESA, delisting decisions are made at the level of the DPS as a whole. This means that steelhead in the Yakima Basin may meet recovery goals, but not be delisted due to conditions elsewhere in the DPS. Communities throughout the DPS must undertake targeted recovery actions to successfully meet recovery goals and delist the DPS. This process will be facilitated by ongoing communication and coordination among these communities. An initial step is being made as part of the development of the Mid-Columbia Steelhead Recovery Plan by NOAA Fisheries, in which local planning groups from Oregon and Washington are meeting regularly to discuss how plans developed for individual MPGs will be 'rolled up' into a DPS-wide plan to be issued by NOAA. The Yakima Basin Fish & Wildlife Recovery Board anticipates that the need to share information and resources and coordinate key recovery actions across the entire DPS will continue during recovery plan implementation. The Board is committed to continuing to engage in discussions at the DPS level.

6.6.3 Integration with Columbia River, Estuary and Ocean Recovery Efforts

Conditions and management actions in the Columbia River, its estuary, and the ocean inevitably affect the fate of steelhead in the Yakima Basin. The rate of progress towards recovery will be determined, in part, by decisions made in these areas. Although this plan focuses on actions within the Yakima Basin, it recognizes that in-basin stakeholders will also need to engage in decision making outside of the basin to ensure that in-basin actions are coordinated with out-of-basin actions. Some stakeholders in the Basin (e.g., WDFW, the Yakama Nation, and the BOR) are directly involved in key out-of-basin management decisions; others have the opportunity to participate via established public participation processes and associations with other decision makers. The Yakima Basin Fish & Wildlife Recovery Board anticipates participating in efforts to coordinate overall Middle Columbia River Steelhead DPS recovery efforts. The Board will also foster discussions about the best way for in-basin stakeholders to ensure that progress outside of the basin continues to complement the concerted efforts underway within the basin.

7 Research, Monitoring and Evaluation

7.1 Steelhead Population Trends	**7.5 Critical Ecological Dynamics**
7.2 Key Factors Affecting Survival	**7.6 Impact of Long-term Trends**
7.3 Habitat Trends and Threats Criteria	**7.7 Coordinating Research & Monitoring**
7.4 Recovery Action Effectiveness	**7.8 Out-of-Basin RME Needs**

Steelhead recovery occurs in a complex setting. There are numerous uncertainties about the status of steelhead populations, trends in habitat conditions, and the response of steelhead to recovery actions. Ongoing research, monitoring, and evaluation will be an essential element of recovery efforts. Research and monitoring must be targeted to address critical uncertainties, many of which were identified earlier in this plan and are described more fully in this chapter. The Yakima Basin Fish & Wildlife Recovery Board is tasked with developing a research, monitoring, and evaluation (RME) plan for steelhead recovery efforts. It will be working closely with in-basin partners, WDFW, the Yakama Nation, and NOAA Fisheries to identify key actions and coordinate their implementation. This chapter gives an overview of topics that will be addressed in more detail in the proposed RME plan.

Chapter 6 addressed monitoring of implementation of recovery actions. Monitoring long-term trends for the basin's four steelhead populations will be essential for assessing progress towards the recovery criteria identified in Chapter 4. Understanding long-term trends in habitat conditions and other factors affecting survival will allow objective assessments of progress towards addressing the threats criteria NOAA Fisheries is developing as part of the Middle Columbia River Steelhead Recovery Plan. Both types of information will be required to assess prospects for de-listing Middle Columbia River Steelhead DPS.

Monitoring and research also improve our understanding of how recovery actions affect steelhead populations. Evaluating how recovery actions affect habitat conditions and how steelhead respond to those changed conditions will guide the choice and design of subsequent recovery actions. Work focusing on the ecological and climatic dynamics of steelhead habitat—both in and outside of the Yakima Basin—will also be critical.

To implement this recovery plan, we will need an adaptive management framework that addresses the key uncertainties identified here through management experiments. This will require:

- Careful coordination between those implementing recovery actions on the ground and the research community
- Identification of key uncertainties and hypotheses about their links to steelhead recovery
- Development of system models that guide discussion about factors affecting steelhead recovery

- Incorporation of experimental design concepts into management actions

This adaptive management framework will be developed in more detail in the upcoming Research, Monitoring and Evaluation Plan.

7.1 Understanding Steelhead Population Trends

The ESA calls for status reviews for listed species every five years. Ongoing monitoring of steelhead populations will be required to allow objective comparisons between current status and trends of key VSP parameters and the recovery criteria identified in Chapter 4. This work should be closely coordinated among NOAA Fisheries, the Interior Columbia Technical Recovery Team, WDFW, the Yakama Nation, and the Yakima Basin Fish & Wildlife Recovery Board.

Research and monitoring efforts should also evaluate the appropriateness of the recovery criteria identified in Chapter 4 so that the criteria can be adjusted as needed. Two areas where research and monitoring efforts will directly inform the revision of recovery goals are:

- Evaluating the current and potential role of mainstem spawning in recovery scenarios and using that information to determine how to produce the “mainstem spawners” block identified under the Satus population in Chapter 4
- Understanding the dynamics underlying the balance between resident and anadromous life histories in the Upper Yakima and Naches populations to determine realistic long-term population goals for both steelhead and rainbow trout

This section gives a brief overview of current and proposed monitoring and research that focuses on understanding steelhead population VSP parameters.

7.1.1 Abundance and Productivity

The existing ability to track MPG-level abundance trends via ladder counts at Prosser is excellent and needs to be maintained. Our current ability to track abundance at the population level is variable, with the strongest estimates from Roza Dam counts for the Upper Yakima and the weakest from the Naches basin, which has no dam counts and redd counting conditions that make it difficult to estimate spawner abundance. Two proposals are currently being developed to allow improved tracking of abundance by population. The first relies on using genetic sampling of the adult and/or juvenile migrations at Prosser and using genetic signatures to attribute fish to specific population areas. Feasibility studies are currently under way by WDFW’s genetics lab in Olympia. The second calls for radio tracking to apportion steelhead passing Prosser to their eventual destination and would repeat and update the 15-year old study referenced in this plan (Hockersmith et al. 1995). The two efforts would be complementary since the radio tracking would help develop pre-spawning mortality rate estimates and help assess effectiveness of genetic population attribution. Both proposals will be developed in more detail in the upcoming RME plan.

7.1.2 Spatial Structure

Existing Monitoring of Spatial Structure

Our current knowledge of spatial structure is based on redd counts and radio-tracking data. The BPA-funded Yakama Nation Watersheds Project conducts extensive monitoring in the Satus, Toppenish, and Ahtanum creek watersheds. The redd surveys conducted by this program are the primary basis for understanding steelhead spatial structure in these watersheds and should be continued.

Redd surveys have been conducted in the Naches basin since 2004. The USFS Naches Ranger District and WDFW have led these efforts with support from other agencies. This has significantly expanded our knowledge of spawner distribution in the area, although high and turbid flows during the spawning season limit the utility of redd counts for estimating spawner abundance.

Our most current knowledge of spatial structure in the Upper Yakima population area comes from radio tracking conducted by BOR and YKFP in 2002 through 2005. This work provided a detailed picture of spawner distribution during this time period; it did not address the portion of the Upper Yakima population that spawns below Roza Dam. This work ended in 2005.

Improve Tracking of Upper Yakima and Naches Distributions

Effectively tracking long-term trends in spawner distributions in the Upper Yakima and Naches populations will require a combination of methods, including targeted redd counts in areas and years when conditions are favorable, periodic radio tracking from Prosser and/or Roza, and the use of new tagging and detection technologies—such as inserting PIT or acoustic tags in adults at Prosser and using detector arrays to track movements into tributaries, and using sonar-based detection systems, and installing automated counting facilities at key passage structures. Specific proposals and budgets will be developed as part of the RME plan.

Role of Mainstem Spawning

Our understanding of past, current, and potential future steelhead spawning in mainstem reaches is limited. The mainstem Yakima and Naches rivers and their complex of side-channels are generally presumed to have supported significant numbers of steelhead spawners prior to the population declines of the last 150 years. Changes in hydrology and significant reductions in the extent and function of floodplains are presumed to have significantly reduced the extent and success of mainstem spawning, especially downstream of Union Gap, but hard data are lacking. Redd surveys are generally not feasible in mainstem reaches because flows are often high during the spawning season. Two major radio-tracking efforts in the basin found relatively high rates of mainstem spawning (Hockersmith et al. 1995; Karp et al. 2003; Karp et al. 2005). Additional radio tracking is likely to be the most effective way to increase our understanding of the current extent of mainstem spawning and the microhabitats used by mainstem spawners. Further work is needed to determine the key factors that affect reproductive success of mainstem spawners. This will be a critical part of evaluating where mainstem spawning should be

encouraged or discouraged in the course of recovery. As noted in Chapter 4, current uncertainties about the feasibility and success of mainstem spawning below Union Gap led recovery planners to identify a block of spawners from the Satus population that could either be produced from the mainstem Yakima or mitigated for by increased production elsewhere in the basin. Research that informs which of these alternatives to choose will help guide recovery efforts.

Rates of Reestablishment of Steelhead in Previously Blocked Areas

Significant efforts are being made to restore passage to parts of the basin that have been blocked by dams and other barriers. Passage barriers have been recently removed from Cowiche and Big creeks. Passage barrier removal is underway in Manastash and Taneum creeks and is proposed for Naneum Creek and the Cle Elum and Bumping rivers. Understanding the recolonization process is critical to 1) ensuring that significant investments in passage provide anticipated benefits, and 2) evaluating the possible need for short-term supplementation to re-establish populations in previously blocked areas.

7.1.3 Diversity

Currently, our understanding of the extent and role of phenotypic and genetic diversity in Yakima Basin steelhead populations is limited. Our understanding of population specific phenological and life history traits will be greatly improved by the anticipated ability to identify upstream migrants by population at Prosser.

Phenotypic Diversity

Fish measured at adult traps associated with fish ladders at Prosser and Roza dams are the best source of data on spawner lengths, weights, condition, and other phenotypic traits. Smolt lengths, weights, and condition can all be assessed at smolt traps (Prosser and Roza dams and tributary screw traps). Improving existing smolt and parr sampling and establishing new trapping locations should be considered. Data on phenological traits should be reviewed for correlation with run timing, genetic differences, and between and within population spatial distribution.

Genetic Diversity

The genetic sampling proposed to improve tracking abundance by population will also provide ample data for analyses of genetic diversity within and among the four populations. Radio-tracking data of genetically profiled individuals and/or spawning ground genetic samples can be used to assess inter-population stray rates and identify genotypic variations in habitat use.

Hatchery Genetic Inputs

Hatchery steelhead are not currently released in the Yakima Basin, and strays from others areas have comprised less than 5% of the total run on average, but the risk of long-term genetic impacts from interbreeding with hatchery stocks remains. We must continue current efforts to:

- Identify and track the hatchery component of steelhead runs, both at Prosser, and where possible, on the spawning grounds
- Assess genetic introgression from hatchery steelhead and rainbow trout in the Upper Yakima and Naches populations

Understanding and Monitoring Life History Diversity

As described in Chapter 2, our current understanding of steelhead life history diversity in the Yakima Basin is limited. Monitoring and research that improves our understanding of life history diversity within and among populations will allow recovery planners to build more explicit recovery criteria for the diversity component of the VSP framework.

Genetic sampling and PIT tagging can be used to build population specific estimates of run timing. Combining scale samples with this information can be used to determine age structures by population.

Understanding juvenile migration patterns between emergence and smoltification will be more challenging but essential. Key questions include:

- Comparing the frequency and relative survival benefits of different juvenile migration patterns (e.g., smoltification upstream vs. downstream movement of pre-smolts in late fall and winter)
- Distinguishing the role of mainstem and floodplain rearing habitat and the impacts on life history patterns from the loss of these rearing habitats in many parts of the basin (e.g., simplified channels throughout the basin, the Wapato Reach and, potentially, the floodplain reaches below Horn Rapids).

7.2 Understanding Key Factors Affecting Survival

In recent years our ability to track anadromous fish survival through multiple life-stages has improved dramatically. This makes it possible to determine the effects of specific habitat conditions on specific life stages. Currently PIT tags inserted at Yakama Nation smolt traps run in Satus, Toppenish, and Ahtanum creeks are the primary source of data on survival rates for smolt and adult life stages. Expanding the use and monitoring of PIT tags and other developing tagging technologies will help us make significant strides in understanding factors affecting survival rates and how those can be addressed via targeted recovery actions.

7.2.1 Role of Life-Cycle Models

Life-cycle models help us quantify how habitat conditions and other variables affect fish populations. Currently the most developed model in the Yakima Basin is the EDT model used in subbasin planning (See Appendix B). These models should be used to identify and evaluate working hypotheses about the effects of specific environmental conditions on survival and abundance of steelhead. Model results can then be used to help set restoration priorities and design management experiments that empirically test model assumptions.

7.2.2 Separating In and Out-of-Basin Survival Rates

To understand the interplay between in-basin and out-of-basin effects in determining the viability of Yakima steelhead populations requires tracking trends in out-of-basin survival rates. The smolt-to-adult return rate (SAR) reflects all agents of mortality affecting the life cycle of salmon and steelhead from migrating smolts through returning adults. There needs to be a way of counting smolts leaving the Yakima Basin each year and then the number of adults returning to the basin from that year's outmigration. The expanding network of PIT-tag detectors within and outside the Yakima Basin now enables us to count PIT-tagged outmigrants and returns. Currently we can estimate SARs for the Satus and Toppenish populations and the Ahtanum component of the Naches population. PIT tagging Upper Yakima and Naches steelhead would help us develop SARs more representative of the Yakima steelhead MPG.

7.2.3 Impacts of Mainstem Conditions on Smolt Survival

A key uncertainty that needs to be addressed is the relationship between flows, habitat conditions, and outmigration timing and survival. Steelhead data are limited, but work is being done based on more extensive PIT tag data and other monitoring of spring Chinook. Developing a more detailed understanding specific to steelhead will inform efforts to improve flow conditions during the spring outmigration and manage habitat in a manner that enhances outmigrant survival. This work should also focus on how refugia associated with in-stream diversity and side channel/floodplain habitats in the lower mainstem contribute to smolt survival. Survival rates through bypass systems associated with major irrigation diversions (Chandler, SVID, and WIP) should also be studied in order to identify if changes can be made to associated infrastructure that would improve passage conditions.

7.2.4 Impacts of High Delivery Flows on Juvenile Rearing

A key uncertainty identified in this plan is the effect on steelhead growth and survival of high summer delivery flows in general and the flip-flop flow regime in particular. Research and monitoring that improves our understanding of these impacts and tracks responses to any changes in delivery flow regimes implemented as part of recovery efforts will be critical. A review of past work on this topic and specific proposals for future research will be included in the RME plan under development.

7.2.5 Factors Affecting Upmigrating Adults

Factors that affect adult spawner survival and condition between passage at McNary and spawning are poorly understood. As detailed in Section 2.5.1.1, current flow and temperature conditions preclude migration into the basin from July until September. PIT tag detections and water temperature data suggest that steelhead hold in McNary pool. Understanding how this change in run-timing and holding habitat affects eventual survival and reproductive success will help guide recovery efforts. No actions recommended in this recovery plan are anticipated to significantly reduce average Columbia mainstem summer temperatures during that time period, although changes in

flow regime may lengthen the period of cooler temperatures in the lower Yakima River. Additional research and monitoring would help determine if targeted efforts to improve specific habitats and create relatively small-scale temperature refugia would improve spawner survival and condition. In addition, as noted in Section 2.5.1, recent data indicates that a portion of steelhead returning to the Yakima continue significant distances up the Columbia before returning downstream and entering the Yakima. Additional monitoring and research is needed to understanding the rates, causes, and implications of these upstream movements.

7.2.6 Resident/Anadromous Interactions

Understanding the interplay between resident and anadromous life histories of *O. mykiss* in the Upper Yakima and Naches populations will help ensure that appropriate goals are set for these populations and that recovery actions are effectively targeted to increase the abundance of steelhead. Research on this topic is currently ongoing and has received new impetus as a result of the listing, formulation of this recovery plan, and work on the Steelhead Master Plan by YKFP. Elements that need additional study include the:

- Genetic differences (if any) between individuals that exhibit anadromy and those that exhibit residency, including examination of subpopulation structure and genetic diversity of the population as a whole
- Effects of habitat conditions and competitive interactions on growth and condition of juvenile *O. mykiss*, and the impact of those patterns on subsequent smoltification or maturation as resident fish
- Population response to newly re-opened habitat from the standpoint of genetic processes and life history diversity
- Role of resident *O. mykiss* in determining the viability of the anadromous form

7.3 Understanding Habitat Trends and Threats Criteria

To address the delisting criteria, NOAA Fisheries is developing—as part of the Middle Columbia Steelhead Recovery Plan—new and existing monitoring and research to assess regarding habitat status and trends, which will need to be integrated into individual recovery plans. An inventory of existing efforts and specific proposals designed to fill gaps will be incorporated into the RME plan under development by the Yakima Basin Fish & Wildlife Recovery Board.

7.4 Evaluating Recovery Action Effectiveness

Effectiveness monitoring is needed to understand the nature and rate of response of habitat conditions and steelhead populations to specific recovery actions. Effectiveness of recovery actions will be monitored using a variety of approaches, including the Before-After-Control-Impact (BACI) design with stratified random sampling described in the Comprehensive Statewide Monitoring Strategy (ISP 2000; Washington State Monitoring Oversight Committee 2002), the Intensively Monitored Watershed Program promoted by

NOAA Fisheries and the Washington Monitoring Forum, and the SRFB Statewide Effectiveness Monitoring Program developed by Tetra Tech Inc. Supplementation actions will continue to be monitored according to the Yakima/Klickitat Fisheries Project (YKFP). Not all recovery actions recommended in this plan need to be monitored for effectiveness, but a sufficient number of replicates of each type of action should be assessed. This work will need to engage ecologists, fish biologists, geologists, hydrologists, and other experts familiar with the region.

Even if all habitat actions could be implemented immediately, which they cannot, there will be delays in the response to actions. Populations will likely respond more quickly to some actions (e.g., diversion screens and barrier removals) than they will to others (e.g., riparian plantings). Targeted monitoring and research will help resolve remaining uncertainties about the effects of recovery strategies on population VSP parameters. This work should focus on the linkages between physical and biological processes so managers can predict changes in survival and productivity in response to selected recovery actions. It will need to address the interactions between multiple recovery actions and their broader ecological context. Work should integrate system models and their underlying hypotheses whenever possible.

Specific topics to be addressed include the:

- Impacts of large woody debris on steelhead rearing, spawning, and incubation conditions
- Long-term effectiveness of the kelt reconditioning program
- Response to reopening suitable habitat
- Response to improvements in channel, floodplain, and riparian conditions

7.5 Understanding Critical Ecological Dynamics

Steelhead exist within a complex ecological setting, and their fate is affected by competition with other species, predation, nutrient cycling, the presence of contaminants and vegetation dynamics. Understanding these diverse factors will improve recovery efforts.

7.5.1 In-Basin Predation

Predation is one of the main factors driving juvenile survival. Research and monitoring is needed to track trends in predator populations, understand their impacts on steelhead, and develop appropriate management techniques to reduce predation.

Predation by bass and pikeminnow on outmigrating smolts is a concern, although it is believed to have a smaller effect on steelhead than other species because most steelhead smolts have left the lower Yakima River before smallmouth bass and northern pikeminnow become active. Monitoring to develop better estimates of piscine predation in the lower river should continue.

Avian predation is known to be significant, with known concentrations of terns and gulls in the lower Yakima River, mergansers throughout the basin, and increasing numbers of white pelicans and cormorants visiting the basin. Research and monitoring that improves understanding of trends in species presence, their impacts on steelhead, and how these impacts can be managed are vital. This should include efforts to understand the interactions between habitat conditions and predation and the impacts of specific infrastructure (e.g., irrigation diversion dams) that may facilitate predation. Detection of excreted PIT tags at sites where predatory birds congregate has helped in estimating consumption of salmonids in the Yakima and Columbia rivers. The Yakima/Klickitat Fisheries Project is currently tracking avian predation (Siegel and Fast 2006); this work should be continued and expanded.

7.5.2 Interspecies Effects

The Yakima/Klickitat Fisheries Project Species Interaction Study is a long-standing effort to understand how fish culture activities (hatchery supplementation of Chinook and coho stocks) affect other species, including steelhead (McMichael et al. 1999; McMichael et al. 1997; Pearsons and Hopley 1999; Pearsons et al. 1996). This project has increased our understanding of the ecological dynamics that affect both resident and anadromous *O. mykiss* in the basin and should be continued and expanded.

Two other sets of questions about interspecies interactions with management implications are:

- How increased interspecific competition in juvenile rearing areas may affect the balance between anadromy and residency for *O. mykiss*
- How the presence of exotic species affects steelhead recovery efforts, and how those species with significant impacts can be eradicated or controlled

7.5.3 Changes in Nutrient Transport

Anadromous fish bring oceanic nutrients inland when they die and decompose in headwaters and transport nutrients accumulated in growing juveniles from the headwaters to the ocean. Pre-1850 returns of salmon and steelhead are estimated to have ranged from 10 to 100 times current runs. The reduction in anadromous fish runs caused significant changes in these nutrient cycles. Effectively managing steelhead requires understanding how these changes affect growth and survival under current conditions, and what can be done to address nutrient limitations (e.g., adding carcasses and analogs). Restoring side channels and natural obstructions, such as woody debris may help retain carcasses in headwaters.

7.5.4 Expansion of Aquatic Vegetation

The lower Yakima mainstem has seen a significant increase in the presence of aquatic vegetation in the last decade. The expansion of water star grass in the lower 100 miles of the river is the most dramatic example. Once a relatively rare native plant, the star grass has expanded to cover much of the riverbed with thick mats of vegetation. This is

generally presumed to have been a response to the significant reduction in turbidity in the lower river over the last decade associated with improved quality of irrigation return flows. Effects on steelhead smolts and returning adults are unknown; the most likely impact is reduced habitat quality in the later part of the smolt outmigration and the early part of the adult immigration due the reduction in dissolved oxygen concentrations associated with star grass respiration. The South Yakima Conservation District's Eutrophication Study (Marie Zurowski, personal communication, 2007) has found that the relationship between vegetative growth and nutrient concentrations is complex. Understanding the factors that drive the spread of aquatic vegetation (increased light penetration and high nutrient concentrations) and those that limit it (scouring in flood events, high turbidity) will help managers respond. The Benton Conservation Districts conducting pilot work on control of water star grass.

7.5.5 Impacts of Pesticides and other Toxins

Agricultural lands in the Yakima Basin support a diversity of crops and more than 180 different pesticides are applied yearly in the basin (Rinella et al. 1999). Some widely used pesticide classes are known to interfere with the normal function of the nervous system in salmon and other fish, including the organophosphates (Beauvais et al. 2000; Brewer et al. 2001; Moore and Waring 2001; Morgan and Kiceniuk 1990; Scholz et al. 2000), the carbamates (Little et al. 1990; Waring and Moore 1997), the pyrethroids (Little et al. 1993; Moore and Waring 2001), and the triazines (Moore and Waring 1998; Saglio and Trijasse 1998). Many pesticides are known to interfere with the behavior or physiology of salmonids at concentrations well below lethal levels and within the range of exposure conditions that have been observed in the Yakima River and its tributaries (Cuffney et al. 1997; Ebbert and Embrey 2002; Joy and Patterson 1997; Morace et al. 1999; Rinella et al. 1999). Sublethal exposures to these chemicals may impair the neurochemistry, neurophysiology, or behavior of exposed salmonids. Recent research has also focused attention on the potential impacts of other contaminants on salmonids, including estrogens and other hormones. The effects of all of these contaminates on steelhead population VSP parameters in the Yakima Basin remain unknown, but the potential effects are significant and merit careful attention.

7.6 Understanding Impact of Long-Term Trends

Yakima Basin steelhead recovery will not happen under static conditions; rather their survival will occur within a dynamic human and climatic context. Understanding future trends in these areas is important.

7.6.1 Global Warming Impacts

There is broad consensus that worldwide climate is warming. Projections global warming impacts on the Pacific Northwest generally agree that there will be less snowpack accumulation and increased summer temperatures. Changes in precipitation are less certain with some models calling for increases and others for decreases. Research efforts are currently underway to understand how this will affect salmonid habitat in the Inland Columbia Basin (Beamish 1995; ISP 2002; 2002; 1989) and the Yakima Basin (Climate

Impacts Group 2009; Mastin 2008). Research will be vital to assuring that recovery efforts create real and sustained long-term improvement in habitat conditions.

7.6.2 Future Growth Impacts

In the last 150 years the landscapes and lifeways of the Yakima Basin have been transformed repeatedly, and such transformations will inevitably continue. Almost all projections for the Yakima Basin call for continued population growth. It is critical that proponents of steelhead recovery in the Yakima Basin anticipate how population growth and accompanying lifestyle decisions can be guided to protect fish habitats, local economies, and human quality of life.

7.7 Coordinating Research and Monitoring Efforts

The Yakima Basin is home to a wide range of long-term monitoring and research efforts, and the technical capacity within the basin and among out-of-basin partners actively engaged in the basin is impressive. Monitoring and research associated with steelhead recovery should be built upon these established resources. Extensive coordination will be required to ensure that existing resources are used effectively and that new resources are brought to bear in a targeted fashion that minimizes costs. The Yakima Basin Fish & Wildlife Recovery Board is currently working with partners in the basin to develop a working group focused on steelhead monitoring and research needs. Initial meetings have focused on understanding how data from current monitoring illuminates steelhead population trends and how gaps in current efforts can be filled to better track key VSP parameters. The hope is that this working group will coordinate and research and monitoring related to steelhead recovery plan efforts.

Currently, the YKFP is the dominant fish management monitoring and research organization for the Yakima Basin. The co-managers, Yakama Nation, and WDFW, develop monitoring and evaluation objectives and tasks through a joint process. The YKFP monitoring and evaluation program is organized into four categories: Natural Production, Harvest, Genetics, and Ecological Interactions. The co-managers' Science/Technical Advisory Committee employs the services of a work committee of scientists, the Monitoring Implementation Planning Team, to develop a Monitoring and Evaluation Plan (Fast and Sampson 2004). Although the YKFP's greatest monitoring emphasis has been on the targets of current YKFP supplementation efforts (spring Chinook, fall Chinook, and coho), the program also provides valuable information on steelhead. Steelhead out-migration is enumerated at Prosser Dam, steelhead have been a subject of YKFP species interactions studies, an EDT model has been developed for Yakima Basin steelhead, and a YKFP steelhead master plan is under development. YKFP also works with the Columbia River Inter-Tribal Fish Commission on the Yakima subbasin kelt reconditioning study and with the BOR on recent steelhead radio-tagging work in the upper Yakima River. Research and monitoring related to steelhead recovery should build upon the capacities of the YKFP program.

7.7.1 Integration with Regional Monitoring Programs

In the last five years, numerous regional monitoring initiatives have been developed, including the:

- Pacific Northwest Aquatic Monitoring Partnership
- Collaborative Systemwide Monitoring and Evaluation Project (CSMEP; administered by the Columbia Basin Fish & Wildlife Authority)
- Integrated Status and Effectiveness Monitoring Program (ISEMP) led by the NOAA Northwest Fisheries Science Center
- Washington Monitoring Forum (previously the Governor's Monitoring Forum)

Specific guidance documents that have been developed to guide monitoring related to recovery efforts include:

- Adaptive Management for Salmon Recovery: Decision Framework and Monitoring Guidance developed by the NOAA Northwest Fisheries Science Center (NMFS 2007)
- The Washington comprehensive monitoring strategy for watershed health and salmon recovery (ISP 2000; Washington State Monitoring Oversight Committee 2002)
- Governor's Forum On Monitoring, Recommendations to the Salmon Recovery Regions (GSRO and NMFS 2005)

Research and monitoring activities in the Yakima Basin will draw on the strategies, indicators, and protocols developed in these programs and documents in order to assure the use of valid sampling and statistical designs and consistent protocols and data management systems.

7.7.2 Out-of-Basin Research Needs

Long-term efforts to increase the survival of Yakima Basin steelhead will benefit from the broad range of monitoring and research already focused on the mainstem Columbia, its estuary, and the ocean. The efforts to better track out-of-basin survival for Yakima steelhead described in Section 7.1.4 will help connect the general work done out-of-basin with the specific impacts on Yakima Basin populations. Monitoring efforts in the basin should be coordinated with efforts outside of the basin; for example fish tagged in-basin can also provide valuable information on Columbia River and ocean survival. Specific research and monitoring efforts that will benefit Yakima Basin steelhead include those that focus on:

- Harvest rates of naturally produced steelhead and indirect mortalities associated with recreational and commercial fisheries in freshwater and ocean fisheries
- Fisheries management techniques that improve access to harvestable stocks while reducing undesirable direct and indirect impacts to naturally produced steelhead

- Interactions between hatchery and naturally produced steelhead in the mainstem Columbia and ocean, including possible density-dependent competition
- Hatchery programs' effects on the incidence of disease and predation on naturally produced fish
- Effects of upstream passage conditions in the Columbia River on the subsequent reproductive success of steelhead
- Factors that affect the survival rate of juvenile steelhead through the Columbia River dams
- Changes in predator prey relationships in the Columbia River, its estuary, and the ocean, and how they can be managed to increase survival rates for summer steelhead
- Factors that drive the variability in ocean conditions

8 Public Education and Outreach

8.1 Introduction
8.2 Education & Outreach Goals & Principles
8.3 Proposed Outreach Actions

8.1 Introduction

A key principle of the Yakima Basin Fish and Wildlife Recovery Board is that decisions regarding salmon recovery must occur within a transparent, inclusive, and collaborative process. This will require a strong public outreach program that informs and engages elected officials, federal, tribal, state, and local agencies, local interest groups, property owners, and the general public. Recovering steelhead in the Yakima Basin is by its very nature a long-term process that will require support and understanding from all of these parties. Without this support, recovery efforts will founder.

Every individual within the Yakima Basin directly or indirectly affects habitat functions essential to the survival of salmon on a daily basis. The most fundamental example of this is our daily consumption of water. Yet most of the public is not familiar with the complex and varied life cycle and habitat needs of salmonids or of the consequences to habitat functions and salmon populations of the choices we make in the daily pursuit of legitimate activities. Salmon recovery will require nurturing a broad understanding of these causes and effects.

Yakima Basin Environmental Education Project, WDFW, the Yakama Nation Fisheries and Wildlife, the USFS Respect the Rivers program, the Benton Conservation District Salmon in the Classroom program, and the Kittitas Environmental Education Network (KEEN) conduct salmon-recovery related outreach efforts in the basin. All of these efforts are to be lauded, but they will need to be supplemented with targeted outreach that focuses specifically on salmon recovery needs. The following factors will need to be addressed:

- Population growth in the Yakima Basin exceeded 25% in the previous decade and is projected to grow 45% more by 2020. Outreach to new residents to explain salmon recovery efforts will be an ongoing need.
- The information and education components of federal, state, and local programs have been drastically reduced over the past five years due to overall budget reductions. Rather than hiring full time personnel to develop and deliver public education, these functions are commonly added to existing staff's responsibilities.
- Agencies and personnel are largely "siloed," meaning there is very little knowledge, much less communication, about public education and outreach activities across agencies. The partnering that does occur is essentially dependent on a small cadre of highly energetic people who go above and beyond their required job responsibilities. The silo effect also occurs within large agencies. This is partly the result of information and education being dramatically reduced,

leaving staff to focus on public comment, and participation activities specific to regulatory requirements.

- Messaging tends to be narrow, focusing on the most critical issues facing an agency or group or meeting a specific regulatory requirement, e.g., a public comment period.
- Scant evidence is available to suggest that the public is aware of specific salmon recovery projects, what they are achieving, and how these projects fit into the big picture.
- Existing programs require local governments and state agencies to regulate land use on private and public property. Local experience shows that land use controls are not widely accepted unless there is broad public agreement with their intent, application, and result. Land use controls are only effective in their application if the property owners understand the purpose and support the limitations imposed on their range of land use activities. Outreach efforts can foster the dialogue and understanding required for existing programs to be implemented in an equitable and effective manner.

8.2 Education and Outreach Goals and Principles

Education and outreach efforts proposed in this plan should be characterized by:

- Close coordination with existing programs and entities, including the Yakima Basin Environmental Education Project (YBEEP) Conservation Districts, school districts, the USFS, local non-profit organizations, the WDFW, and the Washington State Department of Ecology
- Understanding that the future of the Yakima Basin be considered along with continued population and economic growth and that successful salmon recovery be a community-wide effort
- Recognition that salmon recovery efforts depend on voluntary efforts built on transparent processes and outreach to property owners and other stakeholders

8.3 Proposed Outreach Actions

The following list of proposed outreach actions will serve as a starting point for the Yakima Basin Fish & Wildlife Recovery Board's efforts to develop and coordinate a basinwide salmon recovery outreach strategy.

8.3.1 Short-Term Recovery Board Outreach Actions

Initial efforts by the Board will include:

- Summarizing existing education programs and materials in the basin
- Reformulating the education and public involvement committee developed during the Subbasin Planning Process in 2002-5

- Developing an education plan that targets specific audiences (school system, permit applicants, decision-makers, etc)
- Maintaining access to, and transparency of, all Board processes and programs, including regular meetings, special workshops or hearings and products developed by the Board
- Preparing and distributing newsletters and other regular updates on the Board's activities
- Developing a web page that provides the history of salmon recovery efforts in the basin, a calendar of board and committee meeting times, access to educational materials, access to planning and implementation documents, and access to current research
- Developing tools, such as display boards and PowerPoint presentations that staff can use at a variety of public gatherings, including county fairs or stakeholder group meetings, to explain activities and opportunities
- Working with county conservation districts, federal, tribal, and state resource agencies, water purveyors, school districts, and others to identify opportunities to leverage resources in a way that brings educational materials and learning opportunities directly to classrooms, landowners, recreationists, and other target audiences

8.3.2 Stakeholder Group Presentations

The subbasin planning board was very successful in scheduling and presenting information to stakeholder groups. In general, presentations were provided in PowerPoint format. By going directly to the meetings of stakeholders, two critical outcomes occurred. First, they reached a much broader audience; had a series of public meetings been held, perhaps a single representative of an organization would attend. At the organization's own meeting, many more individuals were reached directly. Second, going to "their turf" significantly changes the social dynamics. Individuals and groups believe they are being given greater respect, and they are more comfortable asking questions and sharing perspectives within their "natural setting." It is recommended that a round of stakeholder presentations be given each year. This can be done as part of a) releasing an annual report, b) soliciting review of or announcing the release of study or plan, or c) part of preparing and soliciting feedback on the annual work plan.

8.3.3 Newsletter/Annual Report

The Yakima Basin Fish & Wildlife Board should develop a newsletter/annual report, either on its own or in conjunction with other organizations. The newsletter should describe Board activities and give an overview of salmon recovery efforts throughout the basin. The newsletter should be sent to a broad-based mailing list, be posted online, and be available in hard copy at select public locations.

8.3.4 Project Tours

Even those who are actively engaged with salmon recovery issues often have only limited knowledge of on-the-ground projects. Project tours can help build this connection. A schedule of project tours should be developed and targeted at key audiences. Tours should provide both a general overview of recovery board efforts and project-specific information. “Virtual tours” based on photos taken in the field can be developed and made available on-line.

8.3.5 Posters and Handouts

Posters, brochures, and other handouts related to salmon recovery should be developed at made available in diverse public settings.

8.3.6 Workshops and Conferences

Workshops can cover a broad range of possible subject matter and can be developed to address the needs of specific groups. A conference held annually or every 18 months may also help link stakeholders, elected officials, and natural resource managers; possibilities for coordinating this with the annual Yakima Basin Science and Management conference should be investigated.

8.3.7 Mailing to Shoreline Landowners

One proposed outreach strategy is to send an *informational letter or brochure* to all shoreline property owners from each City Council or Board of County Commissioners. The letter or brochure would provide information on the biological, physical, and habitat values of the natural shoreline and the importance of those functions for water supply, water quality, shoreline stability, flood protection, and fish and wildlife habitat. The letter would inform owners that the natural condition of the shoreline is a State interest and the county/city have policy and codes required by the state legislature that regulate actions along the shoreline in order to protect those functions. It should include information on what property owners can do if they are losing shoreline to erosion and/or want to re-establish natural shoreline vegetation. It should note that the state and federal governments (including BPA) are spending millions of dollars per year in the Yakima Basin to recover a salmon fishery for the benefit of all basin interests and that this expenditure is wasted if actions by individual landowners result in the degradation of shorelines.

8.3.8 Create “Stream Stewards” Positions

This proposal calls for hiring a Stream Steward for each Watershed Resource Inventory Area (WRIA) or County within a basin that would be jointly funded by city, county, state and federal agencies. Possible roles of the steward would be to:

- Provide biological and technical assistance to local governments for projects, planning processes and reviews that involve shoreline habitat issues.

- Assist shoreline property owners interested in preserving natural habitat conditions or that have shoreline issues (erosion or bank protection).
- Act as a liaison between landowners, project proponents, and the local planning permitting/planning offices.
- Serve as a liaison between landowners and the Lead Entity application process for Salmon Recovery Funding Board funding.
- Be a resource for local non-profit organizations (e.g., greenways, land trusts).
- Be a classroom resource for elementary school teachers building shoreline/fish issues into curriculum.

APPENDIX A: Local Review of ICTRT Habitat Model

A.1 Overview of Review of ICTRT Intrinsic Potential Model

This appendix summarizes the results of local reviews of the Interior Columbia Technical Recovery Team (ICTRT)'s Intrinsic Potential Analysis for Middle Columbia River Steelhead in the Yakima Basin. The ICTRT developed a GIS-based model of habitat potential for steelhead that was used to estimate the historically available extent and quality of steelhead spawning and early rearing habitat. For more information on the development of the model and its use in ICTRT viability assessments for steelhead populations, see ICTRT (2007b), especially Appendix C.

As part of developing the Yakima Steelhead Recovery Plan, local biologists reviewed the areas identified as potential habitat by the ICTRT's GIS model. David Lind conducted the reviews for the Satus and Toppenish creek watersheds with the assistance of Tim Resseguie. Both are fish biologists with the Yakama Nation. Richard Visser (WDFW), David Lind (Yakama Nation), and Joel Freudenthal (Yakima County) conducted the Naches and Upper Yakima Area reviews. Alex Conley of the Yakima Basin Fish & Wildlife Recovery Board coordinated the review process. Extensive use was made of correspondence with other colleagues and existing documentation, including current fish distribution records and the Historic/Potential Steelhead Habitat analysis conducted as part of the Conservation Commission Limiting Factors Analysis for the Yakima Basin (Haring 2001).

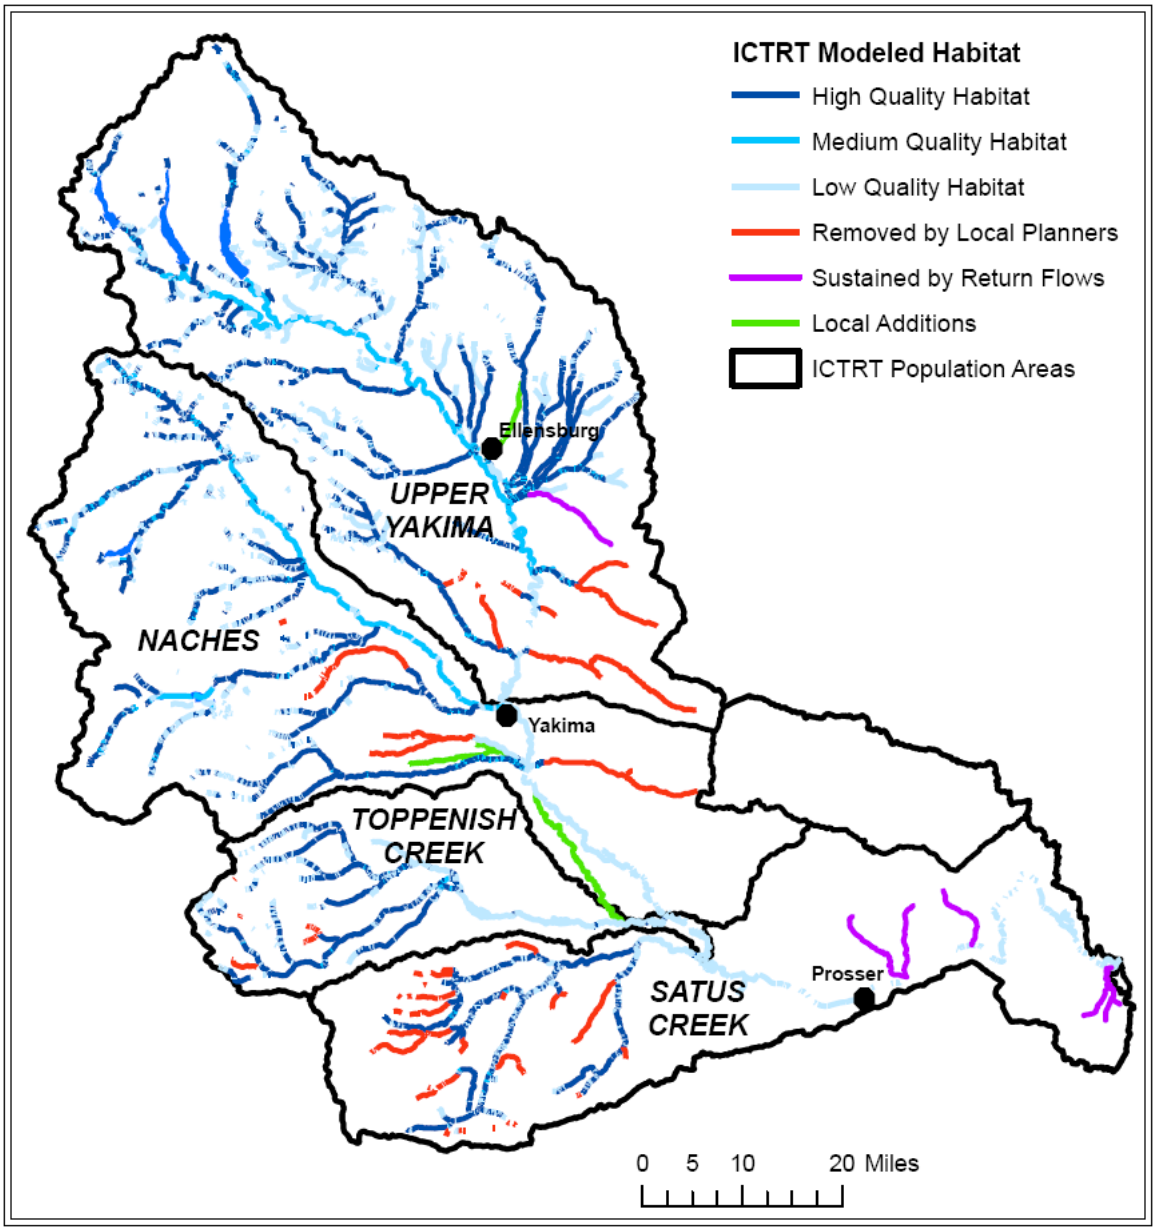
The model results provided by the ICTRT in November of 2006 identified a number of areas as potential steelhead habitat that the local review team did not consider to be or have been potential steelhead habitat. Several reasons were noted:

1) In a number of cases, the model did not include the presence of known natural fish passage barriers. The local reviewers identified these and documentation was provided to the ICTRT; most have been incorporated into the most recent version of the ICTRT model. They are noted in the population-specific discussions below.

2) The model consistently assigned habitat potential to streams in arid portions of the basin that the review team identified as not generating enough flow to support even limited use by steelhead. Correcting this would require refining the model's approach to predicating flow in arid (under 16") rainfall regimes. Inclusion of streams with watersheds that do not have the precipitation and/or watershed area to generate any sustained base flows was primarily an issue in the Satus Creek watershed and the lowest elevations in the Upper Yakima and Naches Watersheds. In areas with over 16" annual precipitation, the model performed much better, and largely matched local surveys and expert opinion. The ICTRT is exploring using additional data sources and analyses to exclude streams with insufficient stream flow from the habitat model, but has not incorporated these into their model at the time of this writing. In the current drafts of the Yakima

MPG Stock Status reports the ICTRT does acknowledge this limitation to their model, and notes the areas excluded in the local review.

3) In a few instances, drainages that would not have generated enough flow to support even limited use by steelhead prior to European settlement currently convey return flow from irrigation systems. Some of these areas may have potential to produce steelhead (Romey and Cramer 2001), and some level of use by salmon and *O. mykiss* is known to occur (Monk 2001) even though they would not have served as habitat prior to irrigation development. These areas should not be included in assessments of historic habitat, and were identified as "sustained by return flows" by local reviewers. In the current drafts of the Yakima MPG Stock Status reports the ICTRT does acknowledge this limitation to their model, and note the areas excluded in the local review.



4) Local reviewers expressed concern that the identification of all of the lower Yakima mainstem as potential spawning and early rearing habitat risked biasing the estimate of available habitat. In response to these concerns and similar ones raised in other areas, the ICTRT developed an analysis based on channel morphology that specifically identifies mainstem areas with spawning potential. This analysis is based on analysis of the location of documented spawning in the Okanogan and Wenatchee rivers. The most recent versions of the ICTRT model incorporate this analysis; the areas it identifies as having spawning potential correspond better with local assessments.

The model consistently extended small extents of lower quality habitat higher up small tributaries and into headwater reaches than locally derived maps of current distributions, but these differences do not make significant differences in overall population-level weighted habitat area, and were considered as feasibly within historic potential by local reviewers.

The model also failed to include a few streams considered by the review team to be potential/historic habitat. In all of these cases the streams were either part of split channels connected to other streams at both upstream and downstream ends, or small spring fed creeks in floodplains. The ICTRT model routed flows down a single channel where channels diverged or did not recognize the streams as having sufficient watershed area to generate flow. The ICTRT has recognized these limitations to their model, but has not added these areas. These areas are limited in extent and are not identified as key areas for restoration, and their exclusion does not have any significant effects on the results of the ICTRT viability analysis.

Overall, the current revised version of the ICTRT Intrinsic Potential Analysis' identification of potential steelhead habitat is a credible broad-brush estimation of the historic and potential habitat accessible to steelhead in the Yakima Basin. The ICTRT analysis or the locally revised analysis should not be used to classify specific areas and their current habitat values and/or potential at a reach or project level.

Figure A.1: July 2007 ICTRT Intrinsic Potential model with local adjustments

A.2 Satus Population Area

Based on our initial review, the ICTRT model significantly overestimated potential steelhead habitat in the Satus Creek watershed. There were two main reasons: 1) several natural fish passage barriers not included in the model, and 2) the inclusion of numerous streams with no sustained base flows, only limited runoff in wet periods, and steep canyons with very little to no developed floodplain. There is also one reach that local biologists believe is of significantly higher quality than indicated by the model.

1) Area above Satus Falls inaccessible per David Lind, Yakama Nation Fisheries staff, 1/28/07) *Incorporated into 7/07 ICTRT model as Barrier*

2) Area above Logy Creek Falls inaccessible per David Lind, Yakama Nation Fisheries staff, 1/28/07). *Incorporated into 7/07 ICTRT model as Barrier*

3) Area of Dry Creek inaccessible due to Gradient Barriers in both forks above confluence; also lack of baseflow flow above canyons (per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Incorporated into 7/07 ICTRT model as Barrier*

4) Several steep canyons without any sustained base flows, limited runoff even in wet periods, and little to no floodplain. In the few areas where floodplains exist in lower ends, ICTRT ratings were left intact to reflect possible historic potential, but are not deemed areas with any current potential (per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Noted in updated text of ICTRT Satus Stock Status Report but not incorporated into GIS model; identified in red on* Figure A.1.

5) Smaller areas without any sustained base flows and limited runoff even in wet periods (per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Noted in updated text of ICTRT Satus Stock Status Report but not incorporated into GIS model; identified in red on* Figure A.1.

6) Reach of mainstem Satus Creek considered high quality habitat for rearing (higher than adjoining areas given a higher rating) per David Lind, Yakama Nation Fisheries staff, 1/28/07. *Not incorporated into ICTRT products at this time.*

7) Adjustments to the designations of the mainstem Yakima based on the ICTRT analysis discussed in A.1, # 4 above. *Revised analysis of lower mainstem incorporated into 7/07 ICTRT model*

This local adjustments described here significantly reduce the amount of habitat available in the Satus Creek Population Area (see Table 2.2) but do not change the ICTRT-designated size class for the population.

A.3 Toppenish Creek Steelhead Population

Generally, the model performed much better in Toppenish Creek, which has a less dendritic drainage structure and more precipitation than the Satus population area. There was some overestimation of habitat due to 1) inclusion of a few smaller tributaries local biologists did not identify as potential steelhead habitat due to flow limitations and 2) extension of habitat beyond known barriers. These were addressed as follows:

1) White Deer Creek has habitat that supports resident rainbow trout, but the steep canyon reach near the mouth precludes use by steelhead (per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Incorporated into 7/07 ICTRT model as Barrier.*

2) Area inaccessible due to Agency Creek Falls (ID#4 in YN Barriers Shapefile) per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Incorporated into 7/07 ICTRT model as Barrier.*

3) Area of steep canyons without any sustained base flows, limited runoff even in wet periods, and little to no floodplain (per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on* Figure A.1.

4) Tributary to South Fork of Toppenish Creek is inaccessible due to Gradient Barrier (per David Lind and Tim Resseguie, Yakama Nation Fisheries staff, 1/28/07). *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on* Figure A.1.

5) Miscellaneous isolated habitat patches in areas not considered potential habitat (per David Lind, Yakama Nation Fisheries staff, 1/28/07). *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on* Figure A.1.

6) There is also one habitat addition proposed here; the tail end of Wanity Slough enters into lower Toppenish Creek, and any fish using the slough are likely to be of Toppenish origin, even as geographically the Slough is mainly in the Naches population area. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in green on* Figure A.1.

The adjustments made by local reviewers have very little affect on the total area and spatial distribution of the Toppenish population, and have no effect on the ICTRT viability analysis results.

A.4 Naches Population Area

Generally, the model performed quite well in the Naches Population Area. Local reviewers identified 1) barriers that were added to the model, 2) three areas that the local review team as having insufficient flows to be identified as habitat, and 3) five areas where the local review team felt that habitat with potential for steelhead had not been included in the model.

Local reviewers identified a number of natural barriers that had not been originally identified by the ICTRT. These were compiled from 1) WDFW's natural barriers coverage (from Brian McTeague), 2) consultations with Jim Cummins, Eric Anderson (fish biologists with WDFW in Yakima), and Yuki Reiss (fish biologist for the Naches Ranger District of the Wenatchee National Forest). These are:

1) Union Creek Falls (total passage barrier, on map). Incorporated by ICTRT; Fall # 470 in ICTRT yrbbarr shapefile.

2) Steep Canyon/gradient barrier on Kettle Creek per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 469 in ICTRT yrbbarr shapefile.

3) 50' falls on Deep Creek per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 468 in ICTRT yrbbarr shapefile.

4) Falls/gradient barrier on Copper Creek per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 466 in ICTRT yrbbarr shapefile.

5) Falls on NF Rattlesnake Ck per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 467 in ICTRT yrbbarr shapefile.

6) Impassable falls in Hindoo Creek per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 465 in ICTRT yrbbarr shapefile.

7) Falls on Oak Ck mapped by WDFW; confirmed by Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 237 in ICTRT yrbbarr shapefile.

8) S. Fork Tieton Falls (50') per Jim Cummins & Eric Anderson & USFS staff. Partially incorporated by ICTRT; Fall # 462 in ICTRT yrbbarr shapefile.

9) Bear Ck Falls (40') per Jim Cummins & Eric Anderson & USFS staff. Incorporated by ICTRT; Fall # 261 in ICTRT yrbbarr shapefile.

10) SF Cowiche Ck barrier falls per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 463 in ICTRT yrbbarr shapefile.

11) Reynolds Creek barrier falls per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 464 in ICTRT yrbbarr shapefile.

12) Crow Creek barrier falls per Jim Cummins & Eric Anderson. Incorporated by ICTRT; Fall # 471 in ICTRT yrbbarr shapefile.

13) An isolated fragment in an Oak Creek Tributary was considered to be inaccessible to steelhead due to gradient and flow limitations in the canyon downstream. Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on Figure A.1.

The following areas were identified as having insufficient historic flows to be classified as steelhead habitat:

1) The upper portion of the North Fork of Cowiche Creek is an arid watershed with only limited intermittent flow. At the townsite of Cowiche there are several large springs, and the local review team concurred with the TRT designation from that point downstream. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on Figure A.1.*

2) The upper portion of the Wide Hollow Creek is an arid watershed with only limited intermittent flow. At 46th Street there are several large springs, and the local review team concurred with the TRT designation from that point downstream. There may be some increased potential above historic between this point and 96th St due to increased flows from irrigation return flows, but this does not apply above the forks. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on Figure A.1.*

3) Moxee Creek is an arid watershed with only limited intermittent flow (see discussion of arid creeks in the Upper Yakima section below); lower portions currently carry irrigation return flows. *Acknowledged in ICTRT Upper Yakima Stock Status Assessment but not incorporated into GIS model; identified in red on Figure A.1*.

There are five additions to the ICTRT-identified historic habitat that were identified by local reviewers:

1) Wanity Slough, which is the most prominent of the relic side channels of the Yakima River in the Wapato area. It is currently managed as an irrigation drain, but likely once served as steelhead habitat, and while a currently low priority for restoration, still has some potential. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in green on Figure A.1*.

2) Bachelor and Spring creeks in the Ahtanum Floodplain. These are historic side channels and/or spring fed creeks that were not identified as habitat by the model, but which would have historic/potential habitat value. Bachelor Creek is now managed as part of an irrigation delivery system and restoring flows to the Ahtanum Creek mainstem has been given much higher priority than work within Bachelor Creek. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in green on Figure A.1*.

3) Initial ICTRT model ended at a partial barrier on Crow Creek; the actual upper extent of fish access is further upstream. *Incorporated by ICTRT in the 7/07 model version.*

4) Initial ICTRT model ended at a partial barrier on the North Fork of Rattlesnake Creek; the actual upper extent of fish access is further upstream. *Incorporated by ICTRT in the 7/07 model version.*

5) Quality habitat extends ~1.5 miles upstream of the upper end of modeled habitat in Upper Rattlesnake Creek. *Not incorporated into ICTRT products at this time*.

The adjustments made by local reviewers have little affect on the total area and spatial distribution of the Naches population, and have no effect on the ICTRT viability analysis results.

A.5 Upper Yakima Population Area

In most of the Upper Yakima Population Area, model results were consistent with review team expectations, except where unidentified passage barriers exist. However in the lower elevations, the model consistently identified low rainfall areas that do not support sufficient flow as steelhead habitat. There is also one proposed addition to the model.

The three barriers were incorporated into the model based on local review:

1) Thorp Creek has a gradient barrier in lower end of creek as identified by BOR's Yakima Storage Reservoir Fish Passage Study. *Incorporated by ICTRT; Fall # 453 in ICTRT yrbbarr shapefile.*

2) The Cooper River has an impassable fall at RM 0.6 (identified by BOR's Yakima Storage Reservoir Fish Passage Study and Jeff Thomas, USFWS). *Incorporated by ICTRT; Fall # 452 in ICTRT yrbbarr shapefile.*

3) Coleman Creek Falls (identified by Kittitas County Conservation District Stream Assessment data & photo). *Incorporated by ICTRT; Fall # 472 in ICTRT yrbbarr shapefile.*

The arid areas identified as not having sufficient flows to support steelhead fall into two classes:

1) Selah, Lmuma, and Whipple Wasteway/Badger creeks all drain larger watersheds at low elevations on the east side of the Yakima Basin. Maps from the Eastern Washington Stormwater Manual[40] show these streams within a climatic region where there are only about two and a half months of the year where precipitation exceeds potential evapotranspiration, and where in most years the excess is fully absorbed by the soils. The local review team was willing to consider the lower end of Lmuma Creek as having some habitat potential, as it is the wettest of these creeks, with a small portion of its watershed extending into a 16" precipitation zone that is expected to produce some runoff in a typical year. *Noted in updated text of ICTRT Upper Yakima Stock Status Report but not incorporated into GIS model; identified in red on Figure A.1*.

2) Roza and two Lower Wenas Tributaries drain small arid watershed, do not have hydric soils or groundwater inputs and are often elevated on fans at their lower ends. The local review team felt these did not have the flow regime needed to support steelhead. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in red on Figure A.1*.

Areas identified as historic/potential steelhead habitat by local reviewers, but not included in the ICTRT model include Wilson Creek splits off from Naneum Creek and was likely historic habitat, though extensive passage barriers in and below Ellensburg preclude current use by steelhead. *Acknowledged in discussions with ICTRT but not incorporated into GIS model; identified in green on* Figure A.1.

Comment Regarding the Caribou, Reecer and Naneum MSAs. Numerous streams drain the hills around Ellensburg, with some arising in the arid foothills, and others extending higher into the forested zone. While the review team and the model both identified these as potential habitat, the relative productivity of streams in this area will be highly variable, with some reaches providing high quality habitat and others being marginal at best. Many of these streams are interconnected and have been incorporated into the irrigations systems. Efforts to restore fish passage and habitat in these areas are currently underway, and are being guided by prioritization efforts that carefully consider the historic potential of each waterway, current conditions and trade-offs associated with the interconnectedness of the stream system.

---

[40] http://watershedpledge.org/biblio/0410076maps.html

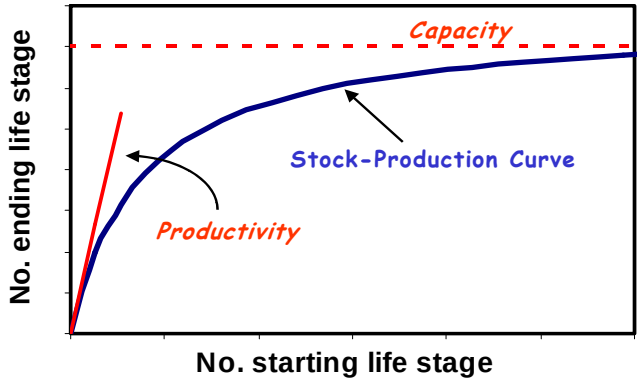
The adjustments made by local reviewers have very little affect on the total area and overall spatial distribution of the Upper Yakima population. They do significantly reduce the habitat area in a few MSAs and MiSAs, but have no effect on the overall ICTRT viability analysis results.

APPENDIX B: EDT Model Results for Yakima Steelhead

B.1 Overview of EDT Estimates of Population Performance

The Ecosystem Diagnosis and Treatment (EDT) was developed by Mobrand Biometrics (now part of Jones & Stokes) to help managers estimate the responses of anadromous fish populations to changes in habitat conditions (Lestelle et al. 1996; Lichatowich et al. 1995; Mobrand Biometrics 1999; Mobrand et al. 1997). The EDT model has been used in the Yakima Basin since the mid-1990s and was a key element in the 2002-2004 Subbasin Planning Process. This section gives an overview of the most recent EDT results for the four Yakima Basin steelhead populations. More detail on the EDT model is available at the Mobrand website (http://www.mobrand.com/MBI/library.html).

The EDT model quantifies the biological response to environmental conditions by estimating several components of population performance, including equilibrium abundance, productivity and life history diversity. It should be noted that these numbers reflect the average performance of a population over duration of years and are not specific to a single year or generation. Though numbers produced by the model reflect "average conditions", the model does take environmental variability into consideration through space and time.



The Beverton-Holt stock recruitment function is foundational to the EDT model. The EDT model generates a unique stock recruitment function for each life stage by stream reach, which are all integrated to calculate population abundance and productivity (Figure B.1). The point where the stock recruitment curve intersects the replacement line defines the population equilibrium abundance. Productivity represents the density independent growth rate of a population and is expressed as the number of recruits per spawner. Productivity also represents the resiliency of a population or ability to endure catastrophic events while sustaining viable numbers. Life history diversity represents the proportion of successful life history pathways offered to a population through space and time. The diversity index indicates the variety of life history pathways offered to a population and is a buffering mechanism against catastrophic events that might occur at a somewhat localized scale and affect a proportion of a population. These population performance parameters indicate the long-term viability and sustenance of the targeted population.

To understand the kinds of information utilized and how it is applied, it is important to understand what the analysis aims to produce. Information is translated through the procedure to address two aspects of fish population performance: productivity and capacity. These two parameters define a theoretical stock-production (S-P) relationship, illustrated using a Beverton-Holt production function in Figure B.1. The S-P curve displayed here is an example of what a relationship might look like between the number of fish at the beginning of a life stage and those surviving to the end of the stage.

Productivity is equivalent to the concept of intrinsic productivity discussed in McElhany et al. (2000) to describe viable salmon populations with respect to the Endangered Species Act. It is survival without density dependence effects, i.e., the approximate rate that would occur when competition for resources among the population is minimal. In

Figure B.1, it is the slope of the S-P curve at its origin. Productivity is a function of the quality of the environment.[41] In contrast, environmental capacity limits how large a population can grow given finite space and food resources. Capacity is represented by the asymptote in Figure B.1 and controls the extent that density dependence is operative at different population levels. Capacity is a function of the quantity of key habitats and food resources available. Sets of rules are used by the EDT method to derive productivity, key habitat, and food parameter values from environmental information—these serve as inputs into the EDT model.[42]

Figure B.1: Example stock-production relationship

The EDT model predicts that the abundance of steelhead in the Yakima Basin declined by 83% to 95% due to the change from historic to current environmental conditions (Table B.1). According to the model, the Naches, Toppenish, and Upper Yakima populations exhibit reductions in life history diversity from 89% to 93% since pre settlement era. A common theme in the reduction in the diversity index centers around major blockages to fish passage in and out of headwater tributaries associated with dam construction. In conjunction with this, major tributaries that historically supported healthy steelhead populations were subject to significant surface water withdrawals and associated dewatered reaches, unscreened diversions and impassable obstructions. These overwhelming burdens not only reduced life history diversity, but also substantially reduced habitat capacity (Table B.1).

To some degree, the productivity values are indicative of the quality of available habitat offered to a population. Riparian corridors and flow regimes have remained relatively intact in the upper portions of Satus and Toppenish systems compared to the Naches and Upper Yakima portions of the basin. As a result, productivity values for Satus and Toppenish Creek steelhead are modestly higher than those of the Naches and Upper Yakima (Table B.1).

---

[41] Productivity measured across a full life cycle also incorporates sex ratio, fecundity, and fitness.

[42] In EDT, food is both a component of environmental quality (thereby affecting productivity) and quantity (since food is assumed to affect both density-independent and –dependent mortality.) Regarding its role in affecting density-dependent mortality, the food parameter is used in conjunction with the key habitat parameter in estimating capacity.

Table B.1 Current and historic performance generated by EDT

Population	Scenario	Diversity index	Productivity	Capacity	Abundance
Naches Steelhead	Current without harvest	10%	1.6	2,287	849
	Current with harvest	10%	1.6	2,287	849
	Historic potential	91%	10.4	16,092	14,542
Satus Steelhead	Current without harvest	38%	2.5	1,552	926
	Current with harvest	38%	2.5	1,552	926
	Historic potential	92%	10.3	6,382	5,761
Toppenish Steelhead	Current without harvest	13%	2.3	876	497
	Current with harvest	13%	2.3	876	497
	Historic potential	94%	8.8	5,234	4,639
Upper Yakima Steelhead	Current without harvest	6%	1.7	2,453	1,047
	Current with harvest	6%	1.7	2,453	1,047
	Historic potential	91%	10.6	23,355	21,152

Ladder diagrams produced by the model evaluate the degree to which restoration[43] and preservation of specific geographic areas will benefit a population. Geographic areas can be defined at a variety of scales from individual stream reaches up to an entire watershed, etc. For our purposes, geographic areas for streams other than the Yakima were primarily defined at the watershed and tributary scale depending on the size of the population. Upper and lower bounds of the Yakima mainstem geographic area were defined by a major tributaries or channel spanning structures such as diversion dams. Restoration and protection potential are generated for each geographic area and represent the potential increase or decrease in the population performance parameters.

B.2 Restoration Potential and Limiting Factors by Populations

Table B.2, Table B.3, Table B.4, and Table B.5 present the geographic areas where restoration actions would make the greatest contribution to increasing abundance, productivity and capacity. The tables include areas that together comprise 75% of the total restoration potential with respect to abundance. The numbers reflect the potential increases in each performance parameter and are expressed as potential gains relevant to the current performance of the population generated by the model. The combined ranking shows the significance of a specific geographic area for a population that is pertinent to restoring all three components of population performance.

The strategic summary diagrams (Figure B.2, Figure B.3, Figure B.4, and Figure B.5) summarize the major physical and biological components limiting production of the target population within each specified geographic area. These limiting factors are known as the level 3 survival factors and are generated from a suite of level 2 attributes. Level 2 attributes are defined by data inputs that characterize the physical and biological environment. A single level 2 attribute acts as the primary component upon the Level 3

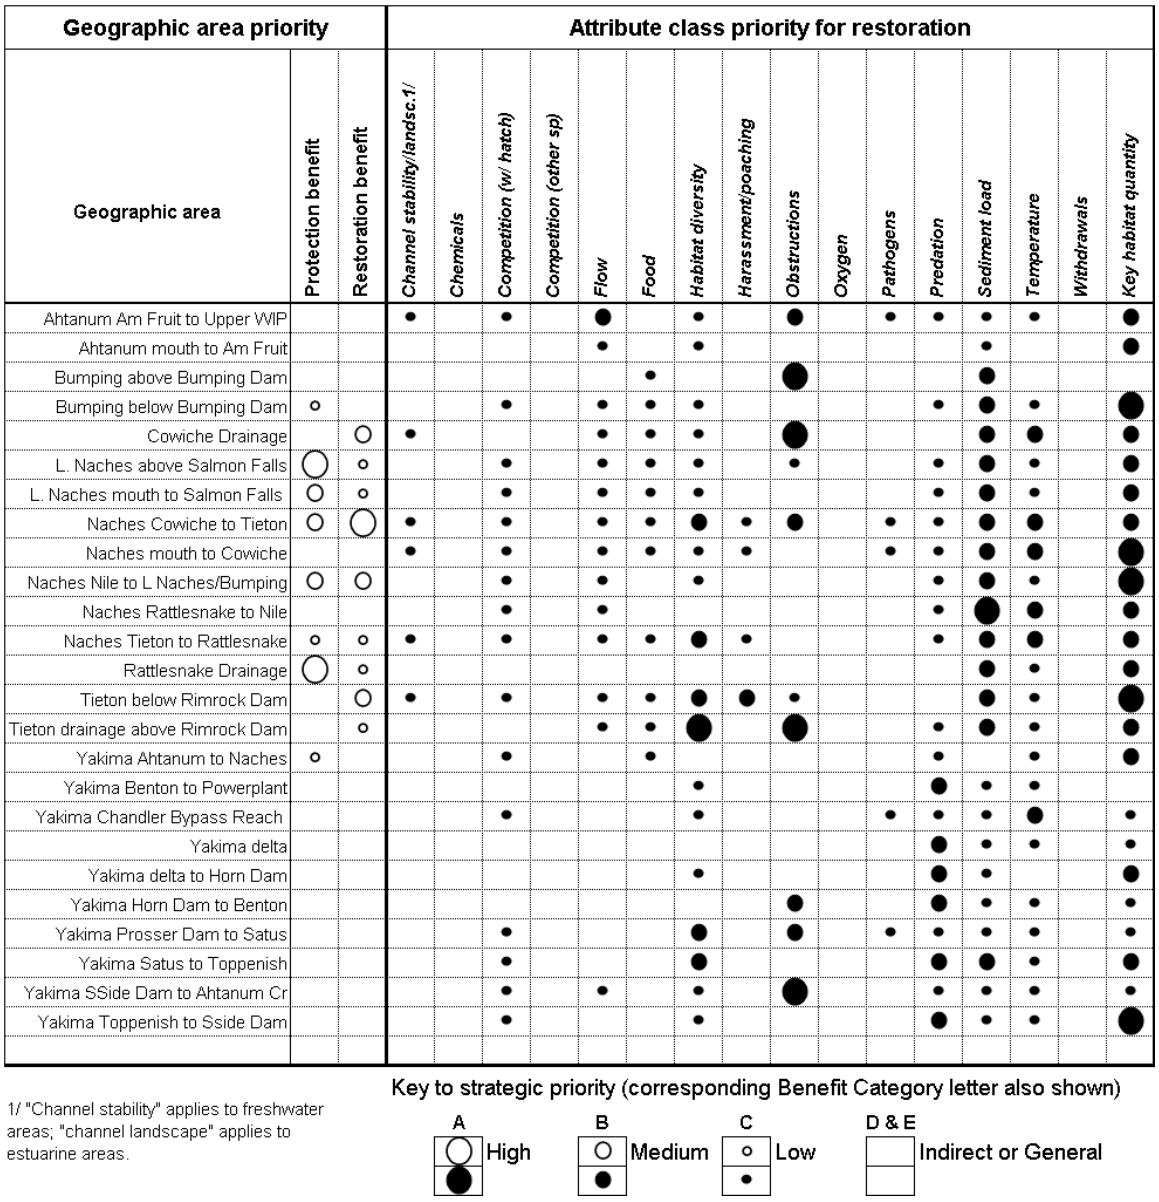
[43] Restoration Potential as referenced in EDT ladder diagrams is a comparison of Historical condition minus Current condition. In many instances it is not feasible to realize the full restoration potential.

Survival Factor. All other related level 2 attributes act as modifiers upon the level 3, which ultimately defines productivity, abundance and diversity index (Lestelle et al. 2004). In a nutshell, the level 3 correlates represent the biological response to the fluctuating environmental conditions through space and time. Negative impacts on survival are integrated across all life stages for each level 3 correlate. In a qualitative sense, the strategic summaries illustrate the severity of a level 3 attribute upon productivity. The large, medium and small dots in the diagram correspond to the three ranges of severity.

B.2.1 Naches River Steelhead

Table B.2 indicates the geographic areas with the greatest restoration potential for the Naches steelhead population. The table also shows the hypothesized potential gains in the performance parameters expressed as percentages increase with respect to current performance if one was to restore the geographic area back to pre settlement era conditions. Figure B.2 qualitatively illustrates the major level 3 correlates compounded across all life stages impacting survival in the specified geographic area.

The Cowiche to Tieton reach is the geographic area that would increase the Naches steelhead population performance the most (+112.1% for abundance) if fully restored to historic conditions. Historically this was the largest floodplain in the Naches arm of the basin. Both currently and historically this geographic area is important for steelhead spawning and, summer and winter rearing. Due to the location of this geographic area in the basin, Naches steelhead spend one or more of their life stages within, stressing the importance of this geographic area. Unfortunately, because of extensive build out and placement of Highway 12 within this floodplain there is limited opportunity to fully realize its historic potential.



The model indicates the diversity index could be twice that of current life history pathways if the Cowiche drainage was fully restored). There have been major passage issues near the mouth of Cowiche that have severely reduced the life history pathways, productivity and abundance of the Naches steelhead population. Other degradations have occurred in the Cowiche geographic area in the form of increased temperatures, flow, sediment loads and habitat simplification.

Table B.2 Restoration geographic areas for the Naches steelhead population

Naches Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area					
Naches Cowiche to Tieton	1	124.5%	72.9%	23.7%	112.1%
Cowiche Drainage	2	100.0%	37.1%	8.2%	57.8%
Tieton below Tieton Dam	3	75.3%	35.0%	11.8%	61.0%
Naches Nile to L Naches/Bumping	4	63.7%	36.4%	4.8%	52.2%
Naches Tieton to Rattlesnake	5	73.1%	28.7%	5.5%	45.3%
L. Naches above Salmon Falls	6	54.9%	28.8%	4.1%	43.5%
Tieton drainage above Tieton Dam	7	41.2%	24.4%	24.5%	65.9%
L. Naches mouth to Salmon Falls	8	65.1%	21.8%	6.3%	38.5%
Rattlesnake Drainage	9	47.6%	28.4%	3.7%	42.6%
Yakima Prosser Dam to Satus	10	55.3%	7.0%	17.3%	30.3%
Naches mouth to Cowiche	12	13.7%	17.7%	4.1%	30.7%

Sorted by the combined rank; geographic areas shown below represent 75% of the restoration potential with respect to abundance.

Figure B.2: Major reach-level limiting factors for the Naches population

B.2.2 Satus Creek Steelhead

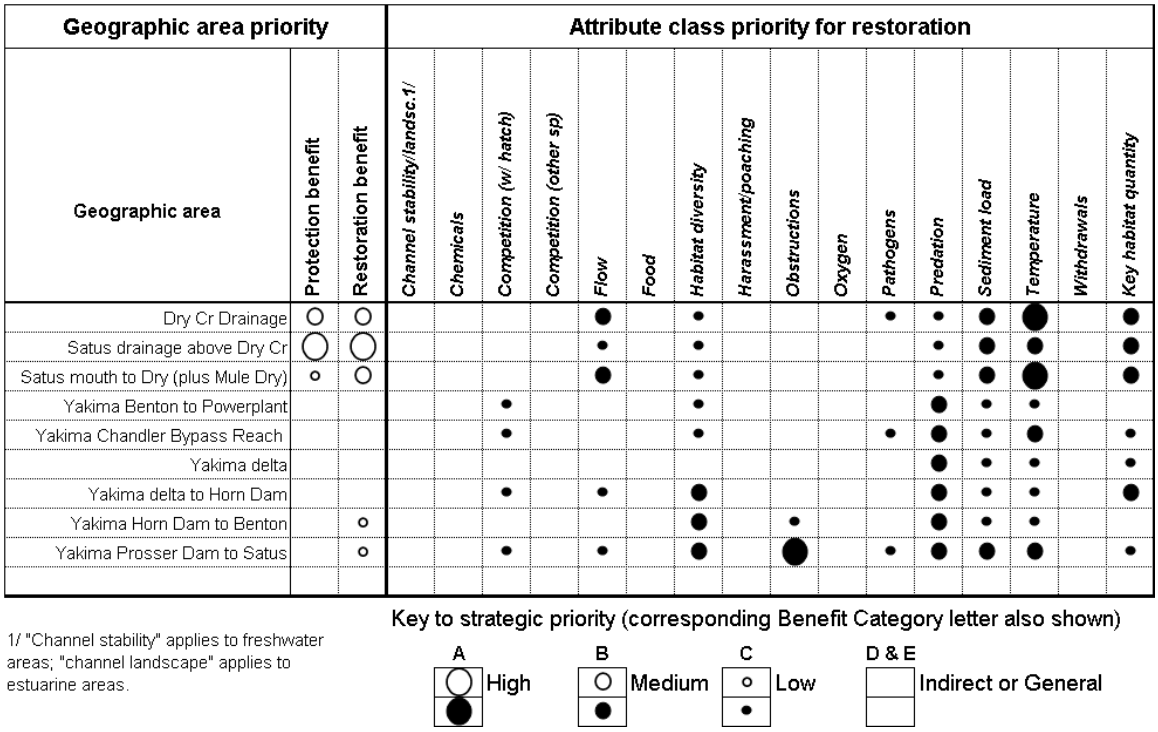


Table B.3 indicates the geographic areas with the greatest restoration potential for the Satus steelhead population. The table also shows the hypothesized potential gains in the performance parameters expressed as percentages increase with respect to current performance if one was to restore the geographic area back to pre settlement era conditions. Figure B.3 qualitatively illustrates the major level 3 correlates compounded across all life stages impacting survival in the specified geographic area.

Table B.3: Restoration geographic areas for the Satus steelhead population

Satus Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area					
Satus drainage above Dry Cr	1	30.6%	59.3%	30.2%	63.0%
Dry Cr Drainage	2	44.8%	21.7%	8.2%	21.2%
Satus mouth to Dry (and Mule Dry)	3	39.1%	14.8%	23.7%	34.4%
Yakima Prosser Dam to Satus	4	5.1%	11.5%	13.2%	21.1%

Sorted by the combined rank; geographic areas shown below represent 75% of the restoration potential with respect to abundance.

Figure B.3: Major reach-level limiting factors for the Satus Creek population

B.2.3 Toppenish Creek Steelhead

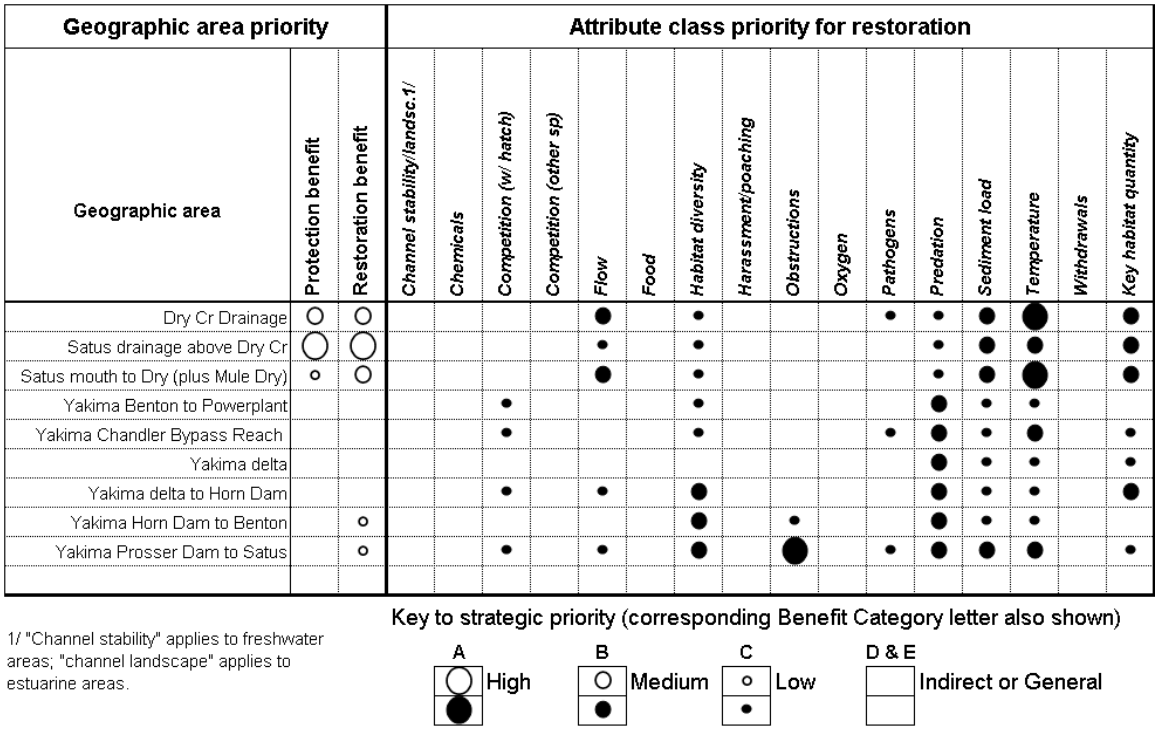

Table B.4 indicates the geographic areas with the greatest restoration potential for the Toppenish steelhead population. The table also shows the hypothesized potential gains in the performance parameters expressed as percentages increase with respect to current performance if one was to restore the geographic area back to pre settlement era conditions. Figure B.4 qualitatively illustrates the major level 3 correlates compounded across all life stages impacting survival in the specified geographic area.

Table B.4: Restoration geographic areas for the Toppenish steelhead population

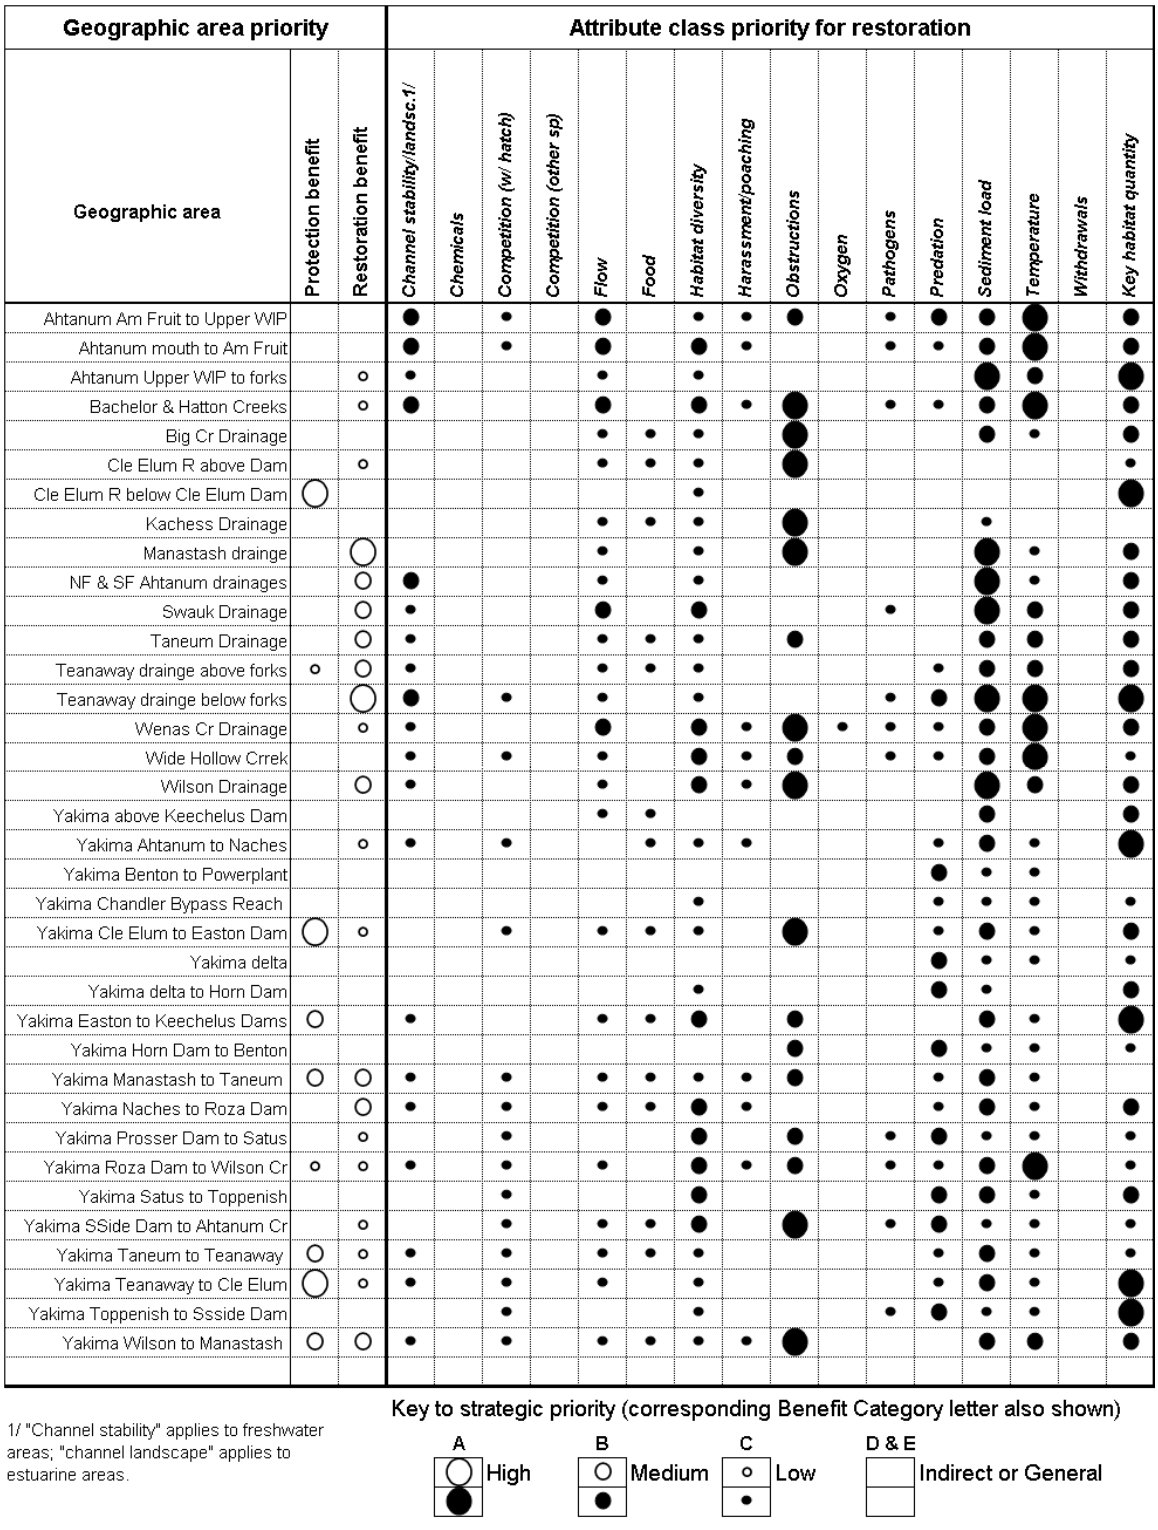
Toppenish Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area:					
Toppenish Unit II to Lateral Canal	1	147.1%	12.3%	34.6%	45.8%
Toppenish above Lateral Canal	2	29.5%	14.0%	21.1%	32.5%
Yakima Prosser Dam to Satus	3	14.6%	14.1%	17.9%	29.1%
Simcoe drainage above Agency	3	97.1%	11.0%	16.8%	25.6%
Topp. mouth to Unit II Diversion	4	96.1%	2.3%	21.5%	23.5%

Sorted by the combined rank; geographic areas shown below represent 75% of the restoration potential with respect to abundance.

Figure B.4: Major reach-level limiting factors for the Toppenish Creek population

B.2.4 Upper Yakima River Steelhead

Table B.5 indicates the geographic areas with the greatest restoration potential for the Upper Yakima steelhead population. The table also shows the hypothesized potential gains in the performance parameters expressed as percentages increase with respect to current performance if one was to restore the geographic area back to pre settlement era conditions. Figure B.5 qualitatively illustrates the major level 3 correlates compounded across all life stages impacting survival in the specified geographic area. Before discussing the results it should be stated that there is disparity between the EDT predicted steelhead equilibrium abundance for the upper Yakima population and what has been observed for the past 10 years based on Roza Dam fish counts. The EDT model does not currently have the capability to segregate population performance parameters between the resident and anadromous life history forms of *Oncorhynchus mykiss*; and the upper Yakima population is largely comprised of resident rainbow trout. Revision of the model to address this issue is currently under discussion.



The upper Yakima steelhead population incorporates the largest geographic area of any of the basin steelhead populations. Not surprisingly 10 of the 15 geographic areas define tributary type watersheds suggesting the historical importance of tributary contribution to the upper Yakima population. This is illustrated by the fact that top three geographic areas were all major tributaries–Manastash, Teanaway (below the forks) and the Wilson drainage (which comprises many small tributaries).

Table B.5: Restoration geographic areas for the Upper Yakima steelhead population

Upper Yakima Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area:					
Manastash drainage	1	72.1%	68.1%	20.6%	86.2%
Teanaway drainage below forks	2	47.7%	57.6%	17.5%	75.2%
Wilson Drainage	3	188.3%	26.4%	19.8%	53.4%
Yakima Manastash to Taneum	4	41.4%	34.8%	4.4%	40.7%
Teanaway drainage above forks	5	113.8%	24.1%	8.8%	37.2%
NF & SF Ahtanum drainages	5	69.4%	28.8%	2.9%	33.7%
Taneum Drainage	6	38.7%	35.1%	3.8%	40.0%
Yakima Wilson to Manastash	7	40.5%	31.6%	4.1%	37.6%
Yakima Naches to Roza Dam	8	27.3%	30.5%	4.6%	37.5%
Swauk Drainage	8	43.5%	24.4%	3.3%	30.5%
Wenas Cr Drainage	9	54.7%	19.0%	7.0%	29.9%
Cle Elum R above Dam	10	36.9%	14.1%	23.4%	43.8%
Yakima Prosser Dam to Satus	12	47.1%	7.7%	17.6%	28.9%
Yakima Ahtanum to Naches	13	16.2%	22.8%	5.6%	31.9%
Ahtanum Upper WIP to forks	15	6.0%	25.6%	1.9%	29.7%

Sorted by the combined rank; geographic areas shown below represent 75% of the restoration potential with respect to abundance.

Figure B.5: Major reach-level limiting factors for the Upper Yakima population

1/ "Channel stability" applies to freshwater areas; "channel landscape" applies to estuarine areas.

B.2.5 Integration of Restoration Priorities Across Populations

Table B.2, Table B.3, Table B.4, and Table B.5 have presented the geographic areas with the greatest potential for restoring the components of performance for the defined populations. The geographic areas listed for each population also represent 75% of the restoration potential in terms of restoring the population's abundance to near historic levels. When viewing these Geographic areas by population with the strategic summaries (Figure B.2, Figure B.3, Figure B.4, and Figure B.5), together they illustrate the "where" and "what" components of restoration specific to individual populations. However, if we want to take a coarsened scale view of the overall benefits for multiple species in terms of restoration, we must integrate overlapping geographic areas across species and populations. This allows identifying the geographic areas that provide the "biggest bang for your buck." Geographic areas totaling 75% of the abundance restoration potential were considered priority areas for each population and were counted across populations of modeled species where overlap occurred. Results from this exercise are presented in. The model indicates restoration actions in the top 13 geographic areas would benefit nearly all anadromous species currently modeled in the basin. Further more, restoration actions within the top six geographic areas listed would improve performance of multiple populations and species. A word of caution, geographic areas in the table below represent areas of significance for a population that also overlap across multiple species and populations, there are other geographic areas not included in Table B.6 with significant restoration potential for individual species or populations.

Table B.6: Summation of individual geographic areas across steelhead populations

Numbers under the species indicate the number of populations benefiting from restoration actions in the listed geographic area. Where only one steelhead population is shown as benefiting, geographic areas are ranked in descending order according to the additional number of populations of other species shown as benefiting in Appendix M of the Yakima Subbasin Plan.

No.	Geographic Area	Steelhead
1	Yakima Prosser Dam to Satus Cr	4
2	Naches Cowiche Cr to Tieton R	1
3	Naches Tieton R to Rattlesnake Cr	1
4	Yakima Ahtanum Cr to Naches R	1
5	Naches Nile Cr to Little Naches/Bumping Confl.	1
6	Teanaway R below forks	1
7	Yakima Naches R to Roza Dam	1
8	Yakima Manastash Cr to Taneum Cr	1
9	Yakima Wilson Cr to Manastash Cr	1
10	Tieton drainage above Tieton Dam	1
11	Tieton R below Tieton Dam	1
12	Naches mouth to Cowiche Cr	1
13	Cle Elum drainage above Cle Elum Dam	1
14	Teanaway drainage above forks	1
15	Little Naches R mouth to Salmon Falls	1
16	Wilson Drainage	1
17	Cowiche Drainage	1
18	Rattlesnake Drainage	1

B.3 Preservation Potential for Individual Populations

Table B.7, Table B.8, Table B.9, and Table B.10 present the geographical areas where degradation of current habitat conditions of individual populations would have the most negative affects on modeled population characteristics. These areas should be priorities areas for efforts to protect existing habitat conditions. Geographic areas listed comprise 75% of the preservation potential with respect to abundance. The percentages should be interpreted as potential decreases in current performance of the designated population if the physical and biological environment was severely degraded. Thus, areas with high percentages should be considered priority areas for preservation. Also, the combined rank next to a geographic area considers losses endured by all performance parameters and is computed by the sum of individual ranks for each parameter.

B.3.1 Naches Steelhead

Table B.7 summarizes the high priority geographic areas for preservation potential as it applies to the Naches steelhead population. The table also shows the hypothesized potential losses in the performance parameters expressed as percentages decrease in the current performance of the population. Due to the quality of spawning/rearing habitat in the Little Naches above Salmon Falls and the Rattlesnake drainage, the model indicates these as the primary Geographic areas for preservation.

Table B.7: Geographic preservation priorities for the Naches population

Geographic areas are sorted by the combined preservation rank of performance parameters.

Naches Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area:					
L. Naches above Salmon Falls	1	-36.7%	-29.9%	-9.1%	-74.8%
Rattlesnake Drainage	1	-28.8%	-33.0%	-9.4%	-85.2%
Naches Nile to L Naches/Bumping	2	-30.0%	-20.5%	-8.5%	-48.6%
Naches Cowiche to Tieton	3	-25.1%	-13.0%	-14.0%	-35.8%
L. Naches mouth to Salmon Falls	4	-17.8%	-14.0%	-6.7%	-32.5%

B.3.2 Satus Steelhead

Table B.8 summarizes the high priority geographic areas for preservation potential as it applies to the Satus Creek steelhead population. Table B.8 also shows the hypothesized potential losses in the performance parameters expressed as percentages decrease in the current performance of the population. The model indicates degradation within the physical and biological environment of the Satus Drainage above Dry Creek would result in the loss of 80% life history pathways and 100% abundance. This is a rather large

geographic area with a high proportion of Satus Creek steelhead spawning within, explaining the consequences of degradation of this reach.

Table B.8: Geographic preservation priorities for the Satus Creek population

Geographic areas are sorted by the combined preservation rank of performance parameters.

Satus Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area:					
Satus drainage above Dry Cr	1	-80.0%	-77.2%	-45.5%	-100.0%
Dry Cr Drainage	2	-14.7%	-20.4%	-17.2%	-31.5%
Satus mouth to Dry (plus Mule-Dry)	3	-29.0%	-14.7%	-18.8%	-28.3%

B.3.3 Toppenish Steelhead

Table B.9 summarizes the high priority geographic areas for preservation potential as it applies to the Toppenish steelhead population. The table also shows the hypothesized potential losses in the performance parameters expressed as percentages decrease in the current performance of the population. The model indicates degradation within the physical and biological environment of Toppenish Creek above Lateral Canal would result in the loss of 88.6% life history pathways and 100% abundance. This is a rather large geographic area with a high proportion of Toppenish Creek steelhead spawning within, explaining the consequences of degradation of this reach.

Table B.9: Geographic preservation priorities for the Toppenish population

Geographic areas are sorted by the combined preservation rank of performance parameters.

Toppenish Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area:					
Toppenish above Lateral Canal	1	-88.6%	-96.2%	-47.9%	-100.0%
Simcoe drainage above Agency	2	-5.8%	-0.7%	-10.2%	-10.7%

B.3.4 Upper Yakima Steelhead

Table B.10 summarizes the high priority geographic areas for preservation potential as it applies to the Upper Yakima steelhead population. The table also shows the hypothesized potential losses in the performance parameters expressed as percentages decrease in the current performance of the population. The top three preservation geographic areas incorporate the Yakima mainstem upstream of the Teanaway River to Easton Dam and the Cle Elum River downstream of the dam to the confluence to the Yakima River. These

three geographic areas rank high because of their vast size, the quality of habitat relative to other geographic areas and the extended period time steelhead reside in these three geographic areas (i.e., spawning through smoltification).

Table B.10: Geographic preservation priorities for the Upper Yakima population

Geographic areas are sorted by the combined preservation rank of performance parameters.

Upper Yakima Steelhead	Combined Rank	Diversity Index	Productivity	Capacity	Abundance
Geographic Area:					
Cle Elum R below Cle Elum Dam	1	-18.6%	-27.5%	-0.2%	-51.0%
Yakima Teanaway to Cle Elum	1	-32.1%	-23.5%	-2.6%	-42.9%
Yakima Cle Elum to Easton Dam	2	-35.1%	-22.9%	-3.5%	-42.0%
Yakima Taneum to Teanaway	3	-27.0%	-15.4%	-2.0%	-25.9%
Yakima Easton to Keechelus dams	4	-15.0%	-12.8%	-1.5%	-21.0%
Yakima Manastash to Taneum	5	-12.9%	-9.8%	-8.3%	-21.8%
Yakima Wilson to Manastash	6	-11.1%	-11.0%	-4.1%	-20.1%
Yakima Roza Dam to Wilson Cr	7	-5.4%	-5.0%	-5.6%	-12.2%
Teanaway drainage above forks	8	-3.0%	-4.5%	-9.1%	-14.8%

B.4 Use of EDT to Model Restoration Scenarios

Currently the best data available for making a quantitative assessment of the response of Yakima Basin steelhead populations to restoration activities comes from two restoration scenarios developed using the EDT model. The first was developed for the Yakima Subbasin Plan in 2004-5. The second is a more intensive restoration scenario developed by modeling restoring habitat to a level that provides 50% of Proper Functioning Condition in the EDT model.[44] The Yakima Basin Fish & Wildlife Recovery Board is working with NOAA Fisheries to integrate the results of these restoration scenario into an All-H Analyzer model that assess population responses to recovery actions in the mainstem Columbia, its estuary, and the Pacific Ocean. This work is detailed in Chapter 8 of the Middle Columbia River Steelhead Recovery Plan currently being developed by

[44] The 50% of PFC model for steelhead has been developed by the Columbia Basin Fish & Wildlife Authority and will be published as part of their 2008 proposals for amendments to the NPCC Fish and Wildlife Program.

NOAA Fisheries. The Board is also investigating the possibility of conducting additional analysis using update EDT data and more detailed modeling of specific recovery actions.

For the restoration scenario developed for the Yakima Subbasin Plan, the Aquatic Technical Committee developed a restoration scenario that characterized how habitat variables would respond to fish habitat restoration efforts, and then used the EDT model to estimate how anadromous fish populations would respond. For those attributes that could be characterized in the EDT model, and were considered major limiting factors to productivity, the technical committee estimated how much they thought a given attribute could be improved over the next 30 years (roughly the time for riparian vegetation to mature if planted) given the current conditions in the subbasin, and an unlimited budget, and using existing protection or restoration techniques such as riparian zone planting, purchase of water rights, levee relocation, etc. For example, in the Upper Yakima it was not thought likely that a massive relocation of Interstate 90 was going to occur, so confinement (a major limiting factor in the upper Yakima) was rated to remain nearly the same, while in the Union Gap reach, it could conceivably improve by over 40% without relocating the freeway or the Cities of Yakima or Union Gap. In a few cases, such as reaches located in Urban Growth Areas or other rapidly developing areas with still good habitat, some slight decreases in habitat quality were also entered into the model. Specific assumptions made in developing the restoration scenario include:

1) Anadromous fish passage is made available at Bumping and Cle Elum dams, but not Tieton, Keechelus or Kachess dams;

2) Full passage is restored at all other existing passage barriers;

3) Based on the Aquatic Technical Committee's assessment of what was likely to be feasible, the model run reflects only a 10 to 15% improvement in flow conditions in the lower Naches (i.e., below the confluence with the Tieton) and lower Yakima (below Wapato Dam), which would still leave them at only an estimated 20 to 30% of unregulated averages.

4) Improvements did not cascade. In the real world, improvements in one attribute could be expected to have secondary effects on other attributes, or "cascade" through the ecosystem. Within the model, changes were made to the selected attributes only, and other attributes were held constant for the model run. This means that the Restoration reference condition is very conservative in regards to estimated productivity, abundance and diversity.

5) The model was based on existing defined populations; new spawning reaches in newly opened habitat, or entirely new populations were not defined for the restoration scenario.

The process of developing the restoration scenario and the specific adjustments to habitat parameters are described in detail in Appendix O of the Yakima Subbasin Plan (2005). In early 2008, the Subbasin plan scenario was adjusted to ensure that baseline and restored out of basin conditions were constant (this required lowering the ocean survival rates in the restoration scenario so that they matched those in the baseline scenario). Anticipated improvements in Columbia River habitat, hatchery and harvest conditions and variability

in ocean conditions will be captured in the AHA modeling process currently being conducted by NOAA Fisheries. A second adjustment was made to redraw population area boundaries to match those used in this plan; this primarily affected the Naches population, which incorporates tributary and mainstem areas that were modeled separately in 2005. The 2005 EDT-based estimates of resulting population parameters are shown in Table B.11; Table B.12 shows the 2008 adjusted version. Compared to other modeled salmon species, steelhead respond well to restoration. All existing populations are modeled to improve substantially, and population levels are well above minimum thresholds for viability. The current abundance estimates in Table B.11 differs slightly from the current levels in Table B.1 due to the use of slightly different population delineations; both tables will be updated based on a new model run based on the ICTRT population delineations that is under development. The updated model run results will be incorporated into this document once available, but significant change in the modeled response of steelhead populations to the restoration scenario is not expected.

Table B.11: EDT Subbasin restoration summary as developed in 2005

Population	Scenario	Diversity index	Productivity	Capacity	Abundance
Satus Steelhead	Current without harvest	37%	2.4	1,516	894
	Current with harvest	37%	2.4	1,516	894
	Restored Conditions	49%	5.2	3,379	2,733
Toppenish Steelhead	Current without harvest	13%	2.5	866	513
	Current with harvest	13%	2.5	866	513
	Restored Conditions	37%	4.9	2,238	1,784
Naches Steelhead	Current without harvest	11%	1.6	2,348	920
	Current with harvest	11%	1.6	2,348	920
	Reference Conditions	60%	2.9	7,563	4,911
Upper Yakima Steelhead	Current without harvest	6%	1.9	3,177	1,479
	Current with harvest	6%	1.9	3,177	1,479
	Restored Conditions	33%	2.9	9,931	6,553

Table B.12: EDT 2005 Subbasin restoration summary as adjusted in 2008

Population	Scenario	Diversity index	Productivity	Capacity	Abundance
Satus Steelhead	Current without harvest	37%	2.4	1,472	861
	Current with harvest	37%	2.4	1,472	861
	Restored Conditions	44%	2.6	1,551	961
Toppenish Steelhead	Current without harvest	12%	2.4	860	505
	Current with harvest	12%	2.4	860	505
	Restored Conditions	20%	2.6	978	609
Naches Steelhead	Current without harvest	27%	2.6	3,192	1,977
	Current with harvest	27%	2.6	3,192	1,977
	Reference Conditions	33%	3.0	3,710	2,472
Upper Yakima Steelhead	Current without harvest	15%	2.6	1,809	1,114
	Current with harvest	15%	2.6	1,809	1,114
	Restored Conditions	27%	2.6	3,131	1,947

APPENDIX C: RECOVERY PROGRAMS OVERVIEW

C.1 Introduction

Fisheries restoration efforts in the Yakima Basin have a long history. Numerous federal, state and local programs have been established over the last 25 years. As noted in Chapter 6, this plan emphasizes implementing recovery actions through established programs and partnerships wherever possible. This appendix gives a brief overview of some of the most relevant programs. For more information, see the Yakima Subbasin Plan.

C.2 NPCC/BPA Programs

The federal Northwest Power Act of 1982 created the Northwest Power and Conservation Council and tasked it with overseeing a fish and wildlife program that is funded by BPA and mitigates for the effects of the Federal Columbia River Power System. The Council/BPA program has been the primary source of funding for fish restoration efforts in the Yakima Basin over the last 25 years, and is likely to continue to be so into the future. Table C.1 lists projects in the Yakima Basin that are currently funded by BPA.

Table C.1: BPA-funded programs in the Yakima Basin

Project #	Project Title	Sponsor	Current FY07 to 09
198812025	YKFP Management, Data, Habitat	Yakama Nation	$454,000*
199200900	Yakima Phase II/Huntsville Screen Operation & Maintenance	WDFW	$484,500
199206200	Yakama Nation - Riparian/Wetlands Restoration	Yakama Nation	$2,275,000
199405900	Yakima Basin Environmental Education Program	Eco-Northwest	$100,000*
199503300	O&M Yakima Basin Fish Screens	BOR	$273,600
199506325	Yakima Klickitat Fisheries Project - Monitoring And Evaluation	Yakama Nation & WDFW	$12,300,753
199506425	YKFP Policy/Plan/Technical	WDFW	$540,000
199603501	Yakama Reservation Watersheds Project	Yakama Nation	$1,016,457*
199701325	Yakima/Klickitat Fisheries Project Operations and Maintenance	Yakama Nation	$7,999,998
199705100	Yakima Basin Side Channels	Yakama Nation	$1,500,000
200201400	Sunnyside Wildlife Mitigation	WDFW	$634,255
200202501	Yakima Tributary Access & Habitat Program	South Central Washington RC&D	$365,178
Capital	*Yakima Tributary Access & Habitat Program*	South Central Washington RC&D	*$2165178*
Capital	*Manastash Creek Passage & Screening*	*Kittitas County Conservation District*	*$2327432*
200600400	Wenas Wildlife Area O&M	WDFW	$868,720
200702000	Manastash Instream Flow Enhancement	Kittitas County Conservation	$892,998
200711200	Teanaway Watershed Protection & Enhancement	Kittitas Conservation Trust	$1,020,000
200711300	Cowiche Restoration and Protection Project	WDFW	$300,000
200719400	Oak Flats Acquisition and Habitat Enhancement	WDFW	$550,000
		Totals	***36,068,069***

***FY 2007 funding commitment only**

BPA is currently making commitments to additional funding for tributary habitat improvements as part of negotiating an ESA Biological Opinion for the Columbia River Power system, and it is likely that at least some of this funding will be used in the Yakima Basin to improve steelhead habitat.

Selected BPA-funded projects with strong ties to steelhead recovery are described below.

C.2.1 The Yakima/Klickitat Fisheries Project

The Yakima Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation Fisheries Program and WDFW that is funded via four separate contracts with BPA. It is the largest fish management program in the basin. Its goals are to:

- Enhance existing stocks of anadromous fish in the Yakima and Klickitat river basins while maintaining genetic resources and minimizing negative ecological interactions with wild populations.
- Reintroduce stocks formerly present in the basins.
- Apply knowledge gained about hatchery supplementation throughout the Columbia River Basin.

The YKFP program runs supplementation hatchery programs for spring and fall Chinook and coho salmon. Opportunities to reintroduce extirpated summer Chinook and sockeye runs are being evaluated. The YKFP program also undertakes extensive research and monitoring to understand factors affecting target populations, and to evaluate the effects of supplementation activities on other components of the ecosystem. The program maintains 15 different fish production and research facilities in the basin and employees approximately eighty people, including managers, scientists, technicians, fish culturists, laborers and office support personnel. It also supports efforts to improve, restore, and protect fish habitat in the basin, and to influence policies related to fish management in the Yakima Basin. The YKFP program is the primary source and steward of fish related data in the basin, and maintains the EDT model used to evaluate the historic, current and potential future conditions of fish habitat within the Yakima Subbasin.

YKFP activities focused on steelhead include the kelt reconditioning program at the Prosser hatchery, research into the genetics of Yakima Basin steelhead, and monitoring of steelhead adults, juveniles and smolts. The fish counting facilities at Roza and Prosser dams are operated by YKFP. The YKFP program is currently developing a steelhead master plan; this process will be coordinated with ongoing recovery planning and implementation, and will identify possible supplementation actions.

C.2.2 Yakima Tributary Access and Habitat Program

The listing of Middle Columbia River Steelhead focused the attention of both landowners and regulatory agencies on the numerous unscreened irrigation diversions and passage barriers in Yakima and Kittitas counties. In response, local organizations, including the South Central RC & D, the Kittitas County and North Yakima Conservation Districts, WDFW, the Yakima Nation and others, partnered to apply for BPA funding for the Yakima Tributary Access & Habitat Program (YTAHP). This program has funded assessments of tributary passage, screening and habitat conditions, and subsequent on-the-ground projects to screen irrigation diversions, remove fish passage barriers and improve riparian habitat conditions. From 2002 to 2008, YTAHP and its partners screened 87 cfs of irrigation water, removed 21 passage barriers to access over 45 miles

of habitat, trusted 4.5 cfs of water to instream use, planted 4.95 miles of stream bank, and used YTHAP funded staff and resources to leverage over $7.6 million in total project funding.

C.2.3 Yakima Side Channels Program

This project has funded acquisition and restoration of side channel and floodplain habitats in alluvial reaches of the Yakima and Naches rivers.

C.2.4 Yakama Reservation Watersheds Project

This project focuses on restoration of anadromous fish bearing streams on the Yakima Reservation. It has funded habitat protection and enhancement in Satus Creek, flow improvements, obstruction removal, and screening in Toppenish Creek, and flow restoration and riparian/floodplain protection on Ahtanum Creek. Redd surveys, smolt trapping and other monitoring are conducted in all three areas. This project has been the main source of funding for restoration actions for the Satus and Toppenish steelhead populations.

C.2.5 Manastash Creek Passage/Screening/Flow Projects

These two projects focus on removing passage barriers and improving instream flows in the lower section of Manastash Creek, which has been inaccessible to steelhead for more than a century. Restoring access to Manastash Creek is a high priority action for the Upper Yakima steelhead population.

C.2.6 Teanaway Watershed Protection and Enhancement

This project focuses on protecting and restoring the floodplains and riparian areas of the Teanaway River, which is one of the main areas currently used by steelhead in the Upper Yakima population area.

C.3 U.S. Bureau of Reclamation Programs

C.3.1 System Operations

The Yakima Field Office (YFO) Manager, in consultation with numerous entities, determines how the BOR's Yakima Project storage reservoirs and diversions are operated. In 1980, the Quackenbush decision required Reclamation to incorporate fish concerns into its management of the Yakima Project. The System Operations Advisory Committee (SOAC) was formed by the Yakima Field Office Manager in response to the supplemental instructions entitled 'Supplementary Instructions to the Water Master' November 28, 1980, in the case of Kittitas Reclamation District, et al. vs. the Sunnyside Valley Irrigation District, et al. SOAC is comprised of fish biologists representing the USFWS, the Yakama Nation, WDFW, and water users represented by the Yakima Basin Joint Board. SOAC and others provide input to the YFO Manager on operations of the Yakima Project for fish and wildlife purposes. The group worked with Reclamation to

develop the flip-flop concept. Phase 2 of the Yakima enhancement legislation (see below) in 1994 directed SOAC to develop a report on biologically based flow needs for fish in the basin. The completed report lists recommendations for studies, models, etc. that may in turn result in biological flow recommendations.

C.3.2 Yakima River Basin Water Enhancement Project

Public Law 103-434, Title XII, Yakima River Basin Water Enhancement Project (YRBWEP) was authorized by Congress in 1994. It is a multi-faceted program intended to promote water conservation, improve the reliability of the water supply for irrigation and protect, mitigate and enhance the fish and wildlife resources of the Yakima River Basin. The legislation authorizes Reclamation to work with partners to plan and implement water conservation measures throughout the Yakima River Basin, and to acquire land and water from willing sellers or lessors to improve instream flow conditions. For conservation projects, two-thirds of the conserved water is dedicated to improving instream flows. Key partners include the WDOE, the Yakama Nation, BPA, Natural Resources Conservation Service and irrigation districts. The Conservation Advisory Group (CAG) provides recommendations to the YFO Manager regarding the structure and implementation of the Basin Conservation Program. Funding for YRBWEP is dependant on Congressional appropriations. Examples of projects completed via YRBWEP include:

1) Purchase of the Wapatox Power Plant, which allows 260,000 acre-feet of water previous diverted out of the lower Naches River for power production to be left instream in an 8-mile long stretch of critical habitat

2) Work with irrigators, BPA and the Yakama Nation to increase instream flows in the Teanaway River by designing and installing two pumping plants and pipelines that increase irrigation efficiencies and divert water three miles below the original diversions

3) Sunnyside Valley Irrigation District’s construction of three reregulation reservoirs and numerous check structures. Close to 100 cfs of conserved water will be used to enhance instream flows in the Wapato reach, the most severely dewatered mainstem reach in the subbasin

4) Purchase of floodplain habitat on Taneum Creek and the Yakima River near Ellensburg

5) Purchase of lands in the Gap-to-Gap reach in the Yakima area. Approximately 600 acres of land purchased are now in various stages of being converted from agricultural or grazing lands to native grass stands

Current YRBWEP priorities include:

1) Continued cooperative work with numerous entities to set back levees and restore natural floodplain habitat and function in the Gap to Gap reach and other key sites

2) Efforts with the Yakama Nation and the Bureau of Indian Affairs to improve the efficiency of the Wapato Irrigation Project and restore the Toppenish Creek floodplain

3) Proposal to move the point of diversion for the Benton Irrigation District downstream. This would result in an additional 58 cfs remaining in the river for a 72 mile reach

4) Proposal to add a diversion at Kiona for the Kennewick Irrigation District. This would reduce the amount of water diverted at Chandler and leave additional water in the reach from Chandler to Kiona

5) Phase II irrigation efficiency improvements by the Sunnyside Irrigation District, such as piping laterals

6) Future conservation projects with other irrigation districts such as Naches-Selah and Roza, and others

C.3.3 Yakima River Basin Water Storage Options Feasibility Study

The BOR and the state Department of Ecology are conducting a joint study of the feasibility of augmenting water supplies in the Yakima River Basin through construction of additional storage reservoirs, including the possibility of using of Columbia River water in the Yakima Basin. The goals of the proposals reviewed in the study are to: 1) improve flow conditions for anadromous fish, 2) provide a more reliable water supply for existing irrigators, and 3) provide additional water supply for future municipal demands. The study will be completed in 2008, and will detail the feasibility and costs and benefits of the:

1) Black Rock Reservoir proposal, which involves pumping water from the Columbia River into the proposed Black Rock Reservoir for subsequent use on the Roza and Sunnyside Irrigation Districts

2) Wymer Reservoir proposal, which involves a smaller reservoir which would be filled by pumping from the Yakima River during higher flow periods and by the winter release of Cle Elum Reservoir irrigation water.

3) Wymer proposal, as above, plus a pipeline that would pump water from the Columbia River to the Roza and Sunnyside Irrigation Districts.

Models and analyses developed as part of the storage study will increase our understanding of the relationship between flows, habitat characteristics such as sediment transport, water temperature and floodplain complexity, and fish production. These products will inform several key recovery actions identified in this plan.

The WDOE is conducting a parallel study of non-storage alternatives for increasing water availability, including: 1) enhanced water conservation, 2) market-based reallocation of water resources, and 3) groundwater storage.

C.3.4 Storage Dam Fish Passage Feasibility Study

The BOR is working with the Yakama Nation, WDFW, USFWS, NOAA Fisheries and others to determine the feasibility of providing fish passage at the five Yakima Project storage dams (Tieton, Bumping, Kachess, Keechelus, and Cle Elum dams). Four of the five reservoirs were originally natural lakes and historically supported sockeye salmon and other anadromous and resident fish. When the dams were built to enlarge (or in the case of Tieton Dam, create) the lakes in the early 20th century, no fish passage facilities were provided. Providing fish passage at these dams has the potential to increase the distribution and abundance of steelhead, coho salmon, and Chinook salmon, allow for reintroduce of sockeye salmon to the basin, and reconnect isolated populations of bull trout. Reclamation began detailed studies to evaluate the feasibility of providing passage at the dams in 2004. Current feasibility-grade investigations are focusing on the engineering, operational, and biological parameters needed to provide fish passage at Cle Elum and Bumping Lake dams. Evaluation of passage opportunities at the other three dams will follow. The feasibility report on Cle Elum and Bumping Lake dams is scheduled for completion in 2008.

C.4 US Forest Service Restoration Programs

The Cle Elum and Naches Ranger Districts of the Wenatchee National Forest encompass significant portions of the Upper Yakima and Naches population areas. Since 2002, both Districts have implemented the Respect the River education and restoration program, with each District expending at least $10-50,000 per year on education and on-the-ground restoration of recreation-impacted stream reaches. Cost-share partners in these projects include RCO, USFWS, Plum Creek, RIDGE, Mid-Columbia Fisheries Enhancement Group, Conservation Northwest, and the Forest Service’s Challenge Cost Share Program and Rural Development Act Title II funds. The USFS has also been actively removing known fish-passage barriers, improving riparian grazing management on Forest Service allotments, and reducing risk of landscape-scale fire.

C.5 Washington State Fish Recovery Programs

C.5.1 Regional Fisheries Enhancement Groups

Mid-Columbia Fisheries Enhancement Group is one of 14 Regional Fisheries Enhancement Groups (RFEGs) in Washington State. The RFEG program was created by the state legislature in 1990 to involve local communities, citizen volunteers, and landowners in the salmon enhancement. Since that time, the groups have become important partners in the state's salmon recovery efforts. The groups receive base funding from a surcharge on sport and commercial fishing license fees, through an account administered by the Washington Department of Fish & Wildlife.

The Mid-Columbia Fisheries Enhancement Group’s region covers south central Washington and includes all of the Yakima Basin. MCFEG is a non-profit organization dedicated restoring self-sustaining salmonid populations through habitat preservation,

restoration and education projects, which assist landowners and promote community partnerships. A volunteer board of directors runs the group. Mid-Columbia Fisheries Enhancement Group supplements their base funding with grants, volunteer efforts, and community donations to promote, support, and sponsor fish habitat restoration and enhancement projects and watershed education programs.

C.5.2 Salmon Recovery Funding Board Programs

After the listing of Columbia River and Puget Sound stocks under the Endangered Species Act, the governor and legislature of Washington State passed the Salmon Recovery Act of 1998. This created the statewide Salmon Recovery Funding Board (SRFB) and tasked it with funding habitat improvement projects with state appropriations and Washington's portion of the federal Pacific Coastal Salmon Recovery Fund administered by NOAA Fisheries. Washington's Recreation and Conservation Office administers the SRFB and its funding programs. The Salmon Recovery Act also called for creation of Lead Entities, which are local organizations that work at a watershed scale to prioritize and propose projects for SRFB funding. Lead Entities operate with technical and financial support from WDFW. The Yakima Basin Fish & Wildlife Recovery Board is under contract with WDFW to act as the Lead Entity for the Yakima Basin. From 1999 to 2006, the Yakima River Basin Salmon Recovery Board, which was administered by the city of Selah, served as the Lead Entity.

Each year, the Lead Entity solicits SRFB proposals from potential project sponsors in the basin, convenes technical and citizen's committees to review and prioritize the proposals, and submits a list of recommended projects to the SRFB. Priorities are guided by the Yakima Watershed Salmon Recovery Strategy, and, since 2006, the Yakima Subbasin Salmon Recovery Plan. Between 1999 and 2007, the SRFB has provided a total of $8.5 million for 44 fish habitat projects in the Yakima Basin. These include acquisitions of key fish habitat, projects to improve fish passage at road crossings and irrigation diversions, and projects that improve riparian and floodplain function. More information is available on the Board's webpage.

C.5.3 Regional Salmon Recovery Organizations

As part of Washington's Strategy for Salmon Recovery, the State has encouraged the formation of local boards that are recognized by the state as "regional salmon recovery organizations." The state has contracted with these boards to develop regional salmon recovery plans that form the basin for federal Endangered Species Act recovery plans for salmonids in Washington. The state has provided technical and logistical support via the Governor's Salmon Recovery Office. The Yakima Subbasin Fish and Wildlife Planning Board (YSPB) was created in 2002, in response to requests from the Northwest Power and Conservation Council and the Washington Governor's Salmon Recovery Office. It drafted the Yakima Subbasin Plan under contract with BPA, and developed the initial 2005 draft of this plan with funding from the State of Washington, as described in Chapter 1. In April 2006, this Board and the Yakima Lead Entity were merged to form the Yakima Basin Fish & Wildlife Recovery Board, which was recognized as the regional salmon recovery organization for the Yakima Basin and took on responsibility for

completion of the Yakima Subbasin Salmon Recovery Plan. It is under contract with the state to complete the plan and coordinate its implementation in the Yakima Basin, as described in Chapter 6.

C.5.4 Ahtanum Creek Watershed Restoration Program

The Washington State Department of Ecology is facilitating development of a watershed restoration program for the Ahtanum Creek watershed. The objectives of the program are to:

- Develop water management strategies to improve water availability for agricultural and other out-of-stream uses in the Ahtanum Creek Watershed and provide a net benefit to the watershed aquatic ecosystem (such as fish, wildlife, plants, and habitat).
- Develop land use protection and restoration strategies to preserve and enhance Ahtanum Creek floodplain and habitat value, as well as the stability and longevity of the agricultural land uses and economy within the Ahtanum Creek Watershed.

A major action that is being considered in the Restoration Program is the Pine Hollow Reservoir, which would improve both irrigation water supplies and instream flows. The program is also developing a comprehensive list of fish habitat enhancement activities for the watershed. The program is described in detail in it Environmental Impact Statement (EIS).

C.6 Washington Department of Ecology Water Quality Programs

In accordance with Section 303(d) of the Clean Water Act, every two years the state must identify its polluted water bodies and the type of pollution contaminating them and submit this list to EPA. In 2000, the state listed over 50 sections of streams and rivers in the Yakima Subbasin as impaired. The WDOE has initiated or completed Total Maximum Daily Load (TMDL) plans for the Granger Drain (sediment), the Teanaway River (temperature), the Lower Yakima River (sediment), the Upper Yakima River (sediment), Wilson Creek (sediment), and Naches (temperature). With cooperation from irrigation districts, agricultural organizations, other state and federal agencies and local governments, implementation of these TMDL plans has resulted in dramatic decreases in pollutant loading in both the upper and lower Yakima River. WDOE also funds water quality projects through its 319 and Centennial Water Quality grants program.

C.8 Yakima Basin Joint Board

The Yakima Basin Joint Board of Control is a group of irrigation districts that works together to address common technical, legal, and policy issues. They are represented on SOAC by a fish biologist. The majority of projects the Joint Board funds are research or monitoring oriented. Past work includes assessments of fish use and habitat conditions within irrigation-district managed facilities, development of a water temperature model for the lower Yakima, and analysis of the population status of species that may be affected by management actions. Most major projects that improve water quality and

irrigation efficiencies are undertaken by each individual irrigation entity, groups of irrigators, or through YRBWEP. The Roza-Sunnyside Board of Joint Control is a separate organization that administers the water quality program in the lower valley in association with South Yakima Conservation District; the Kittitas County Water Purveyors coordinates water quality and irrigation system improvements in the Upper Yakima.

C.9 Local Government Land Use Regulations

C.9.1 Growth Management Act

The Growth Management Act (GMA) (RCW 36.70A) was passed in 1990. Several of its provisions pertain to fish habitat:

- A Comprehensive Plan is the official land use policy for a local government
- Regulatory ordinances to implement the plan are required, and must and be consistent with the plan policy
- For public health and safety, the protection of ground and surface waters from pollution is require.
- Local governments must first identify (i.e., map) and then protect with regulations "natural resource lands" (agricultural and mineral resources lands), and "Critical Resources Areas," of which there are five (frequently flooded areas, geologically hazardous areas, wetlands, critical aquifer recharge areas, and fish and wildlife habitat conservation areas)
- Regulations protecting Critical Resources must be based upon "best available science"

Not all counties and cities within the state are required to prepare and implement comprehensive plans under GMA. But all counties and cities, whether planning under GMA or not, are required to identify Critical Resource Areas and protect them by regulation. Critical Resource Area Ordinances are applied only through a development review process initiated by a submitted application to undertake a regulated action, or through an enforcement/compliance action related to a project action that has not been reviewed and authorized (permitted) by the local jurisdiction.

C.9.2 Shoreline Management Act

The state Shoreline Management Act (SMA) requires cities and counties with lands on "state waters" to adopt a Shorelines Management Plan and implementing regulations. Typical plans prepared prior to the most recent edition of the State Shorelines Guidelines included three or four general land use designations (e.g., Rural, Urban, Industrial), and an implementing ordinance intended to regulate development consistent with the protection of shoreline resources and public access to the shoreline. Local SMA permit actions can be appealed to the State Shorelines Board, which can deny or modify a local permit action. Under the state rules, certain categories of development are exempt from

shorelines review. The boundary of SMA jurisdiction is generally extends 200’ upland of the ordinary high water line but can extend further upland to include the 100 year floodplain and riverine wetlands. Public notice for shoreline actions is required.

APPENDIX D: Stakeholder and Public Meetings

During the initial development of this plan, and extensive series of meeting was held to gather public input (see Section 1.3.2 and D.1 below). The October 2005 draft of the Yakima Subbasin Salmon Recovery Plan was made available via the Yakima Basin Fish & Wildlife Recovery Board's website and was put out for formal public review by NOAA Fisheries in the spring 2006 (See Section 1.1.3). Formal comments were received from American Rivers, the Yakima Basin Joint Board of Control, and the BOR. Meetings held following the Board's assumption of responsibility for the plan are listed in Section D.2. This final review draft will be made available via the Board's website and at public locations throughout the Basin. Additional meetings held after release of this review draft will be listed in section D.3 in the final version of this plan.

D.1 Stakeholder Meetings Held in 2005

The Yakima Subbasin Fish & Wildlife Planning Board and partners met with the following organizations during development of the initial draft of the Yakima Subbasin Salmon Recovery Plan in 2005:

Naches Ranger District, Wenatchee National Forest, USFS	*February 23, 2005*
Bureau of Reclamation, Yakima	*February 28, 2005*
Cle-Elum Ranger District, Wenatchee National Forest, USFS	*March 8, 2005*
North Yakima Conservation District	*March 9, 2005*
Washington State Department of Fish and Wildlife	*March 16, 2005*
Kittitas County Conservation District	*March 18, 2005*
Kittitas County Water Purveyors	*March 18, 2005*
City of Yakima Water Systems	*March 23, 2005*
City of Yakima Maintenance	*March 23, 2005*
City of Yakima Planning	*March 23, 2005*
Washington Department of Ecology	*March 25, 2005*
Yakima Basin Joint Board Of Control	*March 25, 2005*
Kittitas Irrigation District	*March 25, 2005*
Roza Irrigation District	*March 25, 2005*
Sunnyside Irrigation District	*March 25, 2005*
Richland Irrigation District	*March 25, 2005*
Cascade Irrigation District	*March 25, 2005*
Benton County Conservation District	*March 28, 2005*

South Yakima Conservation District	*March 28, 2005*
Barker Ranch	*March 28, 2005*
Yakima County Public Works Maintenance	*March 31, 2005*
City of Richland	*April 4, 2005*
Ahtanum Irrigation District	*April 4, 2005*
Washington Department Of Transportation	*April 4, 2005*
Yakima County Planning	*April 6, 2005*
South Central Washington Resource Conservation & Development	*April 6, 2005*
Yakima Tributary Access and Habitat Project	*April 6, 2005*
Yakima Audubon	*April 12, 2005*
Washington State Cattlemen's Association	*April 18, 2005*
City of Ellensburg Public Works Department	*April 19, 2005*
Washington Department of Natural Resources	*April 22, 2005*
Washington Farm Bureau	*April 25, 2005*

D.2 Stakeholder Meetings Held April 2006 to January 2008

Responsibility for completion of this plan transferred to the Yakima Basin Fish & Wildlife Recovery Board in April 2006. Regular updates on the planning process were held at the regular public meetings of the Yakima Basin Fish & Wildlife Recovery Board's Board of Directors. Additional stakeholder meeting that were held to update interested parties on the planning process following this transfer include:

Selah Kiwanis	*November 28, 2006*
Mid-Columbia Regional Fisheries Enhancement Group	*January 18, 2007*
Yakima Aquatic Science & Management Conference	*June 14, 2007*
South Central WA Resource, Conservation & Development	*September 6, 2007*
Yakima/Klickitat Fisheries Project Policy Group	*September 19, 2007*
Benton County Conservation District	*October 10, 2007*
Yakima Basin Joint Board of Control	*Nov. 14 & 30, 2007*
Bureau of Reclamation, Yakima	*May 22, 2008*
Washington Department of Fish & Wildlife	*May 23, 2008*

In April though June of 2008, the Board received informal comments on the March 24, 2008 review draft. A summary of comments and responses is available on the Board's website (www.ybfwrb.org); changes made to the plan in response to these comments are included in this draft.

D.3 Plan Outreach During 2008 NOAA Comment Period

During the September 23rd to December 23rd formal comment period on the NOAA Middle Columbia Steelhead Recovery Plan, the Yakima Basin Fish & Wildlife Recovery Board conducted the following outreach activities:

General Outreach:

Press release to local papers on release day (resulted in Yakima Herald Article)

Information on plan and comment period posted on Board website

Federal Register notice on Sept. 24th by NOAA

Email about comment period to Board email contacts (last week of Sept & mid-Nov)

Presentations:

Yakima Basin Joint Board (major irrigators)

Yakima Audubon

Yakima Flyfishing Club

Cowiche Canyon Conservancy

Federal Caucus (federal agencies involved in Columbia salmon issues)

Federal legislative staffers (via NOAA conference call)

Yakima Basin Water Resources Agency Board

NOAA Public meeting Nov 19th

Yakima Basin Water Resources Agency Water Resource Advisory Board (Dec 1st)

South Yakima Conservation District

Kittitas Cattle Growers

Informational materials and offer to present if requested provided to:

Conservation Districts (North Yakima, Kittitas, South Yakima & Benton)

Kittitas Field & Stream Club

Mid-Columbia Regional Fisheries Enhancement Group

State legislators (via email on release date of NOAA plan)

Tapteal Greenway Association

Benton Conservation District

Phone Discussions

Bureau of Reclamation staff

US Forest Service staff

Native Fish Society

American Rivers

Recovery Plan Module
Mainstem Columbia River Hydropower Projects

1.0 Purpose

This module summarizes the general effects of Columbia River mainstem hydropower projects on all 13 Endangered Species Act (ESA)-listed anadromous salmonids in the Columbia basin, including the limiting factors and threats and expected actions (including site-specific management actions), or strategy options, to address those threats. The area to be addressed by the module includes the accessible mainstem habitat in the upper Columbia (i.e., to the tailrace of Chief Joseph Dam) and Snake (i.e., to the tailrace of Hells Canyon Dam) rivers, respectively, downstream to the tailrace of Bonneville Dam.[1] This module supports plans for the Snake River, Upper Columbia, Middle Columbia, Lower Columbia, and Upper Willamette River species, replacing the previous version provided as guidance to regional recovery planners, dated September 25, 2006. The material that follows is a synthesis of information that has undergone public processes for review, including, but not limited to, the Federal Columbia River Power System (FCRPS) 2008 Biological Opinion, Federal Energy Regulatory Commission (FERC) licensing proceedings, and Habitat Conservation Plans (HCPs). This module may, however, be updated as additional information becomes available.

1.1 How Salmon and Steelhead Use the Mainstem

All 13 ESA-listed species of salmon *(Oncorhynchus spp.)* and steelhead *(O. mykiss)* in the Columbia basin use the mainstem Columbia River (and Snake River for Snake River species) for migration to and from freshwater natal areas to the Pacific Ocean, where they grow from juveniles to mature adults. Most of the ESA-listed species spawn and incubate in tributaries, but Snake River (SR) fall Chinook, some populations of Lower Columbia River (LCR) fall Chinook, and Columbia River (CR) chum salmon spawn and incubate redds in the mainstem itself. Historically, the peak period for migration to the ocean has been spring and early summer, corresponding with snowmelt in the upper basin and high seasonal flows. However, individual juveniles from one species/population or another can be found in the system throughout the year.

Downstream travel has been shown to be active rather than passive; in addition to water velocity, the rate of travel is affected by date, temperature, the location where the fish begin their migration, fish size, and the extent of the parr-smolt transformation. Survival through the migration corridor declines with distance traveled, whether due to natural hazards (including predation), mortality due to passage at hydroelectric projects, or other factors associated with

[1] A separate module (the Mainstem Columbia River Estuary Recovery Plan Module) provides the same types of information for the lower river below Bonneville, in the estuary and the ocean plume.

development (exotic predators, habitat conditions that make native predators more efficient, water quality, etc.).

Based on emigration and rearing strategies, Connor et al. (2005) described two juvenile life history types for Snake River fall Chinook. At the time of the ESA listing (June 28, 2005; NMFS 2005), it was assumed that all juveniles of this species were ocean-type fish, characterized by entering saltwater at age 0 and spending their first winter in the ocean. However, some of the smaller, later-migrating fall Chinook salmon from the Snake River basin delay seaward movement, wintering in the lower Snake River reservoirs before resuming their seaward movement the following spring at age 1. According to Connor et al. (2005), although the condition of reservoir-type juveniles decreased over winter compared with ocean-type juveniles, the mean condition factor of the former always exceeded 1.0 in the single year of study.

After growth and maturation, whether in freshwater or the ocean, adult salmonids and steelhead generally return to their natal spawning areas for reproduction, though some straying into other basins is natural. As described in ISG (1996), the timing of adult entry and movement in rivers and tributary streams, and even the size, shape, and strength of adult fish represent adaptations to the physical and biological challenges presented by the upstream route to a specific spawning area. For example, waterfalls and similar physical barriers may be passable only at the range of flows that typically occurs during one month of the year, and then only by fish that have the physical ability to jump over or otherwise ascend the barrier. For fall-spawning fish, warm water conditions in late summer often present thermal barriers to movement and there may be little suitable habitat for resting (Berman and Quinn 1991, cited in ISG 1996). Therefore, at the adult life stage, population-specific behavioral patterns, closely attuned to the available habitats, appear to be critical for survival and successful reproduction.

Preferred spawning habitat is determined by the incubation needs of embryos, i.e., high flow of oxygenated water through the interstitial spaces in the streambed (Quinn 2005). Salmon usually avoid both the slowest water (where fine sand and silt accumulate) and the fastest water. Salmon lay their eggs in nests called redds. In areas where winter freezing can destroy embryos, salmon often build redds at sites with upwelling groundwater, which is warmer than river water. In the Columbia basin, two of the listed species, Snake River fall Chinook and Columbia River chum salmon, spawn both in tributaries and in the mainstem. In the vicinity of Ives Island (downstream of Bonneville Dam), chum spawn in shallow areas where it appears that river water is warmed by its transit through the gravel (Geist et al. 2002). At both Ives Island and in the Hanford Reach, fall Chinook salmon select upwelling sites in preference to non-upwelling sites (Geist 2000; Arntzen et al. 2005), but in other locations, fall Chinook prefer to spawn in downwelling areas at the heads of riffles (Healey 1991). At both Ives Island and the Hanford Reach, fall Chinook salmon select redd sites containing the highest dissolved oxygen concentrations in the river and riverbed, which is consistent with the requirements for incubating relatively large eggs (Healy 1991).

2.0 Habitat Limiting Factors and Threats Related to Mainstem Hydropower Projects and Operations

This section identifies the past and continuing effects of dams and reservoirs located in the mainstem Columbia and Snake River migratory corridors on listed species of salmon and steelhead and their designated critical habitat. The mainstem migratory corridor extends from the base of Hells Canyon Dam on the Snake River, and from Chief Joseph Dam on the Columbia River, to the tailrace of Bonneville Dam on the Columbia River.

Columbia River Basin anadromous salmon and steelhead have been affected by the development and operation of dams. Mainstem dams have extirpated anadromous fish from their pre-development spawning and rearing habitats. Dams and reservoirs, within the currently accessible migratory corridor, have altered the river environment and have affected fish passage and survival. The operation of water storage projects has altered the natural hydrograph of the Snake and Columbia Rivers. Water impoundment and dam operations also affect downstream water quality characteristics, including water temperatures, which are important to the survival of anadromous fish. Detailed descriptions of these effects are provided in Williams et al. 2005 and Ferguson et al. 2005 (NOAA Technical Memoranda NMFS-NWFSC-63 and 64) and summarized in NMFS 2008a (Supplemental Comprehensive Analysis of the Federal Columbia River Power System and Mainstem Effects of the Upper Snake and other Tributary Actions – Section 5.1).

2.1 Blocked and Inundated Habitat

The construction of Grand Coulee Dam in 1939 – River Mile 597 (and later Chief Joseph Dam in 1961 – RM 545) blocked access to important historical production areas for Upper Columbia River (UCR) spring Chinook salmon and steelhead (NRC 1996; ICTRT 2003) upstream of River Mile 597 (and RM 545). In addition to mainstem production areas, the Sanpoil, Spokane, Colville, Kettle, Pend Oreille, and Kootenai rivers each may have supported one or more populations of Chinook and/or steelhead.

In the Snake River, the construction of Swan Falls Dam in 1901 blocked access to important historical production areas of salmon and steelhead in the Snake River basin upstream of RM 424.[2] The construction of the Hells Canyon Dam complex (1958–1967) cut off access to the remaining historical habitat upstream of river RM 248, including seven major tributaries that had historically been important for spring/summer Chinook salmon and steelhead (and to sockeye

[2] The area downstream of RM 578 (near the present location of Upper Salmon Falls Dam) was especially important to Snake River fall Chinook salmon, which Evermann (1896) identified as the "... largest and most important salmon spawning ground of which we know in Snake River."

salmon in the Payette River system): Boise, Burnt, Malheur, Owyhee, Payette, Powder, and Weiser rivers (Fulton 1968; Fulton 1970; Gustafson et al. 1997).

Between 1938 and 1971, the construction of Bonneville, The Dalles, John Day, and McNary dams inundated mainstem habitat in the lower Columbia River between Bonneville Dam (RM 146) and the confluence of the Snake River (RM 324). Between 1933 and 1967, the construction of Priest Rapids, Wanapum, Rock Island, Rocky Reach, and Wells dams inundated mainstem habitat in the middle Columbia River between the Snake River confluence (RM 324) and Chief Joseph Dam (545). Another 147 miles (RM 0 to RM 147) of mainstem habitat was inundated in the Snake River with the construction of Ice Harbor, Lower Monumental, Little Goose, and Lower Granite dams between 1962 and 1975 (Groves and Chandler 1999). Upstream from Bonneville Dam, the 41-mile stretch of the Columbia River known as the Hanford Reach between the head of Lake Wallula (McNary Dam pool – RM 356) and the tailrace of Priest Rapids Dam (RM 397), and the approximately 101-mile stretch of the Snake River, often referred to as the Hells Canyon reach (RM 147 to 248), provide the longest remaining unregulated reach of the mainstem ecosystem between Bonneville Dam and Chief Joseph Dam on the Columbia River and Hells Canyon Dam on the Snake River.

2.2 Mainstem Habitats & the Migratory Corridor

The Columbia and Snake Rivers (mainstem habitat) serve as corridors for migrating salmon and steelhead between the Pacific Ocean and their freshwater spawning and rearing habitats. Features of migration habitat important to these fish generally include: substrate, water quality, water quantity, water temperature, water velocity, cover/shelter, food (prey), riparian vegetation, space, and safe passage. For fall Chinook salmon, and to a lesser extent chum salmon, mainstem habitat also serves as important spawning and rearing habitat. Features of spawning and rearing habitat that are important to these fish generally include: spawning gravel, water quality, water quantity, water temperature, food, riparian vegetation, and access to spawning and rearing areas.

Current conditions within much of the mainstem Columbia and Snake Rivers are altered compared to historical conditions. The development of mainstem hydropower projects have resulted in the inundation of many mainstem spawning and shallow-water rearing areas (loss of spawning gravels and access to spawning and rearing areas); altered water quality (reduced spring turbidity levels), water quantity (seasonal changes in flows and consumptive losses resulting from use of stored water for agricultural, industrial, or municipal purposes), water temperature (including generally warmer minimum winter temperatures and cooler maximum summer temperatures), water velocity (reduced spring flows and increased cross-sectional areas of the river channel), food (alteration of food webs, including the type and availability of prey species), and safe passage (increased mortality rates of migrating juveniles) (Williams et. al 2005; Ferguson et. al 2005).

Within the migratory corridor, both dams and their associated reservoirs influence the current status of Columbia Basin salmon. To a greater or lesser extent specific to each dam, the dams present fish passage hazards, causing passage delays and varying rates of injury and mortality.

2.2.1 Adult Passage

Unlike downstream migrating juveniles, there is no indication that reservoirs substantially delay adult upstream migration (Ferguson et al. 2005). While the upstream migration of adults can be slowed as fish search for fishway entrances and navigate through the fishways themselves, they migrate more quickly through the relatively slow reservoirs.

Adult fish passage, in the form of fish ladders, is provided at the eight mainstem projects in the lower Snake and lower Columbia rivers and the five mainstem FERC-licensed projects in the middle Columbia reach. In general, adult passage facilities are highly effective. Nonetheless, salmon may have difficulty finding ladder entrances, and fish also may fall back over the dam, either voluntarily (e.g., adults that "overshoot" their natal stream and migrate downstream through a dam on their own volition), or involuntarily (entrained in spillway flow after exiting a fish ladder). Some adults that fall back or migrate downstream pass through project turbines and juvenile bypass systems. Adult mortality rates have been estimated at between 22% and 59%, depending on the species and size of the individual fish (larger fish are more likely to contact a turbine blade, etc.) (Ferguson et al. 2005). There is even less data on the survival of adults through juvenile bypass systems. It seems logical to assume that survival rates would be much higher through these systems than through turbine units, and indeed, with the possible exception of passage through the 14 to 16" gatewell orifices, conditions within these systems should be easily navigable by adults.

However, in spite of these potential hazards, average survival estimates using known origin PIT-tagged fish indicate that, after adjusting for known harvest and "natural" straying, survival through the mainstem Snake and Columbia River projects is relatively high (see Table 1 and discussion in Section 4 below).

Steelhead Kelts

Unlike other Pacific salmonids, a large fraction of the adult steelhead does not die after spawning and instead attempts to migrate back to the Pacific Ocean. Termed kelts, very few post-spawn adult steelhead survive downstream passage through the hydrosystem and so do not return and spawn again. Estimates of FCRPS passage survival ranged from 4.1 to 6.0% in the low flow year 2001 to 15.6% in 2002 and 34% in 2003 (Boggs and Peery 2004; Wertheimer and Evans 2005). At present, juvenile collection and bypass systems are not designed to safely pass adult fish including kelts. In addition to injury and mortality, kelt downstream migrations are delayed by the mainstem projects (Wertheimer and Evans 2005) in a manner similar to that previously described for juveniles.

The fraction of repeat spawning kelts in steelhead populations varies widely, from 1 to 51% (Wertheimer and Evans 2005). Boggs and Peery (2004) cite an estimated 2% kelt rate for the Clearwater River in 1954. It is estimated that 17 to 25% of the steelhead that pass Lower Granite Dam return downstream as kelts (Boggs and Peery 2004; Wertheimer and Evans 2005). Thus, while there is a relatively large number of kelts present, their relatively poor survival through the FCRPS (and potentially through the Middle Columbia PUD projects) may limit the contribution that they can make to steelhead populations.

Predation

Additionally, at Bonneville Dam, marine mammals (both the more common California sea lion and ESA-listed Stellar sea lion) are increasingly using the Bonneville Dam tailrace as a foraging area, presumably because the adult Chinook, steelhead, and lamprey upon which they feed are concentrated and delayed in this area as they seek entrance to the dam's adult fishways.

2.2.2 Juvenile Passage

Delay

Prior to the development of mainstem dams (c. 1938–1975), the mainstem migratory corridor was free-flowing with high velocities and a broad complex of habitats including rapids, short chutes, falls, riffles, and pools. It is not known how long it took juvenile salmon and steelhead to traverse the free-flowing river. Today, median travel times for yearling Chinook from the Lower Granite Dam on the Snake River to Bonneville Dam range from 14 days to 31 days depending on flow conditions, an increase of 40 to 50% over travel times measured in 1966 (Raymond 1968 and 1979), when fish encountered only the four mainstem dams (Williams et al. 2005).

This increased travel time (migration delay) presents an array of potential survival hazards to migrating juvenile salmon and steelhead: increasing their exposure to potential mortality vectors in the reservoirs (e.g. predation, disease, thermals stress), disrupting arrival timing to the estuary (which likely affects predator/prey relationships),[3] depleting energy reserves, potentially causing metabolic problems associated with smoltification (smoltification is the process of metabolic changes required to allow juvenile fish to convert from freshwater to saltwater environments), and for some steelhead and all Chinook salmon, contributing to residualism (a loss of migratory behavior).

[3] During the spring and summer a series of changes occur in the composition of biotic communities the estuary and near-shore ocean environment. The assemblages of species change through time and disrupting arrival timing may increase the exposure of juvenile salmon to predators and/or diminish the availability of prey species to which the fish are adapted.

Migration delays and biological effects of a similar magnitude have likely also occurred in the middle Columbia River as a result of the construction of the middle Columbia PUD projects.

Dam Passage

A substantial proportion of juvenile salmon and steelhead can be killed while migrating through dams, both directly through collisions with structures and abrupt pressure changes during passage through turbines and spillways, and indirectly, through non-fatal injury and disorientation, which leave fish more susceptible to predation and disease and result in delayed mortality. Some juvenile mortality and injury is associated with any route of dam passage, but turbine passage generally has the highest direct mortality rate—8 to 19 percent. Juveniles passing through project spillways, sluiceways and other surface routes generally suffer the lowest direct mortality rates, 2% or less. However, substantially higher mortality rates have been measured through spillways at several mainstem FCRPS projects (Ferguson et al. 2005, NOAA Technical Memoranda NMFS-NWFSC-64).[4]

Additionally, a significant rate of juvenile mortality (approximately 3 to 5%) can occur in project forebays, just upstream of the dams (Axel et al. 2003; Ferguson et al. 2005; Hockersmith 2007), if fish are substantially delayed (median of 15-20 hours) before passing through the dam (Perry et al. 2007).[5] Forebay delay increases the exposure of juveniles to fish and avian predators and increases their exposure time to adverse water quality conditions (e.g. elevated total dissolved gas levels and high water temperatures), where present. (See discussion in NMFS 2008a—Supplemental Comprehensive Analysis, Section 5.1.2.1 for additional information regarding improvements made at the mainstem hydroelectric dams to improve passage since the mid-1990s, including some discussion of how the newly developed surface passage routes are proving effective at reducing forebay delay.)

Predation

The altered habitats in project reservoirs reduce smolt migration rates and create more favorable habitat conditions (increased growth rates, increased consumption rates, and enhanced foraging opportunities) for fish predators (see Dam Passage), including northern pikeminnow (*Ptychocheilus oregonensis*), and non-native walleye (*Sander vitreus*) and smallmouth bass (*Micropterus dolomieu*).

---

[4] The route-specific mortality rate values given here are averages across several investigations. Higher and lower moralities have been observed and measured route-specific mortality is influenced by an array of factors ranging from the health and species of the test fish to study methods, the performance characteristics and working condition of the system being studied, and environmental conditions.

[5] This study was conducted at McNary Dam; estimates of delay for individual fish ranged from 0 to 172 hours in this study.

Dams also enhance conditions for avian predators - primarily Caspian terns, double-crested cormorants, and several gull species – because these species can more effectively forage in the forebays and tailraces of the mainstem projects than in a more riverine system.

Transportation Program

Following a decade of research that led to the conclusion that in most cases, the average adult return rates of predominantly stream-type salmonids (spring/summer Chinook and steelhead) that were transported as juveniles exceeded the return rates of fish that migrated inriver, the Corps began large-scale juvenile transportation as a management measure in 1975 (Ebel 1980; Ebel et al. 1973; Mighetto and Ebel 1994). Currently, fish collection and transportation systems are operated seasonally at Lower Granite Dam, Little Goose Dam, and Lower Monumental Dam (and at McNary Dam for summer migrating fall Chinook salmon). Most transported fish are barged to release points downstream from Bonneville Dam. When collection numbers become too small for barging to be cost-effective, collected fish are transported via truck. Approximately 60 to 90% of spring migrating smolts (spring/summer Chinook and steelhead) in the Snake River basin have been transported annually (Williams et al. 2005). Higher proportions (>95%) of Snake River migrants are likely to be transported during low water year conditions (defined as years in which spring flows are expected to be less than 65,000 cubic feet per second at Lower Granite Dam). With the addition of surface passage routes at the Snake River dams, far fewer fish may be transported – especially early in the migration season when adult returns from Chinook salmon smolts left to migrate inriver are relatively high (compared to transported fish) [see discussion below] – than has been possible in the past. For example, in 2007 transport rates were estimated to be much lower than previously estimated (approximately 25% for wild and hatchery yearling Chinook salmon and about 41% for wild and hatchery steelhead) (Smith 2008).

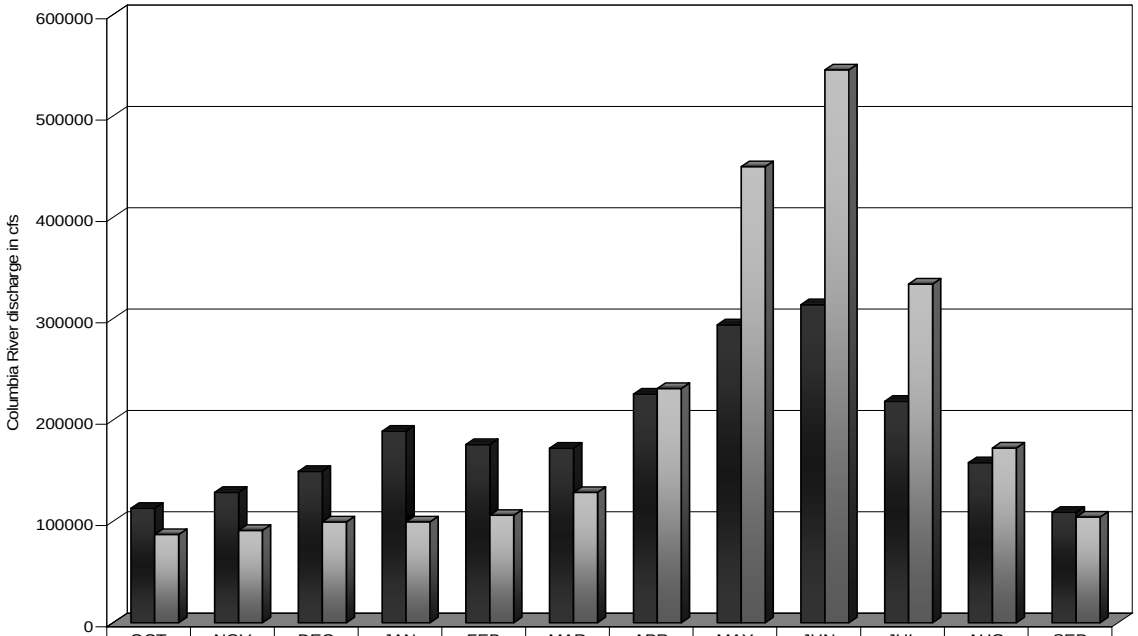
Recent data show that the effectiveness of transportation, in terms of the ratio of returning adults to transported juveniles (termed smolt-to-adult return ratio or SAR) from the Snake River, varies among species, season, and collection location (Williams et al. 2005; Scheuerell and Zabel 2007). In general, the SARs of both transported and inriver migrating Snake River spring/summer Chinook salmon and steelhead tend to decrease once the day of arrival below Bonneville Dam passes early May. For steelhead, SARs of transported fish are typically equal to or higher than those of the surviving inriver migrants arriving downstream of Bonneville Dam (transport-to-in-river SAR ratios > 1.0). For spring/summer Chinook salmon, SARs of surviving inriver migrating fish often are substantially higher in early to mid May than those of transported migrants (transport-to-in-river SAR ratios < 1.0). However, in late May and June, the differences are generally diminished such that SARs are nearly equal (transport-to-in-river ratios ≈1.0).[6]

[6] The ISAB (2008) recently reviewed this information and generally agreed with NOAA Fisheries' assessment of the currently available data regarding the relative returns of adult Chinook and steelhead that were either transported or left inriver to migrate as juveniles. However, they advised NOAA Fisheries, the federal Action Agencies, and other regional managers to continue a "spread the risk" approach to spill and transport management to determine if

2.3 Mainstem Hydrologic Conditions

Flow regulation, water withdrawal, and climate change have reduced the Columbia River's average flow, altered its seasonality, and reduced sediment discharge and turbidity (NRC 1996; Sherwood et al. 1990; Simenstad et al. 1982 and 1990; Weitkamp 1994). Annual spring freshet flows through the Columbia River estuary are about one-half of the pre-development levels that flushed the estuary and carried smolts to sea (Figure 1).

Flow affects juvenile travel time and the distribution of individuals among the various routes of dam passage. In general, the lower the flow through the FCRPS reservoirs, the longer the travel time of juveniles that migrate inriver.[7] The longer juveniles remain in project reservoirs, the greater their exposure to predation, elevated temperatures, disease, and other sources of mortality and injury.



Combined with the influence of reservoirs in the migration corridor, reductions in spring and early summer flows slow juvenile fish emigration, increase their exposure to injury and mortality factors within the reservoirs (e.g. predation, temperature stress, disease, and others), and change the timing of ocean entry.

---

these patterns have been altered by recent structural improvements and operations at the mainstem dams and out of concern for potential effects of spring spill and transport operations [proposed in the 2008 FCRPS biop (NMFS 2008b)] on sockeye and lamprey.

[7] At lower river flows a higher proportion of individuals is collected and transported for some ESUs, thereby avoiding the delay associated with inriver hydrosystem passage.

Figure 1. Simulated mean monthly Columbia River flows at Bonneville Dam under current conditions (black columns) versus flows that would have occurred without reservoir management (gray) (water years 1929 –1978. Source: Current Condition Flows – Bonneville Power Administration, HYDSIM model run FRIII_07rerun2004biop.xls; Pre-Development Flows – USBR (1999) Cumulative Hydrologic Effects of Water Use: An Estimate of the Hydrologic Impacts of Water Resource Development in the Columbia River Basin. 2.4 Mainstem Water Quality

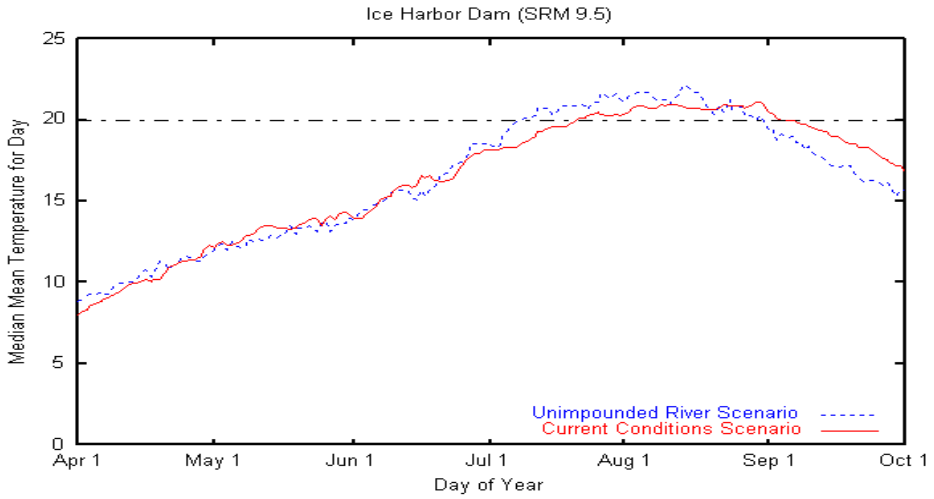
Water quality characteristics of the mainstem Snake and Columbia Rivers are affected by an array of land and water use developments. Water quality characteristics of particular concern are: water temperature, turbidity, total dissolved gas, and chemical pollutants.



2.4.1 Water Temperature

Changes in water temperatures can have significant implications for anadromous fish survival. Dams and reservoirs influence water temperatures through storage, diversion, and irrigation return flows. Comparisons of long-term temperature monitoring in the migration corridor before and after impoundment reveal a fundamental change in the thermal regime of the Snake and

Columbia rivers. As shown in Figure 2, there are three notable differences between the current and the unimpounded river:[8]

- the maximum summer water temperature has been slightly reduced,
- water temperature variability has decreased, and
- post-impoundment water temperatures stay cooler longer into the spring and warmer later into the fall. The latter phenomenon is termed thermal inertia.

Figure 2. Median daily Snake River water temperatures (°C) at Ice Harbor Dam before and after development of the four lower Snake River projects (20°C denotes Washington Department of Ecology standard). Source: Perkins and Richmond 2001 in NMFS 2008a.

High water temperatures stress all life stages of anadromous fish, increase the risk of disease and mortality, affect toxicological responses to pollutants, and can cause migrating adult salmon to stop or delay their migrations and juvenile steelhead to residualize. Warm water temperatures also increase the foraging rate of predatory fish thereby increasing the consumption of smolts.

Though the duration and magnitude of high water temperatures in the migratory corridor is generally less under current, developed conditions than prior to water development, some juvenile fish are exposed to these conditions for a longer period of time due to the adoption of

[8] NOTE: Significant land use practices, including the development of a large number of water storage and diversion projects had already occurred by the 1960s. Therefore, the unimpounded river scenario in this graphic does not be equate to the pre-development condition.

alternative life histories (i.e, juvenile fall Chinook that over-summer in the mainstem reservoirs) or increases in migration travel time.

Coincident with and possibly due to climate change, average annual Columbia Basin air temperatures have increased by about 1 degree C over the past century and water temperatures in the mainstem Snake and Columbia rivers have been affected similarly (ISAB 2007). The influence of this and other large-scale environmental variations are discussed in NMFS 2008a – Supplemental Comprehensive Analysis, Section 5.7.

Also, due to the thermal inertia of the reservoirs (both mainstem and upstream storage projects), atmospheric cooling of water temperatures is delayed in the fall and warming is delayed in the early spring. This can affect Snake River fall Chinook by increasing the exposure of adults to elevated temperatures prior to spawning, resulting in an increased potential of pre-spawning mortality, reduced gamete viability, and subsequent impacts to the development and survival of fish through the egg to fry life stages.

2.4.2 Turbidity

Flow regulation and reservoirs reduces turbidity in the Columbia and Snake rivers. Reduced turbidity can increase predator success through improved prey detection, increasing the susceptibility of smolts to predation. Predation is a substantial contributor to juvenile salmon mortality in reservoirs throughout the Columbia and Snake River migratory corridors.

2.4.3 Total Dissolved Gas

Spill at mainstem dams (either as a means to pass fish or involuntarily in response to over-generational flows) can cause downstream waters to become supersaturated with dissolved atmospheric gasses. Supersaturated total dissolved gas (TDG) conditions can cause gas bubble trauma (GBT) in adult and juvenile salmonids resulting in injury or death. Biological monitoring shows that the incidence of GBT in both migrating smolts and adults remains between 1-2% when TDG concentrations in the upper water column do not exceed 120% of saturation in FCRPS project tailraces and 115% in project forebays. When those levels are exceeded, there is a corresponding increase in the incidence of GBT symptoms.

However, the effects of total dissolved gas (TDG) supersaturation on aquatic organisms are moderated by depth due to hydrostatic pressure. Each meter of depth compensates for about 10% of gas supersaturation as measured at the water surface. Thus, if the dissolved gas concentration is 120% of supersaturation at the surface, then the condition that the aquatic organism actually experiences at a depth of 2.0 meters is reduced to about 100% (i.e., the fishes tissues will be in equilibrium with the surrounding water and it will not develop gas bubble disease or trauma; Weitkamp 2003).

2.4.4 Pollutants

Background or ambient levels of pollutants in inflows from upstream areas are variable and generally unquantified. Growing population centers throughout the Columbia and Snake River basins and numerous smaller communities contribute municipal and industrial waste to the rivers. Mining areas scattered around the basin deliver higher background concentrations of metals. Highly developed agricultural areas of the basin also deliver fertilizer, herbicide, and pesticide residues to the river. While these pollutants are not caused by the mainstem Snake and Columbia rivers projects, they are transported through them to the estuary.

Current environmental conditions in the Columbia River estuary indicate the presence of contaminants in the food chain of juvenile salmonids including DDT, PCBs, and polyaromatic hydrocarbons (PAH) (NMFS 2001). This data also indicates that juvenile salmonids in the Columbia River estuary have contaminant body burdens in the range where sublethal effects can occur. The sources of exposure are not clear, but may be widespread. Several pesticides and heavy metal contaminants have been detected in Columbia River sediments (ODEQ 2007). In field studies, juvenile salmon from sites in the Pacific Northwest have demonstrated immunosuppression, reduced disease resistance, and reduced growth rates associated with contaminant exposure during their period of estuarine residence (Arkoosh et al. 1991, 1994, 1998; Varanasi et al. 1993; Casillas et al. 1995a, 1995b, and 1998). Some impacts may be occurring within the mainstem Columbia and Snake Rivers, to the extent that juvenile fish are rearing in areas that are contaminated to similar levels as in the estuary.

3.0 Current Recovery Strategies and Actions

Current hydropower programs and operations are the result of completed or ongoing ESA section 7 consultations, Habitat Conservation Plans (HCPs) pursuant to section 10 of the ESA; FERC relicensing proceedings and other regulatory processes. In most cases, hydropower programs and operations are intended to avoid jeopardy and contribute to recovery. There is no distinction between the hydropower actions intended to meet ESA regulatory requirements and those intended purely for recovery.[9]

[9] Recovery cost estimates do not include costs for implementing mainstem actions, first, because of their basinwide scope and applicability to all 13 Columbia Basin salmonid species listed as threatened or endangered, and second, because they are considered "baseline actions," a term that NMFS' NWR ESA recovery plans use for actions already incorporated into other processes, such as section 7 consultations, FERC licensing agreements, and Habitat Conservation Plans, and these costs would occur regardless of the recovery plans.

3.1 Federally Owned and Operated Projects in the Columbia Basin

3.1.1 Federal Columbia River Power System

The Federal Columbia River Power System (FCRPS) consists of 14 projects, each composed of dams, powerhouses, and reservoirs, that are operated as a coordinated system for power production and flood control (while also effectuating other project purposes) on behalf of the Federal government under various Congressional authorities. These projects are: Dworshak, Lower Granite, Little Goose, Lower Monumental, and Ice Harbor dams, power plants, and reservoirs in the Snake River basin; Albeni Falls, Hungry Horse, Libby, Grand Coulee and Banks Lake (features of the Columbia Basin Project), and Chief Joseph dams, power plants, and reservoirs in the upper Columbia River basin; and McNary, John Day, The Dalles, and Bonneville dams, power plants, and reservoirs in the lower Columbia River basin.

The plan for operation of the FCRPS through 2018 is described in U.S. Army Corps of Engineers (USACE) et al.'s Comprehensive Analysis Document (USACE et al. 2007a) and Biological Assessment (USACE et al. 2007b) and in NMFS' Supplemental Comprehensive Analysis Document (NMFS 2008a) and Biological Opinion (NMFS 2008b). The following is a general summary of the performance standards, metrics, and targets required in the 2008 Biological Opinion to maintain or improve salmon and steelhead survival in the mainstem migration and rearing corridor and the strategies that will be pursued to achieve these metrics (see RPA 51 in NOAA Fisheries' Reasonable and Prudent Alternative Table of Actions – NMFS 2008b). These actions are intended to address the needs for survival and recovery of all 13 species of ESA-listed salmon and steelhead in the Columbia basin.

- **Adult Passage Performance Standards.** The Actions Agencies must track and confirm that the relatively high levels of adult survival currently observed are maintained or increased through 2018 (see Table 7 of NOAA Fisheries' Reasonable and Prudent Alternatives Table of Actions – NMFS 2008b). These survival rates, which are based on known-origin fish PIT tagged as juveniles, after accounting for known harvest and "natural" rates of straying, range from 81.2% for Snake River fall Chinook salmon up to 91.0% for Snake River spring/summer Chinook salmon (BON to LGR); and from 84.5% for Upper Columbia River steelhead up to 90.1% for Upper Columbia River spring Chinook (BON to MCN).[10]
- **Juvenile Dam Passage Performance Standards.** The Action Agencies must achieve an average Juvenile Dam Passage Performance Standards of 96% survival across Snake

[10] The discrepancy between adult survivals for Upper Columbia River versus Snake River species in the lower Columbia River is recognized and is the subject of directed research, monitoring, and evaluation programs. The objectives of these programs are to determine why the differences exist and what actions might be effective at increasing the survival of the Upper Columbia River species in the lower Columbia River.

River and Lower Columbia River dams for spring Chinook and steelhead and an average of 93% survival across Snake River and Lower Columbia River dams for Snake River sub-yearling fall Chinook.

- **Achieve Juvenile Inriver Survival Performance Metrics.** The Action Agencies must annually measure the survival of inriver migrating fish and compare these numbers with COMPASS model estimates, which will be based on the conditions actually experienced and the expected benefits of completed hydro actions, to assure that survival improvements are occurring as expected.
- **Juvenile System Survival Performance Targets.** The Action Agencies must achieve the expected increase in juvenile fish survival through the hydrosystem (survival to below Bonneville Dam of both transported and inriver migrating fish) that are associated with the proposed hydrosystem actions.

To achieve these metrics, the Action Agencies will pursue the following general objectives and strategies (see NOAA Fisheries' Reasonable and Prudent Alternatives Table of Actions, NMFS 2008b, for specific details):

- Continue collaboration with States and Tribes in the implementation of RPA actions, progress reporting, and adaptive management using fora such as the Regional Implementation Oversight Group.
- Operate the FCRPS to provide flows and water quality to improve juvenile and adult fish survival.[11]
- Modify Columbia and Snake river dams to maximize juvenile and adult fish survival.[12]
- Implement spill and juvenile transportation improvements at Columbia and Snake River dams.
- Operate and maintain facilities at Corps mainstem projects to maintain biological performance.
- Implement piscivorous predation control measures to increase survival of juvenile salmonids in the lower Snake and Columbia rivers.

---

[11] This includes the operation of storage reservoirs to increase the likelihood of achieving seasonal flow objectives: Spring \ 85 – 100 kcfs at Lower Granite dam, 135 kcfs at Priest Rapids dam, and 220 – 260 kcfs at McNary dam; Summer \ 50-55 kcfs at Lower Granite dam and 200 at McNary. It also includes the continued release of cool water from Dworshak dam during the summer to reduce and maintain temperatures in the lower Snake River.

[12] This includes the design, construction, and testing of structures and operations to provide surface oriented routes of passage which should be beneficial to juvenile migrants and downstream migrating adults (overshoots, fallbacks, or steelhead kelts).

- Implement avian predation control measures to increase survival of juvenile salmonids in the lower Snake and Columbia rivers.
- Implement marine mammal control measures to increase survival of adult salmonids at Bonneville Dam.
- Provide information needed to support planning and adaptive management and demonstrate accountability related to the implementation of FCRPS ESA hydropower actions for all ESUs (i.e., implement research, monitoring, and evaluation programs for hydropower actions and predator control actions).

In addition to these objectives, the 2008 FCRPS Reasonable and Prudent Alternative Action Table articulates site-specific management actions that will benefit interior Columbia species (see NOAA Fisheries' Reasonable and Prudent Alternatives Table of Actions, NMFS 2008b, for specific details).

3.1.2 U.S. Bureau of Reclamation Projects in the Upper Snake Basin above Brownlee Reservoir

The USBR's proposed actions in its August 2007 Biological Assessment (USBR 2007) addressed operations at 12 projects in the upper Snake River basin: Baker, Boise, Burnt River, Little Wood River, Lucky Peak, Mann Creek, Michaud Flats, Minidoka, Owyhee, Palisades, Ririe, and Vale (collectively, the Upper Snake Project). The proposed actions encompassed USBR's future operations and routine maintenance, including storage and delivery of water, hydropower generation, and releasing water to augment flows for migrating salmonids. NMFS (2008c) prepared a biological opinion on this proposal and concluded that the action would not jeopardize the listed species nor result in the destruction or adverse modification of their designated critical habitat.

The site-specific action of providing salmon flow augmentation is intended to address the needs for survival and recovery of all 13 species of ESA-listed salmon and steelhead in the Columbia basin. Although the physical project operations take place upstream of the migration barrier at Idaho Power Company's Hells Canyon Complex, water released from the upper Snake River project reaches the lower Snake and Columbia rivers where it benefits juvenile salmon and steelhead migrants.

The USBR provides salmon flow augmentation by acquiring water through rental pools and leasing or acquiring natural flow rights. The Nez Perce Water Rights Settlement and the Idaho law that implemented the settlement provide that up to 487,000 acre-feet may be provided for flow augmentation.

3.2 Federal Energy Regulatory Commission-licensed Projects

The Federal Energy Regulatory Commission (FERC) licenses five hydroelectric dams in the middle Columbia reach (i.e., between Chief Joseph Dam and the confluence of the Snake and Columbia rivers): Wells (owned and operated by Douglas County Public Utility District (PUD)), Rocky Reach and Rock Island (Chelan County PUD), and Wanapum and Priest Rapids (Grant County PUD). FERC also licenses Idaho Power Company's (IPC) Hells Canyon Complex in the Snake River basin.

3.2.1 Hydropower Projects Owned and Operated by Chelan and Douglas PUDs

NMFS (2002) entered into three site-specific 50-year anadromous fish agreements and habitat conservation plans (HCPs), one for each of the three mainstem Columbia River hydroelectric projects owned by Chelan (Rocky Reach and Rock Island) and Douglas (Wells) County PUDs, pursuant to section 10 of the Endangered Species Act. The HCPs were developed to protect the five species of Columbia River steelhead and salmon (spring-run Chinook salmon; summer/fall-run Chinook salmon; sockeye salmon, steelhead, and coho salmon, two of which (Upper Columbia River spring-run Chinook salmon and steelhead) were listed as endangered at that time.[13] They satisfied the PUDs' regulatory obligations with respect to anadromous salmonid species under the Federal Power Act, Fish and Wildlife Coordination Act, Pacific Northwest Electric Power Planning and Conservation Act, the essential fish habitat provisions of the Magnuson-Stevens Fishery Conservation and Management Act, and Title 77 RCW, as well as the ESA. The agreements set a "no net impact" standard to protect salmon and steelhead at the Wells, Rocky Reach, and Rock Island projects, and provide some degree of certainty for the long-term operation of these projects.[14]

Each of the three HCPs established a standard of 91% combined adult and juvenile passage survival at each project (Wells, Rocky Reach, and Rock Island) (NMFS 2002).[15] The combined survival standard is composed of 93% juvenile and 98% adult project passage survival for all anadromous salmonids. At the time the Incidental Take Permits were issued (August 20, 2003), NMFS estimated that the HCPs represented a 22 to 45% survival improvement potential over the survival levels observed under the historical operations at these projects.

---

[13] NMFS (2006) revised its listing of Upper Columbia River steelhead from "endangered" to "threatened" on January 5, 2006.

[14] The HCPs are intended to help prevent conditions that would lead to the need to list additional species of Upper Columbia River salmon and steelhead in the future.

[15] The HCPs allowed the PUDs to compensate for up to 9% project passage mortality through up to 7% hatchery production and up to 2% funding of tributary habitat enhancement projects. That is, the mitigation is intended to match the level of impact.

3.2.2 Hydropower Projects Owned and Operated by Grant County PUD

Grant County PUD's new FERC license includes survival standards required in NMFS (2004) for the Priest Rapids Project (Priest Rapids and Wanapum dams and reservoirs) that are identical to those described above for the HCPs. Furthermore, the following site-specific measures are also included in the new FERC license and are being implemented to ensure that the standards are met:

- Downstream passage measures, including spill through existing and top spill through future units; turbine operations and the installation of advanced turbines; total dissolved gas abatement; avian predator control; and a northern pikeminnow *(Ptychocheilus oregonensis)* removal program

- Continued operation and maintenance, and where needed, improvements to adult fishways at both Priest Rapids and Wanapum dams

- Design and construction of an off-ladder trap and fish-handling facilities at Priest Rapids Dam

- Sluiceway operations for steelhead fallbacks (kelts)

The FERC has completed consultation with NMFS on the terms of a new, 44-year license for the Priest Rapids Project. With respect to site-specific actions for mainstem facilities and operations, FERC adopted the hydro actions in the Reasonable and Prudent Alternative in NMFS' Biological Opinion on Grant County PUD's Interim Protection Plan (NMFS 2004) and in NMFS' February 1, 2008, Biological Opinion (NMFS 2008d) for listed salmon and steelhead, described above.

3.3 Idaho Power Company's Hells Canyon Project

The relicensing of the Hells Canyon Hydroelectric Project is the subject of ongoing administrative proceedings before FERC involving its owner, IPC; Federal, state, and tribal agencies; and other stakeholders. At present, IPC voluntarily operates the project to protect habitat used by fall Chinook salmon for spawning (i.e., by eliminating flow fluctuations), and incubation (i.e., by providing enough flow to prevent the dewatering of redds downstream of the project). As part of an interim settlement agreement in the license proceedings, IPC has agreed to release about 237 thousand acre-feet (kaf) of water – primarily during July - to improve downstream migration conditions (flow) for juvenile fall Chinook salmon (Tucker 2005).

4.0 Survival Rates at Mainstem Federal and Non-Federal Hydro Projects

4.1 Adult Survival

Adult survival estimates presented in this document are based primarily on a simple, straight-forward "conversion rate" method which relies upon the detection and subsequent re-detection of PIT-tagged "known-origin" adults[16] as they migrate upstream through the fishways (some fitted with PIT tag detectors) at the mainstem hydro projects. Detection rates are typically $\geq$ 99% for an individual PIT tag detector and, because there are typically two or three detectors in series within each of the key fishways –virtually every PIT-tagged adult fish migrating upstream through a mainstem fishways is detected.[17]

Minimum adult survival estimates (or conversion rates) can be calculated as the number of fish re-detected at an upstream project divided by the number of fish initially detected at the downstream project of interest. Estimates of "natural" straying rates and of known harvest are also factored in and the resulting number is the proportion of fish that survived between the two projects. For details regarding this method and how "natural" stray rates and harvest rates were used in these analyses, the reader is advised to read the Adult Survival Estimate Appendix of NOAA's Supplemental Comprehensive Analysis (NMFS 2008a). Otherwise, these estimates capture all sources of mortality manifested within the identified reaches, including those resulting from the existence and operation of the FCRPS, as well as unquantifiable levels of mortality from other potential sources (e.g., unreported or delayed mortality caused by fisheries, marine mammal predator attacks, etc.) and unquantifiable levels of "natural" mortality (i.e., levels of mortality in the migratory corridor that would have occurred "naturally" without human influence).

Adult Survival – Federal Projects

Under the 2008 FCRPS Biological Opinion (NMFS 2008b), the federal action agencies are responsible for ensuring that the relatively high rates of survival currently observed in the Bonneville Dam to Lower Granite Dam (7 dams) reach for Snake River species and Bonneville Dam to McNary Dam (3 dam) reach for Upper Columbia River spring Chinook and steelhead is maintained or increased through 2018. Snake River species, for which the most information is available, were used as surrogates for Middle Columbia River steelhead, and Lower Columbia River species. The average survival estimates, annual estimates (ranges), and additional

[16] "Known-origin" means that the release locations for all PIT tagged juvenile fish are available in the PITAGIS data base – and the general area to which these fish are attempting to migrate as adults is also known.
[17] It should be noted that some adults may avoid detection by migrating past the dams via the locks at the federal projects. This is evidenced by individuals not being detected at a particular dam, but being detected at another dam upstream.

information are provided in Table 1 (Column 3 titled "Adult Surv. – FCRPS") and the information for Snake River and Upper Columbia River species is also summarized in the text below.

The average survival estimate for Snake River fall Chinook salmon between Bonneville Dam and Lower Granite Dam was 81% for those that migrated inriver as juveniles and approximately 75% for those that were transported as juveniles, equating to a per project survival (7 dams) of 97% and 96%, respectively.[18]

The average survival estimate for Snake River spring/summer Chinook salmon between Bonneville Dam and Lower Granite Dam was 91% for those that migrated inriver as juveniles and about 84% for those that were transported as juveniles, equating to a per project survival (7 dams) of 99% and 98%, respectively.

The estimated average survival of Snake River sockeye salmon between Bonneville Dam and Lower Granite Dam was 81% equating to a per project survival (7 dams) of about 97%. No estimate can be made with the available data for those fish transported as juveniles (see Table 1, footnote 3).

The average survival estimate for Snake River steelhead between Bonneville Dam and Lower Granite Dam was 90% for those that migrated inriver as juveniles and approximately 83% for those that were transported as juveniles, equating to a per project survival (7 dams) of 99% and 97%, respectively.

The average survival estimate for Upper Columbia River spring Chinook salmon between Bonneville Dam and McNary Dam was 90% (all of these fish migrate inriver as juveniles), equating to a per project survival (3 dams) of approximately 97%.

The average survival estimate for Upper Columbia River steelhead between Bonneville Dam and McNary Dam was 85% (all of these fish migrate inriver as juveniles), equating to a per project survival (3 dams) of 95%.[19]

---

[18] Average per project survival estimates are calculated as Average Survival Estimate ^ 1/n. Average per project survival estimates are useful because they allow for a comparison between species that migrate past different numbers of dams.

[19] Note: The apparent discrepancy between the survival rates of Upper Columbia River spring Chinook salmon and steelhead through a 3 dam reach and Snake River spring/summer Chinook salmon and steelhead through a 7 dam reach is noted in the 2008 FCRPS biological opinion. Reasonable and Prudent Alternative Action 52 requires an investigation into the possible causes of this apparent discrepancy (NMFS 2008b). Once a likely cause is identified, the Action Agencies, NOAA Fisheries and co-managing agencies will develop appropriate corrective actions and a monitoring plan to ensure that the differential survival is minimized or eliminated.

Adult Survival – Non-Federal Projects

Under the terms of the Middle Columbia Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island projects; and under the 2008 biological opinion for the Priest Rapids Project (Wanapum and Priest Rapids dams, NMFS 2008d), the Public Utility Districts must meet or exceed a per project survival of 98% for all adult migrants. At this time, it appears that the average per project survival between Priest Rapids and Wells Dam is 98.7% and 98.2% for Upper Columbia River spring Chinook salmon and steelhead, respectively. The average survival estimates, annual estimates (ranges), and additional information for Upper Columbia River species are provided in Table 1 (Column 4 titled "Adult Surv. – Mid-Columbia" and Column 5 titled "Adult Surv. - Total) and also summarized in the text below.

The average survival estimate for Upper Columbia River spring Chinook salmon migrating between Priest Rapids and the Wenatchee, Entiat, and Methow rivers is approximately 95%, 96%, and 97%, respectively. This survival multiplied by the Bonneville to McNary survival estimate[20] yields a Bonneville to Wenatchee, Entiat, and Methow river survival estimate of about 85%, 87%, and 88%.

The average survival estimate for Upper Columbia River steelhead migrating between Priest Rapids and the Wenatchee, Entiat, and Methow rivers is approximately 93%, 95%, and 96%, respectively. This survival multiplied by the Bonneville to McNary survival estimate[19] yields a Bonneville to Wenatchee, Entiat, and Methow river survival estimate of about 79%, 80%, and 82%.

4.2 Juvenile Survival

Juvenile survival levels are estimated for two periods (See Tables 2 and 3). The "Current" scenario generally translates to survivals recently observed or estimated (modeled using COMPASS) to have occurred due to operational and configuration changes at the mainstem hydroelectric projects through about 2006. The "Prospective" scenario generally translates to attaining survival levels (if not already attained or exceeded) that are required by the Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island projects; the 2008 biological opinion for the Priest Rapids project (Wanapum and Priest Rapids Dam) (NMFS 2008d); or modeled using COMASS for the 2008 FCRPS biological opinion (NMFS 2008b). Full attainment of these standards is expected when the FCRPS biological opinion is fully implemented from 2015 to 2018.

[20] A McNary to Priest Rapids (Hanford Reach) survival estimate has not yet been calculated, but is likely less than 100%.

Juvenile survival through the federal projects under both the "Current" and "Prospective" cases was estimated using NOAA Fisheries' COMPASS model. The COMPASS model was populated with the best empirically derived estimates of route-specific passage and survival rates available for juvenile Chinook or steelhead to reflect the "Current" configuration of the hydrosystem. The Federal Action Agencies assessed the likely benefits (specific survival improvements) that should result from additional dam configuration actions required in the 2008 FCRPS biological opinion and these improvements were included in the modeling runs of the "Prospective" scenario. Both the "Current" and "Prospective" configurations and operations were modeled across a 70-year (1928 through 2000) historical water record.

The model provides estimates of survival to below Bonneville Dam for inriver (and transported, if applicable) migrants, proportion of the migrants that would likely be transported (if applicable), and the arrival timing of migrants to the Bonneville dam tailrace for ESA-listed spring and summer Chinook salmon and steelhead from the Snake River, Upper Columbia River, and Middle Columbia River populations.[21] For the purpose of this module, the most relevant pieces of information are likely the survival estimates.

4.2.1 Juvenile Survival – Current

Estimates of "Current" juvenile survival through the federal projects, ranges of expected survival, and proportion of juveniles expected to be transported are provided in Table 2 (Column 3 - Juv. Survival – FCRPS). These results are broken into two categories (expected average flows at Lower Granite Dam of less than 65 kcfs or greater than >65 kcfs) for Snake River populations to display the likely effect of the "full transport" operation that would occur in the low flow years – which occurs in about 19% (13 of 70) of the years modeled. Estimates of survival for juveniles migrating from the Methow, Entiat and Wenatchee rivers are provided in Column 4 – Juv. Survival – Mid-Columbia; and combined survival estimates are provide in Column 5 – Juv. Survival – Total. A brief summary of this information is provided for spring migrating Snake River and Upper Columbia River Chinook salmon and steelhead populations in the text below.

The average juvenile survival estimate for Snake River spring/summer Chinook salmon is 56% in the LGR > 65 kcfs years and 37% in the LGR < 65 kcfs years. Estimates of the proportion transported are about 64% and 95% in these flow conditions, respectively.

[21] Insufficient data, primarily resulting from the multiple life-history strategies exhibited by Snake River fall Chinook salmon, was available to populate the COMPASS model to estimate juvenile fall Chinook survival through the FCRPS projects. Instead, NOAA Fisheries derived survival estimates from Fish Passage Center data (see NMFS 2008a and 2008b).

The average juvenile survival estimate for Snake River steelhead is 39% in the LGR > 65 kcfs years and 8% in the LGR < 65 kcfs years. Estimates of the proportion transported are about 79% and 94% in these flow conditions, respectively.

The average juvenile survival estimate for Upper Columbia River spring Chinook salmon is 67% through the four FCRPS dams in the lower Columbia River, and 68%, 71%, and 77% for juveniles migrating from the Methow, Entiat, and Wenatchee rivers through the three to five Middle Columbia projects. The total survival estimate for these populations to below Bonneville Dam is 45%, 47%, and 51%, respectively.

The average juvenile survival estimate for Upper Columbia River steelhead is 48% through the four FCRPS dams in the lower Columbia River, and 69%, 72%, and 75% for juveniles migrating from the Methow, Entiat, and Wenatchee rivers through the three to five Middle Columbia projects. The total survival estimate for these populations to below Bonneville Dam is 33%, 34%, and 36%, respectively.

4.2.2 Juvenile Survival – Prospective

Estimates of "Prospective" juvenile survival through the federal projects, ranges of expected survival, and proportion of juveniles expected to be transported are provided in Table 3 (Column 3 - Juv. Survival – FCRPS). These results are broken into two categories (expected average flows at Lower Granite Dam (LGR) of less than 65 kcfs or greater than >65 kcfs) to display the likely effect of the "full transport" operation that would occur in the low flow years – which occurs in about 19% (13 of 70) of the years modeled. Estimates of survival for juveniles migrating from the Methow, Entiat and Wenatchee rivers are provided in Column 4 – Juv. Survival – Mid-Columbia; and combined survival estimates are provide in Column 5 – Juv. Survival – Total. A brief summary of this information is provided for spring migrating Snake River and Upper Columbia River populations in the text below.

The average juvenile survival estimate for Snake River spring/summer Chinook salmon is 63% in the LGR > 65 kcfs years and 52% in the LGR < 65 kcfs years. Estimates of the proportion transported are about 64% and 95% in these flow conditions, respectively.

The average juvenile survival estimate for Snake River steelhead is 45% in the LGR > 65 kcfs years and 9% in the LGR < 65 kcfs years. Estimates of the proportion transported are about 74% and 89% in these flow conditions, respectively.

The average juvenile survival estimate for Upper Columbia River spring Chinook salmon is 73% through the four FCRPS dams in the lower Columbia River, and 72%, 75%, and 81% for juveniles migrating from the Methow, Entiat, and Wenatchee rivers through the three to five Middle Columbia projects. The total survival estimate for these populations to below Bonneville Dam is 53%, 55%, and 59%, respectively.

The average juvenile survival estimate for Upper Columbia River steelhead is 53% through the four FCRPS dams in the lower Columbia River, and 75%, 78%, and 81% for juveniles migrating from the Methow, Entiat, and Wenatchee rivers through the three to five Middle Columbia projects. The total survival estimate for these populations to below Bonneville Dam is 40%, 41%, and 43%, respectively.

Sources: NMFS' 1) Supplemental Comprehensive Analysis Document (May 5, 2008a); and 2) Biological Opinion – Consultation on Remand for Operation of the Federal Columbia River Power System, 11 bureau of Reclamation Projects in the Columbia Basin and ESA Section 10(a)(1)(A) Permit for Juvenile Fish Transportation Program (May 5, 2008b).

[1] Key to Dams: BON = Bonneville Dam, TDA = The Dalles Dam, JDA = John Day Dam, MCN = McNary Dam, PRD = Priest Rapids Dam, WAN = Wanapum Dam, RIS = Rock Island Dam, RRE = Rocky Reach Dam, WEL = Wells Dam, IHR = Ice Harbor Dam, LMN = Lower Monumental Dam, LGS = Little Goose Dam, and LGR = Lower Granite Dam.

[2] These estimates are based on detections of known origin fish returning to the Columbia River, detected passing Bonneville Dam, and redetected at upstream locations. These estimates have been adjusted to account for estimated harvest and "natural" straying rates of adults within the FCRPS migration corridor, but otherwise capture all other sources of mortality manifested within the identified reaches, including those resulting from the existence and operation of the FCRPS, unquantifiable levels of mortality from other potential sources (e.g., unreported or delayed mortality caused by fisheries, marine mammal predator attacks, etc.), and unquantifiable levels of "natural" mortality (i.e. levels of mortality in the migratory corridor that would have occurred "naturally" without human influence).

[3] Adult survival rates for SR fall Chinook, SR spr/sum Chinook, and SR steelhead are reported separately as either inriver or transported (via barge or truck) to properly reflect their migration history as juveniles. Survival estimates for adult SR sockeye are primarily based on unknown origin (though likely from the Lake Wenatchee or Okanogan River sockeye populations) adults PIT tagged at Bonneville Dam and detected at McNary Dam. The average per dam survival is expanded to a seven dam reach (Bonneville Dam to Lower Granite Dam).

[4] The estimates for these ESUs only apply to those adults migrating to tributaries entering the reservoir upstream of Bonneville Dam, or in the case of MCR steelhead, the adult populations migrating to tributaries entering the Columbia River between Bonneville Dam and McNary Reservoir.

[5] Recent adult survival estimates from Priest Rapids to Wells dam are reported in Anchor Env. and Douglas PUD (2008): 93.0% and 94.7% for summer steelhead (2004-2007) and spring Chinook salmon (2003-2007), respectively. The average per project survival estimates ($1/4^{th}$ root of the reach survival estimate) are 98.2% for steelhead and 98.7% for spring Chinook.

[6] NOTE: A separate estimate for the McNary Dam to Priest Rapids Dam reach has not yet been generated. This will be addressed in the next update of the Recovery Planning Hydro Module.

[7] Within the Bonneville pool, Klickitat River and 15 Mile Creek populations of steelhead are part of the Mid Columbia River steelhead Distinct Population Segment.

[8] Within the Bonneville pool, Hood River and Wind River populations of steelhead are part of the Lower Columbia River steelhead Distinct Population Segment.

Sources: NMFS' 1) Supplemental Comprehensive Analysis Document (May 5, 2008a); and 2) Biological Opinion – Consultation on Remand for Operation of the Federal Columbia River Power System, 11 bureau of Reclamation Projects in the Columbia Basin and ESA Section 10(a)(1)(A) Permit for Juvenile Fish Transportation Program (May 5, 2008b).

[1] Key to Dams: BON = Bonneville Dam, TDA = The Dalles Dam, JDA = John Day Dam, MCN = McNary Dam, PRD = Priest Rapids Dam, WAN = Wanapum Dam, RIS = Rock Island Dam, RRE = Rocky Reach Dam, WEL = Wells Dam, IHR = Ice Harbor Dam, LMN = Lower Monumental Dam, LGS = Little Goose Dam, and LGR = Lower Granite Dam.

[2] The estimates for these ESUs only apply to those juveniles migrating from tributaries entering the reservoir upstream of Bonneville Dam, or in the case of MCR steelhead, the juvenile populations migrating from tributaries entering the Columbia River between Bonneville Dam and McNary Reservoir.

[3] Current reach survival estimates for the Mid-Columbia projects are based on the following:

- ***Wells (96.2% for spring Chinook and steelhead)*** - average of the 1998 (99.7%) Chinook study, and 1999 (94.3%) and 2000 (94.6%) steelhead studies as reported in NMFS 2002;

- ***Rocky Reach (92.1% for spring Chinook)*** – average of 2004-2005 studies (93.0% and 91.1%, respectively) as reported in Skalski et al (2006), and ***(95.8% for steelhead)*** - average of 2004-2006 studies (98.3%, 93.0%, and 96.0%, respectively) as reported in Anchor Env. and Chelan PUD (2007) and Skalski et al (2006);

- ***Rock Island (93.4% for spring Chinook)*** – average of 2002-2004 studies (95.6%, 93.4%, and 91.4%, respectively) as reported in Anchor Env. and Chelan PUD (2004) and Skalski et al (2006), and ***(94.1% for steelhead)*** – average of 2004-2006 studies (96.6%, 91.6%, and 94.0%, respectively) as reported in Anchor Env. and Chelan PUD (2007) and Skalski et al (2006);

- ***Wanapum and Priest Rapids (82.0% for spring Chinook)*** – estimated using data from PIT tag studies conducted by Chelan PUD in 1998, 2001, 2002, and 2003 as reported in NMFS 2004 – Table A-2 (90.5% per project); and ***(79.5% for steelhead)*** - estimated using data from PIT tag studies conducted by Chelan PUD in 1999 and 2000 as estimated in NMFS 2004 – Table A-2 (89.1% per project).

[4] Williams et al. 2005 provided estimated survival rates ranging for PIT tagged SR sockeye migrating from Lower Granite to McNary Dams in 2000 to 2003. Of these years, 2001, is most representative of the <65 kcfs flow condition – though still conservative because little spill was provided at the mainstem dams for passage in that year. Survival in this year was estimated at 23.9 percent. The remaining years are representative of the >65 kcfs flow condition. Survival rates ranged from 39.7% to 72.5% (average of 56.1%) in these years. An average per project survival was estimated for this reach (LGR to MCN survival ^ (1/4) = 86.5% per project) and then expanded to a Lower Granite to Bonneville Dam (7 project) reach survival estimate (LGR to BON (per project survival estimate ^ 7 = 36.4%).

[5] Within the Bonneville pool, Klickitat River and 15 Mile Creek populations of steelhead are part of the Mid Columbia River steelhead Distinct Population Segment.

[6] Within the Bonneville pool, Hood River and Wind River populations of steelhead are part of the Lower Columbia River steelhead Distinct Population Segment.

Sources: NMFS' 1) Supplemental Comprehensive Analysis Document (May 5, 2008a); and 2) Biological Opinion – Consultation on Remand for Operation of the Federal Columbia River Power System, 11 bureau of Reclamation Projects in the Columbia Basin and ESA Section 10(a)(1)(A) Permit for Juvenile Fish Transportation Program (May 5, 2008b).

[1] Key to Dams: BON = Bonneville Dam, TDA = The Dalles Dam, JDA = John Day Dam, MCN = McNary Dam, PRD = Priest Rapids Dam, WAN = Wanapum Dam, RIS = Rock Island Dam, RRE = Rocky Reach Dam, WEL = Wells Dam, IHR = Ice Harbor Dam, LMN = Lower Monumental Dam, LGS = Little Goose Dam, and LGR = Lower Granite Dam.

[2] The estimates for these ESUs only apply to those juveniles migrating from tributaries entering the reservoir upstream of Bonneville Dam, or in the case of MCR steelhead, the juvenile populations migrating from tributaries entering the Columbia River between Bonneville Dam and McNary Reservoir.

[3] Prospective reach survival estimates for the Mid-Columbia projects are based on the following:

- ***Wells (96.2% for spring Chinook and steelhead)*** - average of the 1998 (99.7%) Chinook study, and 1999 (94.3%) and 2000 (94.6%) steelhead studies as reported in NMFS 2002;

- ***Rocky Reach (93.0% for spring Chinook)*** – assumes that the minimum survival requirement of the Rocky Reach Habitat Conservation Plan will be met (NMFS 2002), and ***(95.8% for steelhead)*** - average of 2004-2006 studies (98.3%, 93.0%, and 96.0%, respectively) as reported in Anchor Env. and Chelan PUD (2007) and Skalski et al (2006);

- ***Rock Island (93.4% for spring Chinook)*** – average of 2002-2004 studies (95.6%, 93.4%, and 91.4%, respectively) as reported in Anchor Env. and Chelan PUD (2004) and Skalski et al (2006), and ***(94.1% for steelhead)*** – average of 2004-2006 studies (96.6%, 91.6%, and 94.0%, respectively) as reported in Anchor Env. and Chelan PUD (2007) and Skalski et al (2006);

- ***Wanapum and Priest Rapids (86.5% for spring Chinook and steelhead)*** – assumes the minimum survival standard (93.0% per project) for these species will be achieved (NOAA 2004).

[4] Williams et al. 2005 provided estimated survival rates ranging for PIT tagged SR sockeye migrating from Lower Granite to McNary Dams in 2000 to 2003. Of these years, 2001, is most representative of the <65 kcfs flow condition – though still conservative because little spill was provided at the mainstem dams for passage in that year. Survival in this year was estimated at 23.9 percent. The remaining years are representative of the >65 kcfs flow condition. Survival rates ranged from 39.7% to 72.5% (average of 56.1%) in these years. An average per project survival was estimated for this reach (LGR to MCN survival ^ (1/4) = 86.5% per project) and then expanded to a Lower Granite to Bonneville Dam (7 project) reach survival estimate (LGR to BON (per project survival estimate ^ 7 = 36.4%). To estimate the expected increase in survival between the "current" and "prospective" conditions, these estimates were adjusted by the estimated survival improvement of SR steelhead in the >65 kcfs flow year condition (45.3% [Prospective] - 38.9% [Current] = 6.4%) resulting in an estimate of 42.8% (36.4% + 6.4%). This was also done for the <65 kcfs flow year condition (9.1% [Prospective] – 7.5% [Current] = 1.6%) resulting in an estimate of 9.8% (8.2% + 1.6%).

[5] Within the Bonneville pool, Klickitat River and 15 Mile Creek populations of steelhead are part of the Mid Columbia River steelhead Distinct Population Segment.

[6] Within the Bonneville pool, Hood River and Wind River populations of steelhead are part of the Lower Columbia River steelhead Distinct Population Segment.

Columbia River Estuary ESA Recovery Plan Module for Salmon and Steelhead

National Marine Fisheries Service
Northwest Region

January 2011

UNITED STATES DEPARTMENT OF COMMERCE
National Oceanic and Atmospheric Administration
NATIONAL MARINE FISHERIES SERVICE
PORTLAND OFFICE
1201 NE Lloyd Boulevard, Suite 1100
PORTLAND, OREGON 97232-1274

NOTE TO READERS:

This *Columbia River Estuary Recovery Plan Module* will be the basis of estuary recovery actions for Endangered Species Act-listed salmon and steelhead in the Columbia River Basin. The module will be incorporated by reference into recovery plans for listed Columbia Basin salmon evolutionarily significant units (ESUs) and steelhead distinct population segments (DPSs). It is important to have a unified set of actions for the Columbia River estuary to address the needs of all listed Columbia Basin ESUs and DPSs.

This *Columbia River Estuary Recovery Plan Module* was prepared for NOAA's National Marine Fisheries Service (NMFS) by the Lower Columbia River Estuary Partnership, (contractor) and PC Trask & Associates, Inc. (subcontractor).

DISCLAIMER:

Recovery plans delineate such reasonable actions as may be necessary, based upon the best scientific and commercial data available, for the conservation and survival of listed species. Plans are published by the National Marine Fisheries Service (NMFS), sometimes prepared with the assistance of recovery teams, contractors, State agencies, and others. Recovery plans do not necessarily represent the views, official positions, or approval of any individual or agencies involved in the plan formulation, other than NMFS. They represent the official position of NMFS only after they have been signed by the Assistant Administrator. Recovery plans are guidance and planning documents only; identification of an action to be implemented by any public or private party does not create a legal obligation beyond existing legal requirements. Nothing in this plan should be construed as a commitment or requirement that any Federal agency obligate or pay funds in any one fiscal year in excess of appropriations made by Congress for that fiscal year in contravention of the Anti-Deficiency Act, 31 U.S.C. 1341, or any other law or regulation. Approved recovery plans are subject to modification as dictated by new findings, changes in species status, and the completion of recovery actions.

Glossary

Accretion: The accumulation of sediment deposited by natural fluid flow processes.

Alevins: Salmonids at the life stage between egg and fry.

Amphipods: Benthic invertebrates, particularly the amphipod *Americorophium salmonis,* which is found in intertidal and shallow subtidal habitats of the Columbia River estuary and is seasonally important in the diet of juvenile salmonids.

Ancient marshes: Marshes formed between 6,000 and 10,000 years ago.

Bar: A ridge or succession of ridges of sand or other substances, especially a formation extending across the mouth of a river or harbor that may obstruct navigation.

Bathymetry: The measure of the depths of oceans, seas, or other large bodies of water.

Beach erosion: The carrying away of beach materials by wave action, tidal currents, littoral currents, or wind.

Beach nourishment: The process of replenishing a beach by artificial means, such as through deposition of dredged materials; also called beach replenishment or beach feeding.

Bedload: Sand that rolls and bounces along the surface of the riverbed, usually downstream, although there may be a small displacement toward deeper water caused by the side slopes of the riverbed. In sandy riverbeds, bedload transport shapes the bed into a series of sand waves.

Beneficial use: Placement or use of dredged material for some productive purpose. Examples of beneficial uses include habitat development, beach nourishment, aquaculture, parks and recreation, shoreline stabilization, and erosion control.

Benthic: Of or relating to the bottom of a body of water.

Buffer area: A parcel or strip of land that is designed and designated to permanently remain vegetated in an undisturbed and natural condition to protect an adjacent aquatic or wetland site from upland impacts, to provide habitat for wildlife.

Centennial marshes: Marshes formed over the last century.

Continental shelf: The zone bordering a continent extending from the line of permanent immersion to the depth (usually about 100 to 200 meters) at which there is a marked or steep descent toward greater depths.

Delta: An alluvial deposit, usually triangular, at the mouth of a river. It is normally built up only where there is no tidal or current action capable of removing the sediment as fast as it is deposited.

Deposition: The deposit of sediment in an area through natural means, such as wave action or currents, or mechanical means.

Detritus: A loose mixture of organic material (dead plants and animals) and inorganic material (rock fragments) that results directly from disintegration of the material.

Dikes: Earthen walls constructed to contain water; sometimes constructed around dredged material disposal sites but more commonly constructed as flood protection.

Dredging: The removal or redistribution of sediments from a watercourse.

Ecosystem: A community of organisms in a given area together with their physical environment and its characteristic climate.

El Niño/Southern Oscillation: A shorter term climate effect that alternates between cold and warm phases approximately every 3 to 7 years; is associated with a warm-water current that periodically flows southward along the coast of Ecuador, and the southern oscillation

in the atmosphere; affects climatic and ocean conditions throughout the Pacific region.

Emergent marsh: A wet, springy peatland that occurs along the edges of lakes and streams and is covered by grass-like sedges and fed by minerals washing in from surrounding lands.

Emergent vegetation: Rooted plants that can tolerate some inundation by water and that extend photosynthesis parts above the water surface for at least part of the year; emergent vegetation is intolerant of complete inundation over prolonged periods.

Estuarine turbidity maximum (ETM): A circulation phenomenon in an estuary that traps particles and promotes biochemical, microbial, and ecological processes that sustain an important pathway in the estuary's food web.

Estuary: A semi-enclosed coastal body of water with a free connection to the open ocean in which sea water is diluted with runoff from the land.

Exotic species: A non-native plant or animal deliberately or accidentally introduced into a habitat.

Fill: Sand, sediment, or other earth materials that are placed, deposited, or stockpiled.

Fingerling: A juvenile salmonid less than 1 year old.

Floodplain: A flat tract of land bordering a river, mainly in its lower reaches, and consisting of alluvium deposited by the river during flooding.

Fluvial: Involving running water; usually pertains to stream processes.

Forested wetlands: Wetlands that occur in palustrine and estuarine areas and possess an over story of trees, an understory of young trees or shrubs, and a herbaceous layer.

Freshet: High stream flow caused by rains or snowmelt and resulting in the sudden influx of a large volume of freshwater in the estuary.

Fresh water: Water that is less than 0.5 part salt per thousand.

Fry: Juvenile salmonids that have absorbed their egg sac.

Genetic diversity: Variation at the level of individual genes (polymorphism); provides a mechanism for populations to adapt to their ever-changing environment.

Habitat: The physical, biological, and chemical characteristics of a specific unit of the environment occupied by a specific plant or animal; the place where an organism naturally lives.

Habitat capacity: A category of habitat assessment metrics, including "habitat attributes that promote juvenile salmon production through conditions that promote foraging, growth, and growth efficiency, and/or decreased mortality" (Fresh et al. 2005).

Habitat connectivity: A measure of how connected or spatially continuous habitats occur in a larger ecosystem.

Habitat opportunity: A category of habitat assessment metrics that evaluate the capability of juvenile salmon to access and benefit from the habitat's capacity (Fresh et al. 2005).

High marsh: A wetland ecosystem influenced by a marsh surface elevation at approximately mean higher high water that is inundated by only the most extreme high tides and is characterized by salt-tolerant emergent vegetation.

Intertidal: Of or relating to the substrate that is exposed and flooded by tides; includes the associated splash zone.

In-water disposal: Placement of dredged material along the riverbed in or adjacent to the navigational channel or in designated in-water sites; commonly referred to as flow-lane disposal.

Limiting factor: Physical, chemical, or biological features that impede species and their independent populations from reaching viability status.

Littoral: Of, relating to, or situated or growing on or near a shore; especially of the sea.

Littoral current: A current running parallel to the beach and generally caused by waves striking the shore at an angle.

Low marsh: A wetland ecosystem characterized by salt-tolerant emergent vegetation and twice-daily inundation of high tides.

Macroinvertebrates: Invertebrates that are of visible size, such as clams and worms.

Marsh: An area of soft, wet, or periodically inundated land, generally treeless and usually characterized by grasses and other low growth.

Mean high water: The average height of all high waters over 19 years.

Mean higher high water: The average height of the higher of two unequal daily high tides over 19 years.

Mean low water: The average height of all low waters over 19 years.

Mean lower low water: The average height of the lower of two unequal daily low tides over 19 years.

Macrodetritus: Dead or dying matter from a plant or animal that is visible to the unaided eye; usually larger than 1 to 2 mm in diameter.

Microdetritus: Dead or dying matter from a plant or animal; usually smaller than 1 to 2 mm in diameter.

Navigational channels: Channels in estuaries and other water bodies that are created, deepened, and maintained by dredging to enable vessels to navigate safely between, into and out of ports, harbors, and marinas without running aground.

Nearshore: An indefinite zone extending seaward from the shoreline well beyond the breaker zone.

Ocean-type: Of or relating to salmonid juveniles that enter the estuary as fry or fingerlings and stay in the estuary for weeks or months before entering the ocean; examples are chum and subyearling Chinook.

Oligohaline: Of or relating to water having low salinity.

Overbank flooding: Out-of-bank flooding resulting from flow events that exceed the bankfull.

Over-water structures: Human-made structures, such as a pier, that extend over all or part of the surface of a body of water.

Pacific Decadal Oscillation: A longer term climate effect that alternates between cold and warm phases approximately every 30 years.

Pelagic: Pertaining to the open ocean.

Pinnipeds: Seals, sea lions, and walruses that belong to the taxonomic suborder called Pinnipedia, or the "fin-footed." Pinnipeds are carnivorous aquatic mammals that use flippers for movement on land and in the water. The pinnipeds referred to in this document are Pacific harbor seals, California sea lions, and Stellar sea lions.

Pier: A structure, usually of open construction, extending out into the water from the shore, to serve as a landing place, recreational facility, etc., rather than to afford coastal protection.

Piling: A long, heavy timber or section of concrete or metal that is driven into the earth or bottom of a water body to serve as a structural support or protection.

Pile dike: Two parallel rows of piling that are tied together and extend 300 to 500 feet into the river.

Pile dike field: Several pile dikes spaced about 1,200 to 1,500 feet apart, typically built to concentrate flow and stabilize the channel; within the dike field, current velocities are slowed and flow is deflected away from the river bank.

Plume: The layer of Columbia River water in the nearshore Pacific Ocean.

Polychlorinated biphenyls (PCBs): A group of synthetic, toxic industrial chemical compounds that are chemically inert and not biodegradable; they once were used in making paint and electrical transformers.

Polycyclic aromatic hydrocarbons (PAHs): A group of more than 100 different chemicals that are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances like tobacco or charbroiled meat.

Population: A distinct breeding unit of a species that exhibits similar life history strategies.

Redds: Spawning nests used by trout and salmon.

Revetment: A facing of stone, concrete, etc., to protect an embankment or shore structure from erosion by wave action or currents.

Salmonid: Any member of the family Salmonidae, which includes the salmon, trout, char, whitefishes, and grayling of North America.

Salmonid population viability: Measure of the status of anadromous salmonids that uses four performance criteria: abundance, productivity, spatial distribution, and diversity.

Sand: An unconsolidated mixture of inorganic soil (possibly including disintegrated shells and coral) consisting of small but easily distinguishable grains ranging in size from about 0.062 mm to 2.0 mm.

Sand waves: Waves of sand on the bottom of a riverbed that move in response to river discharge and bedload transport. In the Columbia, sand waves cover the riverbed and are typically 4 to 8 feet high and 300 to 400 feet long. When the river discharge is less than 300,000 cfs, sand waves move only a few feet per day; however, when discharge exceeds 400,000 cfs, sand wave movement can reach 20 feet per day or more.

Scour: The removal of underwater material by waves and currents, especially at the base or toe of a structure.

Sediment: Material in suspension in water or recently deposited from suspension; in the plural, all kinds of deposits from the waters of streams, lakes, or seas.

Sediment trapping: The capture of sediments behind structures such as dams and shoreline armoring, which restrict sediments from entering systems.

Shallows and flats: Areas from the 6-foot bathymetric contour line up to the edge of tidal marsh or swamp vegetation, or to mean higher high water where vegetation is absent.

Shoaling: A gradual decrease in water depth as the result of the accretion of sediments.

Smolts: Juvenile salmonids that have left their natal stream and are headed downriver toward the ocean.

Stream-type: Of or relating to salmonid juveniles that rear in freshwater for a year or more before entering the ocean.

Threat: A human action or natural event that causes or contributes to limiting factors; threats may be caused by past, present, or future actions or events.

Tidal marshes: Areas dominated by emergent vegetation and low shrubs; are typically found from mean lower low water to slightly above mean higher high water, although they are rare at the lowest elevations.

Tidal prism: The difference in the volume of water covering an area, such as a wetland, during low tide and the volume covering it during the subsequent high tide.

Tidal swamps: Shrub- and forest-dominated wetlands that extend up to the line of non-aquatic vegetation (the line at which excess water ceases to be a factor controlling the composition of the vegetation); tidal swamps may be of sufficiently high elevation that they are inundated only during spring tides, but they may also extend down below mean higher high water.

Tide: The periodic rising and falling of the water that results from gravitational attraction of the moon and sun acting on the rotating earth.

Turbidity: A condition in bodies of water where high sediment loads cause clouding of the water to varying extents; turbidity is an optical phenomenon and does not necessarily

have a direct linear relationship to particulate concentration.

Viable salmonid population: An independent population of Pacific salmon or steelhead trout that has a negligible (generally ≤5 percent) risk of extinction over a 100-year timeframe.

Executive Summary

What is the Estuary Recovery Module?

This estuary recovery plan module is one element of a larger regional planning effort to develop recovery plans for Endangered Species Act-listed salmon and steelhead trout in the Columbia River basin. Recovery plans are being developed for each of the 13 listed evolutionarily significant units (ESUs) in the Columbia.[1] Figure ES-1 shows the 13 listed ESUs in the Columbia River basin grouped by region. The regions include the Lower Columbia, Upper Willamette, Middle Columbia, Snake, and Upper Columbia River ESUs. Within each of the regions, the ESUs have unique geographical boundaries that are based on similarities among populations.

This estuary recovery plan module complements other recovery plans in the region. The planning area for the module is all tidally influenced areas of the Columbia River. The upstream boundary of this area is Bonneville Dam, at River Mile 146, and the downstream boundary includes the Columbia River plume.[2] With few exceptions, the module's focus is limited to habitat conditions and processes in the Columbia River estuary and plume, rather than hatchery or harvest practices, hydroelectricity production, or tributary habitats in the Columbia River basin. The goal of the module is to identify and prioritize management actions that, if implemented, would reduce the impacts of limiting factors, meaning the physical, biological, or chemical conditions that impede salmon and steelhead survival during their migration through and rearing in the estuary and plume ecosystems. To accomplish this, changes in the physical, biological, or chemical conditions in the estuary are reviewed for their potential to affect salmon and steelhead. Then, the underlying causes of limiting factors are identified and prioritized based on the significance of the limiting factor and each cause's contribution to one or more limiting factors. These causes are referred to as threats and can be either human or environmental in origin. Finally, management actions are identified that are intended to reduce the threats and increase the survival potential of salmon and steelhead during estuarine rearing and migration. Costs are developed for each of the actions using an estimated level of effort to implement actions.

This estuary recovery plan module is intended to help answer questions about the degree to which the estuary and plume can contribute to salmon and steelhead recovery efforts throughout the Columbia River basin. The state of the science surrounding the estuary and plume is such that quantitative answers to questions about estuarine ecology are not necessarily available at this time. This is true in part because of the complexity of the ecological processes in the estuary and plume. However, it is also true because the Columbia River estuary and plume are only now being studied at a level of detail that

[1] NOAA's National Marine Fisheries Service (NMFS) has revised its species determinations for West Coast steelhead under the Endangered Species Act (ESA), delineating steelhead-only "distinct population segments" (DPSs). The former steelhead ESUs included both anadromous steelhead trout and resident, non-anadromous rainbow trout, but NMFS listed only the anadromous steelhead. The steelhead DPS does not include rainbow trout, which are under the jurisdiction of the U.S. Fish and Wildlife Service. In January 2006, NMFS listed five Columbia River basin steelhead DPSs as threatened (71 FR 834). To avoid confusion, references to ESUs in this estuary recovery plan module imply the steelhead DPSs as well.

[2] See Figures 1-1 and 1-2 for a depiction of the planning area.

allows knowledge about this portion of the Columbia River ecosystem to be integrated into the understanding of life history patterns that have been well documented in the upstream portions of the basin.

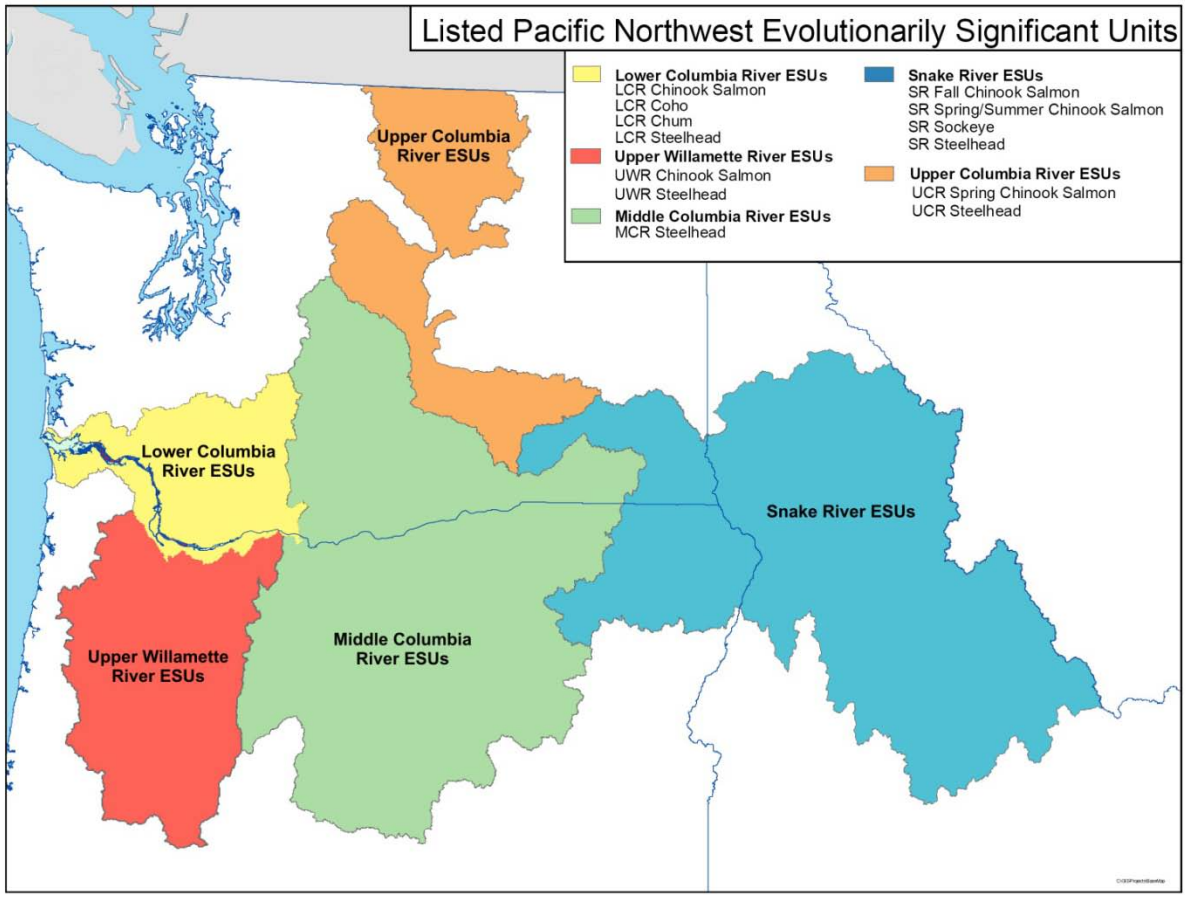

FIGURE ES-1
Listed Pacific Northwest ESUs

This estuary recovery plan module is a synthesis of diverse literature sources and the direct input of estuary scientists. The module was developed by the Lower Columbia Estuary Partnership and a private consultant, PC Trask & Associates, Inc. The primary author was PC Trask & Associates, Inc., with significant involvement from Lower Columbia River Estuary Partnership staff. The author used several key documents as a platform for the module. One of those documents is the "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan," which the Lower Columbia River Estuary Partnership developed, along with its supplement, for the Northwest Power and Conservation Council's *Columbia River Basin Fish and Wildlife Program* (Northwest Power and Conservation Council 2004). In 2005, the Northwest Fisheries Science Center of NOAA's National Marine Fisheries Service (NMFS) produced two important technical memoranda for the estuary: *Salmon at River's End* (Bottom et al. 2005) and *Role of the Estuary in the Recovery of Columbia River Basin Salmon and Steelhead* (Fresh et al. 2005). The author used these two memoranda extensively and consulted other sources as well, including many primary sources. Area experts from the

NMFS Northwest Fisheries Science Center and Northwest Regional Office, the Lower Columbia River Estuary Partnership, and the Lower Columbia Fish Recovery Board provided input and advice on scoring and evaluation processes. Additionally, the author briefed the Northwest Power and Conservation Council, Mid-Columbia Sounding Board, Upper Willamette Recovery Planning Stakeholder Team, and Lower Columbia River Recovery Planning Stakeholder Team and took their feedback into account when refining the module. Lastly, PC Trask & Associates, Inc., and Lower Columbia River Estuary Partnership staff worked with NMFS Northwest Regional Office staff to revise the module in response to comments received during the public comment period.

Why Are the Estuary and Plume Important?

The Columbia River estuary and plume represent one of three major stages in the life cycle of salmon and steelhead. In tributaries, adults spawn and juveniles rear in freshwater. In the ocean, juveniles grow to adults as they forage in food-rich environments. The estuary is where juveniles and adults undergo vast physiological changes needed to transition to and from saltwater. In addition, a properly functioning estuary provides high growth opportunities and refugia from predators.

But why are the estuary and plume so important? The answer lies in the very reason that salmonids grew in numbers to an estimated 16 million over the past 4,000 years. Salmon and steelhead were successful because they exploited a wide array of the habitat niches available to them. They did this by employing a variety of strategies that allowed them to use many diverse habitats across a wide geographic space. In fact, the distribution of salmon and steelhead historically spanned thousands of river miles throughout the basin.

If this were not remarkable enough, salmon and steelhead's traits allowed them to use habitats at varying times, and this is one of the primary reasons the estuary and plume are so important. Every downstream-migrating juvenile salmon or steelhead must use the habitats of the estuary to complete its life cycle. If the progeny of the 16 million adult salmon and steelhead that historically made use of the estuary had converged on the estuary at one time, there likely would not have been enough habitat and food to sustain them. So they developed strategies to enter the estuary at different times, at different sizes, using unique habitats. In fact, it has been hypothesized that each individual population's use of estuarine habitats is discrete in terms of time and location of use. The implication of this for the estuary and plume today is that the area's habitats must be available through time and space and at sufficient quantities to support more than 150 distinct salmon and steelhead populations, which represent 13 ESUs that use many diverse life history strategies.

The number of adult salmon and steelhead that return to the Columbia River basin each year varies, but in recent years, average returns have been about 1.7 million, with approximately 65 to 75 percent of those fish being of hatchery origin.[3] For 2006, scientists from the NMFS Northwest Fisheries Science Center estimated that about 168 million juveniles would enter the estuary (Ferguson 2006b). This suggests that only 1 percent of the juveniles entering the estuary will return as adults and 99 percent are lost as a result of all the limiting factors (human and natural) in the estuary, plume, nearshore, and ocean.

[3] This is an informal estimate; determining the ratio of hatchery-origin fish with more certainty would require stock-by-stock run calculations averaged over many years.

Understanding the extent to which the estuary and plume contribute to these losses is essential to the ultimate recovery of salmon and steelhead ESUs throughout the basin.

What Is the Condition of the Estuary Now?

Flows, Dikes and Filling, and Sediment

The estuary and plume are considerably degraded compared to 200 years ago. In terms of absolute size, the estuary tidal prism is about 20 percent smaller than it was when Lewis and Clark camped along the Columbia's shore (Northwest Power and Conservation Council 2004). This reduction in estuary size is due mostly to dike and filling practices used to convert the floodplain to agricultural, industrial, commercial, and residential uses. Instream flows entering the estuary also have changed dramatically—there has been a 44 percent decrease in spring freshets or floods, and the annual timing, magnitude, and duration of flows no longer resemble those that historically occurred in the Columbia River (Jay and Kukulka 2003). Changes to flow volume and timing are attributed to hydrosystem regulation; water withdrawal for agricultural, municipal, and industrial purposes; and climate fluctuations. Further alterations in flow are likely to occur during the next century as a result of global climate change, the effects of which are expected to include more precipitation falling as rain rather than snow, less snow storage, and—in the estuary—higher peak flows and reduced late-summer/early-fall stream flows (Independent Scientific Advisory Board 2007).

Flow alterations and dike and filling practices are significant to salmon and steelhead in several ways. Historically, vegetated wetlands within the floodplain supplied the estuary with its base-level food source: macrodetritus. The near elimination of overbank events and the separation of the river from its floodplain have altered the food web by reducing macrodetrital inputs by approximately 84 percent (Bottom et al. 2005). At the same time, phytoplankton detrital sources from upstream reservoirs now dominate the base of the food chain. The substitution of food sources likely has profound effects on the estuary ecosystem. In addition, access to and use of floodplain habitats by ocean-type ESUs (salmonids that typically rear for a shorter time in tributaries and a longer time in the estuary) have been severely compromised through alterations in the presence and availability of these critical habitats.

The timing, magnitude, and duration of flows also have important ramifications to in-channel habitat availability and connectivity. Sand transport along the river bottom is highly correlated to flow. With reductions in the magnitude and duration of flows, erosion and accretion processes no longer function as they have for thousands of years. This may have far-reaching consequences to the estuary, plume, and nearshore lands north and south of the river's mouth. At the same time, upstream dams have prevented sediments from entering the estuary, while dredging activities have exported sand and gravel out of the estuary. Studies have shown that sand is exported from the estuary at a rate three times higher than that at which it enters the estuary. The full impact of these changes is unknown; however, sediment transport is a primary habitat-shaping force that determines the type, location, and availability of habitats distributed in the estuary and plume. In addition, decreases in sediments have improved water clarity and increased the effectiveness of predators that consume juvenile and adult salmon and steelhead.

Water Quality

Water quality in the estuary and plume has been degraded by human practices from within the estuary and also from upstream sources. Today, elevated water temperatures and toxic contaminants both pose risks to salmon and steelhead in the estuary. Summer water temperatures entering the estuary are on average 4° F (2.2° C) warmer today than they were in 1938 (Lower Columbia Fish Recovery Board 2004). The upper thermal tolerance range for cold-water fish, including salmon and steelhead, is about 20° to 24° Celsius (68° to 75° Fahrenheit). Temperatures exceeding this threshold have been occurring earlier in the year and more frequently since 1938 (as measured at Bonneville Dam). Degradation of tributary riparian habitat caused by forest, residential, commercial, and industrial practices, as well as reservoir heating and global climate change are responsible for increased temperatures. During the next century, it is likely that the expected effects of global climate change will continue to increase water temperatures.

Another important indicator of water quality degradation in the estuary is the presence of toxic contaminants. One study of contaminant impacts on juvenile salmon estimated disease-induced mortalities of 1.5 and 9 percent as a result of contaminant stressors for residencies in the Columbia River estuary of 30 to 120 days, respectively (Loge et al. 2005). If this estimate is accurate, threats from contaminants may exceed those from Caspian tern predation.

Toxic contaminants are widespread in the estuary, both geographically and in the food chain, with the urban and industrial portions of the estuary contributing significantly to juvenile salmon's toxic load (Lower Columbia River Estuary Partnership 2007). Some of these contaminants are water-soluble agricultural pesticides and fertilizers, such as simazine, atrazine, and diazinon. Industrial contaminants include polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs). Also present are pharmaceuticals, personal care products, brominated fire retardants, and other emerging contaminants. Concentrations of toxic contaminants in the bodies of juvenile salmonids in the estuary sometimes are above levels estimated to cause health effects. In a 2007 study, this was the case for PCBs, PAHs, and DDT, and juveniles showed evidence of exposure to hormone-disrupting compounds (Lower Columbia River Estuary Partnership 2007). Salmon and steelhead experience both short-term exposure to toxic substances and long-term exposure to contaminants that accumulate over time and magnify through the food chain. Even when exposures are sublethal, they can cause significant developmental, behavioral, health, and reproductive impairments. Ocean-type ESUs are more susceptible to bioaccumulation than stream-type ESUs; however, both are equally vulnerable to acute exposures (stream-type ESUs are those ESUs that typically spend longer periods in tributaries and less time in the estuary).

Food Web and Species Interactions

The Columbia River estuary represents a distinct ecosystem that is a unique expression of biological and physical interactions. As physical and biological changes occur in the estuary, the ecosystem responds to those changes. There is general agreement that the estuary ecosystem is degraded and no longer provides the same level of support to native species assemblages that it did historically. Unfortunately, this field of research is perhaps the least understood, and its impact on salmon and steelhead is not well documented or studied.

Limiting factors related to the food web and species interactions can be thought of as the product of all the threats to salmon and steelhead in the estuary. Some examples of food web and species interactions-related limiting factors are easy to understand, but others are subtle and far-reaching. Caspian terns are a good example of an ecosystem shift that is easy to understand. New islands formed through the disposal of dredged materials attracted terns away from their traditional habitats, which may be being degraded. Reduced sediment in the river may have increased terns' efficiency in capturing steelhead juveniles migrating to saltwater at the same time that the birds need additional food for their broods. The result is a predator/prey shift in the estuary that has increased mortality for steelhead juveniles. Double-crested cormorants also prey on juvenile salmonids, in similar numbers as terns.

Other shifts in the ecosystem are more complex, and it can be difficult to understand whether or how they affect salmon and steelhead. For example, the shift in the food base of the estuary—from local macrodetrital sources to imported microdetrital sources such as phytoplankton—has fundamentally changed the food web and species relationships; however, what this means to salmon and steelhead—or, for that matter, to the entire estuarine ecosystem—is unknown. The introduction of exotic species is another poorly understood ecosystem alteration. Examples of exotic species thriving in the estuary include 21 new invertebrates, such as Asian clams and copepods, plant species such as Eurasian water milfoil, and exotic fish such as shad. Shad in particular, because of the sheer tonnage of their biomass, undoubtedly play a large role in the degradation of the estuary ecosystem and may compete with juvenile salmonids for food resources. Natural-origin juvenile salmonids may compete with large pulses of hatchery fish for food and space in the estuary if they overlap in space and time. Given the decreases in habitat opportunity and capacity in the estuary, it may be that too many fish—both salmonids and other species—are competing for too few estuarine resources at key times, with the resulting stressors translating into reduced salmonid survival. It is likely that this density-dependent mortality is manifesting itself in the estuary through limiting factors such as reduced off-channel habitat availability, competition with other fish species, and predation by fish and birds.

Other Threats

The estuary also is influenced by a number of physical structures that contribute to its overall degradation, but the extent of their impacts to salmon and steelhead is poorly understood. Over-water and instream structures in the estuary number in the thousands and alter river circulation patterns, sediment deposition, and light penetration; they also form microhabitats that often benefit predators. In some cases, structures reduce juvenile access to low-velocity habitats. Examples of structures include jetties, pilings, pile dikes, rafts, docks, breakwaters, bulkheads, revetments, groins, and ramps.

Ship wake stranding is an example of another threat to salmon and steelhead in the estuary. A study in 1977 by the Washington Department of Fisheries estimated that more than 150,000 juvenile salmonids, mostly Chinook, were stranded on five test sites as a result of ship bow waves striking shorelines (Bauersfeld 1977). Additional studies since the Bauersfeld study have not documented the same level of mortality. Light Detection and Radar (LIDAR) analysis and results from a new study by the University of Washington and the Portland District of the U.S. Army Corps of Engineers may help characterize this threat in the near future. This threat is most detrimental to ocean-type juvenile fry that are less than 60 millimeters long and that rear inches from shore.

What Can We Do to Improve Salmon and Steelhead Survival?

Identification of Management Actions and Monitoring Activities

This estuary recovery module identifies 23 management actions to improve the survival of salmon and steelhead migrating through and rearing in the estuary and plume environments. Table ES-1 lists these management actions and shows their relationship to threats to salmonid survival; this information is presented by topic, rather than priority.

TABLE ES-1
Management Actions to Address Threats

	Threat	Management Action
Flow-related threats	Climate cycles and global climate change[2]	**CRE[1]-1:** Protect intact riparian areas in the estuary and restore riparian areas that are degraded.[2] **CRE-2:** Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.[2] **CRE-3:** Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.[2]
	Water withdrawal	***CRE-3:*** *Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries*
	Flow regulation	**CRE-4**: Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume. ***CRE-3:*** *Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.*
Sediment-related threats	Entrapment of fine sediment in reservoirs	**CRE-5:** Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.
	Impaired transport of coarse sediment	**CRE-6:** Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially. **CRE-8:** Remove or modify pilings and pile dikes with low economic value when removal or modification would benefit juvenile salmonids and improve ecosystem health. ***CRE-4:*** *Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.*
	Dredging	**CRE-7:** Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.

[1] CRE = Columbia River estuary.

[2] Study of the impacts of global climate change is an evolving field, and additional research is needed to understand the phenomenon's likely effects on estuarine habitats and processes with specificity. At this time, the Independent Scientific Advisory Board of the Northwest Power and Conservation Council expects that the regional effects of global climate change in the next century will include more precipitation falling as rain rather than snow, reduced snow pack, and late-summer/early-fall stream flows, and associated rises in stream temperature (Independent Scientific Advisory Board 2007). The climate-related management actions in Table ES-1 reflect these expected impacts. Although the management actions clearly would not change the threat of global climate change itself, they have the potential to lessen its impact on salmonids in the estuary. Even if climate cycles and global climate change have effects different from those assumed in this document, the management actions that Table ES-1 associates with climate would provide benefits to salmonids by addressing other threats, such as water withdrawal, urban and industrial practices, and reservoir heating. All three of the management actions associated with climate in Table ES-1 are associated with other threats listed in Table ES-1.

Note: Italics indicate an action's second occurrence in the table, in connection with a different threat.

Threat		Management Action
Structural threats	Pilings and pile dike structures	***CRE-8:*** *Remove or modify pilings and pile dikes with low economic value when removal or modification would benefit juvenile salmonids and improve ecosystem health.*
	Dikes and filling	**CRE-9:** Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat. **CRE-10:** Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.
	Reservoir-related temperature changes	***CRE-2:*** *Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.*
	Over-water structures	**CRE-11:** Reduce the square footage of over-water structures in the estuary.
Food web-related threats	Increased phytoplankton production	***CRE-10:*** *Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.*
	Altered predator/prey relationships	**CRE-13:** Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids. **CRE-14:** Identify and implement actions to reduce salmonid predation by pinnipeds. **CRE-15:** Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants. **CRE-16:** Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island. **CRE-17:** Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations. **CRE-18:** Reduce the abundance of shad in the estuary. ***CRE-8:*** *Remove or modify pilings and pile dikes with low economic value when removal or modification would benefit juvenile salmonids and improve ecosystem health.*
	Ship ballast practices	**CRE-19:** Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations ***CRE-7:*** *Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.*
Water quality-related threats	Agricultural practices	**CRE-20:** Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.[3] ***CRE-1:*** *Protect intact riparian areas in the estuary and restore riparian areas that are degraded.* ***CRE-9:*** *Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.*
	Urban and industrial practices	**CRE-21:** Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants. **CRE-22:** Restore or mitigate contaminated sites. **CRE-23:** Implement stormwater best management practices in cities and towns.[3] ***CRE-1:*** *Protect intact riparian areas in the estuary and restore riparian areas that are degraded.* ***CRE-9:*** *Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.*
Other threats	Riparian practices	***CRE-1:*** *Protect intact riparian areas in the estuary and restore riparian areas that are degraded.*
	Ship wakes	**CRE-12:** Reduce the effects of vessel wake stranding in the estuary.

[3] Unless otherwise noted, the term *best management practices* is used in this document to indicate general methods or techniques found to be most effective in achieving an objective. NMFS envisions that in implementation, specific best management practices would be developed or recommended.

Research, monitoring, and evaluation (RME) needs related to the 23 management actions are discussed in Chapter 6. As noted there, some of these needs are addressed in an existing document, *Research, Monitoring, and Evaluation for the Federal Columbia River Estuary Program* (Johnson et al. 2008), while others are identified as new needs specific to the management actions in the module. Together, the existing and new RME activities will provide crucial information on salmonid performance in the estuary, the effectiveness of actions that are implemented in the estuary, associated changes in the ecology of the estuary, and scientific uncertainties that affect implementation of the actions.

Evaluating Management Actions: Relationship of Implementation Constraints to Cost and Survival Improvements

Identifying management actions that could reduce threats to salmon and steelhead as they rear in or migrate through the estuary is an important step toward improving conditions for salmonids during a critical stage in their life cycles. However, actual implementation of management actions is constrained by a variety of factors, such as technical, economic, public health and safety, and property rights considerations. In fact, in some cases it will be impossible to realize an action's full potential because its implementation is constrained by past societal decisions that are functionally irreversible. For example, reclaiming off-channel habitats in the lower Cowlitz River floodplain is constrained by the development of the city of Longview decades ago. An important assumption of the estuary recovery plan module is that the implementation of each of the 23 management actions identified in the module is constrained in some manner.

The module makes another important assumption about implementation: although implementation of actions is constrained, even constrained implementation can make important contributions to the survival of salmonids in the estuary and plume.

It is within the context of these two fundamental assumptions that recovery actions are evaluated in the module, in terms of their costs and potential benefits. The evaluation of survival benefits and costs is highly uncertain because it relies on estimates not only of what is technically feasible, but also of what is socially and politically practical. To help characterize survival improvements, the estuary recovery module uses a planning exercise that involves distributing a plausible survival target across the actions to hypothesize a potential amount of improvement that would result from each action. Costs then are developed by identifying projects for each action and units and per-unit costs for each project. Both the survival improvements and costs reflect assumptions about the constraints to implementation and the degree to which those constraints can be reduced given the technical, social, and political context in the Columbia River basin.

Evaluation Results

The estuary recovery plan module estimates the cost of constrained implementation of all 23 actions over a 25-year time period at $528.05 million. This represents an order-of-magnitude increase over the current level of investment in the estuary and reflects a significant level of effort needed to improve ecosystem health in the estuary and plume over the next 25 years. An additional $64.1 million is identified in Chapter 6 for research, monitoring, and evaluation activities. This effort is necessary because (1) scientific understanding of the estuary and how salmonids respond to conditions there is not yet

mature, and (2) the module proposes some innovative management actions whose effectiveness should be explored before they are fully implemented. Thus the total implementation costs for the module are $592.15 million.

Table ES-2 shows the most important management actions for ocean- and stream-type salmonids that emerged from the analysis and planning exercises in the estuary recovery plan module. Many of these key actions are the same for ocean and stream types.

Implementing the suite of key actions in Table ES-2 for ocean-type salmonids would cost approximately $392 million and be expected to achieve approximately 88 percent of the survival target for ocean-type juveniles. (See Chapter 5 for a description of survival targets.) Implementing the suite of key actions for stream-type salmonids would cost approximately $408 million and be expected to achieve 90 percent of the survival target. Additionally, an estimated annual gain of about 1,000 adult salmon and steelhead is associated with the implementation of CRE-14, "Reduce predation by pinnipeds." The lists of priority actions in Table ES-2 for ocean- and stream-type salmonids contain eight actions that are predicted to benefit both types of salmonids. Implementing this common set of actions would cost approximately $372 million and would be expected to yield survival improvements of roughly 3 million juveniles.

TABLE ES-2
Management Actions Most Important for Survival of Ocean- and Stream-type Salmonids

For Ocean Types	For Stream Types
CRE-01: Protect/restore riparian areas.	CRE-01: Protect/restore riparian areas.
CRE-04: Adjust the timing, magnitude, and frequency of hydrosystem flows.	CRE-04: Adjust the timing, magnitude, and frequency of hydrosystem flows
CRE-08: Remove or modify pilings and pile dikes.	CRE-08: Remove or modify pilings and pile dikes.
CRE-09: Protect/restore high-quality off-channel habitat.	CRE-09: Protect/restore high-quality off-channel habitat.
CRE-10: Breach, lower, or relocate dikes and levees.	CRE-10: Breach, lower, or relocate dikes and levees.
CRE-13: Manage pikeminnow and other piscivorous fish.	CRE-13: Manage pikeminnow and other piscivorous fish.
CRE-21: Identify and reduce sources of pollutants.	CRE-21: Identify and reduce sources of pollutants.
CRE-22: Restore or mitigate contaminated sites.	CRE-22: Restore or mitigate contaminated sites.
CRE-02: Mitigate/reduce reservoir-related temperature changes.	***CRE-14: Reduce predation by pinnipeds.***
	CRE-16: Redistribute Caspian terns.
	CRE-17: Redistribute cormorants.

Note: Bold-face italics indicate management actions that would benefit primarily ocean- or stream-type salmonids, rather than both types.

Other Implementation Considerations: Life History Diversity, Cost-Effectiveness, and Achieving Maximum Benefit

It is tempting to pick and choose among the management actions, looking for the path of least resistance to achieve the desired survival improvements. For example, using the results of the Chapter 7 survival improvement planning exercise, it appears obvious that significant improvements in the survival of stream-type salmonids can be achieved by reducing threats associated with predators such as terns, cormorants, pikeminnow, and pinnipeds. However,

addressing these threats would improve survival primarily for the dominant life-history strategy displayed by stream-type salmonids; in terms of recovery of ESUs, less dominant stream-type life history strategies also must be addressed. This points to the need to implement additional management actions in the estuary not directly related to predation.

For ocean-type juveniles, management actions that improve the health of the estuarine ecosystem appear to be the linchpin. Ocean-type juveniles reside in the estuary longer than stream types do. As a result, they rely more heavily on a healthy estuarine ecosystem to provide them with food and habitat (Bottom et al 2005). Given the challenges of making wide-scale ecosystem change, significant improvements for ocean-type juveniles may depend largely on three of the most constrained actions: adjusting hydrosystem flows (CRE–4), establishing or improving access to off-channel habitats (CRE-10), and restoring contaminated sites (CRE-22). Although these are some of the most expensive actions, their effects could be far-reaching enough that their potential benefits would be at least commensurate with their high costs.

Finally, because the estuary recovery module (by design) takes an optimistic view about what is possible in terms of reducing the constraints to implementation of management actions, in actuality specific actions probably will not be implemented with the level of effort needed to elicit the desired response. In fact, the most important take-home message of the estuary plan module is that recovery of listed ESUs in the Columbia River may not be possible without properly functioning estuary and plume ecosystems. To achieve a meaningful boost in survival from these ecosystems, every ounce of an action's potential benefit should be explored, and serious consideration should be given to implementing all of the 23 management actions to the fullest extent possible.

CHAPTER 1

The Columbia River Estuary and Plume

Purpose and Development of the Estuary Recovery Plan Module

This estuary recovery plan module is a planning document intended to complement other recovery plans in the region. With few exceptions, the module's focus is limited to habitat conditions and processes in the Columbia River estuary and plume, rather than hatchery or harvest practices, hydroelectricity production, or tributary habitats in the Columbia River basin. The purpose of this estuary recovery plan module is to identify and prioritize habitat-related management actions that, if implemented, would reduce threats to salmon and steelhead in the Columbia River estuary and plume.[1]

Chapter 2 provides background information on salmonid use of the estuary and plume within the context of the entire Columbia River basin. Chapter 3 identifies and prioritizes habitat-related salmon and steelhead limiting factors, and Chapter 4 links these limiting factors to the underlying environmental and human threats that have contributed to declines in abundance in the estuary. Chapter 4 also prioritizes threats based on the priority of the limiting factors they contribute to and their relative contribution to those limiting factors. Chapter 5 describes management actions that have the potential to reduce threats and evaluates the actions in terms of their implementation constraints, potential benefits, and costs. Chapter 6 describes research, monitoring, and evaluation needs, while Chapter 7 integrates elements of the earlier chapters to help characterize scenarios for improving the survival of salmonids as they rear in and migrate through the estuary and plume.

This estuary recovery plan module was developed by PC Trask & Associates, Inc., with participation of staff at the Lower Columbia River Estuary Partnership. The author also coordinated closely with staff at NOAA's National Marine Fisheries Service (NMFS) Northwest Regional Office throughout the module development process and obtained additional guidance and input from NMFS Northwest Fisheries Science Center staff and other regional experts (see Acknowledgements).

In drafting the module, the author reviewed and synthesized information from three main source documents:

- *Salmon at River's End: The Role of the Estuary in the Decline and Recovery of Columbia River Salmon* (Bottom et al. 2005)—Technical memorandum by the NMFS Northwest Fisheries Science Center

[1] Although current scientific information on the effects of limiting factors and actions does not differentiate between hatchery- and natural-origin salmon and steelhead, or between salmon and steelhead that are listed under the Endangered Species Act (ESA) and those that are not, the intent of the module is to improve the survival of ESA-listed salmon and steelhead. ESA recovery is determined by the status of naturally produced salmon and steelhead.

- *Role of the Estuary in the Recovery of Columbia River Basin Salmon and Steelhead: An Evaluation of the Effects of Selected Factors on Salmonid Population Viability* (Fresh et al. 2005)—Technical memorandum by the NMFS Northwest Fisheries Science Center
- "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" and its supplement—Northwest Power and Conservation Council (2004)

NMFS Northwest Regional Office staff considered these documents to be timely, comprehensive, and accurate summaries of existing scientific knowledge about the estuary; they proved particularly valuable in providing information about threats and limiting factors affecting salmonids in the estuary.

To clarify key points or address topics that were not included in Bottom et al. (2005), Fresh et al. (2005), and Northwest Power and Conservation Council (2004), the author reviewed additional literature and contacted researchers whose findings were relevant but as yet unpublished; this included researchers at the NMFS Northwest Fisheries Science Center. Area experts (see Acknowledgements) reviewed and helped refine the author's draft products; thus, the module relies heavily on expert opinion rather than an expert panel or "Delphi" process. The author also worked with NMFS Northwest Regional Office and Lower Columbia River Estuary Partnership staff to further revise the module based on comments received during a *Federal Register* public review period. In summary, the final module is a broader, more comprehensive document than the three key source documents and has evolved with input from a diversity of scientists, other specialists, and the public.

Although the estuary recovery plan module is scientifically based, it is primarily a planning document and has important relationships to other planning processes and documents in the region. In the context of Columbia River basin recovery planning, the estuary module provides information on how conditions in the estuary and plume affect the 13 listed Columbia Basin evolutionarily significant units (ESUs). It was distributed in draft form to recovery planning forums around the Columbia River basin, and presentations on the module were made to Oregon's Mid-Columbia Sounding Board, the Upper Willamette Recovery Planning Stakeholder Team, and the Oregon Lower Columbia River Recovery Planning Stakeholder Team.

In the context of lower Columbia River management plans, the estuary recovery plan module is consistent with information in the Northwest Power and Conservation Council's "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" (in *Columbia River Basin Fish and Wildlife Program*, Northwest Power and Conservation Council 2004), the Lower Columbia River Estuary Partnership's *Comprehensive Conservation and Management Plan*, and the Columbia River Estuary Study Taskforce's Columbia River Estuary Data Development Program. In addition, information in the module was used in the Federal Columbia River Power System (FCRPS) 2008 Biological Opinion (BiOp) and later incorporated into the 2010 Supplemental BiOp; information from the module also was used in Washington's Lower Columbia Fish Recovery Board planning process, Oregon's Lower Columbia River recovery planning process, and other recovery planning efforts throughout the Columbia River basin.

The process of identifying and prioritizing management actions in the estuary module has inherent difficulties. Although scientific knowledge about the estuary is advancing, it is still

incomplete. In addition, effective management solutions must acknowledge irreversible changes in estuary conditions over time, reflect the social and political will of the region, and focus on the biological and physical needs of the fish. In the final analysis, it is likely that science will never fully explain how every action affects the viability of fish. It will be up to current and future residents of the basin to determine how much they are willing to pay or do without in order to return salmon and steelhead to viable levels.

Formation and Current Characteristics of the Estuary

The geographic scope of the estuary recovery module encompasses areas from Bonneville Dam (River Mile [RM] 146; River Kilometer [RKm] 235) to the mouth of the Columbia River, including the Columbia River plume. The scope includes the lower portion of the Willamette River (from Willamette Falls, at RM 26.6 [RKm 42.6], to the Willamette's confluence with the Columbia River), along with the tidally influenced portions of other tributaries below Bonneville Dam. (Tidal portions of tributaries entering the estuary also are addressed in the Lower Columbia Fish Recovery Board's *Washington Lower Columbia Salmon Recovery and Fish & Wildlife Subbasin Plan* [2010] and Oregon's *Lower Columbia River Conservation and Recovery Plan for Oregon Populations of Salmon and Steelhead* [ODFW 2010] in a manner consistent with the overall framework of this module.)

The Columbia River estuary is a former river valley that, during the last ice age, was carved to 110 meters (360 feet) below current sea level. As sea levels subsequently rose, the floor of the valley was submerged and began to fill with sediments—initially from eastern drainages and then from the Cascade Range. The Missoula Floods, which occurred roughly 15,000 to 13,000 years ago, filled the valley with sand. This was followed by rapid sea level rise, which increased the size of the estuary and allowed further accumulation of mud and sand. By about 9,500 years ago, the rate of sea level rise had declined, the former river valley had filled with sediments, and most suspended sediment and bed load sand arriving from the Columbia River were being transported through the estuary to marine areas via the action of ebb tides and spring freshets, with some suspended sediment being deposited in floodplains and peripheral bays. This pattern continued to the historical period (Petersen et al. 2003).

The historical (circa 1880) total surface area of the Columbia River estuary has been estimated at up to 186 square miles (482 square kilometers) (Thomas 1983, Simenstad et al. 1984 as cited in Northwest Power and Conservation Council 2004). The current estuary surface area is approximately 159 square miles (412 square kilometers) (Northwest Power and Conservation Council 2004). The Willamette River is the largest tributary to the lower Columbia River. Other major tributaries originating in the Cascade Mountains include the Sandy River in Oregon and the Washougal, Lewis, Kalama, and Cowlitz rivers in Washington. Coastal range tributaries include the Elochoman and Grays rivers in Washington and the Lewis and Clark, Youngs, and Clatskanie rivers in Oregon. The general geography of the estuary is shown in Figure 1-1.

FIGURE 1-1
The Columbia River Estuary and Its Major Tributaries
(Reprinted from Bottom et al. 2005.)

Tidal impacts in water levels are observed as far upstream as Bonneville Dam at RM 146 (RKm 235). During low flows, reversal of river flow has been measured as far upstream as Oak Point at RM 53 (RKm 84.8). The intrusion of saltwater is generally limited to Harrington Point at RM 23 (RKm 36.8); however, at lower daily flows saltwater intrusion can extend past Pillar Rock at RM 28 (RKm 44.8).

Today, the lowest river flows occur during September and October, when rainfall and snowmelt are lowest (Northwest Power and Conservation Council 2004). The highest flows occur from April to June and result from snowmelt runoff. High flows also occur between November and March and are caused by heavy winter precipitation. Discharge at the mouth of the river typically ranges from 100,000 to 500,000 cubic feet per second (cfs). Historically, unregulated flows were both lower and higher—79,000 and 1 million cfs, respectively (Neal 1972 and Lower Columbia River Estuary Partnership 2002 as cited in Northwest Power and Conservation Council 2004).

Estuary Reaches

For the purposes of this estuary recovery plan module, the estuary is broadly defined to include the entire continuum where tidal forces and river flows interact, regardless of the

extent of saltwater intrusion (Fresh et al. 2005, Northwest Power and Conservation Council 2004). For planning purposes, the upstream boundary is Bonneville Dam and the downstream boundary includes the Columbia River plume. These two divisions—the estuary and plume—have been used extensively in this estuary recovery plan module as distinct zones. Further delineation of the estuary has occurred, including efforts by Thomas (1983), Johnson et al. (2003), and the Lower Columbia River Estuary Partnership (2005).

In this estuary recovery plan module, limiting factors, threats, and management actions are identified at the finest reach level possible. In some cases, this may be as general as making a distinction between the estuary and plume. In other cases, additional definition is available at the reach scale. The Lower Columbia River Estuary Partnership, in conjunction with the University of Washington and U.S. Geological Survey, has developed and is continuing to refine several estuary landscape classifications. Of these overlaying classifications, the estuary recovery module uses the Level 3 Stratum, which organizes the estuary between the mouth and Bonneville Dam into eight lettered reaches (Lower Columbia River Estuary Partnership 2005).

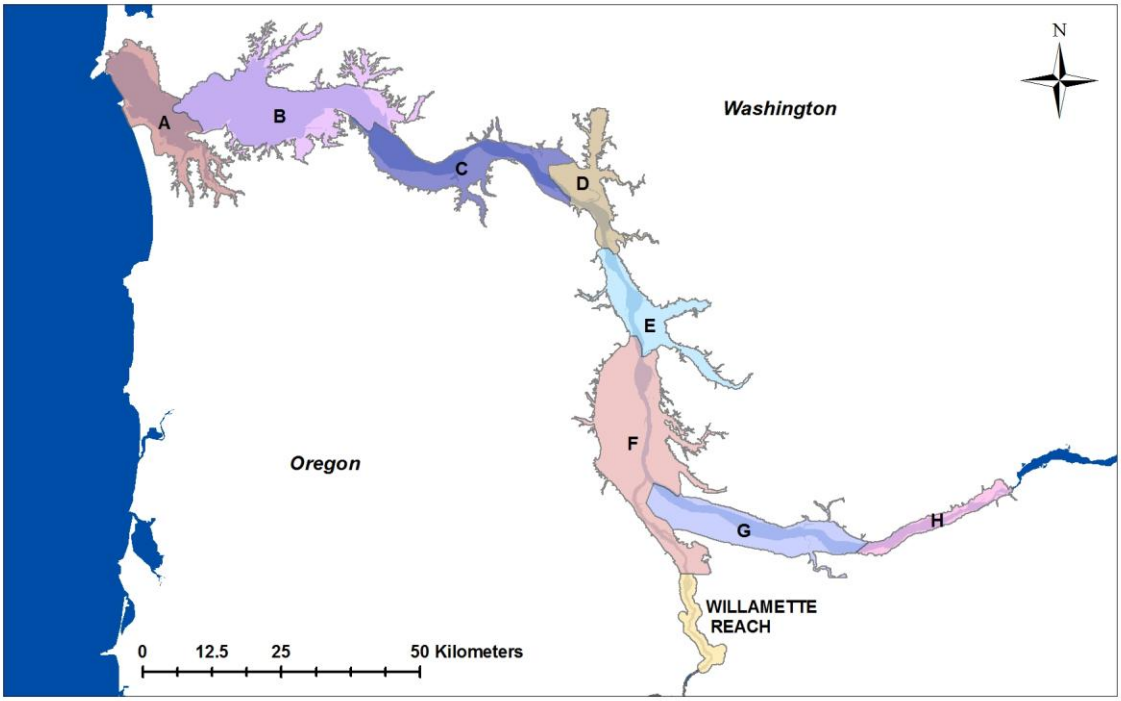

FIGURE 1-2
Lower Columbia River Estuary Reaches
(Adapted from Northwest Power and Conservation Council 2004.)

Figure 1-2 shows these eight reaches, which can be described briefly as follows:

- **Reach A**. This area includes the estuary entrance (Clatsop Spit and Trestle Bay), Bakers Bay, and Youngs Bay. The entrance is dominated by subtidal habitat and has the highest salinity in the estuary. Historically, the estuary entrance was a high-energy area of natural fluvial land forms with a complex of channels, shallow water, and sand bars.

Reach A supports the Columbia River plume, which creates a unique low-salinity, high-productivity environment that extends well into the ocean. The dynamic nature of the entrance area has changed as a result of dredging and the construction of jetties. These activities have limited wave action and the marine supply of sediment.

Historically, ocean currents and wave action made Bakers Bay a high-energy area, but both currents and wave action have been altered by dredging and jetty construction. The migration of mid-channel islands toward the interior of Baker Bay also has sheltered the area from wave action. As a result, tidal marsh habitat has recently started to develop in some areas, although much of the historical tidal marsh and tidal swamp habitat has been lost because of dike construction in the floodplain. Given its proximity to the river mouth, Baker Bay consists primarily of brackish water.

Youngs Bay is characterized by a broad floodplain and historically was abundant in tidal marsh and swamp habitat. Diking and flood control structures have been used to convert floodplain habitat in the area to pasture. The remaining fragmented tidal marsh and tidal swamp habitats in Youngs Bay are thought to be different in structure and vegetative community than historical conditions of these habitats.

- **Reach B**. Reach B generally extends from the Astoria-Meglar Bridge upstream to the westernmost tip of Puget Island. This area includes what has been referred to as the mixing zone (Northwest Power and Conservation Council 2004), along with Grays Bay and Cathlamet Bay. The mixing zone is an area characterized by a network of mid-channel shoals and flats, such as Desdemona and Taylor Sands. It also has the highest variation in salinity within the estuary because of the interactions between tide cycles and river flows. The estuarine turbidity maximum (see p. 3-8), which is created through these interactions, is often located within this area of Reach B. Many islands are found in Reach B, including Tenasillahe, Horseshoe, Marsh, Karlson, Russian, Svensen, Miller Sands, Rice, and Lois islands.

  Grays Bay is found on the Washington side of the river in Reach B. Historically, water circulation in this area was a result of interactions between river flow and tidal intrusion. Pile dike fields constructed adjacent to the main Columbia River navigation channel have decreased circulation in Grays Bay. This circulation change is suspected of causing flooding problems in the Grays and Deep River valley bottoms and may have promoted the beneficial development of tidal marsh habitat in the accreting bay. Dike construction, primarily for pasture conversion, has isolated the main channel from its historical floodplain and eliminated much of the historical tidal swamp habitat.

  Cathlamet Bay is located on the Oregon side of the river in Reach B. This area is characterized by some of the most intact and productive tidal marsh and swamp habitat remaining in the estuary, and a large portion of Cathlamet Bay is protected by the Lewis and Clark National Wildlife Refuge. The western edge of Cathlamet Bay contains part of the brackish oligohaline zone, which is thought to be important during the transition of juvenile anadromous fish from freshwater to saltwater. Portions of Cathlamet Bay have lost substantial acreage of tidal swamp habitat as a result of dike construction. Conversely, tidal marsh habitat has formed along the fringe of dredge disposal locations.

- **Reach C**. This area, which includes deep channels and steep shorelines on the Washington side of the river, extends from the westernmost tip of Puget Island to the western edge of Longview. Historically, Reach C contained significant acres of tidal swamp dominated by sitka spruce. Dike construction and clearing of vegetation have resulted in a substantial loss of tidal marsh habitat on islands and floodplain in the Oregon portion of Reach C. Lord Walker, Hump Fisher, Crims, Wallace and Puget islands are located within Reach C.
- **Reach D**. This area begins west of Longview and ends north of the city of Kalama. Reach D is distinct from the downstream reaches in its geology, vegetation, and climate. It includes flows from the Cowlitz and Kalama rivers. Extensive diking and filling around Longview and the mouth of the Kalama River have significantly reduced access to the floodplain. Islands and shoreline have been extensively modified through the disposal of dredged material. Sediment loading from eruptions of Mount St. Helens have significantly altered hydrology and channel morphology in and downstream of the Cowlitz and Kalama rivers. Dredging and the disposal of sediment from Mount St. Helens have been extensive. The two primary islands in Reach D are Cottonwood and Howard. High levels of polychlorinated biphenyls (PCBs) have been detected in the Longview and Kalama industrial area.
- **Reach E**. This area includes the Columbia River south of the city of Kalama to the confluence with the Lewis River, adjacent to the city of St. Helens, Oregon. The Lewis River system, including the North Fork and East Fork, flows into the Columbia River in Reach E. Sandy, Goat, Deer, Martin, and Burke islands are included in Reach E. Several of these islands, including Sandy and Goat islands, were created through the placement of dredged materials). Extensive diking has occurred on Deer Island and around the city of Woodland, Washington.
- **Reach F**. This area includes the Columbia River south of the confluence with the Lewis River up to and including the mid-point of Hayden Island. Reach F also extends into the Willamette River, to the downstream tip of Ross Island. Reach F is generally rural in character; however, it is located immediately downstream of the most urban/industrial areas in the entire Columbia River. Reach F contains the largest historical floodplain lakes below Bonneville Dam: Sturgeon Lake, at about 3,600 acres, and Vancouver Lake, which is approximately 2,400 acres. The historical floodplain was very wide in Reach F relative to the narrow and constricted channel through the Columbia River Gorge. Islands included in this reach are Bachelor and Sauvie islands. Sloughs include the 13-mile Lake River system and the more than 20-mile-long Multnomah Channel. Scappoose Bay is relatively undiked; however, Sauvie Island and Bachelor Island have been extensively diked. Reach F also includes Portland Harbor, a heavily industrialized stretch of the Willamette River located north of downtown Portland that was listed as a Superfund site in December 2000. Sediments in the river at this site are contaminated with various toxic compounds, including metals, polycyclic aromatic hydrocarbons (PAHs), PCBs, chlorinated pesticides, and dioxin (Oregon Department of Environmental Quality 2008).
- **Reach G**. This area includes the Columbia River west of Hayden Island and extends to just east of Reed Island. Major tributaries include the Washougal and Sandy rivers. The cities of Portland and Vancouver straddle the Columbia River in this reach. Islands included in this reach are Hayden Island, Government Island, Lady Island, and Reed

Island. Extensive diking has reduced the floodplain throughout the reach. Smith and Bybee lakes represent a large floodplain lake system similar to that of Vancouver and Sturgeon lakes in Reach F. Significant numbers of industrial piers and over-water structures line the Columbia rivers in this reach.

- **Reach H**. This area includes the Columbia River from east of Reed Island to the Bonneville Dam. This reach receives flow from many small tributaries, including Gibbons, Duncan, Hamilton, Hardy, and Multnomah creeks. Notable islands in this reach include Ackerman and Skamania islands. Reach H includes the entrance to the Columbia River Gorge, which is characterized by steep slopes. Little diking has occurred in this area, primarily because the steep adjacent slopes on both side of the river have naturally constrained the floodplain.
- **Lower Willamette Reach**. This reach extends upstream from the northern tip of Ross Island to Willamette Falls at RM 26.6 (RKm 42.6). The Lower Willamette reach is highly urbanized, bisecting the city of Portland and flowing past the cities of Milwaukie, Lake Oswego, Gladstone, and Oregon City. Notable islands in the Lower Willamette reach include Ross and Hardtack, Elk Rock, Hog, Cedar, and Goat islands. The primary tributary entering the Lower Willamette reach is the Clackamas River just downstream of Willamette Falls. Other smaller tributaries include Johnson, Tryon, Kellogg, Miller, and Stephens creeks. The shoreline of the Lower Willamette reach has been highly modified for industry, flood control, and other uses. Twelve transportation bridges cross the Willamette River in this reach.

GIS maps of each of the reaches are presented in Appendix A. The maps show additional information such as the locations of pile dikes and some tide gates, the navigation channel, the historical floodplain, diked areas, and dredged material placement sites.

Columbia River Plume

The Columbia River plume is generally defined by a reduced-salinity contour near the ocean surface of approximately 31 parts per thousand (Fresh et al. 2005). In high flows, the plume front is easily recognized by the sharp contrast between the sediment-laden river water and the clearer ocean (see Figure 1-3). The plume's location varies seasonally with discharge, prevailing near-shore winds, and ocean currents. In summer, the plume extends far to the south and offshore along the Oregon coast. During the winter, it shifts northward and inshore along the Washington coast. Strong density gradients between ocean and plume waters create stable habitat features where organic matter and organisms are concentrated (Fresh et al. 2005). The Columbia River plume can extend beyond Cape Mendocino, California, and influences salinity in marine waters as far away as San Francisco (Northwest Power and Conservation Council 2000). For the purposes of this estuary recovery plan module, the plume is considered to be off the immediate coasts of both Oregon and Washington and to extend outward to the continental shelf.

Major Land Uses

A variety of land uses are found adjacent to the Columbia River estuary. The area contains multiple cities and political jurisdictions, including Portland, which is Oregon's largest city, and Vancouver, the fourth largest Washington city. Smaller cities include Astoria,

Cathlamet, Longview, Kalama, Woodland, and Camas. Approximately 2.5 million people live in the vicinity of the estuary, and more are coming. Five deep-water ports in the area support a shipping industry that transports 30 million tons of goods annually (Lower Columbia Fish Recovery Board 2004), worth $13 billion each year (Columbia River Channel Improvement Reconsultation Project). Timber harvest occurs throughout the basin—six major pulp mills contribute to the region's economy. Until the early 2000s, aluminum plants along the river produced more than 40 percent of the country's aluminum. Agriculture is widespread throughout the floodplain and includes fruit and vegetable crops along with beef and dairy cattle. Commercial and recreational fishing activity plays an important role in local economies, bringing in millions of dollars of revenue each year. Primary outdoor recreational activities include fishing, wildlife observation, hunting, boating, hiking, and windsurfing.

Two Centuries of Change

Before Euro-American settlement of the Pacific Northwest, the Columbia River estuary and plume served as a physical and biological engine for salmon. Juveniles from hundreds of populations of steelhead, chum, Chinook, and coho entered the estuary and plume every month of the year, with their timing honed over evolutionary history to make use of habitats rich with food. A beach seine survey during any month of the year would likely have yielded salmon of all species and many populations, with individuals of many sizes. This genetic variation in behavior was an important trait that allowed salmon and steelhead

to occupy many habitat niches in time and space. It also guarded populations against catastrophic events such as volcanic eruptions (Bottom et al. 2005).

Today the Columbia River estuary and plume are much different. Notably, the North and South jetties at the mouth of the river restrict the marine flow of nutrients into the estuary. Dikes and levees lining the Washington and Oregon shores prevent access to areas that once were wetlands. New islands have been formed by dredged materials, and pile dike fields reach across the river, redirecting flows. Less visible but arguably equally important are changes in the size, timing, and magnitude of flows that, 200 years ago, regularly allowed the river to top its banks and provide salmon and steelhead with important access to habitats and food sources. Flow factors, along with ocean tides, are key determinants of habitat opportunity and capacity in the estuary and plume.

Salmon have thrived in the Columbia River for up to 1 million years (Lichatowich 1999). In the last 100 years, the entire Columbia River has undergone tremendous change as a direct result of people living and working in the basin. While the threats to salmon persistence are very diverse, at some level it is the increase in human population in the Northwest that underlies every human threat. There are an estimated 5 million people in the Columbia River basin today, and somewhere between 40 million and 100 million people are predicted to be living in the basin by the end of the twenty-first century (National Research Council 2004). If we want healthy salmon runs at the same time that our population is multiplying, our interactions with land and water must pose fewer threats to salmonids than they have in the last 100 years. Before identifying management actions that could do just that, this document discusses which salmonids currently use the Columbia River basin, and how.

CHAPTER 2

Salmonid Use of the Estuary and Plume

The estuary and plume provide salmonids with a food-rich environment where they can undergo the physiological changes needed to make the transition from freshwater to saltwater habitats, and vice versa. Every anadromous salmonid that spawns in the Columbia River basin undergoes such a transformation twice in its lifetime—the first time during its first year of life (or soon after) when migrating out to sea, and the second time 1 to 3 years later, as an adult returning to spawn. The transition zone where juvenile salmonids undergo this transformation is thought to extend from the estuary itself to the near-shore ocean and plume habitats and into rich upwelling areas near the continental shelf (Casillas 1999).

The estuary and plume also serve as rich feeding grounds where juveniles have the opportunity for significant growth as they make the important transition from freshwater to seawater. Studies have shown that juvenile salmon released within the estuary and plume returned as larger adults and in greater numbers than juveniles released outside the transition zone (Emmett and Schiewe 1997 as cited in Casillas 1999). Thus, although juvenile salmonids face risks from a variety of threats in the estuary and plume (see Chapter 4), these environments can be highly beneficial. In the salmon life cycle, successful estuarine and plume residency by juveniles is critical for fast growth and the transition to a saltwater environment.

Clearly, the Columbia River estuary and plume are uniquely important to salmonids, and conditions in the estuary and plume undoubtedly affect salmonid survival. Yet the estuary and plume represent just one in a series of ecosystems that salmon use in their complex life cycle. Exploring the connections among these ecosystems, the habitats they provide, the salmonid species that use them, and the variety of life histories those salmonids display sheds further light on the role of the estuary and plume in the salmonid life cycle.

Salmonid Species in the Columbia River Basin

Before Euro-American settlement, the Columbia River basin was used extensively by six species of the family Salmonidae and the genus *Oncorhynchus*: Chinook, chum, coho, and sockeye salmon plus two trout species: steelhead and sea-run cutthroat (Lichatowich 1999). Within these six species, 13 ESUs,[1] representing more than 150 populations of salmon and steelhead, have been listed as threatened or endangered under the Federal Endangered Species Act (Bottom et al. 2005). All 13 of the ESUs use the estuary and plume as an essential link in their far-reaching life cycles.

[1] NMFS has revised its species determinations for West Coast steelhead under the Endangered Species Act (ESA), delineating steelhead-only "distinct population segments" (DPSs). The former steelhead ESUs included both anadromous steelhead trout and resident, non-anadromous rainbow trout, but NMFS listed only the anadromous steelhead. The steelhead DPS does not include rainbow trout, which are under the jurisdiction of the U.S. Fish and Wildlife Service. In January 2006, NMFS listed five Columbia River basin steelhead DPSs as threatened (71 FR 834). To avoid confusion, references to ESUs in this estuary recovery plan module imply the steelhead DPSs as well.

It is estimated that historically up to 16 million salmon from perhaps hundreds of distinct populations returned to the Columbia River each year (Lichatowich 1999). This contrasts markedly with recent returns of salmon and steelhead adults, which have averaged about 1.7 million, with 65 to 75 percent of those fish being of hatchery origin.[2] For 2006, scientists from the NMFS Northwest Fisheries Science Center estimated that about 168 million juveniles would enter the estuary (Ferguson 2006b).[3] This suggests that only 1 percent of the juveniles entering the estuary will return as adults and 99 percent are lost as a result of all the limiting factors (human and natural) in the estuary, plume, nearshore, and ocean.

Life History Types and Strategies

In discussing salmonids, fish scientists commonly refer to ocean type and stream type to distinguish two main freshwater rearing strategies. Ocean-type salmonids are characterized by migration to sea early in their first year of life, after spending only a short period in freshwater (Fresh et al. 2005). Ocean types may rear in the estuary for weeks or months, making extensive use of shallow, vegetated habitats such as marshes and swamps, where significant changes in flow and habitat have occurred (Fresh et al. 2005). Conversely, stream-type salmonids are characterized by migration to sea after rearing for more extended periods in freshwater, usually at least 1 year (Fresh et al. 2005). Table 2-1 shows the general characteristics of ocean-type and stream-type ESUs.

TABLE 2-1
Characteristics of Ocean- and Stream-Type Salmonids

Attribute	Ocean-Type Fish: fall Chinook, chum	Stream-Type Fish: coho, spring Chinook, steelhead
Residency time	Short freshwater residence Longer estuarine residence Longer ocean residence	Long freshwater residence (>1 year) Shorter estuarine residence Shorter ocean residence
Size at estuary entry	Smaller	Larger
Primary habitat use	Shallow-water estuarine habitats, especially vegetated ones	Deeper, main-channel estuarine habitats; use plume more extensively

Adapted from Fresh et al. 2005.

In the Columbia River estuary, both ocean- and stream-type salmonids experience significant mortality. However, because the two types typically spend different amounts of time in the estuary and plume environments and use different habitats, they are subject to somewhat different combinations of threats and opportunities.

For ocean-type juveniles, mortality is believed to be related most closely to lack of habitat, changes in food availability, and the presence of contaminants, including persistent, bioaccumulative contaminants present in sediments in the shallow-water habitats where ocean-type juveniles rear in the estuary. Stream types are affected by these same factors, although presumably to a lesser degree because of their shorter residency times in the

[2] This is an informal estimate; determining the ratio of hatchery-origin fish with more certainty would require stock-by-stock run calculations averaged over many years.

[3] 2006 was a normative year and is considered representative.

estuary. However, stream types are particularly vulnerable to bird predation in the estuary because they tend to use the deeper, less turbid channel areas located near habitat preferred by piscivorous birds (Fresh et al. 2005), and they are subject to pinniped predation when they return to the estuary as adults (see Chapter 3). Also, scientists at the NMFS Northwest Fisheries Science Center now hypothesize that larger numbers of stream-type yearling juveniles are susceptible to predation by northern pikeminnow than was previously thought; this predation occurs as the juveniles move into the shallows behind structures such as pilings or pile dikes to forage (Casillas 2007); this and related hypotheses are in the process of being tested through a program initiated by the Federal action agencies (the U.S. Army Corps of Engineers, the U.S. Bureau of Reclamation, and Bonneville Power Administration) and the Lower Columbia River Estuary Partnership. Additionally, stream-type salmonids are thought to use the low-salinity gradients of the plume to achieve growth and gradually acclimate to saltwater. Changes in flow and sediment delivery in the plume may affect stream-type juveniles in a way similar to how estuary conditions affect ocean-type juveniles; however, additional research is needed to determine more precisely how stream types use the plume (Casillas 2006).

Fish scientists also describe salmonids in terms of the life history strategies they employ, meaning a population's unique pattern of preferred spawning substrate, habitat use, migration timing, length of estuarine and marine residency, and so on. For thousands of years, Columbia River salmonids exhibited great diversity in life history strategies, exploiting a wide array of the habitat niches available to them. This rich diversity in life history strategies allowed salmonids to persist as species for millennia even when individual populations were wiped out by disease or natural disturbances such as volcanic eruptions.

Table 2-2 identifies the six basic life history strategies used by salmon and steelhead in the Columbia River and their general attributes.

Changes in Life History Diversity

The 13 listed ESUs in the Columbia River express much less diversity in life history strategies now than they did historically. Formerly, both ocean- and stream-type salmonids entered the estuary and plume throughout the year, at a great variety of sizes, which reflected the various life history strategies in Table 2-2. Today juveniles tend to arrive in pulses and are more uniform in size.

Table 2-3 shows losses in life history diversity in the Columbia River. The table identifies the dominant life history type (ocean vs. stream) and strategies for each ESU, the prevalence of each life history strategy, and whether that prevalence has changed from historical times to the present. The number of life history strategies employed by some ESUs, such as Columbia River chum, have not changed. But for other ESUs—notably the Lower Columbia River coho—several life history strategies that used to exist have been lost. In a research project studying outmigration of juvenile Chinook salmon in the lower Willamette River, results indicated the presence of fry and fingerling juveniles in all months of the year. Although the specific ESUs of these juvenile salmon have not been confirmed, the results indicate more contemporary life history stages present than indicated in Table 2-3 (Friesen et al. 2007).

Losses in life history diversity can also be seen in Figure 2-1, which compares historical and current estuarine life history types for one brood year of Chinook salmon. The figure shows a reduction in the number of strategies available in the contemporary versus historical estimates.

Some of the losses in salmonid life history diversity are attributable to habitat alterations throughout the Columbia River basin that have eliminated entire populations of salmon and steelhead. In other cases, hatcheries and harvest impacts have reduced the health and genetic makeup of species. As a result, many of the populations currently using the estuary and plume are significantly different than the fish that historically used the various habitats available to them, and some existing habitats may not be being used by salmonids at all.

TABLE 2-2
Life History Strategies and Their Attributes

Life History Strategy	Attributes
Early fry	Freshwater rearing: 0 - 60 days Size at estuarine entry: <50 mm Time of estuarine entry: March - April Estuarine residence time: 0 - 40 days
Late fry	Freshwater rearing: 20 - 60 days Size at estuarine entry: <60 mm Time of estuarine entry: May - June, present through Sept. Estuarine residence time: <50 days
Early fingerling	Freshwater rearing: 60 - 120 days Size at estuarine entry: 60 - 100 mm Time of estuarine entry: April - May Estuarine residence time: <50 days
Late fingerling	Freshwater rearing: 50 - 180 days Size at estuarine entry: 60 - 130 mm Time of estuarine entry: June - October, present through winter Estuarine residence time: 0 - 80 days
Subyearling (smolt)	Freshwater rearing: 20 - 180 days Size at estuarine entry: 70 - 130 mm Time of estuarine entry: April - October Estuarine residence time: <20 days
Yearling	Freshwater rearing: >1 year Size at estuarine entry: >100 mm Time of estuarine entry: February - May Estuarine residence time: <20 days

Relationship of the Estuary to the Columbia River Basin

In 2005, scientists working at the NMFS Northwest Fisheries Science Center published a technical memorandum that establishes an ecologically based conceptual framework for understanding the estuary within the larger context of the Columbia River basin. In *Salmon*

at River's End: The Role of the Estuary in the Decline and Recovery of Columbia River Salmon, Bottom et al. (2005) hypothesize that Columbia River salmon's resilience to natural environmental variability is embodied in population and life history diversity, which maximizes the ability of populations to exploit available estuarine rearing habitats. Bottom et al.'s conceptual framework is based on Sinclair's (1988) member/vagrant theory, which proposes general principles for understanding marine species with complex life cycles. The member/vagrant theory serves as a useful tool for evaluating salmon's specific needs in estuaries in relation to the entire continuum of their habitat needs throughout their complex life cycles (Bottom et al. 2005).

Bottom et al. (2005) hypothesize that how an individual salmon or steelhead uses the ecosystems it encounters—when juveniles migrate, how big they are, what habitats they use, and how long they stay in a particular habitat—correlates directly to the discrete population of fish that individual is part of. In other words, different populations within ESUs employ different life history strategies. For example, two populations of steelhead within an ESU may produce juveniles of different sizes that enter the estuary at different times, and these juveniles may use distinct habitats that may be available only at that particular time.

Considering that the estuary is just one of three major ecosystems used by salmon and steelhead, the member/vagrant theory implies that how juveniles migrate and use estuarine habitat may depend as much on the status of upriver habitats and corresponding populations as on environmental conditions in the estuary itself (Bottom et al. 2005). In other words, if there is a close relationship between particular geographical features in the estuary and the life history of a discrete salmonid population, use of the estuary may reflect the abundance and life history strategy of the associated population, which is in part a function of upstream conditions. Thus, if salmonid migration and rearing behaviors in the estuary are linked to specific geographic features and those features are reduced or eliminated, mortality in the population that uses those features increases (Bottom et al. 2005). By the same token, if salmonid populations are lost because of other factors (such as blockage by dams), habitats in the estuary may be left unoccupied.

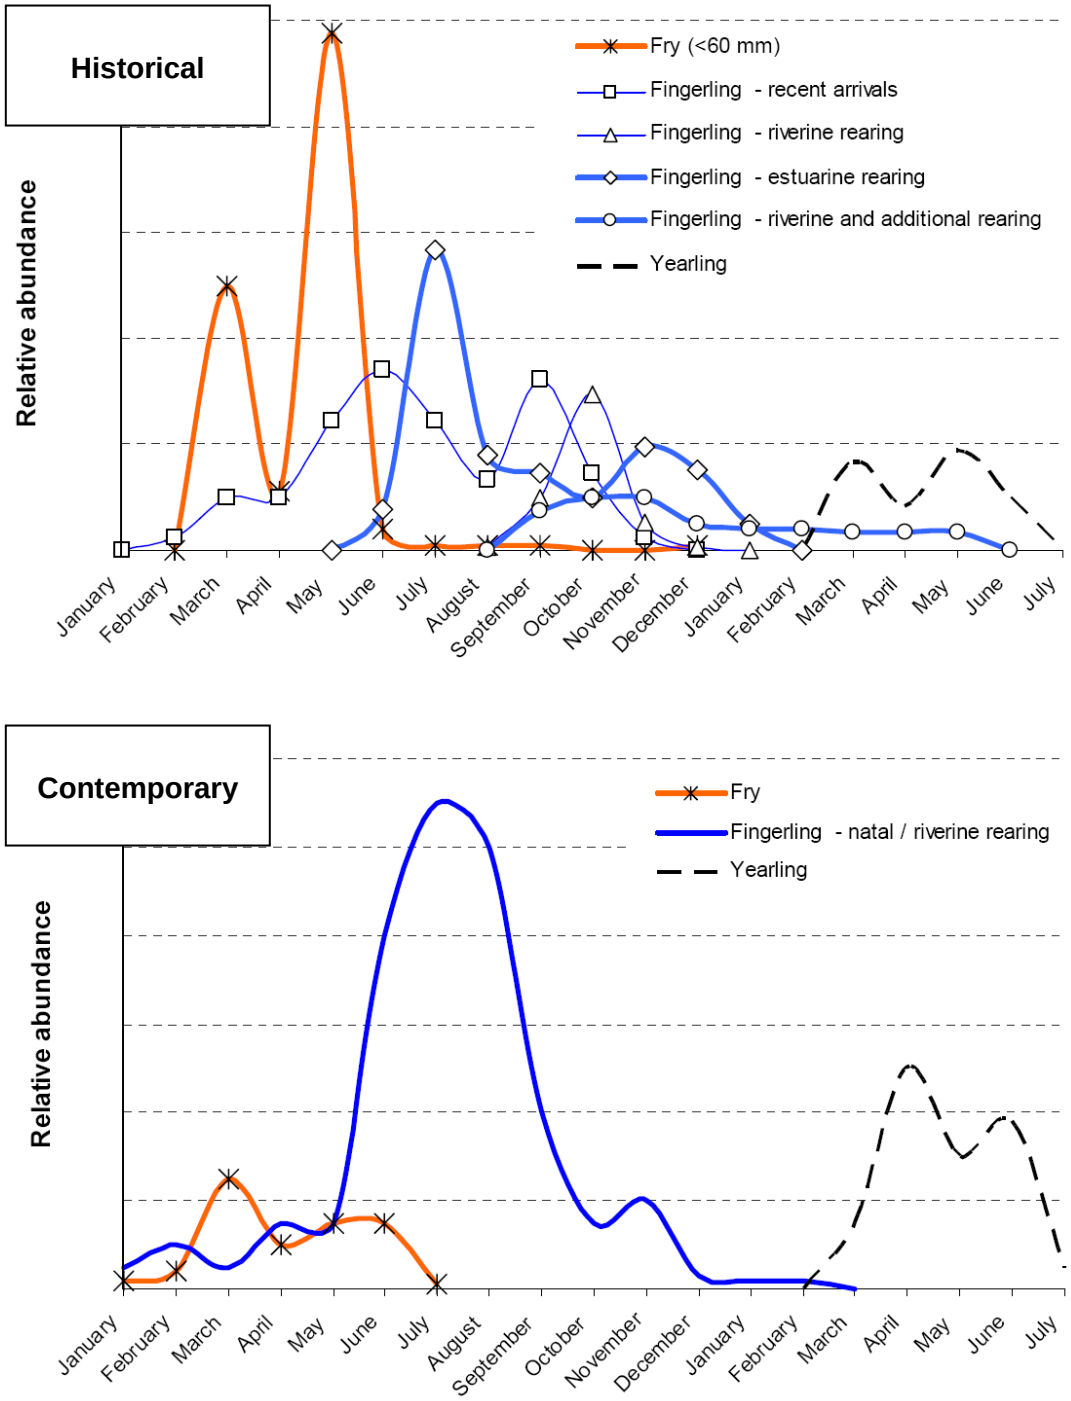

FIGURE 2-1
Historical and Contemporary Early Life History Types of Chinook Salmon in the Columbia River Estuary
(Reprinted from Fresh et al. 2005.)

The implication for salmon recovery in the Columbia River basin is that habitat use by salmonids must be considered from a multi-ecosystem perspective if we are to understand which components of each ecosystem—tributaries, mainstem, estuary, plume, nearshore, and ocean—are limiting the overall performance of salmon.

Summary

Since 1991, 13 Columbia River ESUs have been listed as threatened or endangered under the Federal Endangered Species Act. During their complex life cycles, salmon and steelhead rely on many diverse ecosystems, from tributaries to ocean environments, that span hundreds or thousands of miles. For recovery efforts to be successful, it is necessary to understand salmonids' requirements during all stages of their life cycles. Thus, although the estuary and plume represent important stages in the salmonid life cycle, these ecosystems must be considered within the context of other life cycle stages if management actions are to be effective. Perhaps most central to the recovery of listed ESUs is the importance of conserving biological diversity and the native ecosystems it depends on (Bottom et al. 2005).

CHAPTER 3

Limiting Factors

Chapter 3 identifies and prioritizes the key habitat-related physical, chemical, or biological features that scientific literature and area experts suggest are affecting the viability of ESUs and their component populations in the estuary. These features are referred to as limiting factors.[1] The discussion of limiting factors in this chapter pertains to the estuary and plume; however, upstream limiting factors in some cases have a direct bearing on conditions in the estuary. Discussion of limiting factors in this chapter generally relates to specific factors that limit salmonid productivity; however, it is recognized that the effects of multiple limiting factors may have a compounding effect. The estuary module does not address this compounding effect because of a lack of technical information to address the topic.

Determining Estuary Habitat Limiting Factors

Sources

It would be desirable to know with certainty which factors are responsible for the highest losses of salmon and steelhead in the estuary so that recovery actions could be focused on activities to address those factors. But as described below, researchers have quantified salmonid mortality in the estuary for only a few limiting factors, and additional research on mortality is needed to understand which factor (or factors) is most limiting salmonid viability in the estuary. In the absence of more comprehensive mortality data, the estuary recovery module relies on expert opinion and available information in the literature to identify and prioritize limiting factors.

PC Trask & Associates, Inc., based this chapter on a thorough review and synthesis of pertinent literature, supplemented by input from staff at the NMFS Northwest Fisheries Science Center and Northwest Regional Office, the Lower Columbia River Estuary Partnership, and the Lower Columbia Fish Recovery Board. The following documents, among others, provided consistent guidance:

- *Salmon at River's End: The Role of the Estuary in the Decline and Recovery of Columbia River Salmon* (Bottom et al. 2005)—Technical memorandum by the NMFS Northwest Fisheries Science Center
- *Role of the Estuary in the Recovery of Columbia River Basin Salmon and Steelhead: An Evaluation of the Effects of Selected Factors on Salmonid Population Viability* (Fresh et al. 2005)—Technical memorandum by the NMFS Northwest Fisheries Science Center
- "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" and its supplement—Northwest Power and Conservation Council (2004)

These three literature sources, and others, identified and evaluated limiting factors in a similar manner. But it should be noted that the three sources have separate goals, and this

[1] In this module, the term "limiting factors" is used to indicate the full range of factors that are believed to be affecting the viability of salmon and steelhead in the estuary and not to indicate the single factor that is most limiting.

affects each document's structure and content. Thus, the depth and breadth of information were not always consistent across documents. To develop a relatively comprehensive list of factors that are limiting ESUs' viability in the estuary and to weigh the probable effect of each factor, the author had to synthesize information from multiple sources.

Mortality Estimates

Estimates of salmon and steelhead mortality in the estuary and mainstem are not well supported in the literature, especially in the case of indirect mortality. (There are more reliable estimates of direct impacts to salmonids populations than indirect or combined impacts.) However, some modeling efforts have made assumptions about estuary mortality. One example is Ecosystem Diagnosis and Treatment (EDT), a life-cycle model that accounts for the estuarine stage of salmon and steelhead in tributaries of the Columbia River. For lower Columbia River ESUs, EDT assumes 18 to 58 percent mortality for various populations.

In addition, research is under way by NMFS, the U.S. Army Corps of Engineers, and Battelle Laboratories to estimate the survival rate of juvenile salmonids in the lower Columbia River. This research involves technologies for miniaturizing acoustic tags to a size capable of tracking yearling and subyearling juveniles. Current technology developed for the project allows for the tracking of subyearlings of sizes down to approximately 90 mm. Data from 2005 indicated an approximate range of survival of 65 to 75 percent for subyearlings and yearlings during their residency in the estuary (Ferguson 2006a).[2] It is probable that actual survival rates are lower than these estimates suggest because the research did not address mortality among juveniles smaller than 90 mm, mortality occurring in the plume and nearshore, or delayed mortality.

There are reliable mortality estimates for a few limiting factors. For example, Caspian tern predation was estimated to be responsible for the mortality of about 5.5 million smolts in 2007 (Roby et al. 2008)—up to 14.1 percent of in-river migrant steelhead smolts and 7.7 percent of transported steelhead smolts (Roby et al. 2008). Double-crested cormorants appear to be consuming approximately 6 percent of steelhead, 6 percent of subyearling Chinook, 2 percent of yearling Chinook, and 1 percent of sockeye salmon entering the estuary (Fredricks 2010).

Other limiting factors, such as pinnipeds (primarily affecting adult survival), ship wake stranding, and toxic contaminants, have incomplete mortality estimates associated with them. Toxic contaminants, for instance, can have lethal and sublethal impacts to salmonids, resulting in direct and indirect mortality, both of which are difficult to quantify. In most cases it is very difficult to point to a specific limiting factor and then estimate mortality. This is because of the inherent complexity associated with connecting the physical, chemical, and biological features that limit the productivity of salmon and steelhead.

[2] The mean yearling survival estimate for the years 2005 to 2009 is 75.8 percent (standard deviation = 5.4 percent), while the mean subyearling survival estimate for the same period is 67.6 percent (standard deviation = 9.0 percent) (Casillas 2010). Because these more current survival estimates are very close to the estimates used when the module was initially drafted, and because local recovery planners in the Washington and Oregon Lower Columbia region incorporated the 2005 estimates into their salmon recovery plans, the module was not updated with the most current numbers. In future revisions of the module and the Lower Columbia tributary plans, needed updates will be made.

Density-Dependent Mortality

In the Columbia River estuary, limiting factors such as off-channel habitat availability, competition with native and exotic fish for food and space, disease, and predation by piscivorous fish and native birds may in part be manifestations of density dependence. Density dependence refers to changes in the size of a population that are themselves a result of the size of the population, such as when a population declines because it has exceeded the amount of resources available to support it. Density-dependent mortality can occur through several mechanisms, such as direct competition for limited food and habitat and changes in the foraging activity of predators. With salmon and steelhead, density-dependent mortality can occur at any stage in the animal's life cycle and may be exacerbated by the introduction of large numbers of hatchery fish released over a relatively short period of time, or by the cumulative effects of such releases on natural-origin salmon.[3]

How much density-dependent mortality is taking place in the estuary compared to in the ocean is unclear. There is some evidence that density-dependent mortality is occurring in the open ocean. For example, during years when salmon are especially numerous in the ocean, their growth rates are reduced (Peterman 1984 as cited in Ford 2007). One study found that, during years when nearshore ocean productivity was low, survival of wild Snake River Chinook decreased as releases of hatchery Chinook increased (Levin et al. 2001 as cited in Ford 2007). However, another study found no connection between ocean conditions and density-dependent mortality, which appeared to be occurring among wild Snake River Chinook as hatchery steelhead were released (Levin and Williams 2002 as cited in Ford 2007). The authors suggested that the apparent density-dependent mortality could be better explained by interactions in the tributaries or estuary than by interactions in the ocean.

There is growing awareness among scientists studying the Columbia River estuary that mechanisms related to density dependence may limit salmon and steelhead while they are using estuary and plume habitats. Scientists studying Skagit River fall Chinook have documented density dependence-related mortality as a result of loss of habitat in the Skagit estuary and believe that such mortality can be attributed to a 75 percent loss of tidal delta estuarine habitat (Beamer et al. 2005). With similar habitat losses in the Columbia River estuary, it is possible that too many fish are competing for limited habitat and associated resources in the estuary at key times, and that the resulting stressors translate into reduced salmonid survival. The NMFS Northwest Fisheries Science Center currently is investigating potential density-dependent mortality in the estuary. The "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" raised the specter of density dependence in the estuary and recommended continued research to analyze conditions there (Northwest Power and Conservation Council 2004). Thus, although the occurrence of density dependence-related mortality in the Columbia River estuary has not been proven, given the dramatic changes in habitat opportunity and capacity in the estuary over the last 200 years, it is likely that some of the mortality associated with the limiting factors described in this chapter is related to increased density of juveniles in the estuary.

[3] It is also possible that inverse density dependence processes occur in some situations. For example, large numbers of adult salmon could swamp marine mammal predators at Bonneville Dam, and the adult survival rates could be higher than in scenarios with smaller numbers of adult fish.

Consistent with this concern, the NMFS Northwest Region Salmon Recovery Division and Northwest Fisheries Science Center are working to better define and describe the scientific uncertainty associated with ecological interactions between hatchery-origin and natural-origin salmon in freshwater, estuarine, and nearshore ocean habitats. Needs include an assessment of the state of the science to help identify priority research on the ecological interactions between hatchery-origin and natural-origin salmon in these habitats and to better define the ecological risks of such interactions. A conference on ecological interactions between hatchery-origin and natural-origin salmon held in May 2010 in Portland, Oregon, contributed to describing the state of the science on these interactions. Conference proceedings will be published and priority research needs identified. Follow-up workshops will help refine the assessment, develop specific research plans, and identify funding sources.

The estuary recovery plan module assumes that density-dependent mortality that may be occurring in the estuary is manifested in part through limiting factors related to habitat availability, competition for food and space, disease, and predation. Given the uncertainty about the mechanisms and effects of density dependence in the estuary, density dependence itself is not included as a limiting factor in the module. Neither are the effects of hatchery fish. Although it is likely that hatchery fish influence the estuarine survival of naturally produced fish (possibly through mechanisms of competition, predation, and disease transfer), the focus of this estuary recovery plan module is the effects of habitat conditions and processes in the estuary and plume, rather than the effects of hatchery or harvest practices. But the degree of density-dependent mortality occurring in the estuary, the role of large releases of hatchery fish, and the cumulative impact of hatchery releases on density-dependent mechanisms are worth exploring through further research.

Habitat-Related Limiting Factors

Salmonid populations exhibit diverse strategies that guide them through various habitats and ecosystems in specific sequences and patterns. If those sequences and patterns are interrupted, increased mortality may result. Thus, mismatches between the needs of salmonid populations and the availability of habitats to meet those needs can limit salmonid performance in the estuary and plume. The member/vagrant theory discussed in Chapter 2 underscores the need to consider relationships between ESUs' life history strategies and the quality, quantity, and availability of habitats in the estuary and other ecosystems that are interconnected via the salmon and steelhead's complex life cycle.

The habitats that salmonids occupy during their residency in the estuary and plume are formed through the interaction of ocean forces, land, and river flow (Fresh et al. 2005). Flows entering the estuary govern the general availability of habitats, along with sediment transport, salinity gradients, and turbidity, which are themselves aspects of habitat or habitat formation. Over the last 200 years, the magnitude, timing, and frequency of flows have changed significantly, with corresponding effects on the formation and availability of salmonid habitats. Some habitat has been removed, which has reduced the total acreage of the estuary by approximately 15 percent (Fresh et al. 2005). In other cases, particular habitat types have been transformed into other habitat types, and the resulting mosaic of habitats may not be meeting the needs of salmonids as well as the historical pattern of habitats did. For example, approximately 77 percent of historical tidal swamp has been lost (Northwest

Power and Conservation Council 2004), while other shallow-water habitats have increased significantly. The loss of tidal swamps and other forested or vegetated wetlands represents a loss of habitat that ocean-type salmonids use during their estuarine residence. In short, habitat opportunity and capacity have been degraded in the estuary and plume, and alterations in flow have contributed significantly to losses in in-channel, off-channel, and plume habitat. An accurate accounting of specific habitat type changes from pre-European settlement to the present day has not been initiated estuarywide. This measurement of change is important to guiding restoration priorities and represents a significant data gap in the estuary.

An important goal of this estuary recovery module is to describe the various habitats and limiting factors that both ocean- and stream-type juvenile salmonids encounter in the Columbia River estuary and plume. However, current scientific understanding of how stream-type juveniles use the various habitats they encounter in the estuary and plume is less robust than what is known about ocean types' habitat use. To fill this important knowledge gap, the NMFS Northwest Fisheries Science Center and others are exploring how stream-type juveniles expressing all the different possible life history strategies use individual estuarine habitats.

Affected salmonids: Because of their longer estuary residence times and tendency to use shallow-water habitats, ocean-type ESUs are more affected by flow alterations that structure habitat and/or provide access to wetland or floodplain areas than are stream-type ESUs. Stream types have relatively short estuary residence times and use the plume much more extensively than ocean types do. Thus stream-type salmonids are affected by habitat elements such as the shape, behavior, size, and composition of the plume (Fresh et al. 2005).

Reduced In-Channel Habitat Opportunity

In-channel habitat opportunity in the estuary is a function of the size of river flows, the timing of river flows, incoming and outgoing tides, and the amount and patterns of sediment accretion. Together, tidal action, river flow, and sediment movement create a constantly changing mosaic of channel habitats as water levels rise and fall, sands shift, and salinity gradients move in response to tides. To support salmonids, the various habitats in the estuary need to be connected both spatially and in time. With twice-daily tidal fluctuations, areas that are accessible at one point during the day can be inaccessible 6 hours later or can trap salmonids, exposing them to higher water temperatures and lower dissolved oxygen levels that can result in stress or mortality. Changes in both flow and sediment transport have reduced in-channel habitat opportunity.

Limiting Factor: Flow-Related Estuary Habitat Changes. The ability of juvenile salmon to access and benefit from habitat depends greatly on instream flow (Fresh et al. 2005). Changes in the quantity and seasonality of flows in the estuary have a direct bearing on whether key habitats are available to salmonids, when and how long those habitats are available, and whether and how they connect with other key habitats. In addition, juvenile salmonids have physiological or behavioral traits that set the timing for their transformation to saltwater, and changes in flows may interrupt this timing.

Both the quantity and timing of instream flows entering the Columbia River estuary and plume have changed from historical conditions (Fresh et al. 2005). Jay and Naik (2002)

reported a 16 percent reduction of annual mean flow from 1878 to the present and a 44 percent reduction in spring freshet flows. Jay and Naik also reported a shift in flow patterns in the Columbia to 14 to 30 days earlier in the year, meaning that spring freshets are occurring earlier in the season.[4] In addition, the interception and use of spring freshets (for irrigation, reservoir storage, etc.) have caused increased flows during other seasons (Fresh et al. 2005). These changes in the volume and timing of Columbia River flow are limiting factors for salmon and steelhead and have affected habitat opportunity and capacity in the estuary and plume. It is likely that global climate change will contribute to further flow-related changes in estuary habitat. However, changes in flow entering the estuary as a result of climate change are expected to be less than those caused by construction of the hydrosystem (Independent Scientific Advisory Board 2007).

Limiting Factor: Sediment/Nutrient-Related Estuary Habitat Changes. The transport of sediment is fundamental to habitat-forming processes in the estuary through sediment deposition and erosion (Fresh et al. 2005). An estuary's form is altered primarily through the deposition of sediment—either sediment that is reworked from other parts of the estuary or sediment that enters the estuary from the watersheds or ocean. Sediment moves among each of the components within the estuary, allowing the estuary as a whole to continually be adjusting toward some long-term equilibrium form in response to changes in physical or geomorphic processes (Philip Williams & Associates and Farber 2004). Sediment from the estuary and upstream sources also affects the formation of nearshore ocean habitats north and south of the Columbia River entrance.

Since the late nineteenth century, sediment transport from the interior basin to the Columbia River estuary has decreased about 60 percent and total sediment transport has decreased about 70 percent (Jay and Kukulka 2003). This reduction in the amount of sediment transport in the Columbia River has affected habitat-forming processes in the estuary and plume (Bottom et al. 2005) and is presumed to be a limiting factor for salmon and steelhead because it limits the accretion of sediment and thus the formation of shallow-water habitats. Although the consequences of the reduced transport of sediment through the estuary and plume are not fully understood, the magnitude of change is very large compared to historical benchmarks (Fresh et al. 2005).

Sediment also provides important nutrients that support food production in the estuary and plume. Microdetrital food particles adhere to sediment suspended in the water column, making different food sources available to different species than was the case historically. Currently, organic matter associated with fine sediments supplies the majority of estuarine secondary productivity in the food web (Simenstad et al. 1984 as cited in Northwest Power and Conservation Council 2004).

Reduced Off-Channel Habitat Opportunity

Columbia River access to its historical floodplain is an important factor for rearing ocean-type juvenile salmonids. Stream-type juvenile salmonids also are believed to benefit from access to off-channel habitats, which support less dominant stream-type life histories and provide food resources for stream types during downstream migration (Bottom et al. 2005).

[4] These analysis were calculated by comparing observed flow (data from a gauge), estimated adjusted flow (observed flow corrected for reservoir manipulations), and estimated virgin flow (estimate of river flow without human alteration).

Historically, flows that topped the river's bank provided juvenile salmonids with access to low-velocity areas in the lower river and estuary that juveniles used as refugia and for rearing; many of these areas were dominated by Sitka spruce tidal swamps, which were an integral component of the estuarine ecosystem. Overbank flows contributed key food web inputs to the ecosystem and influenced wood recruitment, predation, and competition in the estuary (Fresh et al. 2005).

Today, mainstem habitat in the Columbia and Willamette rivers has, in many cases, been reduced to a single channel (Northwest Power and Conservation Council 2004), and channelization of the estuary has eliminated access to an estimated 77 percent of historical tidal swamps (Fresh et al. 2005). In fact, over the past 200 years the surface area of the estuary has decreased by approximately 20 percent (Fresh et al. 2005).

The near elimination of overbank flooding is a function of both reductions in peak freshet flows (as a result of flow regulation for electricity generation, storage for irrigation and municipal use, and flood control) and increases in the bankfull level of the Columbia River (as a result of dikes and levees), among other factors.

Figure 3-1 shows diked areas from the estuary mouth to Bonneville dam. This map was generated from a GIS database developed by the University of Washington, U.S. Geological Survey, and Lower Columbia River Estuary Partnership that provides statistics and maps depicting the historical floodplain, diked areas, dredged material disposal sites, over-water structures, contaminant monitoring sites, and other key features in the estuary. Some of these features are shown in GIS-based reach maps presented in Appendix A.

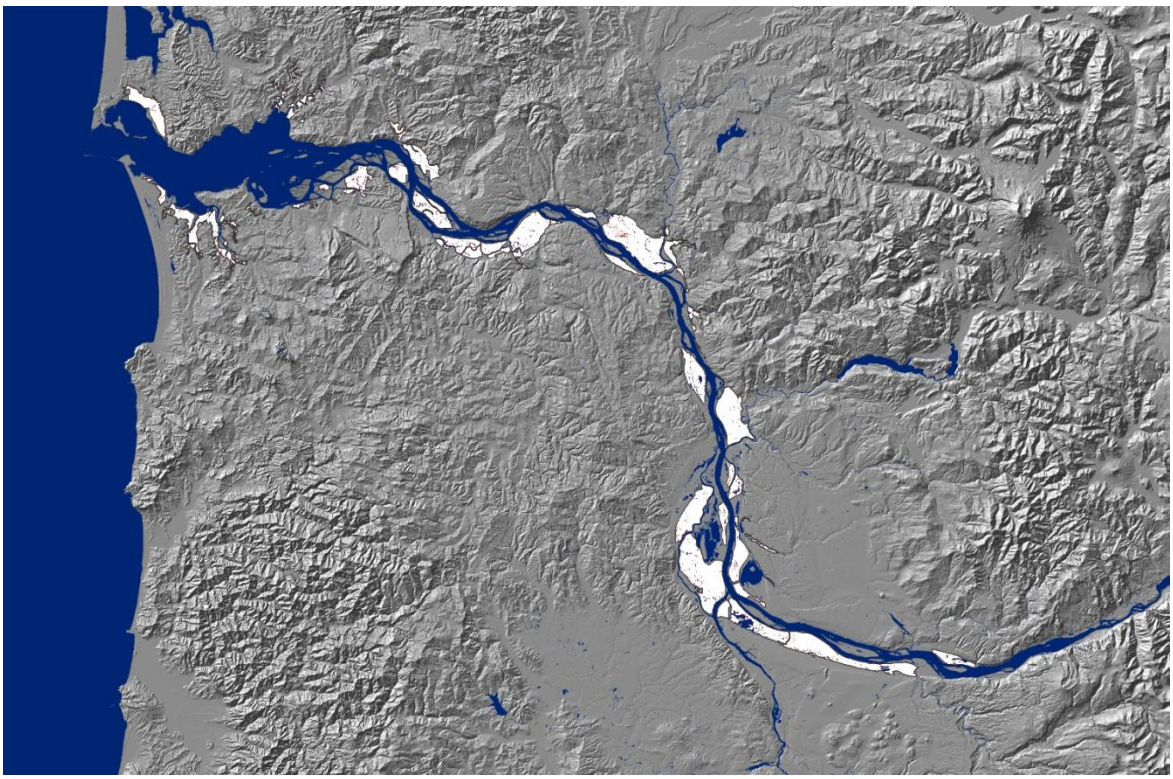

FIGURE 3-1
Diked Areas in the Columbia River Estuary
(Source: Lower Columbia River Estuary Partnership 2005.)

Limiting Factor: Flow-Related Changes in Access to Off-Channel Habitat. Reduced access to off-channel habitats is a limiting factor for salmon and steelhead because of impacts on food webs and the reduced availability of habitats preferred by fry and fingerlings. Typically, overbank flows were driven by spring freshets, which occurred at the time of year when there was the greatest variety of juvenile salmon and steelhead using the estuary (Fresh et al. 2005). Overbank flows occur much less frequently now than they did historically, in part because climate changes and human alterations have reduced the number of high flows in the Columbia (Jay and Kukulka 2003).

Limiting Factor: Bankfull Elevation Changes. The construction of levees also has reduced the frequency of overbank flows because more river water is needed to cause overbank flow. Historically the bankfull level was 18,000 $m^3 s^{-1}$, while today it is 24,000 $m^3 s^{-1}$—fully one-third more. Only five overbank events have occurred since 1948 (Jay and Kukulka 2003). The reduction in overbank events is a limiting factor because it reduces the availability of food and refugia for ocean-type juveniles rearing in the estuary. Less dominant stream-type juveniles are affected in the same manner.

Reduced Plume Habitat Opportunity

Evidence suggests that the plume supports ocean productivity by increasing primary plant production during the spring freshet period, distributing juvenile salmonids in the coastal environment, concentrating food sources such as icthyoplankton (megalopae, for example) and zooplankton, and providing refugia from predators in the more turbid, low-salinity plume waters (Fresh et al. 2005). Changes in the volume and timing of Columbia River flow have altered both the size and structure of the plume during the spring and summer months (Northwest Power and Conservation Council 2000).

Limiting Factor: Flow-Related Plume Changes. For juvenile salmonids preparing for ocean life, the plume is believed to function as habitat, as a transitional saltwater area, and as refugia. As mentioned earlier, stream-type ESUs in particular are affected by the size, shape, behavior, and composition of the plume (Fresh et al. 2005).

Over the past 200 years characteristics of the plume have been altered, and conditions caused by reductions in spring freshets and associated sediment transport processes may now be suboptimal for juvenile salmonids (Casillas 1999). Plume attributes affected by changes in flow include surface areas of the plume, the volume of the plume waters, the extent and intensity of frontal features, and the extent and distance offshore of plume waters (Fresh et al. 2005).

Limiting Factor: Sediment/Nutrient-Related Plume Changes. It is believed that the sediment and nutrients transported in the plume fuel salmon productivity in the ocean and provide relief from predation (Casillas 1999). This is particularly true for stream-type ESUs, who use the plume more extensively than ocean types do and thus are more affected when the amount of plume habitat is reduced.

Limiting Factor: Water Temperature

Higher water temperatures have reduced habitat quality for salmonids that use the estuary during summer months. Since 1938, average summer water temperatures at Bonneville Dam have increased 4° F (2.2° C) (Lower Columbia Fish Recovery Board 2004). Among-year

variability in temperature has been reduced by 63 percent since 1970 (Lower Columbia Fish Recovery Board 2004). As shown in Figure 3-2, temperatures entering the estuary (as measured at Bonneville Dam) have increased steadily since 1938. Temperatures also exceed 20° C (68° F) earlier during the year and more frequently than they did historically (National Research Council 2004).

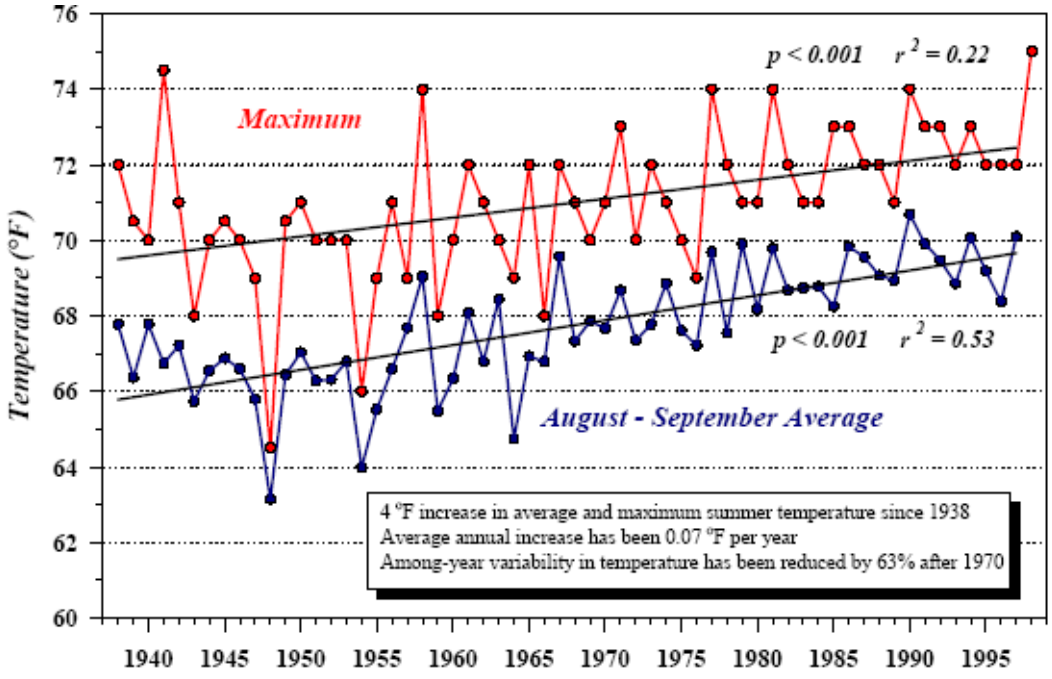

FIGURE 3-2
Temperatures of Water Entering the Estuary
(Reprinted from Lower Columbia Fish Recovery Board 2004.)

(Water temperatures of 20° C (68° F) are considered the upper thermal tolerance limit for cold-water species such as salmonids (National Research Council 2004). Pacific salmon can suffer adverse physiological and behavioral effects as a result of persistent, intermittent, or cumulative exposure to high water temperatures, or from increased daily variation in water temperature (McCullough 1999). Temperatures above 18° C (64.4° F) can impair the metabolism, growth, and disease resistance of salmonids, as well as alter the timing of adult migrations, fry emergence, and smoltification (McCullough et al. 2001, Sauter et al. 2001). Other effects of high water temperatures include adult mortality, reduced pre-spawning survival of eggs and sperm, difficulty competing with non-salmonid fish, prevention or reversal of smoltification, and harmful interactions with certain other habitat stressors (Marine 2004, McCullough 1999, Dunham et al. 2001, Materna 2001, McCullough et al. 2001, and Sauter et al. 2001). For example, the toxicity of some contaminants increases at high water temperatures, and levels of dissolved oxygen go down. Adult sockeye have been known to suffer stress and disease as they are exposed to warm water in estuaries, waiting for cool runoff conditions in their natal stream (Independent Scientific Advisory Board 2007). Warmer temperatures may also enhance conditions for warm-water fish that prey on or compete with juvenile salmonids (Independent Scientific Advisory Board 2007) and cause other changes in the estuarine food web.

During the next century, it is likely that global climate change will contribute to continued water temperature rises in the Columbia River basin as precipitation increasingly falls as rain rather than snow, snow pack diminishes, peak flows increase, and late-summer/early-fall flows are reduced (Independent Scientific Advisory Board 2007). (See Chapter 4 for more on the expected effects of global climate change in the Columbia River basin and estuary.)

Limiting Factor: Stranding

In the estuary, large ships passing through the navigational channel produce bow waves that crash against shorelines in Oregon and Washington. Small ocean-type fry and fingerlings rear within inches of shore and may become stranded as waves intersect the bank and recede (Ackerman 2002), although the extent of this problem is unclear. A 1977 study by Washington Department of Fisheries (WDF) observed 2,397 juvenile salmonids—mostly Chinook—stranded as a result of passage of 216 deep draft vessels (Bauersfeld 1977).

A NOAA technical memorandum (Hinton and Emmett 1994) published in 1994 concluded that the problem was not as significant as documented in the WDF report. Hinton and Emmett found only five juvenile salmonids stranded after observing 145 vessels. A third study, conducted for the U.S. Army Corps of Engineers, observed 21 juvenile Chinook salmon stranded at two sites (Ackerman 2002). In one occurrence, 10 juveniles were stranded by one vessel. As part of the channel deepening project being conducted by the U.S. Army Corps of Engineers, a two-part study of stranding was initiated by the University of Washington and the Portland District of the Corps. The study is designed to measure differences in stranding events before and after channel deepening activities. The first study was published in February 2006 (Pearson et al. 2006). In general, the report documents mortality attributed to stranding events for three test sites; it also builds on other work to determine the conditions that increase the likelihood of stranding events.

Early in 2008, the Port of Vancouver enlisted Entrix, Inc., to perform a spatial analysis of beach susceptibility for the stranding of juvenile salmonids by ship wakes (Pearson 2008). The study examined wave characteristics and the geomorphology of the lower river but did not examine nearshore fish density. The purpose of the study was to estimate the number of miles of shoreline that exhibit traits expected to potentially cause stranding. The study concluded that approximately 33 miles of shoreline between the mouth of the river and the city of Vancouver have shoreline characteristics consistent with stranding (Pearson 2008).

Food Web-Related Limiting Factors

Energy released from the Columbia River and the ocean converges in the estuarine and plume environments where, combined with the biological energy of primary plant production, it forms the basis for life in the estuarine ecosystem. Ultimately, energy that is transferred through the estuarine food web begins with sunlight; sunlight, minerals, and nutrients lead to plant growth in primary production; plants are eaten by animals and animals are preyed upon by other animals in secondary production; and dead plants, animals, and their material are broken down and re-integrated into the base of the food web. Salmon and other native species have evolved together in response to the basic inputs of energy and their circulation through the ecosystem. The result has been the development of an intricately structured food web in the estuary that encompasses food sources, food

availability, and inter- and intra-species relationships. Alterations in any one of the elements of the food web, such as food sources or availability, can ripple throughout the ecosystem, reducing habitat capacity and having potentially far-reaching effects on salmonids and other species.

As part of the food web, decomposing materials known as detritus are consumed by juvenile salmonids, either directly or indirectly through other organisms that feed on the detritus (Northwest Power and Conservation Council 2004). There is evidence that a shift in the food base of the estuary—from macrodetrital to microdetrital—has significantly changed the food web and that complex inter- and intra-species relationships have been permanently altered (Northwest Power and Conservation Council 2004). Microdetrital sources favor production of planktonic copepods and other deep-water organisms that are not typically consumed by juvenile salmon (Bottom et al. 2005). Juvenile salmon that rear extensively in the estuary preferentially consume invertebrates from shallow-water and vegetated habitats, where decomposing plant tissue from emergent plants in estuarine wetlands creates macrodetritus (Bottom et al. 2005). Reductions of wetland and foraging habitat, simplification of habitats, and altered sediment inputs have contributed to the changes in detrital sources in the estuary. By disrupting the food web, these conditions have increased competition and predation (Bottom et al. 2005).

Most studies of prey preferences of juvenile salmon using the estuary focus on stream-type fish, which are less likely than ocean types to rear in estuarine habitats for extended periods. Studies that focus on ocean-type salmonids demonstrate that juvenile salmon appear to feed selectively within particular regions of the estuary (Bottom et al. 2005). In freshwater and brackish habitats, juvenile salmon feed extensively on emergent insects such as chironomids (midges) and epibenthic crustaceans such as mysid shrimp and gammarid amphipods (Macneale et al. 2009 and Miller and Simenstad 1997). Farther downstream in higher salinity portions of the estuary, salmon consume epibenthic crustaceans such as gammarid amphipods and harpaticoid copepods (Bottom et al. 2005). According to a University of Washington master's thesis that demonstrated the importance of midge insects in the diet of juvenile Chinook salmon occupying shallow-water habitats in the Columbia River estuary, emerging chironomids were the dominant prey for Chinook of all sizes (Lott 2004). Additionally, the Oregon Department of Fish and Wildlife found migrating yearling Chinook actively feeding on daphnia. The same study found subyearling Chinook and coho feeding on daphnia year-round in the lower Willamette River (Friesen 2005).

Affected salmonids: Ocean-type ESUs are more likely than stream-type juveniles to be affected by food web alterations because of their use of estuary habitats and their longer residency times. Stream-type ESUs are more influenced in the plume environment because of reduced fine-sediment inputs leaving the estuary.

Food Source Changes

As described below, changes in the detrital sources that form the base of the estuarine food web have been significant and represent a limiting factor for salmonids. Figure 3-3 shows a conceptual model of the estuary food web developed by the U.S. Army Corps of Engineers. The historical tidal marsh macrodetritus-based food web is displayed at the top of Figure 3-3, while the current food web, which is based on imported microdetritus, is shown at the bottom.

Limiting Factor: Reduced Macrodetrital Inputs. The estuarine food web formerly was supported by macrodetrital inputs that originated from emergent, forested, and other wetland rearing areas in the estuary (Northwest Power and Conservation Council 2004). Today, detrital sources from emergent wetlands in the estuary are approximately 84 percent less than they were historically (Bottom et al. 2005). The reduction of macrodetritus in the estuary reduces the food sources for juvenile salmonids. As a result, juveniles may have reduced growth, lipid content, and fitness prior to ocean migration or may need to reside longer in the estuary.

Macrodetrital plant production has declined as a result of the construction of revetments along the estuary shorelines, the disposal of dredged material in what formerly were shallow or wetland areas where plant materials or insects could drop into the water, simplification of habitat through the removal of large wood, and reductions in flow. Flow reductions affect detrital sources by limiting the amount and availability of wetlands—areas that normally would be contributing macrodetritus to the food web—and cutting the number of overbank flows. Historically, much of the detrital inputs occurred during overbank events, which provided additional shallow-water habitat for juvenile salmonids and resulted in significant detrital inputs to the estuary. As mentioned earlier, overbank events occur much less frequently today than they did historically.

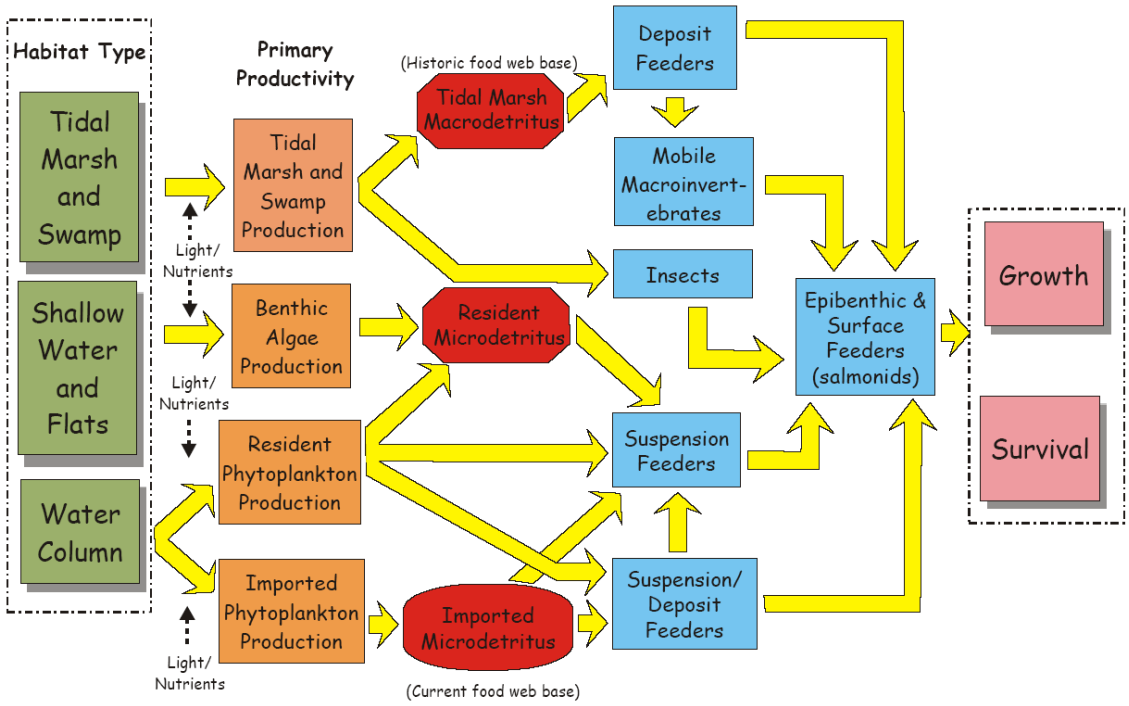

FIGURE 3-3
Conceptual Model of the Columbia River Estuary Food Web

Limiting Factor: Increased Microdetrital Inputs. The current food web is based on decaying phytoplankton delivered from upstream reservoirs and nutrient inputs from urban, industrial, and agricultural development. The amount of this microdetritus has increased dramatically (Bottom et al. 2005). The switch in the estuarine food web from a

macrodetritus-based source to a microdetritus-based source has altered the productivity of the estuary (Bottom et al. 2005).

The substitution of detrital sources in the estuary also has contributed to changes in the spatial distribution of the food web (Bottom et al. 2005). Historically the macrodetritus-based food web was distributed evenly throughout the estuary, including in the many shallow-water habitats favored by ocean-type salmonids. But the contemporary microdetrital food web is concentrated within the estuarine turbidity maximum in the middle region of the estuary (Bottom et al. 2005). This location is less accessible to ocean-type ESUs that use peripheral habitats and more accessible to species such as American shad that feed in deep-water areas.

Pelagic fish such as shad may also benefit from the fact that the estuarine turbidity maximum traps particles and delays their transport to the ocean up to 4 weeks, compared to normal transport of around 2 days (Northwest Power and Conservation Council 2004). The estuarine turbidity maximum is thought to contain bacteria that attach to detritus. Together these represent the primary food source in the estuary today (Northwest Power and Conservation Council 2004).

Competition and Predation

Predation and competition for habitat and prey resources limit the success of juvenile salmonids entering the estuary and plume. Both spatial and energetic losses can involve either density-dependent or density-independent processes (Bottom et al. 2005). Spatial and temporal losses of habitat and large pulses of hatchery juveniles may, under some conditions, result in density-dependent salmonid mortality (Bottom et al. 2005).

Competition among salmonids and between salmonids and other fish may be occurring in the estuary (Lower Columbia Fish Recovery Board 2004), with the estuary possibly becoming overgrazed when large numbers of ocean-type salmonids enter the area. Food availability may be reduced as a result of the temporal and spatial overlap of juveniles from different locations (Bisbal and McConnaha 1998 as cited in Lower Columbia Fish Recovery Board 2004).

Ecosystem-scale changes in the estuary have altered the relationships between salmonids and other fish, birds, and mammal species, both native and exotic. Some native species' abundance levels have decreased from historical levels—perhaps to the point of extinction—while others have increased to levels far exceeding those in recorded history, with associated changes in predation of salmon and steelhead juveniles.

The presence of non-indigenous fish, invertebrates, and plants in species assemblages indicates major changes in aquatic ecosystems (Northwest Power and Conservation Council 2004). Globally the introduction of such species is increasing, a fact that is attributable to the increased speed and range of world trade, which facilitates the transport and release—whether intentional or not—of non-indigenous species (Northwest Power and Conservation Council 2004). In the estuary, the introduction of exotic species has altered the ecosystem through competition, predation, disease, parasitization, and alterations in the food web.

Non-native species affect ocean-type ESUs more than they do stream-type ESUs because of the ocean types' longer juvenile estuary residency times and use of shallow-water habitats.

Limiting Factor: Native Fish. The northern pikeminnow is a native piscivorous fish that preys on juvenile salmonids in the estuary. Although pikeminnows have always been a significant source of mortality for juvenile salmonids in the Columbia River, changes in physical habitats may have created more favorable conditions for predation (Northwest Power and Conservation Council 2004). These changes include reduced flows and favorable micro-habitats formed by pilings, pile dikes, and other over-water structures. The diet of pikeminnows varies with age, with the largest adults representing the biggest risk to juvenile salmonids. Both ocean-type ESUs and stream-type ESUs are affected, but for different reasons. Ocean-type juveniles are susceptible because of their longer estuary residency times and use of shallow-water habitats. Stream-type juveniles are susceptible because they are leaving faster, deeper water to forage for food in shallow areas that are frequented by pikeminnow.

Limiting Factor: Native Birds. As a result of estuary habitat modifications, the number and/or predation effectiveness of Caspian terns, double-crested cormorants, and a variety of gull species has increased (Fresh et al. 2005). In 1997 it was estimated that avian predators consumed 10 to 30 percent of the total estuarine salmonid smolt production in that year (Northwest Power and Conservation Council 2004). The 2007 season summary of *Research, Monitoring, and Evaluation of Avian Predation on Salmonid Smolts in the Lower and Mid-Columbia River* (Roby et al. 2008) estimates that 5.5 million juvenile salmonids were consumed by terns in 2007. Stream-type juvenile salmonids are most vulnerable to avian predation by Caspian terns because the juveniles use deep-water habitat channels that have relatively low turbidity and are close to island tern habitats (Roby et al. 2008). Double-crested cormorants are estimated to have consumed an average of 7 million juvenile salmonids annually over the years 2001 to 2009. Cormorant predation has increased in the past several years and has been as high as 11 million, in 2009 (Fredricks 2010).

Limiting Factor: Native Pinnipeds. The abundance of native pinnipeds has steadily increased since passage of the Marine Mammal Protection Act in 1972. Harbor seals, Steller sea lions, and California sea lions all prey on salmon and steelhead in the estuary (Northwest Power and Conservation Council 2004). Diet studies indicate that pinnipeds consume both juvenile and adult salmonids. U.S. Army Corps of Engineers' annual estimates of adult mortality that occurs at Bonneville Dam because of pinnipeds (primarily California sea lions) ranged from 0.4 percent (2002) to 4.2 percent (2007) during the study period ending in 2010 (U.S. Army Corps of Engineers 2010).[5] Other, radio telemetry-based studies suggest that annual pinniped predation on spring Chinook and winter steelhead at Bonneville Dam may be as high as 8.5 percent and 20 percent, respectively (NMFS 2008b, Appendix G). These estimates do not account for pinniped mortality occurring downstream of Bonneville Dam. There are no official estimates of downstream mortality on adult spring Chinook and winter steelhead (both of which are stream-type salmonids); however, unsubstantiated estimates are as high as 10 percent.

Limiting Factor: Exotic Fish. At least 37 exotic fish species are now found in the Columbia River estuary (Northwest Power and Conservation Council 2004). American shad were introduced into the Columbia River in the 1880s, and adult returns now exceed 4 million in

[5] Estimated consumption of adult salmonids ranged from a low of 1,010 in 2002 to a high of 6,081 in 2010; the percent of run consumed varied among reporting years because of changes in run size.

a single year (Northwest Power and Conservation Council 2004). While shad do not eat salmonids, they exert tremendous pressure on the estuary food web given the sheer weight of their biomass. Some evidence suggests that planktivorous American shad have an impact on the abundance and size of *Daphnia* in Columbia River mainstem reservoirs (Haskell et al. 2006 in Independent Scientific Advisory Board 2008), thereby reducing this important food source for subyearling fall Chinook. Other exotic fish in the estuary, such as smallmouth bass, walleye, and catfish, are piscivorous; however, their abundance levels are relatively small.

Limiting Factor: Introduced Invertebrates. Twenty-seven non-native invertebrate species have been observed in the estuary and documented by the Lower Columbia River Aquatic Non-indigenous Species Survey (Sytsma et al. 2004). Surveys have documented that the estuarine copepod community has changed from a system dominated by a single introduced species, *Pseudodiaptomis inopinus*, to a system dominated by two newly introduced Asian copepods: *Pseudodiaptomis forbesi* and *Sinoclaanus doerri* (Santen 2004). In some cases, the abundance of non-native invertebrates can alter food webs through their wide distribution and key role in the food chain (Northwest Power and Conservation Council 2004).

Limiting Factor: Exotic Plants. The introduction of non-indigenous plant species also has altered the estuary ecosystem. Exotic plant species often out-compete native plants, which results in altered habitats and food webs (Northwest Power and Conservation Council 2004). About 18 aquatic plants have been introduced into the estuary since the 1880s (Sytsma et al. 2004). Examples of non-indigenous plant species include purple loosestrife, Eurasian milfoil, parrot feather, and Brazilian elodea. In addition to out-competing native plants, introduced plant species can contribute to poor water quality and create dense, monospecific stands that represent poor habitat for native species (Northwest Power and Conservation Council 2004). In turn, these new plant communities may alter insect and detritus production in and around vegetated wetlands.

Toxic Contaminants

The quality of habitats and the food web in the Columbia River estuary is degraded as a result of past and current releases of toxic contaminants (Fresh et al. 2005, Lower Columbia River Estuary Partnership 2007), from both estuary and upstream sources. Historically, levels of contaminants in the Columbia River were low, except for some metals and naturally occurring substances (Fresh et al. 2005). Today, contaminant levels in the estuary are much higher, as the estuary receives contaminants from more than 100 point sources and numerous non-point sources, such as surface and stormwater runoff from agricultural and urban sources (Fuhrer et al. 1996). With the cities of Portland, Vancouver, Longview, and Astoria on its banks, the Columbia River below Bonneville Dam is the most urbanized section of the river. In 2000, Portland Harbor was placed on the National Priorities List, which designates Superfund sites. Sediments in the river at Portland Harbor are contaminated with various toxic compounds, including metals, PAHs, PCBs, chlorinated pesticides, and dioxin (Oregon Department of Environmental Quality 2008). Work in recent decades has detected contaminants in aquatic insects, resident fish species, salmonids, river mammals, and osprey, reinforcing that contaminants are widespread throughout the estuary's food web (Tetra Tech 1996, Fuhrer et al . 1996, Lower Columbia River Estuary Partnership 2007).

Depending on concentration, exposure to toxic contaminants can kill aquatic organisms outright or have sublethal effects that compromise their health and behavior. Sublethal concentrations of contaminants affect the survival of aquatic species by increasing stress, decreasing fitness, predisposing organisms to disease, delaying development, and disrupting physiological processes such as reproduction and smoltification.

Acute lethal effects of toxic contaminants, such as fish kills in response to accidental discharges or spills, have been reported but are generally rare. However, research by the NMFS Northwest Fisheries Science Center has revealed some notable exceptions in which toxic contaminants may lead to the direct mortality of salmonids, such as the following situations:

- Coho pre-spawn mortality. For the past several years, NMFS has been documenting the recurrent die-offs of adult coho salmon returning to spawn in restored lowland urban streams in the Puget Sound Basin, at rates ranging from 30 to 90 percent of local coho runs (McCarthy et al. 2008). The weight of evidence to date suggests that pollutants in runoff from urban landscapes are causing the fish kills, and the phenomenon is correlated with high densities of roads and vehicle traffic. Based on findings from Puget Sound, coho spawners are likely at risk in urbanizing watersheds in the greater Columbia Basin (particularly the lower Columbia River).
- Synergistic toxicity of pesticide mixtures. A study by NMFS, in collaboration with Washington State University, has shown that common current-use pesticides (organophosphate and carbamate insecticides) produce unexpectedly synergistic toxicity and death in juvenile salmon following short-term exposure (Laetz et al. 2007). These agricultural pesticides are used in most of the major subbasins, and they reach rearing and migration habitats for salmon via spray drift, surface runoff, and irrigation return flows. In a 10-year study by the U.S. Geological Survey, Gilliom (2007) found that mixtures of pesticide compounds are prevalent in streams in watersheds that are dominated by agricultural, urban, or mixed land use.
- Salmon egg mortality. Increased mortality has been observed in salmon eggs exposed to PAHs in oil, such as at sites in Alaska following the Exxon Valdez oil spill (Heintz et al. 1999, Carls et al. 2005). An unpublished study by NMFS suggests that salmon embryos incubated in urban stream water also show relatively high rates of developmental defects and mortality when compared to embryos raised in the same water passed though an in situ streamside filtration system. At this time, the contaminants in the urban stream water are unidentified contaminants that are toxic to salmon embryos and likely pose an important early life stage threat to salmon in urbanizing watersheds.

Although the lethal effects described above are of concern, sublethal effects of contaminants are probably the greatest threat to juvenile salmon in the Columbia River. In juvenile salmonids, contaminant exposure can result in decreased immune function and generally reduced fitness (Northwest Power and Conservation Council 2004, Arkoosh and Collier 2002). Exposure can also impair growth, development, and reproduction and disrupt olfaction; salmonids depend on olfaction for migration, imprinting on natal streams, homing, and detecting predators, prey, potential mates, and spawning cues. These sublethal effects of contaminant exposure may indirectly increase mortality from other factors like

infectious disease, parasites, predation, exhaustion, and starvation by suppressing salmonid immune systems and impairing necessary behaviors such as swimming, feeding, responding to stimuli, and avoiding predators (Lower Columbia River Estuary Partnership 2007). Contaminants that affect growth can have significant effects. Juvenile growth is necessary for ocean survival (Zabel and Williams 2002 as cited in Lower Columbia River Estuary Partnership 2007), and adult fish size has been correlated to reproductive success and egg size (Healey and Heard 1983, Beacham and Murray 1987). Low lipid content, which has been observed in outmigrating juvenile Chinook salmon in the Columbia River estuary (Johnson et al. 2007b, Lower Columbia River Estuary Partnership 2007), is another sign of poor growth that is correlated with an increased risk of juvenile mortality (Biro et al. 2004). Thus, toxic contaminants that impair salmonid growth can reduce juvenile survival, adult returns, and individual reproduction. Although many effects of contaminants require an exposure period of weeks to months, some impacts, especially those on behavior, can occur very quickly. For example, effects of pesticides and copper on the salmon olfaction system can be seen after exposure periods of only a few hours (Sandahl et al. 2004 and 2007, Hecht et al. 2007).

Toxic contaminants can also indirectly affect salmon via the food web, especially prey such as aquatic and terrestrial insects. Insect bodies accumulate contaminants, which salmon in turn ingest when they consume insects. Additionally, many toxic contaminants are specifically designed to kill insects and plants, reducing the availability of insect prey or modifying the surrounding vegetation and habitats. The availability of prey species is one of the primary determinants of salmonid growth, and reductions in the prey base can affect salmonid survival and productivity (Chapman 1966 and Mundie 1974 as cited in Lower Columbia River Estuary Partnership 2007). Changes in vegetative habitat can shift the composition of biological communities; create favorable conditions for invasive, pollution-tolerant plants and animals; and further shift the food web from macrodetrital to microdetrital sources.

A study by Loge et al. (2005) in the Columbia River will likely bring more attention to the effects of contaminants on salmonids in the estuary. The study documents infectious disease in outmigrating juvenile salmonids attributed to abiotic stressors, such as chemicals, that influence host susceptibility to infection. The study estimates disease-induced mortalities in Chinook salmon related to exposure to contaminants at 1.5 percent and 9 percent for estuary residence times of 30 to 120 days, respectively (Loge et al. 2005).

Other contaminants, including endocrine-disrupting substances such as synthetic hormones, are beginning to be characterized in the estuary, and these contaminants could have substantial effects on salmon and steelhead (Fresh et al. 2005). A study by the Lower Columbia River Estuary Partnership, aided by NMFS and the U.S. Geological Survey, found emerging contaminants such as caffeine, acetaminophen, and human and veterinary antibiotics in the water column of the estuary and evidence of exposure to estrogenic compounds in the blood of juvenile Chinook salmon (Lower Columbia River Estuary Partnership 2007). Several suspected hormone disruptors were detected in the water column, including bisphenol A (a plasticizer), HHCB (a synthetic musk), and polybrominated diphenyl ethers (PBDEs, which are synthetic flame retardants used in everyday products like plastic, cushions, and fabrics). Although some forms of PBDEs have been banned, PBDE concentrations in the environment have increased exponentially during

recent decades. In the Columbia River estuary, they have been found in the water column, on suspended sediment, and in the tissue and stomach contents of juvenile Chinook salmon, which indicates that salmon prey also are contaminated (Lower Columbia River Estuary Partnership 2007). PBDEs are similar to PCBs in their chemical structure and sublethal effects, such as neurotoxicity and hormone disruption.

Affected salmonids: Contaminant exposure by stream-type and ocean-type salmon likely reflects contaminants present in rearing habitats. Stream-type salmon are apt to have contaminant loads that reflect conditions in the upper Columbia River and its tributaries, while ocean-type salmon are apt to have loads that reflect conditions in the lower river and estuary (Leary et al. 2006, Johnson et al. in prep, Dietrich et al in prep a). It is likely that both stream-type and ocean-type juvenile salmonids are affected by short-term exposure to waterborne contaminants such as organophosphate pesticides and dissolved metals that can have acute effects on salmon olfactory function and behavior (Fresh et al. 2005, Johnson et al. in prep a), and both types could be affected by bioaccumulative legacy pesticides, such as DDTs, that are present throughout the Columbia Basin. Additionally, ocean-type juveniles likely experience adverse effects and possibly mortality from urban and industrial bioaccumulative toxics such as PCBs and PBDEs that are present in the Columbia River estuary and are absorbed during longer estuarine residence times (Fresh et al. 2005). Both life history types could be affected by contaminant impacts on prey resources (Johnson et al. in prep). Preliminary data tend to support the hypothesis that contaminant body burdens are generally higher in ocean-type stocks than in stream-type stocks (Johnson et al. 2007a) and higher in outmigrating subyearling Columbia River Chinook than in yearlings, especially for industrial contaminants such PCBs and PBDEs that are present at higher concentrations in the Columbia River estuary (Lower Columbia River Estuary Partnership 2007, Dietrich et al. 2008). However, more work is needed on contaminant uptake and impacts on salmon of different stocks and life history types.

Limiting Factor: Bioaccumulation Toxicity. Bioaccumulative and potentially toxic waterborne contaminants, trace metals, and chlorinated compounds have been observed in the estuary (Fuhrer et al. 1996, Fresh et al. 2005, Lower Columbia River Estuary Partnership 2007). DDT and PCBs have been detected in juvenile salmon from the estuary at concentrations above threshold levels for health effects, and in salmon stomach contents and water quality samples from sites throughout the estuary (Lower Columbia River Estuary Partnership 2007). DDT, PCBs, and trace metals such as copper all bioaccumulate and concentrate in animals near the top of the food chain.

Loge et al. (2005) estimated disease-induced, contaminant-related mortalities at 1.5 percent and 9 percent for juvenile Chinook residing in the Columbia River estuary for 30 to 120 days, respectively (Loge et al. 2005). Figures 3-4 and 3-5 show concentrations of PCBs and DDTs found in the stomach contents of subyearling fall Chinook in several locations of the Columbia River estuary, other Pacific Northwest sites, and hatcheries.

Limiting Factor: Non-Bioaccumulative Toxicity. A variety of organochlorines (including trichlorobenzene, the insecticides aldrin and dieldrin, and PAHs) in the estuary are above state and Federal guidance levels (Northwest Power and Conservation Council 2004). These contaminants tend not to bioaccumulate in salmon and steelhead (although PAHs do bioaccumulate in invertebrates), but they are readily absorbed and can have sublethal

effects. Copper also was detected in juvenile salmon, at concentrations that can impair olfaction (Lower Columbia River Estuary Partnership 2007). In addition, copper can interact with other toxic contaminants—mercury, aluminum, iron, and certain pesticides—to cause synergistic effects, such that the combined toxicity is greater than the toxicity predicted based on the sum of the contaminants present (Eisler 1998 as cited in Lower Columbia River Estuary Partnership 2007).

As mentioned above, sublethal concentrations of contaminants can affect the survival of aquatic species by increasing stress, predisposing organisms to disease, delaying development, and disrupting physiological processes (Northwest Power and Conservation Council 2004). Exposure to PAHs may be a particular problem for salmon in the urbanized portions of the estuary, as these contaminants are very common in stormwater as well as in industrial discharges. Although salmonids can break down PAHs, the metabolites of PAHs can be mutagenic and carcinogenic, especially in cases of chronic exposure. PAHs also can contribute to immune dysfunction in juvenile salmon (Arkoosh and Collier 2002, Bravo et al. 2008) and cause alterations in growth and metabolism that could increase the risk of mortality (Meador et al. 2006 and 2008). Figure 3-6 shows concentrations of PAHs in the stomach contents of subyearling fall Chinook in various locations of the Columbia River estuary, other Pacific Northwest sites, and hatcheries.

One study detected numerous currently used pesticides present in water quality samples from sites throughout the estuary, with the most frequently detected pesticides being the suspected hormone disruptors atrazine, simazine, and metolachlor (Lower Columbia River Estuary Partnership 2007). Exposure to individual pesticides has sublethal effects on salmon behavior, interfering with predator avoidance, altering homing and migration, and reducing egg fertilization. Health effects include reduced olfactory function, impaired growth, and immune suppression. Pesticides also can be toxic to salmon prey.

Although the concentrations of the individual pesticides detected in the study were lower than threshold levels for health effects in juvenile salmonids, pesticides often were found in combination (Lower Columbia River Estuary Partnership 2007). This is of concern because some pesticides are known to have additive effects. For example, when common pesticides such as diazinon, chlorpyrifos, and carbaryl occur together, even if each is at a relatively low concentration, their combined concentration can have toxic effects on fish and wildlife (Scholz et al. 2006 as cited in Lower Columbia River Estuary Partnership 2007). Among salmonids, carbamate and organophosphate pesticides can have additive effects on olfactory function (Scholz et al. 2006 as cited in Lower Columbia River Estuary Partnership 2007). Some studies suggest that synergistic effects may also be occurring when current-use pesticides occur together in the environment (Anderson and Zhu 2004 and Denton et al. 2003 as cited in Lower Columbia River Estuary Partnership 2007). This is a reminder that the effects of toxic contaminants in the estuary may not be directly proportional to measured concentrations.

Habitat Opportunity, Habitat Quality, and Synergistic Effects

A lack of habitat opportunity and reduced habitat quality both play a role in limiting the viability of salmon and steelhead in the Columbia River estuary. In terms of habitat opportunity, changes in the timing and volume of Columbia River flows, combined with higher bankfull elevations, have reduced the amount and accessibility of in-channel, off-channel, and plume habitat. Overbank flooding that normally would aid juveniles in accessing off-channel refugia and food resources has been virtually eliminated, and sediment transport processes that structure habitat have been impaired.

Meanwhile, the quality of the habitat available to salmon and steelhead in the estuary has been compromised. Water temperatures are relatively high for cold-water species such as salmon and steelhead and are expected to continue to climb. Researchers have found a variety of toxic contaminants in water, sediments, and salmon tissue in the estuary. With changes in vegetation and flow, juvenile salmonids' traditional macrodetrital food sources have become scarcer and the food base has switched to a microdetritus-based source, thus altering the productivity of the estuary. Predation by northern pikeminnow, pinnipeds, Caspian terns, and cormorants has increased, and it is likely that the presence of native and exotic fish, introduced invertebrates, and invasive plant species is further altering food web dynamics. These and other changes in habitat quality make the estuary a very different place for salmon and steelhead than it was historically.

Habitat quality often is influenced by features that this analysis considers aspects of habitat opportunity, such as river flow and sediment processes. As one example, alterations in flow

have eliminated much of the vegetated wetlands that ordinarily would supply insect prey for juvenile salmonids and macrodetrital inputs to the estuarine food web. In some cases it may not be not be possible to improve habitat quality without reducing limiting factors related to habitat opportunity. Likewise, it may be necessary to address habitat quality issues, such as toxic contaminants, before increasing access to habitat that could be contaminated.

This type of interplay between habitat opportunity and habitat quality is a reminder of how connected limiting factors in the estuary are, even though this chapter describes them discretely. It is possible that some of the limiting factors have synergistic effects, in which the cumulative negative impact of two or more limiting factors is greater than the sum of the impacts of the individual limiting factors. This likely is the case with flow reductions and increases in bankfull elevation, which combine to limit juveniles' access to off-channel habitats. Although synergistic effects are difficult to identify and quantify, the estuary recovery plan module assumes that they exist and that they can be taken advantage of to enhance the beneficial impacts of management actions in the estuary. Chapter 7 addresses the implications of potential synergistic effects more directly.

Prioritization of Limiting Factors

This estuary recovery module uses a 1-to-5 rating system to prioritize limiting factors by ocean- and stream-type salmon and steelhead, at the estuary scale. PC Trask & Associates, Inc., performed an initial prioritization, based on a synthesis of the three main literature sources (Bottom et al. 2005, Fresh et al. 2005, and Northwest Power and Conservation Council 2004), supplemented by additional literature. (See the discussion of each limiting factors for specific source material.) Staff from the Lower Columbia River Estuary Partnership, NMFS Northwest Fisheries Science Center, NMFS Northwest Regional Office, and Lower Columbia Fish Recovery Board reviewed and provided input on the prioritization.

All three of the main literature sources used in this estuary recovery module identify flow, sediment, water quality, and food web alterations as limiting factors. *Salmon at River's End* (Bottom et al. 2005) analyzes each of the limiting factor categories in the context of habitat opportunity and capacity and how the limiting factor fits within the member/vagrant conceptual framework. The Fresh technical memorandum evaluates selected limiting factors (tern predation, toxics, habitat, and flow) for their impacts on ocean- and stream-type ESUs (Fresh et al. 2005). Finally, the "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" and its supplement (Northwest Power and Conservation Council 2004) evaluate limiting factors for their impacts to salmonids and the level of certainty that the factor is limiting. Of the limiting factors identified in this module, the only one not identified in at least one of the three main documents is stranding, which the author researched at the suggestion of Washington Department of Fish and Wildlife staff.

In prioritizing limiting factors, the author considered the following: (1) how the three main literature sources evaluated and/or prioritized limiting factors, (2) the magnitude or severity of limiting factors as described in the source documents, (3) estimates of mortality caused by a limiting factor, which were available only for predation-related limiting factors, and (4) the frequency with which a limiting factor was identified in the source documents.

Limiting factors were prioritized individually, without trying to account for potential negative synergistic effects, which are difficult to evaluate.

Table 3-1 shows the results of the limiting factor rating process. Each limiting factor received two scores—one for ocean-type salmonids and one for stream-type salmonids. One simplifying assumption in scoring is that both ocean- and stream-type salmonids express a diversity of life history strategies within ESUs and their constituent populations. Relative scores between ocean- and stream-type salmonids generally reflect the dominant life history stage by providing extra weight to the dominant life history strategy; however, less dominant strategies are considered. For example, reduced off-channel habitat is primarily a limiting factor for ocean-type juveniles because the dominant life history strategy is subyearlings that use shallow-water habitats extensively to feed and rear. However, some ocean-type populations and subpopulations also express a yearling strategy as part of the overall genetic makeup of the population. As a result, both ocean- and stream-type salmonids received scores (albeit lower) for other less dominant life history strategies. The far right-hand column of the table is the total score, which adds ocean- and stream-type impact scores into a single composite score. The assumption that within healthy ESUs there is expression of less-dominant life history strategies is central to *Salmon at River's End* (Bottom et al. 2005) and the Fresh technical memorandum.

Table 3-2 organizes limiting factors into groups based on total score. Top-priority limiting factors are those that have the greatest impact on both ocean- and stream-type ESUs, while lowest priority limiting factors have the least combined impact to ocean- and stream-type ESUs. An important assumption in the rating system is that all limiting factors had an effect on one or both ESU types.

The prioritization of limiting factors in this module should be considered a working hypothesis to be tested and refined through research and evaluation (including a formal expert opinion, or "Delphi," process). Future planning efforts would also be enhanced by a limiting factors analysis at the reach or sub-reach scale, although information is generally not available at this time to consistently identify limiting factors at these finer scales. (In Chapter 5, priority reaches are identified for the 23 management actions.)

Summary

The identification of limiting factors in the Columbia River estuary is well supported in a variety of literature sources, although additional research is needed to understand the relative impacts of the limiting factors and their interactions. Source documents take different approaches to lumping limiting factors together or splitting them apart for the purposes of evaluation, but all of the documents generally agree that channel confinement and alterations to flows and sediment have significantly degraded the estuary ecosystem in far-reaching ways. Water quality and food web limiting factors also are well documented.

The interconnectedness of these limiting factors suggests the use of ecosystem-based analysis to understand more exactly their effects on salmonids; however, at this point modeling efforts cannot fully explain the complex relationships among limiting factors.

The next chapter examines human actions and natural events that cause or contribute to the limiting factors described in Chapter 3.

TABLE 3-1
Impact of Limiting Factors on Ocean- and Stream-Type Salmonids

Limiting Factor	Level of Impact		
	Ocean Type*	Stream Type*	Total Score
Habitat-Related Limiting Factors			
Reduced in-channel habitat opportunity			
Flow-related estuary habitat changes	5	3	8
Sediment/nutrient-related estuary habitat changes	4	3	7
Reduced off-channel habitat opportunity			
Flow-related changes in access to off-channel habitat	5	3	8
Bankfull elevation changes	5	2	7
Reduced plume habitat opportunity			
Flow-related plume changes	3	5	8
Sediment/nutrient-related plume changes	2	3	5
Water temperature	5	3	8
Stranding	3	2	5
Food Web-Related Limiting Factors			
Food Source Changes			
Reduced macrodetrital inputs	5	3	8
Increased microdetrital inputs	3	2	5
Competition and Predation			
Native fish	3	3	6
Native birds	2	5	7
Native pinnipeds	2	5	7
Exotic fish	2	2	4
Introduced invertebrates	2	2	4
Exotic plants	2	2	4
Toxic Contaminants			
Bioaccumulation toxicity	4	2	6
Non-bioaccumulative toxicity	4	3	7

*Significance of limiting factor to life history strategy:
1 = No likely effects.
2 = Minor effects on populations.
3 = Moderate effects on populations.
4 = Significant effects on populations.
5 = Major effects on populations.

TABLE 3-2
Limiting Factor Prioritization

Limiting Factor	Limiting Factor Score[a]	Limiting Factor Priority[b]
Flow-related estuary habitat changes	8	Top
Flow-related changes in access to off-channel habitat	8	
Flow-related plume changes	8	
Water temperature	8	
Reduced macrodetrital inputs	8	
Sediment/nutrient-related estuary habitat changes	7	High
Bankfull elevation changes	7	
Native birds	7	
Native pinnipeds	7	
Non-bioaccumulative toxicity	7	
Native fish	6	Medium
Bioaccumulation toxicity	6	
Sediment/nutrient-related plume changes	5	Low
Stranding	5	
Increased microdetrital inputs	5	
Exotic fish	4	Lowest
Introduced invertebrates	4	
Exotic plants	4

[b]Limiting factors have been prioritized in groups, rather than individually, to avoid a false sense of precision in this qualitative analysis.

CHAPTER 4

Threats to Salmonids

Chapter 4 identifies and prioritizes threats to ESUs in the Columbia River basin. Threats are the human actions or natural events, such as volcanic eruptions or floodplain development, that cause or contribute to limiting factors (Gaar 2005). Threats may be caused by past, present, or future actions or events.

PC Trask & Associates, Inc., identified and prioritized threats using the same process and sources used to identify and prioritize limiting factors—that is, a thorough review and synthesis of pertinent literature (particularly Bottom et al. 2005, Fresh et al. 2005, and Northwest Power and Conservation Council 2004), supplemented with input from staff at the NMFS Northwest Fisheries Science Center and Northwest Regional Office, Lower Columbia River Estuary Partnership, and Lower Columbia Fish Recovery Board. The module's three key source documents and a number of other sources document both limiting factors and threats. In most cases the literature addresses limiting factors and threats together, and it required substantial effort to separate them for the purposes of this estuary recovery plan module.

The one threat presented in this chapter that the three main source documents do not mention is ship wakes, which can cause stranding of juvenile salmonids. Although the topic of stranding was first raised in a 1977 report (Bauersfeld 1977), the extent of stranding remains unclear. Washington Department of Fish & Wildlife staff suggested that the topic be addressed in this recovery plan module.

The relationship between limiting factors and threats is not necessarily one-to-one. A single threat can contribute to several limiting factors, and in many cases a limiting factor exists because of the effects of multiple and varied threats. (Table 4-1, which is presented later in this chapter, shows the linkages between the limiting factors in Chapter 3 and the threats described in Chapter 4.) For ease of understanding, this chapter organizes threats to salmonids into the following groupings: flow, sediment, structures such as dikes and jetties, ship wakes, food web (including species relationships), and water quality in the estuary. The presentation of threats as discrete activities or phenomena is an oversimplification of complex physical and biological relationships that affect salmon survival. The threats related to flow, sediment transport, and food webs are particularly difficult to tease apart and discuss discretely. Thus the reader should bear in mind that describing threats individually does not fully capture the dynamic interplay of forces that are currently putting salmonids in the estuary at risk. The complexity of these forces is illustrated in Figure 4-1, which is a representation of a conceptual model of the Columbia River estuary developed by the U.S. Army Corps of Engineers (Diefenderfer et al. 2005). The model provides in-depth detail on the relationships between limiting factors and threats.

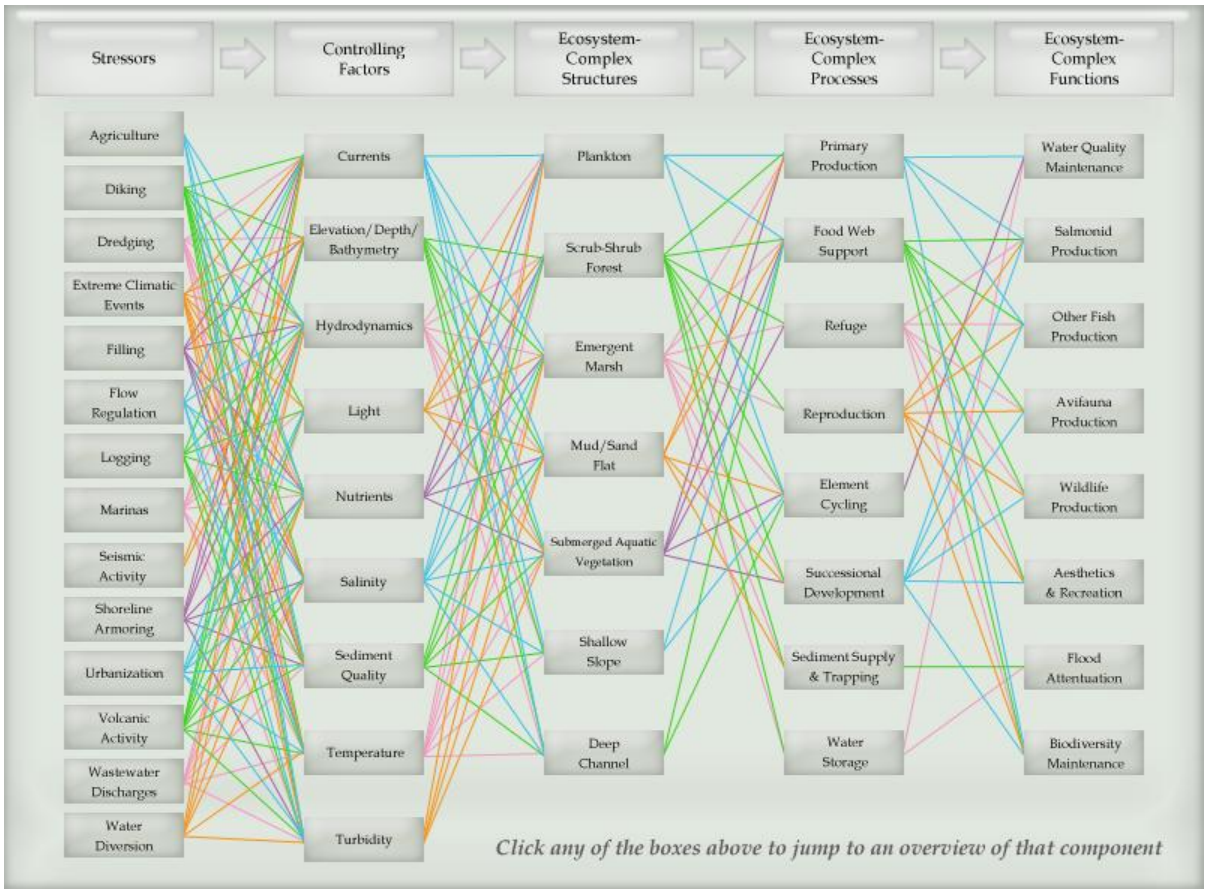

FIGURE 4-1
Conceptual Model of the Columbia River Estuary
(Note: "Stressors" are equivalent to threats as defined in this module.)
(Figure provided courtesy of the U.S. Army Corps of Engineers.)

Most of the human threats described in this chapter are the result of the cumulative impacts of European Americans living in the Northwest. From an ecological perspective these impacts have taken place relatively quickly. Consider that in 1770, when American Robert Gray first crossed the Columbia River bar, about 100,000 Native Americans lived in the Columbia River basin (Oregon State University 1998). Today the population of the Columbia Basin is approximately 5 million (National Research Council 2004). In the early years of Euro-American settlement, the area's abundant natural resources supported farming, mining, logging, fishing, and other activities that modified the landscape into productive uses for people. Later, the availability of cheap hydroelectric power helped fuel expanded agriculture, manufacturing, and development and the rise of urban centers such as Portland. The impacts of these activities on salmonids in the estuary have been substantial.

Flow-Related Threats

Over the last 4,000 years, salmon thrived in the Columbia River by adapting to habitats created by characteristics of the land and water flow (Fresh et al. 2005). Key attributes of flow include magnitude and timing, both of which have changed significantly in the

Columbia River over the last two centuries. Today the mean flow to the estuary is about 16 percent less than it was in the latter part of the nineteenth century (Jay and Kukulka 2003), and spring freshet peak flows have declined about 44 percent in that same time period (Jay and Kukulka 2003). In addition, the timing of peak flows occurs about 14 to 30 days earlier than it did historically (Jay and Kukulka 2003). Reductions in the spring freshet flows are shown in Figure 4-2, which presents simulated mean monthly discharge at Bonneville Dam before development of the hydrosystem and under current hydrosystem configurations and operations.

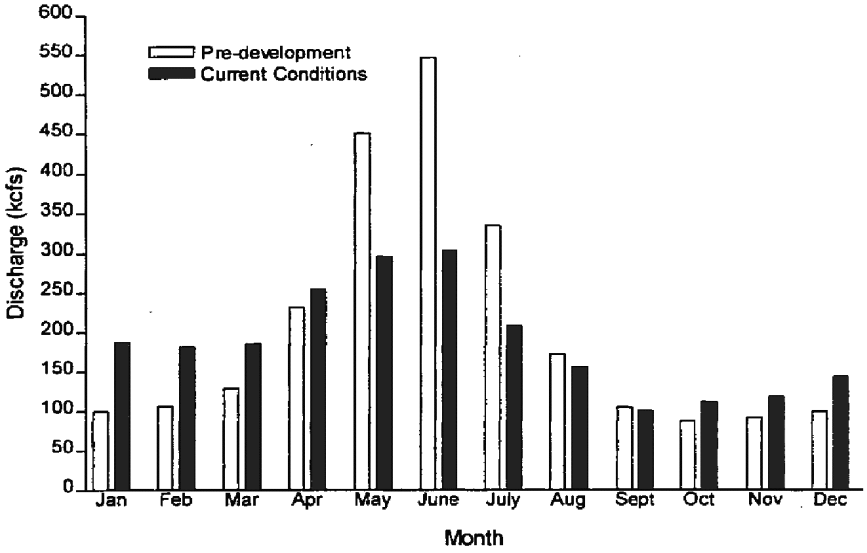

FIGURE 4-2
Changes in the Annual Columbia River Flow
(Adapted from National Marine Fisheries Service 2000.)

Flow alterations, in connection with other factors, can increase or decrease salmonids' ability to access habitats and the capacity of habitats to sustain salmonids (Bottom et al. 2005). In the case of the Columbia River, alterations in the timing, magnitude, and duration of flows are responsible for dramatic changes in habitat opportunity and capacity in the estuary, including effects on groundwater recharge, cold-water upwelling, flooding, off-channel habitat quality and quantity, and water quality. Climate fluctuations, the withdrawal of water, and regulation of river flow have altered the amount and timing of instream flows entering the estuary and plume.

Affected salmonids: Alterations in the magnitude and timing of Columbia River flows affect both ocean- and stream-type juvenile salmonids. Ocean-type juveniles spend more time in the estuary, where they rely on shallow vegetated marsh habitats and upland swamp habitats (Northwest Power and Conservation Council 2004). Chum salmon (ocean-type) also spawn in the mainstem and are affected by low flows during the spawning and egg incubation life stages. In extreme cases, redds may have been dewatered; however, a minimum flow now has been administratively set from November through April to reduce the potential for dewatering of chum redds located immediately below Bonneville Dam. Ocean-type salmonids also rely on seasonal overbank flows to access habitats and preferred food sources.

Stream-type juveniles do not spend much time in the estuary, but research indicates that they may use the Columbia River plume habitat as they adjust to saltwater conditions (Fresh et al. 2005). Columbia River flows have a direct effect on the plume's surface area, volume, frontal features, and extent offshore (Fresh et al. 2005). Flow alterations also affect sediment transport processes and water quality.

Threat: Climate Cycles and Global Climate Change

Natural variations in Columbia River flow as a result of long- and short-term climate fluctuations have occurred throughout history. The Pacific Decadal Oscillation (PDO) alternates between cold and warm phases approximately every 30 years (Fresh et al. 2005). The cold, rainy phase is typical of the Northwest and increases flows, while the warm phase is drier and decreases flows (Fresh et al. 2005). The El Niño/Southern Oscillation (ENSO) is a shorter, 3- to 7-year phenomenon that similarly has cold and warm phases that may magnify or reduce the effects of the PDO.

Climatic fluctuations have a significant effect on the amount and timing of water flowing to the estuary (Fresh et al. 2005). Since 1878, climatic changes have reduced Columbia River flows by 9 percent (Jay and Kukulka 2003). The NMFS Northwest Fisheries Science Center has observed changes in PDO and ENSO indicators that suggest that changes in ecosystem structure can be expected that are unfavorable for salmon and steelhead (Varanasi 2005). These changes may continue over the next several years.

Scientists believe that the release of high levels of carbon dioxide as a result of human activities is contributing to global climate change. The source of these releases includes the use of fossil fuels to run cars, heat homes and offices, and power factories. Over the past century, global climate change has caused sea levels to rise about 4 to 5 inches (10 to 13 centimeters), worldwide precipitation to increase by about 1 percent, and the frequency of extreme rainfall events to increase in much of the United States (U.S. Environmental Protection Agency 2005). Sea level rise is predicted to accelerate worldwide in the coming decades as a result of global climate change (Intergovernmental Panel on Climate Change 2007). The Intergovernmental Panel on Climate Change has observed that sea levels rose at an average rate of 1.8 millimeters per year from 1961 to 2003 and may be 0.18 to 0.59 meter (0.6 to 1.9 feet) higher at the end of the 21st century than they were during the baseline period of 1980 to 1999 (Intergovernmental Panel on Climate Change 2007).

The Independent Scientific Advisory Board for the Northwest Power and Conservation Council (2007) reports that the Pacific Northwest has warmed about 1° C (1.8° F) since 1900 (this is about 50 percent more than the global average for the same time period) and is projected to warm at a rate of 0.1 to 0.6° C (0.18 to 1.1° F) per decade during the next century. Over the long term, winter precipitation is expected to increase, and summer precipitation is expected to decrease. Within the Columbia River basin, expected effects of rising temperatures include more precipitation falling as rain rather than snow, diminished snow pack, associated reductions in late-summer/early-fall flow, altered timing of flows, increased peak flows, and continued rises in water temperatures. In the estuary, these factors could lead to changes in flooding and ecosystem processes and conditions that already are considered limiting factors for salmon and steelhead—namely, flow-related habitat changes, sediment transport, food web dynamics, populations of non-native species, and water temperature (Independent Scientific Advisory Board 2007). Increasingly, water

temperatures in the estuary are approaching the upper thermal limit for salmonids that use the estuary during summer months (National Research Council 2004). Further increases in water temperature could render some current estuarine habitat unsuitable for salmonids, enhance conditions for warm-water fish that prey on or compete with juvenile salmonids, and alter physiological processes such as growth and metabolism among juveniles (Independent Scientific Advisory Board 2007). Some evidence suggests that salmonid response to climate change varies among populations (Crozier and Zabel 2006 as cited in Independent Scientific Advisory Board 2007). Other potential impacts of global climate change in the estuary may include continued rises in sea level and associated effects on intertidal habitat formation and maintenance.

Study of the impacts of global climate change is an evolving field, and additional research is needed to understand the phenomenon's likely effects on estuarine habitats and processes with specificity. Although the estuary recovery plan module does not consider global climate change separately from other climate-related impacts in the estuary, the topic should receive increasing attention for its potential to affect fish management in the Columbia River basin as a whole. As additional scientific information on global climate change becomes available, it will be incorporated into any updates of the estuary recovery plan module and implementation of associated management actions.

Limiting factors this threat contributes to: Flow-related estuary habitat and plume changes, flow-related changes in access to off-channel habitat, water temperature, and reduced macrodetrital inputs.

Threat: Water Withdrawal

Reduction in the amount of instream flow in a river system is an important measure of alterations to the system (Fresh et al. 2005). Water withdrawals affect both the magnitude and timing of flows entering the estuary and plume.

Historically, flow conditions in the estuary were determined by seasonal climate effects (such as precipitation) and hydrology. Since the early 1900s and to a larger degree since the 1960s, irrigation practices have reduced flows in the Columbia River. Water withdrawals as a result of agricultural irrigation and other water uses are estimated to have reduced flows of the Columbia River by 7 percent since the latter part of the nineteenth century (Jay and Kukulka 2003).

Other human activities that reduce flows are the result of upstream use of surface water and groundwater for commercial, industrial, municipal, domestic, and other purposes (National Research Council 2004).

Irrigation withdrawals of surface water account for approximately 96 percent of total water used, while municipal and other uses account for only 4 percent (National Research Council 2004). On the other hand, about 75 percent of all groundwater withdrawals support irrigation and the remaining 25 percent are used for other purposes (National Research Council 2004).

Limiting factors this threat contributes to: Flow-related estuary habitat and plume changes, flow-related changes in access to off-channel habitat, and reduced macrodetrital inputs.

Threat: Flow Regulation

The timing and magnitude of spring freshets have been drastically altered by management of the Columbia River hydrosystem (Fresh et al. 2005). Jay and Kukulka (2003) estimate that 26 percent of the overall reduction of freshet season flow since the late nineteenth century is attributable to flow regulation. Together with irrigation storage and withdrawal, flow regulation has increased fall and winter flows (winter flows have increased because of pre-release before the freshet season), and much of the seasonal timing of flows in the estuary can be attributed to flood control and hydroelectric operations.

Flow regulation is a function of the hydrosystem in the United States and Canada. The first hydroelectric facility in the lower Columbia Basin—the T.W. Sullivan Dam in Oregon City—was constructed in 1888. Since then, more than 450 dams have been built in the Columbia River basin (Columbia Basin Trust). These dams supply British Columbia with 50 percent of its electricity, while the American Northwest relies on hydropower for about two-thirds of its electricity (Columbia Basin Trust). Columbia River dams also provide flood control, enhance irrigation, and improve navigation.

The total active storage of water in the Columbia River Basin is 42 million acre-feet (Northwest Power and Conservation Council 2001), with dams in Canada accounting for about half of the total storage (Northwest Power and Conservation Council 2001). Major Canadian dams include the Duncan, Arrow, and Mica dams. Major U.S. hydroelectric facilities with significant storage include the Grand Coulee, Dworshak, Hungry Horse, and Libby dams. In addition, the U.S. Bureau of Reclamation owns and operates dozens of water storage dams in the Snake and Yakima rivers. The U.S. Army Corps of Engineers also operates many large flood control projects in the Willamette River.

Several recent changes in hydrosystem operations have been implemented to benefit salmonids throughout the basin. These include increasing flows by minimizing winter flood control drafts and reducing the amount of water needed to refill projects during the spring—measures that benefit spring juvenile salmonid migration in the mainstem Snake and Columbia rivers. Also, summer flows have been augmented to cool Snake River temperatures and assist migration of Snake River salmon and steelhead. Finally, a minimum flow has been administratively set from November through April to reduce the potential for dewatering of chum redds, primarily in Reach G in the estuary.

Limiting factors this threat contributes to: Flow-related estuary habitat and plume changes, flow-related changes in access to off-channel habitat, increased microdetrital inputs, and reduced macrodetrital inputs.

Sediment-Related Threats

Changes to seasonal flows, dredging, and the entrapment of sediment in reservoirs have altered those habitat-forming processes in the Columbia River estuary and plume that relate to sediment.

As described in Chapter 3, the transport of sediment is fundamental to habitat-forming processes in the estuary. Sediment helps create and maintain and promote wetlands, which are important to carbon cycling in the estuary and provide habitat for juvenile salmonids. Sediment also provides important minerals and nutrients that support food production in

the estuary and plume. And suspended sediments contribute to turbidity, which is important to salmonids because of the protection it provides from predators. Although the effects of impaired sediment processes on salmonids in the estuary are not fully understood, the magnitude of change and the key role that sediments play in habitat- and food-related processes are significant.

Entrapment of sediment in reservoirs, reduced downstream transport of sediment as a result of altered spring freshets, and dredging are the primary sediment-related threats to salmonids in the estuary. Ocean-type juvenile salmonids are affected by sediment-related changes in habitat in the estuary and by reduced turbidity (which can increase predation). Stream-type juveniles are affected by reduced turbidity in deeper waters in the estuary and plume.

Threat: Entrapment of Fine Sediment in Reservoirs

Reduction in water velocity as a result of upstream reservoirs has altered the transport of organic matter associated with fine sediments such as silt and clay. Fine sediments entering the estuary originate in the upper watersheds of the Snake River (Northwest Power and Conservation Council 2004). Reduced velocities behind upstream reservoirs cause reservoirs to act as a sink to fine sediments and likely reduce amounts delivered to the estuary (Northwest Power and Conservation Council 2004). Currently, organic matter associated with fine sediments supplies the majority of estuarine secondary productivity in the food web (Simenstad et al. 1984 as cited in Northwest Power and Conservation Council 2004). Additionally, reductions in the quantity of fine sediments can increase water clarity and thus contribute to increased predation by piscivorous fish and birds.

Limiting factors this threat contributes to: Flow-related plume changes, sediment/nutrient-related estuary habitat changes, native birds, native fish, and exotic fish.

Threat: Impaired Transport of Coarse Sediment

Historically, the force of spring freshets moved sand down the river and into the estuary, where it formed shallow-water habitats that are vital for salmonids, particularly ocean types. Today, alterations to spring freshet flows have reduced sand discharge in the Columbia River estuary to 70 percent of nineteenth-century levels (Jay and Kukulka 2003). It is likely that the magnitude of change in sand transport affects habitat-forming processes and reduces turbidity, which results in increased predation in the estuary and plume environments.

Limiting factors this threat contributes to: Flow-related plume changes and sediment/nutrient-related estuary habitat changes.

Threat: Dredging

Dredging and the disposal of sand have been a major cause of estuarine habitat loss over the last century (Northwest Power and Conservation Council 2004). Currently, three times more sand is dredged from the estuary than is replenished by upstream sources (Northwest Power and Conservation Council 2004). In addition to causing habitat loss, dredging may have impaired sediment circulation in nearshore ocean areas and resulted in impacts to benthic organisms through disturbance. Still other impacts include the entrainment of crab, juvenile salmonids, sturgeon, and other fish and wildlife species.

Additional losses of vegetated wetlands in the Columbia River estuary are attributable to filling activities, with deposition of dredged materials accounting for most of the filling activities in the estuary (Fresh et al. 2005). Most dredged materials result from maintenance of the shipping channel. Dredged materials are disposed of in-water, along shorelines, or on upland sites; some dredged material disposal sites are shown in the reach maps in Appendix A. Annual maintenance dredging since 1976 has averaged 3.5 million cubic yards per year (Northwest Power and Conservation Council 2004). Significantly more dredged material has resulted from the U.S. Army Corps of Engineers' 43-foot channel deepening project. Dredge fill and diking activities have significantly reduced the availability of wetlands to the river, while placement of dredged material in several areas has increased nesting habitat for Caspian terns and cormorants.

Limiting factors this threat contributes to: Sediment/nutrient-related estuary habitat and plume changes and native birds.

Structural Threats

The development of instream and over-water structures has altered circulation patterns, sediment deposition, sediment erosion, and the formation of habitats in the estuary. Examples of instream and over-water structures include jetties, pile dikes, tide gates, docks, breakwaters, bulkheads, revetments, seawalls, groins, and ramps (Williams and Thom 2001). Such structures create favorable conditions for predators such as northern pikeminnow and walleye, and they can reduce circulation in areas outside of the channel. Instream and over-water structures are found in all reaches of the estuary (for locations, see the reach maps presented in Appendix A).

Another structural threat is reservoirs associated with the hundreds of dams in the Columbia River basin. The construction and operation of these reservoirs has contributed to changes in the temperature of water entering the estuary.

Affected salmonids: Structural threats primarily affect ocean-type juvenile salmonids because of their longer residency time in the estuary and their wider use of off-channel habitats; however, scientists are now hypothesizing that stream-type juveniles forage outside of deeper channels in shallow-water habitats, where they may fall victim to predators that congregate near instream and over-water structures.

Threat: Pilings and Pile Dike Structures

Construction of the North and South jetties has altered sediment accretion and erosion processes near the mouth of the Columbia River. Sediment accretion in the marine littoral areas adjacent to the mouth has decreased the inflow of marine sediments into the estuary (Northwest Power and Conservation Council 2004), while the extensive use of pilings, pile dikes, and other structures to maintain the shipping channel has affected natural flow and sedimentation patterns. Pile dikes maintain the navigation channel by reducing the cross section of the river, increasing the velocity of the river within the channel, and at times slowing velocities immediately downstream of the dike. Development of the navigation channel has reduced flow to side channels and peripheral bays (Northwest Power and Conservation Council 2004). In addition, pile dikes and similar structures may create

conditions that increase predation on juvenile salmonids by northern pikeminnow and other piscivorous fish.

Limiting factors this threat contributes to: Sediment/nutrient-related estuary habitat and plume changes and exotic fish.

Threat: Dikes and Filling

Dikes and filling activities have significantly altered the size and function of the Columbia River estuary. Since the early 1900s, dikes have been built to allow agricultural and residential uses (Fresh et al. 2005). Dikes are thought to have caused more habitat conversion in the estuary than any other human or natural factor (Thomas 1983, as reported in Northwest Power and Conservation Council 2004). The effects of diking on estuarine habitats are directly proportional to elevation, with the greatest impacts on the highest elevation estuarine habitats: forested wetlands, followed by tidal swamps and tidal wetlands. Diking-related impacts to these habitats have reduced their availability to juvenile salmon and steelhead (Thomas 1983, as reported in Northwest Power and Conservation Council 2004). Figure 4-3 shows the various zones found in typical estuaries. The emergent vegetation, diked marsh, shrub wetlands, and forested wetlands are the zones most affected by dike and filling practices (reprinted from Thom 2001). Diked areas and the historical floodplain in the Columbia River estuary are shown in the reach maps presented in Appendix A.

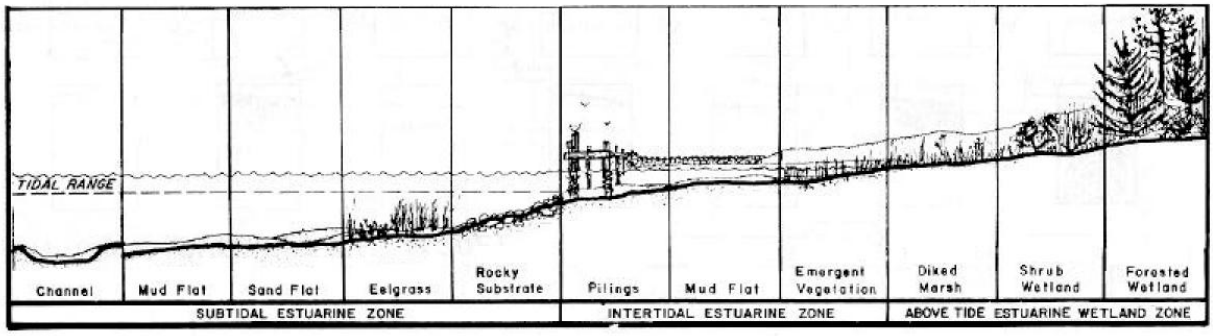

FIGURE 4-3
Subtidal, Intertidal, and Above-Tidal Estuarine Wetland Zones

Before development of the Columbia River hydrosystem and diking and filling, the estuary was dominated by macrodetrital inputs that originated from vegetated wetlands within the estuary. As a result of diking and filling practices and flow alterations (such as changes in the number and timing of spring freshets), emergent plant production in the estuary has decreased by 82 percent and macroalgae production has decreased by 15 percent (Northwest Power and Conservation Council 2004). The availability of insect prey for ocean-type salmonids has been reduced as vegetation has been removed via diking and filling activities and associated dike vegetation maintenance.

Limiting factors this threat contributes to: Reduced macrodetrital inputs, sediment/nutrient-related estuary habitat and plume changes, bankfull elevation increases, and exotic plants.

Threat: Reservoir-Related Temperature Changes

More than 450 dams have been built in the Columbia River basin (Columbia Basin Trust). The associated impoundment of water in upstream reservoirs increases the surface area of the Columbia River, allowing more solar heating of river water than occurs in free-flowing river stretches. This solar heating, combined with the reduced flows from upstream impoundments, has contributed to increased water temperatures in the Columbia River. Measurements at Bonneville Dam indicate that periods of increased temperatures are lasting longer than they did historically (National Research Council 2004). Currently, during summer months, average and maximum values of Columbia River water temperatures are often above 20° C (68°F), which approaches the upper limits of thermal tolerance for cold-water fishes such as salmon (National Research Council 2004). (For additional information on increases in water temperature in the lower Columbia River, see Figure 3-2 and the text that precedes the figure.)

The dynamics of reservoir-related temperature changes in the estuary are complicated and are affected by factors such as thermal inertia, which, among other things, contributes to delayed fall cooling and spring warming of downstream waters. Additional study is needed to better understand reservoir-related temperature changes and their effects on salmonids rearing in the estuary.

Limiting factors this threat contributes to: Water temperature.

Threat: Over-Water Structures

Over-water structures refer to docks, piers, transient moorage, log rafts, and other structures. These structures block sunlight, reduce flow, and trap sediments downstream of pilings (Kahler, Grassley, and Beauchamp 2000; Nightingale and Simenstad 2001). They also change circulation patterns and reduce edge habitats for ocean-type salmonids. Over-water structures contribute to predation on salmonids by altering habitat, creating microhabitats and favorable conditions for predators, especially the northern pikeminnow and non-native species such as small-mouth bass (Kahler, Grassley, and Beauchamp 2000; Nightingale and Simenstad 2001).

Although the actual square footage of over-water structures in the Columbia River estuary has never been inventoried, the structures themselves number in the thousands. Some research has occurred on the effects of breakwaters and over-water structures in the context of marinas. Salmon fry tend to concentrate in higher densities around these structures, thus increasing the risk of predation (Williams and Thom 2001).

Limiting factors this threat contributes to: Sediment/nutrient-related estuary habitat changes, and exotic fish.

Food Web-Related Threats

As described in Chapter 3, changes in the estuarine food web can ripple through the ecosystem, altering energy pathways, feeding patterns, predator/prey relationships, and competition within and among species. As a result of increased nutrients, elevated water temperatures, slower passage of water through reservoirs, and entrapment of organic matter in reservoirs, concentrations of phytoplankton at the base of the food web in the

estuary are higher than they were historically. The introduction of exotic species such as shad may have accelerated the pace of ecological change in the estuary by permanently altering food webs. Food webs also have been altered by sediment transport, in that microdetrital food particles adhere to sediment suspended in the water column, making different food sources available to different species than was the case historically.

Affected salmonids: Both stream- and ocean-type salmonids are affected by energy-related threats—stream types primarily through increased predation in deep-water habitats and ocean types primarily through food web changes in the estuary. Ocean-type juveniles also are affected by reduced availability of insect prey as a result of the construction and maintenance of dikes.

Threat: Increased Phytoplankton Production

A reduction in macrodetrital inputs has shifted the food base in the estuary to phytoplankton produced in and imported from upstream reservoirs (Northwest Power and Conservation Council 2004), or produced as a result of augmented levels of nutrients from urban, industrial, and agricultural development. Phytoplankton support a food web that is less accessible to ocean-type salmonids occupying shallow edge habitats than the historical food web (Northwest Power and Conservation Council 2004). A shift from a generally animal-based salmonid diet to a generally plant-based diet may impair caloric inputs (Garman 1991; Cloe and Garman 1996; Nakano, Miyasaka, and Kuhara, 1999; Henschel, Mahsberg, and Stumpf 2001), and thus the fitness of salmonids that rely on estuarine rearing habitats to grow and prepare for ocean migration. The shift in food sources from a macrodetrital base to a microdetrital base provides different food sources than salmonids historically were accustomed to, in different places within the estuary, and this may favor different species. Because this area of study is immature in the estuary, it is difficult to establish which species benefit more than others.

Limiting factors this threat contributes to: Increased microdetrital inputs.

Threat: Altered Predator/Prey Relationships

Although predation has always occurred in the estuary ecosystem, the cumulative effect of altered flows, changes in sediment transport processes and food sources, introduced species, hatcheries, upstream habitat impacts, hydroelectric impacts, and contaminants have recast estuary and plume environments such that predator/prey relationships have changed significantly. As a result, significant numbers of salmon are lost to fish, avian, and marine mammal predators during migration and residency in the estuary (Northwest Power and Conservation Council 2004). Fish predators include northern pikeminnow, walleye, smallmouth bass, and catfish; avian predators include Caspian terns, double-crested cormorants, and gull species; and marine mammal predators include Steller and California sea lions and harbor seals.

Degraded conditions (loss of habitat and altered food web) in the Columbia River estuary and the timing of large hatchery releases have increased the likelihood that mortality from competition may occur under some circumstances (Northwest Power and Conservation Council 2004). Mortality from intra-species competition has been documented in the Skagit River estuary (Beamer et al. 2005), and there is speculation that it may be a factor in the Columbia River as well (Northwest Power and Conservation Council 2004). If inter-species

competition is occurring, it is likely to have the greatest impact on ocean-type salmonids because of their longer residence time in the estuary (Northwest Power and Conservation Council 2004). If density dependence is affecting stream-type juveniles, it likely happens in the plume.

As the result of human alterations of the estuary environment, native species such as Caspian terns and double-crested cormorants have significantly increased in number, with measurable impacts on stream-type salmonids (Bonneville Power Administration, U.S. Bureau of Reclamation, and U.S. Army Corps of Engineers 2004). These increases in population in the Columbia River estuary are attributed to the deposition of dredged materials in the estuary that represent high-quality habitat for the birds (Bottom et al. 2005) and predation opportunities for cormorants created through the placement of pilings, pile dikes, and other structures. The loss of habitat elsewhere has contributed to terns and cormorants effectively relocating to the Columbia River estuary, with the populations there now representing the largest nesting colonies in the world.

Similarly, the new microdetritus-based food web in the estuary has benefited zooplanktivores, including American shad (an introduced species) (Northwest Power and Conservation Council 2004). Although shad do not appear to be in direct competition with salmonids, their biomass alone—more than 4 million returning adults a year—represents a threat to trophic relationships in the Columbia River. Future increases in water temperatures as a result of climate change may improve conditions for shad in the Columbia River Basin and lead to their continued expansion (Independent Scientific Advisory Board 2008). Other exotic fish species such as introduced walleye and catfish also have been able to capitalize on degraded conditions in the upper reaches of the estuary and altered food web dynamics through predation and competition for food resources (Northwest Power and Conservation Council 2004).

Pinniped predation on adult spring Chinook and winter steelhead continues to increase. On the West Coast the total abundance of California sea lions is approximately 250,000; Stellar sea lions total about 31,000, and Pacific harbor seals total about 25,000 (Griffin 2006). Each spring about 1,000 Stellar sea lions, 3,000 Pacific harbor seals, and 800 California sea lions take up residence in the lower estuary (Griffin 2006). About 1,000 sea lions and harbor seals enter the freshwater portion of the estuary; of these, approximately 80 animals (primarily California sea lions) congregate at Bonneville Dam. The U.S. Army Corps of Engineers' estimates that annual adult mortality at Bonneville Dam because of pinnipeds (primarily California sea lions) ranged from 0.4 percent (2002) to 4.2 percent (2007) during the study period ending in 2010 (U.S. Army Corps of Engineers 2010).[1] Other, radio telemetry-based studies suggest that annual pinniped predation on spring Chinook and winter steelhead at Bonneville Dam may be as high as 8.5 percent and 20 percent, respectively (NMFS 2008b, Appendix G). There is a need for better estimates of the mortality caused by pinnipeds throughout the estuary and plume. Unsubstantiated estimates suggest a mortality rate of 10 percent of the entire adult spring Chinook and steelhead runs in a given year.

Non-native plant species have altered habitat and food webs in the Columbia River estuary. The rate of intentional and unintentional introductions has been increasing over the past 100

[1] Estimated consumption of adult salmonids ranged from a low of 1,010 in 2002 to a high of 6,081 in 2010; the percent of run consumed varied among reporting years in part because of changes in run size.

years, mostly as a result of horticultural practices and the increase in travel and commerce in the Columbia River. Four of those species—purple loosestrife, Eurasian water milfoil, parrot feather, and Brazilian elodea—are of particular concern. Each of these species, in its own way, alters habitat and food webs in the estuary. Purple loosestrife, for example, adapts easily to environmental changes and expands its ranges quickly. The primary ecological effect of purple loosestrife is that it disrupts wetland ecosystems by displacing native plants. Eventually, animals that rely on native flora for food, nesting, or cover also are displaced (Northwest Power and Conservation Council 2004).

Limiting factors this threat contributes to: Native birds, native fish, native pinnipeds, introduced invertebrates, exotic fish, and exotic plants.

Threat: Ship Ballast Practices

Ship ballast practices have been responsible for the introduction of at least 21 exotic species in the Columbia River estuary (Sytsma et al. 2004). When ships release ballast water, non-indigenous species can enter receiving waters. Most of the non-indigenous species in the estuary have originated from Asia (Sytsma et al. 2004). Populations of non-native copepods have established themselves in Reaches A and B (Youngs Bay, Cathlamet Bay, and Grays Bay), and the New Zealand mudsnail has colonized other estuary reaches. The Asian bivalve *Corbicula fluminea* has expanded its range in the estuary, with densities of 10,000 per m^2 being recorded in Cathlamet Bay; however, densities of 100 to 3,000 m^2 are more common (Northwest Power and Conservation Council 2004). These and other non-indigenous invaders disrupt food webs and out-compete juvenile salmonids' native food sources.

An emerging source of concern regarding ship ballast practices is the potential entrainment of juvenile salmonids when large ships take on ballast water as they leave ports unloaded. This issue is being evaluated in relevant Endangered Species Act (ESA) Section 7 consultations (Tortorici 2008).

Limiting factors this threat contributes to: Introduced invertebrates.

Water Quality-Related Threats

The release of toxic contaminants, nutrient loading, and reduced dissolved oxygen have altered the quality of salmonid habitats in the Columbia River estuary. Currently the estuary receives toxic contaminants or nutrients from more than 100 point sources and numerous non-point sources, such as surface and stormwater runoff from urban and agricultural areas (Fuhrer et al. 1996 as referenced in Fresh et al. 2005). In most areas, nonpoint sources such as agricultural, urban, industrial, and timber harvest practices contribute greater nutrient loads than point sources do (Wise et al. 2007). The Snake, Yakima, Deschutes, and Willamette rivers contribute most of the nutrient loads discharged to the Columbia River. Nutrient yields (loads normalized for basin size) are generally greater in basins west of the Cascade Range and are correlated with precipitation and point-source loads (Wise et al. 2007).

Threat: Agricultural Practices

The health of an aquatic ecosystem is substantially affected by agricultural, urban, and industrial practices and wastewater discharge (National Research Council 2004). Specific threats include increased nutrients (nitrogen and phosphorus), sediment, and organic and trace metals (National Research Council 2004). For example, Wise et al. (2007) found a significant correlation between total nitrogen yields in basins west of the Cascades and fertilizer and manure loads. Increased nutrient loads from anthropogenic sources can lead to increased phytoplankton concentrations, decreased water clarity, and depressed dissolved oxygen levels, especially in areas with longer residence times and warmer water temperatures. DDT, other banned pesticides that have persisted in the environment, and pesticides in current use are entering the estuary from agricultural runoff, some of which originates outside the lower Columbia River basin. The middle and upper Columbia are primary sources of DDT and other organochlorine pesticides in the estuary, as are tributaries such as the Yakima and Willamette rivers (Clark et al. 1998, Williamson et al. 1998, Hinck et al. 2006, Johnson and Norton 2005, McCarthy and Gale 2001 as cited in Lower Columbia River Estuary Partnership 2007). A 2007 study confirmed the presence of the pesticides atrazine, simazine, metolachlor, EPTC, DCPA, and diuron at sites throughout the estuary, often in combination (Lower Columbia River Estuary Partnership 2007). The timing of detections suggests that precipitation events play an important role in transporting pesticides to the Willamette River, which is a primary contributor of both agricultural and urban/industrial contaminants to the Columbia River estuary.

The U.S. Geological Survey's National Stream Quality Accounting Network (NASQAN) program also reports detection of a wide range of commonly used pesticides at sampling sites near Bonneville Dam and at the confluence of the Willamette and Columbia rivers (Fresh et al. 2005). Detected pesticides include simazine, atrazine, chlorpyrifos, metolachlor, diazinon, and carbaryl. Arsenic and trace metals such as copper, iron, and manganese also have been detected. Although trace metals occur naturally, they also are introduced through human activities, such as the use of lead arsenate as an insecticide for apples (Fresh et al. 2005). Water-soluble contaminants, trace metals, and chlorinated compounds have been detected in the estuary (Fresh et al. 2005), and DDT, PCBs, dioxins, and metals have been detected at elevated levels in tissue from fish in the estuary (Northwest Power and Conservation Council 2004).

Limiting factors this threat contributes to: Non-bioaccumulative toxicity, bioaccumulation toxicity, and increased microdetrital inputs.

Threat: Urban and Industrial Practices

The Columbia River downstream of Bonneville Dam is the most urbanized stretch in the entire basin. The area has more than 100 point sources that are known to discharge directly into the Columbia River estuary; these include chemical plants, pulp and paper mills, hydroelectric facilities, municipal wastewater treatment plants, and seafood processors (Fuhrer et al. 1996 as cited in Lower Columbia River Estuary Partnership 2007). Potential nonpoint sources include hazardous waste sites, landfills, marinas and moorages, and overland surface runoff that transports nutrients, sediment, PAHs, metals, and pesticides from streets, yards, and industries.

The largest sources of effluent in this area are the Portland and Vancouver sewage treatment plants (Fresh et al. 2005), with Portland's wastewater treatment facility being the largest point-source discharger in the Columbia Basin (Wise et al. 2007). The annual nutrient loads from this facility equal approximately 2 to 3 percent of the annual in-stream nutrient loads at the Beaver Army Terminal water quality sampling site, downstream of Longview, Washington (Wise et al 2007). Contaminants also are transported to the estuary from areas above Bonneville Dam, such as the Deschutes, Yakima, and Snake rivers. These rivers, together with the Willamette, contribute most of the nutrient loads discharged to the Columbia River (Wise et al. 2007).

An intensive study of sediments in Portland Harbor (the stretch of the Willamette River from Sauvie Island to Swan Island) has uncovered pesticides, PCBs, and other toxic chemicals. In general, studies have shown that PCB and PAH concentrations in salmon and their prey in the estuary are comparable to those in organisms in other moderately to highly urbanized areas (Fresh et al. 2005, Lower Columbia River Estuary Partnership 2007, Johnson et al. 2007b). Industrial contaminants such as PAHs have been detected in sediments from the lower Willamette River in Portland at levels that exceed state or Federal sediment quality guidelines. The U.S. Environmental Protection Agency identified PCB and DDT hot spots within the estuary, including near Longview, West Sand Island, the Astoria Bridge, and Vancouver (Fresh et al. 2005). Studies in the 1990s found that sediment contamination was highest near urban and industrial areas, with concentrations in excess of levels of concern for DDE (a breakdown product of DDT), PCBs, dioxins and furans, and PAHs (Tetra Tech 1996). Current studies find higher levels of flame retardants (PBDEs), PCBs, and DDT on bed sediment collected near Portland than in sediment collected from other sites in the estuary (Jones et al. 2008).

In addition, emerging contaminants associated with urban development are beginning to be detected in the Columbia River estuary. These include PBDE flame retardants, which have been found in juvenile salmon tissue, their stomach contents, the water column, and on suspended sediment at sites throughout the estuary (Lower Columbia River Estuary Partnership 2007). Caffeine, human and veterinary antibiotics, synthetic musk, and the plasticizer bisphenol A have also been detected in the water of the estuary (Lower Columbia River Estuary Partnership 2007). Although the effects of these compounds are not yet well understood, some of them are suspected hormone disruptors, and juvenile salmon collected from the estuary show evidence of exposure to estrogenic compounds (Lower Columbia River Estuary Partnership 2007). This could be the result of emerging contaminants or more familiar toxic contaminants in the estuary, such as certain pesticides.

Limiting factors this threat contributes to: Non-bioaccumulative toxicity, bioaccumulation toxicity, and increased microdetrital inputs.

Other Threats

Threat: Riparian Practices

Riparian practices along the estuary mainstem and in tributaries throughout the Columbia River basin have contributed to increases in water temperature in the estuary by changing hydrology and removing riparian habitats (National Research Council 2004) that—among other ecological functions—provide insects and macrodetrital inputs to the food web.

Problematic practices include shoreline modifications, timber harvest, certain agricultural activities within riparian zones, and residential, commercial, and industrial land uses. These activities increase water temperatures, alter hydrology and macrodetrital inputs, and in some cases modify shoreline habitats used by salmonids, especially ocean types (Lower Columbia Fish Recovery Board 2004).

Limiting factors this threat contributes to: Sediment/nutrient-related estuary habitat changes, reduced macrodetrital inputs, water temperature, and exotic plants.

Threat: Ship Wakes

Ships traveling through the Columbia River estuary produce waves and an uprush which, under certain circumstances, causes juvenile salmonids and other fish to become stranded on shore (Bauersfeld 1977). Although Bauersfeld concluded that ship wake stranding was a significant cause of mortality in ocean-type Chinook salmon and other species, other studies have not confirmed the magnitude of this threat. As a part of the U.S. Army Corps of Engineers' channel deepening project, a study is under way that may help characterize the magnitude of ship wake stranding. The purpose of the study is to document ship wake stranding before and after channel deepening. The first half of the study, published in February 2006, documented stranding events at three test sites. The second part of the study will begin after dredging is completed (Pearson et al. 2006). These results should be useful as partial basis for Light Detection and Ranging (LIDAR) analysis and extrapolation of test site mortality throughout the estuary for similar habitat types. Early in 2008, the Port of Vancouver enlisted Entrix, Inc., to perform a spatial analysis of beach susceptibility for the stranding of juvenile salmonids by ship wakes (Pearson 2008). The study examined wave characteristics and the geomorphology of the lower river but did not examine nearshore fish density. The purpose of the study was to estimate the number of miles of shoreline that exhibit traits expected to potentially cause stranding. The study concluded that approximately 33 miles of shoreline between the mouth of the river and the city of Vancouver have shoreline characteristics consistent with stranding (Pearson 2008).

Limiting factors this threat contributes to: Stranding.

Prioritization of Threats

This estuary recovery module establishes priorities for threats by linking them to pertinent limiting factors and estimating their relative contribution to those limiting factors. The threats identified above are well supported in a wide variety of literature sources, including Fresh et al. (2005), Bottom et al. (2005), the "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" (Northwest Power and Conservation Council 2004), and a variety of more topic-specific primary literature sources.[2] The prioritization of threats, though, is not nearly as well supported, partly because of the limited understanding of how threats contribute to limiting factors and to what degree salmon and steelhead are affected by a given limiting factor. While it is attractive to assume that additional study will fully answer these questions, the biological response to environmental conditions will always be difficult to model because of the tremendous complexities of the physical, biological, and

[2] As with the limiting factors, most of the threats identified in this chapter are not supported by data at the reach or sub-reach scale.

ecological interplay that occurs in the environment. On the other hand, new interest in the estuary and its role in the recovery of listed species in the Columbia River has generated better understanding, and it is likely that uncertainty surrounding threats and limiting factors will continue to lessen.

Table 4-1 demonstrates the relationship between limiting factors and threats by showing which threats are causing which limiting factors and estimating the contribution of each threat to each limiting factor. The presumed relative contribution of a threat to each limiting factor is indicated by the primary, secondary, or tertiary designation. The contribution of each threat to its associated limiting factor(s) is multiplied by the relative importance of that limiting factor to salmonids to yield the threat index score. This score expresses the relative priority of the threat in question. (The relative importance of limiting factors is taken from Table 3-2.)

PC Trask & Associates, Inc., developed the initial threat contribution scores for Table 4-1 by reviewing the extent to which the three main literature sources—and other sources—described relationships between limiting factors and threats or evaluated the contribution of multiple threats to a single limiting factor. Although literature sources were useful in making connections between threats and limiting factors, in many cases the literature did not separate limiting factors from threats or did not attempt to identify and rank the full scope of threats that might be contributing to a particular limiting factor. In nearly all cases, authors discussed cause-and-effect relationships in qualitative language. In some cases, authors described quantitative relationships, as in the relationship between flow regulation and sediment transport. Only a handful of sources estimated priorities for threats.

To supplement information gleaned from the literature, the author talked with regional experts (see Acknowledgements) to identify potential threat contributions not described in the literature. The author also refined the initial scores based on review and input by NMFS Northwest Fisheries Science Center, NMFS Northwest Regional office, Lower Columbia River Estuary Partnership, and Lower Columbia Fish Recovery Board staff. The author, in consultation with staff from the Lower Columbia River Estuary Partnership and NMFS, also made minor adjustments to the scores in response to comments received during the public review period.

TABLE 4-1
Linkages Between Limiting Factors and Threats to Ocean- and Stream-Type Salmonids

Limiting Factor	Threat	Limiting Factor Priority & Numerical Score[a]	Contribution of Threat to Limiting Factor, & Numerical Score[b]	Threat Index[c]
Flow-related estuary habitat changes	Climate cycles and global climate change	Top (5)	Secondary (2)	10
	Water withdrawal	Top (5)	Secondary (2)	10
	Flow regulation	Top (5)	Primary (3)	15
Flow-related changes in access to off-channel habitat	Climate cycles and global climate change	Top (5)	Secondary (2)	10
	Water withdrawal	Top (5)	Secondary (2)	10
	Flow regulation	Top (5)	Primary (3)	15
Flow-related plume changes	Climate cycles and global climate change	Top (5)	Secondary (2)	10
	Water withdrawal	Top (5)	Secondary (2)	10
	Flow regulation	Top (5)	Primary (3)	15

Limiting Factor	Threat	Limiting Factor Priority & Numerical Score[a]	Contribution of Threat to Limiting Factor, & Numerical Score[b]	Threat Index[c]
	Impaired transport of coarse sediment	Top (5)	Secondary (2)	10
	Entrapment of fine sediment in reservoirs	Top (5)	Tertiary (1)	5
Water temperature	Climate cycles and global climate change	Top (5)	Secondary (2)	10
	Reservoir-related temperature changes	Top (5)	Secondary (2)	10
	Riparian practices	Top (5)	Secondary (2)	10
Reduced macrodetrital inputs	Climate cycles and global climate change	Top (5)	Secondary (2)	10
	Water withdrawal	Top (5)	Secondary (2)	10
	Riparian practices	Top (5)	Secondary (2)	10
	Flow regulation	Top (5)	Primary (3)	15
	Dikes and filling	Top (5)	Primary (3)	15
Sediment/nutrient-related estuary habitat changes	Impaired transport of coarse sediment	High (4)	Primary (3)	12
	Entrapment of fine sediment in reservoirs	High (4)	Secondary (2)	8
	Dredging	High (4)	Secondary (2)	8
	Pilings and pile dike structures	High (4)	Primary (3)	12
	Dikes and filling	High (4)	Primary (3)	12
	Over-water structures	High (4)	Tertiary (1)	4
	Riparian practices	High (4)	Tertiary (1)	4
Bankfull elevation changes	Dikes and filling	High (4)	Primary (3)	12
Native birds	Entrapment of fine sediment in reservoirs	High (4)	Tertiary (1)	4
	Dredging	High (4)	Secondary (2)	8
	Altered predator/prey relationships	High (4)	Primary (3)	12
Native pinnipeds	Altered predator/prey relationships	High (4)	Primary (3)	12
Non-bioaccumulative toxicity	Agricultural practices	High (4)	Primary (3)	12
	Urban and industrial practices	High (4)	Primary (3)	12
Native fish	Entrapment of fine sediment in reservoirs	Medium (3)	Tertiary (1)	3
	Altered predator/prey relationships	Medium (3)	Primary (3)	9
Bioaccumulation toxicity	Agricultural practices	Medium (3)	Primary (3)	9
	Urban and industrial practices	Medium (3)	Primary (3)	9
Sediment/nutrient-related plume changes	Dredging	Low (2)	Primary (3)	6
	Pilings and pile dike structures	Low (2)	Secondary (2)	4
	Dikes and filling	Low (2)	Secondary (2)	4
Stranding	Ship wakes	Low (2)	Primary (3)	6
Increased microdetrital inputs	Agricultural Practices	Low (2)	Secondary (2)	4
	Urban and industrial practices	Low (2)	Secondary (2)	4
	Increased phytoplankton production	Low (2)	Primary (3)	6
	Flow regulation	Low (2)	Tertiary (1)	2

Limiting Factor	Threat	Limiting Factor Priority & Numerical Score[a]	Contribution of Threat to Limiting Factor, & Numerical Score[b]	Threat Index[c]
Exotic fish	Entrapment of fine sediment in reservoirs	Lowest (1)	Tertiary (1)	1
	Over-water structures	Lowest (1)	Secondary (2)	2
	Pilings and pile dike structures	Lowest (1)	Secondary (2)	2
	Altered predator/prey relationships	Lowest (1)	Primary (3)	3
Introduced invertebrates	Altered predator/prey relationships	Lowest (1)	Tertiary (1)	1
	Ship ballast practices	Lowest (1)	Primary (3)	3
Exotic plants	Dikes and filling	Lowest (1)	Primary (3)	3
	Riparian practices	Lowest (1)	Secondary (2)	2
	Altered predator/prey relationships	Lowest (1)	Primary (3)	3

[a] From Table 3-2.

[b] Indicates how important the threat is in perpetuating the limiting factor:

3 = Threat is a primary cause of the limiting factor. Addressing this threat would significantly improve salmonid performance.

2 = Threat is a secondary cause of the limiting factor. Addressing this threat would improve performance.

1 = Threat is a tertiary cause of the limiting factor. Addressing this threat would benefit performance, but by itself would result in only minor improvement.

[c] Product of the numerical scores for the limiting factor priority and the threat's contribution to the limiting factor. A high threat index score means that the threat is a major contributor to one or more significant limiting factors. A low threat index score means the threat is a small contributor to a minor limiting factor.

Table 4-2 organizes threats by their threat index score, in descending order. However, the state of the science is such that the differentiation of threat priorities in Tables 4-1 and 4-2 should be viewed as reasonable guidance and a set of working hypotheses to be tested and refined through research and evaluation. Given uncertainties about estuarine ecosystems and how they function, some threats that are ranked relatively low in Table 4-2 may eventually prove to have large impacts to the estuary. For example, it is difficult to dispute the importance of flow regulation compared to ship ballast practices. But it is possible that the effects of exotic invertebrates introduced to the estuary through ship ballast practices will significantly degrade the overall health of the estuary ecosystem over time and that this threat will move up in the priority ranking. As another consideration, Tables 4-1 and 4-2 reflect the prioritization of threats across the entire estuary; within each reach, threats could be prioritized differently. A reach-scale analysis of limiting factors and threats was beyond the scope of this document and, in some cases, beyond the limits of currently available science. But such an analysis would be useful as additional scientific information becomes available.

TABLE 4-2
Prioritization of Threats to Ocean- and Stream-Type Salmonids

Threat	Threat Index*	Threat Priority
Flow regulation	15	
Dikes and filling	15	
Altered predator/prey relationships	12	
Urban and industrial practices	12	HIGH
Agricultural practices	12	
Impaired transport of coarse sediment	12	
Pilings and pile dike structures	12	
Reservoir-related temperature changes	10	
Riparian practices	10	
Climate cycles and global climate change	10	
Water withdrawal	10	
Dredging	8	
Entrapment of fine sediment in reservoirs	8	
Ship wakes	6	
Increased phytoplankton production	6	LOW
Over-water structures	4	
Ship ballast practices	3	

* From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

Summary

Chapter 4 provides information on the underlying causes of the factors that influence the viability of ocean- and stream-type ESUs during their residency and migration in the estuary. Analysis of threats is challenging because a single threat often contributes to multiple limiting factors and may originate miles upstream from the estuary. In Chapter 4, threats were identified, described, linked to limiting factors, and prioritized. Chapter 5 turns to management actions, identifying actions that will address threats and thus help reduce risks to the 13 ESA-listed ESUs using the Columbia River estuary.

CHAPTER 5

Management Actions

Chapters 3 and 4 of this recovery plan module identify factors that currently limit salmonids' biological performance in the estuary and the threats that contribute to those limiting factors. Chapter 5 presents 23 management actions that, together, address the range of threats salmonids in the estuary face, from altered habitat-forming processes to physical structures in the estuary, changes in the food web, and poor water quality. If implemented, the actions presented in this chapter would reduce the impacts of threats to salmonids during their migration and residency in the estuary and plume.

In addition to identifying the management actions, Chapter 5 evaluates them in terms of constraints to implementation, potential improvement in salmonid survival, and cost. More specifically, the chapter discusses each management action's potential benefits and implementation constraints, hypothesizes how benefits could translate into increased survival of salmonids, breaks each action into component projects, and estimates the cost of each project, and thus of each action. Also included is a list of actions that would address threats to salmonids in the estuary but that would need to be implemented outside the estuary, either in estuary tributaries or in upstream areas of the Columbia River basin.

As in other chapters of this recovery plan module, the analysis in Chapter 5 does not fully capture the subtleties of the ecological interactions that influence salmonid survival. Despite continuing research, many aspects of the salmonid life cycle are poorly understood, in part because of the sheer complexity of the ecosystems that salmonids transition into and out of during their lives. The actual relationships among threats and management actions are far more intricate than what is described here. Additionally, given the limits in scientific understanding, there is a degree of uncertainty at each step of the analysis in this chapter. Yet the categories, ratings, and associations presented here are useful tools for discussing complex ecological relationships and comparing possible outcomes of different management actions.

Identification of Management Actions

For the purposes of this recovery plan module, a management action is any action that has the potential to reduce the impact of human-caused or naturally occurring threats to salmonids while they migrate or rear in the estuary and plume. PC Trask & Associates, Inc., identified management actions using available literature and input from area experts (see Acknowledgements). Key documents used to identify management actions are the "Mainstem Lower Columbia River and Columbia River Estuary Subbasin Plan" (Northwest Power and Conservation Council 2004) and its supplement; *Role of the Estuary in the Recovery of Columbia River Salmon and Steelhead (*Fresh et al. 2005); *Salmon at River's End* (Bottom et al. 2005); and the *2004 FCRPS Biological Opinion on Remand* (National Marine Fisheries Service 2004). Table 5-1 lists threats to salmonids in the estuary and plume and management actions that would address those threats; this information is organized by topic and does not reflect the priority of either threats or management actions.

TABLE 5-1
Management Actions to Address Threats

	Threat	Management Action
Flow-related threats	Climate cycles and global climate change[2]	**CRE[1]-1:** Protect intact riparian areas in the estuary and restore riparian areas that are degraded.[2] **CRE-2:** Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.[2] **CRE-3:** Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.[2]
	Water withdrawal	***CRE-3:*** *Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries*
	Flow regulation	**CRE-4**: Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume. ***CRE-3:*** *Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.*
Sediment-related threats	Entrapment of fine sediment in reservoirs	**CRE-5:** Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.
	Impaired transport of coarse sediment	**CRE-6:** Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially. **CRE-8:** Remove or modify pilings and pile dikes with low economic value when removal or modification would benefit juvenile salmonids and improve ecosystem health. ***CRE-4:*** *Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.*
	Dredging	**CRE-7:** Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.
Structural threats	Pilings and pile dike structures	***CRE-8:*** *Remove or modify pilings and pile dikes with low economic value when removal or modification would benefit juvenile salmonids and improve ecosystem health.*
	Dikes and filling	**CRE-9:** Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat. **CRE-10:** Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.
	Reservoir-related temperature changes	***CRE-2:*** *Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.*
	Over-water structures	**CRE-11:** Reduce the square footage of over-water structures in the estuary.

	Threat	Management Action
Food web-related threats	Increased phytoplankton production	***CRE-10:*** *Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.*
	Altered predator/prey relationships	**CRE-13:** Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids. **CRE-14:** Identify and implement actions to reduce salmonid predation by pinnipeds. **CRE-15:** Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants. **CRE-16:** Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island. **CRE-17:** Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations. **CRE-18:** Reduce the abundance of shad in the estuary. ***CRE-8:*** *Remove or modify pilings and pile dikes with low economic value when removal or modification would benefit juvenile salmonids and improve ecosystem health.*
	Ship ballast practices	**CRE-19:** Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations ***CRE-7:*** *Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.*
Water quality-related threats	Agricultural practices	**CRE-20:** Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.[3] ***CRE-1:*** *Protect intact riparian areas in the estuary and restore riparian areas that are degraded.* ***CRE-9:*** *Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.*
	Urban and industrial practices	**CRE-21:** Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants. **CRE-22:** Restore or mitigate contaminated sites. **CRE-23:** Implement stormwater best management practices in cities and towns.[3] ***CRE-1:*** *Protect intact riparian areas in the estuary and restore riparian areas that are degraded.* ***CRE-9:*** *Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.*
Other threats	Riparian practices	***CRE-1:*** *Protect intact riparian areas in the estuary and restore riparian areas that are degraded.*
	Ship wakes	**CRE-12:** Reduce the effects of vessel wake stranding in the estuary.

[1] CRE = Columbia River estuary.

[2] Study of the impacts of global climate change is an evolving field, and additional research is needed to understand the phenomenon's likely effects on estuarine habitats and processes with specificity. At this time, the Independent Scientific Advisory Board of the Northwest Power and Conservation Council expects that the regional effects of global climate change in the next century will include more precipitation falling as rain rather than snow, reduced snow pack, and late-summer/early-fall stream flows, and associated rises in stream temperature (Independent Scientific Advisory Board 2007). The climate-related management actions in Table 5-1 reflect these expected impacts. Although the management actions clearly would not change the threat of global climate change itself, they have the potential to lessen its impact on salmonids in the estuary. Even if climate cycles and global climate change have effects different from those assumed in this document, the management actions that Table 5-1 associates with climate would provide benefits to salmonids by addressing other threats, such as water withdrawal, urban and industrial practices, and reservoir heating. All three of the management actions associated with climate in Table 5-1 are associated with other threats listed in Table 5-1.

[3] Unless otherwise noted, the term *best management practices* is used in this document to indicate general methods or techniques found to be most effective in achieving an objective. NMFS envisions that in implementation, specific best management practices would be developed or recommended.

Note: Italics indicate an action's second occurrence in the table, in connection with a different threat.

Given the complexity of the riverine, estuarine, and marine ecosystems that salmon use during their lives, the actual relationships among threats and management actions are more complicated than Table 5-1 suggests. For example, several of the management actions in Table 5-1 are associated with more than one threat (italics indicate an action's second occurrence in the table). This illustrates the complex interplay of ecological processes in the estuary, particularly processes related to flow, sediment, the food web, and water quality, all of which influence salmon survival. Later in this chapter actions are described and analyzed discretely. Some actions are interrelated, both in the problems they attempt to solve and their probable effects. As an example, CRE-2 through CRE-5 (reducing the effects of reservoir heating, protecting/enhancing instream flows influenced by withdrawals and other water management actions in tributaries, adjusting flow timing and magnitude, and addressing entrapment of fine sediments in reservoir) all deal with reservoir and hydrosystem operations. If implemented together, these actions could act in concert to significantly improve water temperature and sediment delivery in the estuary, potentially providing greater benefits through synergistic action than if they were implemented singly. The potential for synergistic effects of management actions is discussed in more detail in Chapter 7.

The estuary recovery module also identifies specific monitoring, research, and evaluation activities appropriate to the 23 management actions. These activities will provide crucial information on the effectiveness of actions that are implemented in the estuary, associated changes in the ecology of the estuary, and scientific uncertainties that affect implementation of the actions. Monitoring, research, and evaluation activities are presented in Chapter 6. Some of these activities are part of the *Research, Monitoring, and Evaluation for the Federal Columbia River Estuary Program* (Johnson et al. 2008), while others are specific to the management actions in this recovery plan module.

Other Recommended Management Actions

In many ways, conditions in the estuary are the sum of ecological stressors that exist throughout the Columbia River basin. Although some threats to salmonids in the estuary originate exclusively in the estuary itself (Caspian tern predation is one example), others are the result of activities in estuary tributaries or in upstream areas; examples of such threats are riparian practices and upstream water withdrawals that reduce stream flow in the estuary. Still other threats, such as land use practices that contribute contaminants to the river, originate in all three areas—estuary, estuary tributaries, and upstream. Because of the geographic scope of these threats, fully addressing them will require effort not just in the estuary but throughout the basin.

When it comes to management actions, though, the geographic scope of this estuary recovery plan module is limited. For the most part the module focuses on management actions that can be implemented within the estuary itself and that will address threats that either originate exclusively within the estuary itself or have a significant in-estuary component. The assumption is that threats originating from outside the estuary are affecting local conditions in tributary and upstream areas and that actions to address these threats will be included in recovery plans being developed for upstream salmonid populations.

Even so, the analysis in Chapters 3 and 4 of this recovery plan module and a review of contemporary literature yielded six management actions that would directly affect threats to salmonids in the estuary yet would need to be implemented almost exclusively outside of the estuary or are otherwise beyond the scope of this document:

- Implement hatchery actions as appropriate throughout the Columbia River basin to reduce the threat of density-dependent mortality as a direct result of ecological interactions (disease, predation, or competition for food or space) between hatchery and wild salmonid juveniles using reduced and/or impaired lower river habitats. The magnitude of the ecological interactions as a function of the cumulative effects of large hatchery releases on natural-origin salmonids, both spatially and temporally, is currently an important scientific uncertainty.
- Upgrade up-river irrigation structures to reduce evaporation and conveyance losses and improve estuary instream flows.
- Implement public and private best management and water system conservation practices to maximize the quantity and quality of instream flows entering the estuary.
- Incorporate water availability analysis in land use planning activities to ensure efficient use of water, improve tributary flows, and reduce stream temperatures.
- Protect and restore riparian areas in tributaries to provide shade and future wood sources.
- Reduce inputs of toxic contaminants originating from upstream tributary and mainstem sources.

Because these six actions are outside the geographic scope of the estuary recovery plan module, they are not analyzed in this chapter. Nevertheless, implementation of these six out-of-estuary actions is important to improving the survival of salmonids in the estuary, so it is recommended that the actions be included in recovery plans being developed for upstream areas of the Columbia River basin.

One factor that is beyond the geographic scope of the estuary recovery plan module but is addressed in the module in a limited manner is hydrosystem operations, which affect water temperature, sediment transport, and various other habitat-forming processes and conditions in the estuary. Although actual operation of the hydrosystem occurs outside the estuary, the system's effects are considered in the module because they are such significant determinants of habitat conditions for juvenile salmonids in the estuary. Also, unlike the recommended out-of-estuary actions listed above, hydrosystem operations that affect estuarine habitat are unlikely to be addressed in recovery plans being developed for upstream areas of the Columbia River basin. For these reasons, the estuary recovery plan module includes two management actions (CRE-2 and CRE-4) that focus specifically on hydrosystem operations.

The recommendation of out-of-estuary actions to improve survival in the estuary is another reflection of the interconnectedness of the various ecosystems salmonids use during their life cycles, the power of the river as a connector, and how the effects of problematic upstream activities are manifested—and sometimes magnified—in the estuary.

Evaluation of Management Actions: Constraints to Implementation

Constraints to implementation are a key factor in evaluating management actions and their likely impacts on salmonids. No management action can benefit salmonids if it cannot be implemented, and in many cases the degree of benefit corresponds to the degree of implementation. For this reason, the 23 management actions identified above are evaluated in terms of the constraints to their implementation, which yields information about the actions' likely outcomes and starts to provide a basis for comparing the probable effectiveness of different actions.

PC Trask & Associates, Inc., performed an initial rating of management action constraints by qualitatively estimating the degree of difficulty in implementing each action, taking into account social, political, and technical factors, including the probable cost of implementation. Staff at the Lower Columbia River Estuary Partnership, NMFS Northwest Fisheries Science Center, NMFS Northwest Regional Office, and Lower Columbia Fish Recovery Board provided input into this process. PC Trask & Associates, Inc., and NMFS also revised some constraint scores in response to the *Federal Register* public comment process. Because the scientific literature generally falls short of prescribing discrete actions to address threats and is even less robust when it comes to evaluating constraints to implementation, the reader should view specific ratings as a qualitative estimate only, but one that is useful in comparing relative implementation constraints across the 23 management actions.

For each management action, Table 5-2 summarizes the primary threat and limiting factors that the action addresses and expresses the significance of those threats and limiting factors in terms of a threat index. (The threat index indicates whether the threat is a major contributor to a significant limiting factor or a minor contributor to a minor limiting factor. The index is useful in distinguishing those actions that, even if they were successful, would affect a relatively small number of fish from those actions that, even if they were only partially implemented or partially successful, would have more profound benefits because they would affect a larger number of fish.) Table 5-2 also provides a score for the potential benefit to salmonids in the estuary if implementation of the action were completely unconstrained, plus a brief rationale for the score.

Assigning a score for potential benefit with unconstrained implementation is just the first step in evaluating management actions. In fact, decisions about management actions will be made within a complex social and political context that includes a wide variety of interests, and it is likely that many of the actions will not be able to be implemented fully because of various technical, financial, political, or social obstacles. To address this issue, Table 5-2 assigns an implementation constraints score to each management action and briefly explains how implementation of the action could be constrained by various factors. It then gives a score that represents the potential benefits of the action if implementation of the action is constrained. By design, the estuary recovery module takes a relatively optimistic view about what is possible in terms of reducing the constraints to implementation of management actions. This means that even the score in Table 5-2 for constrained implementation of an action may represent a higher degree of implementation than is likely to actually occur. However, some constraints may be reduced over time, such as through technology

advances or changes in economic sectors; as a result, some actions may have greater potential for implementation than is represented in this recovery plan module.

The table concludes with a score for potential benefit of each action assuming that implementation of the action is constrained. This score is an attempt to identify more realistically what the results of an action would be given the social, political, and financial climate in which management actions will be decided on, but it also assumes that considerable effort is made to reduce constraints to implementation. Also, the difference in Table 5-2 between potential benefit with unconstrained implementation of an action and potential benefit with constrained implementation is helpful in identifying where it might be worthwhile to expend effort to reduce constraints because the benefits would be great. This topic is discussed more fully in Chapter 7.

The threat index and scoring in Table 5-2 are for the estuary as a whole, instead of by reach, because in most cases the assessment information needed to do a reach-scale analysis currently is lacking. However, the severity of individual threats and limiting factors varies from reach to reach in the estuary, as do the potential benefits of the management actions. It is assumed that implementation of the management actions will involve dialogue and additional evaluation at the reach scale to aid in prioritizing actions and focusing them in the geographical areas where they would be most beneficial.

TABLE 5-2
Constraints to Implementation of Management Actions

Management Action CRE-1:

Protect intact riparian areas in the estuary and restore riparian areas that are degraded.

Primary threat this action would address		**Riparian Practices.** Riparian areas provide key ecological functions that affect water temperature, the availability of insects, and macrodetrital inputs to the ecosystem. Riparian areas in the lower Columbia River have been degraded by a number of factors, including shoreline modifications, diking and dike maintenance practices, and activities related to the disposal of dredged material.
Associated limiting factors		Water temperature, reduced macrodetrital inputs, and exotic plants.
Threat index[1]	10	This threat is a secondary contributor to two top-priority limiting factors (water temperature and reduced macrodetrital inputs) and a tertiary contributor to one additional limiting factor.
Potential benefits with unconstrained implementation of action [2]	4	Protecting intact riparian areas and restoring degraded riparian areas in priority reaches would provide significant benefits to salmonids by reducing water temperatures and increasing macrodetrital inputs to the system.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	3	Levels of protection vary across the lower Columbia region. In some cases, riparian areas in cities and counties are protected through regulatory mechanisms such as growth management or shoreline rules. Regulatory tools such as buffer zones along streams can be effective but require broad public support over time. Restoration projects are expensive and can take decades to provide their full benefit to tributaries directly entering the estuary.
Potential benefits with constrained implementation of action	2	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-2:

Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.

Primary threat this action would address		**Reservoir-related temperature changes.** Low-velocity flows and broad surface area exposure in reservoirs increase the temperature of flows in the estuary. Salmonids are cool-water fish that need stream temperatures of 20º C or lower for normal metabolism, growth, disease resistance, and timing of important life functions such as smoltification and adult migration. Salmonids in the estuary are experiencing water temperatures at the upper limit of their tolerance for longer periods and more frequently than they did historically.
Associated limiting factors		Water temperature.
Threat index[1]	10	This threat is a secondary contributor to a top-priority limiting factor.
Potential benefits with unconstrained implementation of action [2]	3	Given that at many times during the year water temperatures in the estuary are at or above the upper limits of salmonids' thermal tolerance, any lowering of water temperature could provide significant survival benefits. Water temperatures of below 20º C throughout the year would aid salmonids in carrying out essential physiological processes and life functions.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	5	Elevated temperatures that result from reservoir heating are difficult to reduce. Temperatures may be influenced by the volume and speed of flows through the hydrosystem and the source of those flows (some impoundments have cooler water than others do). International treaties, conflicting fish management objectives systemwide, the need for flood control, power management, and other factors constrain management of the hydrosystem to allow cooler flows to enter the estuary.
Potential benefits with constrained implementation of action	2	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-3:

Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.

Primary threats this action would address		**Water withdrawal and impaired transport of coarse sediment.** Instream flows in the estuary are important for salmonids because they maintain habitat-forming processes and conditions in the estuary and plume. Transport of sand and gravel from upstream and estuary sources during high flows helps establish and maintain salmonid habitats, contributes to turbidity that shelters salmonids from predation, and influences food sources in the plume. Some instream flows have been established in Columbia River basin tributaries, but others are needed, especially with human population growth in the basin. This action focuses on water withdrawals in tributaries and the mainstem and other tributary flow issues, including tributary hydropower. It complements CRE-4, which focuses on mainstem hydrosystem flow-related issues, such as hydrosystem regulation, to establish incremental flow improvements in the estuary within the context of power generation and flood control.
Associated limiting factors		Flow-related estuary habitat changes, flow-related changes in access to off-channel habitat, flow-related plume changes, and reduced macrodetrital inputs.
Threat index[1]	12	This threat is a secondary contributor to four top-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	2	This action contributes incremental instream flow improvements that protect/enhance the flow regime in the estuary and plume and support associated habitat-forming processes.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings); stream-type salmonids in the plume.
Implementation constraints[3]	5	Implementation of this action would require the involvement of multiple stakeholders, including irrigation, commercial, industrial, hydrosystem, tribal, Federal, state, and local interests, plus significant public involvement. Establishing protected instream flows is challenging because of competing interests and often takes years.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-4:

Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.

Primary threats this action would address		**Flow regulation and impaired transport of coarse sediment.** The magnitude, frequency, and timing of flows are an important determinant of habitat opportunity for salmonids in the estuary. Salmonids have adapted to historical flows and depend on them to complete their life cycles. The transport of sand and gravel from upstream and estuary sources helps maintain salmonid habitats, contributes to turbidity that shelters salmonids from predation, and influences food sources in the plume. Spring freshets are important habitat-shaping events for the estuary and plume. Improved flow regimes would help ecological processes (and salmonids) by making nutrients and other food sources, such as insects, available in the food web.
Associated limiting factors		Flow-related estuary habitat changes, flow-related changes in access to off-channel habitat, flow-related plume changes, reduced macrodetrital inputs in the estuary, and sediment/nutrient-related estuary habitat changes.
Threat index[1]	15	This threat is a primary contributor to several top-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	5	Return to a more natural flow regime would have significant ecosystem benefits and would affect all facets of salmonid life histories expressed in the estuary and plume. Adjustments to the timing, magnitude, and frequency of hydrosystem flows entering the estuary would be likely to have synergistic effects that would increase the benefit of many of the other actions.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies; stream-type juveniles rearing in the plume.
Implementation constraints[3]	5	Constraints on hydrosystem operations prevent the return to a natural flow regime in the estuary. Implementation of this action would be limited by international treaties, the need for flood control, fish management objectives systemwide, and power production. However, even slight modifications in the flow regime have the potential to provide significant ecosystem benefits.
Potential benefits with constrained implementation of action	3	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-5:

Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.

Primary threat this action would address		**Entrapment of fine sediment in reservoirs.** Fine sediments originating from upstream sources are trapped in low-velocity impoundments in the Columbia River, and their movement into the estuary and plume has been reduced. This alters processes that form shallow-water habitats, affects food sources, and reduces turbidity that otherwise would shelter salmonids from predation.
Associated limiting factors		Flow-related plume changes and sediment/nutrient-related estuary habitat changes.
Threat index[1]	8	This threat is a secondary contributor to several high-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	2	Fine sediment transport processes are important determinants of estuary and plume habitats. Effective mitigation of this threat would reduce predation of salmonids in the main channel and plume and strengthen habitat-forming processes.
Affected salmonids		Ocean- and stream-type salmonids.
Implementation constraints[3]	5	There are no apparent technical solutions to this threat at this time. Mitigation is recommended, but research is needed to identify the magnitude of the threat and potential solutions or mitigation measures.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = significant potential for implementation.
5 = Current constraints to implementation are significant.

Management Action CRE-6:

Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.

Primary threat this action would address		**Impaired transport of coarse sediment.** The transport of sand and gravel from upstream and estuary sources is a primary force that influences the creation, maintenance, and distribution of salmonid habitats in the estuary. While there are many potential beneficial uses of dredged materials—including enhanced nourishment of the littoral cell, land creation, property stabilization, and out-of-stream uses—there is also an important ecological need to retain coarse sediments in the estuary for habitat creation and maintenance.
Associated limiting factors		Sediment/nutrient-related estuary habitat changes and flow-related plume changes.
Threat index[1]	12	Although impaired transport of coarse sediment is a primary contributor to a top-priority limiting factor (flow-related plume changes), this management action is likely to have its greatest effect in addressing sediment/nutrient-related estuary habitat changes, a high-priority limiting factor; thus it has a threat index of 12.
Potential benefits with unconstrained implementation of action [2]	2	The beneficial use of sand resulting from dredge activities could play an important role in restoring habitat capacity and habitat opportunity in the estuary and plume. The beneficial use of dredged materials to provide sand nourishment could reduce the effects of ship wake stranding, improve habitat for *Americorphium* (a food source for salmonids), and be beneficial in the development of intertidal swamps and marshes and other salmonid habitat features. Sand entering the littoral cell could also have important ecological benefits.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings). This particularly applies to ocean-type juveniles because of their significant use of shallow-water habitats and the nearshore environment.
Implementation constraints[3]	3	Beneficial uses of dredged materials, such as through littoral cell sand nourishment and direct beach nourishment, are currently receiving significant attention, The most obvious constraint to implementation is identifying funding sources to pay for activities beyond the minimum required by law.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-7:

Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.

Primary threat this action would address		**Dredging**. Annual dredge operations maintain a navigational channel that concentrates flows, alters tidal influences, reduces circulation patterns around the estuary, and releases toxic contaminants from substrates. Dredging activities can result in deposited contaminants being disturbed and redistributed throughout the estuary. Dredging activities also result in the entrainment of juvenile salmonids and benthic organisms through the physical removal of sand via pipeline or clamshell dredging. Ship ballast intake may also result in the entrainment of juveniles as ships take on ballast water when exiting port facilities.
Associated limiting factors		Sediment/nutrient-related estuary habitat changes, native birds, and sediment/nutrient-related plume changes.
Threat index[1]	8	As it relates to this action, dredging is a secondary contributor to a high-priority limiting factor (sediment/nutrient-related estuary habitat changes) and thus has a threat index of 8.
Potential benefits with unconstrained implementation of action [2]	2	Continued dredge operations represent a physical change to the Columbia River estuary. However, reducing or mitigating the effects of dredging would improve habitat-forming processes that would benefit salmonids. Reduction of entrainment through new technologies or management practices for both dredging and ship ballast intake would reduce mortality of juveniles.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	2	Dredging activities have been occurring since the 1870s to provide sufficient draft for ships entering the Columbia River and will continue into the foreseeable future. Ongoing maintenance is needed to keep the channel to specifications for ships, and additional dredging will be conducted in the estuary as part of the channel deepening process. Maintaining the navigation channel requires dredging and disposal of large volumes of material (4 to 5 million cubic yards) each year. Changing dredging equipment, ballast water intake screens, and practices to reduce entrainment and habitat effects would be expensive.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.

1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.

1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-8:

Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.

Primary threat this action would address		**Pilings and pile dike structures**. Extensive use of pilings and pile dikes has altered sediment accretion and erosion processes and reduced flow circulation through shallow-water habitats in the estuary. Pile structures also have created favorable conditions for predators of salmonids and can reduce physical access to low-velocity juvenile salmonid habitats. In some cases, treated pilings may release toxic contaminants, including PAHs, and it can be beneficial to remove these structures. In other cases, pile structures may protect riparian areas from erosion and wave energy, collect large wood to form complex habitat, and stimulate sediment accretion in the creation of habitat. In these cases, maintenance or modification of existing structures may be beneficial.
Associated limiting factors		Sediment/nutrient-related estuary habitat changes, sediment/nutrient-related plume changes, exotic fish, native birds, and bioaccumulation toxicity.
Threat index[1]	12	This threat is a primary contributor to a high-priority limiting factor (altered predator/prey relationships), a secondary contributor to a high-priority limiting factor (sediment/nutrient-related estuary habitat changes) and two low-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	4	Removing many instream structures would improve circulation in shallow-water habitats and eliminate some salmonid predator habitats.
Affected salmonids		Ocean-type salmonids; stream-type salmonids (yearlings) leaving the heavier flows to forage in shallow waters downstream of pilings and pile dikes; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings);
Implementation constraints[3]	2	Only some of the thousands of pilings, pile dikes, and similar structures in the Columbia River estuary are necessary to maintain the shipping channel, protect property, or serve their intended economic use. Removal of superfluous structures generally is restricted only by cost and would be unlikely to affect property rights or the shipping industry. In cases where pile dikes that do aide in navigation are removed, constraints to implementation would include the cost for additional dredging to maintain the channel.
Potential benefits with constrained implementation of action	2	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-9:

Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.

Primary threat this action would address		**Dikes and filling.** High-quality off-channel habitat provides crucial feeding, rearing, and refuge opportunities for juvenile salmonids and supplies macrodetrital inputs to the estuarine food web. Reduced floodplain inundation has limited juvenile salmonids' access to historical wetland and swamp habitat, much of which has been converted to other land uses. Protecting remaining intact and accessible off-channel habitats and restoring accessible but degraded off-channel areas are critical to maintaining key habitats and food sources for juvenile salmonids.
Associated limiting factors		Reduced macrodetrital inputs, sediment/nutrient-related estuary habitat changes, bankfull elevation changes, sediment/nutrient-related plume changes, and exotic plants.
Threat index[1]	15	This threat is a primary contributor to both top-priority and high-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	5	Protecting high-quality off-channel areas would help maintain important wetland habitats and supply macrodetrital inputs to the food web and insect food sources for juvenile salmonids—a main component of their diet. Restoring or enhancing accessible but degraded off-channel areas in the estuary represents a largely untapped strategy that could provide similar benefits. Benefits from this strategy likely would be realized more quickly than from the passive restoration associated with CRE-10.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	3	Regulatory programs often do not effectively protect floodplains from conversion to other uses. The acquisition of land for habitat protection remains controversial in the estuary. Rural county governments see land disappearing off tax rolls and also listen to citizen disapproval of public ownership of land. Land acquisition is expensive and depends on the willingness of landowners to sell. Restoring accessible off-channel habitat also depends on willing landowners .The fact that many habitats already have been converted to other land uses limits opportunities to protect high-quality off-channel habitat.
Potential benefits with constrained implementation of action	3	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-10:

Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.

Primary threat this action would address		**Dikes and filling.** Many juvenile salmonids rely on off-channel habitats for feeding and refuge opportunities. Historically, insects and macrodetritus from these habitats were important inputs to the estuarine food web. Dikes, levees, tide gates, and filling have limited the amount and accessibility of key off-channel habitats by reducing floodplain inundation and allowing conversion of land to agricultural, residential, and industrial uses. This action would allow juvenile salmonids access to habitats and food sources that currently are unavailable to them and support improved habitat conditions over time.
Associated limiting factors		Reduced macrodetrital inputs, sediment/nutrient-related estuary habitat changes, bankfull elevation changes, sediment/nutrient-related plume changes, and exotic plants.
Threat index[1]	15	This threat is a primary contributor to both top-priority and high-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	5	Establishing or improving access to off-channel areas via dike breaching and similar activities would reclaim habitat that is important to salmonids. Over time, improved hydrology would support reestablishment of wetland vegetation and salmonid food sources in off-channel areas, through passive restoration. In most cases, project benefits would accrue over relatively long periods of time.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	3	Opportunities to establish or improve access to off-channel habitats are limited because many such habitats already have been filled with dredged materials. Breaching, lowering, or relocating dikes and levees or removing tide gates often requires the cooperation of multiple landowners and may fundamentally alter land uses. The associated habitat restoration is expensive.
Potential benefits with constrained implementation of action	4	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-11:

Reduce the square footage of over-water structures in the estuary.

Primary threat this action would address		**Over-water structures.** Over-water structures may provide habitats for predators and affect instream and shoreline plant communities. However, the total surface area of over-water structures in the estuary has not been quantified and the structures' case-by-case functions have not been analyzed.
Associated limiting factors		Sediment/nutrient-related estuary habitat changes and exotic fish.
Threat index[1]	4	This threat is a tertiary contributor to a high-priority limiting factor (habitat changes) and a secondary contributor to one of the lowest priority limiting factors (exotic fish).
Potential benefits with unconstrained implementation of action [2]	3	Given the uncertainty about how much of a threat over-water structures actually pose to salmonids, the potential improvement in survival must be considered low pending additional research and analysis.
Affected salmonids		Ocean-type salmonids (because of their preference for the shallow-water habitats where most structures are located); stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	3	It is assumed that some over-water structures are more important than others and that removing superfluous or less useful structures would not have deleterious effects on adjacent land uses. Removal of over-water structures that are in currently use would likely require compensation. In some cases, structures such as log rafts could be relocated.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-12:

Reduce the effects of vessel wake stranding in the estuary.

Primary threat this action would address		**Ship wakes.** Wakes from deep-draft vessels traveling through the estuary wash subyearling salmonids onto shore, leaving them stranded. Factors that affect stranding include beach slope and time of day as well as vessel draft, speed, and hull design.
Associated limiting factors		Stranding.
Threat index[1]	6	This threat is a primary contributor to a low-priority limiting factor.
Potential benefits with unconstrained implementation of action [2]	2	The extent of mortality caused by ship wake stranding is unknown. Studies in 1977 and 1994 (Bauersfeld 1977, Hinton and Emmett 1994) reached different conclusions, using different approaches. A soon-to-be-released study by the University of Washington and U.S. Army Corps of Engineers may provide further clarification of the issue.
Affected salmonids		Ocean-type salmonids (because of their longer estuarine residency times, their relatively small size, and the habitats they prefer); stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	3	Options for reducing the effects of vessel wake stranding are limited, primarily because of the lost revenues that would result from slower ship travel. Ship traffic through the estuary will continue, ship hull design is unlikely to change, and the speed of ships traveling the estuary may be difficult to alter. Modification of some habitats may be necessary to reduce this threat and would likely be expensive.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-13:

Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.

Primary threat this action would address		**Altered predator/prey relationships.** Pikeminnows have always been a significant source of mortality for juvenile salmonids in the Columbia River, but changes in physical habitat, such as the addition of in-water structures, have created more favorable conditions for predation by pikeminnow. Introduced species such as smallmouth bass, walleye, and channel catfish also prey on juvenile salmonids, primarily in the freshwater reaches.
Associated limiting factors		Native fish and exotic fish.
Threat index[1]	12	This threat contributes to many limiting factors, although the management action addresses only the native and exotic fish limiting factors, which have threat indexes of 12 and 3, respectively.
Potential benefits with unconstrained implementation of action [2]	4	Ecosystem alterations in the estuary as a result of pikeminnow, smallmouth bass, walleye, and channel catfish are uncertain. Scientists speculate that pikeminnow may be preying on both ocean- and stream-type juveniles. Stream-type juveniles may be affected significantly more than previously thought because evidence suggests that they forage in shallow areas downstream of piling structures.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	2	Because of their abundance, pikeminnow appear to be a far greater threat to juvenile salmonids than bass, walleye, and channel catfish, at least at this time. Implementation activities to reduce pikeminnow predation are constrained by the challenge of reducing their preferred slack-water habitats. Bounty programs can be effective at removing older pikeminnow, which represent the largest threat to salmonids. Although the introduction of exotic fish to the estuary may be irreversible, there are viable tools for managing smallmouth bass, walleye, and channel catfish; these include habitat management and less restricted harvest management. It is likely that warm-water fishers would actively support maintaining the abundance of these species at current—rather than reduced—levels.
Potential benefits with constrained implementation of action	2	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-14:

Identify and implement actions to reduce salmonid predation by pinnipeds.

Primary threat this action would address		**Altered predator/prey relationships.** Pinniped predation on adult salmonids at Bonneville Dam has been estimated at between 0.4 percent (2002) and 4.2 percent (2007) of the spring Chinook and winter steelhead runs, or possibly as high as 8.5 percent and 20 percent, respectively (based on radio-telemetry studies). The extent of predation needs further study and documentation.
Associated limiting factors		Native pinnipeds.
Threat index[1]	12	This threat contributes to many limiting factors, although the management action relates only to native pinnipeds.
Potential benefits with unconstrained implementation of action [2]	3	Actions to reduce predation by pinnipeds would have moderate impacts on salmonid survival, depending on how many adults are actually being consumed by pinnipeds—a question that remains uncertain.
Affected salmonids		Ocean- and stream-type salmonids.
Implementation constraints[3]	4	Methods for reducing salmonid predation by pinnipeds are limited because pinnipeds are protected under the Marine Mammal Protection Act (MMPA). It could take years to amend the act to allow additional pinniped management tools. Non-lethal methods have been only minimally successful, although it is possible that additional testing would identify effective non-lethal methods. In 2008, NMFS granted Washington, Oregon, and Idaho authority to use and evaluate lethal methods of control under Section 120 of the MMPA.
Potential benefits with constrained implementation of action	2	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-15:

Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.

Primary threat this action would address		**Altered predator/prey relationships.** Exotic plants in the estuary often out-compete native plants and change the structure of plant communities. The resulting habitat frequently does not provide the same food or shelter that other species, including salmonids, have adapted to over time.
Associated limiting factors		Exotic plants.
Threat index[1]	3	This threat contributes to many limiting factors, although the management action relates only to exotic plants, one of the lowest priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	2	Preventing and controlling invasive plants would help maintain the estuarine food web and habitats that juvenile salmonids rely on.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	4	Controlling existing infestations of certain species is functionally impossible once the species are established. Although landowners are the most important agents in preventing and controlling exotic plant infestations, landowner education is a significant task that requires a large effort.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-16:

Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.

Primary threat this action would address		**Altered predator/prey relationships.** Caspian tern predation represents a significant source of mortality for stream-type juveniles migrating to saltwater. Stream-type salmonids are particularly vulnerable because of the timing of their out-migration (during tern nesting season) and their preference for deep-channel habitats near tern nesting sites.
Associated limiting factors		Native birds.
Threat index[1]	12	This threat contributes to many limiting factors, although the management action relates only to Caspian terns.
Potential benefits with unconstrained implementation of action [2]	5	Reducing tern predation could have significant effects on the survival of stream-type salmonids, as terns have been documented to consume as much as 3 percent of stream-type juveniles migrating through the estuary.
Affected salmonids		Stream-type salmonids; ocean-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	2	Management efforts have helped reduce mortality by relocating terns to nearby habitats. Long-term solutions will require habitat improvements elsewhere for Caspian terns.
Potential benefits with constrained implementation of action	3	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-17:

Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.

Primary threat this action would address		**Altered predator/prey relationships.** Predation by double-crested cormorants represents a significant source of mortality for stream-type juveniles migrating to saltwater.
Associated limiting factors		Native birds.
Threat index[1]	12	This threat contributes to many limiting factors, although the management action relates only to double-crested cormorants.
Potential benefits with unconstrained implementation of action [2]	4	Studies indicate that double-crested cormorants prey on salmonid juveniles in the estuary at a rate equal to or greater than the rate by Caspian terns. Cormorants are estimated to have consumed an average of 7 million juvenile salmonids annually over the years 2001 to 2009.
Affected salmonids		Ocean- and stream-type juvenile salmonids are preyed upon by double-crested cormorants with some fluctuation from year to year. In 2009 double-crested cormorants consumed approximately 11 million juvenile salmonids.
Implementation constraints[3]	4	Double-crested cormorants are more difficult to relocate than Caspian terns. Techniques such as the use of decoys and audio playback have not been as effective compared to terns. Perch habitats are plentiful enough in the estuary that removal of pile dikes and other structures may not be an effective tool.
Potential benefits with constrained implementation of action	2	

[1] *From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.*

[2] *Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.*
1 = very low benefits.
5 = very high benefits.

[3] *Indicates the feasibility of implementing the action.*
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-18:

Reduce the abundance of shad in the estuary.

Primary threat this action would address		**Altered predator/prey relationships.** Shad returns to the Columbia River number approximately 4 million annually. Shad's effects on the estuary ecosystem and salmonids are poorly understood. However, shad are an introduced species and their biomass alone represents a threat to trophic relationships in the Columbia River.
Associated limiting factors		Exotic fish.
Threat index[1]	3	This threat contributes to many limiting factors, although the management action relates only to shad.
Potential benefits with unconstrained implementation of action [2]	2	The impacts of shad in the estuary are unclear. However, it is likely that reducing shad numbers would have some benefits for salmonids.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	5	Shad are thought to have permanently altered the estuary ecosystem, and their complete removal from the estuary is neither practical nor feasible. Effective management tools to limit shad productivity in the Columbia River basin currently are not available. Research is needed in the near term to determine the significance of this threat and identify potential management actions to manage the abundance of shad.
Potential benefits with constrained implementation of action	1	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-19:

Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations.

Primary threat this action would address		**Ship ballast practices.** Ship ballast water is responsible for the introduction of non-native aquatic invertebrates in the estuary. The effects of these introductions are poorly understood, but it is likely that exotic invertebrates disrupt food webs and out-compete juvenile salmonids' native food sources.
Associated limiting factors		Introduced invertebrates.
Threat index[1]	3	This threat is a primary contributor to one of the lowest priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	2	Reducing the impacts of non-native aquatic invertebrates would help maintain traditional salmonid food sources and the trophic relationships that salmon have adapted to.
Affected salmonids		Ocean-type salmonids; stream-type salmonids displaying less dominant life history strategies (e.g., early and late fingerlings and subyearlings).
Implementation constraints[3]	4	Improvements in ship ballast practices have already been implemented by the industry as a result of new regulations, and stricter regulations are currently being debated at the Federal level. However, there are inherent challenges in managing ballast water that contains organisms from other ecosystems. Also, once non-native aquatic invertebrates have been introduced, they represent a permanent alteration of the ecosystem and opportunities to reduce their effects may be few. Current understanding of how the estuary ecosystem is affected by introductions of exotic invertebrates is very limited.
Potential benefits with constrained implementation of action	1	

[1] *From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.*

[2] *Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.*
1 = very low benefits.
5 = very high benefits.

[3] *Indicates the feasibility of implementing the action.*
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-20:

Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.[1]

Primary threat this action would address		**Agricultural practices.** Fertilizers include different forms of nutrients that are important for plant growth. When fertilizers make their way to the estuary through overland runoff, they contribute nutrients to the estuary that increase phytoplankton production, alter the food web, and in some instances depress dissolved oxygen levels. Water-soluble contaminants such as simazine, atrazine, chlorpyrifos, metolachlor, diazinon, and carbaryl enter the estuary as a result of tributary and upstream agricultural practices. DDT and PCBs have been detected at elevated levels in the estuary. These and other agricultural contaminants can cause salmonid mortality through bioaccumulation or non-bioaccumulative toxicity.
Associated limiting factors		Non-bioaccumulative toxicity, bioaccumulation toxicity, and increased microdetrital inputs.
Threat index [2]	12	This threat is a primary contributor to a high-priority limiting factor (non-bioaccumulative toxicity) and a medium-priority limiting factor.
Potential benefits with unconstrained implementation of action [3]	3	Reducing the level of pesticides and herbicides in the estuary would improve survival by reducing ocean-type salmonids' acute and chronic exposure to toxic contaminants and stream-type salmonids' acute exposure.
Affected salmonids		Ocean- and stream-type salmonids.
Implementation constraints[4]	4	Impacts from pesticides and fertilizers have lessened dramatically since the 1950s as a result of new application technologies, new products, and better understanding and regulation of these toxins. More extensive compliance with existing regulations and usage guidelines, along with development of additional best management practices, could further reduce the impacts of pesticides and fertilizers. The integration of new practices can be expensive and time-consuming.
Potential benefits with constrained implementation of action	1	

[1] The term best management practices is used here to indicate general methods or techniques found to be most effective in achieving an objective. NMFS envisions that in implementation, specific best management practices would be developed or recommended.

[2] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[3] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[4] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-21:

Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.

Primary threat this action would address		**Urban and industrial practices.** The estuary has been affected by historical and current releases of toxic contaminants, including industrial and commercial pollutants such as PCBs and PAHs. These substances have been found near Portland, Vancouver, Longview, and Astoria. Studies have demonstrated significant juvenile mortality in the estuary as a result of toxic contaminants. In addition, urban and industrial effluent and stormwater runoff are principal sources of nutrients that can support increased phytoplankton levels.
Associated limiting factors		Non-bioaccumulative toxicity, bioaccumulation toxicity, and increased microdetrital inputs.
Threat index[1]	12	This threat is a primary contributor to high- and medium-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	4	Reducing sources of pollutants would lower water temperature, nutrient loading, and the amount of toxic contaminants in the estuary. This would improve both habitat capacity in the estuary and the fitness level of salmonids.
Affected salmonids		Ocean- and stream-type salmonids (particularly ocean types because of their longer residency in the estuary).
Implementation constraints[3]	4	While some discharges of industrial and commercial pollutants are permitted, others are not. Efforts to reduce industrial and commercial pollutants are already under way, and there is potential to reduce point-source emissions. Efforts to reduce sources of pollutants are expensive and time-consuming and often have a negative economic effect on operations.
Potential benefits with constrained implementation of action	3	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-22:

Restore or mitigate contaminated sites.

Primary threat this action would address		**Urban and industrial practices.** The estuary has been affected by historical and current releases of toxic contaminants, including industrial and commercial pollutants such as PCBs and PAHs. These substances have been found near Portland, Vancouver, Longview, and Astoria. Studies have demonstrated significant juvenile mortality in the estuary as a result of toxic contaminants. The action is intended to address the need to monitor the entire estuary for contaminants; however, actual restoration activities are feasible only in specific reaches.
Associated limiting factors		Non-bioaccumulative toxicity and bioaccumulation toxicity.
Threat index[1]	12	This threat is a primary contributor to high- and medium-priority limiting factors.
Potential benefits with unconstrained implementation of action [2]	5	Reducing toxic contaminants in the estuary would improve both habitat capacity and the fitness level of salmonids.
Affected salmonids		Ocean- and stream-type salmonids (particularly ocean types because of their longer residency in the estuary).
Implementation constraints[3]	3	Monitoring activities are already occurring; however, actual restoration of contaminated sites is expensive and technically challenging in many cases. In cases where restoration is not feasible, the effects of contaminated sites should be mitigated.
Potential benefits with constrained implementation of action	3	

[1] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[2] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[3] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Management Action CRE-23:

Implement stormwater best management practices in cities and towns.[1]

Primary threat this action would address		**Urban and industrial practices.** Municipal stormwater runoff can convey nutrients and toxic contaminants to the estuary, reduce groundwater recharge, and increase the "flashiness" of stream flows. Although cities and towns in the Columbia River basin generally have programs to reduce the impacts of stormwater runoff, stormwater best management practices have not been universally accepted or implemented throughout the basin.
Associated limiting factors		Non-bioaccumulative toxicity, bioaccumulation toxicity, and increased microdetrital inputs.
Threat index[2]	9	This threat is a secondary contributor to a medium-priority limiting factor as it relates to this management action.
Potential benefits with unconstrained implementation of action [3]	2	Identifying and implementing stormwater best management practices throughout the Columbia River basin would improve conditions and provide a net benefit to salmonids in the estuary through a more normal flow regime, reduced exposure to contaminants, and lower water temperatures.
Affected salmonids		Ocean- and stream-type salmonids (particularly ocean types because of their longer residency in the estuary).
Implementation constraints[4]	2	Some cities lack the resources or will to implement or enforce stormwater best management practices. The benefits of improved stormwater practices generally are associated only with new development and do not offset the full impact of the impervious surfaces in those developments, or the existing impervious surfaces in areas that have already been developed.
Potential benefits with constrained implementation of action	1	

[1] The term best management practices is used here to indicate general methods or techniques found to be most effective in achieving an objective. NMFS envisions that in implementation, specific best management practices would be developed or recommended.

[2] From Table 4-1. Indicates the significance of the associated limiting factor and the threat's contribution to that limiting factor. High numbers indicate threats that have a major contribution to high-priority limiting factors; lower numbers indicate threats that have a minor contribution to low-priority limiting factors. Numbers indicate the highest score per threat category and do not account for multiple limiting factor contributions.

[3] Estimate of the expected benefits to salmonids (ocean- and stream-types combined) if the action were fully implemented, with no constraints.
1 = very low benefits.
5 = very high benefits.

[4] Indicates the feasibility of implementing the action.
1 = Current constraints to implementation are minimal.
5 = Current constraints to implementation are significant.

Table 5-2 estimates the potential of each management action to benefit salmonids under two different implementation scenarios. Assuming that implementation of most actions is significantly constrained, which management actions would be likely to result in the greatest survival improvements?

In partial answer to this question, Table 5-3 summarizes the potential benefits of each action under both unconstrained and constrained implementation scenarios. It is tempting to sort the actions in Table 5-3 by potential benefit with constrained implementation and view the sorted list as a prioritized list of management actions, with the actions at the top being those predicted to have the greatest benefits. Although Table 5-3 does provide insight into the relative benefits of the various management actions, it is perhaps most useful as a means of contrasting the benefits that might be achieved with unconstrained implementation of an action with the benefits that might be achieved under a more likely scenario of constrained implementation.

To provide greater insight into the relative benefits of each management action, PC Trask & Associates, Inc., developed a second analysis based on survival improvement targets. This analysis, which is presented in the next section of the document, is more refined and specific than the analysis in Table 5-3. For instance, it focuses more on how the potential benefits of the 23 management actions would compare to each other and on the survival benefits that might be gained from each action. It also evaluates the benefits of each action to both ocean- and stream-type salmonids.

TABLE 5-3
Summary of Constraints to Implementation of Management Actions

Number	Action Description	Benefit with Unconstrained Implementation of Action[1]	Benefit with Constrained Implementation of Action[2]
CRE-01	Protect intact riparian areas in the estuary and restore riparian areas that are degraded.	4	2
CRE-02	Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.	3	2
CRE-03	Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.	2	1
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.	5	3
CRE-05	Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.	2	1
CRE-06	Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.	2	1

Number	Action Description	Benefit with Unconstrained Implementation of Action[1]	Benefit with Constrained Implementation of Action[2]
CRE-07	Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.	2	1
CRE-08	Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.	4	2
CRE-09	Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.	5	3
CRE-10	Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.	5	4
CRE-11	Reduce the square footage of over-water structures in the estuary.	3	1
CRE-12	Reduce the effects of vessel wake stranding in the estuary.	2	1
CRE-13	Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.	4	2
CRE-14	Identify and implement actions to reduce salmonid predation by pinnipeds.	3	2
CRE-15	Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.	2	1
CRE-16	Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.	5	3
CRE-17	Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.	4	2
CRE-18	Reduce the abundance of shad in the estuary.	2	1
CRE-19	Prevent new introductions of invertebrates and reduce the effects of existing infestations.	2	1
CRE-20	Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.	3	1
CRE-21	Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.	4	3
CRE-22	Restore or mitigate contaminated sites.	5	3
CRE-23	Implement stormwater best management practices in cities and towns.	2	1

[1]Estimate of potential benefit if action is fully implemented, with no constraints.

Evaluation of Management Actions: Survival Improvement Targets

The Columbia River estuary and plume are only two of many ecosystems that salmonids travel in their complex and lengthy journey from headwaters to ocean and back again. Mortality occurs at every stage of this journey. Each year, scientists from the NMFS Northwest Fisheries Science Center estimate the number of juvenile salmonids that enter the estuary from upstream of Bonneville Dam and from estuary tributaries. For 2006, scientists from NMFS estimated that about 168 million juvenile salmonids (both wild and hatchery) would enter the estuary (Ferguson 2006b). Some years later, the surviving fish return to the estuary in varying numbers, with the average return in the last 10 years being approximately 1.7 million fish; roughly 65 to 75 percent of those fish are of hatchery origin.[1] This means that less than 1 percent of the juveniles that enter the estuary are returning as adults.

Estimating Juvenile Mortality in the Estuary and Plume

How much juvenile mortality is occurring in the estuary and plume? The answer to this question is fundamental to developing an understanding of the role the estuary will play in the recovery of salmonid populations basinwide. The answer also is critical in evaluating the benefits and costs of potential management actions because it helps establish the level of effort needed to offset threats to salmonids in the estuary. Unfortunately, determining how much juvenile mortality is occurring in the estuary and plume is challenging for scientists. Counting juveniles in the Columbia River estuary and plume is problematic because available tracking technologies are limited, and it is difficult to monitor juveniles—which tend to move in and out of saltwater—in large, high-energy sites such as the mouth of the Columbia River.

However, some efforts have been made to separate mortality that occurs in the estuary and plume from mortality that occurs in the ocean. One such effort has been the underlying assumptions in the Ecosystem Diagnosis and Treatment (EDT) model, which is used extensively throughout the Columbia River basin. For juveniles entering the estuary from tributaries to the lower Columbia River, EDT assumes mortality rates in the estuary and plume of between 18 and 58 percent, depending on the salmonid species and the amount of time juveniles spend in the estuary (Lower Columbia Fish Recovery Board 2004). In a study of juvenile mortality in the estuary, Schreck et al. (2006) estimated spring/summer Chinook mortality at between 11 and 17 percent, largely from avian predation.

In addition, research is under way by NMFS, the U.S. Army Corps of Engineers, and Battelle Laboratories to estimate the survival rate of juvenile salmonids in the lower Columbia River. This research involves new technologies for miniaturizing acoustic tags to a size capable of tracking yearling and subyearling juveniles. Current technology developed for the project allows for the tracking of subyearlings of sizes down to approximately 90 mm. Results for the first year (2005) indicated an approximate range of survival of 65 to 75 percent for subyearlings and yearlings during their residency in the estuary (Ferguson 2006a). It is probable that actual survival rates are lower than these preliminary estimates suggest

[1] This is an informal estimate; determining the ratio of hatchery-origin fish with more certainty would require stock-by-stock run calculations averaged over many years.

because the research did not address mortality among juveniles smaller than 90 mm or mortality occurring in the plume and nearshore. The studies above have not been conclusive, and separating estuarine and ocean mortality for juvenile salmonids in the Columbia River remains significant challenge.

Some specific estimates of salmonid mortality are known in the estuary; they include estimates for double-crested cormorants and Caspian terns. For other threats to salmonids, such as toxic contamination, ship wake stranding, and pinniped predation, information on mortality in the estuary is incomplete or relatively new in the literature. Still other threats, especially those related to the food web, are poorly understood and have no mortality estimates associated with them, although in some cases the change in conditions from the historical template to the present has been well documented.

Establishing Survival Improvement Targets

An important goal of this estuary recovery plan module is to estimate the potential benefits—in terms of increased survival of salmonids in the estuary—that could result from the implementation of different management actions. To accomplish this goal, PC Trask & Associates, Inc., used available information about limiting factors, threats, and constraints to the implementation of management actions to assign benefits that could possibly result from different actions.

If scientific understanding of the relationships between ecological conditions and biological responses in estuarine systems were robust, it would be attractive to assign specific mortality rates to each of the factors limiting salmonids' biological performance in the Columbia River estuary. Then one could follow a deterministic logic path that associates mortality rates with specific threats, relates the mortality rates to management actions, and ultimately arrives at an estimate of the survival improvement that would be likely to result from each action. This is not possible at this time, and it will likely not be possible until there have been significant advances in scientific understanding of the complex estuarine environment.

To compensate for the lack of detailed information on mortality in the estuary, PC Trask & Associates, Inc., established targets for improved survival of wild ESA-listed salmonids rearing and migrating in the estuary and plume, assuming that the implementation of management actions is constrained to the degree indicated in Table 5-2. PC Trask & Associates, Inc., then allocated these survival targets to individual management actions. These targets are intended to serve as a planning tool useful in characterizing the potential results of actions and describing the level of effort needed to recover salmonids.

The primary purpose of the survival improvement targets is to help compare the potential benefits of different management actions, particularly actions that partially address major limiting factors versus actions that fully address minor limiting factors. In addition, the survival improvement targets provide insight into the specific survival benefits of each action and the differential benefits of each action to stream- and ocean-type salmonids. Numerically, the survival improvement targets in this chapter were based on an estimate of the number of naturally produced ESA-listed ocean- and stream-type juvenile salmonids entering the estuary. The total number of naturally produced ESA-listed juvenile salmonids

estimated to enter the estuary in 2006 was approximately 39 million (Ferguson 2006b).[2] Of these, approximately 25 million were estimated to be ocean type and 14 million were estimated to be stream type.

To establish survival improvement targets, PC Trask & Associates, Inc., developed some assumptions about the overall mortality of juvenile salmonids during estuary and plume residency. Ocean-type juveniles were assumed to have an overall mortality rate of 50 percent during their estuary residency; this includes the 35 percent mortality suggested by the unpublished micro-acoustic tagging research (Ferguson 2006a) plus an additional 15 percent to account for juveniles too small to be tracked. Stream-type juveniles were assumed to have an overall mortality rate of 40 percent during estuary and plume residency. This rate was based on the 25 percent mortality found in the micro-acoustic tagging research (Ferguson 2006a) plus an additional 15 percent to account for mortality occurring in the plume, which was not part of study. These assumptions about estuary mortality are based on best professional judgment by PC Trask & Associates, Inc., after a review of pertinent literature and discussions with subject matter experts, including scientists at the NMFS Northwest Fisheries Science Center.

Table 5-4 shows the number of wild, ESA-listed ocean- and stream-type juveniles thought to be entering the lower Columbia estuary and plume, their estimated mortality and survival rates based on the assumptions above, and the number of juveniles estimated to survive their journey through the estuary and plume—again, based on the assumptions above.

TABLE 5-4
Estimated Mortality Rates, Survival Rates, and Survival Improvement Targets for Wild, ESA-Listed Juveniles

Type	Juveniles Entering Estuary*	Assumed Mortality Rate	Assumed Survival Rate	Estimated Number of Juveniles Exiting Estuary and Plume*	Survival Improvement Target (20 percent)**
Ocean Type	25 million	50%	50%	12.5 million	2.5 million***
Stream Type	14 million	40%	60%	8.4 million	1.68 million***

* = Wild, ESA-listed juveniles.

** = Twenty percent of the estimated number of juveniles exiting the estuary and plume; this target represents additional fish surviving their estuary and plume residency.

*** These numbers are used to characterize the potential, relative benefits of implementing various management actions and do not represent actual numbers of additional fish expected to survive.

Table 5-4 also presents survival improvement targets for ocean- and stream-type salmonids in the estuary and plume. For planning purposes only, this estuary recovery plan module selects 20 percent as a target for improvement in the survival rate of wild, ESA-listed ocean- and stream-type juveniles in the estuary and plume. Twenty percent represents a hypothetical level of improvement that might be realized through the implementation of the management actions, assuming that considerable effort is expended to help offset constraints to implementation, such that threats and limiting factors are reduced. For ocean types, increasing survival by 20 percent would result in a total of 15 million juveniles exiting

[2] Current scientific information on the effects of limiting factors and actions does not differentiate between hatchery- and natural-origin salmon and steelhead, or between salmon and steelhead that are listed under the ESA and those that are not. Because ESA recovery is determined by the status of natural-origin fish, the intent of the module is to improve the estuarine survival of naturally produced, ESA-listed salmon and steelhead. Naturally produced fish are the focus of the analysis of survival improvement targets because they are the focus of the module.

the estuary and plume—2.5 million more juveniles than the current estimate of 12.5 million. For stream types, a 20 percent improvement would equal 10.08 million—1.68 million additional juveniles beyond the current 8.4 million that are estimated to exit the estuary and plume. Thus the survival improvement targets for ocean- and stream-type salmonids are 2.5 million and 1.68 million, respectively, as shown in Table 5-4. Targets for both types were set at 20 percent to avoid the appearance of a false level of precision in establishing them. Ocean-type juveniles were assumed to incur more mortality in the estuary and nearshore compared to stream types. Stream types were assumed to incur less mortality in the estuary than ocean types but significantly more mortality in the plume.

PC Trask & Associates, Inc., selected the 20 percent survival improvement number for ocean- and stream-type juvenile salmonids based on a qualitative analysis of the level of improvement that reasonably and plausibly might be expected if the 23 management actions were implemented. In establishing the 20 percent target, PC Trask & Associates, Inc., reviewed existing management plans, other literature sources, and the constraints analysis in Table 5-2. However, setting 20 percent as the target for improvement, rather than 15 or 30 percent, is inherently subjective and relies in part on the following assumptions:

- That estuary mortality for juveniles (currently between 40 and 50 percent, depending on population) can be reduced by initiating restoration projects and reducing uncertainties through research and monitoring
- That mortality rates associated with certain threats, such as Caspian terns and cormorants, are well understood and will be lessened through actions specified in management plans that are reasonably likely to be implemented
- That all of the actions identified in this chapter are implemented to a reasonable degree and historical and current constraints to action implementation are thoroughly challenged

Actual improvements in survival will depend on which management actions are implemented, how fully they are implemented, and their efficacy—factors that at this point are open to interpretation and can be qualitatively estimated only. Although the 20 percent targets for ocean- and stream-type salmonids are intended to be reasonable and plausible given the information available to date, open technical, political, and social discussion could refine the targets until science can substantiate them.

The survival improvement targets in Table 5-4 were developed using ocean- and stream-type life history strategies to characterize the 13 ESUs in the Columbia River basin. As a result, the survival improvement targets do not account for important variations found at the ESU, population, and subpopulation scales. For example, not all ocean-type ESUs in the Columbia River basin exhibit the same run timing, size at estuary entry, or use of particular habitats (Fresh et. al 2005). In fact, this variability in estuarine use by the ESUs is fundamental to the member/vagrant theory proposed by the NMFS Northwest Fisheries Science Center and a central premise of the estuary recovery plan module (see Chapter 2 for more information on the member/vagrant theory). Although genetic and spatial diversity are not explicitly accounted for in survival improvement targets, the suite of management actions identified in the estuary recovery plan module is intended to collectively address all life history strategies historically expressed in the estuary and plume. This further

emphasizes that the survival improvement targets are best viewed as a planning tool only. In reality, there will be significant variability among ESUs, populations, and subpopulations in how much additional survival might result from improvements in estuary and plume habitat.

Assigning Survival Improvement Targets to Recovery Actions

The usefulness of the 20 percent target lies not in the 20 percent number itself, but in the distribution of the targets (2.5 million ocean-type juveniles and 1.68 million stream-type juveniles) across the various management actions, as a way of characterizing the relative benefits of the various management actions.[3] Table 5-5 shows this allocation of survival improvement targets to the 22 management actions for juvenile salmonids.[4] In cases where there is good scientific literature that supports the allocation of survival targets, as with terns and cormorants, PC Trask & Associates, Inc., used that information as a basis for the analysis in Table 5-5. In other cases, such as reservoir-related temperature changes, PC Trask & Associates, Inc., estimated survival improvements based on literature discussion of related limiting factors and threats. The reader should view the resulting survival improvement targets as the product of a planning exercise, not a representation of deterministically based estimates. (Appendix B presents more information on how PC Trask & Associates, Inc., allocated survival improvement targets to the different actions.)

Although the survival improvement targets in Table 5-5 are estimates only, they complement the analysis summarized in Table 5-3.[5] In addition, they provide a useful way to show the potential magnitude of juvenile survival at the action scale relative to other actions. The survival improvement targets illustrate how a small increment of implementation of a far-reaching action could offer significantly more potential for recovery than full implementation of an action that is more limited in scope. Comparison of Tables 5-3 and 5-5 and the cost estimates that are developed in the next section form the basis for prioritization of actions in Chapter 7, "Perspectives on Implementation."

A special case in assigning survival improvement targets to actions are those actions (CRE–01 and CRE–09) that use land protection as a means of achieving the target. In theory, protection projects contribute only to maintenance of baseline conditions and not to recovery. However, the estuary recovery plan module does assign a portion of the survival improvement targets to protection projects. The reasoning here is that without protection of baseline environmental conditions, significantly more effort would be required in restoration projects to offset the continued loss of functioning habitat that would result from increases in the human population and corresponding conversion of habitats to economically beneficial land uses. Thus, assigning survival improvement targets to

[3] Although for the purposes of this analysis 20 percent is considered a hypothetical number, it is a plausible number. The 20 percent figure is based on overall estimates of juvenile mortality in the estuary, known mortality that can be attributed to specific threats, and professional judgment regarding the efficacy of the different management actions and the likelihood that constraints to their implementation can be overcome.

[4] Although the survival improvement targets are expressed in terms of numbers of natural-origin ESA-listed fish, this is simply to illustrate the potential benefits of actions, not to analyze differential benefits to natural-origin listed fish versus unlisted or hatchery-origin fish; what is important is the allocation of relative benefits among the management actions.

[5] Table 5-2 contrasts the difference between constrained and unconstrained implementation of an individual action, while Table 5-5 compares potential benefits across the entire set of actions. Given the two tables' different purposes, there is not a mechanistic relationship between them. However, there is a rough correlation between the potential benefits of constrained implementation in Table 5-2 and where an action falls in the relative rankings presented in Table 5-5.

protection projects reflects the value of avoiding the additional effort that would be required to restore functioning habitats lost because they were not protected.

Uses of the Survival Improvement Targets

The purpose of the survival improvement targets in Table 5-5 is to address a particular planning challenge in the estuary module: how to compare the potential benefits of management actions that are disparate in their scope and feasibility, especially when scientific information about the causes of salmonid mortality in the estuary is incomplete. In the absence of comprehensive scientific data, the targets provide a useful framework for evaluating the relative merits of different actions. However, survival improvement targets do not represent actual numbers of fish.

For example, it would be inappropriate to use the survival improvement targets to estimate total juvenile mortality in the estuary, attribute a level of mortality to a specific limiting factor or threat, or calculate "per-fish" costs of actions. Because the survival improvement targets are not scientifically derived, they have limited use for life-cycle modeling. On the other hand, the targets could serve as a starting point for life-cycle modeling in the absence of rigorous data.

It also would be unwise to predict specific outcomes of an action or suite of actions based solely on the survival improvement targets. Although it would be appropriate to use the targets to guide expenditures and the selection of individual projects that are consistent with the module's management actions, monitoring should accompany any implementation of those projects—to evaluate their effectiveness, test the assumptions underlying the targets, and provide a basis for refining them.

Because the survival improvement targets are a tool for comparing the relative benefits of actions, they are particularly useful in weighing the trade-offs involved in implementing some actions but not others, or implementing actions only partially. For example, in theory, if a certain action were implemented partially or not at all, the potential 20 percent gain in the number of wild, ESA-listed juveniles leaving the estuary and plume could not be achieved unless other actions were implemented to a greater extent than envisioned in the module, to compensate. Survival improvement targets provide a way of evaluating various scenarios for implementation. This is critical because the implementation of every action already is constrained (often significantly) and, in most cases, the opportunities to remove constraints and implement actions more fully are limited.

TABLE 5-5
Survival Improvement Targets Allocated to Management Actions[1]

Number	Action Description	Survival Improvement Target[1] with Constrained Implementation (numbers of wild, ESA-listed fish)			
		Ocean Type[1]	% of Total Improvement Target	Stream Type[1]	% of Total Improvement Target
CRE-01	Protect intact riparian areas in the estuary and restore riparian areas that are degraded.	150,000	6%	100,000	6%
CRE-02	Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.	90,000	4%	20,000	1%
CRE-03	Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.	25,000	1%	20,000	1%
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.	225,000	9%	125,000	7%
CRE-05	Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.	5,000	<1%	5,000	<1%
CRE-06	Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.	50,000	2%	15,000	<1%
CRE-07	Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities in the estuary.	8,000	<1%	10,000	<1%
CRE-08	Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.	150,000	6%	100,000	6%
CRE-09	Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.	400,000	16%	150,000	9%
CRE-10	Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.	450,000	18%	100,000	6%
CRE-11	Reduce the square footage of over-water structures in the estuary.	25,000	1%	3,000	<1%
CRE-12	Reduce the effects of vessel wake stranding in the estuary.	55,000	2%	2,000	<1%

Number	Action Description	Survival Improvement Target[1] with Constrained Implementation (numbers of wild, ESA-listed fish)			
		Ocean Type[1]	% of Total Improvement Target	Stream Type[1]	% of Total Improvement Target
CRE-13	Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.	140,000	6%	122,000	7%
CRE-14	Identify and implement actions to reduce salmonid predation by pinnipeds.	N/A[2]	N/A	1,034[2]	N/A
CRE-15	Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.	20,000	<1%	15,000	<1%
CRE-16	Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.	2,000	<1%	350,000	21%
CRE-17	Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.	2,000	<1%	250,000	15%
CRE-18	Reduce the abundance of shad in the estuary.	5,000	<1%	5,000	<1%
CRE-19	Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations.	8,000	<1%	2,000	<1%
CRE-20	Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.	50,000	2%	42,000	3%
CRE-21	Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.	275,000	11%	72,000	4%
CRE-22	Restore or mitigate contaminated sites.	300,000	12%	142,000	8%
CRE-23	Implement stormwater best management practices in cities and towns.	65,000	3%	30,000	2%
	Total	2.5 million		1.68 million	

[1] Appendix B presents more information on how survival improvement targets were developed.

[2] The survival improvement targets are assigned for juvenile salmonids only. Although CRE-14 relates specifically to adult salmonids, the survival numbers for CRE-14 are not included in the 20 percent survival improvement targets for juvenile salmonids. The stream-type survival number is based upon an estimated 17 percent reduction in adult fish mortality applied to 2010 run-size information reported in U.S. Army Corps of Engineers (2010). Some mortality may be occurring as a result of pinniped predation on ocean-type juvenile salmon and steelhead. The extent to which this is occurring has not been established.

Evaluation of Management Actions: Costs and Schedule

Implementing recovery actions in the estuary will require a long-term commitment by many entities. In Tables 5-2 and 5-5, two approaches were used to portray the potential survival improvements associated with implementing actions. In Table 5-6, each action is broken down into one or more projects that can be considered elements of that action.

For some management actions, the first project involves conducting a study or assembling existing technical information. There are several reasons for this. In some cases, existing information about how to reduce the associated threat to salmonids is limited, and additional study is needed to identify and pilot-test possible actions to determine which ones would be most effective. This is particularly important when funds for implementing management actions are limited. Additionally, conducting a study or assembling technical information involves stakeholders who may have local knowledge about the threat or will be responsible for implementing projects. Lastly, studies and information gathering provide an opportunity to understand the constraints of management actions, to reexamine assumptions about what is and is not possible, and to explore the lengths to which, as a society, we are willing to go to implement actions that will contribute to the recovery of salmon and steelhead in the Columbia River basin. The intent of including studies and information gathering in the management actions, when appropriate, is not to postpone taking on-the-ground action but to ensure that any actions that are taken are truly effective, that stakeholders are involved in the process, and that important dialogue occurs about the value of reducing constraints and implementing management actions as fully as possible, even in situations where implementation is highly constrained.

The recovery plan module does not present a detailed list of projects waiting to be completed in the estuary. This is because in many cases, additional work is needed to develop complex, large-scale projects that will provide maximum benefit, or to work with landowners and other stakeholders to gain their support, or to understand the most effective avenue for implementation.

Table 5-6 provides cost estimates for each of the 23 actions in the estuary recovery plan module and a timeframe for their implementation. Each project in Table 5-6 has a corresponding unit and cost, and the project costs are summed to produce a total cost for each action. The costs identified in this section do not represent a detailed economic analysis; in fact, they are not economic costs in that they have not been discounted across time. Instead, the cost estimates are in constant dollars over a 25-year period. A 25-year implementation period was selected for several reasons. Many of the actions identified in the estuary module include project types that have never been implemented in the estuary, and it will take time to establish or modify programs to implement these projects; some will require new research and monitoring to guide their effective implementation. In addition, a 25-year implementation period will allow time to identify funding sources and build the landowner buy-in and project sponsor capacity needed to implement the 23 actions.

In most cases the costs listed in Table 5-6 are direct, incremental costs, meaning that they are (1) out-of-pocket costs that a public or private interest would pay to initiate and complete a management action, and (2) costs in addition to the baseline costs for existing programs and activities, which may or may not be focused on salmon recovery. This approach is consistent

with NMFS Northwest Regional Office guidance on cost estimates for ESA recovery plans. In some cases, distinctions between baseline and incremental costs are clear. For instance, reducing the abundance of shad (CRE-18) is an action that includes only incremental costs because it is a new action that has yet to be implemented in the estuary. Other actions, such as breaching, lowering, or relocating dikes (CRE-10), have been implemented in the estuary at a relatively modest scale. For such actions, the estuary recovery plan module cost estimate is still entirely incremental in that it identifies an additional level of effort needed to achieve the survival improvement targets identified later in this chapter.

Several of the 23 actions do contain some baseline costs, because in some cases these baseline costs represent a small fraction of the overall implementation cost of the action and it was deemed infeasible to separate out the incremental costs. In these cases, this fact is noted in Table 5-6 under the key assumptions for the individual management action. For example, Caspian tern management (CRE-16) is supported by an existing management plan, and some efforts are already under way to implement the action. The other two examples are managing pikeminnow and other piscivorous fish (CRE-13) and implementing stormwater best management practices (CRE-23). In these examples, programs are in place, but major portions of the estuary recovery plan module action have not been implemented to date. In addition, for one action—adjusting the timing, magnitude, and frequency of hydrosystem flows (CRE-4)—the primary costs are the costs of foregone power generation. Generally, recovery action cost estimates do not include such opportunity costs. We have included an estimate of such costs in this case because otherwise this action would have skewed the cost-effectiveness assessment in Chapter 7 (see Table 7-5) in a way that would preclude constructive dialogue about adjusting flows.

The cost estimates in Table 5-6 were developed by PC Trask & Associates, Inc., and reviewed by the Lower Columbia Fish Recovery Board, the Lower Columbia River Estuary Partnership, and NMFS. In addition, an economist at the NMFS Northwest Fisheries Science Center reviewed Chapter 5 and provided comments (although not a detailed evaluation of the costs). Lower Columbia River Estuary Partnership staff contributed substantively to cost estimates for actions for which the Estuary Partnership has some history of implementation. For example, the Estuary Partnership has funded multiple dike breaches (CRE-10), riparian protection projects (CRE-1), and off-channel protection/restoration projects (CRE-9). In other cases, where possible, experts knowledgeable about implementing similar actions were consulted. For example, staff from the NMFS Northwest Regional Office were consulted to estimate costs for managing pinnipeds (CRE-14).

In still other cases, a coarse estimate was established based on the component projects and assumptions about the feasibility of their implementation. These were generally cases in which the extent of on-the-ground actions could not be determined until certain scientific or technical questions have been answered more definitively through studies or information gathering (see, e.g., CRE-2, CRE-7, CRE-12, CRE-18). In these cases, costs of any assessment work were estimated, and then a coarse-scale, placeholder cost estimate was developed based on assumptions about the magnitude and nature of subsequent projects needed to implement the management action. It is expected that such cost estimates will be refined as more specific projects are defined.

Thus the cost estimates in Table 5-6 attempt to establish a realistic cost for recovery, but the precision with which costs can be estimated at this time is limited, and there is considerable

uncertainty in all the cost estimates. In Chapter 6, some additional costs are identified for research, monitoring, and evaluation activities (see Table 6-7).

The estuary recovery plan module addresses habitat conditions for all Columbia River basin ESUs during a single stage of their life cycle, but many additional management actions—including actions in the tributaries—will be needed to achieve recovery of any particular ESU. Because the management actions in the module are only a subset of all the actions needed for recovery of an ESU, the costs in Table 5-6 do not reflect the total costs to achieve recovery. Total costs for recovery are more appropriately represented in the recovery plans for each ESU, as these plans deal with multiple life stages for a specific ESU.

Each action in Table 5-6 includes a proposed schedule for implementation. The schedule is designed to place projects in a logical order and spread costs over a long period of time when possible. Costs are estimated over a 25-year span, with some projects being implemented once over a relatively short period and others continuing over the entire 25 years.

Other elements contained in Table 5-6 include the association of actions to specific geographical reaches, key assumptions about actions, a list of potential implementers,[6] notes that help explain how costs were developed, and a brief summary of some of the existing programs that address limiting factors identified in this recovery plan module. The summaries of existing programs are not exhaustive and are intended to emphasize that opportunities exist to build on existing programs to improve salmon and steelhead survival in the estuary. The relationship of actions to the eight geographic reaches and the plume helps to define the breadth of the action and may also indicate which jurisdictions may implement actions in the future. Key assumptions relate primarily to implementation and provide insight into the level of effort reflected in the action costs. Notes are specific information that helps clarify a particular unit or cost.

[6] The list of potential implementers is intended only to indicate entities that *may* have a role in implementation and to serve as a guide to begin discussion of implementation roles. It does not imply any budgetary, regulatory, or other responsibility for implementation.

TABLE 5-6
Estimated Cost and Schedule

Management Action CRE-1:

Protect intact riparian areas in the estuary and restore riparian areas that are degraded.

Project	Unit	Cost	Schedule
1. Educate landowners about the ecosystem benefits of intact riparian areas and the costs of degraded riparian areas.[1]	20 years @ $50,000/year	$1 million	2008 - 2028
2. Encourage and provide incentives for local, state, and Federal regulatory entities to maintain, improve (where needed), and enforce consistent riparian area protections throughout the lower Columbia region.[2]	10 years @ $500,000/year	$5 million	2008 - 2018
3. Actively purchase riparian areas from willing landowners in urban and rural settings when the riparian areas cannot be effectively protected through regulation or voluntary or incentive programs and (1) are intact, or (2) are degraded but have good restoration potential.	Rural: 3,500 acres at $5,000/acre[3] Urban: 100 acres at $75,000/acre	$25 million	2007 - 2031
4. Restore and maintain ecological benefits in riparian areas; this includes managing vegetation on dikes and levees to enhance ecological function and adding shoreline/instream complexity for juvenile salmonid refugia.	28 miles @ $250,000/mile	$ 7 million	2006 - 2031

Total costs: $38 million

Geographical priority: Reaches A-H and the Lower Willamette reach.

Key assumptions: (1) New homes, businesses, and industry will increase with population growth in the basin. (2) Some intact riparian areas are not adequately protected. (3) Protecting intact riparian areas would be cheaper than restoring degraded areas. (4) Some degraded riparian areas could be restored and gain ecological function, with associated downstream benefits. (5) Comprehensive protection and restoration of riparian habitats would occur concurrently with population growth, which will continue at a high rate.

Existing efforts: Protection of riparian areas relies heavily on local governments; the content and implementation of their land use plans specifically for shoreline and floodplain protection will be key to this action. Multiple Federal and state resource agencies provide funding for land acquisition and restoration, and multiple entities such as land trusts and watershed councils actively acquire and restore lands in the lower river. The Division of State Lands in Oregon and the Department of Natural Resources in Washington own and/or regulate submerged and submersible lands. The Natural Resource Conversation Service and conservation districts provide technical assistance to private landowners. Where water quality issues (such as toxic or conventional contaminants) are involved, agencies such as Washington's Department of Ecology and Oregon's Department of Environmental Quality may provide additional support.

Potential implementers:

- U.S. Army COE
- BPA
- WA Dept. of Fish & Wildlife
- OR Dept. of Fish & Wildlife
- Cities\Counties
- Port districts
- Conservation districts
- Columbia Land Trust
- The Wetlands Conservancy
- The Nature Conservancy
- Ducks Unlimited
- Natl. Fish & Wildlife Foundation
- Tribes
- OR Watershed Enhance. Bd.
- Salmon Recovery Fund. Bd.
- Lower Col. River Est. Partnership
- National Marine Fisheries Service
- Col. River Estuary Study Taskforce
- Utility districts
- Watershed councils

Notes:

[1] Projects CRE-1.1 and CRE-9.1 both call for outreach efforts. Outreach efforts for these two actions will be combined in a single outreach program whose costs will be shared.

[2] Projects CRE-1.2 and CRE-9.2 both call for incentives for local, state, and Federal entities to maintain, improve, and enforce regulatory protections. Given their similarities, activities for CRE-1.2 and CRE-9.2 could be coordinated or combined into one effort.

[3] Acreage amounts are 25-year targets that depend on willing sellers and funding.

Management Action CRE-2:

Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.

Project	Unit	Cost	Schedule
1. Conduct a reservoir heating study to determine the extent of the issue and identify hydrosystem operational changes (including design) that would reduce effects and/or mitigate downstream temperature issues.	1 study	$2.5 million	2007 - 2013
2. Implement hydrosystem operational changes to reduce temperature effects; if no change is possible, mitigate effects through restoration of tributary riparian areas.	25 years @ $700,000/year[1]	$17.5 million	2010 - 2032

Total costs: $20 million

Geographical priority: Reaches A-H and the plume.

Key assumption: (1) Either there is potential to alter management practices in the hydrosystem to reduce flow temperatures or a commensurate level of mitigation in tributaries would reduce temperatures in the estuary. (2) If temperatures continue to increase above 19° C, the estuary could become completely lethal for salmonids and other native species.

Existing efforts: The U.S. Environmental Protection Agency (EPA) is concerned about water temperature issues in the Columbia and Snake River system and their impacts on ecosystem health, particularly in light of global climate change. Oregon and Washington have listed the Columbia River as impaired for temperature under the Clean Water Act Section 303(d). In 2003, EPA issued a Preliminary Draft Total Maximum Daily Load (TMDL) for the mainstem Columbia River, but the TMDL has not been finalized. EPA plans to work with the states of Oregon and Washington to revisit the TMDL and decide how to address mainstem Columbia River temperature issues.

Potential implementers:

- Bonneville Power Administration
- U.S. Army Corps of Engineers
- Utility districts
- Oregon Department of Environmental Quality
- Washington State Department of Ecology

Notes:

[1] Assumes that some level of improvement is possible but that the level of possible improvement is likely to be minor because of complexities of the hydrosystem; assumes that mitigation will be needed to offset temperature increases.

Management Action CRE-3:

Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.

Project	Unit	Cost	Schedule
1. Explore technical options and develop policy recommendations on instream flows.	5 years @ $1 million/year	$5 million	2007 - 2015
2. Implement instream flow regulations in accordance with the policy recommendations in Project No. 1.	5 years @ $1 million/year	$5 million	2015 - 2023

Total costs: $10 million

Geographical priority: Reaches A–H and the plume.

Key assumptions: (1) Demand for water for human use will grow as the human population in the basin increases. (2) Additional instream flows in the Columbia River mainstem and tributaries could be established through the efforts of affected parties basinwide. (3) Establishing an instream flow regime would protect flows entering the estuary in the future. (4) An instream flow regime would help develop additional water conservation efforts and guide land use development in concert with water availability. (5) Protecting and/or enhancing estuary instream flows would require coordination with the Columbia River hydrosystem to achieve lasting results.

Existing efforts: Resource agencies can request instream flows to support fish and wildlife, water quality, and recreational needs in tributaries entering the estuary. In Oregon, the Department of Environmental Quality, Department of Fish and Wildlife, and Department of Parks & Recreation are authorized to request instream water rights to support their statutory obligations. The Oregon Water Resources Department and Commission review these requests and establish instream water rights. In Washington, the Department of Ecology established instream flows in all of the major Washington tributaries entering the estuary. Tributary flows also are often addressed in the relicensing processes for hydropower facilities regulated by the Federal Energy Regulatory Commission. Over the past decade, many tributary hydropower facilities (e.g., the Cowlitz River Project and the Lewis River Hydroelectric Projects) have been relicensed. Establishing an instream flow regime for the estuary would involve many Federal and state agencies and would require an organizational framework that currently does not exist.

Potential implementers:

- States (Washington, Oregon, Idaho, Montana)
- Cities and counties
- Irrigators
- Tributary hydropower utilities
- U.S. Army Corps of Engineers
- Bonneville Power Administration
- U.S. Bureau of Reclamation

Management Action CRE-4:

Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.

Project	Unit	Cost	Schedule
1. Conduct a flood study to determine the risks and feasibility of returning to more normative flows in the estuary.	2 years @ $500,000/year	$1 million	2009 - 2010
2. Conduct a study to determine the habitat effects of increasing the magnitude and frequency of hydrosystem flows (i.e., how much access of river to off-channel habitats would increase).	3 years @ $500,000/year	$1.5 million	2009 - 2011
3. Conduct additional studies to determine the extent of other constraints, including international treaties, systemwide fish management objectives, and power management.	4 years @ $500,000/year	$2 million	2010 - 2014
4. Make policy recommendations to action agencies on flow, taking into consideration beneficial estuary flows, flood management, power generation, irrigation, water supply, fish management, and other interests.	25 years @ $100,000/year	$2.5 million	2010 - 2035
5. Implement modified estuary flow regime annually in concert with other interests, including hydroelectric, flood control, and water withdrawals.	25 years @ $1.5 million/year[1]	$37.5 million	2011 - 2036

Total costs: $44.5 million

Geographical priority: All reaches (A-H) and the plume.

Key assumptions: (1) Even incremental changes in the magnitude and frequency of hydrosystem flows would improve salmonid habitat opportunity and food inputs, which would have benefits throughout the ecosystem. (2) Studies of flood risk and the effect of flow changes on estuarine habitat would provide data useful in modifying hydrosystem operations to benefit salmonids. (3) Studies of constraints to implementation would identify some obstacles that could be overcome. (4) Small to moderate changes in the magnitude, frequency, and timing of flows would improve sediment transport-related habitat opportunity in the estuary. (5) Increased spring freshets would yield greater sediment transport-related benefits than would other flow modifications.

Existing efforts: Large-scale efforts to adjust flows entering the estuary and return hydrology to more historical conditions have not yet begun because of the level of uncertainty regarding potential scenarios for adjusting the timing and volume of flow and the associated habitat benefits. Significant efforts have been undertaken by Bonneville Power Administration, the U.S. Army Corps of Engineers, and the U.S. Bureau of Reclamation to manage the hydrosystem for passage of juvenile salmonids. In addition, flows entering the estuary currently are managed to minimum seasonal flows to protect chum redds in the mainstem below Bonneville Dam.

Potential implementers:

- Bonneville Power Administration
- U.S. Army Corps of Engineers
- U.S. Bureau of Reclamation

Notes:

[1] Assumes $1.5 million per year cost of decreased hydrosystem generation revenues associated with minor and incremental adjustments to flows; also assumes that the flood risk associated with beneficial estuary flows does not increase significantly. The $1.5 million per year cost is included primarily as an indicator that there would be some foregone revenues even with minor changes in the flow regime. Specific costs will be evaluated during implementation as specific scenarios for modifying flows are developed and considered.

Management Action CRE-5:

Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.

Project	Unit	Cost	Schedule
1. Identify the effects of reservoir sediment entrapment on economic and ecological processes; this includes effects on ship channels, turning basins, port access, jetty activities, and habitat availability.	1 study	$2 million	2008 - 2011
2. Develop a regionwide sediment plan for the estuary to address salmonid habitat-forming processes.	10 years @ $100,000/year	$1 million	2006 – 2031
3. Implement projects recommended in the plan to mitigate the effects of sediment entrapment.	5 projects @ $1 million/project	$5 million	2010 - 2020

Total costs: $8 million

Geographical priority: Reaches A-H and the plume.

Key assumptions: (1) Sediment entrapment in reservoirs will continue. (2) Sediment entrapment has negative effects, both ecologically and economically. (3) The extent of these effects warrants exploration and implementation of potential mitigation measures. (4) Studying potential mitigation measures would identify some actions that would be effective and could be implemented. (5) Synergistic ecological effects may be realized as a result of implementing CRE-5 and CRE-6, which could increase sediment inputs into the estuary (CRE-5) and optimize beneficial uses of dredged materials (CRE-6).

Existing efforts: The Lower Columbia Solutions Group, a bi-state organization made up of local, state, and Federal governmental and non-governmental stakeholders, was formed by the governors of Washington and Oregon to address activities related to the disposal of dredged materials in the estuary. Developing a sediment budget is one of the activities of the Lower Columbia Solutions Group; it is likely that this sediment management budget will include the effects of reservoir sediment entrapment.

Potential implementers:

- U.S. Army Corps of Engineers
- Bonneville Power Administration

Management Action CRE-6:

Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.

Project	Unit	Cost	Schedule
1. Develop a regionwide sediment plan for the estuary and littoral cell.	See CRE-5.	See CRE-5.	See CRE-5.
2. Identify and implement dredged material beneficial use demonstration projects, including the notching and scrape-down of previously disposed materials and placement of new materials for habitat enhancement and/or creation.	100 acres @ $10,000/ acres	$1 million	2006 - 2012
3. Dispose of dredged materials using techniques identified through the demonstration projects and regionwide planning.	500 acres @ $10,000/acre[1]	$5 million	2008 - 2033

Total costs: $6 million

Geographical priority: Reaches A, B, C, and G, the Lower Willamette reach, and the plume and nearshore.

Key assumptions: (1) Dredging activities will continue or increase over time. (2) Opportunities to beneficially use dredged materials for habitat can be identified. (3) Beneficial use of dredged material would have a positive effect on sediment transport and habitat-forming processes in the estuary, plume, and littoral cell.

Existing efforts: Several agencies and organizations are actively engaged in the evaluation of dredged material for ecosystem-based beneficial uses. The Lower Columbia Solutions Group currently is focused on reducing the disposal of dredged materials in open waters off the mouth of the Columbia River in favor of supplementing the nearshore littoral cell with sediments. The Portland District of the U.S. Army Corps of Engineers is exploring tidal wetland development in the estuary based on an assessment of wetlands that have formed accidentally where dredged materials were placed historically. The Port of Portland also is exploring the use of dredged materials for potential development of subtidal habitats.

Potential implementers:

- U.S. Army Corps of Engineers
- Port districts
- Cities
- Lower Columbia River Solutions Group
- Oregon Department of Environmental Quality
- Oregon Department of State Lands
- Oregon Department of Fish and Wildlife
- Oregon Department of Land Conservation and Development
- Washington Department of Ecology
- Washington Department of Fish and Wildlife

Notes:

[1]Unit cost is funding to pay for activities beyond the minimum required by law, to achieve regional-scale ecosystem benefits.

Management Action CRE-7:

Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.

Project	Unit	Cost	Schedule
1. Identify and evaluate dredge operation techniques designed to reduce entrainment and other habitat effects.	1 project	$500,000	2008 - 2010
2. Initiate demonstration projects designed to test and evaluate dredge operations.	5 projects @ $200,000/project	$1 million	2009 - 2012
3. Implement best management techniques.	10 years @ $250,000/year[1]	$2.5 million	2011 – 2036
4. Study the effects of entrainment of juvenile salmonids from ship ballast water intake.	1 study @ $250,000	$250,000	2009 – 2011
5. Implement a demonstration project to evaluate the feasibility of reducing entrainment of juvenile salmonids from ship ballast intake.	1 project @ $250,000	250,000	2012 -- 2015

Total costs: $4.5 million

Geographical priority: Reaches A, B, C, D, E, F, G, and the Lower Willamette reach.

Key assumptions: (1) Improved best management practices can be identified that would help reduce the impact of dredging. (2) Mitigation activities would help offset changes to the estuary caused by dredging.

Existing efforts: The U.S. Army Corps of Engineers and ports in the lower Columbia River have studied the effects of entrainment on aquatic species and have implemented actions to reduce negative effects. Screening and other ship ballast activities to decrease entrainment of juvenile salmonids have been implemented.

Potential implementers:

- U.S. Army Corps of Engineers
- Port districts
- Private entities, such as ports and sand and gravel dredgers
- Counties and cities

Notes:

[1]This is an estimate of the incremental cost above permitted dredge activities. Cost may vary significantly depending on site-specific conditions.

Management Action CRE-8:

Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.

Project	Unit	Cost	Schedule
1. Inventory, assess, and evaluate in-channel pile dikes for their economic value and their negative and positive impacts on the estuary ecosystem; develop working hypotheses for removal or modification.	1 plan	$250,000	2007 - 2009
2. Implement demonstration projects designed to test working hypotheses and guide future program priorities.	4 pile dike removal projects @ $125,000/project	$500,000	2009 - 2010
3. Remove or modify priority pilings and pile dikes.	25 years @ $1 million/year	$25 million	2008 - 2033
4. Monitor the physical and biological effects of pile dike removal and/or modification.	10 years @ $150,000/year	$1.5 million	2010 - 2020

Total costs: $27.25 million

Geographical priority: Reaches A – H and the Lower Willamette reach.

Key assumption: (1) Many pilings, pile dikes, and similar structures could be removed or modified without compromising the shipping channel or protection of property. (2) Over time, the removal or modification of superfluous pile dikes would improve conditions for salmonids and the ecosystem.

Existing efforts: This action was incorporated into the 2008 Federal Columbia River Power System Hydropower Biological Opinion (BiOp) Remand as Reasonable and Prudent Alternative 38: Piling and Dike Removal Program. A project team composed of the Lower Columbia River Estuary Partnership, Bonneville Power Administration, and the U.S. Army Corps of Engineers is working to develop a strategic plan to remove, modify, or retain pile structures within the mainstem lower river. (Modification could include adding large wood to make complex habitat, for example.) The program currently is funded at a level of $1 million per year and is expected to be funded through 2018 if the program proves successful in providing benefits to salmonids.

Potential implementers:

- U.S. Army Corps of Engineers
- Bonneville Power Administration
- Washington Department of Natural Resources
- Washington Department of Fish and Wildlife
- Oregon Department of Fish and Wildlife
- Oregon Department of Lands
- Lower Columbia River Estuary Partnership
- Counties and cities
- Tribes

Management Action CRE-9:

Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.

Project	Unit	Cost	Schedule
1. Educate landowners about the ecosystem benefits of protecting and stewarding intact off-channel areas and the costs of restoring degraded areas.[1]	(See CRE-1.1)	$500,000	2008 - 2028
2. Encourage and provide resources for local, state, and Federal regulatory entities to maintain, improve (where needed), and consistently enforce habitat protections throughout the lower Columbia region.[2]	10 years @ $500,000 million/year	$5 million	2008 - 2018
3. Actively purchase off-channel habitats in urban and rural settings that (1) cannot be effectively protected through regulation, (2) are degraded but have good restoration potential, or (3) are highly degraded but could benefit from long-term restoration solutions.[3]	Rural: 5,000 acres at $3,000/acre Urban:150 acres at $100,000/acre	$30 million	2007 – 2031
4. Restore degraded off-channel habitats with high intrinsic potential for increasing habitat quality.	Rural: 6,000 acres at $5,000/acre Urban: 500 acres at $5,000/acre	32.5 million	2007 - 2031

Total costs: $68 million

Geographical priority: Reaches A, B, C, and G and the Lower Willamette reach.

Key assumptions: (1) Protection opportunities can be increased over the next decade through public awareness, educational, regulatory, and acquisition programs. (2) Protection of off-channel habitats is less expensive than restoration. (3) High-quality off-channel habitats offer benefits to salmonids that cannot be provided in other ways. (4) Protection will be needed to offset increasing threats resulting from human population increases in the estuary and basin. (5) Restoring off-channel habitat function in the estuary is critical to ecosystem processes. (6) Restoring off-channel habitats enhances juvenile salmonid growth by increasing access to food sources and provides refugia from high flows and predation.

Existing efforts: Protection of off-channel habitats relies heavily on local governments; the content and implementation of their land use plans specifically for shoreline and floodplain protection will be key to this action. Multiple Federal and state resource agencies provide funding for land acquisition and restoration, and multiple entities such as land trusts and watershed councils actively acquire and restore lands in the lower river. The Division of State Lands in Oregon and the Department of Natural Resources in Washington own and/or regulate submerged and submersible lands. The Natural Resource Conversation Service and conservation districts provide technical assistance to private landowners. Where water quality issues (such as toxic or conventional contaminants) are involved, agencies such as Washington's Department of Ecology and Oregon's Department of Environmental Quality may provide additional support. The Lower Columbia River Estuary Partnership's Habitat Restoration Program largely is directed toward this action, CRE-1, and CRE-10. Organizations such as the Columbia Land Trust and the Columbia River Estuary Study Taskforce are actively involved in off-channel restoration activities.

Potential implementers:

- U.S. Army COE
- BPA
- Columbia Land Trust
- The Wetlands Conservancy
- Ducks Unlimited
- Col. River Est. Study Taskforce
- The Nature Conservancy
- Lower Col. River Est. Partnership
- Watershed councils
- OR Watershed Enhancement Bd.
- OR Dept. of Fish and Wildlife
- WA Dept. of Ecology
- Port districts
- Cities
- Conservation districts
- Other special districts
- Tribes

Notes:

[1] Projects CRE-1.1 and CRE-9.1 both call for outreach efforts. Outreach efforts for these two actions will be combined in a single outreach program whose costs will be shared.

[2] Projects CRE-1.2 and CRE-9.2 both call for incentives for local, state, and Federal entities to maintain, improve, and enforce regulatory protections. Given their similarities, activities for 1.2 and 9.2 could possibly be coordinated or combined into a single effort.

[3] Assumes purchases are made over a 25-year period with willing sellers.

Management Action CRE-10:

Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.

Project	Unit	Cost	Schedule
1. Breach, lower the elevation of, or relocate dikes and levees; create and/or restore tidal marshes, shallow-water habitats, and tide channels.	5,000 acres[1] @ $10,000/acre	$50 million	2006 - 2031
2. Remove tide gates to improve the hydrology between wetlands and the channel and to provide juveniles with physical access to off-channel habitat; use a habitat connectivity index to prioritize projects.	2,000 acres[1] @ $10,000/acre	$20 million	2006 - 2031
3. Upgrade tide gates or perched culverts where (1) no other options exist, (2) upgraded structures can provide appropriate access for juveniles, and (3) ecosystem function would be improved over current conditions.	1,000 acres[1] @ $5,000/acre	$5 million	2006 - 2031

Total costs: $75 million

Geographical priority: Reaches A, B, C, E, F, and G and the Lower Willamette reach.

Key assumptions: (1) Additional opportunities to restore off-channel habitats can be developed through long-term outreach and improved landowner relationships. (2) Restoration of sites, including elevation restoration, would yield broad-scale ecosystem benefits over time. (3) A habitat connectivity index would help target efforts toward the projects that would provide the greatest benefits. (4) Restoration of highly degraded sites may be necessary to yield long-term benefits.

Existing efforts: Multiple Federal and state resource agencies provide funding for restoration activities, including improving hydrologic conditions and access for juvenile salmonids. In the estuary, the U.S. Army Corps of Engineers, Columbia River Estuary Taskforce, and Columbia Land Trust have significant experience breaching dikes or retrofitting tide gates. Other entities, including watershed councils, conservation districts, and private firms, also have experience but sometimes lack sufficient technical and infrastructure capacity. Extensive community outreach and long-term relationship building will be needed to implement this action. The Lower Columbia River Estuary Partnership's Habitat Restoration Program largely is directed toward this action, CRE-1, and CRE-9.

Potential implementers:

- U.S. Army Corps of Engineers
- Bonneville Power Administration
- U.S. Fish and Wildlife Service
- Oregon Watershed Enhancement Board
- Oregon Department of Fish and Wildlife
- Columbia Land Trust
- Columbia River Estuary Study Taskforce
- Salmon Recovery Funding Board
- Conservation districts
- Other districts
- Cities
- Counties
- Lower Columbia River Estuary Partnership
- Lower Columbia Fish Recovery Board
- Watershed councils
- Tribes

Notes:

[1]Acreage equals amount of affected area. Costs include those associated with protecting other land uses from renovated hydrology (i.e., moving dikes and levees).

Management Action CRE 11:

Reduce the square footage of over-water structures in the estuary.

Project	Unit	Cost	Schedule
1. Inventory over-water structures and develop a GIS layer with detailed metadata files.	2 projects @ $150,000/project	$300,000	2007 - 2009
2. Initiate a planning process to evaluate existing and new over-water structures for their economic, ecological, and recreational value.	2 phases[1] @ $100,000/phase	$200,000	2009 - 2013
3. Remove or modify over-water structures to provide beneficial habitats.	10 projects @ $500,000/project[2]	$5 million	2012 - 2037
4. Establish criteria for new permit applications to consider the cumulative impacts of over-water structures.	1 project	$300,000	2008 - 2010

Total costs: $5.8 million

Geographical priority: Reaches D and G and the Lower Willamette reach.

Key assumptions: (1) Over-water structures pose some threat to salmonids. (2) A fair number of over-water structures are no longer in use or have relatively minor value to owners. (3) An inventory of over-water structures would aid in assessing individual structures' economic, ecological, and recreational value.

Existing efforts: Over-water structures are regulated by specific sections of the Federal Clean Water Act, state statute, or both. These laws are administered by Federal agencies (U.S. Army Corps of Engineers, U.S. Environmental Protection Agency) or state agencies (Oregon Department of Environmental Quality, Oregon Division of State Lands, Oregon Department of Land Conservation and Development, Washington Department of Ecology, and Washington Department of Natural Resources). The Lower Columbia River Estuary Partnership created a shoreline condition inventory that maps all over-water structures using GIS. Currently, there are no targeted efforts to remove over-water structures in the estuary.

Potential implementers:

- U.S. Army Corps of Engineers
- Cities
- Washington Department of Natural Resources
- Oregon Department of Land Conservation and Development
- Oregon Department of State Lands

Notes:

[1]The first phase is technical and the second phase is policy.

[2]A project is defined as a set of structures that have been identified for removal; cost is level of effort.

Management Action CRE-12:

Reduce the effects of vessel wake stranding in the estuary.

Project	Unit	Cost	Schedule
1. Analyze factors contributing to ship wake stranding to determine potential approaches to reducing mortality in locations where juveniles are most vulnerable. Design and implement demonstration projects and monitor their results.	1 study @ $1 million	$1 million	2007 - 2010
2. Implement projects identified in Project No. 1 that are likely to result in the reduction of ship wake stranding events.	12 projects @ $1 million/project[1]	$12 million	2011 - 2026

Total costs: $13 million

Geographical priority: Reaches C, D, E, and F.

Key assumptions: (1) Vessel wake stranding is a significant issue for ocean- and stream-type salmonids employing the fry life history strategy in the estuary.

Existing efforts: The U.S. Army Corps of Engineers initiated a two-phase study on vessel wake stranding associated with the channel deepening project. Phase 1 was completed in 2006 as part of the channel deepening project. Results could be used to design follow-up studies analyzing factors that contribute to ship wake stranding. In addition, in 2008 the Port of Vancouver completed a study designed to estimate the total acres of estuary shoreline (downstream of the port) that may contribute to ship wake stranding.

Potential implementers:

- U.S. Army Corps of Engineers
- Columbia River pilots
- Ports
- US Coast Guard
- River and bar pilots

Notes:

[1] This is a level-of-effort cost approach that will require information generated in Projects No. 1 and 2.

Management Action CRE-13:

Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.

Project	Unit	Cost	Schedule
1. Monitor the abundance levels of pikeminnow, smallmouth bass, walleye, and channel catfish.	5 monitoring events @ $100,000/event (every 5 years)	$500,000	2006 - 2031
2. Implement actions as necessary to prevent population growth (i.e., modify habitat)[1]; increase the northern pikeminnow bounty program in the estuary.	25 years @ $500,000/year	$12.5 million	2006 - 2031

Total costs: $13 million

Geographical priority: Reaches D, E, F, G, and H and the Lower Willamette reach.

Key assumption: Management techniques would maintain populations at levels that would maintain or reduce predation impacts to salmonids. A pikeminnow management plan exists and is being implemented. Costs associated with this action are partly covered as a baseline cost. Costs associated with managing other piscivorous fish, including smallmouth bass, walleye, and channel catfish, are entirely incremental costs.

Existing efforts: Bonneville Power Administration funds the Northern Pikeminnow Sport Reward Fishery Program whereby anglers receive $4 to $8 for every qualifying northern pikeminnow 9 inches or longer returned to a registration station. Since 1990, more than 3.1 million northern pikeminnow have been removed from the Snake and Columbia rivers as a result of this program. The annual budget for the Northern Pikeminnow Management Program has varied from $2.0 to $6.4 million, with an average of about $3.0 million basinwide.

Potential implementers:

- U.S. Army Corps of Engineers
- Washington Department of Fish and Wildlife
- Oregon Department of Fish and Wildlife
- Bonneville Power Administration
- National Marine Fisheries Service

Notes:

[1] It is unknown whether projects will be needed to manage warm-water fish. In some cases, there may be warm-water habits close to juvenile habitat, in which case site-specific action would be required.

Management Action CRE-14:

Identify and implement actions to reduce salmonid predation by pinnipeds.

Project	Unit	Cost	Schedule
1. Expand Federal and state activities at Bonneville Dam to test non-lethal and potentially lethal methods of reducing pinniped populations throughout the estuary. This includes efforts to manage pinnipeds through the Marine Mammal Protection Act.	5 years @ $500,000/year	$2.5 million	2007 - 2011
2. Implement actions likely to reduce pinniped predation on adult salmonids.	25 years @ $500,000/year[1]	$12.5 million	2007 - 2032

Total costs: $15 million

Geographical priority: Reaches A-H (especially H).

Key assumptions: (1) Mortality from pinnipeds throughout the lower Columbia River may be a larger source of salmonid mortality than previously understood. (2) Further study would clarify the impact of pinniped predation on salmonids; studies by the U.S. Army Corps of Engineers at Bonneville Dam represent a good start on this task. (3) Mortality from pinniped predation could be reduced through non-lethal and lethal methods. (4) The Marine Mammal Protection Act could be modified over time to allow more tools for managing pinnipeds in the estuary. In 2008, NMFS granted authority under Section 120 of the Marine Mammal Protection Act to the states of Oregon, Washington, and Idaho to intentionally take, by lethal methods, individually identifiable California sea lions that prey on Pacific salmon and steelhead at Bonneville Dam (Federal Register 2008).

Existing efforts: The National Marine Fisheries Service, Oregon and Washington, the U.S. Army Corps of Engineers, and Bonneville Power Administration have initiated efforts to manage pinnipeds, primarily at Bonneville Dam. As of 2010, efforts included both lethal and non-lethal methods sanctioned under Section 120 of the Marine Mammal Protection Act.

Potential implementers:

- U.S. Army Corps of Engineers
- Bonneville Power Administration
- National Marine Fisheries Service
- Columbia River Inter-Tribal Fish Commission
- Oregon Department of Fish and Wildlife
- Washington Department of Fish and Wildlife

Notes:

[1] Units are years; given the constraints to this action, it is likely that ongoing efforts to prevent predation will continue over the next 25 years.

Management Action CRE-15:

Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.

Project	Unit	Cost	Schedule
1. Increase public awareness of exotic plant species and proper stewardship techniques.[1]	10 years @ $100,000/year	$1 million	2008 – 2018
2. Inventory exotic plant species infestations and develop a GIS layer with detailed metadata files.	5 phases @ $200,000/phase	$1 million	2007 – 2012
3. Implement projects to address infestations on public and private lands.	10,000 acres @ $1,000/acre	$10 million	2008 – 2028
4. Monitor infestation sites.	20 years @ $25,000/year	$500,000	2010 - 2030

Total costs: $12.5 million

Geographical priority: Reaches A-H and the Lower Willamette reach).

Key assumptions: (1) Aquatic invasive plants have a negative effect on the estuary ecosystem and affect juvenile salmonids by altering habitat and causing food webs to deteriorate. (2) Additional information is needed on the location, extent, and type of infestations and their effects on the estuary ecosystem. (3) Because introductions of invasive plants can permanently alter the estuary ecosystem, prevention activities are crucial. (4) Education, outreach, and monitoring would help prevent further introductions of invasive plants.

Existing efforts: The fish and wildlife departments of Oregon and Washington have management responsibilities for fish and wildlife, including the control of non-indigenous species. The Washington Department of Fish and Wildlife has developed an Aquatic Non-indigenous Species Management Plan. The Pacific States Marine Fisheries Commission promotes interstate communication and facilitates the coordination of aquatic non-indigenous species activities on the West Coast. The Oregon and Washington Sea Grant programs combined to form the Northwest Marine Invasive Species Team to raise the level of awareness about the threats of invasive species. The Invasive Alien Species Executive Order at the Federal level created the Invasive Species Council and directed development of an Invasive Species Management Plan. Multiple Federal and state resource agencies provide funding for restoration projects that remove exotic invasive plants, and entities such as land trusts and watershed councils actively eradicate exotic native plants and plant native species in the lower river. Noxious weed control entities exist in Oregon and Washington to help educate landowners and control invasive plants.

Potential implementers:

- U.S. Army Corps of Engineers
- Bonneville Power Administration
- US Fish and Wildlife Service
- State agencies
- Conservation districts
- Noxious weed districts
- Counties
- Cities
- Tribes
- Watershed councils
- Lower Columbia River Estuary Partnership
- The Nature Conservancy
- Landowners

Notes:

[1]This project is recommended for upstream mainstem and tributaries, but the costs presented here are for activities in the estuary only. Many exotic plants have established themselves upstream and represent a constant downstream threat to the estuary.

Management Action CRE-16:

Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.

Project	Unit	Cost	Schedule
1. Enhance or create tern nesting habitat at alternative sites in Washington, Oregon, and California.	3 sites @ $1 million/site	$3 million	2008 - 2012
2. Reduce tern nesting habitat on East Sand Island from 6 acres to 1 to 1.5 acres.	1 project @ $4.5 million/project	$4.5 million	2007 - 2010
3. Monitor the regional tern population.	25 years @ $100,000/year	$2.5 million	2010 - 2035

Total costs: $10 million

Geographical priority: Reaches A and B.

Key assumption: Ongoing and new management actions directed to Caspian tern nesting habitat would continue to reduce salmonid mortality from tern predation. A management plan exists and is being implemented. Costs associated with this action are partially covered as a baseline cost.

Existing efforts: The U.S. Army Corps of Engineers has recently constructed alternative habitat for Caspian terns outside of the estuary. The Corps also funds studies assessing Caspian tern population levels and predation rates on juvenile salmonids. These studies track terns along the West Coast to determine whether management actions in the lower river result in redistribution of terns elsewhere along the West Coast. A predatory bird Web site (www.birdresearchnw.org) keeps the public and others informed on the status of management plans and research.

Potential implementers:

- U.S. Army Corps of Engineers
- U.S. Fish and Wildlife Service
- U.S. Geological Survey
- Oregon Department of Fish and Wildlife
- Washington Department of Fish and Wildlife

Management Action CRE-17:

Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.

Project	Unit	Cost	Schedule
1. Identify, assess, and evaluate methods of reducing double-crested cormorant abundance numbers.	1 multiphase study	$1 million	2007 - 2011
2. Implement demonstration projects resulting from Project No. 1 (i.e., decoys and audio playback methods).	5 pilot projects @ $500,000/project	$2.5 million	2010 - 2015
3. Implement projects resulting in reduced predation by cormorants.[1]	10 years @ $700,000/year	$7 million	2013 - 2023

Total costs: $10.5 million

Geographical priority: Reaches A and B.

Existing efforts: The U.S. Army Corps of Engineers funds studies assessing cormorant population levels and predation rates on juvenile salmonids. These studies track cormorants along the West Coast to determine whether management actions in the lower river result in redistribution elsewhere along the West Coast. A predatory bird Web site (www.birdresearchnw.org) keeps the public and others informed on the status of management plans and research.

Potential implementers:

- U.S. Army Corps of Engineers
- U.S. Fish and Wildlife Service
- U.S. Geological Survey
- Oregon Department of Fish and Wildlife
- Washington Department of Fish and Wildlife

Notes:

[1]This is a level-of-effort cost estimate; efforts to manage cormorants in the estuary are significantly lagging Caspian tern management efforts and will likely be more difficult to implement.

Management Action CRE-18:

Reduce the abundance of shad in the estuary.

Project	Unit	Cost	Schedule
1. Organize existing technical information about shad and identify data gaps and potential control methods.	2 phases @ $250,000/phases	$500,000	2007 - 2011
2. Implement demonstration projects to evaluate effective shad management methods.	4 projects @ $500,000/project	$2 million	2008 - 2015
3. Implement shad population management techniques.[1]	10 years @ $250,000/year	$2.5 million	2010 - 2015
4. Monitor and evaluate shad management techniques.	10 years @ $50,000/year	$500,000	2011 - 2021

Total costs: $5.5 million

Geographical priority: Reaches A-H and the Lower Willamette reach.

Key assumptions: (1) Shad have negative affects on salmonids in the estuary. (2) Additional research would shed light on how shad affect salmonids and suggest new management techniques. (3) New management techniques would be unlikely to cause significant change.

Existing efforts: The U.S. Geological Survey, with funding from Bonneville Power Administration, is studying the presence of American shad in the Columbia River throughout the year, assessing shad diet trends, and PIT tagging up to 1,000 adult pre-spawn shad in the estuary to examine their time of arrival at dams using PIT tag detection technologies in fishways.

Potential implementers:

- U.S. Army Corps of Engineers
- U.S. Geological Survey
- Oregon Department of Fish and Wildlife
- Washington Department of Fish and Wildlife

Notes:

[1]This is a level-of-effort cost estimate; currently there are no plans to manage shad abundance levels in the Columbia River.

Management Action CRE-19:

Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations.

Project	Unit	Cost	Schedule
1. Assemble existing technical information on introduced aquatic invertebrates in the estuary and develop a plan for managing existing infestations and preventing new infestations.	2 phases @ $250,000/phase	$500,000	2007 - 2010
2. Implement recommendations from the plan for managing existing infestations and preventing new infestations (Project No. 1, above).[1]	5 projects @ $500,000/project	$2.5 million	2008 – 2013

Total costs: $3 million

Geographical priority: Reaches A-H and the Lower Willamette reach.

Key assumptions: (1) Ship ballast practices could be improved to help prevent further degradation of the estuary ecosystem. (2) Additional research would help scientists understand the effects of exotic invertebrates on the ecosystem. (3) Because the effects of exotic invertebrates on the ecosystem usually cannot be reversed, it is important to prevent introductions when possible.

Existing efforts: Following the direction of the 2007 Oregon Legislature, the Shipping Transport of Aquatic Invasive Species Task Force was convened in 2008 to examine how Oregon can better handle aquatic invasive species coming into the state via shipping activities. The task force compiled a report outlining various aspects of preventing the introduction of aquatic invasive species from shipping-related pathways. The report also recommended steps that the Oregon Department of Environmental Quality, working with other agencies and the shipping industry, can take to bolster efforts to halt the arrival and spread of aquatic invasive species that degrade existing ecosystems and displace native species.

Likewise, the Aquatic Nuisance Species Unit of the Washington Department of Fish and Wildlife (WDFW) has implemented the Washington State ballast water program since 2000. This program receives state funds for program management, vessel report tracking, and vessel inspection efforts. Two vessel inspectors stationed in Puget Sound and the SW/Columbia River regions target high-risk vessels for boarding and ballast sampling. Washington established discharge standards that, as of 2009, had not yet been implemented.

In 2008, the Environmental Protection Agency issued a Vessel General Permit (VGP) as part of the National Pollutant Discharge Elimination System under the Federal Water Pollution Control Act. This permit is intended to regulate discharges resulting from the normal operation of all non-recreational vessels 79 feet or longer. In addition, the ballast water discharge provisions apply to any non-recreational vessel of less than 79 feet and commercial fishing vessels of any size discharging ballast water, and require adoption of best management practices for discharges. Currently, the VGP regulations adopt U.S. Coast Guard ballast water exchange requirements and coastal exchange requirements for domestic voyages along the West Coast but do not include ballast water treatment technology. Under the Clean Water Action Section 401 certification requirements, states can adopt more stringent conditions than the VGP in their certifications if so needed to meet requirements of either the Clean Water Act or state law.

Potential implementers:

- Port districts
- Oregon Department of Fish and Wildlife
- Washington Department of Fish and Wildlife
- U.S. Fish and Wildlife Service
- Oregon Department of Agriculture
- Washington State Department of Agriculture
- Portland State University
- Oregon State Marine Board
- Washington State Parks and Recreation Commission
- Oregon Department of Environmental Quality

Notes:

[1]This is a level-of-effort cost estimate.

Management Action CRE-20:

Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.

Project	Unit	Cost	Schedule
1. Educate landowners, businesses, and other users about practices to reduce usage and the effects of pesticides and fertilizers.[1]	10 years @ $50,000/year	$500,000	2008 - 2018
2. Implement pesticide, fertilizer, and nutrient best management practices to reduce contaminants entering the estuary.	10 years @ $1.15 million/year[2]	$11.5 million	2008 – 2018
3. Evaluate the adequacy of best management practices and update as needed.	2 reviews @ $250,000	$500,000	2012 and 2017

Total costs: $12.5 million

Geographical priority: Reaches A-H and the Lower Willamette reach.

Key assumptions: (1) Some users of pesticides and fertilizers are not adequately informed about best management practices for these toxic contaminants. (2) Additional benefits to salmonids could be realized through continued efforts by farmers, chemical manufacturers, and regulatory programs to reduce impacts from fertilizers and pesticides. (3) Benefits to salmonids would increase over a relatively long period of time as agricultural practices improve. Several of the projects identified in this action are being implemented and therefore could be considered baseline costs. The costs in this action are considered additive to baseline costs because of the significant effort needed to reduce nutrients and toxic contaminants entering the estuary.

Existing efforts: Both Washington and Oregon produce and encourage implementation of best management practices (BMP) manuals to address non-point sources of pollution. In both states, load allocations and reduction strategies are identified through the total maximum daily load (TMDL) process. The Oregon Department of Environmental Quality is now conducting “pesticide stewardship partnerships” in five Oregon watersheds that eventually flow into the Columbia or Willamette rivers. These partnership programs work through outreach with the agricultural community to implement BMPs that will reduce pesticides in rivers and streams. The U.S. Department of Agriculture, through Senate Bill 1010 authorities, is developing plans to ensure BMPs on agricultural lands. The U.S. Environmental Protection Agency convened the Columbia River Basin Toxics Reduction Working Group in 2005 to coordinate monitoring, cleanup, and reporting efforts basinwide. In September 2010, the working group produced the Columbia River Basin Toxics Reduction Action Plan.

Potential implementers:

- Washington Department of Agriculture
- Oregon Department of Agriculture
- Cities
- Conservation districts
- U.S. Environmental Protection Agency
- Washington Department of Ecology
- Oregon Department of Environmental Quality
- Lower Columbia River Estuary Partnership
- Natural Resources Conservation Service

Notes:

[1] Projects CRE-20.1 and CRE 21.1 both call for outreach efforts. Outreach efforts for these two projects will be combined into a single outreach program whose costs will be shared.

[2] Unit cost includes estimates for the estuary and estuary tributaries only; the action recommends similar upstream activities.

Management Action CRE-21:

Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.

Project	Unit	Cost	Schedule
1. Educate the industrial and commercial sectors and the general public on how to reduce the introduction of pollutants into the estuary and its tributaries.[1]	10 years @ $20,000/year	$200,000	2008 - 2028
2. Identify sources, loads, and pathways of pollutants in the estuary.	8 years @ $100,000/year	$800,000	2010 - 2018
3. Provide cost-share incentives for National Pollution Discharge Elimination System (NPDES) permit holders to upgrade effluent above their permit requirements.	10 years @ $1.5 million/year	$15 million	2010 – 2020
4. Study and establish threshold treatment standards for pharmaceuticals and other unregulated substance discharges; update existing NPDES permits to reflect the new standards.	5 years @ $2 million/year	$10 million	2007 – 2012
5. Provide grants and low-cost loans to permit holders required to treat effluent to standards established in Project No. 3.	10 years @ $2 million/year	$20 million	2012 - 2017

Total costs: $46 million

Geographical priority: Reaches D and G and the Lower Willamette reach.

Key assumptions: (1) Non-permitted discharges that currently are occurring would be identified and curtailed. (2) Financial incentives or support would motivate NPDES permit holders to raise their effluent treatment levels above permit requirements. (3) Releases of industrial and commercial pollutants into the estuary would be reduced over time. Several of the projects identified in this action are being implemented and therefore could be considered baseline costs. The costs in this action are considered additive to baseline costs because of the significant effort needed to reduce inputs of pollutants.

Existing efforts: In both Oregon and Washington, pollutant load allocations and reduction strategies are identified through the total maximum daily load (TMDL) process. The Oregon Department of Environmental Quality's (DEQ) Water Quality Program is developing a list of key, persistent bioaccumulative toxic contaminants that have a documented effect on human health, wildlife, and aquatic life. The Oregon Legislature has directed DEQ to report on where persistent bioaccumulative toxic contaminants are coming from and options to reduce their discharge. In addition, legislation required Oregon's 52 largest municipal wastewater treatment plants to develop plans by 2011 to reduce priority persistent pollutants through pollution prevention and toxic reduction. Initial monitoring and reduction efforts are to focus on the Willamette River. The U.S. Environmental Protection Agency convened Columbia River Basin Toxics Reduction Working Group in 2005 to coordinate monitoring, cleanup, and reporting efforts basinwide. In September 2010, the working group produced the Columbia River Basin Toxics Reduction Action Plan. The Lower Columbia River Estuary Partnership has created a long-term monitoring strategy that calls for baseline conventional and toxic contaminant data along with data sufficient to assess trends and biological integrity.

Potential implementers:

- U.S. Environmental Protection Agency
- Washington Department of Ecology
- Oregon Department of Environmental Quality
- Cities
- Trade groups such as the Oregon Association of Clean Water Agencies that represent wastewater dischargers

Notes:

[1] Projects CRE-20.1 and CRE-21.1 both call for outreach efforts. Outreach efforts for these two actions will be combined into a single program whose costs are shared.

Management Action CRE-22:

Restore or mitigate contaminated sites.

Project	Unit	Cost	Schedule
1. Develop criteria and a process for evaluating contaminated sites to establish their restoration potential.	1 phase @ $500,000/phase	$500,000	2007 - 2017
2. Develop an integrated multi-state funding strategy to address contamination cleanup in the estuary from non-identifiable upstream sources.	Out-of-Estuary[1]	n/a	2007 - 2012
3. Restore those contaminated sites that will yield the greatest ecological and economic benefits.	20 years @ $3 million/year	$60 million	2007 - 2027

Total costs: $60.5 million

Geographical priority: Reaches A-H and the Lower Willamette reach.

Key assumptions: (1) Monitoring will continue to provide vital data needed to understand the toxic contaminant problem and identify potential solutions. (2) Monitoring will identify hot spots of contamination. (3) Contamination sites will be identified for which responsible parties cannot be determined. (4) Additional analysis would identify contamination sites whose restoration would yield significant ecological and economic benefits. (5) Restoration of contaminated sites would benefit salmonids and the ecosystem over time. (6) The action will include improving the condition of habitats that have been impaired by the contaminants, not just removing pollutants. (7) Clean up will be to levels that support survival and recovery in both the short-term and long-term. Several of the projects identified in this action are being implemented and therefore could be considered baseline costs. The costs in this action are considered additive to baseline costs because of the significant effort needed to address contamination cleanup.

Existing efforts: The U.S. Environmental Protection Agency regulates cleanup of contaminated sites under Superfund and other programs, which include monitoring of these sites. The U.S. Environmental Protection Agency convened the Columbia River Basin Toxics Reduction Working Group in 2005 to coordinate monitoring, cleanup, and reporting efforts basinwide. In September 2010, the working group produced the Columbia River Basin Toxics Reduction Action Plan. The Lower Columbia River Estuary Partnership has created a long-term monitoring strategy that calls for baseline conventional and toxic contaminant data along with data sufficient to assess trends and biological integrity. The Estuary Partnership, U.S. Geological Survey, and NMFS completed a 3-year study that compiled and analyzed monthly toxic and conventional pollutant data at five sites, primarily for PAHs, PCBs, estrogenic compounds, flame retardants, current-use pesticides, nutrients, and trace elements, Toxics monitoring of juvenile salmon also was conducted at six sites (for PCBs, PAHs, organochlorine pesticides, and flame retardants) (Lower Columbia River Estuary Partnership 2007). In addition, the Estuary Partnership and NMFS developed three models that describe the role that toxics play in a salmon's life history: a conceptual model of the interactions between contaminants and endangered salmonid species, a contaminant transport and uptake model, and an ecological risk model to provide a quantitative measure of the impact of contaminant exposure on salmonid populations in the Columbia River basin (Spromberg and Johnson 2008, Leary et al. 2005, and Leary et al. 2006).

Potential implementers:

- Lower Col. River Est. Partnership
- Col. River Est. Study Taskforce
- Cities
- Conservation districts
- OR Dept. of Env. Quality
- WA State Dept. of Ecology
- Port districts
- U.S. Geological Survey
- Federal regulatory agencies such as the National. Marine Fisheries Service and U.S. Geological Survey

Notes:

[1] Cost is considered to be outside the purview of estuary-specific projects.

Management Action CRE-23:

Implement stormwater best management practices in cities and towns.

Project	Unit	Cost	Schedule
1. Monitor stormwater outputs to measure treatment compliance with existing local and state regulations throughout the basin; develop a network of monitoring sites and establish a data repository that includes data collected by permittees.	10 years @ $200,000/year	$2 million	2007 - 2015
2. Establish a fund source for regulatory agencies and local governments to use when insufficient resources are available to (1) access best available science, (2) develop standards beyond requirements, or (3) adequately enforce regulations.	3 years @ $2 million/year	$6 million	2009 – 2011
3. Evaluate the adequacy of best management practices and update as needed.	3 evaluations @ $500,000	$1.5 million	2010 – 2025
4. Provide incentives for low-impact development practices.	20 years @ $500,000/year	$10 million	2010 - 2030

Total costs: $19.5 million

Geographical priority: Reaches D and G and the Lower Willamette reach.

Key assumptions: (1) Population growth in the Columbia River basin will continue to influence the hydrology and water quality in the estuary. (2) Stormwater practices could be improved by monitoring and enforcing compliance with existing regulations, making best scientific information available, and developing higher standards. (3) The resulting improvements in hydrology and contaminant exposure in the estuary would occur slowly over time. (4) This action is protective in nature; costs are not associated with retrofitting existing stormwater facilities. Several of the projects identified in this action are being implemented and therefore could be considered baseline costs. The costs in this action are considered additive to baseline costs because of the significant effort needed to address stormwater-related water quality issues.

Existing efforts: Both the Washington Department of Ecology and Oregon Department of Environmental Quality produce best management practices manuals to address certain non-point sources. Local governments develop and update land use plans that include stormwater practices and that guide future development. The Lower Columbia River Estuary Partnership has worked with three schools on Schoolyard Stormwater Projects and engaged corporate partners to design and construct stormwater facilities.

Potential implementers:

- Cities and counties
- Washington Department of Ecology
- Oregon Department of Environmental Quality
- U.S. Environmental Protection Agency
- Lower Columbia River Estuary Partnership

Notes:
This action is recommended for upstream mainstem and tributaries, but the costs presented here are for activities in the estuary only.

Table 5-7 is a summary of costs for the 23 management actions. The total estimated budget for constrained implementation of the actions as described in Table 5-6 approaches is $528.05 million over 25 years. This number contrasts with the $1.1 billion estimated to help restore salmon in Puget Sound tributaries over a 10-year period. Other major ecosystem restoration efforts across the United States, including San Francisco Bay, Chesapeake Bay, the Everglades, and the Louisiana Coast, are estimated to cost several billion dollars apiece.

TABLE 5-7
Summary of Costs of Management Actions

Number	Action Description	Cost for Constrained Implementation	%*
CRE-01	Protect intact riparian areas in the estuary and restore riparian areas that are degraded.	$38 million	7%
CRE-02	Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.	$20 million	4%
CRE-03	Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.	$10 million	2%
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.	$44.5 million	8%
CRE-05	Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.	$8 million	2%
CRE-06	Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.	$6 million	1%
CRE-07	Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.	$4.5 million	1%
CRE-08	Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.	$27.25 million	5%
CRE-09	Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.	$68 million	13%
CRE-10	Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.	$75 million	14%
CRE-11	Reduce the square footage of over-water structures in the estuary.	$5.8 million	1%
CRE-12	Reduce the effects of vessel wake stranding in the estuary.	$13 million	2%

Number	Action Description	Cost for Constrained Implementation	%*
CRE-13	Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.	$13 million	2%
CRE-14	Identify and implement actions to reduce salmonid predation by pinnipeds.	$15 million	3%
CRE-15	Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.	$12.5 million	2%
CRE-16	Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.	$10 million	2%
CRE-17	Implement projects to reduce double-breasted cormorant habitats and encourage dispersal to other locations.	$10.5 million	2%
CRE-18	Reduce the abundance of shad in the estuary.	$5.5 million	1%
CRE-19	Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations.	$3 million	1%
CRE-20	Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.	$12.5 million	2%
CRE-21	Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.	$46 million	9%
CRE-22	Restore or mitigate contaminated sites.	$60.5 million	11%
CRE-23	Implement stormwater best management practices in cities and towns.	$19.5 million	4%
	Total	$528.05 million	

*Column shows the relative percentage of each action to the total cost. Percentages do not add up to 100 percent because of rounding.

Summary

The estuary and plume ecosystems are especially vulnerable to threats because these ecosystems are affected by factors across a wide geographic range—from upstream to the estuary itself, and even well out in the Pacific Ocean. A set of actions has been identified to help reduce threats to salmonids in the estuary and plume. Other recovery venues must also address upstream threats to effectively improve degraded habitats in the estuary. This estuary recovery plan module uses survival improvement targets to help estimate the level of effort required and the costs of that effort.

CHAPTER 6

Research, Monitoring, and Evaluation[1]

Research, monitoring, and evaluation (RME) is a critical element of recovery planning for ESA-listed species (Crawford and Rumsey 2010). RME provides essential information for planners, implementers, and managers of recovery programs on the effectiveness of their programs, whether individual actions are improving the performance[2] of listed salmonids, and how limiting factors and threats are affecting salmonids. This chapter describes RME needed to assess juvenile salmonid performance in the estuary and to evaluate the effectiveness of the 23 management actions described in Chapter 5. It also describes existing monitoring plans, programs, and projects that relate to estuary module RME needs and identifies gaps and potential projects to fill those gaps.

Monitoring plans for ESA-listed Columbia Basin salmonids have been or will be drafted for all domain recovery plans in the basin. These monitoring plans address the most basic question in recovery planning: Is the status of the listed population or ESU improving? Estuary RME will address other key questions, such as whether the performance of juvenile salmonids passing through and using the estuary is improving or worsening, and whether the limiting factors that affect the status of a population or ESU within the estuary are changing. Accordingly, estuary RME will complement monitoring for recovery plans for all domains in the Columbia River basin. Additional questions addressed by estuary RME are as follows:

- Are the actions identified in the estuary recovery plan module being implemented correctly, in sufficient scope, and according to schedule?
- What are the effects of estuary management actions on juvenile salmonids and their habitat?
- Are additional actions needed?
- Are there additional or new threats and limiting factors within the estuary beyond those considered in the estuary recovery plan module?
- How will the monitoring data be managed, analyzed, interpreted, and disseminated?
- How will monitoring data be incorporated into management decisions to best allow an adaptive management approach?

Monitoring for this estuary recovery plan module needs to build on ongoing efforts. In particular, *Research, Monitoring, and Evaluation for the Federal Columbia River Estuary*

[1] Catherine Corbett of the Lower Columbia River Estuary Partnership and Gary Johnson of Pacific Northwest National Laboratories provided the principal input to this chapter.

[2] Salmonid performance refers to life history diversity, foraging success, spatial structure, and growth (Bottom et al. 2005).

Program (ERME) (Johnson et al. 2008) is an appropriate monitoring plan on which to base the estuary recovery plan module RME. The ERME monitoring plan is important because it formed the basis for estuary RME in the 2008 Federal Columbia River Power System (FCRPS) Biological Opinion (National Marine Fisheries Service 2008a and 2008b), and was carried over into the 2010 FCRPS Supplemental Biological Opinion (National Marine Fisheries Service 2010). In addition, versions of the ERME monitoring plan have been reviewed by the Independent Scientific Review Panel of the Northwest Power and Conservation Council (Independent Scientific Review Panel 2006a and 2006b), along with state and tribal fisheries management agencies. Finally, the ERME monitoring plan was initially developed and refined by an inter-agency estuary/ocean subgroup for Federal RME that included members from the Bonneville Power Administration, the U.S. Army Corps of Engineers, the Lower Columbia River Estuary Partnership, NMFS, and the Pacific Northwest National Laboratory. This chapter borrows greatly from the Johnson et al. (2008) ERME plan.

In addition to the *Research, Monitoring, and Evaluation Program for the Federal Columbia River Estuary* (Johnson et al. 2008), nine other monitoring plans and guidance documents are applicable to a framework for estuary recovery plan module RME (see Table 6-1). The earliest planning document for estuary RME—*Lower Columbia River Estuary Plan, Aquatic Ecosystem Monitoring Strategy for the Lower Columbia River and Information Management Strategy* (Lower Columbia River Estuary Partnership 1998)—outlined a general monitoring strategy that addressed coordination and oversight, data management and quality assurance, conventional and toxic contaminants, habitat, exotic species, and primary production. This document continues to be germane today. More recently, NMFS produced a document for recovery plans called *Guidance for Monitoring Recovery of Pacific Northwest Salmon and Steelhead Listed under the Federal Endangered Species Act* (Crawford and Rumsey 2010). This chapter is consistent with the guidance provided in that document, especially regarding the monitoring framework and adaptive management approach.

RME Framework

The main elements of estuary RME are status and trends monitoring, action effectiveness research, critical uncertainties research, and implementation and compliance monitoring. These elements inform an adaptive management approach that includes synthesis, reporting, and evaluation of monitoring data and use of results to modify management actions and monitoring programs. The main elements of the estuary RME are described below.

Status and Trends Monitoring

The overall objective of status and trends monitoring in the estuary is to determine the status of ESA-listed salmonids, determine environmental conditions that are ecologically significant to listed species, and track how the status changes over time. The results of status and trends monitoring should provide information on ambient environmental conditions and insight into the cumulative effects of existing and new management actions and anthropogenic impacts as they occur.

TABLE 6-1
Monitoring Plans Applicable to Estuary RME

Title	Lead Agency(s)	Description	Application
Guidance for Monitoring Recovery of Pacific Northwest Salmon and Steelhead Listed under the Federal Endangered Species Act (Crawford and Rumsey 2010)	NMFS	This document provides general guidance for monitoring and evaluation within an adaptive management framework for recovery plans for ESA-listed salmonids in the Pacific Northwest.	Estuary recovery plan module RME used the monitoring elements and adaptive management approach espoused in this work.
Lower Columbia River Estuary Plan, Volume 2: Aquatic Ecosystem Monitoring Strategy (Lower Columbia River Estuary Partnership 1998)	Estuary Partnership	The *Monitoring Strategy* makes specific recommendations for monitoring oversight, data management, and monitoring and research on pollutants, toxics, habitat, exotic species, and primary production.	Many of the recommendations in this strategy pertain to the management actions in the estuary recovery plan module and, thus, were inherently applied to module RME.
Columbia River Basin Research Plan (Northwest Power and Conservation Council 2006a)	NPCC	This plan identifies key uncertainties that, if resolved, would support actions to conserve and recover fish and wildlife populations addressed in the BPA/NPCC's Fish and Wildlife Program. There are three uncertainties listed for the estuary, one of the plan's focal areas.	Research called for in this plan informs many of the management actions in the estuary recovery plan module.
Research, Monitoring, and Evaluation for the Federal Columbia River Estuary Program (Johnson et al. 2008)	BPA/ NMFS/ NPCC/USACE	This plan for RME in the tidally influenced area, from Bonneville Dam to the ocean, including the plume, has specific goals and objectives, a conceptual ecosystem model, monitored indicators, method and protocols, and an action plan. This is a working document that is periodically updated based on new knowledge and program maturation.	Estuary recovery plan module RME relied on applicable content in this plan.
Guidance for Developing Monitoring and Evaluation as a Program Element of the Fish and Wildlife Program (Northwest Power and Conservation Council 2006b)	NPCC	This report concerns monitoring and evaluation for the Fish and Wildlife Program. It develops monitoring and evaluation guidance at two levels: Council policy-makers and project implementers. The Council's Fish and Wildlife Program was last approved in 2009.	The guidance in this report, although general, is basic to monitoring and evaluation planning and was applied as appropriate in estuary recovery plan module RME.
Lower Columbia Salmon Recovery and Fish and Wildlife Subbasin Plan (Lower Columbia Fish Recovery Board 2010)	LCFRB	The plan includes an extensive section on monitoring and research designed to evaluate biological status of listed salmon and steelhead, tributary habitat status, implementation compliance, and action effectiveness.	Applicability to estuary recovery plan module RME is limited because the material focuses on tributary watersheds of the lower Col. R. and estuary.
Lower Columbia River Conservation and Recovery Plan for Oregon Populations of Salmon and Steelhead (ODFW 2010)	ODFW	This plan includes an extensive section on monitoring and research designed to evaluate biological status of listed salmon and steelhead, status of tributary habitat and other limiting factors, implementation compliance, and action effectiveness.	Applicability to estuary recovery plan module RME is limited because the material focuses on tributary watersheds of the lower Col. R. and estuary
FCRPS 2008 Biological Opinion and 2010 Supplemental Biological Opinion (NMFS 2008 and NMFS 2010)	NMFS	The Reasonable and Prudent Alternative in the 2008 BiOp includes estuary RME actions and subactions. These were incorporated by reference into the 2010 Supplemental BiOp.	There is some overlap between the management actions in the estuary recovery plan module and the RPAs in the Biological Opinions. As appropriate, RME from the Biological Opinions was incorporated into estuary recovery plan module RME.

Title	Lead Agency(s)	Description	Application
Supplement to the Mainstem Lower Columbia River and Estuary Subbasin Plan (Lower Columbia River Estuary Partnership 2004b)	Estuary Partnership	This supplement clarifies and provides additional details about the key elements in the subbasin plan for the estuary. It does not, however, explicitly develop an RME plan.	The supplement supports estuary RME, although specific recommendations are not provided.
Upper Columbia Monitoring and Evaluation Plan (Upper Columbia Technical Recovery Team 2007)	Upper Columbia Technical Recovery Team	This working draft provides a comprehensive plan for tributary RME. Many of the monitoring concepts are consistent with those used in the estuary.	Estuary recovery plan module RME used the monitoring guidance categories in this plan.

The U.S. Environmental Protection Agency (2000) developed 15 guidelines for developing environmental indicators that provide this type of information, including the following:

- Relevance to the assessment. Monitored indicators should be responsive to an identified question and provide information useful for management decisions.
- Linkage to management action. An indicator is useful only if it can provide adequate information to support management decisions or quantify the success of past decisions.
- Temporal variability across years. Although an indicator may show inter-annual variability, the indicator should reflect true trends in environmental conditions for the assessment question. To determine variability across years, monitoring must proceed for several years at relatively stable sites. Having a long time series of data is particularly important in the estuary, where the benefits of habitat restoration could be masked by salmonid population changes that are due to variable ocean conditions.

Examples of indicators include direct measurements (such as nutrient concentrations), indices, and multimetrics (fish assemblage, for example) (U.S. Environmental Protection Agency 2000).

There are two major objectives for status and trends monitoring in the estuary: (1) assess habitat conditions and limiting factors and threats as described in the estuary recovery plan module and (2) assess juvenile salmonid performance in the estuary. Johnson et al. (2008) list the following status and trends objectives for the estuary:

1. Status and Trends Monitoring (STM): Habitat Conditions – Determine the status and trends of monitored indicators for estuary/ocean conditions that are ecologically significant to listed salmonids in the lower river, estuary, plume, and nearshore ocean.

    STM 1. Map bathymetry and topography of the estuary as needed for RME.

STM 2. Establish a hierarchical habitat classification system based on hydrogeomorphology, ground-truth it with vegetation cover monitoring data, and map existing habitats.

STM 3. Develop an index of habitat connectivity and apply it to each of the eight reaches of the study area.

STM 4. Monitor habitat conditions periodically, including water surface elevation, vegetation cover, plant community structure, substrate characteristics, dissolved oxygen, temperature, conductivity, and primary and secondary production at representative locations in the estuary and plume.

2. Status and Trends Monitoring: Juvenile Salmonid Performance – Determine the status and trends of monitored indicators for juvenile salmonid performance in the estuary and plume.

   STM 5. Evaluate migration characteristics, including juvenile salmonid abundance, residence times, growth rates, diets, and prey resources at representative locations in the estuary and plume to understand habitat usage and relative ecological importance of various habitats to juvenile salmonids.

   STM 6. Monitor and evaluate juvenile salmonid survival from Bonneville Dam through the estuary into the plume.

   STM 7. Develop an index and monitor and evaluate life history diversity of juvenile salmonid populations at representative locations in the estuary.

   STM 8. Monitor and evaluate temporal and spatial species composition, abundance, and foraging rates of juvenile salmonid predators at representative locations in the estuary and plume.

Johnson et al. (2008) also provide guidance on potential indicators that can be monitored to provide information relevant to these objectives. Additional information about status and trends monitoring objectives can be found in the *Research, Monitoring, and Evaluation for the Federal Columbia River Estuary Program* (Johnson et al. 2008).

Action Effectiveness Research

The overall objective of action effectiveness research in the estuary is to provide information about the effects of management actions. Using a representative set of management actions, such as specific types of habitat restoration, researchers monitor a suite of variables to evaluate the effects of individual actions on juvenile salmon and their estuarine habitats and provide feedback on potential methods for improving techniques, locations, or other aspects of the action. Action effectiveness research usually involves project-scale monitoring of site-specific conditions to determine whether implemented actions were effective in creating the desired change and whether project- or program-specific performance goals were met. This type of monitoring also can include long-term post-project implementation monitoring to see whether the actions continue to function as they were designed or intended. In some cases the information needed for action effectiveness monitoring may be provided by status and trends monitoring, but action effectiveness research generally requires focused evaluations of more specific parameters directly associated with actions.

The intent of action effectiveness research (AER) is to use quantitative studies to demonstrate how habitat restoration actions affect factors controlling ecosystem structures and processes at site and landscape scales and produce changes in juvenile salmonid performance. The following sub-objectives are from Johnson et al. (2008):

Using a representative set of projects, monitor and evaluate the effects of habitat restoration actions in the estuary, as follows:

> AER 1. Develop a limited number of reference sites for typical habitats, e.g., tidal swamp, marsh, island, and tributary delta, to use in action effectiveness evaluations.
>
> AER 2. Evaluate the effects of selected individual habitat restoration actions at project sites relative to reference sites and evaluate post-restoration trajectories based on project-specific goals and objectives. ("Effectiveness Monitoring")
>
> AER 3. Develop and implement a methodology to estimate the cumulative effects of habitat conservation and restoration projects in terms of cause-and-effect relationships between ecosystem controlling factors, structures, and processes affecting salmon habitats and performance. ("Validation Monitoring")

Critical Uncertainties Research

The overall objective of critical uncertainties research in the estuary is to investigate uncertainties in the state-of-the-science that are pivotal to understanding fish performance within the estuary. Uncertainties include cause-and-effect relationships among fish, limiting factors, threats, and activities meant to protect or enhance fish performance. The following three critical uncertainties were identified as particularly relevant to this module:

- Extent of density dependence mortality in the estuary and the role of large releases of hatchery fish in density dependence
- Effects of climate cycles and global warming on salmonid performance in the estuary
- The amount of increased juvenile survival in the estuary that could reasonably be expected if all 23 management actions in the module were implemented, and the proportion of that increased survival that could be attributed to each action

Critical uncertainties were also identified in Johnson et al. (2008). The following sub-objectives pertain to critical uncertainties research (CUR):

> CUR 1. Continue work to define the ecological importance of the tidal freshwater, estuary, plume and nearshore ocean environments to the viability and recovery of listed salmonid populations in the Columbia Basin.
>
> CUR 2. Continue work to define the causal mechanisms and migration/behavior characteristics affecting survival of juvenile salmon during their first weeks in the ocean.
>
> CUR 3. Investigate the importance of the early life history of salmon populations in tidal freshwater of the lower Columbia River.

CUR 4. Investigate the effects of hatchery fish on wild (naturally produced) fish in the estuary.

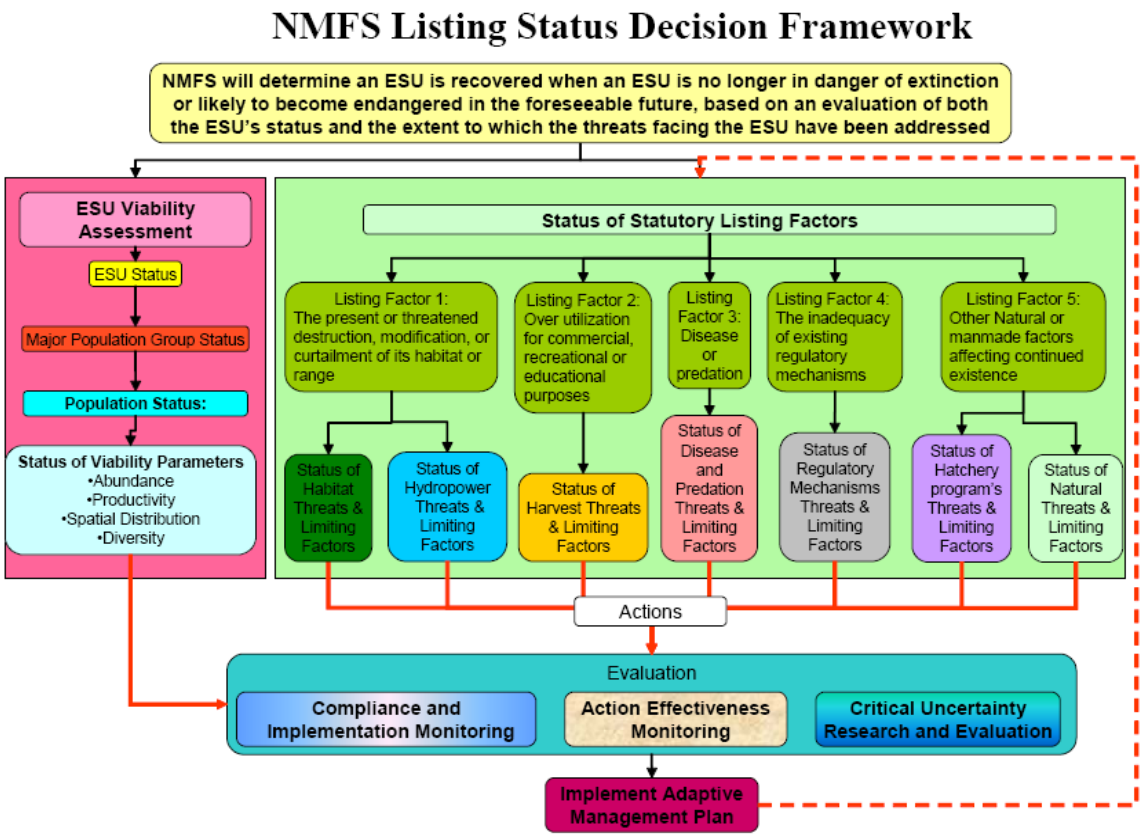
CUR 5. Understand the wetting and drying of the floodplain habitats caused by complex hydrodynamic interactions of tides, mainstem and tributary flows, and the effect of the FCRPS on river conditions.

By testing assumptions related to these and other critical uncertainties, recovery program planners, implementers, and managers can refine the foundation, implementation, and effectiveness of the management actions described in Chapter 5 to incorporate the best available science as it becomes accessible.

Implementation and Compliance Monitoring

The overall objective of implementation and compliance monitoring is to determine whether projects that address management actions are being implemented correctly, in sufficient quantities, and according to schedule. This monitoring is important for evaluating whether recovery programs are meeting objectives and performance measures, such as the number of estuary habitat acres conserved or restored annually. Objectives and performance measures for implementation and compliance monitoring are specific to the programs they evaluate; thus, in this case, performance measures and the resulting implementation monitoring would need to reflect targets derived from the 23 management actions in Chapter 5. Johnson et al. (2008) identified the following implementation and compliance monitoring (ICM) objectives:

ICM 1. Determine whether restoration projects were carried out as planned, i.e., whether specified project criteria were met ("Implementation Monitoring").



ICM 2. Total the amount of estuary habitat conserved and restored annually by habitat type.

Adaptive Management Approach

Estuary recovery plan module RME will employ an adaptive management approach. Adaptive management is the process of adjusting management actions based on new information. Management actions must be taken in an adaptive, experimental manner because ecosystems are inherently variable and highly complex (Independent Scientific Review Panel 2007). The process works by coupling decision making with the collection and evaluation of performance data and offering an explicit process through which alternative strategies to achieve the same ends can be proposed, prioritized, and implemented when necessary (Crawford and Rumsey 2010).

Figure 6-1 shows the role of RME and adaptive management in NMFS decisions regarding listing salmonids under the Endangered Species Act. The estuary recovery plan module addresses limiting factors and threats, which led to the management actions listed in Chapter 5. The RME described in this chapter will result in new information for use in evaluating the status of statutory listing factors and limiting factors and adjusting management actions as needed.

FIGURE 6-1
NMFS Listing Status Decision Framework (Crawford and Rumsey 2010)

The adaptive management approach in the estuary recovery plan module is intended to achieve effective management actions in the Columbia River estuary ecosystem. For the estuary recovery plan module, adaptive management entails the following:

- Management actions
- Research, monitoring, and evaluation actions
- Coordination and implementation
- Data and information management
- Synthesis, reporting, and evaluation
- Decisions

Estuary-scale adaptive management will benefit from adaptive management planning by individual organizations (such as the Lower Columbia River Estuary Partnership and the U.S. Army Corps of Engineers) for their habitat restoration projects and programs (see Thom et al. 2007).

Coordination

Coordination is critical in implementing RME for the Columbia River estuary, where multiple entities collect data for numerous individual projects with various objectives and potentially different monitoring protocols. Successful implementation and

evaluation of estuary recovery plan module RME will require that ongoing and future RME efforts be coordinated and carried out within an adaptive management framework. An estuary RME information-sharing forum should be established that includes technical representatives of Federal, state, and local government agencies; the Lower Columbia River Estuary Partnership; and other entities involved in research, monitoring, and implementation of recovery actions. This forum would be a valuable mechanism for fulfilling the coordination need and would complement corresponding groups of policy representatives responsible for implementation.

Data and Information Management

Data and other information pertinent to estuary RME are collected by many parties for a wide variety of applications. Data analysis and management are performed at a project and sometimes agency level, but not often at the estuary-wide level. It is neither desirable nor feasible to centrally manage or analyze all data within the Columbia River estuary. However, data should be managed so that synthesis and evaluation occurs through a coordinated, communal information network that includes the following elements:[3]

- Incorporation of data produced by existing programs and information systems to avoid duplication of effort.
- Integration with other basinwide and regional RME groups, including the Pacific Northwest Aquatic Monitoring Partnership.
- Regular written project-level reporting by RME partners within a coordinated system for peer review of project plans and reports.
- Periodic estuary RME workshops to present new data, discuss findings, and exchange information on future plans.
- A system for tracking implementation of RME projects throughout the estuary.
- Establishment of a central, Web-accessible repository and library for estuary data and references.
- Guidelines for metadata standards to facilitate data exchange and application.
- Centrally facilitated program-level review for comprehensive synthesis and evaluation of pertinent information relative to the goals and objectives of this plan.
- Periodic program-level summary reports.
- Communication and information exchange with other West Coast estuary and adaptive management programs, such as the Puget Sound Partnership.
- Consistent participation and funding commitments by partners.

A data management program for the estuary should build on existing efforts, such as the Lower Columbia River Estuary Partnership's monitoring and data management activities. The Estuary Partnership's science work group (and board of directors)

[3] Adapted from Johnson et al. (2008) and Lower Columbia River Estuary Partnership (2004a).

includes technical representatives of Federal, state, and local government agencies and other entities involved in restoration, monitoring, and implementation of recovery programs. This work group complements corresponding groups of policy representatives.

Synthesis, Reporting, and Evaluation

The information from status and trends monitoring, action effectiveness research, critical uncertainties research, and implementation and compliance monitoring should be synthesized and integrated in periodic reports for decision makers and other interested parties. The intent is to "roll up" project-specific data into program-level information. Annual reporting at the project level should be a key mechanism for data dissemination; biennial reporting at the program level should be key to disseminating results of evaluations. The estuary RME information-sharing forum described above could guide the synthesis and roll-up in the biennial report. In an adaptive management process, program evaluation includes adjusting program objectives and methodologies based on new information. As Noon (2003) stated, monitoring programs "must be constantly revisited and revised as scientific knowledge is acquired." Procedures should be established that link decision makers to estuary RME monitoring overseers and data managers. To conclude, Johnson et al. (2008) recommended the following synthesis and evaluation activities:

> SE 1. Upload, compile, manage, and disseminate project-level data at the Estuary Program level.
>
> SE 2. Synthesize the data and periodically report it to the region.
>
> SE 3. Use the synthesized data to evaluate the Estuary Program and refine the estuary RME effort as necessary.

Existing Programs and Projects and Additional Monitoring Needs

Activities conducted as part of the ERME program (Johnson et al. 2008) and other efforts do not fully address all of the monitoring needs associated with the 23 management actions identified in the module. The following sections describe (1) existing monitoring programs and projects and their applicability to the 23 management actions identified in the module; (2) gaps between existing monitoring efforts and needed monitoring for the management actions; (3) additional monitoring activities to fill those gaps and ensure monitoring to support all of the 23 management actions; (4) recommended indicators and protocols; and (5) estimated costs of estuary module RME.

Existing Programs and Projects

Estuary recovery plan module RME will take advantage of ongoing monitoring programs and the projects implemented within them wherever possible to avoid duplication of effort. At least 21 ongoing programs include projects that address aspects of research and monitoring in the estuary (see Table 6-2). The largest RME programs are the Columbia Basin Fish and Wildlife Program, which is funded by Bonneville Power Administration via the Northwest Power and Conservation Council, and the

Anadromous Fish Evaluation Program, which is funded by the U.S. Army Corps of Engineers. These two programs address estuary RME explicitly. The other programs exist for purposes other than estuary RME, but are applicable in a limited fashion.

The research and monitoring effort in the estuary includes at least 42 projects (see Table 6-3). This project list was derived from data in Johnson et al. (2008), the Estuary Partnership's RME inventory (conducted by K. Jones), and the Pacific Northwest Aquatic Monitoring Partnership's RME Project Inventory (database provided by M. Banach, Pacific States Marine Fisheries Commission). The projects include status and trends monitoring, action effectiveness research, and critical uncertainties research.

RME Needs, Existing Project Coverage, and Recommended Projects

Table 6-4 identifies monitoring needs for each of the 23 management actions in the estuary recovery plan module (see Tables 5-2 and 5-6), lists existing projects and programs that help address the needs, and identifies gaps. Table 6-5 identifies potential new projects to fill the RME gaps identified in Table 6-4. In addition, all of the management actions will require implementation and compliance monitoring.

Monitoring Recommendations

Table 6-6 provides recommendations specific to each need identified in Table 6-4. Recommendations include sampling design, spatial and temporal scale, measured variables, measurement protocols, derived variables, analysis, possible funding entities, and potential entities for implementation and coordination. Many of the measured variables and measurement protocols were obtained from Johnson et al. (2008). Specific monitoring methods will developed on a project basis. Habitat restoration monitoring protocols for the Columbia River estuary have been developed and disseminated in Roegner et al. (2009) (Table 6-3, Project J15). Mention of possible funding entities in Table 6-6 does not imply a funding commitment of any kind.

Estimated Costs

Table 6-7 presents estimates of costs and implementation schedules for estuary recovery plan module RME. These cost estimates were developed by Gary Johnson of Pacific Northwest National Laboratories, Catherine Corbett of the Lower Columbia River Estuary Partnership, and Phil Trask of PC Trask & Associates, Inc., by researching existing programs and estimates. The costs identified in this section do not represent a detailed economic analysis; in fact, they are not economic costs, in that they have not been discounted across time. Instead, the cost estimates are in constant dollars over a 25-year period. As mentioned previously, some module actions included specific RME projects and associated cost estimates (see Table 5-6). In those cases, Table 5-6 is referenced. Other costs in Table 6-7 ($64.1 million) were estimated by evaluating the monitoring needs in Table 6-6. The total cost of the RME projects identified in the estuary recovery plan module is $85.1 million.

Summary

Monitoring, research, and evaluation elements identified in *Guidance for Monitoring Recovery of Pacific Northwest Salmon and Steelhead Listed under the Federal Endangered*

Species Act (Crawford and Rumsey 2010) and *Research, Monitoring, and Evaluation for the Federal Columbia River Estuary Program* (Johnson et al. 2008) provide a consistent methodology that supports the RME detailed in this chapter for the estuary recovery plan module. As management actions identified in the module are implemented, it will be important that monitoring and research data are returned to the managers of the recovery effort to determine whether the management actions in the estuary recovery plan module are achieving the desired results.

TABLE 6-2
Ongoing Monitoring Programs Applicable to Estuary RME (as of July 2009). *The program "ID" number was invented for the purpose of this module to provide linkages to Table 6-3.*

ID	Program	Lead Entity	Description	More Information
P1	National Stream Quality Accounting Network (reported in National Streamflow Information Program)	USGS (and OHSU)	Monitoring at Beaver Terminal (RM54); includes water quality and discharge measurements. Water quality components enhanced by OHSU collaboration since summer 2009.	NASQAN: http://water.usgs.gov/nasqan/ Water quality (as of summer 2009): http://columbia.loboviz.com/loboviz/ Columbia River Factsheet: http://water.usgs.gov/ nasqan/progdocs/factsheets/ clmbfact/clmbfact.html
P2	National Water-Quality Assessment Program	USGS	Routine water quality monitoring nationwide; it includes the Willamette basin, but not the estuary.	NAWQA: http://water.usgs. gov/nawqa/ Willamette page: http://or.water.usgs.gov/ projs_dir/pn366/ nawqa.html
P3	Columbia Basin Fish and Wildlife Program	BPA/ NPCC	Contains a measure addressing the question, "Is the Columbia River estuary improving or deteriorating relative to desired conditions?" BPA/NPCC implements estuary RME projects here.	http://www. nwcouncil.org/ library/2000/
P4	Columbia River Channel Improvements Project	USACE	Monitoring occurs as required for ESA concerns.	https://www.nwp. usace.army.mil/ issues/crcip/
P5	Mouth of the Columbia River Project	USACE/ Ports	Monitoring occurs as required for ESA concerns.	https://www.nwp. usace.army.mil/op/n/ projects/
P6	Anadromous Fish Evaluation Program (AFEP)	USACE	Implements the Columbia River Fish Mitigation Project designed to improve survival through the hydrosystem. The USACE does estuary research in AFEP.	https://www.nwd. usace.army.mil/ps/
P7	NOAA General Funds Program	NOAA	Provides funds for specific estuary/ocean research projects by NOAA.	Unknown
P8	Oregon Dept. of Environmental Quality/106/General Funds	ODEQ	Focus is on Willamette, including its confluence with the Columbia River.	http://www.deq.state. or.us/lab/ wqm/watershed.htm
P9	Total Dissolved Gas Monitoring Program	USACE/ USGS	Routine monitoring.	USGS: http://or.water.usgs.gov/ projs_dir/pn307.tdg/ USACE: http:// 137.161.202.92/TMT/ WQ/2001/ MonitorPlan/ tdgmgt01.pdf
P10	Washington Dept. of Ecology Ambient Monitoring Program	WDE	Usually includes at least one mainstem site, in addition to tributary water quality monitoring.	Monitoring Home: http://www.ecy.wa.gov/ programs/eap/ fw_riv/rv_main.html

ID	Program	Lead Entity	Description	More Information
P11	Water Resources Development Act – Ecosystem Restoration Programs	USACE	USACE conducts monitoring of specific restoration actions conducted under these authorities; monitoring maximum cost is 3% total project cost.	https://www.nwp. usace.army.mil/pm/lcr/
P12	Lower Columbia River Ecosystem Restoration General Investigations Feasibility Study (GI Study)	USACE	The purpose of the GI Study is to "investigate and recommend appropriate solutions to accomplish ecosystem restoration in the lower Columbia River and estuary, including wetland/riparian habitat restoration, stream and fisheries improvement, water quality, and water-related infrastructure improvements."	https://www.nwp.usace.army.mil/ pm/cr/envres.asp
P13	Portland Harbor Superfund Assessment Program	EPA	Implements cleanup at the Superfund site in Portland harbor.	EPA: http://yosemite.epa.gov/R10/ CLEANUP.NSF/sites/ ptldharbor
P14	Estuary Partnership Ecosystem, Action Effectiveness and Pile Structure Monitoring Programs	Estuary Partnership	Implements an Ecosystem Condition Status and Trends Monitoring Strategy, Restoration Actions Effectiveness Research and Pile Structure Modification action effectiveness research and critical uncertainties. Funding by BPA/NPCC, EPA, NOAA, and others.	http://www.lcrep.org
P15	NOAA Tides and Currents	NOAA	Geodetic monitoring	http://tidesandcurrents.noaa.gov/
P16	Surface Water Data Collection Program	USGS	Water quality monitoring (at Beaver Terminal combined with OHSU as of summer 2009)	http://columbia.loboviz.com/loboviz/
P17	Volunteer Water Quality Monitoring Program	Will. River Keeper	Volunteer water quality monitoring	
P18	Zebra Mussel Monitoring Program	Portland State Univ.	Monitoring of zebra mussels, an invasive species	Contact: Steven Wells
P19	National Fish and Wildlife Foundation, Columbia River Estuarine Coastal Fund	National Fish and Wildlife Foundation (NFWF)	The Columbia River Estuarine Coastal Fund was established in 2004 to receive community service payments ordered by court settlements resulting from violations of Federal pollution laws.	http://www.nfwf.org/
P20	Ship-wake program	Port of Vancouver/NOAA	Spatial analysis of beach susceptibility for stranding of juvenile salmonids by ship wakes	
P21	(Untitled)	City of Portland	Monitoring of project effectiveness, fish and wildlife, water quality, and stormwater within Portland's waterways, including the lower Willamette River. The City is in the process of revising its monitoring approach, modeling the design on EPA's Environmental Monitoring and Assessment Program.	http://www.portlandonline.com/bes/ Kaitlin.Lovell@bes.ci.portland.or.us

TABLE 6-3
Ongoing Projects Addressing Estuary RME (as of July 2009)
The project "ID" number (e.g., J4) was invented for the purpose of this module to provide linkages to Table 6-4. Project numbers (e.g., 2000-012-00) are specific to the respective program. Program numbers (e.g., P3) correspond to the program ID numbers in Table 6-2.

TABLE 6-4
Management Actions, Associated Monitoring Needs, and Existing Coverage
Existing projects with "J" prefixes refer to projects listed in Table 6-3.

Management Action	Type	Monitoring Need	Existing Projects and Gaps
CRE-1: Protect intact riparian areas in the estuary and restore riparian areas that are degraded.	STM	Periodic mapping and areal measurement of riparian habitats and their condition using aerial photography to inform prioritization efforts	J5 and J21, although the projects do not do this at this time, but eventually could.
CRE-2: Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.	STM	Water temperature monitoring in the estuary to establish baseline	J1, J2, J28
	AER	Monitoring during the hydrosystem temperature experiment	At dams, the US Army Corps of Engineers (USACE) monitors water temperature; revive hydrodynamic modeling
	UR	Reservoir heating study and downstream effects	No existing projects.
CRE-3: Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.	STM	Continuous monitoring of Col. River discharge at Beaver Terminal in the estuary	J3 USGS National Streamflow Information Program
CRE-4: Adjust the timing, magnitude and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.	STM/ AER	Continuous monitoring of Col. River discharge at Beaver Terminal in the estuary and at Bonneville dam Plume turbidity monitoring using remote sensing	J3 USGS National Streamflow Information Program; J36 NOAA Tides and Currents
	UR	Flood, habitat, and constraints study(s)	No existing projects; revive modeling, e.g., Jay and Kukulka 2003
CRE-5: Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.	UR	Effects of reservoir sediment entrapment	No existing projects; the USACE measured sediment entrapment previously.
CRE-6: Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.	UR	Evaluate the long-term trajectory of beneficial use of shallow- water habitat creation sites	No existing projects; the USACE applies dredged material for beneficial uses when possible
CRE-7: Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.	UR	Dredge technique and operations study	No existing projects; the USACE studied crab entrainment previously (Pearson et al. 2006).
CRE-8: Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.	STM	Periodic mapping and length and density measurements of pile structures using the Estuary Partnership's estuary GIS system	J29, J21
	AER	Monitor physical and biological effects of pile removal	J29, J21
	UR	Study fundamental physical and biological characteristics to understand where removal or modification would be advantageous	No existing projects.

Management Action	Type	Monitoring Need	Existing Projects and Gaps
CRE-9: Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.	STM	Periodic mapping and areal measurement of off-channel habitat types to inform prioritization and monitoring efforts	J5 and J21
CRE-10: Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.	STM	Periodic mapping and length measurements of dike structures using the Estuary Partnership's estuary GIS system.	J21 GIS map of dikes and tide gates
	AER	Effectiveness monitoring studies of tidal reconnections	J30 JBH study, J15 Cumulative effects, J20 Young's Bay
	UR	Ecological importance of tidal reconnections	J15 Cumulative effects J17 Habitat linkages
CRE-11: Reduce the square footage of over-water structures in the estuary.	STM	Periodic mapping and areal measurements of over-water structures using the Estuary Partnership's estuary GIS system. Track permits for construction of shoreline structures	J21 GIS map of over-water structures – needs to be expanded to areal extent, not just linear extent
	UR	Study fundamental physical and biological characteristics to understand where removal would be advantageous	No existing projects in the estuary.
CRE-12: Reduce the effects of vessel wake stranding in the estuary.	STM	Total stranding estimate for entire estuary	No existing projects.
	UR	Factors and stranding reduction study	J31 Before/after CRCIP addresses factors
CRE-13: Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.	STM	Monitor trends in predator abundance	J38
CRE-14: Identify and implement actions to reduce salmonid predation by pinnipeds.	STM	Pinniped predation monitoring	J32
	AER	Effectiveness of actions. Monitor actions under Section 120 of the Marine Mammal Protection Act	J32, J33 Section 120 monitoring
	UR	Magnitude of pinniped impact in the estuary	J32 (at BON) - expand to include magnitude of impact throughout estuary
CRE-15: Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.	STM	Inventory and map invasive plants	No existing projects; revive Sytsma et al. 2004
	AER	Effectiveness monitoring	Wahkiakum. Community Foundation Columbia Estuary Environmental Education Program (LCEEEP) identification and treatment of invasive weeds on Julia Butler Hansen Wildlife Refuge
CRE-16: Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.	STM	Tern monitoring	J25, J34 Tern monitoring
	AER	Effectiveness of habitat shift	J25, J34 Tern management
CRE-17: Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.	STM	Cormorant monitoring	J35
	AER	Methods to reduce cormorant abundance	J35 Cormorant management

Management Action	Type	Monitoring Need	Existing Projects and Gaps
CRE-18: Reduce the abundance of shad in the estuary.	STM	Monitor passage of adult shad at Bonneville Dam	USACE Fish counting
	AER	Evaluate effectiveness of control methods	No existing projects.
	UR	Assess ecological effects of shad	J24 Shad impact study
CRE-19: Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations.	STM	Monitor trends in abundance, distribution, and species composition of invertebrate invasives	No existing projects; revive Sytsma et al. 2004
CRE-20: Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.	STM	WQ/toxics monitoring downstream of Bonneville Dam	No existing projects.
	AER	Pre- and post-project monitoring	No existing projects.
	UR	Source tracking; fish health; sublethal and lethal thresholds	No existing projects; J5; no existing projects.
CRE-21: Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.	STM	WQ/toxics monitoring	No existing projects; minimal WQ in J1, J2, J3, J5
	AER	Pre- and post-project monitoring	No existing projects.
	UR	Source tracking; fish health; sublethal and lethal threshold.	No existing projects; J5; none
CRE-22: Restore or mitigate contaminated sites.	STM	WQ/toxics monitoring	No existing projects; minimal WQ in J1, J2, J5
	AER	Pre- and post-project monitoring	No existing projects.
	UR	Source tracking; fish health; sublethal and lethal thresholds	No existing projects; J5; none
CRE-23: Implement stormwater best management practices in cities and towns.	STM	Stormwater monitoring	No existing projects; limited monitoring with NPDES permit requirements
	AER	Directed stormwater monitoring	No existing projects.
	UR	Source tracking; improve BMPs and regulations	No existing projects.

TABLE 6-5
Recommended New RME Projects or New Objectives in Existing Projects
These projects would fill gaps where "no existing projects" were noted in Table 6-4.

Action	Type	Project
CRE-2	UR	Water temperature monitoring and modeling for a reservoir heating study
CRE-4	UR	Flood, habitat, and constraints study(s) of the effects of "more normative" flows in the estuary
CRE-5	UR	Measurement of sediment entrapment in mainstem Columbia River reservoirs
CRE-6	UR	Demonstration study of beneficial use of dredged material to create shallow-water habitat
CRE-7	UR	Dredging technique and operations to minimize entrainment of juvenile salmonids
CRE-8	UR	Study fundamental physical and biological characteristics to understand where removal would be advantageous
CRE-11	UR	Assessment of impacts and benefits of removing over-water structures
CRE-12	STM	Total, estuary-wide stranding estimates by species of juvenile salmonid
CRE-15	STM	Routine monitoring of percent cover and distribution of invasive plants by species
CRE-18	AER	Effectiveness study of shad control methods
CRE-19	STM	Routine monitoring of percent cover and distribution of invasive aquatic invertebrates by species
CRE-20, 21, 22, 23	STM	Water quality, stormwater, and toxic contaminants monitoring below Bonneville Dam
CRE-20, 21, 22, 23	AER	Pre- and post-project implementation water quality, stormwater and toxic contaminants monitoring below Bonneville Dam
CRE-20, 21, 22, 23	UR	Determine sources, concentrations, timing, types, and pathways of water quality and toxic contaminant pollutants; sublethal and lethal thresholds in fish and food web

TABLE 6-6
Monitoring Guidance for Estuary Recovery Plan Module RME. Adapted from Appendix C, Johnson et al. (2008).

Mngt. Action	Monitoring Need[1]	Sampling Design	Spatial/ Temporal Scale	Measured Variables	Measurement Protocols	Derived Variables	Analysis	Possible Funding Entities	Possible Implementation & Coordination
CRE-1	Periodic mapping and areal measurement of riparian habitats and their condition	Complete census with ground-truthing	Estuary-wide every 5 years	Length of riparian habitat by type of habitat	GIS-linked aerial photography, Landsat imagery and videography (Evans et al. 2006)	Proportions for each riparian habitat type	Trend analysis	BPA/NPCC, USACE, NOAA	Estuary Partnership
CRE-2	Water temperature monitoring in the estuary to establish baseline	Stratified random sampling by reach	At representative sites throughout the estuary essentially continuously	Water temperature	Data loggers (Callaway et al. 2001)	Maximum daily/weekly maximum, seasonal averages	Trend analysis	BPA/NPCC, USGS	BPA/NPCC Fish and Wildlife Program
	Hydrosystem temperature experiment	Modeling	Estuary-wide	Water temperature	Hydrodynamic model	Maximum daily/weekly maximum, seasonal averages	Compare/ contrast	BPA/NPCC, EPA, USGS	Ibid.
	Reservoir heating study and downstream effects	Systematic sampling and modeling	At representative sites throughout the estuary essentially continuously	Water temperature	Data loggers (Callaway et al. 2001)	Maximum daily/weekly maximum, seasonal averages	Compare/ contrast	BPA/NPCC	Ibid.
CRE-3	Continuous monitoring of Columbia River discharge at Beaver Terminal in the estuary	Systematic sampling	Hourly sampling at Beaver Terminal	Stream discharge (cfs)	USGS gauging station	Annual maximum and minimum, seasonal averages	Trend analysis	USGS	USGS program

Mngt. Action	Monitoring Need[1]	Sampling Design	Spatial/ Temporal Scale	Measured Variables	Measurement Protocols	Derived Variables	Analysis	Possible Funding Entities	Possible Implementation & Coordination
CRE-4	Continuous monitoring of Columbia River discharge at Beaver Terminal in the estuary and at Bonneville Dam	Systematic sampling	Hourly sampling at Beaver Terminal and BON	Stream discharge (cfs)	USGS gauging station	Annual maximum and minimum, seasonal averages	Trend analysis	USGS, USACE	USGS program (See CRE-3); also USACE O&M program for mainstem dams
	Plume turbidity monitoring using remote sensing	Complete census with ground-truthing	Plume-wide every 5 years	Turbidity	GIS-linked aerial photography	Time series of turbidity maps	Trend analysis	BPA/NPCC, NOAA	BPA/NPCC Fish and Wildlife Program (See CRE-2)
	Flood, habitat, and constraints effects study(s)	Modeling effort	Estuary-wide	Inundation	Hydrodynamic model	Cumulative inundation curves	Compare/ contrast	BPA/NPCC, NOAA	USACE's AFEP
CRE-5	Effects of reservoir sediment entrapment	Complete census	All 13 main-stem Snake and Columbia dams every 5 years	Thickness of reservoir sediment	Acoustic bottom typing (multibeam sonar)	Sediment maps	Trend analysis	USACE	USACE's AFEP (See CRE-4)
CRE-6	Evaluation of beneficial use of dredged material – create shallow-water habitat	Before-after-control-impact (BACI)	Site-specific, 1 year before and 5 years after	Vegetation, bathymetry	Roegner et al. 2009, bathymetry	Percent cover, shallow-water habitat	Effectiveness evaluation	USACE	USACE's Sediment Management Program
CRE-7	Dredge technique and operations study	Focused field experiments	TBD	Crab entrainment	Pearson et al. 2006	Entrainment rates	Statistical analysis	USACE	USACE's Sediment Management Program (See CRE-6)
CRE-8	Periodic mapping and length and density measurements of pile structures	Complete census with ground-truthing	Estuary-wide every 5 years	Length of pile structure	GIS-linked videography (Evans et al. 2006)	Length and locations of pile structure	Trend analysis	BPA/NPCC, USACE, NOAA	Estuary Partnership (See CRE-1)
	Monitor physical and biological effects of pile removal	BACI	Site-specific, 1 year before and 3 years after	Water velocity, fish species composition and abundance	Data loggers (Callaway et al. 2001), fish by Roegner et al. 2009	Annual max and min velocity, fish species composition proportions	Effectiveness evaluation	USACE	Ibid.

Mngt. Action	Monitoring Need[1]	Sampling Design	Spatial/ Temporal Scale	Measured Variables	Measurement Protocols	Derived Variables	Analysis	Possible Funding Entities	Possible Implementation & Coordination
	Study fundamental physical and biological characteristics to understand where removal would be advantageous	Systematic sampling	Selected sites for all four seasons over 3 years	Ibid.	Ibid.	Ibid.	Ecological characterization	Ibid.	Ibid.
CRE-9	Periodic mapping and areal measurement of off-channel habitat types	Complete census with ground-truthing	Estuary-wide every 5 years	Length of riparian habitat by type of habitat	GIS-linked aerial photography	Amount of off-channel habitat	Trend analysis	BPA/NPCC, USACE, NOAA	Estuary Partnership (See CRE-1, 8)
CRE-10	Periodic mapping and length measurements of dike structures	Complete census with ground-truthing	Estuary-wide every 5 years	Length of dike/levee structures	GIS-linked aerial photography	Length of dike/levee structures	Trend analysis	BPA/NPCC, USACE, NOAA	Estuary Partnership (See CRE-1, 8, 9)
	Effectiveness monitoring studies of tidal reconnections	BACI	Site-specific, 1 year before and 5 years after	Hydrology, vegetation, fish	Roegner et al. 2009	Water surface elevation, percent cover, fish species comosition proportions	Statistical comparison	BPA/NPCC, USACE, NOAA	Estuary Partnership (See CRE-1, 8, 9), BPA/NPCC Fish and Wildlife Program (See CRE-2, 4), USACE's AFEP (See CRE-4,5)
	Ecological importance of tidal reconnections	BACI	Site-specific, 1 year before and 5 years after	Prey availability, fish diet, fish residence time, fish stock	Roegner et al. 2009	Diet composition charts	Ecological characterization	BPA/NPCC, USACE, NOAA	Ibid.
CRE-11	Periodic mapping and areal measurements of over-water structures	Complete census with ground-truthing	Estuary-wide every 5 years	Length of over-water structures	GIS-linked aerial photography and videography	Length of over-water structures	Trend analysis	BPA/NPCC, USACE, NOAA	Estuary Partnership (See CRE-1, 8, 9, 10)
	Track construction permits for shoreline structures	Census	Estuary-wide annually	No. and location of shoreline structures	Contact permitting agencies	Map of structures planned or under construction	Trend analysis	USACE	USACE Regulatory Program

Mngt. Action	Monitoring Need[1]	Sampling Design	Spatial/ Temporal Scale	Measured Variables	Measurement Protocols	Derived Variables	Analysis	Possible Funding Entities	Possible Implementation & Coordination
	Study fundamental physical and biological characteristics	Systematic sampling	Selected sites for all four seasons over 3 years	Water velocity, light, fish species composition and abundance	Data loggers (Callaway et al. 2001), fish by Roegner et al. 2009	Annual max and min velocity and light levels, fish species composition proportions	Ecological characterization	USACE, NOAA	Estuary Partnership (See CRE-1, 8, 9, 10), BPA/NPCC Fish and Wildlife Program (See CRE-2, 4, 10), USACE's AFEP (See CRE-4, 5, 10)
CRE-12	Total stranding estimate for entire estuary	Stratified random sampling by reach	Estuary-wide over all four seasons of 1 year	Number of juvenile salmonids stranded	Direct counts	Extrapolation to total no. stranded; map of stranding densities	Correlation analysis of factors associated with stranding	USACE	USACE's Channel Improvement Project

	Evaluate effectiveness of control methods	Site experiments	Selected sites	Ibid.	Seine, sonar	Number of shad by treatment	Statistical comparison	BPA/NPCC, USACE, NOAA	Ibid.
	Assess ecological effects of shad	Systematic sampling	Selected sites for summer over 3 years	Number of shad, diet, distribution, sex ratio	Various	Total population size, fecundity, etc.	Ecological characterization	BPA/NPCC	Ibid.

Mngt. Action	Monitoring Need[1]	Sampling Design	Spatial/ Temporal Scale	Measured Variables	Measurement Protocols	Derived Variables	Analysis	Possible Funding Entities	Possible Implementation & Coordination
CRE-19	Monitor trends in abundance, distribution, and species composition of invasive invertebrates	Stratified random sampling by reach	Estuary-wide every 5 years	Species composition, abundance, distribution	Site surveys (Sytsma et al. 2004)	Density distribution maps	Trend analysis	BPA/NPCC, USACE, NOAA	Estuary Partnership (See CRE-1, 8, 9, 10, 11, 15)
CRE-20, 21, 22, 23	Water quality and toxics monitoring downstream of BON	Stratified random sampling by reach, directed source and load tracking	Estuary-wide annual	Concentrations and loads of pollutants, contaminants by source and type	Various	Maps of distribution of pollutant concentration loads, pathways, and sources by type	Every 3 years - trend analysis; concentration loads, and yields by tributary and source	EPA, NOAA, USGS, ODEQ, WDOE	Estuary Partnership (See CRE-1, 8, 9, 10, 11, 15, 19)
	Fish health, sublethal and lethal thresholds	Focused experiments	Laboratory	Fish health/ mortality	Ibid.	Dose response curves	Statistical analysis	Ibid.	Ibid.

[1]Monitoring needs are those identified in Table 6-4.

TABLE 6-7
Estimated Cost and Schedule for Monitoring Needs (includes ongoing projects in some cases)

Management Action	Monitoring Need	Unit	Est. Cost	Schedule
CRE-1: Protect intact riparian areas in the estuary and restore riparian areas that are degraded.	Periodic mapping and areal measurement of riparian habitats and their condition using aerial photography to inform prioritization efforts	Every 5 years, base flyover for data acquisition @ $250K and analysis for riparian zones @ $200K	$1M base plus $800K riparian	2007-2022
CRE-2: Operate the hydrosystem to reduce the effects of reservoir surface heating, or conduct mitigation measures.	Water temperature monitoring in the estuary to establish baseline	Continuous monitoring at four sites (Bonneville Dam, Beaver, St. Helens, and Astoria) for 3 years @ $20K per year and one retrospective study of temperature	$60K (new data from Beaver, St. Helens) plus $50K study	2007-2009
	Monitoring during the hydrosystem temperature experiment	Continuous monitoring at four sites (Bonneville Dam, Beaver, St. Helens, and Astoria) for 5 years @ $20K per year	$100K	2010-2014
	Reservoir heating study and downstream effects	see Table 5-6	see Table 5-6	see Table 5-6
CRE-3: Protect and/or enhance estuary instream flows influenced by Columbia River tributary/mainstem water withdrawals and other water management actions in tributaries.	Continuous monitoring of Columbia River discharge at Beaver Terminal in the estuary	Data collection and dissemination are routine and ongoing.	$0 (already covered)	2007-2035
CRE-4: Adjust the timing, magnitude and frequency of hydrosystem flows (especially spring freshets) entering the estuary and plume to better reflect the natural hydrologic cycle, improve access to habitats, and provide better transport of coarse sediments and nutrients in the estuary and plume.	Continuous monitoring of Columbia River discharge at Beaver Terminal in the estuary and at BON dam	See CRE-3	$0 (already covered)	2007-2035
	Plume turbidity monitoring using remote sensing (satellite)	3 years @ $100K/year	$300K	2009-2011
	Flood, habitat, and constriant study(s)	see Table 5-6	see Table 5-6	see Table 5-6
CRE-5: Study and mitigate the effects of entrapment of fine sediment in reservoirs, to improve nourishment of the estuary and plume.	Effects of reservoir sediment entrapment	see Table 5-6	see Table 5-6	see Table 5-6
CRE-6: Reduce the export of sand and gravels via dredge operations by using dredged materials beneficially.	Evaluate the beneficial use of dredged material – create shallow-water habitat	see Table 5-6	see Table 5-6	see Table 5-6
CRE-7: Reduce entrainment and habitat effects resulting from main- and side-channel dredge activities and ship ballast intake in the estuary.	Dredge technique and operations study	see Table 5-6	see Table 5-6	see Table 5-6

Management Action	Monitoring Need	Unit	Est. Cost	Schedule
CRE-8: Remove or modify pilings and pile dikes when removal or modification would benefit juvenile salmonids and improve ecosystem health.	Periodic mapping and length and density measurements of pile structures using the Estuary Partnership's estuary GIS system	One assessment every 5 years @ $200K per assessment	$800K	2007-2022
	Monitor physical and biological effects of pile removal	see Table 5-6	see Table 5-6	see Table 5-6
	Study fundamental physical and biological characteristics to understand where removal would be advantageous	One study for 3 years @ $250K/year	$750K	2007-2009
CRE-9: Protect remaining high-quality off-channel habitat from degradation and restore degraded areas with high intrinsic potential for high-quality habitat.	Periodic mapping and areal measurement of off-channel habitat types to inform prioritization and monitoring efforts	See CRE-1 cost for base flyover, plus analysis of off-channel habitats every 5 years @ $200K per assessment	$800K	2007-2022
CRE-10: Breach, lower, or relocate dikes and levees to establish or improve access to off-channel habitats.	Periodic mapping and length measurements of dike structures using the Estuary Partnership's estuary GIS system.	See CRE-9; additional analysis @ $50K per assessment every 5 years	$200K	2007-2022
	Effectiveness monitoring studies of tidal reconnections	Two case studies each in Reaches A-E and one study each in Reaches F-H with samplings in Years 0, 1, 4, 7 @ $100K per sampling-year	$5.2M	2007-2035
	Ecological importance of tidal reconnections	Building on the data from the effectiveness monitoring, one study for 5 years @ $400K per year	$2M	2007-2011
CRE-11: Reduce the square footage of over-water structures in the estuary.	Periodic mapping and areal measurements of over-water structures using the Estuary Partnership's estuary GIS system.	Assessments every 5 years @ $250K per assessment	$1M	2007-2022
	Track permits for construction of shoreline structures	Annual compilation and reporting @ $60K per year	$1.5M	2007-2031
	Study fundamental physical and biological characteristics to understand where removal would be advantageous	One study for 3 years @ $250K/year	$750K	2008-2010
CRE-12: Reduce the effects of vessel wake stranding in the estuary.	Total stranding estimate for entire estuary	One study with sampling three seasons per year at eight sites for 2 years @ $1M per yr	$2M	2009-2010

Management Action	Monitoring Need	Unit	Est. Cost	Schedule
	Factors and stranding reduction study	see Table 5-6	see Table 5-6	see Table 5-6
CRE-13: Manage pikeminnow and other piscivorous fish, including introduced species, to reduce predation on salmonids.	Monitor trends in predator abundance	see Table 5-6	see Table 5-6	see Table 5-6
CRE-14: Identify and implement actions to reduce salmonid predation by pinnipeds.	Pinniped predation monitoring	One study estuary-wide for 5 years @ $250K per year	$2.5M	2008-2012
	Effectiveness of actions. Monitor actions under Sec. 120	Study every 5 years for 20 years @ $200K (see above)	$0 (already covered)	2013-2032
	Magnitude of pinniped impact in estuary	See pinniped predation monitoring above	$0 (already covered)	2008-2012
CRE-15: Implement education and monitoring projects and enforce existing laws to reduce the introduction and spread of invasive plants.	Inventory and map invasive plants	see Table 5-6	see Table 5-6	see Table 5-6
	Effectiveness monitoring	see Table 5-6	see Table 5-6	see Table 5-6
CRE-16: Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.	Tern monitoring	see Table 5-6	see Table 5-6	see Table 5-6
	Effectiveness of habitat shift	see Table 5-6	see Table 5-6	see Table 5-6
CRE-17: Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.	Cormorant monitoring	see Table 5-6	see Table 5-6	see Table 5-6
	Methods to reduce cormorant abundance	see Table 5-6	see Table 5-6	see Table 5-6
CRE-18: Reduce the abundance of shad in the estuary.	Monitor passage of adult shad at Bonneville Dam	Data collection and dissemination are routine and ongoing.	$0 (already covered as part of adult fish counts)	2007-2035
	Evaluate effectiveness of control methods	see Table 5-6	see Table 5-6	see Table 5-6
	Assess ecological effects of shad	One study for 3 years @ $300K per year	$900K	2008-2010
CRE-19: Prevent new introductions of aquatic invertebrates and reduce the effects of existing infestations.	Monitor trends in abundance, distribution, and species composition of invasive invertebrates	Recurring study every 3 years for 30 years @ $500K per year	$5M	2008-2037

Management Action	Monitoring Need	Unit	Est. Cost	Schedule
CRE-20: Implement pesticide and fertilizer best management practices to reduce estuarine and upstream sources of nutrients and toxic contaminants entering the estuary.	WQ/toxics monitoring downstream of Bonneville Dam	Annual ambient and directed sampling for 25 years @ $1M/year	$25M	2008-2032
	Pre- and post-project monitoring	Twice annual upstream + downstream sites @ $10K per project @ one project per year for 25 years	$250,000	2008-2032
	Source tracking, fish health, sublethal and lethal thresholds	One study for 5 years @ $500K; fish health @ 5-6 sites per year @ $250K for 25 years; one study for eight priority toxics @ $1.5M for 3 years	$8.25M	2008-2032
CRE-21: Identify and reduce terrestrially and marine-based industrial, commercial, and public sources of pollutants.	WQ/toxics monitoring	See CRE-20	See CRE-20	See CRE-20
	Pre- and post-project monitoring	Ibid.	Ibid.	Ibid.
	Source tracking, fish health, sublethal and lethal thresholds	Ibid.	Ibid.	Ibid.
CRE-22: Restore or mitigate contaminated sites.	WQ/toxics monitoring	See CRE-20	See CRE-20	See CRE-20
	Pre- and post-project monitoring	Ibid.	Ibid.	Ibid.
	Source tracking, fish health, sublethal and lethal thresholds	Ibid.	Ibid.	Ibid.
CRE-23: Implement stormwater best management practices in cities and towns.	Stormwater monitoring	see Table 5-6	see Table 5-6	see Table 5-6
	Directed stormwater monitoring	Twice annual @ 5 cities @ $24K per site for 25 years	$3M	2008-2032
	Source tracking, improve BMPs and regulations	1 study for 5 years @ $500K (see CRE-20); 1 study for 3 years @ $1.5M	$2M	2008-2013

CHAPTER 7

Perspectives on Implementation

Substantial investment is being made in the Columbia River basin to recover listed Chinook, coho, steelhead, and chum. How much of this investment should be made in the estuary? How much do the estuary and plume environments contribute to the survival of upstream ESUs, and is recovery of upstream ESUs possible without a healthier estuary ecosystem? If not, what does the information in Chapters 3, 4, and 5 tell us about which management actions to implement in the estuary?

Chapter 7 explores issues related to the selection of management actions to be implemented in the estuary and how those choices will shape future conditions for salmonids in the estuary and plume. It also suggests next steps in implementation and identifies implementation challenges.

Putting the Estuary in Context

This recovery plan module reflects current scientific understanding that the Columbia River estuary and plume provide habitat that wild salmonids need to complete their life cycles. Historically, juveniles from hundreds of distinct salmonid populations, at various life history stages, used the estuary for refuge and rearing as they prepared physiologically for life in the ocean. Over evolutionary time populations developed life history strategies in which juveniles from different populations staggered their use of the estuary throughout the year, exploiting estuarine habitats in different ways for different lengths of time. Although the estuary posed risks to juvenile salmonids, the diversity in life history strategies allowed salmon and steelhead to take maximum advantage of estuarine resources, which offered tremendous opportunities for refuge and growth. Unlike an upstream tributary, through the year the estuary provided habitat for all of the salmonid populations in the Columbia River basin during a critical stage in their life cycles.

Over the last 200 years the ability of the Columbia River estuary to meet the needs of salmon and steelhead has been seriously compromised. There is no question about the extent of changes in the estuary: the timing, magnitude, and duration of flows do not resemble those of historical flows, access to the estuary floodplain has been virtually eliminated, sediment transport processes that depend on flows and upstream sediment sources are radically different than they were historically, water quality has degraded as a result of contamination, temperatures are approaching and sometimes exceeding lethal limits, and there have been fundamental changes at the base of the estuarine food web, with associated alterations in inter- and intra-species relationships. A central premise of this recovery plan module is that although the estuary ecosystem is degraded, it can be improved, and that a healthier estuary ecosystem would contribute meaningfully to the basinwide recovery of ESA-listed salmonids.

Factors That Influence Decision Making

Decisions about implementation would be easy if protecting and restoring salmonids were the only consideration. However, as much as we value healthy native fish runs, as a society we also value a stable economy, financial opportunity for individuals and businesses, public safety, and property rights. These values will play into decisions about which management actions to implement, as will the three factors used to evaluate the management actions in Chapter 5: cost, constraints, and potential benefits to salmonids.

Also affecting choices about implementation is scientific uncertainty. Although fisheries science has matured over the last 100 years, how salmonids interact in complex ecosystems is not well understood; this is especially true in the estuary and plume. Yet we cannot wait until uncertainty has been eliminated before taking action. In the face of scientific uncertainty, then, decisions about implementing management actions will have to be made using the most current scientific information available, combined with best professional judgment. Historically, it has been a mix of science and policy choices that have guided decisions that affected the estuary; it is likely that these same forces will also determine the effectiveness of science-driven recovery efforts.

Significance of Constraints to Implementation

Not a single management action identified in Table 5-1 will be easy to implement. In one way or another, implementation of each of the 23 actions is constrained, in some cases greatly. Understanding the nature and magnitude of constraints to the implementation of management actions is important for several reasons. First, it grounds the actions in the real world and tempers expectations for results. Second, it provides insights into the level of effort that would be required for an action to have a sizable impact on salmonid populations. Third and most important, it reveals that every proposed action in this recovery plan module has significant obstacles to implementation.

Because it will be difficult to implement any single action fully and gain all of its potential benefit to salmonids, it will be important to implement a relatively large number of the proposed management actions. In other words, if each management action in the estuary has significant constraints, it may take partial implementation of all or most of the actions to improve the health of the estuary ecosystem to the point that the ecosystem provides the benefits that salmonids need to recover.

To illustrate the relative constraints of different actions, Table 7-1 presents management actions by degree of constraint to implementation, in descending order.

Table 7-1
Management Actions Sorted by Degree of Constraint

#	Action	Degree of Constraint
CRE-02	Operate the hydrosystem to reduce reservoir heating.	5
CRE-03	Protect/enhance instream flows influenced by water withdrawals and other water management actions in tributaries.	5
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows.	5
CRE-05	Mitigate entrapment of fine sediment in reservoirs.	5
CRE-18	Reduce shad abundance.	5
CRE-19	Prevent aquatic invertebrate introductions.	5
CRE-14	Reduce predation by pinnipeds.	4
CRE-15	Reduce invasive plants.	4
CRE-17	Redistribute cormorants.	4
CRE-21	Identify and reduce sources of pollutants.	4
CRE-20	Implement pesticide/fertilizer BMPs.	4
CRE-9	Protect/restore high-quality off-channel habitat	3
CRE-10	Breach, lower, or relocate dikes and levees.	3
CRE-12	Reduce vessel wake stranding.	3
CRE-22	Restore or mitigate contaminated sites.	3
CRE-11	Reduce over-water structures.	3
CRE-01	Protect/restore riparian areas.	3
CRE-06	Use dredged materials beneficially.	3
CRE-16	Redistribute Caspian terns.	2
CRE-07	Reduce entrainment/habitat effects of dredging and ballast.	2
CRE-13	Manage pikeminnow and other piscivorous fish.	2
CRE-23	Implement stormwater BMPs.	2
CRE-08	Remove or modify pilings and pile dikes	2

Another useful table when considering implementation constraints is Table 5-3, which shows the differences in potential benefit to salmonids if implementation of actions is unconstrained, versus constrained, which represents a more realistic scenario. However, although Table 5-3 demonstrates the size of the gap between unconstrained and constrained implementation of actions, it does not adequately characterize the magnitude of response that might be expected from constrained implementation. The next section of this document is intended to help show the potential benefit from constrained implementation of actions.

Management Actions Offering the Greatest Survival Benefits

If we were to increase our investment in restoration of the Columbia River estuary by an order of magnitude, what would the ecological return on that investment be? Our ability to answer that question is limited by a lack of understanding of how much mortality actually occurs in the estuary and plume. Still, we do have some information about potential gains that reasonably could be expected as a result of such investment.

Juvenile Survival Improvement. In Chapter 5, survival improvement targets were developed as a tool for comparing the potential benefits of implementing different management actions. This planning exercise used the best available information about estuary mortality for wild, ESA-listed stream- and ocean-type juveniles and then established a 20 percent survival improvement target for the 22 management actions that would affect the survival of juveniles. The survival improvement targets were then allocated across the various management actions to help characterize where survival gains might occur. The results are not intended to represent a deterministically based analysis; however, they do reflect information in the scientific literature, especially about mortality resulting from terns, cormorants, ship wake stranding, contaminants, and pinnipeds.

Tables 7-2 and 7-3 summarize the results of this planning exercise, sorting actions by their potential to improve survival of stream- and ocean-type juveniles, respectively, assuming that implementation of the actions is constrained. This ordering is simply an exercise to hypothesize where survival improvements equal to 20 percent of the number of juveniles exiting the estuary and plume might be expected for stream-type and ocean-type juveniles.

For stream-type salmonids, the following observations can be made from Table 7-2:

- Approximately 60 percent of the survival improvements are assigned to the top five actions, which include adjusting flow, protecting or restoring off-channel habitat, restoring or mitigating contaminated sites, and managing birds that prey on salmonids.
- Approximately 30 percent of the survival improvements are assigned to establishing or improving access to off-channel habitat, protecting and restoring riparian areas, reducing sources of pollutants, managing piscivorous fish, and removing or modifying pilings and pile dikes.
- Approximately 10 percent of the survival improvements are assigned across the remaining actions, with varying degrees of improvements.

For ocean-type salmonids, the following observations can be made from Table 7-3:

- Approximately 65 percent of the survival improvements are assigned to the top five actions, which include adjusting flows, establishing or improving access to off-channel habitat, protecting or restoring off-channel habitat, and addressing issues of contamination.
- Approximately 30 percent of the survival improvements are assigned to protecting and restoring riparian areas, reducing reservoir heating, removing or modifying pilings and pile dikes, reducing vessel wake stranding, using dredged materials beneficially,

managing piscivorous fish, and implementing pesticide, fertilizer, and stormwater BMPs.

- Approximately 5 percent of the survival improvements are assigned across the remaining actions, with varying degrees of improvements.

Table 7-2
Management Actions Sorted by Benefit to Stream-type Juveniles

#	Action	Survival Target (Stream Types)	Percentage of Target Improvements
CRE-16	Redistribute Caspian terns.	350,000	~60%
CRE-17	Redistribute cormorants.	250,000	
CRE-09	Protect/restore high-quality off-channel habitat.	150,000	
CRE-22	Restore or mitigate contaminated sites.	142,000	
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows.	125,000	
CRE-13	Manage pikeminnow and other piscivorous fish.	122,000	~30%
CRE-10	Breach, lower, or relocate dikes and levees.	100,000	
CRE-01	Protect/restore riparian areas.	100,000	
CRE-08	Remove or modify pilings and pile dikes	100,000	
CRE-21	Identify and reduce sources of pollutants.	72,000	
CRE-20	Implement pesticide/fertilizer BMPs.	42,000	~10%
CRE-23	Implement stormwater BMPs.	30,000	
CRE-02	Operate the hydrosystem to reduce reservoir heating.	20,000	
CRE-03	Protect/enhance instream flows influenced by water withdrawals and other water management actions in tributaries.	20,000	
CRE-06	Use dredged materials beneficially.	15,000	
CRE-15	Reduce invasive plants.	15,000	
CRE-07	Reduce entrainment/habitat effects of dredging and ballast.	10,000	
CRE-05	Mitigate entrapment of fine sediment in reservoirs.	5,000	
CRE-18	Reduce shad abundance.	5,000	
CRE-11	Reduce over-water structures.	3,000	
CRE-19	Prevent aquatic invertebrate introductions.	2,000	
CRE-12	Reduce vessel wake stranding.	2,000	
	Total:	1.68 million	

TABLE 7-3
Management Actions Sorted by Benefit to Ocean-type Juveniles

#	Action	Survival Target (Ocean Types)	Percentage of Target Improvements
CRE-10	Breach, lower, or relocate dikes and levees.	450,000	~65%
CRE-09	Protect/restore high-quality off-channel habitat.	400,000	
CRE-22	Restore or mitigate contaminated sites.	300,000	
CRE-21	Identify and reduce sources of pollutants.	275,000	
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows.	225,000	
CRE-01	Protect/restore riparian areas.	150,000	~30%
CRE-08	Remove or modify pilings and pile dikes	150,000	
CRE-13	Manage pikeminnow and other piscivorous fish.	140,000	
CRE-02	Operate the hydrosystem to reduce reservoir heating.	90,000	
CRE-23	Implement stormwater BMPs.	65,000	
CRE-12	Reduce vessel wake stranding.	55,000	
CRE-20	Implement pesticide/fertilizer BMPs.	50,000	
CRE-06	Use dredged materials beneficially	50,000	
CRE-03	Protect/enhance instream flows influenced by water withdrawals and other water management actions in tributaries.	25,000	~5%
CRE-11	Reduce over-water structures.	25,000	
CRE-15	Reduce invasive plants.	20,000	
CRE-07	Reduce entrainment/habitat effects of dredging and ballast.	8,000	
CRE-19	Prevent aquatic invertebrate introductions.	8,000	
CRE-05	Mitigate entrapment of fine sediment in reservoirs.	5,000	
CRE-18	Reduce shad abundance.	5,000	
CRE-16	Redistribute Caspian terns.	2,000	
CRE-17	Redistribute cormorants.	2,000	
	Total:	2.5 million	

While many of the actions are highly constrained, the planning exercise summarized in Tables 7-2 and 7-3 assumes that, even with incremental changes associated with constrained implementation, certain actions could yield significant results, especially when coupled with complementary actions. For example, ocean-type juveniles rely heavily on off-channel habitats for food sources and rearing opportunities. The two primary actions intended to improve access to off-channel habitats are CRE-10, "Breach, lower, or relocate dikes and levees," and CRE-4, "Adjust the timing, magnitude, and frequency of hydrosystem flows." Implementation of both of these actions is highly constrained, yet they could have synergistic effects and their joint implementation—even if only partial—could result in significant survival improvements for ocean-type salmonids. In contrast, if only one of these actions were implemented (or, worse yet, neither), other actions would need to be implemented as fully as possible in an attempt to compensate for the foregone opportunity to address one of the main factors limiting juvenile salmonid performance in the estuary.

Adult Survival Improvement. Because CRE-14, "Reduce predation by pinnipeds," is the only action that directly addresses the adult life history stage of salmonids, this action is treated separately and is not included in Tables 7-2 and 7-3. In 2010, which saw the largest spring Chinook and steelhead runs from 2002 to 2010, pinniped predation on spring Chinook and steelhead (both of which are stream types) at Bonneville Dam was estimated to be 2.2 percent. This equates to 6,081 spring Chinook and steelhead out of a run size of 267,194 fish (U.S. Army Corps of Engineers 2010). Projects to reduce pinniped predation have had limited success, and more stringent management techniques are constrained by protections afforded by the Marine Mammal Protection Act. Although the act does provide for lethal control, the process for implementing that provision is challenging. In 2008, NMFS granted authority under Section 120 of the Marine Mammal Protection Act to the states of Oregon, Washington, and Idaho to intentionally take, by lethal methods, individually identifiable California sea lions that prey on Pacific salmon and steelhead at Bonneville Dam, but the effectiveness of this approach is unknown. Given these constraints, PC Trask & Associates, Inc., in consultation with NMFS Northwest Regional Office staff, estimated that CRE-14 might result in a 17 percent reduction in pinniped-related mortality of adults at Bonneville Dam each year (approximately 1,034 fish annually as applied to 2010 run returns).

Costs for Constrained Implementation of Management Actions

As discussed in Chapter 5, estimating the cost of the management actions in this module is inherently difficult and involves significant uncertainties. This is partly because in many cases, the constraints to implementation have not yet been explored in enough detail to be able to determine what is and is not possible, and key scientific and technical questions about the estuary have not yet been answered. In Chapter 5, Table 5-6 established cost estimates for constrained implementation of actions by assuming an optimistic view—that constraints can be reduced through focused effort and that positive changes in the estuary can be made. A more pessimistic view would likely yield a significantly lower cost estimate, with correspondingly smaller survival improvements. Costs were assigned at the project scale to help identify possible components to actions, with the expectation that future refinements would yield a more sophisticated estimate. Finally, project costs were estimated over a 25-year time horizon.

Table 7-4 organizes management actions by total estimated cost (from Table 5-6). The following observations can be made:

- Costs for the top six actions total $332 million, or about 63 percent of the entire budget. The actions include restoring contaminated sites, modifying flows, reducing sources of pollutants, establishing or improving access to off-channel habitats, protecting or restoring off-channel habitats, and protecting and restoring riparian areas.
- Costs for the next six actions on the list equal $108 million, or about 20 percent of the budget. This group of actions consists of reducing reservoir-related temperature changes, implementing stormwater BMPs, addressing vessel wake stranding, removing or modifying pilings and pile dikes, and managing fish and pinnipeds that prey on salmonids.
- The final 11 actions on the list equal $88 million, or about 17 percent of the budget.

TABLE 7-4
Management Actions Sorted by Estimated Cost

#	Action	Cost of Action	Cost per Group of Actions
CRE-10	Breach, lower, or relocate dikes and levees.	$75 million	~$332 million, or 63% of total
CRE-09	Protect/restore high-quality off-channel habitat.	$68 million	
CRE-22	Restore or mitigate contaminated sites.	$60.5 million	
CRE-21	Identify and reduce sources of pollutants.	$46 million	
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows.	$44.5 million	
CRE-01	Protect/restore riparian areas.	$38 million	
CRE-08	Remove or modify pilings and pile dikes	$27.25 million	~$108 million, or 20% of total
CRE-02	Operate the hydrosystem to reduce reservoir heating.	$20 million	
CRE-23	Implement stormwater BMPs.	$19.5 million	
CRE-14	Reduce predation by pinnipeds.	$15 million	
CRE-13	Manage pikeminnow and other piscivorous fish.	$13 million	
CRE-12	Reduce vessel wake stranding.	$13 million	
CRE-15	Reduce invasive plants.	$12.5 million	~$88 million, or 17% of total
CRE-17	Redistribute cormorants.	$10.5 million	
CRE-20	Implement pesticide/fertilizer BMPs.	$12.5 million	
CRE-03	Protect/enhance instream flows influenced by water withdrawals and other water management actions in tributaries.	$10 million	
CRE-16	Redistribute Caspian terns.	$10 million	
CRE-05	Mitigate entrapment of fine sediment in reservoirs.	$8 million	
CRE-06	Use dredged materials beneficially.	$6 million	
CRE-11	Reduce over-water structures.	$5.8 million	
CRE-18	Reduce shad abundance.	$5.5 million	
CRE-07	Reduce entrainment/habitat effects of dredging and ballast.	$4.5 million	
CRE-19	Prevent aquatic invertebrate introductions.	$3 million	
	Total:	$528.05 million	

As also discussed in Chapter 5, there is significant uncertainty in these cost estimates because of the ambiguity about the degree to which constraints to implementation can be overcome, the level of effort that would be required to achieve a measurable result, and how new information could change current understanding about the cost and effectiveness of management actions. However, it is assumed that if restoring the ecosystem of the Columbia River estuary were established as a goal, this would require financial investment on a par with that for other major ecosystem recovery efforts around the United States.

Cost-Effectiveness of Management Actions

Cost-effectiveness is an important consideration when attempting to achieve large goals with limited resources, and the more limited the resources with respect to the goal, the more important it is that the maximum benefit be obtained from each expenditure. In the case of the Columbia River estuary, improving conditions for salmonids is likely to be an expensive and long-term effort—one that will require careful consideration of the survival benefits and costs of possible actions.

The linkage between the survival benefits and costs in this recovery plan module is difficult to characterize accurately because of the margin of error that, at this point, exists in both the estimated costs and the survival targets. Because the survival improvement targets were allocated across the set of actions as a planning exercise rather than as results of a scientific analysis, it is the allocation that is most important, not the target numbers themselves. In the case of costs, estimates were made assuming that constraints to implementation of actions could be partially overcome; this assumption served as a way to explore the degree of constraints and the level of effort that would be required to bring about significant benefits to salmonids. The resulting costs should be viewed as preliminary numbers useful in starting critical discussions about decisions that will shape the future of the estuary.

Understanding that, as outlined above, there are limitations governing the survival improvement targets and cost estimates, these sets of numbers can be compared to provide clues about which management actions might be the most cost-effective. Table 7-5 makes such a comparison, using cost information from Table 7-4 and target survival improvements from Table 7-3 to estimate the cost-effectiveness of each action, expressed as a cost/survival index. The actions are sorted in ascending order to show the most cost-effective actions first.

Table 7-5 is intended as a general indication of cost-effectiveness to help frame the discussion about implementing management actions. Also, some actions were assigned very conservative survival improvement numbers because of the level of uncertainty about underlying ecological processes. This is the case with several actions related to the food web because the connection between food web changes and effects on juveniles is not fully defined. As a result, the cost-effectiveness ratings of these actions appear high.

TABLE 7-5
Management Actions Sorted by Cost/Survival Index

#	Action	Survival (Ocean Types)	Survival (Stream Types)	Total Survival	Cost of Action	Cost/ Survival Index
CRE-16	Redistribute Caspian terns.	2,000	350,000	352,000	$10 million	28
CRE-17	Redistribute cormorants.	2,000	250,000	252,000	$10.5 million	42
CRE-13	Manage pikeminnow and other piscivorous fish.	140,000	122,000	262,000	$13 million	50
CRE-06	Use dredged materials beneficially.	50,000	15,000	65,000	$6 million	92
CRE-08	Remove or modify pilings and pile dikes	150,000	100,000	250,000	$27.25 million	109
CRE-09	Protect/restore high-quality off-channel habitat.	400,000	150,000	550,000	$68 million	124
CRE-04	Adjust the timing, magnitude, and frequency of hydrosystem flows.	225,000	125,000	350,000	$44.5 million	127
CRE-21	Identify and reduce sources of pollutants.	275,000	72,000	347,000	$46 million	133
CRE-20	Implement pesticide/fertilizer BMPs.	50,000	42,000	92,000	$12.5 million	136
CRE-10	Breach, lower, or relocate dikes and levees.	450,000	100,000	550,000	$75 million	136
CRE-22	Restore or mitigate contaminated sites.	300,000	142,000	442,000	$60.5 million	137
CRE-01	Protect/restore riparian areas.	150,000	100,000	250,000	$38 million	152
CRE-02	Operate the hydrosystem to reduce reservoir heating.	90,000	20,000	110,000	$20 million	182
CRE-23	Implement stormwater BMPs.	65,000	30,000	95,000	$19.5 million	205
CRE-11	Reduce over-water structures.	25,000	3,000	28,000	$5.8 million	207
CRE-03	Protect/enhance instream flows influenced by water withdrawals and other water management actions in tributaries.	25,000	20,000	45,000	$10 million	222
CRE-12	Reduce vessel wake stranding.	55,000	2,000	57,000	$13 million	228
CRE-07	Reduce entrainment/habitat effects of dredging and ballast.	8,000	10,000	18,000	$4.5 million	250
CRE-19	Prevent aquatic invertebrate introductions.	8,000	2,000	10,000	$3 million	300
CRE-15	Reduce invasive plants.	20,000	15,000	35,000	$12.5 million	357
CRE-18	Reduce shad abundance.	5,000	5,000	10,000	$5.5 million	550
CRE-05	Mitigate entrapment of fine sediment in reservoirs.	5,000	5,000	10,000	$8 million	800

The following observations can be made from Table 7-5:

- The median of all assigned cost/survival index numbers is 144. (The median is the middle number of a group of numbers, with half the numbers having values greater than the median and half having values less than the median).
- Some of the actions that appeared most cost-prohibitive in Table 7-4, such as establishing or improving access to off-channel habitat (CRE-10), adjusting flows (CRE-04), and restoring or mitigating contaminated sites (CRE-22), emerge as cost-effective when viewed in the context of the survival improvements they could bring about. All three of these actions have a cost/survival index value that is less than the median and that puts them in the top—or more cost-effective—half of Table 7-5.
- Several actions, including redistributing terns (CRE-16), redistributing cormorants (CRE-17), and managing piscivorous fish such as pikeminnow (CRE-13), appear to be very cost-effective.

In this planning exercise, the total survival improvement of actions listed above the median is 3.5 million juveniles (2.0 million ocean type and 1.5 million stream type), or about 17 percent of the total number of juveniles currently thought to be exiting the estuary.

Improving Ecosystem Health

The Columbia River estuary and plume ecosystems are degraded compared to historical conditions. One hypothesis of this recovery plan module is that if the estuary and plume remain in their degraded state, recovery of all 13 ESUs may not be possible. The remainder of this section is intended to help characterize choices that will ultimately govern the health of the estuarine ecosystem in the Columbia River.

Is there really a problem for salmonids in the estuary? Sources such as *Salmon at River's End* (Bottom et al. 2005), and emerging micro-acoustic tagging studies make clear that the mortality rate in the estuary is very high and almost certainly approaches 50 percent for some ESUs. This alone argues for discarding the old paradigm of the estuary as primarily a transportation corridor for salmonids on their journey to the ocean. Stream- and ocean-type salmonids clearly rely on estuary and plume habitats for crucial rearing and refuge opportunities during one of the stages in their life cycles. Chapters 3 and 4 of this estuary recovery module describe the mechanisms by which a degraded estuarine ecosystem puts juvenile salmonids at risk.

Is ecosystem restoration necessary in the estuary, or can we surgically reduce specific threats to improve salmonid survival? Ecosystem health in the estuary and plume is the cumulative result of many stressors that originate within the estuary and also outside of the estuary. The level of constraint observed in each of the management actions identified in this estuary recovery module is high, and it is extremely unlikely that one or more actions could be implemented to the degree that they would essentially eliminate a threat to salmonids. Thus each management action should be implemented to the greatest degree practical, unless it is proven that to do so would seriously undermine public safety, the economy, or property rights.

What suite of actions is most important to implement for ocean-type salmonids? There is no single correct answer to this question. In the long term, ecosystem restoration will provide the most stable, self-supporting conditions for salmonids and other native species. Ocean-type juvenile salmonids rear longer in the estuary than stream types do and therefore would benefit the most from improved ecosystem health.

The analysis and planning exercises in this recovery plan module suggest that the following actions are most important for ocean-type salmonids:

- CRE-01: Protect/restore riparian areas.
- CRE-02: Operate the hydrosystem to reduce reservoir heating.
- CRE-04: Adjust the timing, magnitude, and frequency of hydrosystem flows.
- CRE-08: Remove or modify pilings and pile dikes.
- CRE-09: Protect/restore high-quality off-channel habitat.
- CRE-10: Breach, lower, or relocate dikes and levees.
- CRE-13: Manage pikeminnow and other piscivorous fish.
- CRE-21: Identify and reduce sources of pollutants.
- CRE-22: Restore or mitigate contaminated sites.

Implementing this suite of actions would cost approximately $392.3 million and would be expected to yield survival improvements of roughly 2.2 million wild, ESA-listed ocean-type juveniles, or 88 percent of the survival target for ocean-type salmonids. In other words, for ocean-type juveniles, 88 percent of the gain to be had from the management actions could be achieved by implementing these nine actions.

What suite of actions is most important to implement for stream-type salmonids? Stream-type salmonids prefer deeper waters with higher velocities than ocean-types do. They also reside in the estuary for shorter periods of time, but they tend to use the plume more extensively than do ocean-type salmonids. Stream-type juveniles are thought to actively feed in the estuary; information indicates that stream types travel out of the channel to forage and may encounter predators such as the northern pikeminnow (Casillas 2006). For stream types, it is very important to reduce Caspian tern and double-crested cormorant predation. In addition, predation by pinnipeds on adult spring Chinook and winter steelhead is a significant threat.

The analysis and planning exercises in this recovery plan module suggest that the following actions are most important for stream-type salmonids:

- CRE-01: Protect/restore riparian areas.
- CRE-04: Adjust the timing, magnitude, and frequency of hydrosystem flows.
- CRE-08: Remove or modify pilings and pile dikes.
- CRE-09: Protect/restore high-quality off-channel habitat.
- CRE-10: Breach, lower, or relocate dikes and levees.
- CRE-13: Manage pikeminnow and other piscivorous fish.
- CRE-14: Reduce predation by pinnipeds.
- CRE-16: Redistribute Caspian terns.
- CRE-17: Redistribute cormorants.
- CRE-21: Identify and reduce sources of pollutants.
- CRE-22: Restore or mitigate contaminated sites.

Implementing this suite of actions would cost approximately $407.8 million and would be expected to yield survival improvements of roughly 5,000 stream-type adults (ESA-listed and non-listed adults) and 1.51 million wild, ESA-listed stream-type juveniles, or 90 percent of the survival target for stream-type juveniles. In other words, for stream-type juveniles, 90 percent of the gain to be had from the management actions could be achieved by implementing these 11 actions.

How cost-effective are the top actions for ocean- and stream-type salmonids? Of the top 11 priority actions for stream- and ocean-type salmonids, nine are listed at or above the median cost/survival index.

What would be gained by implementing actions that benefit both ocean- and stream-type salmonids? The lists of priority actions identified above for ocean- and stream-type salmonids contain eight actions that are predicted to benefit both types of salmonids. These actions are as follows:

- CRE-01: Protect/restore riparian areas.
- CRE-04: Adjust the timing, magnitude, and frequency of hydrosystem flows.
- CRE-08: Remove or modify pilings and pile dikes.
- CRE-09: Protect/restore remaining high-quality off-channel habitat.
- CRE-10: Breach, lower, or relocate dikes and levees.
- CRE-13: Manage pikeminnow and other piscivorous fish.
- CRE-21: Identify and reduce sources of pollutants.
- CRE-22: Restore or mitigate contaminated sites.

Implementing this set of actions would cost approximately $372.25 million and would be expected to yield survival improvements of roughly 3 million wild, ESA-listed juvenile salmonids (ocean- and stream-types combined). Although the majority of these would be ocean types, there is an argument to be made for favoring actions that would benefit both salmonid types—namely, that implementing such actions would be likely to provide benefits across the spectrum of life history strategies that juvenile salmonids of both types employ in the estuary. Many of the actions that benefit stream-type salmonids would also benefit ocean types displaying less dominant life history strategies, while many actions benefiting ocean-type salmonids would also benefit stream types displaying less dominant life history strategies. Actions that benefit both ocean and stream types, then, presumably would affect a wide range of less dominant life history strategies and thus would help preserve the diversity that contributes to salmonids' ability to persist in the face of changing environmental conditions.

However, this is not to suggest implementation only of those actions that would benefit both ocean- and stream-type juveniles because there are limitations to this approach. For instance, avian and pinniped predation actions, which would primarily benefit stream types, are cost-effective and critical to improving the survival of stream-type salmonids.

Will management actions have synergistic effects? Many of the management actions could have far-reaching effects if they were implemented together, either because they address multiple interrelated threats, such as flow regulation and impaired sediment transport, or because their effects could amplify the benefits of other, complementary management actions. An example would be the two actions of improving flows and establishing access to off-channel habitat by breaching dikes or levees. Although each action by itself would

increase salmonid access to off-channel habitat, implementing both actions has the potential to offer exponentially greater access, as well as contribute macrodetrital inputs to the food web and offer other ecosystem benefits. Although such benefits are difficult to quantify, the potential for synergistic effects of complementary actions is real and should be taken into consideration when management actions are selected.

The U.S. Army Corps of Engineers currently is studying the cumulative effects of various combinations of restoration activities in the estuary; results of the study are expected to provide valuable data on the potential synergistic effects of the management actions presented in the estuary recovery plan module. Meanwhile, several actions have the potential to be complementary in their effects, at the very least, and possibly to offer significant synergistic benefits. While it is not possible to identify all such actions, examples include using dredged materials to reduce vessel wake stranding (CRE-6 and CRE-12) or improving access to off-channel habitats by breaching dikes and adjusting flows (CRE-10 and CRE-4). At the same time, management actions need to be sequenced to avoid possible negative synergistic effects, such as by restoring contaminated sites (CRE-22) in off-channel habitat before restoring access to that habitat through dike breaching and flow modifications (CRE-10 and CRE-4). Considering the possible complementary, cumulative, or synergistic effects of management actions and sequencing actions for maximum benefit will be important aspects of implementing the estuary recovery plan module.

What about the lower ranking actions? In many ways, the lower ranking actions are the most difficult to characterize in terms of survival improvements and costs. Low ratings may be due more to a lack of scientific information than a lack of effectiveness. For example, basic changes to the food web in the estuary as a result of increased phytoplankton production or the introduction of aquatic invertebrates may have profound effects on the estuary, but the degree of impact is unknown. These threats must be more fully understood if their contribution to overall ecosystem health is to be determined with accuracy.

What planning tasks remain? The process of developing this estuary recovery plan module pointed to several areas where recovery planning for the estuary could be refined. Additional scientific information about juvenile mortality in the estuary would clarify the ecological significance of the estuary relative to tributaries and the middle and upper mainstem Columbia River. A finer scale analysis of limiting factors, threats, and the benefits of management actions would aid in prioritizing actions and focusing them in the geographical areas where they would be most beneficial. Testing the assumptions underlying the allocation of benefits across management actions would increase the value of survival improvement targets as a planning tool, as would further evaluation of the constraints to implementation of the management actions. Lastly, understanding the potential cumulative or synergistic effects of management actions could lead to implementation decisions that would enhance the benefits of actions. Obtaining more information about these topics—mortality in the estuary, biological effects at a finer level, potential benefits of management actions, and synergistic effects—could represent the next level of planning for salmon recovery in the estuary.

Implementation Issues

Implementation of the 23 actions in the module will require the efforts of a variety of Federal, state, and local agencies, organizations, private enterprises, and citizens. (Some potential implementers have been identified in Table 5-6.) While many of these entities have already been working to identify, prioritize, and implement salmon and steelhead recovery actions, effective implementation of all module actions will require additional coordination.

Goals of coordination include using existing processes, programs, and forums efficiently; ensuring the appropriate scale, scope, and sequencing of projects; coordinating funding; tracking and reporting on implementation progress; coordinating monitoring efforts; and providing data management. In addition, implementing the module will require further evaluation of the constraints associated with the 23 actions as well as consideration of potential cumulative and synergistic effects. Also, implementers of module actions will need to remain abreast of current scientific information and ensure that it is continually incorporated into implementation decisions. Although some elements of these larger processes are in place, additional organizational capacity is necessary if these needs are to be adequately addressed.

Table 5-6 includes a rudimentary schedule for implementing each of the 23 management actions described in Chapter 5, but this schedule will need to be refined as the considerations mentioned above are addressed. The first step in coordinated implementation of the module will be a conversation among all relevant entities and stakeholders to discuss near-term implementation priorities, with a goal of developing a 5-year implementation plan that provides specificity and certainty regarding near-term actions and that identifies lead entities for implementation of specific actions or projects. Given the complexities involved in implementing the full suite of module actions, this conversation also will be an opportunity to explore options for and recommend an organizational structure for coordinating and overseeing implementation of the module. The Lower Columbia River Estuary Partnership, a National Estuary Program established to bring about collaboration, would be an appropriate convener of this discussion.

Education and outreach are important aspects of module implementation. Threats to salmonids in the estuary are likely to continue unabated unless resource users in the Columbia River basin make different choices about consumption and development—choices that may be socially and politically challenging. In the face of social and political obstacles, education is one way of garnering support for implementation of the management actions; in fact, education about stewardship and the ecosystem benefits that implementation would provide is an essential component of the management actions in the module; to the extent possible, these education efforts should be coordinated to create efficiencies.

Relationship of the FCRPS BiOp to the Estuary Module

Drafts of this module were available during the Federal Columbia River Power System (FCRPS) Biological Opinion (BiOp) remand collaborative process, which led to the 2008-2018 FCRPS Biological Opinion and Supplemental Comprehensive Analysis (National Marine Fisheries Service 2008a and 2008b). Among the provisions of the 2008 FCRPS Biological Opinion (2008 BiOp) were requirements for the Federal action agencies to

implement habitat improvement and predation control actions in the estuary. Estimates of the survival benefits that would be gained from those actions were included in the 2008 BiOp, and those survival estimates were derived from the allocation of survival improvements among actions in this module.

In February 2010, NMFS issued the 2010 Supplemental BiOp for the FCRPS (National Marine Fisheries Service 2010), which integrated elements from the 2008 BiOp and Adaptive Management Implementation Plan (AMIP). The AMIP included accelerated and enhanced actions to protect Columbia Basin salmon and steelhead, including (1) commitments to additional estuary actions under an agreement with the state of Washington, and (2) efforts to control native predators and invasive species. The AMIP also included enhanced research and monitoring and incorporated specific biological triggers for contingencies linked to unexpected declines in the abundance of listed fish.

The 2010 Supplemental BiOp retained the estimates of survival improvements from estuary habitat and predation control actions that had been incorporated into the 2008 BiOp and that were based on a draft version of this estuary module. The 2010 Supplemental BiOp also summarized and assessed relevant new information that had become available since the 2008 BiOp was issued, including information on climate change, juvenile salmonid use of the estuary and plume, predation, toxics, and ecological interactions between hatchery- and natural-origin fish. The new information summarized in the 2010 BiOp will be useful in informing implementation decisions regarding actions in the module.

Actions in the 2008 BiOp and its 2010 Supplement that relate to estuarine habitat, predation, and flow will contribute to implementation of actions in this module. The module, however, identifies habitat, predation, and flow actions that are larger in scope than the actions that will be implemented under the 2008 BiOp and its 2010 Supplement. NMFS projects that the 2008 BiOp actions related to estuarine habitat, flow, and predation will yield only a portion of the total survival improvements that the estuary module hypothesizes are possible for actions in those categories. The intent of the estuary module was to lay out the full suite of limiting factors and threats affecting the estuary; to identify actions or assessments needed to address—or inform the potential to address—those limiting factors and threats; and to provide a basis for future discussions and societal decisions about recovery efforts in the Columbia River estuary.

Preparation for Decision Making

Chapter 7 is intended to help organize a much-needed conversation about recovery efforts in the estuary, plume, and other ecosystems that salmonids depend on to complete their life cycles. While there are many decisions to be made, perhaps the most important is what our level of effort and commitment will be to improving conditions in the estuary. This boils down to deciding how much we are willing to do to recover salmon and steelhead in the Columbia River basin and how comfortable we are with the sacrifices that will be necessary.

The planning exercises in Chapters 5 and 7 were based on the best available science pertaining to limiting factors and threats. However, although science can help inform the key analyses in these chapters (the identification of management actions, constraints evaluation, survival improvement targets, and cost estimates), it cannot tell us which management actions to implement. This is so partly because of the gaps in our understanding of the physical and biological world of the estuary but also because other

decision-making processes come into play when we make choices about the future and what we most value. Ultimately, the degree to which the estuary module is implemented will be determined by the social and political will of the region, and what current and future residents of the basin are willing to pay for—or do without—in order to return salmon and steelhead to viable levels.

Perhaps the single most important conclusion that can be made about the prioritization of management actions is that threats remain threats to salmonids because tough choices have yet to be made—choices that are difficult because of the myriad conflicting goals of the various public, private, individual, and organizational interests within the Columbia River basin. The variety and extent of those interests are reflected in the high degree of constraint for each of the 23 management actions identified in the recovery plan module. The take-home message from this is that the estuary and plume are crucial to ocean- and stream-type salmonids and that achieving a meaningful boost in survival from these ecosystems will require a major investment and implementation of all 23 management actions, to the extent possible.

APPENDIX B

Development of Survival Improvement Targets

APPENDIX B

Development of Survival Improvement Targets

The survival improvement targets in Table 5-5 are a planning tool intended to help initiate a comprehensive discussion about salmonid mortality in the estuary and plume. This tool is an important first step in setting recovery targets for salmonids in the estuary and also for the Columbia River basin. PC Trask & Associates, Inc., developed the survival improvement targets because, in many cases, estimates of mortality resulting from individual limiting factors and of the effectiveness of management actions in reducing threats and limiting factors do not exist. On the other hand, there are reliable estimates of mortality resulting from several of the predators, ship wake stranding, and toxic contamination, and emerging acoustic wire tagging studies are helping to estimate the extent of mortality that juvenile salmonids experience during residency in the estuary.

PC Trask & Associates, Inc., took the following steps to develop the survival improvement targets:

1. Determined the abundance of wild, ESA-listed ocean- and stream-type juveniles entering the estuary using Ferguson (2006b), which estimated 25 million ocean-type juveniles and 14.3 million stream-type juveniles for 2006.

2. Assumed a 50 percent overall juvenile mortality rate for ocean-type salmonids in the estuary and a 40 percent mortality rate for stream-type juveniles. PC Trask & Associates, Inc., reached the 50 percent mortality estimate for ocean type juveniles by taking the 35 percent rate from 2005 micro-acoustic tagging results (Ferguson 2006b) and adding an additional 15 percent to account for smaller ocean-type juveniles not tracked by the study. PC Trask & Associates, Inc., reached the 40 percent mortality estimate for stream-type juveniles by taking the 25 percent rate from the same micro-acoustic tagging study and adding 15 percent to account for presumed deaths occurring in the plume. Continued annual study results will help refine these estimates over time.

3. Used a survival improvement target of 20 percent for both ocean- and stream-type juveniles. The 20 percent number is not scientifically based; instead, it represents a planning target that will require refinement as the extent to which actions are implemented and effective becomes clearer. Survival improvement numbers attempt to reflect wild, ESA-listed fish only. In most cases, known mortality to salmonids (such as from terns) does not break out wild fish from hatchery fish or ESA-listed fish from non-listed fish.

4. Allocated the two targets described above across 22 actions (CRE-14, "Reduce predation by pinnipeds," was treated separately for adult mortality), based on an extensive literature review and personal communication with various agency staff. PC Trask & Associates, Inc., evaluated each action using limiting factor information from Chapter 3, threat information from Chapter 4, and action evaluations from Chapter 5. As a result, the allocation takes into consideration a combination of factors, including the magnitude of the limiting factor, the degree of the associated threat(s), how well the action

addresses the threat, how constrained implementation of the action is likely to be, and the assumption that a considerable level of effort will be applied to implementing each action.

5. Assigned survival improvement targets on a relative scale across all of the actions. The reader should not view the survival improvement targets as an absolute numerical result for each action, but rather a relative indication of the importance of each action. In cases where the scientific community has determined the mortality associated with a particular limiting factor and developed a management plan with mortality reduction goals, such as with predation by Caspian terns, PC Trask & Associates, Inc., used these numbers to the degree possible.

Survival improvement targets are intended to be correlated with cost estimates presented in Table 5-6 for constrained implementation of the management actions. The resulting cost/survival estimates (see Table 7-5) are intended to initiate discussions about the validity of cost estimates and potential survival improvement targets; the cost/survival index values in Table 7-5 are highly uncertain because of the gross assumptions on both sides of the equation.

Disclaimer: Survival improvement numbers are for illustration only and are intended to demonstrate social choices in the face of significant uncertainty. Literature sources generally do not prescribe actions, and relatively few actions have been specifically evaluated for associated survival estimates.

Table B-1
Notes on Development of Survival Improvement Targets

Action	Notes
CRE-1: Protect/restore riparian areas.	Estimate is unsupported in the literature. Estimate was assigned a high value in recognition of its importance relative to food sources and shoreline habitats. This is a protection action that is intended to reduce the potential for increased threat over time.
CRE-2: Operate the hydrosystem to reduce reservoir heating.	Estimate is unsupported in the literature. Estimate was assigned a relatively high value because temperatures commonly exceed 19 degrees Celsius and are doing so more frequently and for longer periods of time. (Nineteen degrees Celsius is considered the upper range of survival for salmonids). Estimate is based on a relatively large level of effort to reduce the threat. It is likely that mitigation will be required in tributaries to implement the action.
CRE-3: Protect/enhance instream flows influenced by withdrawals and other water management actions in tributaries.	Estimate is unsupported in the literature. This is a protection action that is intended to reduce the potential for increased threat. Estimate is closely aligned with CRE-4 and probably has overlapping benefits.

CRE-4: Adjust the timing, magnitude, and frequency of hydrosystem flows.	Estimate is unsupported in the literature. The action affects nearly every facet of estuary ecosystem health. Estimate is intended to demonstrate that changes to the hydrograph are possible and that small increments of change may produce a significant survival improvement. This action is worthy of further analysis that may help support a more defensible survival estimate.
CRE-5: Mitigate entrapment of fine sediment in reservoirs.	Estimate is unsupported in the literature. Estimate was assigned a low survival improvement because of the high degree of uncertainty about its potential to improve salmonid survival. Entrapment of sediment may have significantly larger effects.
CRE-6: Use dredged materials beneficially.	Estimate is unsupported in the literature. Estimate was assigned a low survival improvement because of the high degree of uncertainty about its potential to improve salmonid survival. Currently, beneficial uses are most often associated with nearshore erosion management, and little is known about potential benefits to salmonids in the nearshore.
CRE-7: Reduce entrainment/ habitat effects of dredging and ballast.	Estimate is unsupported in the literature. Estimate is relatively low because of the uncertainty and lack of mortality documentation associated with entrainment.
CRE-8: Remove or modify pilings and pile dikes	Estimate is unsupported in the literature. Estimate is relatively high because of the number of pile dikes in the estuary and the suspected predation effects that result from the threat, including predation by cormorants, pikeminnow, bass, walleye, and catfish. Altered flow circulation and reduced juvenile access to low-velocity habitats may also be a threat.
CRE-9: Protect/restore high-quality off-channel habitat.	Estimate is unsupported in the literature. This is a protection action that is intended to reduce the potential for increased threat. The high estimate reflects the magnitude of importance that off-channel habitats represent to juveniles, especially ocean types. Because restoration activities are highly constrained, it is vital not to lose additional functioning habitats. Protection alone will only help preserve the status quo.
CRE-10: Breach, lower, or relocate dikes and levees.	Estimate is unsupported in the literature. Estimate is intended to demonstrate that dike or levee breaching is one of the top few actions that will increase ocean-type survival in the estuary. If substantial improvements for ocean-type life histories in the estuary are to occur, this is one of a handful of actions that must be implemented. Estimate assumes a significantly higher level of implementation than what is currently occurring.
CRE-11: Reduce over-water structures.	Estimate is unsupported in the literature. Estimate is relatively high because of the number of over-water structures in the estuary and the suspected predation effects that result from the threat, including predation by cormorants, pikeminnow, bass, walleye, and catfish. Other effects, such as decreased light penetration, are not well understood.

CRE-12: Reduce vessel wake stranding.	Mortality estimates for test sites have demonstrated a wide range of confirmed mortality. In Bauersfeld (1977), an assessment of five test sites estimated approximately 150,000 stranded juveniles (on those sites). No estuary-wide estimates have been developed. The emerging availability of LIDAR imagery for the estuary may provide for analysis to extrapolate confirmed site-specific information to estuary-wide predictions. Estimate is relatively high within the range of study estimates.
CRE-13: Manage pikeminnow and other piscivorous fish.	Estimate is unsupported in the literature. Some information exists about predation rates. The threat does not currently appear to be on the increase. Estimate is relatively high based upon conjecture by the NMFS Northwest Fisheries Science Center regarding pikeminnow predation rates, but the threat should be studied further and monitored over time.
CRE-14: Reduce predation by pinnipeds.	An estuary-wide mortality estimate is unsupported in the literature. Estimates are for adults only. Annual counts at Bonneville Dam indicate between 0.4 percent and 3.4 percent mortality of spring Chinook and winter steelhead. A 500-pound Stellar sea lion consumes about 40 to 60 pounds of fish each day. An unsubstantiated estimate of all pinniped predation in the estuary of approximately 10 percent of spring Chinook and winter steelhead is probably reasonable.
CRE-15: Reduce invasive plants.	Estimate is unsupported in the literature. Noxious weeds alter food webs and habitat and work at the ecosystem scale. Very little is understood about the connection between noxious weeds and juvenile salmonid survival. Estimate is relatively high for noxious weeds compared to other ecosystem-scale threats because, although associated actions are difficult, they have a greater likelihood of success than do actions to address other similar threats, such as invertebrate infestations.
CRE-16: Redistribute Caspian terns.	Estimate is supported by the literature. Recent successes in relocating terns have been documented. Efforts to implement the action are under consideration. Estimated mortality attributed to Caspian tern predation is approximately 3.6 million juveniles in 2005. Current planning calls for a two-thirds reduction in the East Sand Island nesting.

CRE-17: Redistribute cormorants.	Estimate is supported by the literature. Efforts to manage cormorants are not nearly as mature as efforts to manage terns. There is less certainty about implementation potential because cormorants have not responded to management efforts to the degree that terns have. Estimated mortality attributable to predation by double-crested cormorants is considered to be comparable to that of predation by terns. Assignment of the target survival improvement was lower than for terns because cormorants may be harder to manage than terns.
CRE-18: Reduce shad abundance.	Estimate is unsupported in literature. Estimate is low because of the high degree of uncertainty about the relationship between shad, salmonids, and ecosystem health. Estimate is also low because the literature does not identify potential actions to reduce shad abundance levels.
CRE-19: Prevent aquatic invertebrate introductions.	Estimate is unsupported in the literature. Extent of the threat is well-documented; however, invertebrate infestations occur at the ecosystem scale, and the degree of mortality that occurs because of food web changes at this scale is unknown. Estimate is relatively low because of the uncertainty of the threat and the inherent challenges of reducing the threat.
CRE-20: Implement pesticide/fertilizer BMPs.	Emerging literature (Loge et al. 2005) hypothesizes that mortality resulting from estuary contamination ranges from 1.5 percent to 9 percent, depending on the amount of time juveniles spend in the estuary. Estimates for CRE-21, CRE-22, and CRE-23 form the basis for survival improvements (using estimates from Loge et al. 2005).
CRE-21: Identify and reduce sources of pollutants.	Emerging literature (Loge et al. 2005) hypothesizes that mortality resulting from estuary contamination ranges from 1.5 percent to 9 percent. Estimates for CRE-20, CRE-22, and CRE-23 form the basis for survival improvements (using estimates from Loge et al. 2005).
CRE-22: Restore or mitigate contaminated sites.	Emerging literature (Loge et al. 2005) hypothesizes that mortality resulting from estuary contamination ranges from 1.5 percent to 9 percent. Estimates for actions CRE-20, CRE-21, and CRE-23 form the basis for survival improvements (using estimates from Loge et al. 2005).
CRE-23: Implement stormwater BMPs.	Estimate is unsupported in the literature. This is a protection action that is intended to reduce the potential for increased threat. This action does not assume retrofitting of existing stormwater function.

ESA Recovery Plan for the White Salmon River Watershed

June 2013

Prepared by
National Marine Fisheries Service
Northwest Region

DISCLAIMER

Endangered Species Act (ESA) recovery plans delineate reasonable actions which the best available information indicates are necessary for the conservation and survival of listed species. Plans are published by the National Marine Fisheries Service (NMFS), usually with the assistance of recovery teams, state agencies, local governments, salmon recovery boards, non-governmental organizations, interested citizens of the affected area, contractors, and others. ESA recovery plans do not necessarily represent the views, official positions, or approval of any individuals or agencies involved in the Plan formulation, other than the NMFS. They represent the official position of NMFS only after they have been signed by the Northwest Regional Administrator. ESA recovery plans are guidance and planning documents only; identification of an action to be implemented by any public or private party does not create a legal obligation beyond existing legal requirements. Nothing in this plan should be construed as a commitment or requirement that any Federal agency obligate or pay funds in any one fiscal year in excess of appropriations made by Congress for that fiscal year in contravention of the Anti-Deficiency Act, 31 U.S.C. 1341, or any other law or regulation. Approved recovery plans are subject to modification as dictated by new information, changes in species status, and the completion of recovery actions.

The White Salmon River Watershed Recovery Plan straddles two NMFS Recovery Domains: the lower Columbia/Willamette River Recovery Domain, and the middle Columbia River (MCR) Steelhead Recovery sub-domain of the Interior Columbia River Recovery Domain. As such, the White Salmon River Watershed Recovery Plan is appended to both the lower Columbia/Willamette River and the MCR Steelhead Recovery Plans.

With respect to both the lower Columbia/Willamette River Recovery Plan and the MCR Steelhead Recovery Plan to which the White Salmon Watershed Recovery Plan is appended, where areas of disagreement arose between a management unit plan and a species level, evolutionarily significant unit or distinct population segment plans, NMFS worked with the relevant parties to resolve the differences, and, in a few cases, identified in the evolutionarily significant unit/distinct population segment plans, decided not to incorporate the disputed material in the evolutionarily significant unit or distinct population segment plans. NMFS reserves the right to decide whether or not to incorporate any such disputed materials into the species level plans.

ESA recovery plans provide important context for NMFS determinations pursuant to section 7(a)(2) of the ESA. However, recovery plans do not place any additional legal burden on NMFS or the action agency when determining whether an action would jeopardize the continued existence of a listed species or adversely modify critical habitat. The procedures for the section 7 consultation process are described in 50 CFR 402 and are applicable regardless of whether or not the actions are described in a recovery plan.

Recovery Planning Glossary

Abundance: In the context of salmon recovery, unless otherwise qualified, abundance refers to the number of adult fish returning to spawn.

Adaptive management: Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. An overall implementation plan incorporates a monitoring, evaluation, and feedback framework in which the results of actions become feedback on design and implementation of future actions.

Anadromous fish: Species hatched in freshwater, migrate to and mature in salt water, and return to freshwater to spawn.

Baseline monitoring: In the context of recovery planning, scientists conduct baseline monitoring to establish historical and/or current conditions to measure progress (or lack of progress).

Broad-sense recovery goals: Goals defined in the recovery planning process, that go beyond the requirements for delisting, to address, for example, other legislative mandates or social, economic, and ecological values. Local recovery planning groups usually developed these goals.

Compliance monitoring: Determining whether recovery implementation or actions are meeting a specific performance standard, environmental standard, regulation, or law.

Delisting criteria: Criteria incorporated into Endangered Species Act (ESA) recovery plans that define both biological viability (biological criteria) and alleviation of the causes for decline (threats criteria based on the five listing factors in ESA section 4[a][1]), and that, when met, would result in a determination that a species is no longer threatened or endangered and can be proposed for removal from the Federal list of threatened and endangered species. These criteria are a National Marine Fisheries Service (NMFS) determination and may include both technical and policy considerations.

Diel flow: Flow that occurs during a 24-hour period.

Distinct Population Segment (DPS): A listable entity under the ESA that meets tests of discreteness and significance according to U.S. Fish and Wildlife Service (USFWS) and NMFS policy. A population is considered distinct (and hence a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics, it occupies an unusual or unique ecological setting, or its loss would represent a significant gap in the species' range.

Diversity: All the genetic and phenotypic (life history, behavioral, and morphological) variation within a population. Variations could include anadromy *v*. lifelong residence in freshwater, fecundity, run timing, spawn timing, juvenile behavior, age at smolting, age at maturity, egg size,

developmental rate, ocean distribution patterns, male and female spawning behavior, physiology, molecular genetic characteristics, etc.

Effectiveness monitoring: Monitoring set up to test cause-and-effect hypotheses about recovery actions: Did the management actions achieve their direct effect or goal? For example, did fencing a riparian area to exclude livestock result in recovery of riparian vegetation?

ESA recovery plan: A plan to recover a species listed as threatened or endangered under the U.S. ESA. The ESA requires that recovery plans, to the extent practicable, incorporate (1) objective, measurable criteria that, when met, would result in a determination that the species is no longer threatened or endangered; (2) site-specific management actions that may be necessary to achieve the Plan's goals; and (3) estimates of the time required and costs to implement recovery actions.

Evolutionarily Significant Unit (ESU): A group of Pacific salmon or steelhead trout that is (1) substantially reproductively isolated from other conspecific units and (2) represents an important component of the evolutionary legacy of the species.

Extinct: There are no individuals of this former population or species anywhere.

Extirpated: Zero population or individuals in a certain area but conspecifics exist elsewhere.

Factors for decline: Five general categories of causes for decline of a species, listed in the ESA section 4(a)(1)(b): (A) the present or threatened destruction, modification, or curtailment of its habitat or range; (B) overutilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; or (E) other natural or manmade factors affecting its continued existence.

Functionally extirpated: A species or population that has been extirpated from an area; although a few individuals may occasionally be found, they are not thought to constitute a population.

Hyporheic zone: Area of saturated sediment and gravel beneath and beside streams and rivers where groundwater and surface water mix.

Implementation monitoring: An examination to determine whether the responsible public or private implementing entity performed the activity and/or completed it as planned.

Independent population: Any collection of one or more local breeding units whose population dynamics or extinction risk over a 100-year time period is not substantially altered by exchanges of individuals with other populations.

Indicator: A variable used to forecast the value or change in the value of another variable.

Integrated hatchery program: The purpose of an integrated hatchery program is to increase abundance, while minimizing the genetic divergence of a hatchery broodstock from a naturally spawning population. To maintain the genetic characteristics of a local, natural population among hatchery-origin fish, an integrated program attempts to minimize the genetic effects of domestication. The expected result is a reduction of the genetic risks that hatchery-origin fish may pose to the naturally spawning population.

Interim regional recovery plan: A recovery plan intended to lead to an ESA recovery plan but that is not yet complete. These plans might address only a portion of an ESU or lack other key components of an ESA recovery plan.

Intrinsic potential: The estimated relative suitability of a habitat for spawning and rearing of anadromous salmonid species under historical conditions inferred from stream characteristics including channel size, gradient, and valley width.

Intrinsic productivity: The expected ratio of natural-origin offspring to parent spawners at levels of abundance below carrying capacity.

Kelts: Steelhead that are returning to the ocean after spawning and have the potential to spawn again in subsequent years (unlike most salmon, steelhead do not necessarily die shortly after spawning).

Large Woody Debris (LWD): A general term for wood naturally occurring or artificially placed in streams, including branches, stumps, logs, and logjams. Streams with adequate LWD tend to have greater habitat diversity, a natural meandering shape, and greater resistance to flooding.

Legacy effects: Impacts from past activities that continue to affect a stream or watershed in the present day.

Limiting factor: Physical, biological or chemical features (e.g., inadequate spawning habitat, high water temperature, insufficient prey resources) experienced by the fish that result in reductions in Viable Salmonid Population (VSP) parameters (abundance, productivity, spatial structure, and diversity). Key limiting factors are those with the greatest impacts on a population's ability to reach its desired status.

Locally developed recovery plan: State, tribal, regional, and local planning entities throughout the region drafted plans to address the ESA as well as other mandates and recovery needs. Local and regional citizen and business groups were also involved in these planning efforts.

Maintained status: Population status in which the population does not meet viability criteria but does support ecological functions and preserve options for ESU/DPS recovery.

Major Population Group (MPG): A group of salmonid populations that is geographically and genetically cohesive. The MPG is a level of organization between demographically independent populations and the ESU or DPS.

Management Unit: A geographic area defined for recovery planning purposes on the basis of state, tribal or local jurisdictional boundaries that encompass all or a portion of the range of a listed species, ESU or DPS.

Metrics: Quantification of a characteristic of a situation or process; for example, the number of natural-origin salmon returning to spawn to a specific location is a metric for population abundance.

Morphology: The form and structure of an organism, with special emphasis on external features.

Natural-origin fish: Fish spawning and rearing in the wild, regardless of parental origin.

Parr: The stage in anadromous salmonid development between absorption of the yolk sac and transformation to smolt before migration seaward.

Phenotype: Any observable characteristic of an organism, such as its external appearance, development, biochemical or physiological properties or behavior.

Piscivorous: (Adj.) Describes fish that eat other fish.

Productivity: The average number of surviving offspring per parent. Used as an indicator of a population's ability to sustain itself or its ability to rebound from low numbers. The terms "population growth rate" and "population productivity" are interchangeable when referring to measures of population production over an entire life cycle. Often expressed as the number of recruits (adults) per spawner or the number of smolts per spawner.

Recovery domain: A NMFS-defined administrative unit for recovery planning based on ESU boundaries, ecosystem boundaries, and existing local planning processes. Recovery domains may contain one or more listed ESUs.

Recovery goals: Goals incorporated into a locally developed recovery plan, which may include recovery, delisting, reclassification, and/or other goals. Broad-sense goals are a subset of recovery goals.

Recovery plan supplement: A NMFS supplement to a locally developed recovery plan that describes how the plan addresses ESA requirements for recovery plans. The supplement also proposes ESA delisting criteria for the ESUs addressed by the plan, since a determination of these criteria is a NMFS decision.

Recovery scenarios: Scenarios that describe a target status for each population within an ESU, generally consistent with Technical Recovery Team (TRT) recommendations for ESU viability.

Redd: A female salmonid constructs a nest, or redd, in streambed gravels where she deposits her eggs and males fertilize them.

Recovery strategy: Statements that identify the assumptions and logic-the rationale-for the species' recovery program.

Riparian area: Area with distinctive soils and vegetation between a stream or other body of water and the adjacent upland.

Salmonid: Fish of the family *Salmonidae*, including salmon, trout, char, grayling, and whitefish. In general usage, the term usually refers to salmon, trout, and char.

Segregated hatchery program: The intent of a segregated hatchery program is to maintain a genetically distinct hatchery population. The only way to reduce risk (genetic and ecological) to natural populations from segregated programs is to minimize the contribution of hatchery fish to natural spawning.

Smolt: A juvenile salmonid that is undergoing physiological and behavioral changes to adapt from freshwater to saltwater as it migrates toward the ocean.

Spatial structure: Characteristics of a fish population's geographic distribution. Current spatial structure depends upon the presence of fish, not merely the potential for fish to occupy an area.

Stakeholders: Agencies, groups, or private citizens interested in or affected by recovery planning and/or actions.

Technical Recovery Team (TRT): NMFS convenes work groups, the TRTs, to develop technical products related to recovery planning. Planning forums unique to specific states, tribes, or regions both complement and use TRTs and other technical products to identify recovery actions.

Threats: Human activities or natural events (e.g., road building, floodplain development, fish harvest, hatchery influences, volcanoes) that cause or contribute to limiting factors. Threats may exist in the present or be likely to occur in the future.

Viability criteria: NMFS appointed TRTs to define criteria to describe a VSP based on the biological parameters of abundance, productivity, spatial structure, and diversity. NMFS and others use these viability criteria as technical input into the recovery planning process and provide a technical foundation for development of biological delisting criteria.

Viability curve: A curve describing combinations of abundance and productivity that yield a particular risk or extinction level at a given level of variation over a specified time frame.

Viable Salmonid Population (VSP): An independent population of Pacific salmon or steelhead trout that has a negligible risk of extinction over a 100-year time frame.

VSP parameters: Abundance, productivity, spatial structure, and diversity. These describe characteristics of salmonid populations that are useful in evaluating population viability. See NOAA Technical Memorandum NMFS-NWFSC-42, *viable salmonid populations and the recovery of evolutionarily significant units*, McElhany et al., June 2000.

Executive Summary

The Endangered Species Act (ESA) of 1973 requires National Oceanic and Atmospheric Administration (NOAA)'s National Marine Fishers Service (NMFS) to develop recovery plans for species listed under the Act. The purpose of recovery plans is to identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA. Recovery plans are not regulatory documents; they are guidance for anyone involved in species recovery efforts as well as for the various state, Federal, tribal, and local entities whose activities and jurisdictions may affect endangered species. A recovery plan provides a roadmap for restoring a listed species or population to biological viability and greater likelihood of long-term survival.

This is a plan for re-establishing the White Salmon River populations of lower Columbia River (LCR) Chinook salmon, LCR coho salmon, Columbia River (CR) chum salmon, and MCR steelhead. The Plan aims for these populations to contribute to the conservation and survival of their respective Evolutionarily Significant Units (ESUs)/Distinct Population Segments (DPSs)[1] (Table ES-1).

The White Salmon River fall and spring Chinook salmon are included in the LCR Chinook salmon (*Oncorhynchus tshawytscha*) ESU, which NMFS listed as threatened on March 24, 1999 and reconfirmed June 28, 2005. The ESU includes all naturally spawned populations of Chinook salmon in the CR and its tributaries from its mouth at the Pacific Ocean upstream to a transitional point east of Hood River in Oregon and the White Salmon River in Washington. The White Salmon River spring Chinook salmon are considered extirpated (Good et al. 2005; Myers et al. 2006).

The White Salmon River coho salmon are part of the LCR coho salmon (*Oncorhynchus kisutch*) ESU, which NMFS listed as threatened on June 28, 2005. The ESU includes all naturally spawned coho salmon populations in the CR and its tributaries from the mouth of the CR to a transitional point east of the Hood and White Salmon Rivers. The White Salmon River coho salmon are considered extinct (Good et al. 2005; Myers et al. 2006).

The White Salmon chum salmon are part of the CR chum salmon *(Oncorhynchus keta*) ESU, which NMFS listed as threatened on March 25, 1999. The CR chum salmon ESU includes all naturally spawning populations in the CR and its tributaries in Washington and Oregon. Presently, all CR chum salmon spawning populations are located downstream of Bonneville Dam. Annual fish passage reports (U.S. Army Corps of Engineers (USACE), 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008) for Bonneville Dam provided data that adult

[1] An 'evolutionarily significant unit' (ESU) of Pacific salmon (Waples 1991) and a 'distinct population segment' (DPS) of steelhead (71 FR 834, January 5, 2006) are considered to be 'species,' as defined in section 3 of the ESA.

chum salmon continue to pass upstream of Bonneville Dam, with adult counts averaging 139 and ranging from a low of 46 to high of 411 from 2000 to 2008.

The White Salmon River historically included a population of MCR steelhead (*Oncorhynchus mykiss*). The MCR steelhead DPS is made up of steelhead populations in Oregon and Washington tributaries of the CR upstream of the Hood and Wind River systems, up to and including the Yakima River. The White Salmon steelhead population is considered "functionally extirpated" for the following reasons: the population's current lack of access to sufficient habitat to support sustained natural production; the presence of a large in-basin hatchery release program below the dam that uses out-of-basin broodstock (ICTRT 2007a); and only a few individual fish may still be present from the original White Salmon population. Functionally extirpated populations are those with so few remaining numbers that there are not enough fish or habitat in suitable condition to support a fully functional population.

Table ES-1. ESA listed DPS/ESU in the White Salmon River

Species	ESU/DPS	Status	Federal Register Notice	
Chinook salmon (*Oncorhynchus tshawytscha*)	LCR Chinook salmon	Threatened	70 FR 37160	6/28/2005
Coho salmon (*O. kisutch*)	LCR coho salmon	Threatened	70 FR 37160	6/28/2005
Chum salmon (*O. keta*)	CR chum salmon	Threatened	70 FR 37160	6/28/2005
Steelhead (*O. mykiss*)	MCR steelhead	Threatened	71 FR 834	1/5/2006
Critical Habitat Designation	LCR Chinook salmon, CR chum salmon, LCR coho salmon, MCR steelhead		70 FR 52630	9/2/2005

Context of Plan Development

This recovery plan provides direction for potential recovery of the White Salmon River's historical salmon and steelhead populations. This plan builds on the past and current efforts of the many parties currently working to rebuild populations and improve their habitat. This approach reflects NMFS's belief that it is critically important to base ESA (4f) recovery plans on the many state, regional, tribal, local, and private conservation efforts that are already underway. NMFS initiated a process that incorporated input from the Yakama Nation (YN), Washington Department of Fish and Wildlife (WDFW), Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal and state agencies, local governments, and the public. That process produced the White Salmon Recovery Plan.

Currently, there are 18 ESA-listed species of Pacific salmon and steelhead in the Pacific Northwest. For the purpose of recovery planning for these species, NMFS Northwest Region

designated five geographically based "recovery domains": Interior Columbia, Willamette/lower Columbia, Puget Sound and Washington Coast, Oregon Coast and the Southern Oregon/Northern California Coast. The White Salmon watershed is in an area where the Interior Columbia and Willamette/lower Columbia recovery domains overlap.

In each domain, NMFS has worked with state, tribal, and local entities and other Federal entities to develop planning forums that build to the extent possible on ongoing, locally led recovery efforts. NMFS defined "Management Units" based on jurisdictional boundaries as well as areas where local planning efforts were underway. In the LCR there are three management units for the LCR ESUs, these are 1) Oregon; 2) Washington; 3) the White Salmon River ESUs (not including the Steelhead DPS). In the MCR steelhead recovery domain the management units are 1) Oregon; 2) Washington Gorge, which, in turn, NMFS subdivided into three planning areas, White Salmon, Klickitat, and Rock Creek; 3) Yakima Basin; 4) Southeast Washington.

NMFS intends to incorporate the White Salmon Watershed Recovery Plan as an appendix to both the LCR Salmon and Steelhead Recovery Plan and the MCR Steelhead Recovery Plans since the White Salmon River watershed has ESA-listed species in both of the two NMFS Recovery Domains.

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each TRT was to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. The Willamette/lower Columbia Technical Recovery Team (W/LC TRT) provided technical support for the LCR ESUs recovery plan, while the Interior Columbia Technical Recovery Team (ICTRT), provided technical support for the White Salmon Steelhead Recovery Plan. These TRTs included biologists from NMFS, states, tribal entities, and academic institutions.

All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population viability criteria-criteria to be used, along with criteria based on mitigation of the factors for decline, to determine whether a species has recovered sufficiently to be downlisted or delisted. A NMFS technical memorandum, *Viable Salmon Populations and the Recovery of Evolutionarily Significant Units* describes these principles (McElhany et al. 2000). The memorandum defines VSPs in terms of four parameters: abundance, population productivity or growth rate, population spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework and based on data availability, the unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective experience and expertise. Although NMFS has encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs are working from a common scientific foundation.

Physical Setting

The White Salmon watershed drains approximately 386 square miles in south central Washington (Figure ES-1). The river begins along the south slope of Mt. Adams and flows south 45 miles to enter the CR at Underwood, Washington at river-mile (RM) 168.3. White Salmon River salmon populations pass one mainstem CR dam, Bonneville Dam, during their migration to and from the Pacific Ocean.

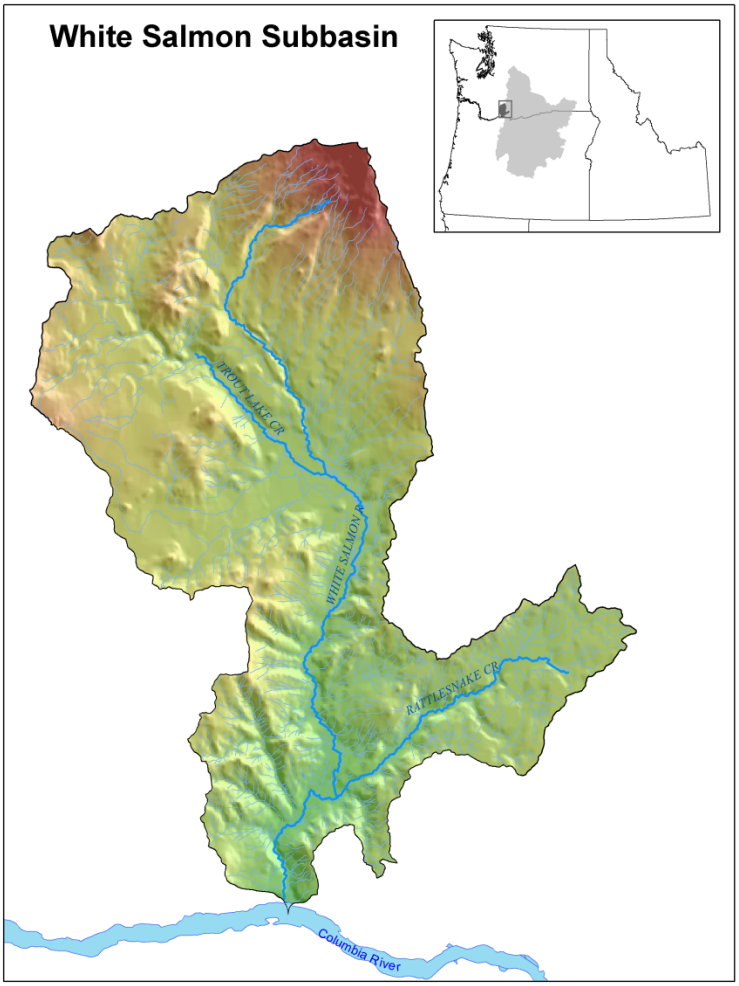

Figure ES-1. White Salmon watershed in Washington State (NPCC 2004)

Salmon and steelhead production in the White Salmon River watershed dropped significantly in the early 1900s after construction of Condit Dam at RM 3.3 on the White Salmon River. Condit Dam's original owners built a fish ladder; however, high flows twice destroyed the ladder and subsequent owners did not reconstruct it after 1919.

Fish passage, either through removal of the dam or installation of upstream and downstream fish passage facilities has been under evaluation as part of the Federal Energy Regulatory Commission (FERC) re-licensing process. PacifiCorp Power, the owner of Condit Dam,

rejected the proposal to install fish passage facilities and is currently removing the dam. This Plan includes a proposal to establish or re-establish natural production of salmon and steelhead in the White Salmon watershed, based on natural re-colonization of the habitat above the dam after removal. Recovery actions may also include implementation of hatchery augmentation of populations and/or hatchery preservation of genetic stocks.

The White Salmon watershed is part of both of Washington State's LCR salmon recovery domain and the MCR Steelhead Recovery sub-domain. White Salmon River is within parts of Skamania, Yakima, and Klickitat counties. In addition, the watershed falls within the state's Water Resource Inventory Area (WRIA) 29b. Half of the watershed lies within the Gifford Pinchot National Forest and supports timber production and recreational uses.

The White Salmon watershed contains lands the YN ceded to the United States in the Treaty of June 9, 1855. Within this area, the Tribe reserves the right "to hunt and fish at all usual and accustomed places." An in-lieu fishing site is located at the mouth of the White Salmon River, allowing tribal fishers to launch boats in an enclosed area and move out into the C R to their usual and accustomed fishing grounds.

Ecosystem Conditions

Condit Dam, at RM 3.3 on the mainstem White Salmon River, blocked all anadromous fish migration to historical habitats in the upper drainage. Dam removal began on October 26, 2011. Historical operations at Condit Dam altered flows in the lower White Salmon River, causing flows to drop to as low as 15 cubic feet per second (cfs) in the 1.1-mile bypass reach. Average natural flows are about 700 cfs. Power peaking at the dam affected the river system, causing diel flow variations and impairing watershed processes, such as the transportation of spawning gravels and Large Woody Debris (LWD) to areas downstream of the project (NPCC 2004). The lack of sediment transport into these reaches has affected habitat conditions downstream of Condit Dam. Conditions in the lower river below the former location of Condit Dam and under the former reservoir are anticipated to change substantially in response to the removal of the dam and subsequent stabilization actions.

Upstream of Condit Dam, the White Salmon River has a relatively constant natural flow pattern because of glacial melt and a large water storage capacity. Tributary stream flows drop to low levels in the summer and peak in the winter. Upstream of the dam, Northwestern Lake occupied the portion of the river between Buck Creek and the dam. Removal of the dam is exposing the lakebed. The coarseness of substrate sediment in the former lakebed is variable, with coarser material deposited at the top of the former reservoir and finer material downstream. Riparian vegetation is currently non-existent, and banks will be unstable until restoration actions are completed.

The extent of time it will take to re-establish channel and watershed processes in the former lakebed and the area below the former dam is unknown. Upstream of the former Northwestern Lake, some tributaries have warm water temperature, sparse riparian vegetation, high nutrient levels, low instream LWD abundance, and poor pool volume and frequency. Biologists have documented fish-borne diseases, Bacteria Kidney Disease (BKD) and Black Spot in the watershed (section 5.6, Predation, Competition and Disease).

Populations and Major Population Groups

Historically, MCR steelhead, likely ranged up the White Salmon River to the falls at RM 16 and into Buck, Spring, Indian, and Rattlesnake creeks (NPCC 2004). Based on accessible spawning habitat and a combination of notes, diary logs, and interviews (Lane and Lane Associates 1981), biologists assume that spring Chinook salmon and coho salmon were present historically in the watershed. Husum Falls, RM 7.6, may have blocked fall Chinook salmon migration and created a partial barrier for steelhead and coho salmon (NPCC 2004). All anadromous fish passage to historical habitats in the White Salmon drainage above RM 3.3 ended after construction of Condit Dam and the failure of the fish ladder in 1919. Now that Condit Dam has been removed, populations are anticipated to repopulate the watershed.

Presently, the historical spring Chinook salmon population is considered extirpated (Good et al. 2005; Myers et al. 2006), the historical steelhead population is considered functionally extirpated (ICTRT 2007b), the historical coho salmon population is considered extinct (Good et al. 2005; Myers et al. 2006), and the historical fall Chinook salmon population is considered at very high risk of extinction (ICTRT 2006; McElhany et al. 2004; Ford et al. 2011).

Biological Viability Criteria

White Salmon River fall Chinook salmon

The W/LC TRT gave the White Salmon River fall Chinook salmon population a weighted average extinction risk score of 0.86 on a scale of 0 to 4, with 0 = extirpation or nearly so, and 4 = very low extinction risk. This suggests that the population is at a very high risk of extinction (McElhany et al. 2004). Most W/LC TRT members considered hatchery strays to heavily influence the in-river fall-run Chinook salmon population, although some team members included the Spring Creek National Fish Hatchery (NFH) in their diversity evaluation as a potential source for re-establishing a native-run.

White Salmon River spring Chinook salmon

The W/LC TRT rated the White Salmon River spring-run Chinook salmon with a weighted average extinction risk score of 0.07, indicating the population is likely extirpated. The team concluded that any population that may have been historically present is currently extirpated because of construction of Condit Dam.

White Salmon River coho salmon

McElhany et al. weighted the White Salmon coho salmon population with an average extinction risk score of 0.39, indicating that the population is likely very near extinction (2004) or extinct (Good et al. 2005).

White Salmon River chum salmon

The lower Columbia Fish Recovery Board (LCFRB) identified the entire population of upper Gorge Chum salmon, which includes the historical population of chum salmon spawning in the White Salmon River, to have a very low viability (LCFRB 2004). Bonneville Reservoir inundates most of historical habitat for this population. T

White Salmon River steelhead

The ICTRT classified the White Salmon River steelhead population as functionally extirpated (ICTRT 2008). The ICTRT considers extirpated populations as those entirely cut off from anadromy. Functionally extirpated populations are those with so few remaining that there are not enough fish or habitat in suitable condition to support a fully functional population. The ICTRT identified one historical Major Spawning Area (MaSA) within the White Salmon watershed. A few individuals from the original population may have been spawning in the reach below Condit Dam and some evidence suggests that resident *O. mykiss* may have retained anadromous potential (Allen et al. 2006a and 2006b; Allen, personal communication, 2008).

Limiting Factors

Chapter 5 discusses in-watershed and out-of-watershed factors and related threats influencing the viability of the White Salmon River salmon and steelhead populations. NMFS defines limiting factors as the biological and physical conditions that limit a species' viability - e.g., high water temperature and defines threats as those human activities or naturally induced actions that cause the limiting factors. For example, removing the vegetation along the banks of a stream (the threat) can cause higher water temperatures (the limiting factor), because the stream is no longer shaded. Analysis of limiting factors and threats across the species' entire life cycle forms the basis for designing recovery strategies and actions.

"Threats" are present or likely anthropogenic activities or natural events that cause or contribute to the factors limiting the species' recovery. The development of threat reduction strategies can be complex, especially when human activities that pose threats to the species satisfy otherwise "beneficial" societal or cultural functions (e.g., flow management may threaten the species by reducing summer flows an increasing water temperatures, but the flow management may support an agricultural economy or protect human safety and property through flood prevention). In such circumstances, it is desirable to manage a threat in such a way that it minimizes or eliminates the negative impacts to the species, while retaining essential societal or cultural functions.

Blocked Passage

Until recently, blockage of fish passage upstream of Condit Dam was the single greatest factor limiting salmon abundance and productivity in the White Salmon River watershed. When the dam was in place, fall Chinook salmon accessed only a small percentage of their historical spawning and rearing habitat in the watershed. While the area directly below the dam was not "blocked," the hydraulics and substrate composition of this habitat had changed rendering it unsuitable for spawning. With the removal of Condit Dam, the hydraulics and substrate composition is evolving and now can support natural spawning though the habitat and substrates directly influence by the Bonneville Dam pool continue to limit spawning. Bonneville Dam has also flooded 80 percent of the spawning area used by chum salmon (NPCC 2004).

Tributary Habitat

The upstream habitats are currently being re-occupied by anadromous fish now that access has been provided. Spawning and rearing habitat upstream of the dam may eventually limit anadromous salmonid population abundance in the White Salmon River. Opportunities exist to improve upstream habitats to support future population levels. Sections 5.2, Freshwater Habitat and 6.2, Freshwater Habitat Strategies and Actions, for further discussion on tributary habitat.

Hatchery Practices and Releases

Chinook salmon

Most of the fish spawning naturally in the White Salmon River were assumed to be hatchery-origin tule fall Chinook salmon based on CWT recoveries. Spring Creek NFH began marking all of its hatchery production in 2004 and as a result, recent spawning ground surveys have shown that the majority of the tule fall Chinook salmon returning to the White Salmon River are of natural origin (Roler 2011). Spring Creek NFH tule fall Chinook salmon were originally derived from White Salmon tule fall Chinook salmon and are anticipated to contribute to natural production now that Condit Dam has been removed. Stray upriver bright (URB) hatchery fall Chinook salmon may adversely affect productivity of the tule fall Chinook salmon in the White Salmon River. These hatchery-origin strays are from releases at the Little White Salmon (LWS) NFH, located 3 miles downstream from the White Salmon River, and other releases in and below the Bonneville Pool. No facility releases hatchery-produced Chinook salmon into the White Salmon River watershed.

Coho salmon

Biologists found coho salmon from past releases by the LWS NFH to stray into the White Salmon watershed. Coho salmon releases from LWS NFH ended in 2004. Biologists consider these strays along with releases from other upstream Columbia Basin hatchery programs as the source of naturally spawning coho salmon in the White Salmon River.

Chum salmon

There are no hatchery chum salmon programs releasing fish above Bonneville Dam, although some incubated at the Washougal Hatchery and released as fry into Duncan Creek may be among those that ascend the Bonneville ladders.

Steelhead

Releases of Skamania stock winter steelhead and summer steelhead may limit the diversity of any naturally produced winter steelhead in the watershed. Scientists consider neither as part of the LCR or MCR steelhead DPSs. Fisheries managers terminated the releases of Skamania stock hatchery steelhead in 2010 in anticipation of breaching Condit Dam.

Harvest

Harvest currently does not limit the abundance or diversity of White Salmon River populations of steelhead, spring Chinook salmon, coho or chum salmon. All of these populations are extirpated or functionally extirpated (Good et al. 2005; ICTRT 2007b). Any

coho salmon, chum salmon, steelhead, and spring Chinook salmon found in the White Salmon River are strays from other basins. To protect naturally produced coho salmon, spring Chinook salmon, fall Chinook salmon, and steelhead in the White Salmon River, sport fisheries may only retain hatchery fish that are adipose fin-clipped and release all unmarked salmon and steelhead https://fortress.wa.gov/dfw/erules/efishrules/ (accessed January 3, 2013). Ocean and mainstem fisheries heavily harvest fall Chinook salmon, and harvest rates are likely to affect the rate of population growth once additional habitat in the watershed becomes available (section 5.4, Harvest, for further discussion).

Federal Columbia River Hydrosystem

Much of the mainstem Columbia and Snake rivers' current conditions are altered compared to historic conditions. The development of hydropower and water storage projects within the CR Basin have resulted in the inundation of many mainstem spawning and shallow-water rearing areas (e.g., loss of spawning gravels and access to spawning and rearing areas); altered water quality (e.g., reduced spring turbidity levels), water quantity (e.g., seasonal changes in flows and consumptive losses resulting from use of stored water for agricultural, industrial, or municipal purposes), water temperature (e.g., including generally warmer minimum winter temperatures and warmer maximum summer temperatures), water velocity (e.g., reduced spring flows and increased cross-sectional areas of the river channel), food (e.g., alteration of food webs, including the type and availability of prey species), and safe passage (e.g., increased mortality rates of migrating juveniles and steelhead kelts) (Williams et. al 2005; Ferguson et. al 2005).

Model studies indicate that the hydrosystem has decreased the delivery of suspended particulate matter to the LCR and estuary by about 40 percent (as measured at Vancouver, Washington) and has reduced fine sediment transport by 50 percent or more (Bottom et al. 2005). Overbank flow events, important to habitat diversity, have become rare, in part because flow management and irrigation withdrawals prevent high flows and in part because diking and revetments have increased the "bankfull" flow level (from about 18,000 to 24,000 m3/s). The dynamics of estuarine habitat have changed in other ways relative to flow. With increasing flow, the availability of shallow (between 10 cm and 2 m depth), low-velocity (less than 30 cm/s) habitat now appears to decrease at a steeper rate than during the 1880s, and the flow absorption capacity of the estuary appears to have declined.

The CR Estuary Module, at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Estuary-Module.cfm (accessed April 11, 2012) provides more information on factors that may limit viability of anadromous salmonids in the CR Estuary.

Predation, Competition and Disease

Because of Bonneville Dam's reservoir habitat, the abundance of predatory native and exotic fishes in the lower river has increased. Primary predators of juvenile salmonids in the CR include northern pikeminnow, smallmouth bass, and walleye. Terns, cormorants, and sea lions also consume large numbers of salmonids.

Hatchery steelhead juvenile releases into the White Salmon River probably led to competition with any natural origin smolts produced below the former Condit Dam, but hatchery managers have terminated these releases. Hatchery adults that stray into the White

Salmon River may compete for spawning and rearing habitat. Spawning of later returning URB fall Chinook salmon can reduce the productivity of naturally spawning tule fall Chinook salmon through redd superimposition.

Researchers have reported BKD and Black Spot throughout the White Salmon watershed (Allen et al. 2006a, 2006b). Now that Condit Dam has been removed, diseased fish may introduce other pathogens and diseases into the watershed. The effects of disease on current or any potential future populations are unknown.

Ocean Conditions

The effects of ocean conditions on abundance of Pacific salmon and steelhead vary among species and populations within species. Migration patterns in the ocean may differ dramatically and expose different stocks to different conditions in different parts of the ocean. Ocean survival of salmonids has been dramatically affected by widespread changes in ocean conditions; smolt-to-adult survival rates generally vary 10-fold between good and bad years.

Climate Change

Climate change represents a potentially significant threat to recovery of White Salmon River salmon and steelhead populations. Changes in climate may adversely affect salmon and steelhead by exacerbating existing problems with water quantity (e.g., lower summer stream flow) and water quality (e.g., higher summer water temperatures) and could be detrimental to many populations of salmonids and native fish species throughout the CR Basin. Changing conditions could also affect salmonid health and survival in the ocean through a variety of mechanisms, including increased ocean temperatures, increased stratification of some waters, changes in the upwelling season, shifts in the distribution of salmonids, long-term variability in winds and ocean temperatures, increased acidity, and increased atmospheric and oceanic variability (NMFS 2008a, Supplemental Comprehensive Analysis Chapter 5), available at http://www.nwr.noaa.gov/Salmon-Hydropower/Columbia-Snake-Basin/upload/Final_SCA_Ch1_7.pdf (accessed April 11,2012). See also ISAB 2007.

Recovery Goals and Criteria

The primary goal of this plan is to restore White Salmon River salmon and steelhead populations to viable status. McElhany et al. (2000) defines a VSP as an independent population that has negligible risk of extinction over a 100-year timeframe.

The visions, goals, and actions of many of the parties involved in the White Salmon recovery planning process may go beyond ESA delisting. These visions for broad-sense recovery incorporate ESA delisting goals. During the process of achieving broad-sense recovery goals, NMFS could delist White Salmon River salmon and steelhead. Broad-sense recovery goals incorporate many local and traditional uses, including those associated with rural and Native American values, which are important in the Pacific Northwest.

Biological Viability Criteria

One of the main tasks assigned to the TRTs was to develop biologically based criteria for ESA-listed salmon and steelhead. Viability criteria identify characteristics and conditions that, when met, would describe viable populations and a viable ESU or DPS.

The TRTs based their approaches to recovery on guidance from the NMFS Technical Memorandum *Viable Salmonid Populations and the Recovery of Evolutionarily Significant* Units (McElhany et al. 2000). This memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels. In their VSP guidelines, McElhany et al. (2000) recommend that a viable DPS population should be large enough to:

- Have a high probability of surviving variation observed in the past and expected future
- Be resilient to environmental and anthropogenic disturbances
- Maintain genetic diversity
- Support/provide ecosystem functions

NMFS organized the viability guidelines provided by McElhany et al. (2000) around four major considerations: abundance, productivity, spatial structure, and diversity. ESU-level viability criteria consider the appropriate distribution and characteristics of component populations to maintain the ESU/DPS in the face of longer-term ecological and evolutionary processes (ICTRT 2005a). NMFS adopted the ICTRT and W/LC TRT-defined viability criteria as the biological criteria for delisting of the ESUs and DPS that include the listed White Salmon populations discussed in this Plan.

Recovery Strategy and Actions

Chapter 6 describes the recovery strategies for the White Salmon River salmon and steelhead populations. The recovery strategies for each population contain three key components: 1) reintroducing naturally produced salmon and steelhead into historical habitat upstream of the former Condit Dam, 2) improving and increasing habitat for salmon and steelhead production downstream of Buck Creek, 3) improving habitat upstream of Buck Creek in anticipation of the growth of anadromous populations. The Plan also recommends that harvest or hatchery actions do not impede efforts to improve salmon and steelhead viability.

Table ES-2 lists the strategies and actions proposed as an integrated approach to address limiting factors and threats to salmon and steelhead and achieve broad-sense goals in four categories: freshwater habitat, hatcheries, harvest, and hydrosystem operations.

The Plan also proposes a number of actions focused on data gathering and analysis. These efforts are needed to monitor the current population status and habitat conditions and to improve the likelihood that efforts to reintroduce salmon and steelhead in the White Salmon are efficient and successful.

Together, NMFS expects the proposed strategies and actions to increase abundance, productivity, spatial structure, and diversity of White Salmon River salmon and steelhead.

The strategies and actions build from past and current efforts to restore passage and improve habitat conditions in the watershed.

Introduction/Restoration of Anadromous Salmonid Populations

In anticipation of the removal of Condit Dam, the White Salmon Working Group, made up of Federal, state, and tribal fisheries managers, as well as representatives of PacifiCorp (Condit Dam operators), developed several options for the reintroduction of salmon and steelhead into the White Salmon River. The group fleshed out each option with a description of the biological basis for the approach, operational and maintenance needs, and monitoring and evaluation needs. For details about the options and considerations, see Appendix I.

Fall Chinook salmon Reintroduction Plan Options

1. Salvage adipose-fin present Coded-Wire-Tag (CWT) - negative tule fall Chinook salmon from the White Salmon River in the fall of 2010 to start tule fall Chinook salmon restoration.
2. The Spring Creek NFH would spawn adults and rear eggs. The hatchery would acclimate and release the resulting juveniles at White Salmon Ponds.
3. No salvage effort in the White Salmon River or at Spring Creek NFH.
4. Salvage adipose-fin present CWT - negative tule fall Chinook salmon returning to the White Salmon River and outplant above Condit Dam prior to removal.

The White Salmon Working Group recommended the outplant Option 4 because they believed habitat is currently available above Condit Dam that can support natural spawning tule fall Chinook salmon. The White Salmon Working Group completed the salvage of native fish in late summer and early fall of 2011 prior to breaching the dam.

Spring Chinook salmon Reintroduction Plan Options

1. Natural colonization, i.e. no reintroduction efforts from outside sources.
2. Wild Klickitat spring Chinook salmon as brood source for juvenile release into the White Salmon River. Eggs collected and reared at Klickitat Hatchery, juveniles acclimated and released at White Salmon Ponds.
3. Klickitat Hatchery spring Chinook salmon as brood source for juvenile releases into upper White Salmon River (from Klickitat Hatchery thinning release or other surplus juveniles).
4. Klickitat Hatchery integrated stock spring Chinook salmon as brood source for juvenile release into White Salmon River, in future years (broodstock source would be hatchery-reared offspring of wild fish).
5. Transport surplus Klickitat Hatchery adults to White Salmon River.
6. Trap and transport Klickitat wild adults to White Salmon River.
7. Monitor natural escapement and production for 4-5 years then evaluate need and suitability of Option 4.

The White Salmon Working Group recommended Option 7. Under this option Working Group members propose to monitor escapement of spring Chinook salmon into the upper White Salmon River, including the proportion of Carson stock hatchery spring Chinook salmon on the spawning grounds. The White Salmon Working Group will also monitor spring Chinook salmon smolt production in the upper White Salmon. The 4-5 year monitoring period will determine if natural production is occurring and the source of that production. The monitoring period will also allow time for the development of the Klickitat Hatchery integrated spring Chinook salmon program and determine whether production capacity at this facility is available. The White Salmon Working Group considered the Klickitat Hatchery spring Chinook salmon program the best source of broodstock for reintroduction, even though it is not part of the LCR Chinook salmon ESU. The two nearest populations of spring Chinook salmon within the LCR ESU are in the Lewis River in Washington and the Sandy River in Oregon. Each of these basins have spring Chinook salmon hatchery programs, but reintroduction efforts in the Lewis River Basin require current local production in the Lewis River is needed for reintroduction efforts in that basin, while broodstock collection and funding shortfalls constrain production in the Sandy River. The result is the unavailability of a suitable source of LCR spring Chinook salmon to support the reintroduction efforts in the White Salmon River.

Coho salmon Reintroduction Plan Options

1. Natural re-colonization, i.e., no reintroduction efforts from outside sources.
2. Juveniles from Washougal and/or Bonneville/Cascade hatcheries released into White Salmon River.
3. Collection of wild adult broodstock in Klickitat River with spawning and rearing at hatchery facility and juvenile release in White Salmon River.
4. Collection of wild adult broodstock in White Salmon River with spawning and rearing at hatchery facility and juvenile release in White Salmon River.
5. Monitor natural escapement and production for 4-5 years then evaluate need and suitability of Options 2, 3, or 4.

The White Salmon Working Group decided on Option 5 for coho salmon. As described for spring Chinook salmon, White Salmon Working Group members propose to monitor escapement, hatchery- and natural-origin coho salmon on the spawning grounds, and juvenile production in the White Salmon River watershed. Sources of stray hatchery coho salmon include releases from Bonneville Hatchery and releases into the Klickitat and the Umatilla river basins. All of these releases derive from hatchery programs that are part of the LCR coho salmon ESU. A recovery team will use the results of the monitoring to determine future reintroduction activities.

Chum salmon Reintroduction Plan Options

1. Natural re-colonization, i.e., no reintroduction efforts from outside sources.
2. Active adult outplanting in years after Condit Dam removal.

3. Active stocking of juvenile chum salmon or outplanting of eggs in egg baskets and hatch boxes via WDFW's Washougal Hatchery or Willard NFH.

4. Initiate provisional hatchery program for chum salmon using existing US Fish and Wildlife Service (USFWS) hatcheries (White Salmon Ponds) for spawning and subsequent outplanting using chum salmon captured at Bonneville Dam.

The White Salmon Working Group decided on Option 1 for chum salmon. The group chose this option because of the uncertainty regarding the status of chum salmon above Bonneville Dam. This option calls for expanded spawning ground surveys in the Bonneville Pool using the mainstem chum salmon spawning habitat criteria developed for the population below Bonneville Dam. Those conducting surveys should focus in the lower reaches of suitable tributaries and include habitat suitability assessments for the reservoir and the tributaries.

Steelhead Reintroduction Plan Options

1. Natural re-colonization, i.e., no reintroduction efforts from outside sources.

2. Wild donor from local watershed as brood source for juvenile release into the White Salmon River. Eggs collected and reared at suitable hatchery, juveniles acclimated and released at White Salmon Ponds.

3. White Salmon resident *O. mykiss* as brood source, with locally suitable anadromous wild donor stock spawned for juvenile release into upper White Salmon River.

4. White Salmon steelhead captive brood program using captured outmigrating juveniles.

5. White Salmon steelhead kelt reconditioning. Recondition local spawners to enhance survival.

Based on the potential to re-establish natural production of steelhead in the watershed, the White Salmon Working Group decided Option 1, natural re-colonization, was the best approach. The indication that the (resident) population of *O. mykiss* in the White Salmon River above the former Condit Dam still produces smolts, even though the construction of Condit Dam and the end of passage in 1919 eliminated anadromy, was the basis of the group's decision. Recent monitoring in the White Salmon River above Condit Dam has identified *O. mykiss* juveniles displaying smolt behavior and morphology. Passive Integrated Transponder (PIT)-tagged juveniles have been detected passing Bonneville Dam, with one being recovered at the tern colony on East Sand Island (B. Allen personal communication, 2007). In addition, biologists detected an individual juvenile *O. mykiss* PIT-tagged above Condit Dam in September 2004 at 98 mm and again as an adult ascending Bonneville Dam in July 2006. Genetic analysis of juvenile *O. mykiss* collected in the upper watershed above Husum Falls found differences from hatchery trout released in the watershed; additional samples are needed, however, to confirm this finding (Allen et al. 2006a).

Additional research by Carmichael (Ruzycki et al. 2003) in the Grande Ronde and by Thrower et al. (2004) in Alaska supports the theory that even though the population is functionally extirpated, there is some potential for re-establishing anadromous steelhead in the White Salmon River watershed. Using resident *O. mykiss* above the former Condit Dam could provide a genetic link to historical anadromous *O. mykiss*.

Restoration of Habitat Impacted by Condit Dam and Formerly Occupied by Northwestern Lake

At the time this document was prepared, PacifiCorp had breached the dam and was in the process of removing the structure. PacifiCorp is currently implementing numerous decommissioning management plans that address protection of aquatic biota, bank stabilization, management of sediment and erosion, revegetation, and several other projects. The condition of the habitat downstream of the dam and that habitat recently occupied by the dam will be unknown for a period of time. A Research, Monitoring and Evaluation (RM&E) entity will complete an assessment of habitat conditions after the dam is fully removed and stabilization efforts are complete. Based on this information, a proposed Washington Gorge Management Unit entity will identify priority restoration actions. These will likely include riparian planting and bank stabilization, as well as other actions to be determined.

Habitat Improvement Upstream of Buck Creek in Anticipation of Future Population Growth

Biologists have completed, or are in the process of completing, assessments of current habitat condition in the upper watershed (particularly Rattlesnake Creek). Based on this information, the Plan identified actions that would improve habitat in the upper watershed in anticipation of eventual anadromous fish population growth and occupation of existing habitat. Actions include placement of LWD, planting and management of riparian areas, improvements in passage, reduction of sediment inputs, reduction of anthropogenic effects on stream flow, and other actions.

Table ES-2. Recovery Strategies and Actions for White Salmon River Salmon and Steelhead Populations

Action Type	Specific Action(s)
Dam Removal and Species Reintroductions	
Complete dam removal	Complete removal of Condit Dam
Restore channel, stabilize banks, replant banks, and restore habitat in inundated area previously occupied by the reservoir, as well as the habitats impacted downstream of the former Condit Dam site	Implement PacifiCorp's Decommissioning Management Plans
	Restore channel mainstream above the former Condit Dam
	Restore riparian condition
	Dredge mouth of White Salmon River if needed
Restore populations	Implement reintroduction plan for the White Salmon River salmonids
Post-Dam Removal RM&E	
Baseline habitat data collection	Gather information needed to identify and prioritize habitat actions that will provide the greatest opportunity to contribute to recovery
Population monitoring: - Monitor population abundance and productivity	Install & maintain large multiplexing PIT-tag detectors in the lower White Salmon mainstem and in Buck & lower Rattlesnake creeks. Report findings
  - Monitor proportion and origin of hatchery salmon and steelhead on the spawning grounds	Implement population monitoring in the White Salmon River & major anadromous-accessible tributaries.
	Install two small stationary instream PIT-tag detectors in the lower most portion of Spring Creek

Action Type	Specific Action(s)
- Assess the resident trout contribution to smolts downstream of the former Condit Dam; assess change in resident population after steelhead re-colonization/reintroduction	Pit-tag 3,000 juvenile salmonid each year upstream and downstream of the former Condit Dam to track individual movement and seasonal growth rates
	Conduct adult spawning ground surveys and monitor
	Create and maintain fish counts & biological database
	Mark adults for mark-recapture population estimates
	Derive estimates of salmonid population abundance & complete reporting
- Genetic analyses	Compare adult and smolt genetic analyses to ongoing adult salmon escapement estimates of WDFW and smolt outmigration estimates of United States Geographic Survey (USGS) studies in the White Salmon River
Habitat Restoration	
Protect and conserve existing natural ecological processes	Protect existing habitat from future degradation through land use planning
	Protect existing habitat from future degradation though land management plans, conservation easements, acquisitions, re-classification of lands as natural areas
Restore vegetation along stream sections that exceed state standards for temperature	Identify stream segments that are excessively warm; within those areas, work with willing landowners to implement actions to increase density of riparian vegetation where sparse; implement programs to protect existing riparian vegetation, reduce sediment inputs to streams
Restore passage and connectivity to habitats blocked or impaired by artificial barriers	In cooperation with irrigation district and others, remove or replace barriers inhibiting upstream passage including dikes, culverts, and irrigation structures, provide/upgrade screening of irrigation diversions
	Indian Creek culvert replacement
Reduce nutrient inputs	Reduce runoff of nutrients from septic tanks, dairies, agricultural lands, and other sources
Improve LWD abundance and recruitment	In cooperation with landowners plan, design and install stable wood and other large debris in streambeds and develop approaches to ensuring long-term LWD recruitment
	In cooperation with landowners develop grazing strategies that promote riparian recovery
Invasive species	Eradicate invasive plant species from riparian areas
Restore channel	With willing landowners, stabilize stream banks, restore natural channel form, reduce sediment inputs as needed from roads
Reduce anthropogenic effects on stream flow	Quantify anthropogenic effects on stream flow and identify priority actions
	With willing landowners, implement water conservation measures
	Improve irrigation conveyance and efficiency
	Employ Best Management Practices (BMP)s with willing landowners
	Protect/restore springs with willing landowners
	Increase pool habitat
	Restore wetlands with willing landowners
	Hydrologically disconnect roads from streams

Action Type	Specific Action(s)
	Control road/stream interactions by reducing erosion potential
Public awareness	Public awareness regarding restoration projects and importance of wood in streams and riparian areas
Harvest	
Harvest management	Manage harvest for low impact fisheries and rapid anadromous fish population growth
	Adjust tributary harvest regulations in areas where harvest significantly impacts salmon and steelhead population growth
Hatcheries	
Reintroduction: Hatchery production	Rehabilitate White Salmon Ponds and update intake screen
Hydrosystem and Mainstem Predation	
Maintain or improve hydropower operations and facilities at Bonneville Dam to enhance salmon and steelhead survival	Decrease water travel time during smolt outmigration
Maintain or improve hydropower operations and facilities at Bonneville Dam to enhance salmon and steelhead survival	Improve operation of adult passage, maintain high standards of adult fish passage at Bonneville Dam
Reduce predation on salmonids	Reduce predation by pinnipeds, piscivores, cormorants and Caspian terns

Implementation and Cost Estimates

This plan provides specific management strategies and actions needed to address re-establishing viable anadromous salmonid populations in the White Salmon River watershed. These actions represent activities with the greatest potential for protecting and recovering salmon and steelhead, as well as for achieving broad-sense recovery goals. Implementation of recovery actions is not a one time or short-term initiative. The programs and actions will likely need sustaining, evaluating, adjusting, and augmenting over the full recovery period.

NMFS encourages the formation of a planning group for the Washington Gorge Management Unit, a forum or entity that would take responsibility for coordinating implementation of the White Salmon River Watershed Recovery Plan. Implementing the proposed recovery actions for MCR steelhead in the Washington Gorge Management Unit, which includes the White Salmon watershed, would be a primary task for a Washington Gorge Area Regional Board, subject to state, tribal, and local government concurrence and the opportunity for public involvement and comment.

Chapter 7 provides cost estimates developed by the Washington Gorge Implementation Team (WAGIT) for implementing the proposed habitat actions described in Chapter 6 for the White Salmon drainage. The Plan identified numerous RM&E actions. The results of studies will help to identify the priority actions within the watershed. The estimated RM&E actions will cost roughly $1,540,000 over a 5-year period. Implementation of PacifiCorp's decommissioning plans is estimated to cost $0.9 to $1.1 million. Additional actions could cost up to $15,100,000. The total cost over a 5-year period for restoring anadromous populations in the White Salmon River could be as much as $16,781,000. Funding is not yet available to cover $13,200,000 of this cost.

Monitoring, Research and Adaptive Management Framework

As part of implementing the White Salmon Recovery Plan, the proposed Washington Gorge Management Unit or another entity will design a detailed monitoring and evaluation program, which will be incorporated into an adaptive management framework based on the principles and concepts laid out in the NMFS guidance document, *Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance* (available at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Other-Documents.cfm (accessed April 11, 2012).

The White Salmon monitoring and evaluation program will build on existing programs designed for monitoring tributary habitat in the White Salmon River. Additionally, the program will provide 1) a clear statement of the metrics and indicators by which progress toward achieving goals can be assessed, 2) a plan for tracking such metrics and indicators, 3) a decision framework in which new information from monitoring and evaluation can be used to adjust strategies or actions aimed at achieving the Plan's goals.

1 Introduction

The ESA of 1973 requires NOAA's NMFS to develop recovery plans for species listed under the Act. The purpose of recovery plans is to identify actions needed to restore threatened and endangered species to the point where they are again self-sustaining elements of their ecosystems and no longer need the protection of the ESA.

This is a plan for the recovery of White Salmon River populations of fall Chinook salmon and steelhead, and for establishing or re-establishing spring Chinook salmon, coho, and chum salmon populations in the White Salmon River so that they can contribute to the conservation and survival of the threatened LCR Chinook salmon, LCR coho salmon, and CR chum salmon ESUs, and the threatened MCR steelhead DPS.[2]

The White Salmon River drains approximately 386 square miles in southwestern Washington and joins the CR at Underwood, Washington, CR RM 163 (See Figure 1-1).

Salmon and steelhead production in the White Salmon River watershed dropped significantly in the early 1900s after construction of Condit Dam at RM 3.3 on the White Salmon River. Although the original owners constructed Condit Dam with a fish ladder, high flows twice destroyed the ladder, which was not rebuilt after 1919. The dam blocked access to most of the historical range of both spring and fall Chinook salmon, steelhead, and coho salmon populations that once spawned in the watershed. PacifiCorp breached Condit Dam in October 2011 and is currently removing the dam. This recovery plan includes the proposal developed as part of the FERC decommissioning process to re-establish natural production of spring and fall Chinook salmon, coho, chum salmon, and steelhead in the White Salmon watershed, based on natural re-colonization of the habitat above the dam after removal is complete. In addition, the Bonneville Dam reservoir inundated much of the historical spawning habitat of the chum salmon population that historically spawned in the watershed (NMFS 2005). Some salmon and steelhead currently spawn and rear in accessible habitat below Condit Dam.

The watershed's native salmon and steelhead populations are not viable and their respective ESUs/DPSs are now listed for protection under the ESA. The MCR steelhead population in the White Salmon River is considered functionally extirpated (ICTRT 2008) and also the LCR spring Chinook salmon and coho salmon and the CR chum salmon are considered extirpated (Myers et al. 2006).

[2] An 'evolutionarily significant unit' (ESU) of Pacific salmon (Waples 1991) and a 'distinct population segment' (DPS) of steelhead (71 FR 834, January 5, 2006) are considered to be 'species,' as defined in section 3 of the ESA.

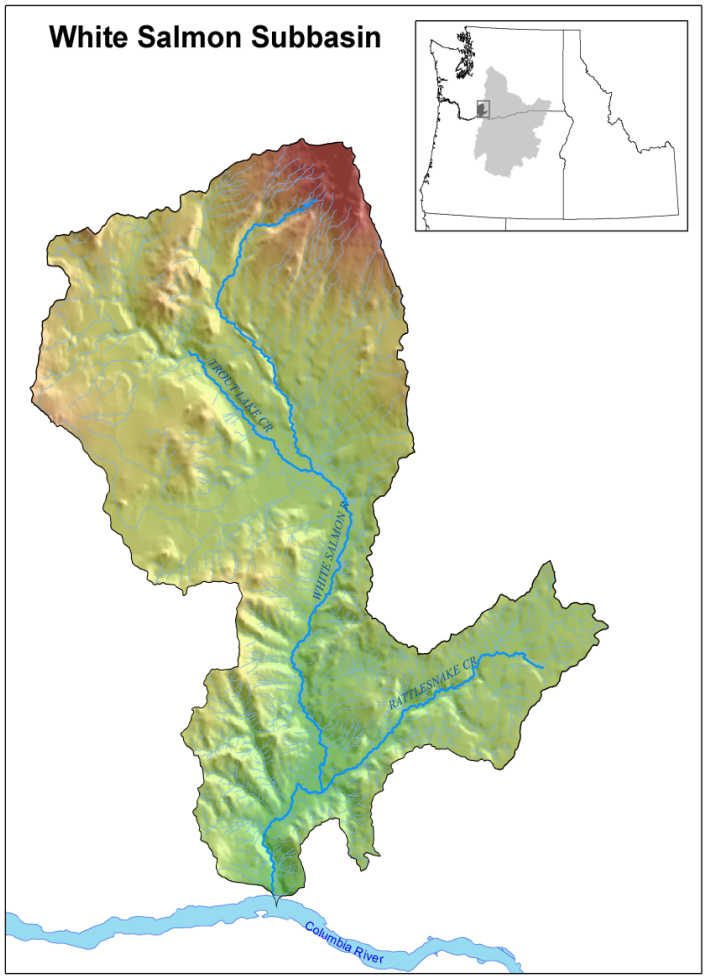

Figure 1-1. White Salmon watershed in Washington State

NMFS developed this recovery plan with participation and technical contributions from the YN, WDFW, Klickitat County, Washington State Governor's Salmon Recovery Office, other Federal and state agencies, local governments, and the public. While NMFS is the agency responsible for recovery planning for salmon and steelhead under the ESA, NMFS believes it is critically important to base ESA recovery plans for salmon and steelhead on the many state, regional, tribal, local, and private conservation efforts already underway throughout the region, and has attempted to do so in this plan.

1.1 Purpose of Plan

A recovery plan provides a roadmap for restoring a listed species or population to the point where it becomes a viable component of its ecosystem. Recovery plans are not regulatory; they are guidance for recovery efforts. This Plan describes the current status of the White Salmon River salmon and steelhead populations and their habitat in the White Salmon watershed. The Plan also identifies the major limiting factors and threats affecting the populations and proposes strategies and actions designed to aid in population recovery by building on past and current efforts. Finally, the Plan provides an implementation and

adaptive management framework for making needed future adjustments on the road to recovery.

1.1.1 ESA Requirements

Section 4(f) of the ESA requires that a recovery plan be developed and implemented for species listed as endangered or threatened under the statute. ESA section 4(a)(1) lists factors for re-classification or delisting, which are to be addressed in recovery plans:

a. Present or threatened destruction, modification, or curtailment of [the species'] habitat or range

b. Over-utilization for commercial, recreational, scientific, or educational purposes

c. Disease or predation

d. Inadequacy of existing regulatory mechanisms

e. Other natural or human made factors affecting its continued existence

ESA section 4(f)(1)(B) directs that recovery plans, to the extent practicable, incorporate:

a. Description of such site-specific management actions as may be necessary to achieve the Plan's goal for the conservation and survival of the species;

b. Objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this chapter, that the species be removed from the list;

c. Estimates of the time required and the cost to carry out those measures needed to achieve the Plan's goal and to achieve intermediate steps toward that goal.

Once a species is deemed recovered, and therefore removed from a listed status, section 4(g) of the ESA requires the monitoring of the species for not less than 5 years to ensure that it retains its recovered status.

1.1.2 Coordination with Others

This Plan has been developed to achieve consistency with other related planning and management efforts.

Federal Treaty and Trust Responsibilities

Northwest Indian Tribes have legally enforceable rights reserving to them a share of the salmon harvest. In the Treaties of 1855 between the U.S. Government and the Confederated Tribes of the Warm Springs Reservation of Oregon, the Confederated Tribes and Bands of the Yakama Indian Nation, the Confederated Tribes of the Umatilla Indian Reservation, and the Nez Perce Tribe, the tribes, in exchange for the preponderance of their lands, reserved the rights to fish within their reservations and "at all other usual and accustomed places." The usual and accustomed places are understood to include the millions of acres of aboriginal land ceded to the United States in the 1855 treaties, which extends to the upper Columbia and Snake River Basins, and includes most of the geographic range of the middle Columbia

steelhead DPS. A complex history of treaties, executive orders, legislation, and court decisions have culminated in the recognition of tribes as co-managers who share management responsibilities and rights for fisheries in the Columbia Basin.

Achieving the basic purpose of the ESA (to bring the species to the point that it no longer needs the protection of the Act) may not by itself fully meet these rights and expectations, although it will lead to major improvements in the current situation. Ensuring a sufficient abundance of salmon to sustain harvest is an important element in fulfilling trust and treaty rights as well as garnering public support for these plans. ESA and tribal trust responsibilities complement one another. Both depend on a steady upward trend toward ESA recovery and delisting in the near term, while making aquatic habitat, harvest, and land management improvements for the long-term.

It is appropriate for recovery plans to take these considerations into account and plan for a recovery strategy that includes harvest. In some cases, increases in the naturally spawning populations may be sufficient to support harvest. In others, the recovery strategy may include appropriate use of hatcheries to support a portion of the harvest. So long as the overall plan is likely to achieve the recovery of the listed ESU/DPS, it will be acceptable as a recovery plan.

The NMFS Regional Administrator, in testimony before the U.S. Senate Indian Affairs Committee (June 2003), emphasized the importance of this co-manager relationship: "We have repeatedly stressed to the region's leaders, tribal and non-tribal, the importance of our co-management and trust relationship to the tribes. NMFS enjoys a positive working relationship with our Pacific Northwest tribal partners. We view that relationship as crucial to the region's future success in recovery of listed salmon."

Treaty Indian fishing rights in the CR Basin are under the continuing jurisdiction of the U.S. District Court for the District of Oregon in the case of *U.S. v. Oregon*, No. 68-513 (filed in 1968). The parties to *U.S. v. Oregon* are the United States acting through the Department of Interior (USFWS and Bureau of Indian Affairs (BIA)) and Department of Commerce (NMFS), the Warm Springs, Umatilla, Nez Perce, Yakama, and Shoshone-Bannock Tribes, and the states of Oregon, Washington, and Idaho. In *U.S. v. Oregon*, the Court affirmed that the treaties reserved for the tribes 50 percent of the harvestable surplus of fish destined to pass through their usual and accustomed fishing areas.

The White Salmon watershed contains lands ceded to the United States by the YN in the Treaty of June 9, 1855. Within this area, the Tribe reserves the right "to hunt and fish at all usual and accustomed places." An in-lieu fishing site is located in the White Salmon River upstream of the bridge at the mouth. This location allows tribal fishers to launch boats in an enclosed area and move out into the CR to their usual and accustomed fishing sites.

Several historical seasonal encampments and fishing areas used by local Indian bands were located on the White Salmon and its tributaries. Historically, before European settlement of the area, significant fisheries and winter village sites were located at the mouth of the White Salmon, at Husum Falls, RM 7.6 and at the falls at BZ Corner, RM 12.4. Another important winter village was located at Trout Creek (Lane and Lane Associates 1981). The Yakama people occupied the entire Rattlesnake Creek drainage. Villages were located near the confluence of the White Salmon River and Rattlesnake Creek, and another approximately

four miles up the creek. The upper White Salmon watershed also contains current and historical huckleberry fields traditionally used by the YN. Archaeological sites throughout the area testify to the importance of the White Salmon watershed as a seasonal and perennial area of aboriginal use. Present day tribal groups whose treaty reserved fisheries were affected by Condit Dam are the Confederated Tribes and Bands of the Yakama Indian Nation, Confederated Tribes of the Warm Springs Reservation of Oregon, Confederated Tribes of the Umatilla Reservation of Oregon, and the Nez Perce Tribe of Idaho (Lane and Lane Associates 1981).

Other Federal, State and Local Responsibilities

To ensure consistency in goals, strategies, and actions and to eliminate duplication of effort, planners and program administrators have endeavored to achieve consistency between ESA recovery plans, the Northwest Power and Conservation Council (NPCC) fish and wildlife program, the State of Washington watershed management and salmon recovery programs, and local planning and regulatory efforts.

This Recovery Plan builds upon the White Salmon Subbasin Plan (NPCC 2004), which was developed for the NPCC by the YN, WDFW, and other Federal, state, and local entities. The Plan contains an assessment and inventory of fish and wildlife resources in the watershed, as well as a management plan identifying locally informed fish and wildlife protection and restoration priorities. The NPCC adopted the White Salmon Subbasin Plan into its Fish and Wildlife program. Additional scientific data are drawn from other more recent sources, including technical products developed by TRTs appointed by NMFS for the Interior Columbia and Willamette/lower Columbia Willamette lower Columbia recovery domains and studies completed by the YN Fisheries, the U.S. Geological Survey (USGS), USFWS, and the Underwood Conservation District (UCD).

This Plan is the product of a process initiated by NMFS, involving technical input from the YN, WDFW, Klickitat County, the Washington State Governor's Salmon Recovery Office, LCFRB, other Federal agencies, state agencies, local governments, and the public. The Plan's recovery strategy for White Salmon River salmon and steelhead includes recommendations by these parties.

1.2 Context of Plan Development

Currently, there are 18 ESA-listed ESUs/DPSs of Pacific salmon and steelhead in the Pacific Northwest. For the purpose of recovery planning for these species, NMFS Northwest Region designated five geographically based "recovery domains": Interior Columbia; W/LC; Puget Sound and Washington Coast; the Oregon Coast; and the Southern Oregon/Northern California Coast.

The White Salmon watershed is in an area of overlap between the Interior Columbia and W/LC recovery domains. Columbia River Chinook salmon, coho, and chum salmon are included in the W/LC domain. A run of fall Chinook salmon continues to exist in the watershed. Chum, coho and spring Chinook salmon are considered extinct, extirpated, or functionally extirpated (Myers et al. 2006).

The range of the middle Columbia River Steelhead DPS includes the White Salmon River watershed. The White Salmon River steelhead population is considered functionally extirpated. The entire recovery plan for the White Salmon River population of Middle Columbia River steelhead was not included in the *Middle Columbia River Steelhead Distinct Population Segment ESA Recovery Plan*. The Middle Columbia River plan explains that while the White Salmon watershed, which historically supported a population of Middle Columbia River steelhead, is part of the Washington Gorge management unit, the recovery plan for that population was being finalized as part of the *Lower Columbia ESA Recovery Plan*. The reason for including the White Salmon River population of Middle Columbia steelhead in the Lower Columbia ESA Recovery Plan was because the White Salmon River also includes single populations of three listed ESUs of salmon (Lower Columbia River Chinook and coho salmon and Columbia River chum). The need for an ecosystem approach warranted addressing all the listed salmonids that spawn in the White Salmon watershed in one plan. However, the delisting criteria, actions, and costs for the White Salmon River steelhead population are included in the Middle Columbia DPS plan in order to have all the information on the Middle Columbia steelhead DPS in one place. The Middle Columbia River steelhead DPS recovery plan will be updated to include the White Salmon Management Unit plan as an appendix. However, inclusion of the White Salmon Management Unit plan does not alter the recovery criteria articulated for the White Salmon River steelhead population in the Middle Columbia River steelhead DPS recovery plan.

Technical Recovery Teams (TRT)

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each TRT was to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. Both the W/LC TRT and the ICTRT did work relevant to the White Salmon populations. Each TRT included scientists from NMFS, states, tribal entities, academic institutions, and other Federal agencies.

All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population level viability criteria-criteria to be used, along with criteria based on mitigation of the factors for decline, to determine whether a species has recovered sufficiently to be downlisted or delisted. These principles are described in a NMFS technical memorandum, *Viable Salmon Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). VSPs are defined in terms of four parameters: abundance, productivity or growth rate, spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework and based on data availability, the unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective experience and expertise. Although NMFS has encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs are working from a common scientific foundation.

1.2.1 Planning Forum

In each of the W/LC and Interior Columbia recovery domains, NMFS has worked with state, tribal, local, and other Federal entities to develop planning forums that build to the extent possible on ongoing, locally led recovery efforts. NMFS defined "Management Units" based on jurisdictional boundaries as well as areas where local planning efforts were underway. The W/LC Domain has four management units: 1) Oregon, 2) Washington, 3) White Salmon and 4) Upper Willamette. The middle Columbia, a sub-domain of the Interior Columbia, also has four management units: 1) Oregon; 2) Washington Gorge, which, in turn, is subdivided into three planning areas; White Salmon, Klickitat, and Rock Creek; 3) Yakima Basin; 4) Southeast Washington.

NMFS works with recovery planning forums developed by the State. In Washington State these forums typically include representatives from state, tribal, local governments, and other stakeholders. The appropriate jurisdictions have not yet established a planning forum for the Washington Gorge Management Unit. Therefore, NMFS has worked independently with the YN, Klickitat County, WDFW, and local entities to develop the recovery plan for White Salmon River salmon and steelhead populations. NMFS encourages creation of a local planning forum that could provide guidance for further development and implementation of recovery plans for the Washington Gorge Management Unit.

1.3 How NMFS Intends to Use the Plan

Although recovery plans are not regulatory and their implementation is voluntary, they are important tools that help to do the following:

- Provide context for regulatory decisions
- Guide decision making by Federal, state, tribal, and local jurisdictions
- Provide criteria for status reporting and delisting decisions
- Organize, prioritize, and sequence recovery actions
- Organize research, monitoring, and evaluation efforts

NMFS will encourage Federal agencies and non-Federal jurisdictions to take recovery plans under serious consideration as they make the following sorts of decisions and allocate their resources:

- Actions carried out to meet Federal ESA section 7(a)(1) obligations
- Actions that are subject to ESA sections 4d, 7(a)(2), or 10
- Hatchery and Genetic Management Plans and permit requests
- Harvest plans and permits
- Selection and prioritization of basin and watershed planning actions
- Development of research, monitoring, and evaluation programs
- Revision of land use and resource management plans

- Other natural resource decisions at the state, tribal, and local levels

NMFS will emphasize recovery plans in ESA section 7 (a)(2) consultations, section 10 permits, and application of the section 4(d) rule by considering:

- Delisting criteria that address both viability and threats
- Description of limiting factors and threats (factors for decline)
- Description of a recovery program (site specific management actions necessary to achieve recovery of the species)
- Estimates of the time and cost to carry out measures to achieve the Plans' goals

In implementing these programs, recovery plans will be used as a reference and a source of context, expectations, and goals. Under section 7 of the ESA, NMFS staff will encourage the Federal "action agencies" to describe in their biological assessments how their proposed actions will affect specific populations, the limiting factors identified in the recovery plans, and any mitigating measures and voluntary recovery activities in the action area.

2 Biological Background

This chapter describes population and habitat characteristics for the White Salmon River salmon and steelhead populations. The chapter also discusses hatchery production and releases and harvest management in the White Salmon River watershed.

2.1 Populations and Major Population Groups

Lower Columbia River Chinook salmon

White Salmon River fall and spring Chinook salmon are included in the LCR Chinook salmon (*Oncorhynchus tshawytscha*) ESU, which NMFS listed as threatened on March 24, 1999, and reaffirmed on June 28, 2005. The ESU includes all naturally spawned populations of Chinook salmon in the CR and its tributaries from its mouth at the Pacific Ocean upstream to a transitional point east of Hood River in Oregon and the White Salmon River in Washington. The historical site of Celilo Falls on the CR is considered the transitional point for this ESU, since it may have been a migration barrier to Chinook salmon at certain times of year (Myers et al. 1998). The ESU exhibits three major life history types: fall-run (tules), late fall-run (brights), and spring-run. The White Salmon River historically supported two of these life history strategies: fall-run Chinook salmon tules (Figure 2-1), and spring-run Chinook salmon (Figure 2-2).

There is no direct documentation of a historical (pre-Condit Dam) population of naturally spawning spring Chinook salmon (Myers et al. 2006). Fulton (1968) speculated that tribal members historically caught Chinook salmon upstream of Husum Falls, which were likely spring Chinook salmon, citing Bryant (1949) and USFWS (1951). These reports, however, did not indicate direct observations. Evermann and Meek (1898) surveyed the White Salmon River in August and September. No Chinook salmon were observed in August, possibly due to conditions not being conducive to observation due to flooding from the CR and to investigating only the lower mile of the river. Additionally, LeMier and Smith (1955) interviewed a long time resident who was unable to confirm the presence of spring Chinook salmon in the watershed.

Even though documentation of direct observations of spring Chinook salmon by 20th-centery residents, Myers et al. 2006 determined, based on the historically available habitat, that spring Chinook salmon were historically present in the basin. The observation of a spring Chinook salmon redd above Husum Falls on September 20, 2012, further supports the historical presence of spring Chinook salmon in the basin (personal communication R. Engle, USFWS, 2012). The determination that the redd observed belonged to spring Chinook salmon was based on the timing of the redd (prior to tule fall Chinook salmon spawning), the size (too large for resident trout), and its location above Husum Falls (no fall Chinook salmon have been observed above Husum Falls).

LeMier and Smith (1955) evaluated the capacity of the White Salmon River to support salmon if passage was re-established. Under conditions existing in 1955, they estimated the river could support 732 spring Chinook salmon and 452 fall Chinook salmon, but noted that conditions in the White Salmon River were degraded substantially in 1955 relative to historical levels. Ecosystem Diagnosis and Treatment (EDT) modeling indicated the historic

potential abundance of fall Chinook salmon was roughly 775 adults. This figure is less than the estimated current potential without harvest, which suggests some error in the model assumptions or the reporting of results (Allen and Connolly 2005). The EDT modeling indicated the historic potential abundance of spring Chinook salmon was roughly 825 adults.

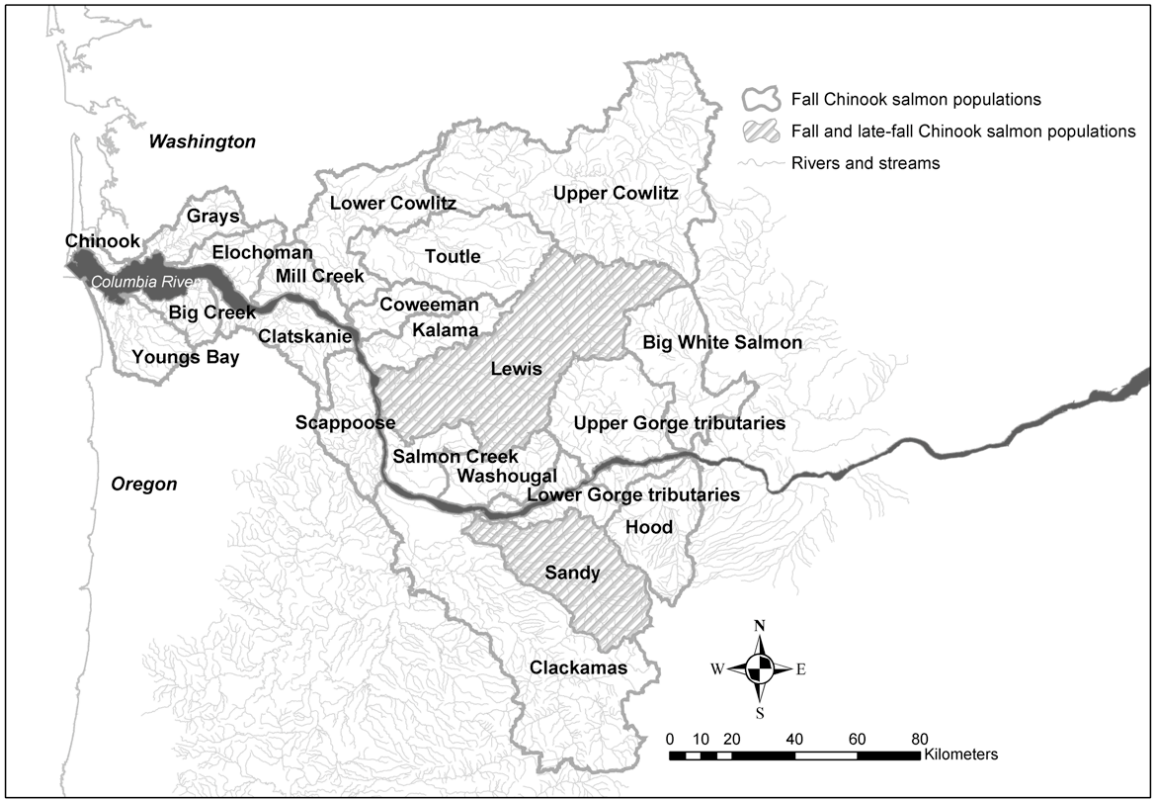

Figure 2-1. Historical fall and late fall demographically independent populations in the lower Columbia River Chinook salmon ESU (Myers et al. 2006)

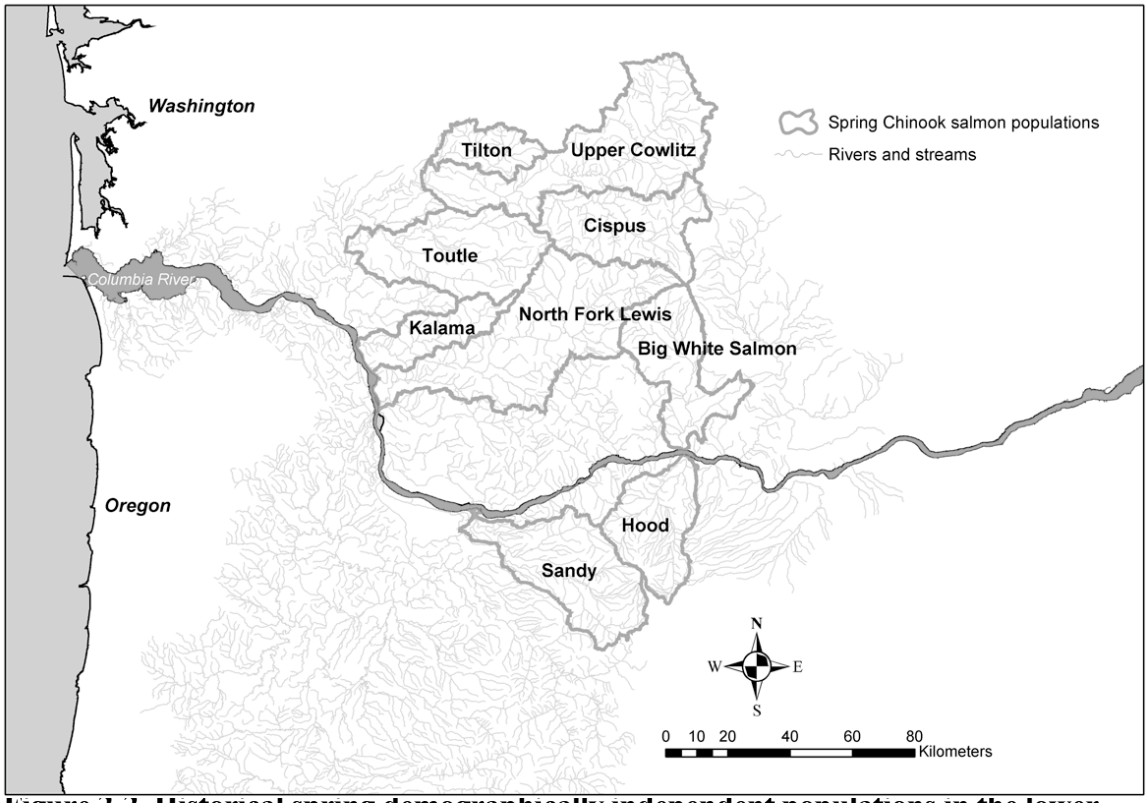

Figure 2-2. Historical spring demographically independent populations in the lower Columbia River Chinook salmon ESU (Myers et al. 2006)

Lower Columbia River coho salmon

White Salmon River coho salmon are part of the LCR coho salmon (*Oncorhynchus kisutch*) ESU, which NMFS listed as threatened on June 28, 2005. The ESU includes all naturally spawned coho salmon populations in the CR and its tributaries from the mouth of the CR to a transitional point east of the Hood River in Oregon and the White Salmon River in Washington (Figure 2-3). At the time of listing, biologists identified only two naturally spawning populations: the Sandy River and the Clackamas River populations in Oregon.

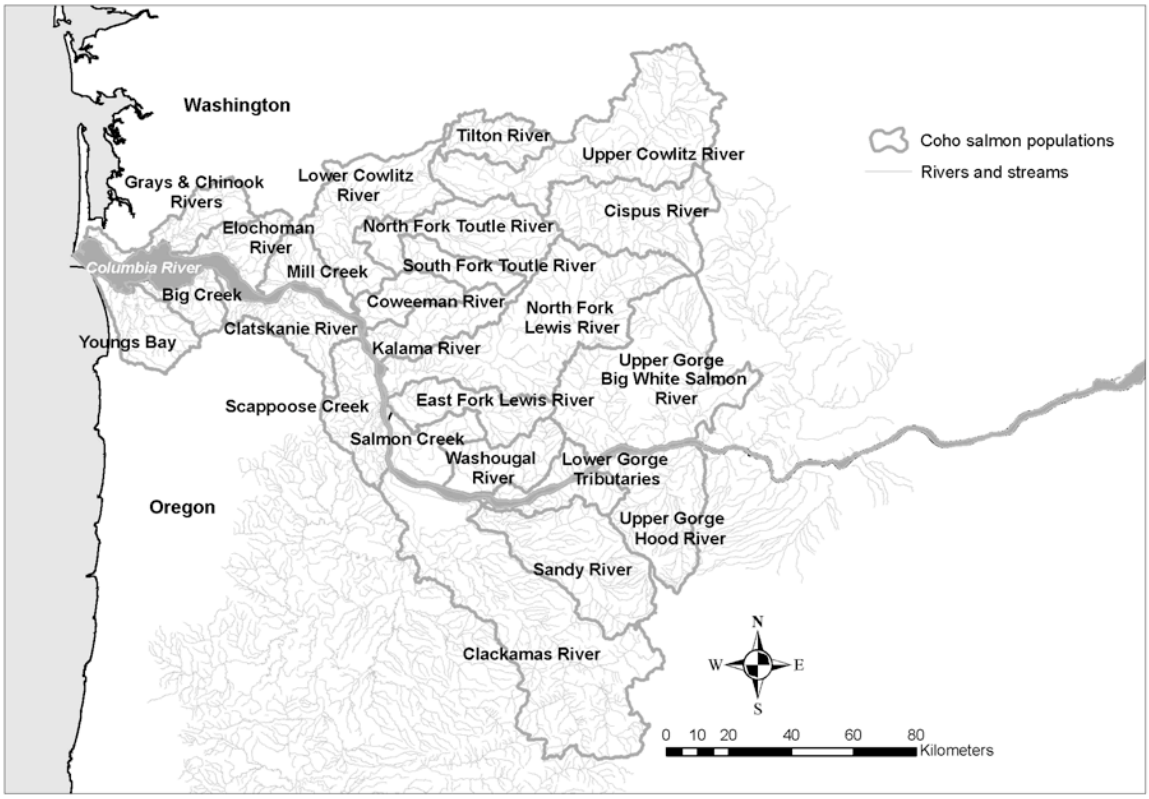

Figure 2-3. Historical demographically independent populations in the lower Columbia River Coho salmon ESU (Myers et al. 2006)

Columbia River chum salmon **-** White Salmon River chum salmon were part of the upper Gorge Tributaries population of CR chum salmon *(Oncorhynchus keta*) ESU, which NMFS listed as threatened on March 25, 1999, and reaffirmed on June 28, 2005. The ESU includes all naturally spawning populations in the CR and its tributaries in Washington and Oregon (Figure 2-4).

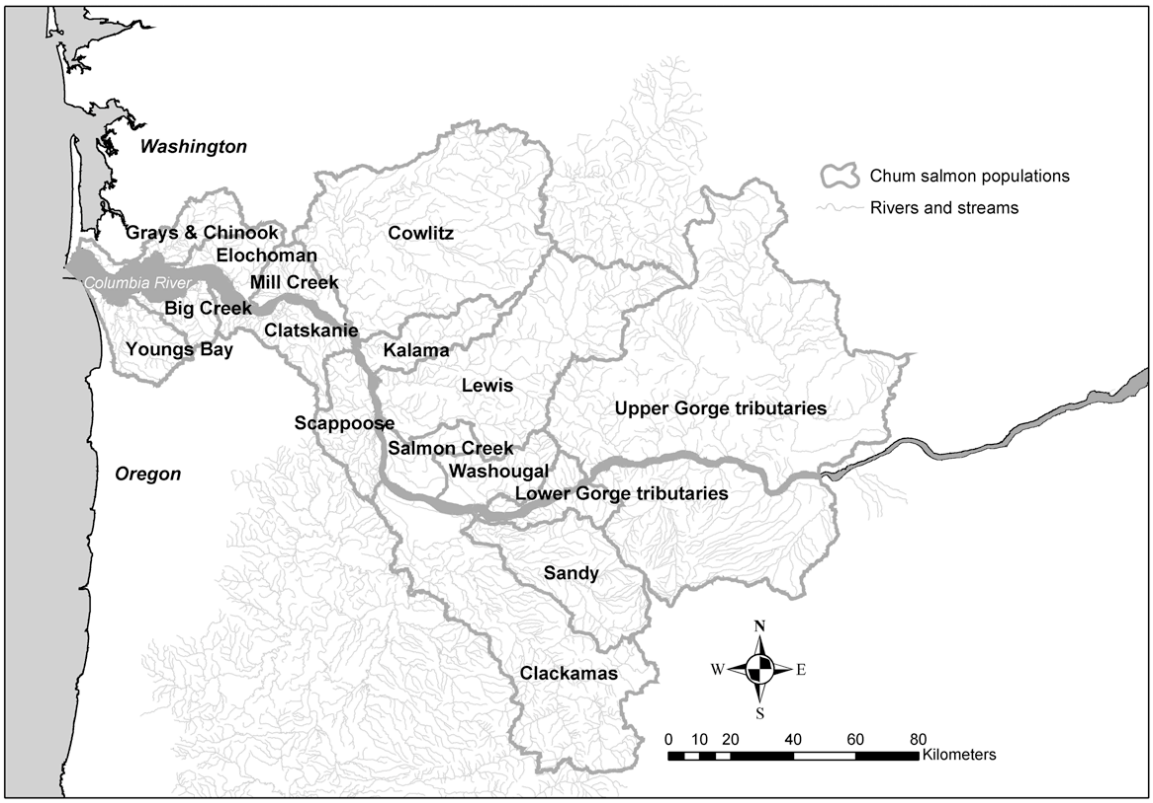

Figure 2-4. Historical demographically independent populations in the Columbia River chum salmon ESU (Meyers et al. 2006)

Middle Columbia River Steelhead

White Salmon River steelhead are part of the MCR Steelhead (*Oncorhynchus mykiss*) DPS, which NMFS listed as threatened on January 5, 2006. This DPS includes all naturally produced steelhead in the CR Basin upstream of the Wind River in Washington and the Hood River in Oregon (exclusive) to the Yakima River in Washington. Excluded are steelhead from the Snake River Basin (Busby et al. 1996). The MCR Steelhead DPS includes the only populations of inland winter steelhead in the United States (in the Klickitat and White Salmon rivers, Washington, and in Fifteenmile Creek, Oregon). The ICTRT identified 20 populations within the DPS (16 summer-run and 4 winter-run). In addition the ICTRT identified the historical populations that have been extirpated in Willow Creek due to dam construction in the Deschutes River Basin (ICTRT 2004). Figure 2-5 shows populations within the DPS. The White Salmon population was initially considered to be one of the extirpated populations, (however, later analysis defined the population as being functionally extirpated (ICTRT 2007b).

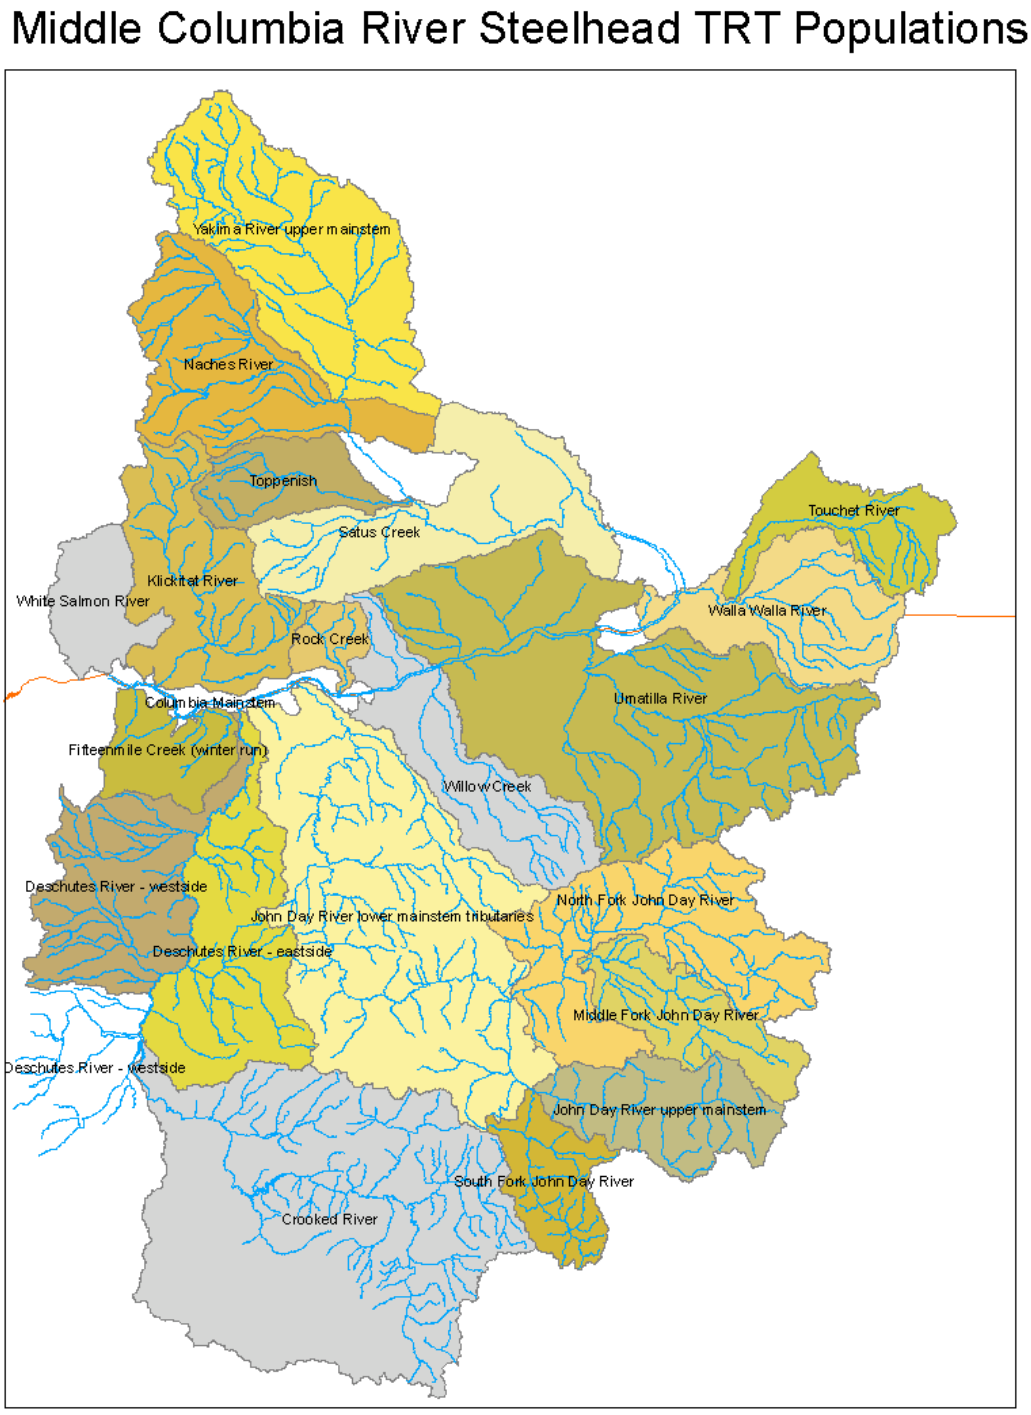

Figure 2-5. Historical summer and winter steelhead populations in the middle Columbia River DPS (ICTRT 2004; ICTRT 2007b). Note populations in gray are extirpated or functionally extirpated

2.2 Physical Setting

The White Salmon River watershed drains approximately 386 square miles in south central Washington. The river begins along the south slope of Mt. Adams and flows south 45 miles to enter the CR at Underwood, Washington at CR RM 168.3. Elevation in the watershed ranges from 12,307 feet on Mt. Adams to 72 feet at the river's mouth.

The White Salmon River watershed lies primarily within Klickitat County, however, the lower river below the top end of the former Northwestern Lake is shared with Skamania County, and the headwaters of the watershed also extend into Skamania and Yakima counties. These counties have a combined human population of 395,000 with less than 9,000 people living in the White Salmon watershed, http://www.ofm.wa.gov/pop/smallarea/default.asp (accessed April 11, 2012). The watershed falls within Washington State's WRIA 29b. Half of the watershed lies within the Gifford Pinchot National Forest and supports timber production and recreational uses.

Several reaches of the White Salmon River have received special designations because of their scenic value. The nine-mile reach from the confluence of Gilmer Creek near BZ Corner to Buck Creek was designated a Federal Wild and Scenic River in 1986. The upper White Salmon from the headwaters to the boundary of the Gifford Pinchot National Forest, and Cascade Creek from its headwaters to its confluence with the White Salmon River was designated as a National Wild and Scenic River in 2005. The reach from the former location of Condit Dam, RM 3.3, to the mouth is within the boundaries of the CR Gorge National Scenic Area. Recovery actions within these designated scenic areas should be coordinated with the U.S. Forest Service (USFS) to ensure the scenic values are maintained.

2.3 Ecosystem Conditions

The watershed lies within a transitional ecosystem area. Western portions of the watershed receive moderate to heavy precipitation. Eastern portions of the watershed are substantially more arid. Vegetation reflects this transitional location, with mixed forests covering about 95 percent of the watershed and grasslands and shrub steppe dominating remaining areas (Haring 2003). Trout Lake Valley, the major watershed valley, is surrounded by hills to the west and rolling plateaus to the east.

The White Salmon River and tributaries carve a watershed that is often rugged and steep, reflecting its past volcanic activity (Figure 2-6). From its headwaters, the White Salmon cuts sharply through mountains with precipitous cliffs and deeply incised canyons, dropping more than 5,000 feet in elevation before it reaches Trout Lake near RM 26, with a gradient change of 200 feet per mile (4 percent) between RM 35 and RM 30. The White Salmon loses another 1,800 feet in elevation from Trout Lake to the Columbia River. Gradient drops an average of 100 feet per mile (2 percent) from RM 17 to RM 12 as the river flows through a steep gorge with several falls. Tributaries between RM 7.6 and 16.3 are inaccessible to fish because of high falls at their mouths (NPCC 2004; WDFW and YN 1990).

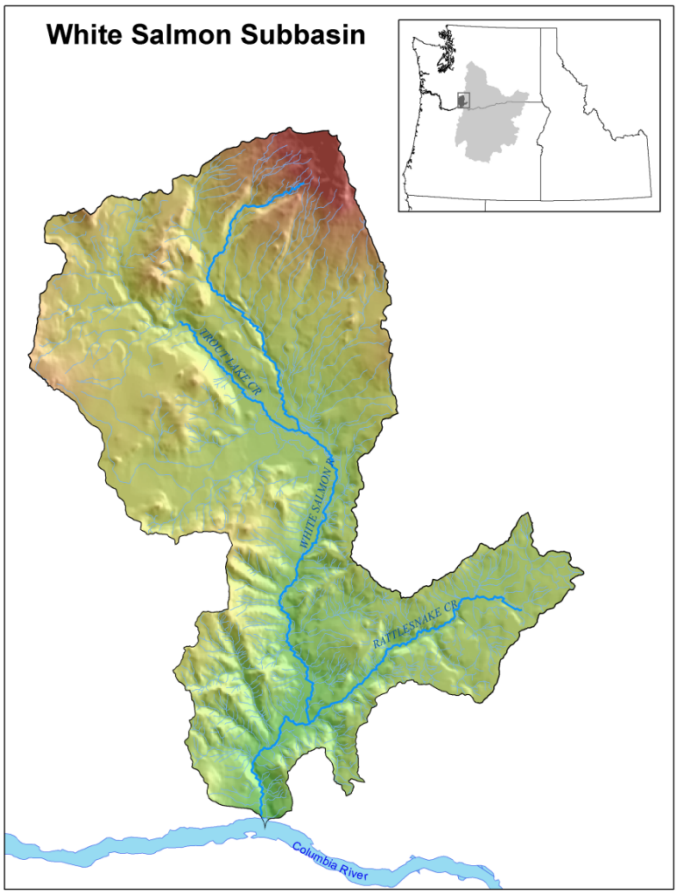

Figure 2-6. White Salmon River watershed topography and hydrology (NPCC 2004)

2.3.1 Hydrology

The White Salmon River mainstem naturally has a relatively constant natural flow pattern because of glacial melt, large water recharge, and storage capacity. Today this constant flow regime continues throughout the mainstem. Recharged water is released mostly in the middle portion of the mainstem canyon between the Trout Lake Valley and Husum Falls. Peak flows in the mainstem reflect snowmelt runoff, increasing from an average daily flow of 644 cfs during fall months to flows of 1,538 cfs in the spring (Haring 2003).

Operations at Condit Dam altered flows in the White Salmon River below the dam, causing flows to drop to as low as 15 cfs in the 1.1-mile bypass reach compared to natural flows of about 700 cfs. Power peaking at the dam affected the river system by causing diel flow variations and by impairing watershed processes, such as the transportation of spawning gravels and LWD to areas downstream of the project (NPCC 2004). The dam was breached in October, 2011 and flows will return to the natural condition as the final stages of dam removal are completed.

Tributary reaches of the White Salmon generally have more volatile flows than the mainstem, dropping to low levels in the summer and peaking in the winter. Some tributaries flow only during high flow events and are dry the remainder of the year (NPCC 2004). Some

of these tributaries may also be affected by exempted wells that can reduce recharge rates and flows.

2.3.2 Migration Barriers

Condit Dam, constructed at RM 3.3, was completed in 1913 and blocked upstream migration of anadromous fish since that time, as well as causing high mortality for outmigrating juveniles. The dam was breeched in 2011 and completely removed by October 2012. Anadromous salmonids now have complete access to habitat upstream of RM 3.3.

Prior to construction of the dam, the upstream limit of all anadromous fish migration in the White Salmon River, except for possibly Pacific lamprey, was the upper falls at Big Brother Falls, RM 16.2, which is approximately 29 feet high. Historic reports of steelhead occurring above Big Brother Falls (Lane and Lane Associates1981) were apparently large resident rainbow trout (*O. mykiss*) confused as being steelhead (Chapman et al. 1990; Bair et al. 2002). BZ Falls at RM 12.4, about 15 to 17 feet high, is likely to be the upstream limit for all salmonids, except for steelhead. Steelhead will likely be able to pass BZ Falls, but the upstream extent of the potential steelhead habitat will not extend beyond Big Brother Falls. Downstream of BZ Falls, Husum Falls, RM 7.6, was probably the historical barrier to fall-run Chinook salmon, sea-run coastal cutthroat trout, and perhaps coho salmon. Blasting shortly after the construction of Condit Dam reduced the height of the falls (Lane and Lane Associates 1981). In its current configuration, Husum Falls is not a barrier to the passage of adult resident or anadromous salmonids, except at low fall flows, and will likely be a barrier to the upstream passage of juvenile salmonids and adult chum salmon. Numerous barrier falls 4 feet in height or greater on the river between Husum and Big Brother Falls will be partial or complete barriers to the upstream migration of juvenile salmonids (LeMier and Smith 1955).

Barriers also restrict salmon and steelhead production in several White Salmon tributaries. With the exception of steelhead, and possibly coho salmon under ideal flow conditions, the falls at RM 1.5 on Rattlesnake Creek and RM 0.8 on Mill Creek will be barriers to upstream migration for all salmonids. A 4-foot high diversion dam at RM 1.9 on Buck Creek will be a barrier to the upstream migration of salmonids < 9 inches in length (Bair et al. 2002). A waterfall at RM 3.2 on Buck Creek and the hydro project dam at RM 0.7 on Spring Creek will be complete barriers to upstream salmonid migration, as is a double-fall (72-82 feet) at RM 10.6 on Rattlesnake Creek (Allen et al. 2003).

2.3.3 Riparian Function and Conditions

In comparison to other CR subbasins, the White Salmon watershed is lightly to moderately developed. However, historical logging practices, including mainstem splash damming, and associated road building and inappropriate riparian grazing have likely resulted in modification of flows, increased sedimentation, reduced riparian vegetation, loss of LWD, and increased summer temperature in some areas (NPCC 2004).

Until 1974, timber harvest typically extended to the edge of the stream/river. These practices were restricted in 1974 and have been further restricted in subsequent modifications of the Washington State Forest Practices Rules

http://www.dnr.wa.gov/Publications/fp_rules_history.pdf (accessed April 11, 2012). Additionally, the USFS prohibits harvest in riparian areas along fish bearing streams www.reo.gov/general/aboutNWFP.htm (accessed July 13, 2010).

Grazing has occurred since the late 1800s in the Rattlesnake Creek watershed and Trout Lake Valley, reducing native vegetation. Large historic marsh areas in the upper Rattlesnake Creek watershed were drained in the early 1900s to improve grazing conditions (Haring 2003). Today timber practices have improved, grazing is better managed, and wetland draining has stopped. Nevertheless, many impacts of past land use actions remain in the watershed (Haring 2003). Residential development is occurring with increasing frequency in the lower watershed and along State Route 141; however, construction within the riparian area is largely prohibited.

Some habitat areas in the White Salmon River and tributaries remain healthy, but land use activities affect many areas. EDT modeling results suggest that mainstem habitat is in better shape than tributary habitat, with maximum temperatures, minimum temperatures, and dissolved oxygen remaining at optimum levels (Allen and Connolly 2005). The EDT modeling was completed prior to removal of the dam in 2011, and the model results do not reflect current conditions in the former lakebed or downstream of the dam. New data collected since the modeling was completed indicate that temperature meets Washington state water quality standards throughout the anticipated anadromous range with the exception of Rattlesnake Creek, which occasionally approaches lethal temperatures in some locations in some years (White and Plumb 2004; White and Plumb 2005; White and Cochrane 2005; Connolly 2003; Morris 2005). Habitat surveys completed in the watershed indicate that large wood and pools are low in frequency throughout the Rattlesnake watershed and many of the existing pools are of poor quality (shallow with little cover) (Allen and Connolly 2006a). Unscreened diversions in some locations may potentially affect juvenile survival. Nutrient levels in many portions of the watershed are quite high, up to two times the EPA recommended standard (White and Plumb 2004, 2005; White and Cochrane 2005, Environmental Protection Agency (EPA) 2000).

2.4 Life History Characteristics

2.4.1 White Salmon River Chinook salmon

This section describes fall and spring Chinook salmon populations in the White Salmon River watershed.

Abundance and Productivity

The W/LC TRT recognizes two historical independent Chinook salmon populations in the watershed: White Salmon River fall-run Chinook salmon and White Salmon River spring-run Chinook salmon (Myers et al. 2003; Myers et al. 2006). These historical Chinook salmon populations are considered to be part of the Gorge stratum (or Major Population Group (MPG)) of the lower Columbia Chinook salmon ESU (Myers et al. 2006). These populations are described below.

Fall Chinook salmon

Biologists consider tule fall Chinook salmon native to the system, although the historical size of the fall-run to the White Salmon River is unknown. Past hatchery records indicate that fall-run Chinook salmon in the LWS and White Salmon rivers began spawning in early September, with peak egg takes in the later part of the month (September 21, 1901); 12,840,700 eggs were collected in 1901 (Myers et al. 2003; Myers et al. 2006; Bowers, 1902).

The current stock origin for the naturally spawning tule fall Chinook salmon is considered mixed (NOAA 2005). Hatchery tule fall Chinook salmon were last released in the White Salmon River in the 1980s, but strays are commonly recovered in the river (WDFW 2003). The Spring Creek NFH is located on the CR approximately one mile west of the mouth of the White Salmon River.

Most of the fish spawning naturally in the White Salmon River were assumed to be hatchery-origin tule fall Chinook salmon based on CWT recoveries. The USFWS (2004) estimated natural-origin fall Chinook salmon escapement in the White Salmon River by subtracting the hatchery component calculated by expanding the number of CWT recovered during carcass surveys by the Spring Creek Hatchery brood year tag rate from the total tule escapement (Figure 2-7). Spring Creek NFH began marking all of its hatchery production in 2004 and as a result, recent spawning ground surveys have shown that the majority of the tule fall Chinook salmon returning to the White Salmon River are of natural origin (Roler 2011). The total number of fall Chinook salmon spawners (natural-origin and hatchery) has averaged 2,750 from 1998-2007, even with low returns in the early 2000s (USFWS 2004; Roler 2009). The recent 10-year average (2002-2011) for escapement of natural spawning tule fall Chinook salmon in the White Salmon River has increased to 3,127 adults (Roller 2012). Smith et al. (2007) determined that Spring Creek NFH tule fall Chinook salmon and natural-origin fall tule fall Chinook salmon in the White Salmon were genetically similar and were distinct from other tule fall Chinook salmon populations in the LCR ESU. Natural spawning tule fall Chinook salmon were also found to have not interbred with URB fall Chinook salmon that also spawn in the White Salmon River (Smith and Engle 2011).

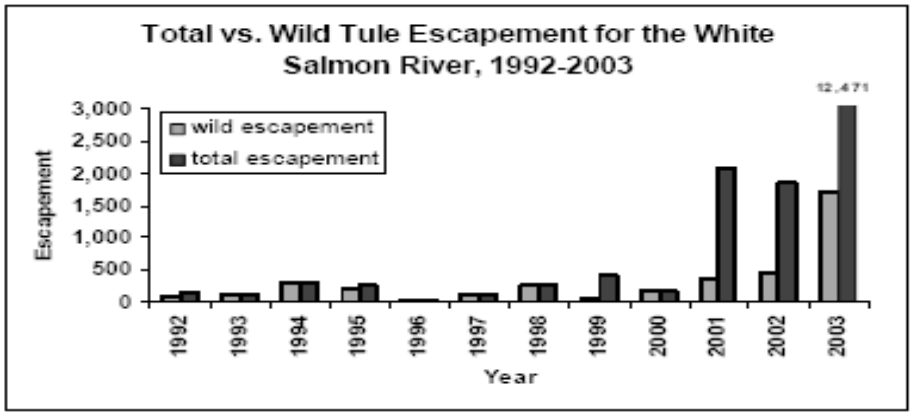

Figure 2-7. Wild and total tule fall Chinook salmon escapement for the White Salmon River from 1992-2003 (USFWS 2004)

Spring Chinook salmon

Biologists generally believe the White Salmon spring Chinook salmon population was historically significant, but declined to low numbers after construction of Condit Dam (LCFRB 2004). Fulton (1968) speculated that Chinook salmon historically caught by tribal members upstream of Husum Falls were likely spring Chinook salmon, citing Bryant (1949) and USFWS (1951) but these reports did not indicate direct observations of spring Chinook salmon. Evermann and Meek (1898) surveyed the White Salmon River in August and September and did not observe Chinook salmon in August, however, the conditions were not conducive to observation due to flooding from the CR, and only the lower mile of the river was investigated. If the life history timing of the White Salmon spring Chinook salmon were similar to other LCR spring Chinook salmon populations, adult spring Chinook salmon would be expected to be on the spawning grounds in the upper river during the month of August, not entering their natal river. Lane and Lane Associates (1981) document early indications of the presence or absence of spring Chinook salmon in the White Salmon River. Some of the persons interviewed remembered the presence of spring Chinook salmon, while others could not verify these observations. The W/LC TRT deduced that there was an historical population of spring Chinook salmon in the White Salmon River (Myers et al. 2006).

LeMier and Smith (1955) evaluated the capacity of the White Salmon River to support salmon if passage was provided upstream of Condit Dam. Under conditions existing in 1955, they estimated the White Salmon River could support 732 spring Chinook salmon and 452 fall Chinook salmon, but noted that conditions in the White Salmon River were degraded substantially in 1955 relative to historical levels. Chapman (1981), using instream flow measurements, estimated that in pristine conditions prior to the construction of Condit Dam the White Salmon River supported 625 adult Chinook salmon (spring and fall runs combined). Using similar methods, Young and Rybak (1987) estimated that the habitat upstream of Northwestern Reservoir could support 35,000 spring Chinook salmon smolts, and from 140 to 1,120 spring Chinook salmon adults. Chapman (1981) and Young and Rybak (1987) noted that the watershed has cool summer water temperatures and deep canyon pools, conducive to spring Chinook salmon holding and rearing. The EDT modeling effort estimated capacity for approximately 560 to 650 spring Chinook salmon in the watershed. W/LC TRT members generally believe that the construction of Condit Dam extirpated spring Chinook salmon in the White Salmon River and eliminated the genetic resources of the population (McElhany et al. 2004, p. 71). As recently as 2009, stray hatchery spring Chinook salmon have been observed holding and spawning below Condit Dam, but their reproductive success is unknown (McElhany et al. 2004; NPCC 2004; Engle et al. 2010).

Spatial Structure and Diversity

Prior to the construction of Condit Dam, spring Chinook salmon probably ranged up the White Salmon River to above Husum Falls, RM 12, and probably up to Big Brother Falls at RM 16.2 (Chapman 1981; Young and Rybak 1987). They may have also migrated into Rattlesnake Creek (NPCC 2004). Fall Chinook salmon were limited to spawning and rearing habitat below Husum Falls (NPCC 2004). This conclusion was confirmed using Radio-tagged adult fall Chinook salmon released above Condit Dam (Engle and Skalicky 2009).

Since 1913, Condit Dam has limited distribution for Chinook salmon to the 3.3-mile area below the dam. While the dam was in place, Chinook salmon spawned and reared in the lower White Salmon River below Condit Dam, (Figure 2.8). Most of these spawners were fall Chinook salmon and many were hatchery strays. In 2011, fisheries co-managers transported and released upstream of Northwestern Lake naturally spawning Chinook salmon entering the White Salmon River in order to preserve the year class. Any redds present downstream of the dam when it was breached would have been destroyed though scour and subsequent deposition of sediments.

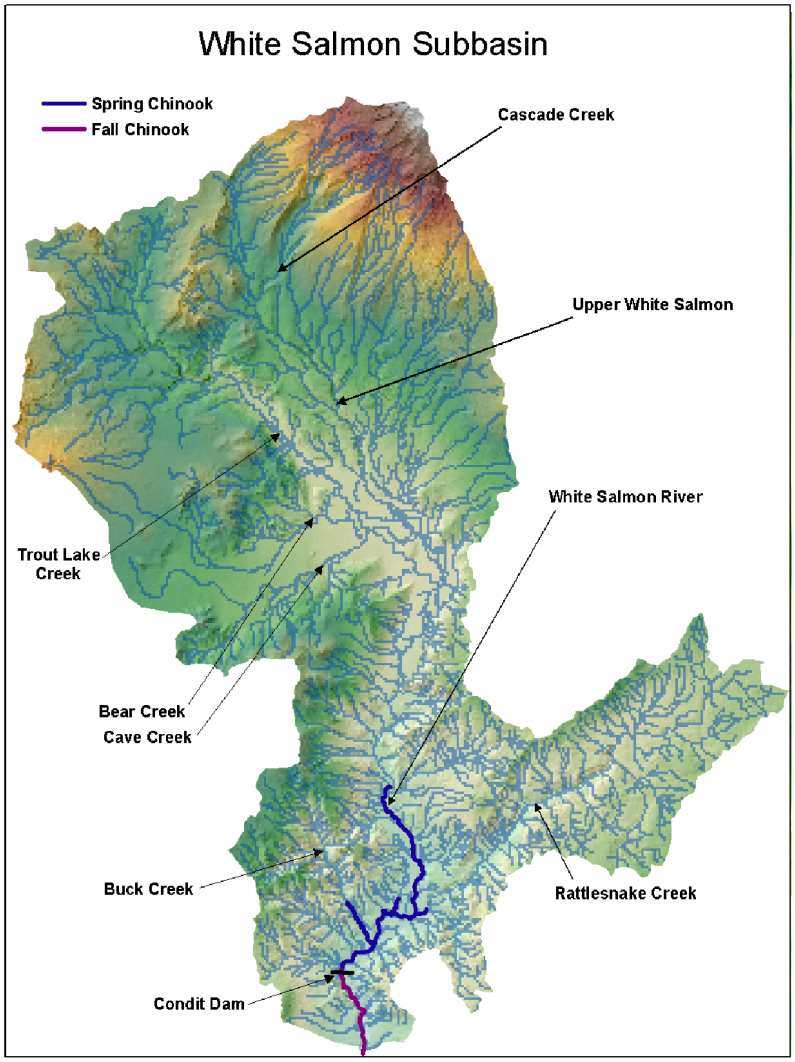

Figure 2-8. Possible extent of historic spawning distribution of Chinook salmon in the White Salmon River (NPCC 2004)

Key Habitat during Different Life Stages

Biologists consider White Salmon River fall-run Chinook salmon an ocean-type salmon because they migrate to the ocean as subyearlings. Tule Chinook salmon begin entering the CR in early August, with the greatest abundance in the estuary between late August and early September. Tule counts at Bonneville Dam generally peak between September 4 and

September 9. Most tules mature at age three, with very few five-year-olds. Fall Chinook salmon spawning in the White Salmon River peaks in late September through early October. The adults tend to spawn in mainstem rivers and large tributaries.

Since human activities have extirpated native spring-run Chinook salmon in the White Salmon River, scientists know little about their life history. Biologists would expect the historical spring-run Chinook salmon population to have a life history similar to other LCR ESU spring Chinook salmon populations. These spring Chinook salmon are a stream type because they primarily smolt as yearlings. Fecundity varies within and among Chinook salmon populations. Adult spring-run Chinook salmon enter the Columbia River from February to Mid-May and spawn from late July to late September (Fulton 1968).

Both fall and spring Chinook salmon generally spawn in stream reaches at least 10 feet wide. They construct redds in gravel and small cobble substrate in pool tailouts, riffles, and glides. Eggs remain in the gravel until emergence, which occurs from February to April depending on water temperatures. Emerging fry seek out shallow, low velocity areas in the stream channel, preferring backwater and dammed pools, along with glides. Shortly after fry colonization, however, tule fall Chinook salmon juveniles begin their outmigration, while the spring Chinook salmon juveniles can continue rearing until October. During the inactive or overwintering life stage, spring Chinook salmon juveniles prefer non-turbulent deeper water habitat types (primary pools) in the main channel, but also use slower portions of large cobble riffles. Yearling spring Chinook salmon outmigrate during the following spring.

Table 2-1 shows key habitat for fall and spring Chinook salmon during different life stages.

Table 2-1. Key habitat by life stage and time period for fall/spring Chinook salmon (NPCC 2004)

Life Stage	Relevant Months	Key Habitat Descriptions
Spawning	Tule Sep-Oct Spring Aug-Sep	Riffles, tailouts, and the swifter areas in glides containing a mixture of gravel and cobble sizes with flow of sufficient depth for spawning activity
Incubation	Aug-May	Riffles, tailouts, and the swifter areas of glides as described for spawning with sufficient flow for egg and alevin development
Fry Colonization	Feb-May	Shallow, slow velocity areas within the stream channel, including backwater areas, often associated with stream margins and back eddies and usually in relatively low gradient reaches
Active Rearing	Tule Feb-June Spring Mar-Oct	Relatively slow water habitat types, often near velocity shears, often associated with relatively low gradient stream channel reaches, including primary pools, backwaters, tailouts, glides, and beaver ponds
Inactive Rearing	Oct-Mar	Non-turbulent habitat types, particularly deeper water types within the main channel, but also including slower portions of large cobble riffles
Migrant	Tule, Age 0 Mar-Jun Spring, Age 1 Mar-May	All habitat types having sufficient flow for free movement of juvenile migrants

Life Stage	Relevant Months	Key Habitat Descriptions
Pre-spawning Migrant	Tule Aug-Oct Spring Feb-Sep	All habitat types having sufficient flow for free movement of sexually mature adult migrants
Pre-spawning Holding	Tule Aug-Oct Spring Aug-Sep	Relatively slow, deep water habitat types typically associated with (or immediately adjacent to) the main channel

2.4.2 White Salmon River coho salmon

Myers et al. (2006) included the historic coho salmon population in the White Salmon River as part of the Gorge Stratum within the lower Columbia coho salmon ESU. This section describes the White Salmon River coho salmon population.

Abundance and Productivity

The W/LC TRT determined that coho salmon are native to the White Salmon River based on habitat and historical presence of coho salmon in other CR gorge tributaries (Myers et al. 2006). Rich (1938) indicated that only a very small portion of the total CR coho salmon run migrated beyond Bonneville Dam. None of the early surveys of fisheries identified coho salmon in the White Salmon River, although the timing of these surveys did not coincide with coho salmon presence. Interviews with long-term residents and notes found in diaries indicate that coho salmon were likely present, but in low numbers (Lane and Lane Associates 1981; Cobb 1924).

Chapman (1981), using instream flow measurements, estimated that in pristine conditions prior to the construction of Condit Dam the White Salmon River supported 5,489 adult coho salmon. Young and Rybak (1987) estimated that the habitat could support 45,000 coho salmon smolts, and from 1,600 to 2,300 coho salmon adults. Scientists consider the current population in the White Salmon River extirpated (Johnson et al. 1991; Weitkamp et al. 1995; Schiewe 1996; Good et al. 2005). Good et al. (2005) suggested that recovery efforts could use existing hatchery programs to build naturally spawning populations. Currently, the size of this population is unknown. In a 2004 population status evaluation, W/LC TRT members found insufficient data to determine the productivity and abundance of the White Salmon River coho salmon population (McElhany et al. 2004). Some members noted that construction of Condit Dam probably resulted in the population's extirpation, as most historical spawning habitat for the population lies above the dam. Myers et al. (2006) in designating the historical population structure for coho salmon in the Gorge strata identified two populations above Bonneville Dam: Oregon tributaries and Hood River and Washington tributaries and the White Salmon River (including the Wind River, Spring Creek, and the LWS River).

The LCFRB Recovery Plan (LCFRB 2004) proposed an abundance goal for recovery of 150 fish. However, potential production estimates for coho salmon in the White Salmon River, completed for the NPCC subbasin planning (Allen and Connolly 2005; NPCC 2004) and for other efforts (Chapman et al. 1990; Washington Department of Fisheries (WDF) 1990) suggest that the drainage could support 950 to 2,300 coho salmon, if decision makers and scientists are able to restore passage to historical habitats above the dam.

Spatial Structure and Diversity

With the removal of Condit Dam, habitat that could potentially support coho salmon extends from the mouth up to RM 14 in the mainstem and into Buck, Spring, Indian, and Rattlesnake creeks (Figure 2-8) (NPCC 2004). This range may provide up to 21 miles of spawning and rearing habitat for coho salmon, with most potential spawning habitat above the location of

the former Condit Dam. Prior to breaching the dam, hatchery strays occasionally use the area below Condit Dam (NPCC 2004).

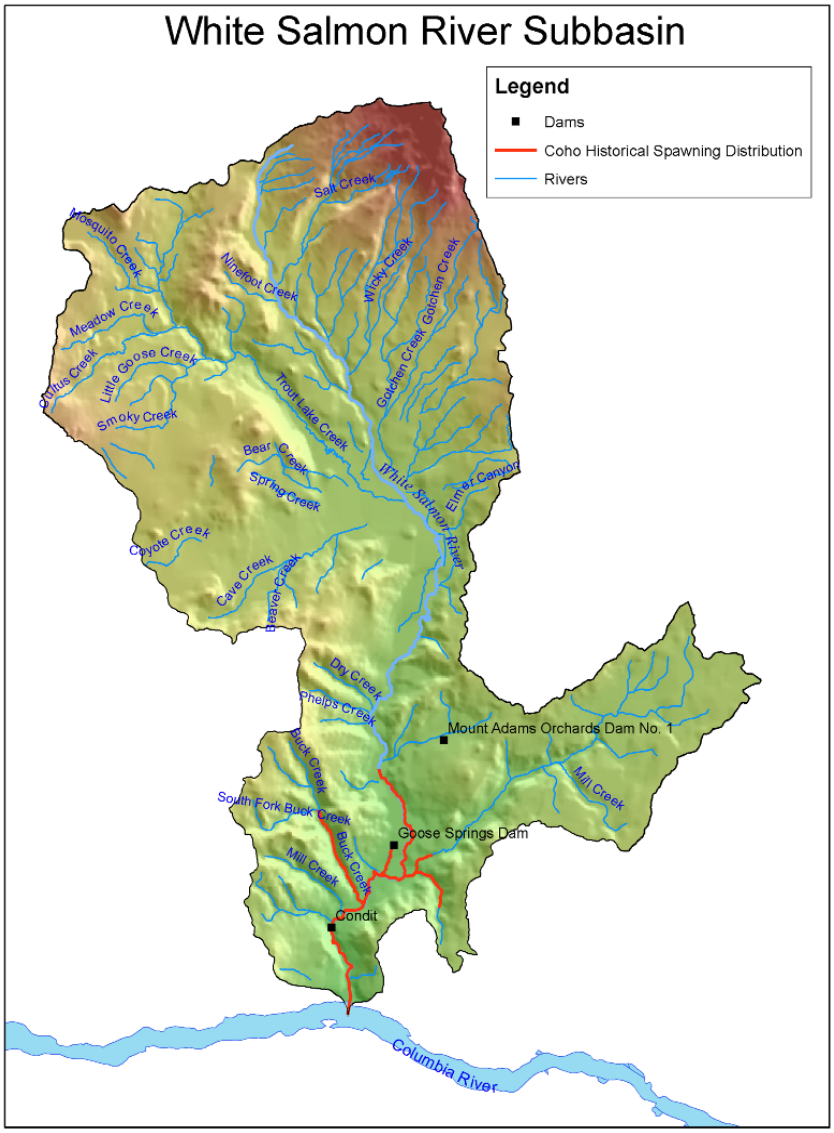

Figure 2-9. Potential extent of historical spawning distribution of coho salmon in the White Salmon River (McElhany et al. 2004)

Key Habitat during Different Life Stages

LCR coho salmon adults typically return to their spawning rivers from September through November, and typically spawn from October through January, with peak activity in November. Redds are constructed in gravel and small cobble substrate in pool tailouts, riffles, and glides, with sufficient flow depth for spawning activity. The eggs incubate in the gravel from October to May and generally emerge from February to April, depending on water temperatures. Emerging fry migrate to shallow, low velocity areas, which are associated with stream margins and back eddies.

After fry colonization, juvenile coho salmon seek out slow water habitat types near velocity shears, which are often associated with relatively low gradient stream reaches where they continue rearing until October. Preferred areas are primarily backwater and dammed pools. As winter approaches, juveniles become inactive and prefer off channel pool habitat over primary pool habitat for overwintering. Coho salmon yearling migration occurs the following spring, peaking in May.

Table 2-2 describes key habitat by life stage.

Table 2-2. Key habitat by life stage and time period for White Salmon River coho salmon (NPCC 2004)

Life Stage	Relevant Months	Key Habitat Descriptions
Spawning	Oct-Jan	Riffles, tailouts, and the swifter areas in glides containing a mixture of gravel and cobble sizes with flow of sufficient depth for spawning activity
Incubation	Oct-May	Riffles, tailouts, and the swifter areas of glides as described for spawning with sufficient flow for egg and alevin development
Fry Colonization	Mar-May	Shallow, slow velocity areas within the stream channel, including backwater areas, often associated with stream margins and back eddies and usually in relatively low gradient reaches
Active Rearing	0-age Mar-Oct 1-age Mar-May	Relatively slow water habitat types, often near velocity shears, often associated with relatively low gradient stream channel reaches, including primary pools, backwaters, tailouts, glides, and beaver ponds
Inactive Rearing	Oct-Mar	Non-turbulent habitat types, particularly deeper water types within the main channel, but also including slower portions of large cobble riffles
Migrant	Mar-May	All habitat types having sufficient flow for free movement of juvenile migrants
Pre-spawning Migrant	Sep-Nov	All habitat types having sufficient flow for free movement of sexually mature adult migrants
Pre-spawning Holding	Oct-Dec	Relatively slow, deep water habitat types typically associated with (or immediately adjacent to) the main channel

2.4.3 Upper Gorge chum salmon

This section describes the segment of the upper Gorge chum salmon population that historically occupied the White Salmon River.

Abundance and Productivity

Chum salmon that returned to the White Salmon River were part of the upper Gorge Tributaries population (McElhany et al. 2004). Annual fish passage reports by the U.S. Army Corps of Engineers (USACE) (2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008), for Bonneville Dam provided data that adult chum salmon continue to pass upstream of Bonneville Dam, with adult counts averaging 139 from 2000 to 2008 and ranging from a

low of 49 to a high of 411. Recent chum salmon surveys by WDFW have identified fewer than five chum salmon carcasses above Bonneville Dam annually; no carcasses were observed in 2005 (Jenkins 2006), however researchers in Oregon observed chum salmon spawning at the mouth of Eagle Creek above Bonneville Dam in 2008 and 2009 (M. Weeber, personal communication 2010). Today, chum salmon are limited almost exclusively to habitats downstream of Bonneville Dam, with most spawning in Washington waters.

Biologists know little about the chum salmon production potential of the LCR or the White Salmon River. Chum salmon fecundity data are variable. In North America, the literature reports individual fecundity ranged from 2,018 to 3,977 eggs per female (Salo 1991). Fecundity data are available for wild chum salmon in the LCR, but not for the White Salmon River. Chum salmon broodstock collected from the lower Gorge population in 2007 had an average fecundity of 2,255 eggs and a range of 1,630 to 2,922 eggs (Hillson 2009).

In the upper Gorge Tributaries population, researchers assumed a 96 percent reduction in abundance due to the existence and operation of Bonneville Dam. They assumed impacts to be predominantly due to inundation of historical habitat by the reservoir (see spatial structure and diversity below), but to include about 5 percent passage mortality for juveniles and an additional 3 percent for adults (Tables 14-1 and 14-2 in NMFS 2008b).

Spatial Structure and Diversity

Small et al. (2006) analyzed genetic samples from populations in the coast, cascade, and gorge regions of the CR chum salmon ESU. They found significant heterogeneity in genotype distributions between zones and that collections formed regional groups in a neighbor joining tree. Cascade collections had higher allelic richness and private alleles, and the Cowlitz River supported genetically divergent fall and summer runs, the only summer chum salmon run extant in the CR drainage. They propose that chum salmon in the Cascade zone are remnants of original populations and they attributed the divergence between zonal groups to diverse ecological conditions in each zone, which promoted regional genetic adaptation, and to genetic drift experienced in small populations. No information is available regarding the historical diversity for chum salmon in the White Salmon River.

In the White Salmon River, the pool behind Bonneville Dam has inundated approximately 80 percent of the historical chum salmon spawning habitat, rendering it unusable (NPPC 2004).

Key Habitat during Different Life Stages

Chum salmon usually spawn in lower river reaches, dig their redds in the mainstem, tributaries or in side channels and tend to use shallower, slower running streams and side channels more frequently than do other salmonids. Water velocity in spawning areas varies widely for chum salmon. In Washington, Johnson et al. (1991) measured water velocities near 1,000 chum salmon redds and found that velocities where fish spawned varied from 0.0 to 5.5 ft/sec (0.0 to 167.6 cm/sec), and that over 80 percent of the fish spawned in velocities between 0.7 and 2.7 ft/sec (21.3 and 83.8 cm/sec). This range is similar to that found in other species of salmon.

One detectable difference between chum salmon populations in different areas is the time it takes for eggs to incubate, hatch, and emerge as alevins from the gravel. Differences

between populations are caused by physical factors such as stream flow, water temperature, dissolved oxygen, and gravel composition, and by such biotic factors as genetics, spawning time, and spawning density, all of which can affect survival (reviewed in Bakkala 1970; Salo 1991). Scientists believe water temperature has the most influence on the rate of embryonic development in chum salmon (reviewed in Bakkala 1970; Koski 1975; Salo 1991). The amount of heat, measured in Thermal Units (TUs), required by fertilized chum salmon eggs to develop and hatch is about 400-600 TUs, and the heat required to complete yolk absorption is about 700-1,000 TUs. Lower water temperatures can prolong the time required from fertilization to hatching by 1.5-4.5 months.

Chum salmon do not typically have substantial freshwater rearing time. Most chum salmon juveniles begin seaward migration with minimal time spent in natal streams. Consequently, the period of estuarine residence appears to be the most critical phase in the life history of chum salmon and may play a major role in determining the size of the subsequent adult-run back to fresh water. Chum salmon juveniles, like other anadromous salmonids, use estuaries to feed before beginning long distance oceanic migrations. However, chum salmon and ocean-type Chinook salmon usually have longer residence times in estuaries than do other anadromous salmonids (Dorcey et al. 1978; Healey 1982).

Biologists know little about the seaward migration of juvenile chum salmon from the Columbia River. Generally, however, researchers find migration of chum salmon juveniles out of estuaries appears to closely correlate with prey availability (LCFRB 2004). For information about conditions in the CR Estuary and how chum salmon may be affected, see the Proposed CR Estuary ESA Recovery Plan Module for Salmon & Steelhead http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Estuary-Module.cfm (accessed April 11, 2012).

2.4.4 White Salmon River steelhead

Oncorhynchus mykiss, of which steelhead and rainbow trout are members, displays a wide variety of life history strategies (Busby et al. 1996). Anadromy is not obligatory in *O. mykiss*, but scientists extensively debate the heritability of anadromy (Rounsefell 1958; Mullan et al. 1992). Progeny of anadromous steelhead can spend their entire lives in freshwater (residualize), while progeny of rainbow trout can migrate seaward. The White Salmon River watershed supports both forms of *O. mykiss*. Although rainbow trout are not in the MCR steelhead DPS, genetic analysis shows that White Salmon steelhead and rainbow trout are an inland race of *O. mykiss* (Phelps et al. 1990; Phelps et al. 1994). The White Salmon population is as part of the Cascade Eastern Slope Tributaries MPG (Figure 2-10).

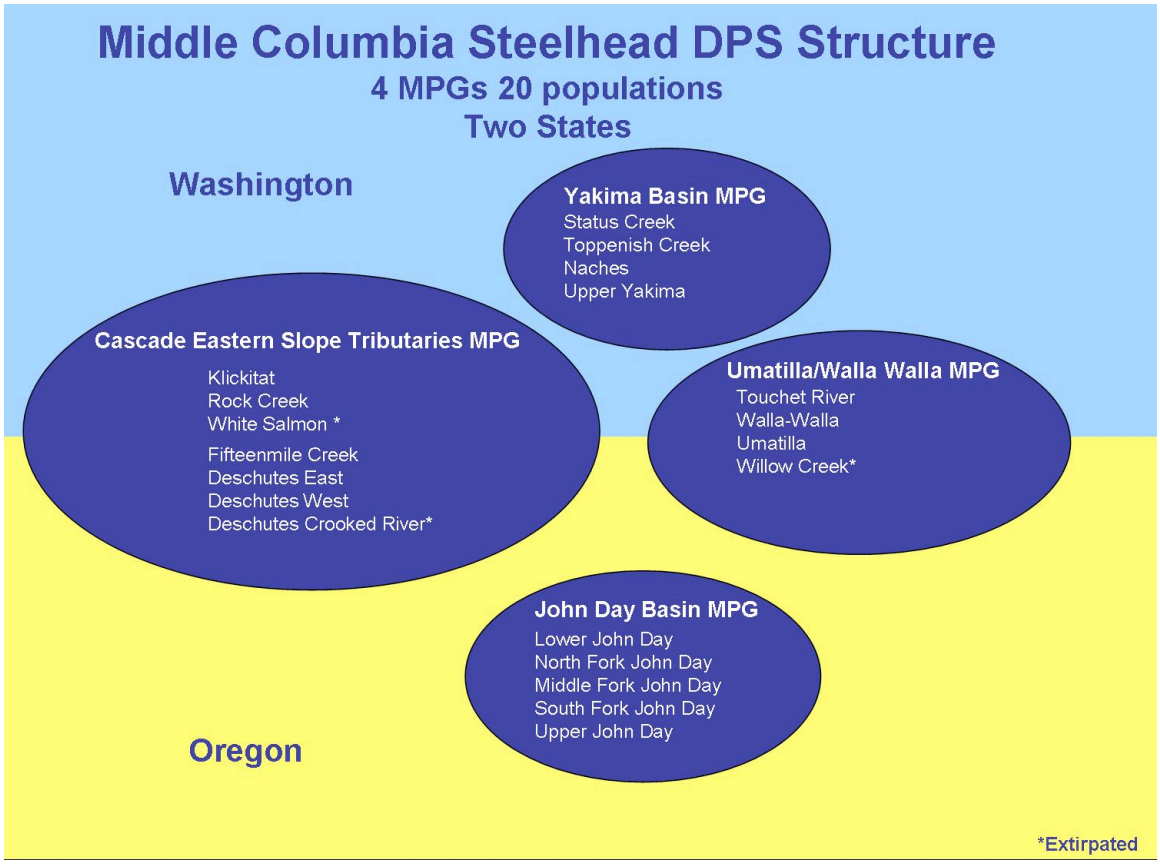

Figure 2-10. Major Population Groups (MPGs) and populations of middle Columbia steelhead. Note the White Salmon steelhead population is considered functionally extirpated (ICTRT 2007b)

Some biologists believe that residual steelhead populations in the form of resident trout may contribute to anadromy in the watershed. Phelps et al. (1990) found that introgression from hatchery rainbow plants was not evident in wild rainbow trout samples and high levels of genetic diversity still exist in this population. Seiler and Neuhauser (1985) caught more steelhead smolts than were predicted by the modeling. One hypothesis is that resident rainbow trout spawning upstream of the former Condit Dam continue to produce some steelhead smolts, indicating that anadromous *O. mykiss* has maintained genetic diversity and fitness (NPCC 2004).

Pre-removal monitoring in the White Salmon River above Condit Dam has identified *O. mykiss* juveniles displaying smolt behavior and morphology, and PIT-tagged juveniles have been detected passing Bonneville Dam with one being recovered at the tern colony on East Sand Island (B. Allen, personal communication, 2007). In addition, a juvenile *O. mykiss* PIT-tagged above Condit Dam September of 2004 at 98 mm was detected ascending Bonneville Dam in July of 2006. Genetic analysis of juvenile *O. mykiss* collected in the upper watershed above Husum Falls are different from hatchery trout released in the basin, however additional samples are needed to confirm this finding (Allen et al. 2006). This information supports the theory that even though the population is functionally extirpated

there is still the potential for re-establishing anadromous steelhead in the White Salmon River Basin.

Biologists divide steelhead into two basic run types based on the salmonid species' level of sexual maturity at the time they enter fresh water and the duration of the spawning migration. The stream maturing type, or summer steelhead, enters fresh water in a sexually immature condition and requires several months in fresh water to mature and spawn. The ocean-maturing type, or winter steelhead, enters fresh water with well-developed gonads and spawns relatively shortly after river entry (Bambrick et al. 2004). Based on habitat conditions and the composition of nearby populations, it is likely that the White Salmon River population historically supported both summer and winter life history patterns (ICTRT 2008). Chapman (1981), using instream flow measurements, estimated that in pristine conditions prior to the construction of Condit Dam, the White Salmon River supported 763 adult steelhead. Young and Rybak (1987) estimated that the habitat could support 39,000 steelhead smolts, and 2,770 adults.

Key Habitat during Different Life Stages

Steelhead generally return to the White Salmon River between April and October, although some hold over in the CR throughout the year and enter the river as they approach spawning. Wild steelhead spawn from February to June with peak spawning in April. Hatchery-reared summer steelhead in the White Salmon River watershed, however, typically spawn earlier, from December to February, with peak activity in January. Steelhead spawning and rearing currently occurs in the lower White Salmon and will occur in both mainstem and tributary habitats after dam removal.

Steelhead eggs incubate in their gravel beds for four to seven weeks, depending on water temperature, before hatching. After emergence, the small fry seek shallow, slow velocity areas within the stream channel, often associated with stream margins. As young steelhead mature they move into water with increasing depth and velocities. Juvenile steelhead typically spend two to three years in freshwater before outmigrating to the ocean. They typically move to interstitial spaces between cobble and boulders for cover during the fall, and remain in this habitat until March. In April, they return to a more active rearing life stage and seek out suitable habitat types. Outmigration occurs in spring and typically peaks in early May (NPCC 2004). Table 2-3 shows key habitat for steelhead during different life stages.

Some steelhead are iteroparous (do not die after spawning). A small proportion of repeat spawners, known as kelts, may return to the ocean for a short period and repeat the spawning migration, a life history adaptation that may be fundamental to ensuring population stability. Iteroparity for Mid-Columbia steelhead ranges from reported rates of 2-4 percent above McNary Dam (at RM 292 measured from the mouth of the Columbia) (Busby et al. 1996) up to 17 percent in the unimpounded tributaries below Bonneville Dam (at RM 146.1) (Leider et al. 1986). Iteroparity rates of summer and winter steelhead in the Kalama River, a tributary to the CR below Bonneville Dam have been estimated at 15 percent and 21 percent respectively (Withler 1966; Leider et al. 1986), while repeat spawners in the Hood River, an Oregon tributary in the impounded Bonneville Pool above Bonneville Dam, make up 9

percent of the summer and 13 percent of the winter-run of steelhead (Olsen 2004). The combined sampling from 1979 to 1981 (Howell et al. 1985) and the 2005 adult trapping data from YN and WDFW reported iteroparity rates for Klickitat River steelhead at 3.2 percent. Sampling of adults at the Klickitat River's Lyle Falls Fishway in 2004 and 2005 has indicated repeat spawning rates of 2.9 percent for summer steelhead and 8.8 percent for winters. Most repeat spawners are females. Iteroparity is a life history trait that should be assessed once steelhead re-colonize the White Salmon River and taken into account when management decisions for White Salmon steelhead are made.

Table 2-3. Key habitat by life stage and time period for steelhead (NPCC 2004)

Life Stage	Relevant Months	Key Habitat Descriptions
Spawning	Mar-Jun	Riffles, tailouts, and glides containing a mixture of gravel and cobble sizes with flow of sufficient depth for spawning activity
Incubation	Mar-Jun	Riffles, tailouts, and glides as described for spawning with sufficient flow for egg and alevin development
Fry Colonization	May-Jul	Shallow, slow velocity areas within the stream channel, often associated with stream margins
Active Rearing	0-age May-Jul; 1-age, Mar-Oct; 2+-age, Mar-Oct	Gravel and cobble substrates with sufficient depth and velocity, and boulder/large cobble/wood obstruction to reduce flow and concentrate food
Inactive Rearing	0,1-age Oct-Mar	Stable cobble/boulder substrates with interstitial spaces
Migrant	1-age, Mar-Jun 2+-age, Mar-Jun	All habitat types having sufficient flow for free movement of juvenile migrants
Pre-spawning Migrant	Winter, Nov-Apr Summer, All	All habitat types having sufficient flow for free movement of sexually mature adult migrants
Pre-spawning Holding	Winter, Dec-May Summer, All	Relatively slow, deep water habitat types typically associated with (or immediately adjacent to) the main channel

2.5 Hatchery Production and Releases

Fall Chinook salmon

No hatchery fall Chinook salmon are released directly in the White Salmon River watershed; however, hatchery tule fall Chinook salmon from Spring Creek NFH do stray into the watershed, contributing to natural production. Fish technicians have also recovered hatchery-origin URB fall Chinook salmon in the White Salmon River. These URB fall Chinook salmon are primarily from the LWS NFH, Bonneville Hatchery, and Klickitat Hatchery programs and are not part of the LCR Chinook salmon ESU. Biologists and recovery planners are considering Spring Creek NFH tule fall Chinook salmon for use in the reintroduction of fall Chinook salmon after PacifiCorp completes decommissioning of Condit Dam. This program is described below.

Spring Creek NFH Tule fall Chinook salmon

Hatchery managers used fall Chinook salmon from the White Salmon River to establish the Spring Creek NFH fall Chinook salmon program; the hatchery program is part of the LCR Chinook salmon ESU. The program uses only returns to the hatchery for broodstock, but has incorporated other tule stocks in the past. Hatchery workers last released non Spring Creek NFH tule fall Chinook salmon from the hatchery in 1991; the fish were Bonneville tule fall Chinook salmon. The Spring Creek NFH tule fall Chinook salmon is the most representative of the native Chinook salmon population that was historically present in the White Salmon River.

The hatchery program mitigates for lost and degraded habitat because of the construction and operation of the CR hydrosystem by producing locally adapted broodstock for sport, commercial, tribal, and international harvest. The production goal for the current program is for an on-station release of 10,500,000 sub-yearlings annually, with 1,700,000 acclimated and released at the LWS NFH, and 2,800,000 eggs transferred downstream to the Bonneville State Hatchery. This production requires a minimum of 7,000 adults (4,000 females). As mentioned previously, recovery planners are considering fall Chinook salmon from the program for reintroduction into the watershed once decommissioning of Condit Dam is completed. Genetic analysis of naturally spawning fall Chinook salmon in the White Salmon and other Bonneville Pool tributaries determined that Spring Creek NFH fall Chinook salmon are representative of the naturally spawning population of fall Chinook salmon in the White Salmon River (Smith et al. 2007; Smith and Engle 2011).

Non ESU Little White Salmon NFH Upriver Bright fall Chinook salmon

Biologists collected the original source of this stock of URB fall Chinook salmon at the Bonneville State Fish Hatchery. The current source of URB fall Chinook salmon is fish returning to the LWS NFH. The URB fall Chinook salmon stock is not native to the LWS and is not considered part of the LCR Chinook salmon ESU.

The purpose of the hatchery program is to successfully rear and release URB fall Chinook salmon into the LWS, which will mitigate for lost and degraded habitat because of the construction and operation of the CR hydrosystem, meet *U.S. v. Oregon* court agreements,

and provide a 1.7 million fry release in the Yakima River Basin. The program production goal is to release 2.0 million sub-yearling URB fall Chinook salmon at the hatchery, and 2.5 million sub-yearlings that come from the Bonneville State Hatchery and are acclimated for 4 weeks before being released on-station.

Spring Chinook salmon

Presently there are no hatchery programs associated with this population, however hatchery spring Chinook salmon have been observed spawning in the White Salmon River. In 2009, biologists examined 110 spring Chinook salmon carcasses at a weir installed at RM 1.1 at the White Salmon Ponds fish facility downstream of Condit Dam (Engle et al. 2010). All the spring Chinook salmon carcasses were hatchery-origin and post-spawn, i.e., near death or in a state of decay (Engle et al. 2010). The lack of natural-origin spring Chinook salmon examined at the weir supports the observation that spawning does occur in the lower White Salmon River but rearing habitat is lacking (Engle et al. 2010).

Coho salmon

There are no hatchery programs that directly release hatchery coho salmon into the White Salmon River. The coho salmon program at the LWS NFH released coho salmon that may have contributed to straying into the White Salmon River in the past, but stray rates were not estimated. The LWS NFH discontinued the program after releases in 2004 because of funding shortfalls. Stray coho salmon currently entering the White Salmon River may come from releases in the Klickitat and Umatilla rivers and from Bonneville Hatchery.

Chum salmon

Historical and current hatchery influences on chum salmon are minimal. Hatcheries have released chum salmon into only 4 of 10 Washington populations. Hatchery fish do not comprise a substantial fraction of any naturally spawning chum salmon population and all originate from local wild populations. Current chum salmon hatchery programs focus on reintroduction (Chinook River) and conservation (Duncan Creek, and Grays River) (LCFRB 2004).

Steelhead

Scientists and recovery planners do not consider the hatchery programs in the White Salmon River watershed to be part of the MCR steelhead DPS. From 1995 to 2010, fisheries co-managers annually released both summer and winter steelhead smolts from broodstock collected at the Skamania Hatchery on the West Fork of the Washougal River into the White Salmon River below Condit Dam. The summer steelhead broodstock derives from summer steelhead from the Washougal and Klickitat Rivers. The winter steelhead broodstock derives from returns to the Washougal River.

The Skamania Hatchery program goal was to provide fisheries for summer and winter steelhead in the White Salmon River as mitigation for losses from human development and concomitant habitat loss and to meet the obligations of the *U.S. v. Oregon* agreement. The program involved an annual release of 24,000 summer and 20,000 winter steelhead smolts, although actual releases varied from year to year. Production consisted of adipose-fin-clipped fish to allow for selective fisheries and to facilitate assessment of the ratio of

hatchery adults to wild adults. Workers trucked smolts from Skamania Hatchery and stream-released them into the White Salmon River at RM 1.5. Fish managers terminated the program with the 2009 releases.

Biologists would need to develop or identify a more suitable broodstock to expedite the reintroduction of steelhead in habitats upstream of the former Condit Dam. Monitoring steelhead escapement and production, after dam decommissioning is complete, will determine whether there are impacts from these Skamania Hatchery releases.

2.6 Harvest

Primarily ocean and mainstem CR commercial, tribal, and sport intercept Chinook salmon and coho salmon. Tributary sport fisheries also harvest some Chinook salmon and coho salmon. The LCFRB recovery plan (LCFRB 2004) and the ESA section 7 Biological Opinion for fisheries managed under the *U.S. v. Oregon* Agreement (NMFS 2008c) describe in detail harvest management and harvest effects.

In 2012, the fisheries regulations in the White Salmon River prohibited the retention of unmarked Chinook salmon from April 1 to July 31, and unmarked Chinook salmon and coho salmon from August 1 to March 31, in the area from the mouth to the Northwestern Lake Road bridge (WDFW 2012).During the removal of Condit Dam the White Salmon was closed to fishing from the Northwestern Lake Road bridge downstream to the old county road bridge below the powerhouse. Regulations also prohibit the retention of chum salmon in tributary recreational fisheries.

Steelhead harvest, while locally important, was historically likely less substantial than salmon harvest because of lower abundance and spawning times that coincided with higher flows (NPCC 2004). The YN reports that tribal members fished for salmon and steelhead historically as high as Husum Falls and Rattlesnake Falls on the White Salmon River (J. Meninick, YN Cultural Resources Department, personal communication, 2006). Section 5.4, Harvest, for an expanded discussion of harvest impacts.

3 Recovery Goals and Viability Criteria

The primary goal of ESA recovery plans is for the species to reach the point that it no longer needs the protection of the Act, i.e., NMFS delists the species. Recovery plans may also contain "broad-sense goals," defined in the recovery planning process as going beyond the requirements for delisting to address, for example, other legislative mandates or social, economic, and ecological values.

NMFS applies the delisting criteria at the ESU/DPS level based on determinations of the viability of the independent populations that make up the ESU/DPS. The LCR ESA Recovery Plan describes the criteria for delisting the LCR ESUs. As noted, this Plan is an appendix of the LCR ESA Recovery Plan. The middle Columbia Steelhead ESA Recovery Plan describes the criteria for delisting the MCR Steelhead DPS. This plan is also an appendix to the middle Columbia Steelhead ESA Recovery Plan. This chapter provides recovery goals for the White Salmon River Chinook salmon, coho, chum salmon, and steelhead populations and describes the criteria NMFS will use to assess progress toward those goals and the role of the White Salmon River salmon populations in overall ESU/DPS viability.

There are two kinds of criteria that enter into a delisting decision: biological criteria defining viable populations (section 3.2, Biological Viability Criteria) and "threats" criteria related to the five listing factors detailed in the ESA (section 3.3, Threats Criteria). The threats criteria define the conditions under which NMFS can determine that responsible parties have addressed or mitigated the listing factors or threats. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B). This chapter discusses both kinds of criteria.

3.1 Recovery Goals

The primary goal of this plan is for the White Salmon River salmon and steelhead populations to contribute to the delisting of the LCR ESUs and the MCR Steelhead DPS. McElhany et al. (2000) defines a VSP as an independent population that has negligible risk of extinction over a 100-year timeframe. However, all populations within an ESU or DPS do not have to reach viable status for NMFS to delist the ESU/DPS (section 3.2.2, DPS and MPG Viability Criteria).

The visions, goals, and actions of many of the parties involved in the White Salmon recovery planning process may go beyond ESA delisting. The vision for broad-sense recovery incorporates ESA delisting goals in the sense that NMFS could delist White Salmon River salmon and steelhead during an extended and stepwise process of achieving broad-sense recovery goals. Broad-sense recovery goals incorporate many of the local and traditional uses, including those associated with rural and Native American values, which are important in the Pacific Northwest.

The proposed local, collaborative recovery board may choose to define additional, broad-sense goals for the White Salmon River watershed and other areas within the Washington Gorge Management Unit. The board's broad-sense goals for the area would likely build upon direction already adopted by various stakeholders in the area. These goals would then

guide the board as it defines and implements future recovery actions for the White Salmon River watershed.

3.2 Biological Viability Criteria

One of the main tasks assigned to the TRTs was to develop biologically based criteria for determining the viability of ESA listed salmon and steelhead. Viability criteria identify characteristics and conditions that, when met, describe viable populations and a viable ESU or DPS.

The TRTs based their approaches to recovery on guidance from the NMFS Technical Memorandum *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). This memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels. VSP guidelines provided by McElhany et al. (2000) recommend that a viable DPS population should be large enough to:

- Have a high probability of surviving variation observed in the past and expected future
- Be resilient to environmental and anthropogenic disturbances
- Maintain genetic diversity
- Support/provide ecosystem functions

NMFS organized the viability guidelines provided by McElhany et al. (2000 around four major considerations: abundance, productivity, spatial structure, and diversity. ESU/DPS-level viability criteria consider the appropriate distribution and characteristics of component populations to maintain the ESU/DPS in the face of longer-term ecological and evolutionary processes (ICTRT 2005a). The viability criteria defined by the ICTRT and W/LC TRT have been adopted as the biological criteria for delisting of the ESUs and DPS that include the listed White Salmon populations discussed in this Plan.

3.2.1 ESU/DPS Viability Criteria

Defining ESU and DPS Structure

The TRTs applied overall ESU/DPS-level viability criteria based on smaller units of MPG and independent populations to determine paths toward viability. Central to this approach is the recognition that salmonid population structure is hierarchical. The TRT based the biological criteria for populations and ESU/DPS-level viability on the existence of a biological hierarchy that spans ESUs/DPSs, major groupings, populations, and substructure within populations (Figure 3-1). The approach recognizes that historical salmonid populations within an ESU or DPS retain some genetic similarities because they move between different habitats during their life cycle. This distribution across the landscape and the diverse genetic, life history and morphological characteristics that evolve/contribute significantly to a population's long-term persistence.

- **Evolutionarily Significant Unit:** Two criteria define an ESU or DPS listed under the ESA: 1) it must be substantially reproductively isolated from other conspecific units, 2) it must represent an important component of the evolutionary legacy of the species (Waples 1991).
- **Major Population Grouping:** A group of populations that share similar genetic, geographic (hydrographic), and/or habitat characteristics within an ESU/DPS (ICTRT 2005b). The ICTRT termed this level in the hierarchy a MPG, and the W/LC TRT called it a "stratum." The TRTs consider MPGs, strata, and the "geographic regions" described by the Puget Sound TRT to be analogous.
- **Independent Population:** McElhany et al. (2000) defined an independent population as "…a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season. Groups are considered to be independent populations if they are isolated to such an extent that exchanges of individuals among the populations do not substantially affect the population dynamics or extinction risk of the independent populations over a 100-year time frame."

Hierarchy in Salmonid Population Structure

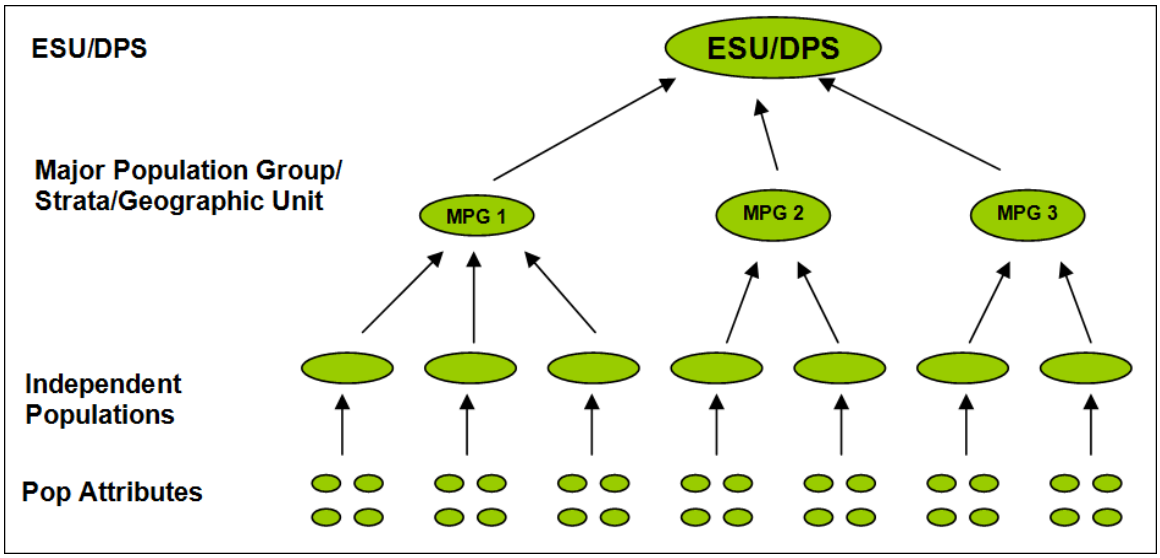

Figure 3-1. Hierarchical levels of salmonid population structure as defined by the TRTs for ESU/DPS recovery planning

The TRTs established ESU/DPS-level viability criteria based on the VSP guidelines identified by McElhany et al. (2000). The W/LC TRT identified five essential elements to address in its approach (McElhany et al. 2006). The ICTRT (2007) adapted these five elements for the middle Columbia Steelhead DPS. The five elements are:

Stratified Approach: Life history and ecological complexity that historically existed should have a high probability of persistence. The W/LC TRT aggregated populations into MPG, or strata, based on each combination of life history type and ecological zone. The ICTRT stratified the MCR steelhead DPS into groups based on ecoregion characteristics (Eastern Cascades, Columbia Plateau, John Day and Yakima), life history types (summer, winter and summer/winter) and other geographic and genetic considerations.

Viable Populations: Some individual populations within a MPG should have persistence probabilities consistent with a high probability of MPG persistence. The W/LC TRT defined high persistence probability based on the presence of at least two populations with a negligible risk of extinction and a strata average of a medium-low risk of extinction. The ICTRT defined high persistence probability based on the presence of at least two or one-half of historical populations with a negligible risk of extinction.

Representative Populations: Representative populations must achieve criteria or maintain viability criteria, but not every historical population needs to meet viability criteria. Viable combinations of populations should include "core" populations that are highly productive, "legacy" populations that represent historical genetic diversity, and dispersed populations that minimize susceptibility to catastrophic events.

Non-deterioration: No population should be allowed to deteriorate until ESU/DPS recovery is assured, and all extant populations should be maintained. Current populations and population segments should be preserved. Recovery measures will be needed in most areas to arrest declining status and offset the effects of future impacts.

Safety Factors: Higher levels of recovery should be attempted in more populations than the minimum needed to achieve ESU/DPS viability because not all attempts will be successful. Recovery efforts should target more than the minimum number of populations and more than the minimum population levels thought to ensure viability. Some populations should be highly viable.

W/LC TRT Recommended Viability Criteria

The W/LC TRT document*, Interim Report on Viability Criteria for Willamette and Lower Columbia Basin Pacific Salmonids* (McElhany et al. 2003) describes recommended viability criteria for salmon ESUs in the W/LC recovery domain. The LCFRB applied these 2003 criteria to assess viability and develop the recovery direction for the listed White Salmon River Chinook salmon, coho, and chum salmon populations that NMFS and the NPCC adopted as part of the lower Columbia Salmon Recovery and Subbasin Plan (LCFRB 2004). This direction is also included in this recovery plan. Summarized below are the criteria and approach defined by the W/LC TRT in 2003. In 2006, the W/LC TRT (McElhany et al. 2006) revised the 2003 criteria by incorporating new analyses by the W/LC TRT itself, other TRTs and state agencies, among others. The LCFRB and the WAGIT which includes White

Salmon stakeholders will eventually use the new criteria to update goals and status evaluations for Washington populations through the recovery plan revision process. The 2006 revised viability criteria (McElhany et al. 2006) are available at http://www.nwfsc.noaa.gov/trt/wlc/viability_report_revised.cfm (accessed April 11, 2012).

Independent Population Viability Criteria

The W/LC TRT's 2003 viability criteria (McElhany et al. 2003) use five population-level attributes as indicators for viability: 1) adult productivity and abundance, 2) juvenile out-migrant productivity, 3) population diversity, 4) habitat, 5) spatial structure. The 2003 report also provides a set of guidelines for examining viability for each indicator (McElhany et al. 2003). Shown in Table 3-1 are the 2003 viability criteria.

Table 3-1. Population viability criteria (McElhany et al. 2003; McElhany et al. 2006)

Adult Population Productivity and Abundance

1. In general, viable populations should demonstrate a combination of population growth rate, productivity, and abundance that produces an acceptable probability of population persistence. Various approaches for evaluating population productivity and abundance combinations may be acceptable, but must meet reasonable standards of statistical rigor.
2. A population with a non negative growth rate and an average abundance approximately equivalent to estimated historical average abundance is in the highest persistence category. The estimate of historical abundance should be credible, the estimate of current abundance should be averaged over several generations, and the growth rate should be estimated with adequate statistical confidence. This criterion takes precedence over criteria 1.

Juvenile Outmigrant Production

The abundance of naturally produced juvenile migrants should be stable or increasing as measured by observing a median annual growth rate or trend with an acceptable level of confidence.

Within Population Spatial Structure

The spatial structure of a population must support the population at the desired productivity, abundance, and diversity levels through short-term environmental perturbations, longer-term environmental oscillations, and natural patterns of disturbance regimes. The metrics and benchmarks for evaluating the adequacy of a population's spatial structure should specifically address:

a. Quantity: Spatial structure should be large enough to support growth and abundance, and diversity criteria.

b. Quality: Underlying habitat spatial structure should be within specified habitat quality limits for life history activities (spawning, rearing, migration, or a combination) taking place within the patches.

c. Connectivity: Spatial structure should have permanent or appropriate seasonal connectivity to allow adequate migration between spawning, rearing, and migration patches.

d. Dynamics: The spatial structure should not deteriorate in its ability to support the population. The processes creating spatial structure are dynamic, so structure will be created and destroyed, but the rate of flux should not exceed the rate of creation over time.

e. Catastrophic Risk: The spatial structure should be geographically distributed in such a way as to minimize the probability of a significant portion of the structure being lost because of a single catastrophic event, either anthropogenic or natural.

Within Population Diversity

1. Sufficient life history diversity must exist to sustain a population through short-term environmental perturbations and to provide for long-term evolutionary processes. The metrics and benchmarks for evaluating the diversity of a population should be evaluated over multiple generations and should include:

    a. Substantial proportion of the diversity of a life-history trait(s) that existed historically,

    b. Gene flow and genetic diversity should be similar to historical (natural) levels and origins,

    c. Successful utilization of habitats throughout the range, and

    d. Resilience and adaptation to environmental fluctuations.

General Habitat

1. The spatial distribution and productive capacity of freshwater, estuarine, and marine habitats should be sufficient to maintain viable populations identified for recovery.

2. The diversity of habitats for recovered populations should resemble historical conditions given expected natural disturbance regimes (e.g., wildfire, flood, volcanic eruptions, etc.). Historical conditions represent a reasonable template for a viable population; the closer the habitat resembles the historical diversity, the greater the confidence in its ability to support viable populations.

At a large scale, habitats should be protected and restored, with a trend toward an appropriate range of attributes for salmonid viability. Freshwater, estuarine, and marine habitat attributes should be maintained in a non-deteriorating state.

The W/LC TRT's revised criteria, described in their 2006 report *Revised Viability Criteria for Salmon and Steelhead in the Willamette and Lower Columbia Basins* (McElhany et al. 2006), use three population-level attributes as indicators of viability instead of the five identified in 2003. The 2006 attributes are: 1) abundance and productivity, 2) spatial structure, 3) diversity. The revised criteria include juvenile out migrant productivity as a subset of abundance and productivity and address habitat criteria as part of the discussion of listing factors criteria (McElhany et al. 2006).

The W/LC TRT's 2003 system for integrating population attributes to assess population extinction risk used a 0-4 qualitative scale, with zero indicating a population with a low probability of persistence, and four indicating a population with high probability of persistence. The TRT's 2006 report (McElhany et al. 2006) maintains this system (Table 3-2).

Table 3-2. Population persistence*/viability categories (McElhany et al. 2003; McElhany et al. 2006)

Scale	*Viability*	*Description*	*Persistence Probability**
0	Very Low (VL)	Either extinct or very high risk of extinction	0-40%
1	Low (L)	Relatively high risk of extinction	40-74%
2	Medium (M)	Medium high risk of extinction	75-94%
3	High (H)	Low (negligible) risk of extinction (represents a "viable" level)	95-99%
4	Very High (VH)	Very low risk of extinction	>99%

** 100-year persistence probabilities*

Strata and ESU Viability Criteria

The criteria developed by the W/LC TRT for recovery planning in 2003 state that for an ESU as whole to be viable, all of the historical strata need to have a high probability of persistence (McElhany et al. 2003). The W/LC TRT used ratings of individual population's extinction risk to determine viability at the strata and ESU levels. Table 3-3 shows criteria guidelines identified by the W/LC TRT to complete these evaluations. The TRT maintained its support for the guidelines in its 2006 report (McElhany et al. 2006).

Table 3-3. Criteria guidelines for determining strata and ESU viability (McElhany et al. 2003, 2006)

ESU-Level Criteria Guidelines
1. Every Stratum (life history and ecological zone combination) that historically existed should have a high probability of persistence
Strata-Level Criteria Guidelines
1. Individual populations within a stratum should have persistence probabilities consistent with a high probability of strata persistence 2. Within a stratum, the populations restored/maintained at viable status or above should be selected to: a. Allow for normative metapopulation process, including the viability of "core" populations that are defined as the historically most productive populations b. Allow for normative evolutionary processes, including the retention of the genetic diversity represented in relatively unmodified historic gene pools c. Minimize susceptibility to catastrophic events
ESU-Level Recovery Strategy Criteria Guidelines
1. Until all ESU viability criteria have been achieved, no population should be allowed to deteriorate in its probability of persistence 2. High levels of recovery should be attempted in more populations than identified in the strata viability criteria because not all attempts will be successful

ICTRT Recommended Biological Viability Criteria

The ICTRT developed biologically based viability criteria for ESA-listed salmon and steelhead in the Interior Columbia domain. The ICTRT based its approach to recovery on guidance from the NMFS Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). As stated above, this memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels.

Viability criteria at the population level address four VSP parameters (McElhany et al. 2000):

- *Abundance* - the average number of spawners in a population over a generation or more
- *Productivity* - the performance of a population over time in terms of recruits produced per spawner
- *Spatial Structure* - a population's geographic distribution and the processes that affect that distribution
- *Diversity* - the distribution of genetic, life history, and phenotypic variation within and among populations

The ICTRT grouped specific population-level criteria into two categories to assess viability at the independent population level: measures addressing abundance and productivity, and measures addressing spatial structure and diversity. The viability of an independent population is determined by integrating risks across the four parameters.

The ICTRT's objective for population abundance and productivity is that abundance should be high enough that 1) in combination with intrinsic productivity, declines to critically low levels would be unlikely assuming recent historical patterns of environmental variability; 2) compensatory processes provide resilience to the effects of short-term perturbations; 3) subpopulation structure is maintained (e.g., multiple spawning tributaries, spawning patches, life history patterns) (ICTRT 2005a).

The ICTRT developed criteria for characterizing the relative size and complexity of Interior Columbia Basin steelhead populations based on their analysis of the intrinsic or historical potential habitat available to the population (ICTRT 2005a). This analysis used available Geographic Information System (GIS) data layers showing stream characteristics (e.g. channel width, gradient, and valley confinement) and empirically derived relationships between habitat type, stream structure, landscape processes, and spawning. The ICTRT built a model that also incorporated information from local biologists and recovery planners to identify natural barriers to migration and other local variations.

Mid-Columbia steelhead spawn in a wide range of tributary drainage areas: from small creeks such as Fifteenmile or Rock Creek to very large rivers such as the lower John Day. The ICTRT categorized historical population sizes as Basic, Intermediate, Large, and Very Large, and set minimum abundance thresholds for steelhead populations of each type as follows: Basic: 500 spawners; Intermediate, 1,000 spawners; Large, 1,500 spawners; Very Large, 2,250. The abundance thresholds are associated with minimum productivity thresholds, based on modeling studies described by the ICTRT (March 2007a and November 2007b). Modeling studies link abundance and productivity, within limits: above a certain threshold, higher productivity can compensate for lower abundance and vice versa.

The ICTRT used the concept of the viability curve (ICTRT 2007a, 2007b; McElhany et al. 2006) as a framework for defining population specific abundance and productivity levels to meet the objectives (Figure 3-2). A viability curve describes combinations of abundance and productivity that yield a particular risk threshold. The viability curve links the two parameters relative to extinction risks associated with short-term environmental variability. Given a particular productivity level, larger populations are more resilient in the face of year-to-year variability in overall survival rates than are smaller populations. Populations with relatively high intrinsic productivity (expected ratio of spawners to their parent spawners at low levels of abundance) are also more robust at a given level of abundance than populations with lower intrinsic productivity.

The ICTRT generated viability curves for each population to define the combinations of abundance and productivity corresponding to a range of extinction risks over a 100-year period - less than 1 percent (very low), less than 5 percent (low), less than 25 percent (moderate), and greater than 25 percent (high), see Figure 3-2. It targeted population level recovery strategies to achieve less than a 5 percent (low) risk of extinction in a 100-year period. This is consistent with the VSP guidelines and conservation literature (McElhany et al. 2000; NRC 1995).

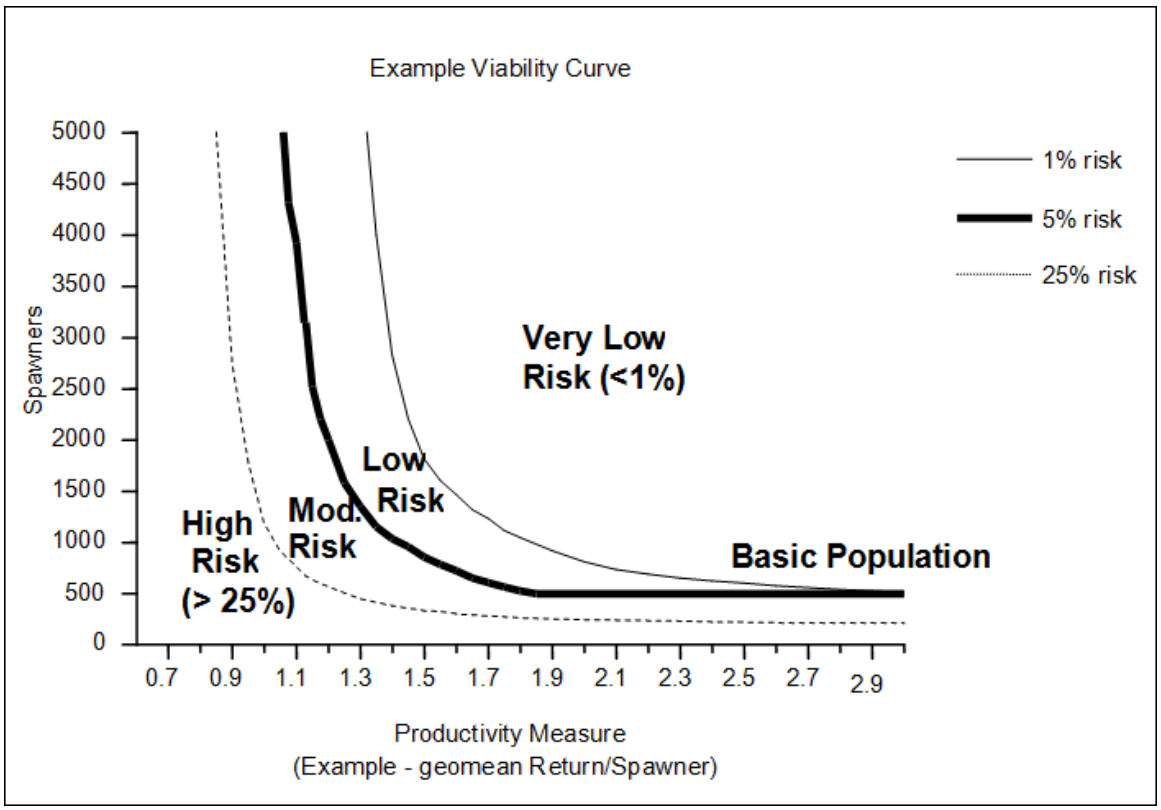

Figure 3-2. Example of an abundance/productivity viability curve (ICTRT 2007a)

3.2.2 DPS and MPG Viability Criteria

Similar to the W/LCR TRT approach to strata and ESU viability criteria (Table 3-3) the ICTRT (2007) developed criteria based on recovery of MPGs. MPGs are geographically and genetically cohesive population groups, and are critical components of ESU/DPS spatial structure and diversity (Figure 2-10). Having all MPGs within an ESU/DPS at low risk provides the greatest probability of persistence for the ESU/DPS. Thus, the ICTRT criterion for a viable ESU/DPS is that all extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS should be at low risk.

Further, the following five criteria should be met for an MPG to be regarded as at low risk (viable) (ICTRT 2007b):

1. At least one-half of the populations historically within the MPG (with a minimum of two populations) should meet viability standards.
2. At least one population should be classified as “Highly Viable.”
3. Viable populations within an MPG should include some populations classified (based on historical intrinsic potential) as “Very Large," "Large," or “Intermediate,” generally reflecting the proportions historically present within the MPG. In particular, Very Large and Large populations should be at or above their composite historical fraction within each MPG.

4. All major life history strategies (e.g., spring and summer-run timing) that were present historically within the MPG should be represented in populations meeting viability requirements.
5. Remaining MPG populations should be maintained with sufficient abundance, productivity, spatial structure, and diversity to provide for ecological functions and preserve options for ESU/DPS recovery.

Population Recovery Classifications

The W/LC TRT and LCFRB used the results of the 2003 Population Viability Criteria report to build a recovery scenario that describes the target status for each population. The W/LC TRT and the LCFRB classified individual populations as *primary* (targeted for restoration to high or high + probability of persistence), *contributing* (targeted for restoration to low or medium probability of persistence), or *stabilizing* (populations that are to be maintained at current levels and likely to have low probabilities of persistence). They identified the following target levels for White Salmon Chinook salmon, coho, and chum salmon. The LCFRB has updated the 2004 recovery plan and proposed to maintain the classifications for all of the White Salmon River populations except coho salmon, which has been elevated to a primary population classification (LCFRB 2010).

White Salmon River Fall Chinook salmon (Contributing, Medium)

Historically, the tule fall Chinook salmon population in the White Salmon was large. Condit Dam affected the population, although a small amount of fall Chinook salmon habitat was available downstream of the dam and upstream from Bonneville Reservoir inundation. The Spring Creek Hatchery program, which originated from White Salmon River fall Chinook salmon stock, is located three miles downstream of the river mouth and straying of returning hatchery adults to the White Salmon River is consistent with a *contributing* population designation. A tribal fishery targets Spring Creek Hatchery fish near the river mouth. The W/LC TRT and the LCFRB targeted the White Salmon population for medium viability to reflect concerns with hydro impacts (Bonneville and Condit dams) and higher harvest rates associated with combined treaty and non-treaty fisheries. Based on the TRT's findings, the Plan proposed an abundance goal for recovery of 900 fish (LCFRB 2004).

White Salmon River Spring Chinook salmon (Contributing, Low)

This population was historically significant but is currently extinct. Reintroduction would include use of an outside stock. The best source stock may be from the Klickitat, which is outside the lower Columbia ESU. The W/LC TRT would need to provide criteria for evaluating appropriate source stocks for reintroduction. The low viability target for White Salmon spring Chinook salmon recognizes the long period required to restore a locally adapted natural population from an out-of-basin stock. Based on TRT findings, the Plan proposed an abundance goal for recovery of 400 fish (LCFRB 2004).

White Salmon River coho salmon (Primary, High)

The White Salmon River coho salmon are part of the Washington upper Gorge Tributaries and White Salmon River population. Lack of access to habitats upstream of Condit Dam

limits current potential for coho salmon production in the White Salmon River. There may be some coho salmon production occurring in the one-mile reach downstream of Condit Dam. Based on TRT findings, the Plan proposed an abundance goal for recovery of 150 fish (LCFRB 2004).

Upper Gorge chum salmon, including White Salmon River chum salmon (Contributing, Medium)

The LCFRB identified the entire population of upper Gorge chum salmon to have a very low viability (LCFRB 2004). Bonneville Reservoir inundates most of historical habitat for this population and passage at Bonneville Dam impacts both juvenile and adult migration. The LCFRB proposed an abundance goal for recovery of 600 fish.

White Salmon River steelhead (Low Risk)

The ICTRT did not apply the same classification system to MCR steelhead populations but did identify that to be viable, the White Salmon steelhead population needs to reach a minimum abundance threshold of 500 naturally produced spawners with a sufficient intrinsic productivity to achieve a five percent or less risk of extinction over a 100-year timeframe (ICTRT 2007b). The ICTRT recognizes that recovering this functionally extirpated population to a viable level may not be necessary to achieve viability at the MPG and DPS levels.

3.3 Threats Criteria

NMFS evaluated listing factors under section 4(a)(1) when the agency made the initial determination to list the species for protection under the ESA. In the future, when NMFS reevaluates the status of the species to determine whether these factors continue to limit recovery, the agency can decide whether the protections of the ESA are still warranted. If no longer warranted, NMFS could delist the species.

At the time of a delisting decision, NMFS will examine whether the entities responsible for recovery have addressed the section 4(a)(1) listing factors. To assist in this examination, NMFS will use the listing factors (or threats) criteria described below in addition to evaluation of biological recovery criteria and other relevant data and policy considerations.

To determine that the affected DPS has recovered to the point that it no longer requires the protections of the ESA, NMFS will review the status of the listing factors according to the specific criteria identified for each of them (see below). The threats need to have been addressed to the point that delisting is not likely to result in their re-emergence. It is possible that current perceived threats will become insignificant in the future as a result of changes in the natural environment or changes in the way threats affect the entire life cycle of salmon. Consequently, as the result of RM&E, NMFS expects that the agency will change the ranking of threats over time and identify new threats. During the 5-year status reviews, NMFS will evaluate and review the listing factor criteria under conditions at the time.

The specific criteria listed below for each of the relevant listing/delisting factors help to ensure that responsible entities address and mitigate the underlying causes of prior to considering a species for delisting. NMFS expects that if the proposed actions described in

the Plan are implemented, they will make substantial progress toward meeting the following listing factor (threats) criteria:

Factor A: The present or threatened destruction, modification, or curtailment of its habitat or range

To determine that the ESU or DPS is recovered, threats to habitat should be addressed to a degree sufficient to support a viable ESU or DPS as outlined below:

1. Impaired fish passage (e.g., dams and culverts) is addressed, either through removal or modification of obstructions, to improve survival and restore access to historically accessible habitat where necessary to support recovery goals.
2. Flow conditions that support sufficient salmonid rearing, spawning, and migration of a viable ESU or DPS are achieved, where possible, through management of White Salmon River mainstem and tributary irrigation operations, and through the improvement of other water user efficiencies and conservation, including for municipal supply and other consumptive purposes.
3. Forest management practices that protect watershed and stream functions are implemented on Federal, state, tribal, and private lands.
4. Agricultural best management practices, including grazing, are implemented to protect and restore riparian areas, floodplains, and stream channels, and to protect water quality from sediment, pesticide, herbicide, and fertilizer runoff.
5. Urban and rural development, including land use conversion from agriculture and forestland to residential uses, avoids impairment of water quality or impairment of natural stream conditions.
6. The effects of toxic contaminants on salmonid fitness and survival in the White Salmon mainstem and tributaries are sufficiently limited so as not to affect recovery.
7. Channel function, including vegetated riparian areas, canopy cover, streambank stability, off-channel and side-channel habitats, natural substrate and sediment processes, and channel complexity, is restored to provide adequate rearing and spawning habitat.
8. Floodplain function and the availability of floodplain habitats for salmon are restored to a degree sufficient to support a viable ESU/DPS. This restoration should include connectivity between river and floodplain and the restoration of altered sediment routing.
9. Water operations management in the mainstem White Salmon and tributaries maximize survival of juvenile rearing, emigrating smolts, and immigrating and spawning adults.

Factor B: Over-utilization for commercial, recreational, scientific or educational purposes

To determine that the ESU or DPS is recovered, any utilization for commercial, recreational, scientific, or educational purposes should be managed as outlined below:

1. Fishery management plans for salmon are in place that (a) accurately account for total fishery mortality (i.e., both landed catch and non-landed mortalities) and constrain mortality rates to levels that are consistent with achieving population viability (i.e., provide for adequate spawning escapement given their productivity); (b) are implemented in such a way as to avoid deleterious genetic effects on populations or negatively affect the distribution of populations.
2. Federal, state, and tribal fishing rules and regulations are effectively enforced.
3. Technical tools accurately assess the effects of the harvest regimes so that harvest objectives are met but not exceeded.
4. Scientific handling of fish from adult and juvenile trapping operations is minimized to reduce indirect mortalities associated with education or scientific programs, while recognizing that monitoring, research, and education are key actions for conservation of the species.
5. To the degree sufficient to support a viable ESU or DPS, routine instream construction and maintenance practices are implemented in a manner to reduce or eliminate mortality of listed species.

Factor C: Disease or predation

To determine that the DPS is recovered, any disease or predation that threatens its continued existence should be addressed as outlined below:

1. Hatchery operations do not subject salmon populations to deleterious diseases and parasites and do not result in increased predation rates of wild salmon.
2. Predation by avian predators is managed in a way that promotes recovery of salmon populations.
3. The northern pike minnow are managed to reduce predation on salmon to a degree sufficient to meet recovery goals.
4. Populations of introduced smallmouth bass, walleye, and catfish are managed such that competition or predation does not impede salmon recovery. Predation by marine mammals on salmon runs below Bonneville Dam is managed within the framework of applicable statutes and to the degree necessary to protect upstream migration of salmon.
5. Physiological stress and physical injury that may cause disease or increase susceptibility to pathogens during rearing or migration should be reduced during critical low flow periods (e.g., low water years) or poor passage conditions (e.g., at diversion dams or bypasses).

Factor D: The inadequacy of existing regulatory mechanisms

To determine that the ESU or DPS is recovered, any inadequacy of existing regulatory mechanisms that threatens its continued existence should be addressed to the degree necessary to support a viable ESU or DPS, as outlined below:

1. Sufficient resources, priorities, regulatory frameworks, and coordination mechanisms are established and/or maintained for effective enforcement of land and water use regulations that protect and restore habitats and for the effective management of fisheries.
2. Habitat conditions and watershed functions are protected through land-use planning that guides human population growth and development.
3. Habitat conditions and watershed function are protected through regulations that govern resource extraction such as timber harvest and gravel mining.
4. Habitat conditions and watershed functions are protected through land protection agreements as appropriate and where existing policy or regulations do not provide adequate protection.
5. Regulatory, control, and education measures to prevent additional exotic plant and animal species invasions are in place.

Factor E: Other natural or human-made factors affecting its continued existence

To determine that the ESU or DPS is recovered, other natural and human-made threats to its continued existence should be addressed as outlined below:

1. Hatchery programs are being operated in a manner that is consistent with individual watershed and region-wide recovery approaches, recognizing Federal obligations; appropriate criteria should be used for the integration, where appropriate, of hatchery populations and extant natural populations inhabiting watersheds where the hatchery fish return.
2. Hatcheries operate using appropriate ecological, genetic, and demographic risk containment measures for: (1) hatchery-origin adults returning to natural spawning areas, (2) release of hatchery juveniles, (3) handling of natural-origin adults at hatchery facilities, (4) withdrawal of water for hatchery use, (5) discharge of hatchery effluent, (6) maintenance of fish health during their propagation in the hatchery.
3. Mechanisms are in place to effectively continue monitoring the proportion of hatchery and wild spawners in the watershed.
4. Mechanisms are in place to reduce the incidence of, and impacts from, introduced, invasive, or exotic plant and animal species.
5. Nutrient enrichment programs should be evaluated to determine where additional nutrient inputs can provide significant benefits.

4 Current Status Assessment

In 2004, the W/LC TRT completed a population extinction risk evaluation of salmon and steelhead populations in the Willamette and LCR Basins, including White Salmon River populations (McElhany et al. 2004). During the evaluation, biologists ranked each population for absolute extinction risk on a scale of 0 to 4, with 0 = extirpation or nearly so, and 4 = very low extinction risk (McElhany et al. 2003). Each member of the W/LC TRT, based on the information available, ranked the VSP attributes such that the score for each attribute added up to 10, and then they provided an estimate of "data quality" based on their assessment of the overall amount of information available for each attribute (McElhany et al. 2004). Discussed below are the results of this evaluation.

4.1 Risk of Extinction: Willamette/Lower Columbia TRT

White Salmon River Fall Chinook salmon

White Salmon River fall-run Chinook salmon received a weighted average score of 0.86, suggesting that the population is at a very high risk of extinction (Table 4-1). In their review, W/LC TRT members recognized the population's low total abundance, some team members commented that the population is extirpated from its historical range, except for 2 to 2.5-mile reach below Condit Dam, and that the overwhelming majority of fish observed in the river are strays from nearby hatcheries. Other members considered the observed adults as *de facto* population members (McElhany et al. 2004). Overall, most TRT members considered the in-river fall-run Chinook salmon population to be heavily influenced by hatchery strays, although some members included the Spring Creek NFH in their diversity evaluation as a potential source for re-establishing a native-run.

Table 4-1. Evaluation scores for White Salmon fall-run Chinook salmon (McElhany et al. 2004)

*Attribute**	*0.00*	*1.00*	*2.00*	*3.00*	*4.00*	*Average*	*Data quality*
Productivity	3.17	4.67	2.17	0.00	0.00	0.90	1.83
Juvenile outmigrants				NR			
Diversity	2.00	3.33	3.83	0.83	0.00	1.35	2.00
Habitat	3.50	5.00	1.50	0.00	0.00	0.80	1.50
Spatial Structure	7.17	2.83	0.00	0.00	0.00	0.28	3.00

* W/LC TRT scores rated on a 0-4 scale: 0 = extirpated or nearly so, 1 = relatively high extinction risk, 3 = low extinction risk, and 4 = very low extinction risk. NR = not relevant

White Salmon River Spring Chinook salmon

McElhany et al. (2004) gave the White Salmon spring-run Chinook salmon a weighted average extinction risk score of 0.07, indicating the population is extirpated (Table 4-2). The team concluded that the population is extirpated from construction and over 90 years of blocked passage at Condit Dam. Some members included observed spring-run-timed spawners at the base of Condit Dam, while others considered these fish as strays spawning in unsuitable habitat for spring-run Chinook salmon (McElhany et al. 2004).

Table 4-2. Evaluation scores for White Salmon spring-run Chinook salmon (McElhany et al. 2004)

*Attribute**	*0.00*	*1.00*	*2.00*	*3.00*	*4.00*	*Average*	*Data quality*
Productivity	9.33	0.67	0.00	0.00	0.00	0.07	1.33
Juvenile outmigrants	10.00	NR	NR	NR	NR	NR	4.00
Diversity	8.33	1.33	0.33	0.00	0.00	0.20	1.50
Habitat	10.00	0.00	0.00	0.00	0.00	0.00	1.50
Habitat (w/o dams)	3.75	3.50	2.75	0.00	0.00	0.90	1.50
Spatial structure	9.67	0.33	0.00	0.00	0.00	0.03	3.17

* W/LC TRT scores rated on a 0-4 scale: 0 = extirpated or nearly so, 1 = relatively high extinction risk, 3 = low extinction risk, and 4 = very low extinction risk. NR = not relevant

White Salmon River coho salmon

White Salmon coho salmon received a weighted average extinction risk score of 0.39, indicating that the population is extirpated or nearly so (Table 4-3). TRT members, however, used a default score for no data, which assumes that fish may exist but are not monitored; other members noted that the White Salmon coho salmon population was probably extirpated following construction of Condit Dam, implying the default score might not be appropriate (McElhany et al. 2004). The TRT determined that hatchery introductions, the near absence of accessible spawning habitat, and the low probability of any successful natural reproduction suggest that most genetic diversity native to the White Salmon is extirpated and was replaced by hatchery introductions. In evaluating the habitat criterion, many TRT members included historical spawning habitat above the dam in their considerations (McElhany et al. 2004).

Table 4-3. Evaluation scores for White Salmon coho salmon (McElhany et al. 2004)

Attribute*	**0.00**	**1.00**	**2.00**	**3.00**	**4.00**	**Average**	**Data quality**
Productivity	5.00	5.00	0.00	0.00	0.00	0.50	0.17
Juvenile outmigrants	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Diversity	7.83	2.17	0.00	0.00	0.00	0.22	1.50
Habitat	5.33	3.67	1.00	0.00	0.00	0.57	2.00
Spatial structure	9.17	0.83	0.00	0.00	0.00	0.08	1.83

* W/LC TRT scores rated on a 0-4 scale: 0 = extirpated or nearly so, 1 = relatively high extinction risk, 3 = low extinction risk, and 4 = very low extinction risk.

Upper Gorge Tributaries chum salmon

Upper Gorge Tributaries chum salmon, including those that occupied the White Salmon historically, received a weighted average extinction risk score of 0.18, indicating that the population is extirpated or nearly so (Table 4-4). Data are limited to Bonneville Dam passage counts, although many fish that ascend fall back to spawning areas below the dam. Fish technicians have recovered only a few carcasses above Bonneville Dam; no one has reported spawning aggregations, although biologist M. Weeber, (Weeber, M. personal communication, Oregon Department of Fish and Wildlife (ODFW), 2010), observed individual spawners in Eagle Creek, Oregon. The Bonneville Pool eliminated spawning habitat in both the mainstem and lower creek reaches, creating a series of disconnected spawning sites and culverts, and, stream modifications on the transit corridor on the Washington side of the CR may limit access for a few chum salmon that may be present. Low abundance for the species as a whole may also restrict population dispersal (McElhany et al. 2004).

Table 4-4. Evaluation scores for upper Gorge chum salmon (McElhany et al. 2004).

Attribute*	0.00	1.00	2.00	3.00	4.00	Average	Data quality
Productivity	9.50	0.50	0.00	0.00	0.00	0.05	1.00
Juvenile outmigrants	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Diversity	8.67	1.33	0.00	0.00	0.00	0.13	1.17
Habitat	6.67	2.67	0.50	0.17	0.00	0.42	1.83
Spatial structure	7.33	1.83	0.67	0.17	0.00	0.37	1.83

* W/LC TRT scores rated on a 0-4 scale: 0 = extirpated or nearly so, 1 = relatively high extinction risk, 3 = low extinction risk, and 4 = very low extinction risk.

4.2 Extinction Risk: Interior Columbia TRT

White Salmon River Steelhead

Scientists consider the White Salmon River steelhead population functionally extirpated. The abundance of native summer and winter steelhead in the White Salmon River before 1919, when the loss of the fish ladder at Condit Dam blocked passage to upriver spawning and rearing grounds is unknown. However, some natural steelhead production in the reach below Condit Dam continued to occur (Bambrick et al. 2004). Some biologists believe that residual steelhead populations in the form of resident trout may contribute to anadromy in the watershed. *O. mykiss* from Rattlesnake Creek have been observed showing physiological changes consistent with smoltification, and fish have been detected outmigrating during the typical smolt migration period (B. Allen, personal communication, 2007). As further evidence in support of the retention of anadromous life history traits, a PIT-tagged *O. mykiss* was detected outmigrating from lower Rattlesnake Creek in March 2005, and was detected again in July 2006 moving up through the adult fish ladder at Bonneville Dam, possibly as a

one-salt steelhead (B. Allen, personal communication, 2007). Even with this observation, remnant genetic influences from the original White Salmon River steelhead population in fish spawning in the small section of the White Salmon River below Condit Dam is thought to be minor with natural production coming primarily from the large releases of out-of-basin hatchery stock.

Biologists generally believe that White Salmon River steelhead historically ranged from the mouth to RM 16.3 in the mainstem and into Buck, Spring, Indian, and Rattlesnake creeks (Figure 4-12) (ICTRT 2008). Some anecdotal historic records (WDF 1951), suggest that anadromous fish may have once ascended the White Salmon River as far as Trout Lake, RM 28.2. Most biologists, however, consider Big Brother Falls, RM 16.2, to be the upper limit of historical steelhead migration (NPCC 2004). This historical range provided approximately 33 to 40 miles of steelhead spawning and rearing habitat (NPCC 2004; Bambrick et al. 2004; Ecology 2007).

The ICTRT identified one MaSA, below Big Brother Falls, within the White Salmon watershed based on its historical intrinsic potential analysis. The ICTRT defines a MaSA as a system of one or more branches that contains sufficient habitat to support at least 500 spawners. The ICTRT does not consider any population fewer than 500 spawners to be viable, regardless of its intrinsic productivity.

Figure 4-1 shows the intrinsic habitat potential and MaSA for the White Salmon River summer/winter steelhead populations as identified by the ICTRT in their 2008 analysis (ICTRT 2008). Intrinsic potential is the estimated relative suitability of a habitat for spawning and rearing of anadromous salmonids species under historical conditions inferred from stream characteristics including channel size, gradient, and valley width.

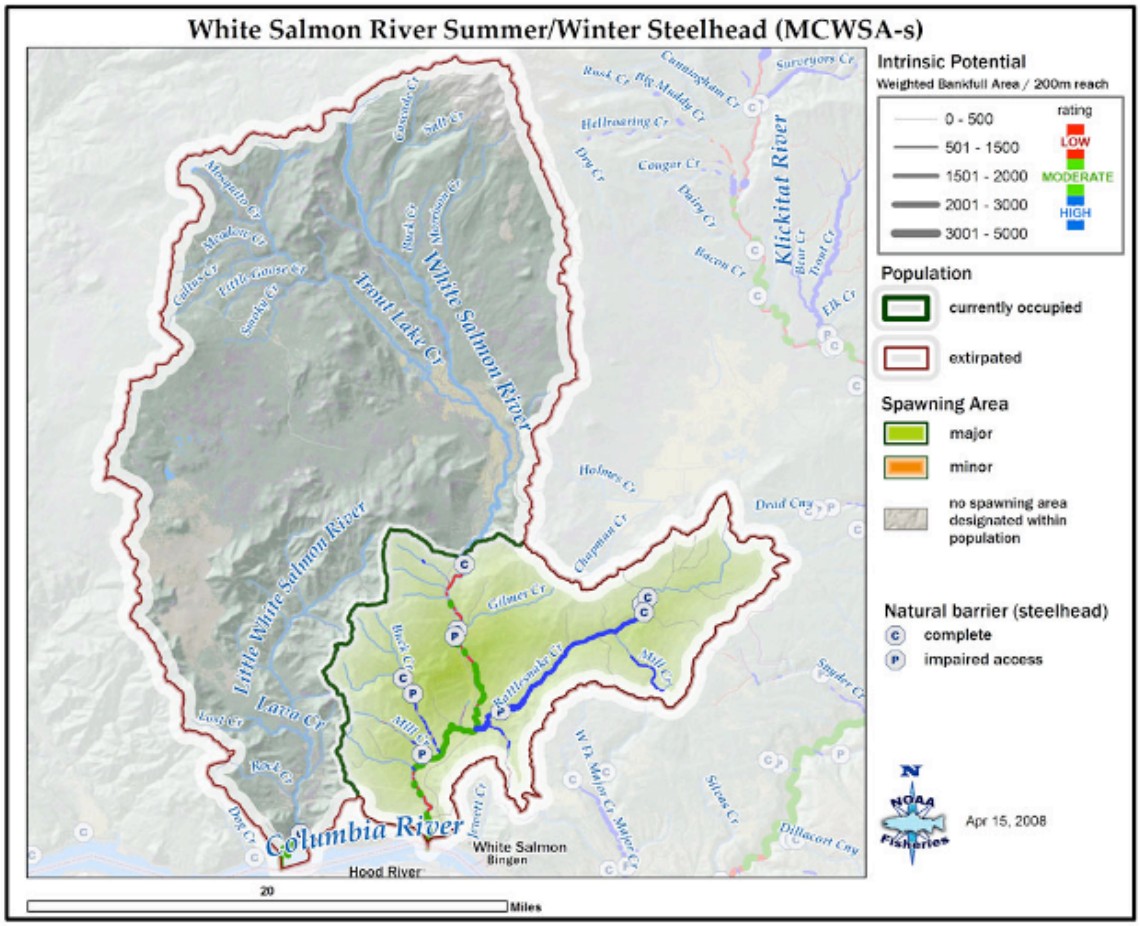

Figure 4-1. Intrinsic habitat potential and Major Spawning Area for the White Salmon River summer/winter steelhead (ICTRT 2008)

5 Limiting Factors and Threats

Scientists generally describe the reasons for a species' decline in terms of limiting factors and threats. Analysis of limiting factors and threats across the entire species' life cycle forms the basis for designing recovery strategies and actions. NMFS defines limiting factors as the biological and physical conditions limiting DPS and population status (e.g., elevated water temperature), and defines threats as those human activities or naturally induced actions that cause the limiting factors (e.g., removal of riparian vegetation for agricultural or residential purposes, which causes loss of shade and, consequently, elevated water temperature).

For salmon and steelhead, survival to reproduce depends on a complex, interacting system of environmental conditions, with different conditions needed for each life stage. Optimal water temperature, for example, varies (within limits) for adult migration versus egg incubation or juvenile rearing. Because of this complexity, in many cases, scientists have a poor understanding of the actual limiting factors.

The list of limiting factors for the White Salmon River salmon and steelhead populations, as for the other populations that make up the LCR salmon ESUs and the MCR steelhead DPS addressed in this recovery plan, is based on a substantial body of research on salmonids, local field data and field observations, and the considered opinions of regional experts. These are implicitly hypothetical statements, made with the expectation that by taking action in the face of some degree of scientific uncertainty, then monitoring the results, continuing to conduct research as a high priority, and adapting our management actions in response, the state of our knowledge will improve and so will fish survival, although not necessarily in a directly parallel process.

Until recently, the primary factor limiting production of all White Salmon species was the presence of Condit Dam. PacifiCorp breached the dam in October 2011, and has removed the structure. Now that the dam no longer serves as a barrier to upstream migration, the primary factor affecting recovery in the White Salmon River watershed is the lack of native stocks. Spring Chinook salmon, coho, chum salmon, and steelhead populations are either extirpated or functionally extirpated (Good et al. 2005, ICTRT 2007b, Ford et al. 2011). The development of local populations will necessitate natural re-colonization or require the introduction of stocks from other basins, but may be limited by the quality of habitat within the watershed.

Salmon and steelhead have not occupied the habitat upstream of the dam for decades. An abundance of unoccupied habitat is present in the basin. Therefore, habitat quality upstream of the former dam is not currently limiting the populations. Fall Chinook salmon and some strays of other species utilize the lower river below the former Condit Dam. The numbers of fall Chinook salmon spawners increased from low levels in the early 2000s (WDFW 2002) to an average of 2,750 for the 2007-08 period (Roler 2009). The majority of the fall Chinook salmon, spawning in the lower river, were assumed to be strays from Spring Creek NFH. The marking of all of the production at Spring Creek NFH has shown that the escapement in recent years has been overwhelmingly from natural-origin fall Chinook salmon (Roler 2011). Prior to breaching of the dam, the habitat in the lower river may have been limiting Chinook salmon production in the years of high abundance.

In the future, some of the species that historically occupied the watershed may slowly begin to occupy upstream habitat through natural re-colonization/straying. More direct stocking may also occur to facilitate the rate of population growth. As the populations recover, some factor related to in-river habitat, quality may eventually become the factor limiting salmonid production. To a certain degree, this will depend upon the species that come to occupy that habitat and also on the degree that the various natural waterfalls in the basin end up restricting dispersion of the species.

When the dam was breached, the reservoir drained quickly. Biologists have not yet had the opportunity to evaluate the current condition of habitat downstream of the dam, but they anticipate large amounts of sediment entering the lower river and moving into the Columbia River. They cannot predict, with any certainty, other habitat conditions after removal; however, the reduction of habitat carrying capacity of the habitat is likely to persist for some unknown period of time. Habitat downstream of the dam may limit population production in the lower river until that habitat recovers from the effects of the removal of the dam, though redds were observed in the lower river in 2012 (R. Engle, USFWS, personnel communication December 2012).

The discussion below further describes what biologists currently know about the condition of the basin's habitat. Numerous studies completed since 2002, including the applicable results of the EDT run completed in 2004 (Allen and Connolly 2005), form the basis of this habitat discussion. In that spirit, this chapter describes potential factors that may limit future anadromous salmon and steelhead populations in the White Salmon River watershed. Chapter 5 is organized as follows:

- Section 5.1 addresses the migration barrier at Condit Dam.
- Section 5.2 identifies freshwater life cycle factors.
- Section 5.3 describes effects on the populations from hatchery production and releases.
- Section 5.4 discusses impacts from harvest.
- Section 5.5 identifies effects from the CR hydrosystem.
- Section 5.6 discusses effects of predation.
- Section 5.7 discusses ocean effects.
- Section 5.8 discusses climate change.
- Section 5.9 discusses other large-scale threats.

5.1 Blocked Migration and Impaired Passage

The single greatest factor limiting salmon and steelhead populations in the White Salmon River watershed was the migration barrier at Condit Dam. Only a small percentage of the historical anadromous spawning and rearing areas was accessible. Table 5-1 presents the current or pre-Condit Dam removal and historical distribution (post Bonneville Dam) within the White Salmon River watershed based on the assumptions built into the EDT model. Note

that as an artifact of the EDT model, it defined fall and spring Chinook salmon spawning habitat with no overlap. As a result, the fall Chinook salmon habitat was reduced to cover an area less than what biologists generally believe to be historically accessible. Biologists have considered fall Chinook salmon habitat to have historically extended up to Husum Falls at RM 7.6, which may overlap with possible spring Chinook salmon spawning habitat between Condit Dam and Husum Falls. Chum salmon is the only species that would have access to all of its remaining historical range with the dam in place.

Table 5-2 summarizes primary limiting factors for LCR fall Chinook salmon. Table 5-3 summarizes additional limiting factors affecting anadromous fish in the White Salmon River Basin. Described below are these limiting factors.

Table 5-1. River miles of salmon and steelhead habitat above and below Condit Dam (NPCC 2004).

Species	*Historical Distribution*	*Current Distribution*	*% of Historical Access*	*Comments*
Chum salmon	1.2 miles	1.2 miles	20%	80 percent of spawning area flooded by Bonneville Dam
Fall Chinook salmon	3.6 miles	3.4 miles	94%	6 percent of spawning area above Condit Dam
Spring Chinook salmon	12.8 miles	0 miles	0%	All of spawning area above Condit Dam
Coho salmon	21.1 miles	3.4 miles	16%	Majority of spawning area above Condit Dam
Steelhead	32.9 miles	3.4 miles	10%	Majority of spawning area above Condit Dam

5.2 Freshwater Habitat

5.2.1 Lower White Salmon River Habitat Below Condit Dam

Prior to removal, operations at Condit Dam had reduced the rearing potential in the bypass reach downstream of the dam because minimum flows were 15 cfs, which was only a small percentage of the natural low flows of approximately 626 cfs (United States Geographic Survey (USGS) 2010). Power peaking associated with dam operation caused further diel flow variation, which has led to dewatering, stranding, and an increase in bioenergetic losses because of movements associated with daily flow changes.

The transport of rock and sediment, as well as nutrients, cold water and large wood down the White Salmon River stopped at Northwestern Lake. As a result, coarse material tends to dominate the reach downstream of the dam. Historically, this reach likely had more gravel,

cobble, and large wood which salmon and steelhead used as spawning habitat, than is currently present.

The removal of Condit Dam has restored normative flows in the reach. Sediment and woody material transport is also being re-established. During the years after dam removal, flows will transport fine sediment out of the previous reservoir area downstream to the CR. These sediments are likely to affect the quality of spawning habitat in the reach downstream of the dam until the river re-establishes a stable channel and the banks of the new channel also become relatively stable. The reduced habitat quality may decrease the numbers of fall Chinook salmon (and other species that stray into the lower river) that the river can support for an unknown number of years.

Steelheads use the lower reach of the White Salmon River and the area at the mouth of the White Salmon River. Other species migrating to rivers upstream of the White Salmon River use the river as a cool water refuge in the summer and also as temporary overwintering habitat (High et al. 2006; Keefer et al. 2008). By filling in rearing area and holding pools, the sediment released from behind the dam may alter this cool water refuge area for upstream migrants. The return of downstream wood transport may help to eventually deposit wood that helps to scour pools, sort sediments and create holding habitat.

5.2.2 Habitat Upstream of Condit Dam

Flow Regimes

A watershed analysis conducted by the USFS in the upper White Salmon River indicated that, based on past management activities, portions of the upper White Salmon River may be subject to increased peak flow events (USFS 1998). Tributary reaches of the White Salmon generally have more volatile flows than the mainstem White Salmon. Road building, removal of trees from riparian areas, clearing of forests and agricultural lands, loss of wetlands, and other impacts on ecosystem function may have modified the intensity of flows in some tributary reaches.

Channel Structure, Riparian Condition, and Floodplain Connectivity

Some stream reaches in the tributaries have few deep pools and little instream wood (Allen et al 2006a, 2006b; Morris 2004). Substrate in Rattlesnake Creek has a low percentage of ‘fines’ and abundance of spawning sized material (Morris 2003). No additional data representing habitat quality in the mainstem White Salmon River are available to date.

Both timber harvest and fires have impacted forested lands within the lower reaches of the watershed. Biologists consider 72 percent of riparian areas within the upper White Salmon to be late successional, as compared with 38 percent for the entire basin (USFS 2002). Small red alder tends to dominate riparian areas along Rattlesnake and Buck Creeks; conifers in the riparian area are sparse (Allen et al. 2006a, 2006b).

Roads can affect salmonid habitat by reducing natural infiltration and increasing hydro-confinement, leading to altered flow regimes, peak flows, and increased delivery of fine sediment to streams. The magnitude of effect as measured by road density is dependent upon

the number of roads, the locations of roads, the surfacing used, traffic levels, and mid-slope engineering of the road (Dubé et al. 2004).

Researchers calculated road densities (road miles/square-mile) in the upper, middle, and lower White Salmon River at 3.7 miles per square mile (2.3 kilometers per square km), 3.1 miles per square mile (1.9 kilometers per square kilometer), and 4.0 miles per square mile (2.5 km per square km), respectively. Tributary road density in the upper White Salmon ranged from 0.2 to 4.4 miles per square mile (0.1 to 2.7 km per square km) (USFWS 2002). Rattlesnake Creek has a density of 3.54 miles per square mile (2.2 km per square km) and Buck Creek a density of 5.05 miles per square mile (3.1 km per square km) (Allen and Connolly 2005). Analyses of the effects of roads on sediment inputs or stream flow have been limited to the headwaters of the mainstem (USFS 2002) and the headwaters of Rattlesnake Creek (Panakanic Watershed Analysis, http://fortress.wa.gov/dnr/forestpractices/wsasmt.cgi?wsaval=acme (accessed April 11, 2012). The Forest Service assessment identified roads that needed addressing. The upper Rattlesnake assessment found that roads were not contributing high amounts of sediment.

After the dam decommissioning efforts are completed, fine sediment will likely dominate habitat in the area previously occupied by the reservoir until such time as the fine materials deposited behind the dam are transported out of the reach, a new channel becomes established, and banks stabilize. Riparian seeding and tree planting, described in PacifiCorp's Re-vegetation and Wetlands Management Plan (PacifiCorp Energy 2010), will address the lack of riparian vegetation in the inundated area. Wood abundance may be high because the reservoir stopped downstream transport of woody debris since 1919; actual abundance will depend on the amount of wood transported into the reservoir and the decay rate of that wood.

Water Quality

Water temperature and dissolved oxygen levels in the mainstem White Salmon River are at or near optimum levels for salmonids (White and Plumb 2004). Maximum temperature within the expected anadromous range meets Washington state water quality standards with the exception of Rattlesnake Creek which approaches lethal temperatures in some locations in some years (White and Plumb 2004; White and Plumb 2005; White and Cochrane 2005, Connolly 2003; Morris 2005). Phosphorus and nitrate/nitrite in the basin (mainstem and tributaries) is very high. Phosphorus levels tend to be roughly twice the recommended EPA standard for creeks and streams and nitrate/nitrite is as much as two orders of magnitude higher that the EPA recommended standard (White and Plumb2004, 2005; White and Cochrane 2005, EPA 2000).

There are currently several segments of the mainstem White Salmon and tributaries listed as impaired waterways, 303(d) listings, by the Washington State Department of Ecology, although some of the data on which the listings are based needs updating. Ecology lists individual reaches on Gilmer Creek, Rattlesnake Creek, the mainstem White Salmon, and Trout Lake Ditch as Category 5 (water quality impaired) for fecal coliform. Temperature impairments have led to the Category 5 listing of reaches on Indian and Rattlesnake creeks http://www.ecy.wa.gov/programs/wq/303d/2008/index.html (accessed April 11, 2012).

5.3 Hatchery Production and Releases

Discussed below are effects of hatchery production and releases on White Salmon River salmon and steelhead populations.

Chinook salmon

Tule fall Chinook salmon from Spring Creek NFH contribute to natural production of fall Chinook salmon in the White Salmon River. Most of the fish spawning naturally in the White Salmon River were assumed to be hatchery-origin tule fall Chinook salmon based on CWT recoveries. Spring Creek NFH began marking all of its hatchery production and as a result, recent spawning ground surveys have shown that the majority of the tule fall Chinook salmon returning to the White Salmon River are of natural origin (Roler 2011). Spring Creek NFH tule fall Chinook salmon originally derive from White Salmon tule fall Chinook salmon and biologists and recovery planners anticipate that Spring Creek NFH tule fall Chinook salmon may be used to supplement natural production in the future. Smith and Engle (2011) collected genetic samples from juvenile salmon emigrated from the White Salmon River and determined that the naturally produced fall Chinook salmon juveniles grouped with Spring Creek NFH tules when compared to other LCR tule fall Chinook salmon populations and stray URB fall Chinook salmon.

Stray URB hatchery fall Chinook salmon may be affecting the productivity of the tule fall Chinook salmon in the White Salmon River. These URB fall Chinook salmon are strays from releases at the LWS NFH and other releases in the Bonneville Pool. Through redd superimposition, URB fall Chinook salmon can adversely affect tule fall Chinook salmon: Peak spawning time for URB fall Chinook salmon is in late October and into November after tule fall Chinook salmon spawning has been completed. Since habitat has been very limited in the White Salmon River, URB fall Chinook salmon that spawn on top of tule fall Chinook salmon redds can decrease the productivity of the White Salmon River population. The LWS NFH is taking measures to decrease the number of stray URB fall Chinook salmon. Recent escapement data for the White Salmon River has shown a decrease in the abundance of URB fall Chinook salmon spawners, but in some years, their abundance exceeds that of tule fall Chinook salmon (Roler 2011). If these measures are unsuccessful in reducing the number of stray URB fall Chinook salmon to acceptable levels, the hatchery will implement other actions.

Biologists do not know the actual stray rate of Spring Creek NFH tule fall Chinook salmon into local tributaries, but these Spring Creek hatchery fish do contribute to naturally spawning tule fall Chinook salmon in upper gorge tributaries, including the White Salmon River. The exact proportion of these hatchery fish on the spawning grounds could not be determined because only a small number of the hatchery's fish were marked. The estimated number of tule fall Chinook salmon spawners has increased in recent years peaking in 2003 with 1,575 being observed in the Wind River, 12,471 in the White Salmon River, and 10,686 in the Klickitat River (Jenkins, 2006; Roler 2009). All recent production at Spring Creek NFH fall Chinook salmon have been externally marked allowing for differentiation between natural-origin and hatchery fall Chinook salmon in the White Salmon River. All age-classes of the hatchery tule fall Chinook salmon returning to Spring Creek NFH were marked in 2010, and escapement to the White Salmon River was estimated to be composed of 1,142

natural-origin and 558 hatchery-origin tule fall Chinook salmon adults (Roler 2011). Smolt-to-adult survival rates averaged 0.136 percent for the 1991-95 brood years (Spring Creek NFH Hatchery Genetic Management Plan (HGMP) 2002). The total exploitation rate for the hatchery program was as high as 75.3 percent for the 1982-89 brood years. An estimate for brood years 1990-93 has the total exploitation rate at 67 percent, with nearly half of the impacts occurring in the CR, primarily in the Zone 6 area above Bonneville Dam (Spring Creek NFH HGMP 2002).

Hatchery-produced spring Chinook salmon are not released into the White Salmon River Basin though strays from the LWS NFH and other programs were recovered at a weir on the White Salmon River in 2009 (Engle et al. 2010).

Coho salmon

Hatchery biologists found that coho salmon from the LWS NFH had strayed into the White Salmon watershed prior to the closure of the program in 2004. Biologists consider these strays and others from releases further upstream in the CR to be the likely source of naturally spawning coho salmon in the White Salmon River.

Steelhead

Until 2010, fisheries managers released summer and winter steelhead from Skamania broodstock into the White Salmon River below Condit Dam to support tribal and recreational fisheries. Technicians marked all hatchery fish to allow for selective fisheries. These releases may limit the diversity of any naturally produced winter steelhead in the basin. However, the primary constraint on summer and winter steelhead in the White Salmon River has been the limited spawning and rearing habitat. Further, biologists do not believe Skamania stock steelhead are reproductively successful when spawning naturally; thus, adverse effects on natural populations may be limited. The hatchery terminated releases of these hatchery fish as of 2010 and biologists expect any potential impacts associated with these releases within the White Salmon will diminish after 2011. There may also be significant straying of migrating hatchery fish from other basins into the White Salmon seeking a cold water refugia (High et al. 2006, Keefer et al. 2008). These strays may originate from different DPSs including the Snake River Basin. While some may contribute to rebuilding the population, other strays may have a negative impact.

5.4 Harvest

Harvest currently does not limit the abundance or the diversity of White Salmon River steelhead, and spring Chinook salmon, coho salmon, and chum salmon, populations. NMFS considers all of these populations extirpated or functionally extirpated (Good et al. 2005; ICTRT 2007b; Ford et al. 2011). Any coho, chum, spring Chinook salmon, and most steelhead found in the White Salmon River are strays from other basins. In the White Salmon River, non-tribal coho salmon and steelhead fisheries are selective for marked hatchery fish, requiring the release of unmarked salmon and steelhead. Regulations prohibit retention of fall Chinook salmon in the White Salmon River from October 1 to December 31.

Fall Chinook salmon

Ocean fisheries off the coasts of Oregon, Washington, and British Columbia catch LCR fall-run (tule) Chinook salmon populations (NMFS 2008c). Total exploitation rates were generally higher through 1993 (averaging 69 percent), lower from 1994 to 1999 (averaging 34 percent), then increasing since 2000 (averaging 49 percent). From 2002 to 2006, regulators limited fisheries to a 49 percent exploitation rate. Total exploitation rates have been higher in some years but have averaged 49 percent from 2002 to 2006. The average exploitation rates for non-treaty fisheries in the CR for these same periods were 16 percent, 8 percent and 9 percent respectively. Tribal fisheries have a higher harvest rate on the Bonneville Pool tule populations, including the White Salmon River population (NPCC 2004; NMFS 2000).

For the last several years, NOAA Fisheries has limited Pacific Fisheries Management Council (Council) and in-river fisheries by specifying a total exploitation rate limit. From 2002 to 2006, the limit was 49 percent. The Council reduced the exploitation rate to 42 percent in 2007. NOAA Fisheries' guidance to the Council for 2008 was that Council fisheries should be managed such that the total exploitation rate on LCR Chinook salmon tule populations, from all fisheries does not exceed 41 percent. For 2009 and thereafter, NOAA Fisheries has set a total exploitation rate limit for tule Chinook salmon through their annual guidance letter to the Council. The Council's Salmon Forest Management Plan (FMP) requires NOAA Fisheries to provide such guidance. Fisheries subject to the 2008 *U.S. v. Oregon* Agreement that are part of the set of Prospective Actions must be managed subject to the overall exploitation rate limit as proposed in 2008 and have been since 1999 (NMFS 2008c). Biologists believe that tribal fisheries do not have a significant impact on the entire LCR tule fall Chinook salmon run, but do have a higher harvest rate on the Bonneville Pool tule populations, including the White Salmon River (NPCC 2004; NMFS 2000). Under the *U.S. v. Oregon* Agreement, there are a number of escapement and management objectives that limit the harvest of fall Chinook salmon in fisheries that would impact White Salmon River fall Chinook salmon, for example, a minimum escapement goal of 7,000 adults (4,000 females) to meet broodstock needs at Spring Creek NFH can restrain ocean, lower river mainstem, and above Bonneville Dam treaty fisheries (NMFS 2008c).

Tributary fisheries minimally impact tule fall Chinook salmon. The White Salmon River tributary fishery accounts for less than one percent of the total run-size of LCR fall Chinook salmon and less than 4 percent of the White Salmon River tule fall Chinook salmon (NMFS 2008c). Currently, Washington fisheries regulations allow fall Chinook salmon retention in the lower White Salmon River from July 1 to March 31 annually, but close the river to the retention of Chinook salmon ½ mile upstream from the Highway 14 bridge from October 1 to December 31 to protect spawning salmon (WDFW 2009). Catch record cards are the basis for the estimated total recreational Chinook salmon catch in the White Salmon River. These data can contain recording errors and fish misidentification, along with dip-in fish destined for upriver systems. The exploitation rate of White Salmon River tule fall Chinook salmon during WDFW-regulated fisheries in the White Salmon River is less than 5 percent of the terminal run. Biologists estimate the terminal run-size based on the annual catch rate and spawning escapement estimate data collected since 1995 (NPCC 2004). The average annual catch of wild tule fall Chinook salmon is approximately 30 fish and the average annual escapement estimate is 461, therefore, the average annual terminal run of White Salmon

River tule fall Chinook salmon is approximately 491 fish. Biologists extrapolate total run-size of the White Salmon River tule fall Chinook salmon and total fisheries impact from these data. Using the estimated annual terminal run-size and estimated annual exploitation from ocean and CR mainstem fisheries, the estimated average total run-size of White Salmon River tule fall Chinook salmon is 784 fish (NPCC 2004). The total number of fall Chinook salmon spawners (natural-origin and hatchery) has increased from low levels in the early 2000s (USFWS 2004) to an average of 2,750 for the 1998-2007 period (Roler 2009). The sport harvest has remained at roughly 30 adult fall Chinook salmon (Kraig and Smith 2008). Therefore, in recent years the proportion of the total escapement caught in the fishery has remained small.

Spring Chinook salmon

If the White Salmon River produced spring Chinook salmon, they would contribute to lower Columbia mainstem fisheries and treaty fisheries in the Bonneville Pool. Spring Chinook salmon originating from above Bonneville Dam do not contribute to ocean fisheries compared to other LCR spring Chinook salmon populations (NMFS 2008c). Fishery managers would deal with spring Chinook salmon originating from the White Salmon River as part of the upriver spring and Snake River summer Chinook salmon group. This group includes all natural and hatchery produced spring Chinook salmon originating from the CR and its tributaries above Bonneville Dam (NMFS 2008c). The abundance of this group and the status of natural-origin spring Chinook salmon from the Snake River and upper CR is the basis for establishing harvest rates for both lower river commercial and recreational fisheries and tribal treaty fisheries above Bonneville Dam. The harvest rate for this group averaged 14.5 percent from 1999 to 2008, but the actual harvest rate for prospective White Salmon spring Chinook salmon would be less because they are not exposed to the full Zone 6 (above Bonneville) treaty fishery (ODFW and WDFW 2009). Tributary sport regulations for the White Salmon River require the release of unmarked Chinook salmon from April 1 to June 30 protecting natural-origin spring Chinook salmon that may enter the White Salmon River (WDFW 2009).

Coho salmon

NMFS considers White Salmon coho salmon extinct and therefore allows no fisheries targeting coho salmon in the White Salmon River (Good et al. 2005). Stray hatchery coho salmon can be retained and all wild coho salmon must be released in fisheries downstream of the location of Condit Dam from July 1 to March 31 (WDFW 2009) LCR coho salmon are caught in both ocean and in-river fisheries. Until 1993 the exploitation rates of LCR coho salmon have been very high, contributing to their decline (NMFS 2008c). The combined ocean and in-river exploitation rates for LCR coho salmon averaged 91 percent through 1983, averaged 69 percent from 1984-1993, and decreased to an average of 16.7 percent from 1994-2007 (NMFS 2008c). The exploitation of hatchery coho salmon has remained approximately 50 percent through the use of selective fisheries.

The Pacific Fishery Management Council in accordance with the 2008 *U.S. v. Oregon* Agreement and related biological opinions regulates LCR coho salmon harvest, which is subject to a total exploitation rate limit for the combined ocean and in-river fisheries. Previously, ocean regulators used Oregon Coast natural coho salmon as a surrogate for

estimating ocean fisheries impacts to LCR coho salmon. In 2006, largely as a consequence of increased attention resulting from its listing, the methods for assessing harvest in ocean fisheries changed so that they were more specific to LCR coho salmon (NMFS 2008c).

Each year, harvest managers in the CR will set coho salmon fishing regulations, after accounting for anticipated ocean harvest, so as not to exceed the total exploitation rate limit. In 2008, the total exploitation rate limit was 8 percent based on the year specific circumstances. For 2009 and thereafter, NOAA Fisheries will set a total exploitation rate limit for LCR coho salmon through their annual guidance letter to the Council. Fisheries subject to the 2008 *U.S. v. Oregon* Agreement that are part of the set of Prospective Actions must be managed subject to the overall exploitation rate limit as proposed in 2008 and as they have been since 1999. Under the *U.S. v. Oregon* Management Agreement (NMFS 2008c) these non-treaty fisheries do not exceed the 50 percent catch sharing objective for coho salmon destined for above Bonneville Dam.

Chum salmon

In the first half of the 20th century there was a substantial commercial chum salmon fishery with a harvest rate of more than 500,000 chum salmons in some years (Myers et al. 2006). Harvest of chum salmon in the CR is limited to indirect fishery mortality. Regulators closed or drastically minimized commercial chum salmon fisheries in the 1950s due to severe population declines. Currently, there are no recreational or commercial fisheries in the CR. The number of chum salmon landed as take incidental to lower river commercial gill net fisheries has been fewer than 50 fish in each of the last five years. Harvest impacts to chum salmon from CR commercial and recreational fisheries are constantly below 5 percent and since 1998 have averaged 1.6 percent. Biologists assume ocean fishing mortality on CR chum salmon to be zero. Regulations prohibit retention of chum salmon in the White Salmon River.

Middle Columbia River steelhead

NMFS considers White Salmon River steelhead functionally extirpated (ICTRT 2007b). Any future White Salmon River produced steelhead would have similar fishery impacts as biologists have observed for steelhead destined for the other MCR Basins in Bonneville Pool. Various fisheries can catch these steelhead as they migrate through the CR and Pacific Ocean. These fisheries are discussed briefly below.

Ocean Fisheries

Ocean fisheries rarely catch steelhead; therefore, biologists do not consider these fisheries a significant source of mortality to MCR steelhead (NMFS 2000). Biologists assume ocean fishing mortality on MCR steelhead to be zero.

Columbia River Mainstem Non-Tribal Fisheries

There has been no direct freshwater non-tribal harvest on wild steelhead from the MCR steelhead DPS since 1992, when the last wild fish catch-and-release regulations on these populations became effective. Therefore, all current non-tribal harvest impacts on Mid-Columbia DPS steelhead are due to incidental by-catch in commercial or recreational fisheries that target hatchery steelhead or other species. Monitoring these impacts is

complex. Released fish experience a mortality rate, possibly delayed and difficult to measure, that is highly variable and depends on what gear is used, how the fish are caught by the gear, how the fish are handled during capture and release, and environmental conditions. Biologists estimate release mortality to be very low (below one percent of encounters (NMFS 2008c)), with an unknown range of error. Fish technicians monitor recreational fisheries by conducting creel surveys, interviewing anglers about their catch, gear, and wild steelhead releases. Biologists estimate the total recreational impact on winter and summer steelhead as they move through the mainstem to the tributaries to be less than 2.5 percent (ODFW 2008).

There are three stocks of summer steelhead used for management of treaty and non-treaty mainstem fisheries, including the LCR Skamania stock, upriver A-run stock, and upriver B-run stock. All MCR steelhead populations are designated A-run, with two populations being winter-run. In NOAA's Biological Opinion for the 2008-2017 *U.S. v. Oregon* Fisheries Agreement, the wild MCR Steelhead DPS in the non-treaty winter, spring, and summer mainstem fisheries are subject to a 2 percent harvest rate limit (NMFS 2008c). Non-treaty fall fisheries are also limited to a 2 percent harvest rate limit for A-run summer steelhead. The total annual harvest rate limit for A-run steelhead in non-treaty fisheries is 4 percent and 2 percent for the summer-run and winter-run of the MCR steelhead DPS, respectively. The expected harvest impacts from non-treaty fisheries are less than the limits proposed in the *U.S. v. Oregon* Fisheries Agreement. The yearly incidental catch of A-run steelhead in non-treaty fisheries has averaged 1.6 percent since 1999; co-managers do not expect to the incidental catch rate to change over the course of the Agreement (NMFS 2008c).

Treaty Indian Fisheries

Tribal fishers in Zone 6 of the Columbia mainstem (between Bonneville Dam and McNary Dam) continue to retain wild steelhead for commercial sale or for personal use. The *U.S. v. Oregon* Fisheries Agreement does not establish specific harvest rate limits for tribal fisheries on steelhead during the spring or summer seasons that extend through July 31. Reported steelhead catch in Zone 6 winter and spring fisheries for 2003 to 2005 ranged from 0.7 percent to 7.9 percent of the winter steelhead run over Bonneville Dam. In 2004, reported and estimated non-reported steelhead catch together amounted to 4.8 percent of the run at Bonneville, with an unknown range of error (ODFW 2008).

Harvest restrictions for B-run steelhead and upper CR bright fall Chinook salmon limit tribal fishery impacts on MCR steelhead (NMFS 2008b). The harvest rate on MCR summer-run steelhead in spring, summer, and fall Zone 6 tribal fisheries combined averaged 11.7 percent since 1985 and 6.64 percent since 1998 (NMFS 2008b, Table 8.8.5.5-1). Co-managers expect the impacts resulting from the tribal fisheries to be similar to the 1998-2006 average of 6.64 percent. The harvest rate is mostly for populations that pass more dams in Zone 6 than the White Salmon steelhead population, which passes only one Zone 6 dam. White Salmon steelheads are therefore subject to fewer non-Native American and tribal treaty fisheries and experience a harvest rate estimated to be less than 10 percent.

White Salmon River Fisheries

The White Salmon River was open year-round for marked hatchery steelhead up to the Powerhouse outfall. After dam breaching, the area open to steelhead fisheries is the lower three miles of the mainstem river, and also upriver as far as Husum. This fishery harvests

marked Skamania hatchery steelhead released in the basin as juveniles and out-of-basin steelhead that dip-in to the White Salmon River when seeking cooler water temperatures in the summer. According to catch card data available for the 2002-03 return year, fisheries harvested 3,135 marked summer steelhead and 133-marked winter steelhead (WDFW 2008). Non-tribal fisheries for Chinook salmon and coho salmon are open in the lower White Salmon River all year and require the release of unmarked Chinook salmon and coho salmon by non-tribal fishers.

5.5 Federal Columbia River Hydrosystem

Hydropower system construction and operation (flow regulation) in the CR Basin has been a major cause of changes in the CR and estuary from historical conditions.

Within the White Salmon watershed, creation of the Bonneville Dam pool on the mainstem CR affected steelhead and salmon by effectively inundating the lower 0.96 miles of the habitat. This resulted in the loss of riparian, spawning, and rearing habitat and increased predation by native and non-native fish in the lower river. The effects are greatest on White Salmon chum salmon, since the dam inundated all but 0.24 miles of their original habitat. A lack of historical data inhibits quantitative evaluation of the impacts of Bonneville pool inundation on native fish, plant, and wildlife species.

Dams altered conditions within much of the mainstem Columbia and Snake Rivers compared to historic conditions. The development of hydropower and water storage projects within the CR Basin resulted in the inundation of many mainstem spawning and shallow-water rearing areas (e.g., loss of spawning gravels and access to spawning and rearing areas); altered water quality (e.g., reduced spring turbidity levels), water quantity (e.g., seasonal changes in flows and consumptive losses resulting from use of stored water for agricultural, industrial, or municipal purposes), water temperature (e.g., including generally warmer minimum winter temperatures and cooler maximum summer temperatures), water velocity (e.g., reduced spring flows and increased cross-sectional areas of the river channel), food (e.g., alteration of food webs, including the type and availability of prey species), and safe passage (e.g., increased mortality rates of migrating juveniles) (Williams et. al 2005; Ferguson et. al 2005).

Model studies indicate that the hydrosystem and reduced river flows caused by climate change together have decreased the delivery of suspended particulate matter to the lower river and estuary by about 40 percent (as measured at Vancouver, Washington) and have reduced fine sediment transport by 50 percent or more (Bottom et al. 2005). Overbank flow events, important to habitat diversity, have become rare, in part because flow management and irrigation withdrawals prevent high flows and in part because diking and revetments have increased the "bankfull" flow level (from about 18,000 to 24,000 m3/s). The dynamics of estuarine habitat have changed in other ways relative to flow. The availability of shallow (between 10 cm and 2 m depth), low-velocity (less than 30 cm/s) habitat now appears to decrease at a steeper rate with increasing flow than during the 1880s, and the absorption capacity of the estuary appears to have declined.

The CR Estuary Module, at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Estuary-Module.cfm (accessed April 11, 2012), provides more information on factors that limit viability of LCR Chinook salmon and coho salmon, CR chum salmon, and MCR steelhead in the CR Estuary.

5.5.1 Hydro Project Impacts on Outmigrating Smolts

As anadromous juvenile salmonids migrate from freshwater rearing habitats to the ocean, they are vulnerable to a host of factors that affect their survival. Scientists have conducted many studies in recent years to determine both the direct effects associated with project passage (e.g., instantaneous mortality, injury, loss of equilibrium, reservoir and tailrace predation) and indirect effects (e.g., vulnerability to predation in the estuary or plume, disease, and physiological stress), which contribute to the total mortality of seaward migrating salmonids (Counihan et al. 2005).

White Salmon River salmonids must pass only Bonneville Dam on their way to and from the Pacific Ocean. The 2008 Federal Columbia River Power System (FCRPS) Biological Opinion's Reasonable and Prudent Alternative (RPA) requires a 10-year program of configuration improvements at the dam including the installation of turbines with minimum gap runners at Powerhouse 1 and increased guidance into the juvenile bypass systems at both powerhouses (NMFS 2008b). BPA will continue and further increase the pike minnow sport fishery incentive program, removing more of these predators from Bonneville pool. Upon implementation of these changes, juvenile survival from the mouth of the White Salmon to below Bonneville Dam is expected to be 95.5 percent for Chinook salmon, coho and chum salmon and 90.8 percent for steelhead (NMFS 2008b, Table 14.3 of the Incidental Take Statement).

5.5.2 Hydro Project Impacts on Migrating Adults

Passage Survival

Fish returning to the White Salmon watershed must pass Bonneville Dam and Reservoir. Prospective actions under the 2008 FCRPS Biological Opinion's RPA are expected to maintain the current high survival rates of 98.6 percent for spring-run Chinook salmon, 98.5 percent for steelhead, and 96.9 percent for fall-run Chinook salmon, coho, and chum salmon (NMFS 2008b, Table 14.1 of the Incidental Take Statement). Sea lions take about 22 percent of adult winter steelhead and 8.5 percent of adult spring Chinook salmon in the tailrace of Bonneville Dam (NMFS 2008b).

The 2008 FCRPS Biological Opinion RPA requires that the USACE install, and improve as needed, sea lion excluder gates at all main adult fish ladder entrances and must continue to support land and water based harassment efforts by NOAA Fisheries, ODFW, WDFW and the Tribes to keep sea lions away from the area immediately downstream of Bonneville Dam.

5.6 Predation, Competition and Disease

There has been an increase in abundance of predatory native and exotic fishes below Condit Dam within the reservoir created by Bonneville Dam. Primary predators of juvenile salmonids in the CR include northern pike minnow, smallmouth bass, channel catfish, walleye, terns, cormorants, and sea lions. Northern pike minnow are native cyprinids that are widely distributed throughout the CR Basin. Because these predators consume millions of salmonid smolts per year in the LCR, they are the subjects of an extensive predator control effort.

Hatchery steelhead juvenile releases into the White Salmon have probably led to competition with any natural-origin smolts produced below Condit Dam; these releases were discontinued in 2010. Hatchery adults that stray into the White Salmon River may compete for spawning and rearing habitat. Spawning of later returning URB fall Chinook salmon can reduce the productivity of naturally spawning tule fall Chinook salmon through redd superimposition.

Hatchery managers have reported Bacterial Kidney and Black Spot diseases throughout the White Salmon Basin (Allen et al. 2006a, 2006b). Now that PacifiCorp has breached Condit Dam, diseased fish moving into waters upstream of the former dam site may introduce other pathogens and/or diseases into the basin. The effects of disease on current or any potential future populations are unknown.

5.7 Ocean Conditions

The effects of ocean conditions on abundance of Pacific salmon and steelhead vary among species and populations within species. Migration patterns in the ocean may differ dramatically and expose different stocks to different conditions in different parts of the ocean. Some species have broad, offshore migration patterns that may extend as far as the Gulf of Alaska (steelhead, chum, and some Chinook salmon). Others have migration patterns along the Washington, British Columbia, Oregon, and California coasts (Chinook salmon, coho, and cutthroat salmon). Thus, ocean conditions do not have coincident effects on survival across species or populations.

Widespread changes in ocean conditions have dramatically affected ocean survival of steelhead. Cooper and Johnson (1992) showed that variation in steelhead run sizes and smolt-to-adult survival was highly correlated between runs up and down the West Coast. Smolt-to-adult survival rates generally varied 10-fold between good and bad years. Scientists know little about the early ocean life history of CR chum salmon.

5.8 Climate Change

Climate change represents a potentially significant threat to recovery of listed salmon and steelhead populations. The Independent Scientific Advisory Board (ISAB) for the NPCC, CR Basin Indian Tribes, and NMFS reviewed the potential effects of climate change on salmonids in the CR Basin (ISAB 2007). The ISAB report shows that changes in climate may adversely affect steelhead in freshwater habitats across the MCR DPS by exacerbating existing problems with water quantity (lower summer stream flows) and water quality (higher summer water temperatures). Impacts on snow pack, stream flow, and water quality in the Columbia Basin include the following (ISAB 2007):

- Warmer temperatures will result in more precipitation falling as rain rather than snow.
- Snow pack will diminish, and the timing of stream flow will be altered.
- Peak river flows will likely increase.
- Water temperatures will continue to rise.

These changes may affect steelhead more than other salmonids because of their long rearing period in freshwater.

Changing conditions could also affect salmonid health and survival in the ocean through a variety of mechanisms, including increased ocean temperatures, increased stratification of some waters, changes in the upwelling season, shifts in the distribution of salmonids, long-term variability in winds and ocean temperatures, increased acidity, and increased atmospheric and oceanic variability (NMFS 2007, 2008a; ISAB 2007).

All other threats and conditions remaining equal, future deterioration of water quality, water quantity, and/or physical habitat can be expected to cause a reduction in the number of naturally produced adult steelhead returning to these populations across the DPS. This possibility further reinforces the importance of achieving survival improvements throughout the entire steelhead life cycle. Recent research also indicates that neighboring populations with differences in habitat may show different responses to climate changes (Crozier and Zabel 2006; Crozier et al. 2008). This research reinforces the importance of maintaining habitat diversity.

5.9 Other Large-Scale Threats

Other large-scale threats that may affect salmon and steelhead populations in the White Salmon watershed in the future include the following:

- Human population growth. Pressures may increase for conversion of forestry and agricultural land uses to residential uses and residential water development, with potential impacts on habitat and water conditions.
- Increase in exotic invasive species that potentially compete with native flora and fauna. Such invasive species could provide food and/or cover to species that potentially compete with, prey on, or carry diseases that could affect native species.
- New diseases and/or pathogens. Migrating steelhead can introduce them through exposure to marine aquaculture operations or illegal stocking of out-of-watershed species, among other means.
- Natural catastrophic events.(e.g., earthquakes, volcanic eruptions, and large-scale forest fires).

Table 5-2 lists the primary factors limiting the production of fall Chinook salmon, the only extant population in the White Salmon River drainage. Table 5-3 lists the combined factors limiting the production of the extirpated or functionally extirpated spring Chinook salmon, coho, and chum salmon, and steelhead populations within the White Salmon watershed. Also listed are the potential impacts on population VSP parameters, sites where these impacts may be observed, the underlying anthropogenic threats, life stage affected, significance, and actions that would address the limiting factors.

Table 5-2. Primary limiting factors for lower Columbia River fall Chinook salmon in the White Salmon River drainage

Limiting Factor	VSP Parameter Impacted	Sites Affected	Threats	Life Stages Affected	Significance (Scope/Severity)	Actions
Lack of spawning gravel and spawning area	Abundance, productivity	Lower 3.3 RM of mainstem White Salmon River	High fine sediment loads delivered from the former Northwestern Lake	Spawning and incubation	Fine sediments accumulated in the bottom of the former Northwestern Lake will be transported into the lower 3.3 miles of the river for potentially many years. These fine sediments will tend to settle out in lower gradient areas and will also tend to build up during lower flow periods. The net effect on habitat remains unknown.	Restoration of habitat in the reaches formerly occupied by Northwestern Lake and downstream of the former dam site. Natural processes will eventually come to an equilibrium.
Harvest	Abundance, productivity	All, but especially ocean and Columbia River fisheries	Commercial, recreational, and tribal fisheries	Upstream migration, ocean survival	Significant harvest of fall Chinook salmon is allowed annually. While the specified allowed harvest is expected to result in gradual population growth, the allowable rate of harvest may slow recovery	Modify fisheries
Genetic changes and/or competition with hatchery fish	Genetic diversity, abundance and productivity	All spawning areas	Strays from other areas	Spawning and rearing	Unknown	Monitor

Table 5-3. Additional factors potentially limiting anadromous fish (lower Columbia River spring Chinook salmon and coho salmon, Columbia River chum salmon, and middle Columbia River steelhead in the White Salmon River drainage). The primary limiting factors are highlighted in light yellow; factors that may become limiting in the future are highlighted in light gray.

Limiting Factor	VSP Impacted Parameter	Sites Affected	Threats	Life Stages Affected	Significance (Scope/Severity)	Actions
Lack of an extant viable population	Abundance and Productivity	All	Populations of steelhead, spring Chinook salmon, coho salmon, and chum salmon are considered extirpated or functionally extirpated	All stages	Re-colonization by the extirpated species will be limited to natural repopulation of the basin through straying	The preferred approach for reintroduction of species into the basin is to allow natural straying into the river. Hatchery alternatives may be implemented if population recovery is determined to be too slow.
Harvest	All	All	Now that the dam has been removed, an abundance of unoccupied habitat has become available. Harvest will directly affect the rate of species re-colonization and population growth.	All	Will delay the rate of recovery in direct proportion to the numbers of fish potentially spawning in the basin that are caught	Manage fisheries to increase the potential for escapement into the White Salmon River.
High sediment loads in the reaches formerly occupied by Northwestern Lake and the reaches downstream of the former lake and a lack of suitable spawning habitat downstream of Buck Creek	Abundance and Productivity, spatial structure and diversity	All	The high sediment loads mobilized out of the area of the former lake may eradicate suitable spawning habitat downstream of Buck Creek for many years. The absence of quality spawning habitat in the lower reaches may deter stray fish from moving into the upper basin where	All	May delay re-colonization of the basin	Implementation of PacifiCorp's Dam Decommissioning Plans. Additional analysis of both habitat and re-colonization rates will be required to determine if additional actions are needed.

Limiting Factor	VSP Impacted Parameter	Sites Affected	Threats	Life Stages Affected	Significance (Scope/Severity)	Actions
			good spawning habitat is available.			
Factors that may become limiting as the populations grow						
Stream flow	Primarily abundance and productivity	Buck Creek	Water diversions.	Fry colonization, inactive age-0 and 1, juvenile rearing, migration	Diversion withdraws 70 percent of flow from Buck Cr., while unused portion returns to White Salmon via gully	Address Buck Creek water diversion
Large Woody Debris abundance	Primarily abundance and productivity	Mainstem White Salmon upstream of Buck Creek and lower White Salmon River mainstem.	Removal of wood for recreation; land use practices that reduce riparian forests	Fry colonization, juvenile rearing, overwintering, pre-spawners, spawners	Lack of LWD reduces pool habitat, sediment sorting and habitat complexity	Place LWD as appropriate and feasible. Address wood removal by boaters. Add structure to form pools
Stream temperatures	Abundance, productivity, spatial structure and diversity	Indian and Rattlesnake Creeks, lower Buck Creek, and possibly the reaches formerly occupied by Northwestern Lake	Land use practices that reduce riparian function; lack of riparian vegetation within the footprint of the former Northwestern Lake	Juvenile rearing, active age-0, spawning, migration	Currently the problem exists primarily in Rattlesnake and Indian Creeks, but may become a problem in the reaches previously occupied by the reservoir.	Increase shading along temperature limited reaches.
Harassment, predation and competition	Primarily abundance, productivity	Bonneville Pool	Inundation by Bonneville Pool	Adult migrants, pre-spawners, holding	Increase in exotic species and recreational activity in lower river	Improve programs that target exotic piscivorous fish in the mainstem Columbia

6 Recovery Strategy and Actions

The preceding chapters summarize recovery goals, biological and threats criteria, current status assessment, and the major limiting factors and threats identified for the White Salmon River salmon populations. How will we reach recovery? The White Salmon recovery strategy contains two key parts: 1) a plan for reintroducing naturally produced salmon and steelhead into historical habitat after the removal of Condit Dam, 2) improving and increasing freshwater habitat for salmon and steelhead production in key reaches of the watershed. The Plan also recommends ensuring that harvest or hatchery actions do not impede efforts to improve salmon and steelhead viability.

Blocked passage at Condit Dam was the primary limiting factor for both salmon and steelhead until the dam was breached in October 2011, and completely removed in October 2012. The methods considered to reintroduce salmonids to their historical habitat, included natural re-colonization, artificial propagation, or some combination of the two. Section 6.1 and Appendix I describe reintroduction plans.

Sections 6.2 through 6.5 also propose additional actions regarding freshwater habitat, hatcheries, harvest, and hydrosystem operations.

6.1 Salmon and Steelhead Reintroduction Plans

The White Salmon Working Group, made up of Federal, state, and tribal fisheries managers, as well as representatives of PacifiCorp (Condit Dam operators), developed several options to consider for the reintroduction of salmon and steelhead into the White Salmon River. The group fleshed out each option with a description of the biological basis for the approach, operational and maintenance needs, and monitoring and evaluation needs. For more details about the options and considerations, see Appendix I.

Some members of the White Salmon Working Group proposed that after Condit Dam removal or passage restoration, the reintroduced/re-colonized populations in the White Salmon River be experimental populations pursuant to section 10(j) of the ESA. However, these fish would not meet the ESA's definition for an experimental population, which is defined, in part, as one that is "wholly separate geographically from non-experimental populations of the same species."

After the removal of Condit Dam, populations of Chinook salmon, coho salmon, and steelhead cannot remain "wholly separate geographically" from other populations within the listed ESU/DPS. Keeping the populations "wholly separate" from the other populations within the listed species is also not consistent with the recovery strategy where the goal is for listed species from neighboring populations to re-colonize the habitat above Condit Dam after its removal. Furthermore, as Sections 2.4.4 and 6.1.5 (MCR steelhead) describe, the steelhead population in the White Salmon River still evidence some of its ability for anadromy and is not wholly extirpated.

6.1.1 Fall Chinook salmon

The White Salmon Working Group agreed on a salvage plan for tule fall Chinook salmon to maintain natural production assuming Condit Dam removal. Beginning in 2008, biologists tested a salvage plan to see if technicians could capture enough adult tule fall Chinook salmon below Condit Dam and safely transport them to spawning habitat above the dam. Biologists monitored the transported tule fall Chinook salmon to determine post-release survival, movement, and spawning habitat preferences (Engle and Skalicky 2009). In 2009, technicians installed a weir at the White Salmon Ponds site and tested increasing adult salmon collection and estimating escapement above the White Salmon Ponds site (Engle et al. 2010).

The White Salmon Working Group evaluated the following options for tule fall Chinook salmon (see Appendix I for detailed descriptions).

1. Salvage adipose present CWT-negative tule fall Chinook salmon from the White Salmon River in the fall of 2010 to start tule fall Chinook salmon restoration.
2. Spring Creek NFH would spawn adults and rear eggs. The hatchery would acclimate and release the resulting juveniles at White Salmon Ponds.
3. Salvage adipose present CWT-negative tule fall Chinook salmon returning to Spring Creek NFH to start tule fall Chinook salmon restoration.
4. Outplant adults, adipose present, in 2011 above Condit Dam prior to removal.
5. No salvage effort in the White Salmon River or at Spring Creek NFH. Salvage adipose present CWT-negative tule fall Chinook salmon returning to the White Salmon River and outplant above Condit Dam prior to removal.

The White Salmon Working Group selected the outplant option (Option 4) for tule fall Chinook salmon because they believed that the habitat currently available above Condit Dam that can support natural spawning tule fall Chinook salmon and because this option would minimize the potential impacts of hatchery rearing. Biologists tested a number of collection alternatives 2008 to ensure that technicians could collect unmarked tule fall Chinook salmon in adequate numbers and safely transport them above Condit Dam (Engle and Skalicky 2009). In 2008, the goal was to transport up to 500 adults made up of marked hatchery fall Chinook salmon collected in the lower White Salmon River and fall Chinook salmon from Spring Creek NFH. Hatchery fall Chinook salmon were used for this test because Condit Dam did not have a system to safely pass juvenile salmon during their outmigration. In 2008, technicians collected 90 adults in the White Salmon River and transported 333 adults from Spring Creek NFH to habitat above Condit Dam (Engle and Skalicky 2009).

Monitoring of the transported adults determined the movement of adults after release, where spawning occurred, and determined that spawning was successful. The White Salmon Working Group is finalizing an operating plan for collection and transportation of adult tule fall Chinook salmon in 2010 (see Engle and Skalicky 2009). In 2009, technicians installed a weir and tested it adjacent to the White Salmon Ponds, using the historic weir location to collect more tule fall Chinook salmon adults (Engle et al. 2010). In 2011, prior to Condit Dam breaching, a total of 679 tule fall Chinook salmon were collected from the lower White

Salmon River and transported and released between Husum Falls and Northwestern Lake, of these 552 were determined to be natural-origin. Furthermore, spawning ground surveys determined that spawning was successful below Husum Falls (R. Engle, USFWS, November 2012, personal communication).

6.1.2 Spring Chinook salmon

The White Salmon Working Group reviewed the following options for reintroducing spring Chinook salmon into White Salmon River (see Appendix I for detailed descriptions).

1. Natural colonization, i.e., no active reintroduction efforts from outside sources.
2. Wild Klickitat spring Chinook salmon as brood source for juvenile release into the White Salmon River. Eggs collected and reared at Klickitat Hatchery, juveniles acclimated and released at White Salmon Ponds.
3. Klickitat Hatchery spring Chinook salmon as brood source for juvenile release into upper White Salmon River, starting in the spring of 2010 (from Klickitat Hatchery thinning release or other surplus juveniles).
4. Klickitat Hatchery integrated stock spring Chinook salmon as brood source for juvenile release into White Salmon River, in future years (broodstock source would be hatchery-reared offspring of wild fish).
5. Transport surplus Klickitat Hatchery adults to White Salmon starting in the fall of the year of removal.
6. Trap and transport Klickitat wild adults to White Salmon starting in the fall of the year of removal.
7. Monitor natural escapement and production for 4-5 years then evaluate need and suitability of Option 4.

The White Salmon Working Group decided on Option 7 for spring Chinook salmon. Under this option Working Group members propose to monitor escapement of spring Chinook salmon into the upper White Salmon River, including the proportion of Carson stock hatchery spring Chinook salmon on the spawning grounds. The Working Group also will monitor spring Chinook salmon smolt production in the upper White Salmon River. The 4-5 year monitoring period will determine if natural production is occurring and the source of that production. The monitoring period will also allow time for the development of the Klickitat Hatchery integrated spring Chinook salmon program and determine whether production capacity at this facility is available. The White Salmon Working Group considered the Klickitat Hatchery spring Chinook salmon program the best source of broodstock for reintroduction, even though it is not part of the LCR Chinook salmon ESU because it is within the transition zone between LCR and interior CR populations (Ford et al. 2011). The two nearest populations of spring Chinook salmon within the LCR ESU are in the Lewis River in Washington and the Sandy River in Oregon. Each of these basins have spring Chinook salmon hatchery programs but reintroduction efforts in the Lewis River Basin require current local production, while broodstock collection and funding shortfalls constrain production in the Sandy River. The result is the unavailability of a suitable source

of spring Chinook salmon stock to support the reintroduction efforts in the White Salmon River. NMFS is currently reviewing whether a population re-established in historic habitat using a non-ESU spring Chinook salmon stock can be part of the listed ESU for recovery and delisting purposes. The Hood River spring Chinook salmon recovery efforts are using a non-ESU spring Chinook salmon stock for reintroduction.

6.1.3 Coho salmon

The White Salmon Working Group reviewed the following options for reintroducing coho salmon into White Salmon River (see Appendix I for detailed descriptions).

1. Natural re-colonization, i.e., no reintroduction efforts from outside sources.
2. Juveniles from Washougal and/or Bonneville/Cascade hatcheries released into White Salmon River.
3. Collection of wild adult broodstock in Klickitat River with spawning and rearing at hatchery facility and juvenile release in White Salmon River.
4. Collection of wild adult broodstock in White Salmon River with spawning and rearing at hatchery facility and juvenile release in White Salmon River.
5. Monitor natural escapement and production for 4-5 years then evaluate need and suitability of Options 2, 3 or 4.

The White Salmon Working Group decided on Option 5 for coho salmon. As described for spring Chinook salmon, the Working Group members propose to monitor escapement, hatchery- and natural-origin coho salmon on the spawning grounds, and juvenile production in the White Salmon River Basin. Sources of stray hatchery coho salmon include releases from Bonneville Hatchery and releases into the Klickitat and Umatilla River basins. All of these releases derive from hatchery programs that are part of the LCR coho salmon ESU. A recovery team will use the results of the monitoring efforts to determine future reintroduction activities.

6.1.4 Chum salmon

The White Salmon Working Group reviewed the following options for reintroducing chum salmon into White Salmon River (see Appendix I for detailed descriptions).

1. Natural re-colonization, i.e., no reintroduction efforts from outside sources.
2. Active adult outplanting in years after Condit Dam removal.
3. Active stocking of juvenile chum salmon or outplanting of eggs in egg baskets and hatch boxes via WDFW's Washougal Hatchery or Willard NFH.
4. Initiate temporary hatchery program for chum salmon using existing USFWS hatcheries for subsequent outplanting of chum salmon captured at Bonneville Dam.

The White Salmon Working Group decided on Option 1 for chum salmon. The group chose this option because of the uncertainty regarding the status of chum salmon above Bonneville

Dam. This option calls for expanded spawning ground surveys in the Bonneville Pool using the mainstem chum salmon spawning habitat criteria developed for the population below Bonneville Dam. Those conducting surveys should focus in the lower reaches of suitable tributaries and include habitat suitability assessments for the reservoir and the tributaries.

6.1.5 Steelhead

The White Salmon Working Group reviewed the following options for reintroducing steelhead into White Salmon River (see Appendix I for detailed descriptions).

1. Natural re-colonization, i.e., no reintroduction efforts from outside sources.
2. Wild donor from local watershed as brood source for juvenile release into the White Salmon River. Eggs collected and reared at suitable hatchery and juveniles acclimated and released at White Salmon Ponds.
3. White Salmon resident *O. mykiss* as brood source, with locally suitable anadromous wild donor stock spawned for juvenile release into upper White Salmon River.
4. White Salmon steelhead captive brood program using captured outmigrating juveniles.
5. White Salmon steelhead kelt reconditioning. Recondition local spawners to enhance survival.

Based on the potential to re-establish natural production of steelhead in the basin, the White Salmon Working Group decided that Option 1, natural re-colonization, was the best approach. Indications that the (resident) population of *O. mykiss* in the White Salmon River above Condit Dam still produces smolts, even though the construction of Condit Dam and the end of passage in 1913 eliminated anadromy, was the basis of the group's decision. Recent monitoring in the White Salmon River above Condit Dam has identified *O. mykiss* juveniles displaying smolt behavior and morphology. Biologists detected juveniles PIT-tagged in Rattlesnake Creek passing Bonneville Dam, with one recovered at the tern colony on East Sand Island (B. Allen, personal communication, 2007). In addition, biologists detected a juvenile *O. mykiss* PIT-tagged above Condit Dam in September 2004 at 98 mm ascending Bonneville Dam in July 2006. Genetic analysis of juvenile *O. mykiss* collected in the upper watershed above Husum Falls found differences from hatchery trout released in the basin; additional samples are needed, however, to confirm this finding (Allen et al. 2006).

Additional research by Carmichael (Ruzycki 2003) in the Grande Ronde and by Thrower et al. (2004) in Alaska has identified a potential strategy for steelhead in the White Salmon. Research conducted by Thrower et al. (2004) indicated that:

> after 70 years of freshwater residency, a formerly anadromous, wild, freely breeding population of *O. mykiss* has retained large amounts of genetic variability associated with growth, precocious maturation and smolting despite complete selection against the phenotypic expression of at least one of the fitness related characters (smolting migration) critical for the re-establishment of an anadromous population…. Genetic potential for smolting can lie dormant or be maintained through a dynamic

> interaction between smolting and early maturation for decades despite complete selection against the phenotype. The results have significant implications for the preservation of threatened anadromous stocks in fresh water and the inclusion of resident fish of formerly anadromous populations, currently trapped behind longstanding barriers to migration, as one component of the same population.

This information supports the theory that even though the population is functionally extirpated, there is some the potential for re-establishing anadromous steelhead in the White Salmon River Basin. Using resident *O. mykiss* above Condit Dam will provide a genetic link to historical anadromous *O. mykiss*.

6.1.6 Monitoring and Evaluation

The key to the success of all of these options is to implement all of the proposed monitoring and evaluation activities, including development and implementation of an approach to monitor adult escapement, adult movement, presence/absence of stray hatchery-origin salmon and steelhead, and population productivity. In the future, if the need arises, and after careful evaluation and consensus among the co-managers, biologists could use a weir to exclude hatchery-origin adults, thus creating a refuge for naturally produced salmon and steelhead. Another reason that the White Salmon Working Group supported these options was that the removal of Condit Dam provides a rare opportunity to study the natural re-colonization of newly available habitat without using hatchery intervention. The proposed White Salmon Recovery Board and NMFS will evaluate the proposed options and make an assessment after 5 years to determine the next steps for reintroduction of salmon and steelhead in the White Salmon River.

Much remains unknown about the current status of the historical salmon and steelhead populations in the White Salmon and the capability of the habitat to support increased production. This Plan proposes the following actions to establish a baseline of current population status and habitat conditions and to help ensure that efforts to reintroduce salmon and steelhead in the White Salmon are efficient and successful. The YN, USGS, WDFW, USFWS, and UCD identified these actions. Chapter 8 offers further discussion of basin-wide monitoring and evaluation activities.

Biologists need to gather data and analyze information needs upstream and downstream of Condit Dam now that PacifiCorp has removed the dam. This information will inform project selection and implementation and improve the rate and success of reintroduction.

Below is a description of a multi-agency cooperative process for planning reintroduction. Table 6-1 summarizes the biological objectives, actions, and existing strategies for data gathering and analysis; it also outlines some needed habitat restoration. The YN, USGS, WDFW, USFWS, and UCD agreed to these general biological objectives and provided the detailed actions for which they would accept responsibility. In 2012, the White Salmon Working Group will work to refine the monitoring and evaluation plan to reflect the removal of Condit Dam in 2011.

Various management entities have implemented some of these monitoring and evaluation activities starting in 2006 and continued these activities through the removal of Condit Dam

(e.g., Allen et al. 2006; Smith et al. 2007). Recovery planners are seeking funding to continue the monitoring post-dam removal.

Table 6-1. Biological objectives, management strategies, and actions to enhance/reintroduce anadromous salmonid populations and acquire baseline habitat information in the White Salmon River Basin

Biological Objective	Full Description	Actions and Existing Strategies
Implement reintroduction plan	Salmon and steelhead will be allowed to naturally re-colonize habitat above the former Condit Dam. Intensive monitoring activities will be implemented, including implementation of a program designed to monitor adult and juvenile abundance	Continue monitoring activities already occurring in the basin and expand to include population monitoring in the White Salmon River and Rattlesnake Creek
Complete gathering of information on existing salmonid stocks	Determine the status, life histories, and genetic composition of fish populations in the White Salmon River and its tributaries that are now accessible to anadromous salmonids.	Finalize adult and juvenile monitoring program for existing stocks in the White Salmon River. Assess interaction of bright and tule Chinook salmon populations and rainbow and steelhead
Hatchery status monitoring	Monitor the proportion and origin of hatchery salmon and steelhead on the spawning grounds	Continue to count adipose marked and unmarked carcasses and tagged adults
Maintain genetic diversity of listed salmonids	Continue to monitor current salmonid species composition and viability to determine effects of reintroduction actions	To maintain the genetic diversity of salmonid species in the White Salmon River complete analysis of information that describes the stocks and genetic diversity that currently exists
Population status monitoring	Monitor salmon and steelhead spawning escapement to estimate viable salmonid population parameters	Estimate population abundance using statistically robust methodologies
Assess effect of anadromous fish on resident fish	Assess the resident fish population prior to the reintroduction of anadromous salmonids	Assess resident trout contribution to smolts. Establish comprehensive monitoring program (of trout population). Assess change in resident population after steelhead re-colonization/reintroduction begins

6.2 Freshwater Habitat Strategies and Actions

This plan proposes a number of freshwater habitat strategies and actions to rebuild the salmon and steelhead populations in the White Salmon River drainage to the desired levels of viability. The Plan recognizes that anadromous salmonids did not occupy the habitat upstream of the former Condit Dam; therefore habitat upstream of the dam was not limiting the population. However, now that the river upstream of the dam is becoming accessible, and anadromous salmonids are beginning to use this habitat, factors such as head cutting at the head of the old reservoir and the practice of removing large woody debris could limit the carrying capacity of the existing habitat. The factors limiting the populations during the process of rebuilding will be habitat affected by dam removal, or an out-of-basin factor such as harvest, predation, or ocean conditions which affects the rate of population growth.

Habitat downstream of the dam currently affects salmon production. With the removal of Condit Dam, the habitat downstream of the dam has changed dramatically and the habitat within the footprint of the existing reservoir may be of very low quality. Restoration of the habitat in those areas will be a priority.

Restoration of upstream habitats is also included in this Plan. Salmonids will eventually fully occupy the upstream habitats. Immediate initiation of restoration activities in the upstream habitats will ensure that quality habitat is available as the populations grow.

Maintenance and protection of existing high quality habitats to ensure no net loss in quantity or quality of existing available habitat can also be an important element in providing for the development of salmonid populations in the basin. Land use planning, implementation of BMPs, acquisitions, easements, cooperative agreements, protective land designations, and voluntary commitments are potential tools for protecting and maintaining high quality habitat.

The Plan defines four freshwater habitat strategies: 1) gain information needed to identify and prioritize habitat actions that will provide the greatest opportunity to contribute to recovery, 2) restore mainstem habitat downstream of Buck Creek, 3) protect and conserve existing natural ecological processes, 4) improve habitat in upriver reaches. The fourth strategy addresses habitat improvement in upriver reaches that anadromous populations have recently begun to occupy. Because the fourth strategy does not address a known limiting factor, it is therefore a broad-sense strategy. The White Salmon Working Group defined the strategies and actions through review and analysis of currently available information. Many reaches in the White Salmon watershed have quality habitat and functional ecological processes that are currently capable of supporting anadromous fish populations or have moderate habitat quality and quantity and the potential to become high quality habitat (White and Cochrane 2005; Morris 2003, 2004, 2005; Allen et al. 2006a, 2006b; White and Plumb 2004, 2005). The strategies and actions address risks that the TRT identified in viability assessments for the populations.

This Plan designed the strategies and actions together to protect and improve freshwater habitat in the drainage and, thus, improve the potential productivity of White Salmon salmonid populations. The Plan's actions to restore passage and habitat also expect to benefit other anadromous and resident species, including cutthroat trout and Pacific lamprey

(*Lampetra tridentata*), a candidate for ESA listing and an important food source for members of the YN. Table 6-2 summarizes the strategies and actions related to improvement of freshwater habitat. Table 6-3 summarizes proposed habitat related actions associated with the fourth strategy: improve habitat that anadromous populations may eventually occupy.

Table 6-2. Primary biological objectives, management strategies, and actions to improve habitat in the White Salmon River watershed

Biological Objective	Species	Full Description	VSP Parameter Addressed	Actions and Existing Strategies
Gain information needed to identify and prioritize habitat actions that will provide the greatest opportunity to contribute to recovery	All species	Complete habitat surveys to help prioritize restoration needs and measure select habitat attributes above and below Condit Dam to document changes associated with removal of the dam as well as documenting time to recovery	All	An assessment of existing conditions is needed to prioritize recovery efforts
Restore mainstem habitat downstream of Buck Creek	All species	The effects of dam removal can only be estimated. With the dam removed, surveys will need to be conducted to a) document the habitat conditions immediately after removal, b) document changes in habitat over time, and c) identify and prioritize habitat restoration projects	All	Restore habitat through the implementation of PacifiCorp's Decommission Management Plans Complete surveys following dam removal. Identify and implement priority actions for habitat restoration such as bank stabilization of restoration of native vegetation.
Protect and conserve existing natural ecological processes.	All species	Protection and conservation of existing habitat will ensure that quality habitat is available as populations grow and will help to avoid additional impacts to habitats currently in use	All	• Land use planning to minimize anthropogenic effects • Land acquisition and conservation • Adoption and management of conservation agreements • Application of BM P BMPs • Public outreach to educate river uses and others

Biological Objective	Species	Full Description	VSP Parameter Addressed	Actions and Existing Strategies
Restore riparian vegetation along stream sections that exceed state standards for temperature	All species	Some stream segments within the expected range of anadromous salmonid distribution are known to be excessively warm. Since it takes time to grow trees that will eventually provide shade, planting of trees and implementing other programs to restore and protect riparian conditions is desirable in the near term	All	• Identify stream segments that are excessively warm within the expected anadromous salmonid distribution • Where riparian trees are sparse, implement programs to increase the density of the riparian vegetation • Implement programs to protect existing riparian vegetation

Table 6-3. Biological objectives, management strategies, and actions to improve habitat in the upper White Salmon River watershed

Biological Objective	Species	Full Description	VSP Parameters Addressed	Actions and Strategies
Additional Freshwater Habitat Strategies and Actions Addressing Likely Future Limiting Habitat Factors and Habitat Quality				
Improve habitat in upriver reaches	All populations	Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle Priority locations: Rattlesnake Creek, Indian Creek, Buck Creek, White Salmon River (Buck Creek to Husum Falls),	All Parameters	• Protect highest quality habitats through acquisition and conservation • Adopt and manage conservation agreements • Consistently apply BMP BMPs and existing laws to protect and conserve natural ecological processes • Provide public outreach to educate river uses and others

Biological Objective	Species	Full Description	VSP Parameters Addressed	Actions and Strategies
		Spring Creek		
	All populations	Gain information needed to identify and prioritize habitat actions that will provide the greatest opportunity to contribute to recovery Priority locations: Watershed areas above Buck Creek, with emphasis on the mainstem	All	• Conduct habitat surveys to help prioritize restoration needs • Implement projects to improve habitat
	All populations	Restore passage and connectivity to habitats blocked or impaired by artificial barriers Priority locations: Buck Creek	Abundance Productivity Spatial Structure	• Remove or replace barriers blocking or impairing passage including dams, dikes, road culverts, and irrigation structures • Provide screening at 100 percent of irrigation diversions • Replace screens that do not meet criteria
	All populations	Reduce nutrient loads; Nutrient levels in the White Salmon Basin are high (White and Plumb 2005; White and Cochrane 2005). The nutrient enrichment may decrease juvenile or adult fish survival. A rehabilitation strategy is recommended. Monitoring will help determine if actions taken have improved the situation	Abundance Productivity Spatial Structure	• Reduce runoff from septic tanks • Reduce nutrient runoff from dairies and agricultural lands
	All populations	Improve floodplain connectivity and function and channel migration processes	Abundance Productivity	• Reconnect side channels and off-channel habitats to stream channels • Restore wet meadows • Reconnect floodplain to channel

Biological Objective	Species	Full Description	VSP Parameters Addressed	Actions and Strategies
		Priority locations: Rattlesnake Creek, Indian Creek, Buck Creek, White Salmon River (Buck Creek to Husum Falls), Spring Creek	Spatial Structure	• Relocate or improve floodplain infrastructure and roads • Conduct public awareness and education about restoration efforts
	All populations	Improve channel structure and complexity Priority locations: Rattlesnake Creek, Indian Creek, Buck Creek, White Salmon River (Buck Creek to Husum Falls), Spring Creek	Abundance Productivity	• Place stable wood and other large organic debris in streambeds • Stabilize streambanks • Restore natural channel form
	All populations	Improve riparian condition and LWD recruitment Priority locations: Rattlesnake Creek, Indian Creek, Buck Creek, White Salmon River (Buck Creek to Husum Falls), Spring Creek	Abundance Productivity	• Restore natural riparian vegetative communities • Develop grazing strategies that promote riparian recovery • Eradicate invasive plants species from riparian areas
	Steelhead Spring Chinook salmon Coho salmon	Reduce anthropogenic effects on hydrograph to provide appropriate flows during critical periods Priority locations: Rattlesnake Creek, Indian Creek, Buck Creek	Abundance Productivity	• Implement agricultural water conservation measures • Improve irrigation conveyance and efficiency • Restore natural functions and processes through actions identified in strategies above • Employ BMPs to forest, agriculture, and grazing practices and to road management • Protect and/or rehabilitate springs • Increase pool habitat • Restore wetlands and other water holding capacity on plateau

Biological Objective	Species	Full Description	VSP Parameters Addressed	Actions and Strategies
	All populations	Reduce summer water temperatures Priority locations: Rattlesnake Creek, Indian Creek, Buck Creek	Abundance Productivity	• Improve riparian vegetation • Reduce sediment inputs to streams

6.2.1 High Priority Reaches for Habitat Protection/Restoration and Proposed Actions

The White Salmon Subbasin Plan (NPCC 2004) identifies the following areas as high priority reaches for protection and restoration (based on anticipated potential distribution):

- Steelhead habitats are likely concentrated in the White Salmon River mainstem upstream to Husum Falls and in Rattlesnake Creek. The reach between Husum Falls and Big Brother Falls, RM 16.2, may also contain potential habitat. Rattlesnake Creek has an abundance of rainbow trout as well as numerous restoration opportunities.
- Spring Chinook salmon will likely concentrate in habitats in the mainstem reaches downstream of BZ Falls, RM 12.4. This habitat area would include the reaches downstream of the former Condit Dam, the footprint of the reservoir, and reaches between Buck Creek and BZ Falls. With the dam's removal, significant, high priority restoration opportunities exist.
- Coho salmon would likely utilize both the lower river and the upper river habitats, including the tributaries (Rattlesnake, Spring, and Buck creeks).
- Fall Chinook salmon are likely to concentrate in areas downstream of Condit Dam, and upstream as far as Husum Falls after passage resumes.
- Chum salmon are likely to concentrate near the mouth of the White Salmon River.

The following areas rank as the highest priorities for habitat restoration. Reasons for their ranking and actions proposed to address limiting factors and threats are summarized below based on information provided in White and Cochrane (2005), Morris (2003, 2004, 2005), Allen et al. (2006a, 2006b), White and Plumb (2004, 2005), EDT modeling results (Allen and Connolly 2005), the White Salmon Subbasin Plan (NPCC 2004), and Klickitat Lead Entity Region Salmon Recovery Strategy (Klickitat Lead Entity 2005).

White Salmon River Mainstem - Site of Condit Dam, RM 3.3

Achieving multiple DPS/ESU population recovery goals depends largely on the success of efforts to restore passage to upriver spawning and rearing habitats and improve flow and habitat conditions in the lower river.

Actions:

- The complete removal of Condit Dam to provide unimpeded upstream passage by adult and juvenile salmonids.
- Improve flow and habitat conditions in the lower White Salmon River.

White Salmon River Mainstem - Mouth to Condit Dam

After breaching, sediment loads below the dam site have increased, directly impacting fall Chinook salmon present in the reach at the time of dam removal. Sediment loads will impact potential spawning and rearing habitat for Chinook salmon, chum and coho salmon in the lower White Salmon River, and will impact the migration corridors for all anadromous species. An assessment of conditions after dam removal will determine the best approach to restoration.

Actions:

- Restore habitat through the implementation of PacifiCorp's Decommissioning Management Plan.
- Assess limiting habitat features due to dam removal and restore habitat as needed to provide for spawning, rearing, and adult holding and migration.
- Place LWD and gravel as appropriate.

White Salmon River Mainstem - Condit Dam to Buck Creek

This reach currently contains the section under the former Northwestern Reservoir. It should provide important habitat for salmon and steelhead spawning, rearing, migration, and adult holding after the effects of the Condit Dam removal are addressed. Large quantities of sediment have accumulated in the reservoir since the original owners built the dam in 1913. With the dam's removal, it may require years for the river to establish a stable channel. The banks of the river will tend to slough and erode until they reach a stable angle of repose and attain sufficient vegetation to reduce erosion and stabilize slopes. The time needed to re-establish a stable channel with clean gravels is unknown. Recovery planners and fish managers could take actions to hasten restoration. Biologists cannot identify the precise set of actions with any confidence until they evaluate the habitat conditions post-dam removal.

Actions:

- Restore habitat through the implementation of PacifiCorp's Decommissioning Management Plan.
    - Assess habitat-limiting features and identify restoration needs.
    - Implement projects to restore habitats, including planting of native vegetation.

White Salmon River Mainstem - Buck Creek to Husum Falls

This reach extends from the headwaters of the former Northwestern Lake to Husum Falls. The reach has high potential for salmon and steelhead spawning, rearing, and adult holding. USFWS also listed the mainstem White Salmon River up to Husum Falls as proposed critical habitat for bull trout; that same habitat is important for coastal cutthroat trout. Habitat in the reach generally remains in good condition. Therefore, recovery planners proposed no actions, though as use by anadromous fish increases, an assessment of the habitat in this section should be completed.

White Salmon River Husum to BZ Falls

There is little data available regarding habitat conditions between Husum and BZ Falls. This reach would likely support coho salmon and steelhead and possible spring Chinook salmon. Biologists generally think the reach is in good condition, making restoration in this reach a lower priority. The primary action for this section would be to assess habitat features and restore habitat as needed to provide for spawning, rearing, and adult holding and migration.

Rattlesnake Creek

Rattlesnake Creek and its tributaries provide significant spawning and rearing habitat for rainbow trout and likely highly productive habitat for coho salmon and steelhead once fish can pass to these upstream areas. The reach has low quality pools, excessive fine sediment in some spawning gravels, limited instream cover, and high summer stream temperatures in some areas (Morris 2003, 2004, 2005, White and Plumb; 2004, 2005, White and Cochrane 2005, Allen et al. 2006a, 2006b). Alders dominate riparian areas and limit long-term wood recruitment potential (Allen et al. 2006a; 2006b).

Actions:

- Protect functional riparian areas.
- Place LWD and other instream structure as appropriate to create pools, increase cover, and retain spawning gravels.
- Restore floodplain connectivity.
- Restore wetlands and other water holding capacity on the plateau through use of check dams and other methods.
- Establish conifers in riparian areas.
- Plant trees to reduce sediment input from banks.
- Implement measures to reduce cattle impacts to stream.

Buck Creek

Buck Creek provides potential spawning and rearing habitat for coho salmon and steelhead. Biologists believe that habitat quality is currently limited because of insufficient pools and spawning gravels, low summer flows, and unscreened agricultural diversion. No data currently supports these suppositions, except for that relating to temperature. Available data indicate that temperatures in Buck Creek meet WA state standards (White and Plumb 2004; White and Cochrane 2005).

Actions:

- Conduct habitat studies to identify limiting factors within Buck Creek.
- Place LWD and other instream structure, as appropriate, to create pools and retain spawning gravels.

- Assess instream flows and initiate actions to improve base flow.
- Screen agricultural diversion and improve passage at irrigation diversion.

Spring Creek

Spring Creek may provide productive habitat for reintroduced anadromous coho salmon and steelhead runs. Production potential is currently limited because of decreased habitat diversity and increased sediment. Biologists have not evaluated the factors limiting habitat in Spring Creek.

Actions:

- Conduct assessments to identify factors
- Protect or improve instream wood and functional riparian areas as necessary.
- Place LWD as appropriate.

6.3 Hatcheries

Artificial production may play a role in the recovery of salmon and steelhead populations in the White Salmon. The White Salmon Working Group has proposed a strategy to allow for the natural re-colonization of the White Salmon River after Condit Dam removal. As described above in section 6.1, biologists will evaluate the natural re-colonization of the newly accessible habitat and, if escapement and productivity goals are not being achieved, then the White Salmon Working Group or a new recovery planning body will consider additional strategies using artificial propagation. Innovative programs, such as those employed by the Yakima/Klickitat Fisheries Project, as described in the Klickitat Anadromous Fisheries Master Plan (YN 2008), would be consulted and appropriate methodologies adopted (Table 6-4).

6.4 Harvest-Related Strategies and Actions

WDFW will continue to manage non-tribal fisheries for selective fisheries that target marked hatchery salmon and steelhead, requiring the release of unmarked (wild) fish. Overall impacts are very low for these tributary fisheries, with impacts generally less than 5 percent of the naturally produced fish (NPCC 2004).

In 2009, the recreational fishing regulations in the White Salmon River prohibited the retention of unmarked Chinook salmon from April 1 to June 30 and closed the river to retention of all Chinook salmon ½ mile above the Hwy 14 Bridge from October 1 to December 31. Fishing regulations prohibit retention of wild (unmarked) coho salmon and unmarked Chinook jack salmon (Chinook salmon less than 24 inches) in the White Salmon River annually from July 1 to March 31. Fishing regulations also prohibit retention of chum salmon in tributary recreational fisheries.

Mainstem harvest will continue to be managed through the *U.S. v. Oregon* process, and will be subject to consultation with NMFS. Co-managers will incorporate enhanced public education and non-tribal fisheries along with new selective fisheries regulations to ensure understanding and compliance.

Treaty Indian fishing rights in the Columbia basin are under the continuing jurisdiction of the U.S. District Court for the District of Oregon in the case of *U.S. v. Oregon*, No. 68-513 (filed in 1968). The parties to *U.S. v. Oregon* are the United States acting through the Department of Interior (USFWS) and BIA and Department of Commerce (NMFS), the Warm Springs, Umatilla, Nez Perce, Yakama, and Shoshone-Bannock Tribes, and the states of Oregon, Washington, and Idaho. In *U.S. v. Oregon*, the Court affirmed that the treaties reserved for the tribes 50 percent of the harvestable surplus of fish destined to pass through their usual and accustomed fishing areas.

A new *U.S. v. Oregon* Management Agreement has been completed, and NMFS has completed a section 7 Biological Opinion addressing the impacts of the fisheries management action and hatchery production in the new agreement (NMFS 2008c). The new management agreement will cover CR fisheries management and hatchery production actions from 2008 to 2017.

During the last 10-15 years, *U.S. v. Oregon*, the CR Fish Management Plan and successor agreements that contain restraints on the fisheries necessitated by ESA listings have managed harvest regulations. The agreements quantify and allocate between tribal and non-tribal fishing subject to ESA-imposed constraints for listed species (Table 6-4).

6.5 Hydro-Related Strategies and Actions

Actions to address out-of-watershed hydro-related limiting factors and threats are included in the recently released 2008 FCRPS Biological Opinion (NMFS 2008b). (Available at https://pcts.nmfs.noaa.gov/pls/pcts-pub/pcts_upload.summary_list_biop?p_id=27149) (accessed April 11, 2012).

Within the White Salmon River watershed, removal of Condit Dam will achieve the goals of restoring flows to the 1.1-mile bypass reach; recruiting gravel to the lower 3 miles of river; and, in the long-term, restoring MCR steelhead spawning habitat. Removal will also provide unimpeded movement of adult and juvenile lower Columbia salmonids (fall Chinook salmon, coho, and chum salmon) in the White Salmon River (Table 6-4).

Table 6-4. Summary table addressing hatchery, harvest and hydrosystem-related recovery strategies and actions

Priority Strategies	Populations Affected and Addressed	Key Types of Actions	VSP Parameters Addressed	Potential Limiting Factors Addressed
Hatchery				
Restore natural production into historically utilized habitats, including blocked areas above the former Condit Dam	All populations	• Monitor escapement and natural re-colonization of historical habitat • Develop preferred option from reintroduction plan based on monitoring of natural re-colonization	All parameters	Lack of native stock
Harvest				
Manage harvest for low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts	All populations	• Manage harvest for low impact fisheries • Adjust tributary harvest regulations in areas where harvest significantly impacts salmon and steelhead population growth	Abundance Productivity	Commercial, recreational, and tribal fisheries in ocean, mainstem CR and tributaries
Hydrosystem Issues and Mainstem Predation				
Maintain or improve hydropower operations and facilities at Bonneville Dam to enhance salmon and steelhead survival	All populations	• Maintain surface passage routes to improve juvenile passage at Bonneville Dam • Decrease water travel time during smolt outmigration • Improve operation of adult passage • Maintain high standards for adult fish passage at Bonneville Dam	All parameters	Hydrosystem development and operations in mainstem CR alter steelhead migration conditions and delay passage.
Reduce predation on, and competition between, salmonids	All populations	• Reduce predation by pinnipeds • Reduce predation by piscivores • Reduce predation by cormorants • Reduce predation by and relocate Caspian terns	Abundance Productivity	Hydrosystem development and operations in mainstem CR increase predation on, and competition between, salmonids.

7 Implementation and Cost Estimates

NMFS recognizes that there are significant uncertainties regarding expected future habitat conditions, that actions will need to restore habitat, and that actions require successful recolonization of salmonid populations in the White Salmon River watershed. NMFS is committed to an ongoing effort to address these uncertainties. This will require rigorous application of an adaptive management process that identifies key uncertainties, proposes competing hypotheses, and uses recovery actions and appropriate research and monitoring to test these hypotheses and adjust management accordingly.

Recovery is achievable only through the combined and coordinated actions of Federal and state agencies, tribes, and local governments, and with the participation of non-profit organizations, the business sector, and citizens. Collectively, NMFS refers to these parties as implementing partners. It will be essential that a collaborative implementation structure be set up to improve communication and work on a shared sense of priorities.

7.1 Implementation

The Washington Gorge Implementation Team (WAGIT) will coordinate implementation of the recovery plan for the White Salmon River watershed. The WAGIT is comprised of Klickitat County, the Yakama Nation, Washington Department of Ecology, Washington Department of Fish and Wildlife, the United States Geological Service, NMFS, the Central Klickitat and Underwood Conservation Districts, and various other stakeholders such as the Middle Columbia Regional Fisheries Enhancement Group. Representatives of the White Salmon Working Group are also participating on the WAGIT.

Implementation is being facilitated through the various existing programs in the area, including harvest management programs, the Yakama Nation Fisheries Program, Washington's Lead Entity Process, watershed planning and implementation processes initiated under state regulations and coordinated through the Klickitat County, various state and local habitat and watershed programs, and the various programs administered by the conservation districts. The WAGIT chose to draw upon and work within the many ongoing programs rather than developing a parallel, potentially duplicative process.

A balance between the biological benefit of a recovery action, its cost, and feasibility of implementation provides the basis for the WAGIT prioritization framework. Projects that address primary limiting factors, have high biological benefit to listed fish, are relatively inexpensive, and are feasible, receive highest funding priority. Projects with high cost, low biological benefit to listed fish species, and relatively low feasibility receive lowest funding priority.

Funding sources for salmon and steelhead recovery actions in the Columbia basin vary. They include:

- Pacific Coastal Salmon Recovery Fund (PCSRF) (states and tribes)
- Salmon Recovery Funding Board (SRFB) (a combination of PCSRF and Washington State funds)
- Columbia Basin Fish Accords
- Congressional appropriations (Federal agencies)

- State appropriations (state agencies)
- NPCC Fish and Wildlife program (states and tribes)
- Federal/state grants
- Non-profit organization programs and grants

7.2 Costs

NMFS, in coordination with the WAGIT and the White Salmon Working Group, provided cost estimates for implementing the White Salmon River Recovery Plan. The team developed cost estimates for a range of actions necessary to successfully reestablish anadromous fish populations in the White Salmon River watershed. There are numerous research, monitoring, and evaluation actions, specified in this Plan. Completed RM&E studies will help identify priority projects. In the absence of needed information, NMFS developed interim cost estimates for all potential recovery actions. NMFS and the area biologists estimated that RM&E actions will cost roughly $1,540,000 over a 5-year period. Chapter 8 provides further discussion of monitoring. Implementing PacifiCorp's decommissioning plans for Condit Dam is estimated at $0.9 to $1.1 million. Habitat actions related to the dam decommissioning could cost up to $15,100.000. The total cost over a 5-year period for restoring anadromous populations in the White Salmon River is estimated to be $16,781,000 (Table 7-1). More detailed information regarding these costs is provided in Appendix IV, White Salmon River Implementation Schedule: Summary of Actions and Potential Costs to Restore White Salmon River Anadromous Fish Populations and Their Habitat.

Table 7-1. Summary of potential costs to restore the White Salmon River fish populations and their habitat

ACTION CATEGORY	COST
Implementation of PacifiCorp's decommissioning plans	**$900,000 to 1,100,000**
RM&E	**$1,540,000**
Habitat Restoration and other actions	**15,100,000**
Hydrosystem and Mainstem Predation	**Not Estimated**
TOTAL	**$16,781,000**

The action categories listed in Appendix IV are derived from Chapter 6 Recovery Strategy and Actions. In many cases the specific actions provided in Appendix IV offer more detail than that described in Chapter 6. This is particularly true with regard to data collection and population monitoring. As discussed in Chapter 6, there is uncertainty regarding the primary factors that will limit the White Salmon populations in the long-term. Proposed data collection will fill those data gaps and provide direction for specific habitat restoration actions.

8 Monitoring, Research, and Evaluation for Adaptive Management

The various research and monitoring efforts proposed and underway in the White Salmon watershed regarding salmon and steelhead reintroduction, habitat restoration, and other activities require comprehensive empirical monitoring data on fish populations and habitat to identify appropriate project actions and strategies, select suitable sites and priority locations for actions, populate habitat/production capacity modeling efforts (such as EDT and All H's Analyzer [AHA]), and inform adaptive management for the salmonid recovery plan. Needed is additional information on fish distribution, abundance, productivity, habitat conditions, genetic diversity, pathogen levels, and other population parameters, as well as on population limiting factors. White Salmon recovery also requires a coordinated monitoring program to meet these various needs, as well as to help direct and evaluate the recovery effort.

8.1 Designing a Monitoring and Evaluation Program to Support Adaptive Management

Because of the length and complexity of the salmonid life cycle, there are many uncertainties involved in improving salmonid survival. To simply identify cause-and-effect relationships between any given management action and the characteristics of salmon populations can be a scientific challenge. It is essential to design a monitoring and evaluation program that will answer these basic questions: How will we know we are making progress? How will we get the information we need? How will we use the information in decision-making?

Designing an effective monitoring program for salmon recovery involves the following initial steps:

1. Clarify the questions regarding policy and management decision-making. Include the full ESU and the full salmonid life cycle.
2. Identify entity or entities responsible for coordinating development of this program.
3. Identify:
    - Which populations and associated limiting factors to monitor.
    - Metrics and indicators.
    - Frequency, distribution, and intensity of monitoring.
    - Tradeoffs and consequences of these choices.
4. Assess the degree to which existing monitoring programs are consistent with NMFS guidance.
5. Identify needed adjustments in existing programs, additional monitoring needs, and strategy for filling those needs.
6. Develop a data management plan (See Appendix B of *Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring*

Guidance (May 1, 2007) http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf (accessed April 11, 2012).

7. Prioritize research needs for critical uncertainties, testing assumptions, etc.
8. Identify entities responsible for implementation.

8.2 Adaptive Management

Adaptive management means taking an experimental approach to a complex task, making one's assumptions clear, and continuously evaluating them in the light of new information. Adaptive management works best when the design of performance data collection and evaluation methods helps the information managers make sound decisions. As outlined in the NMFS *Adaptive Management* guidance document, several types of monitoring are needed: 1) implementation and compliance monitoring, which is used to evaluate whether the recovery plan is being implemented; 2) status and trend monitoring, which assesses changes in the status of an ESU (or a DPS) and its component populations, as well as changes in status or significance of the threats to the ESU (or the DPS); 3) effectiveness monitoring, which tests hypotheses and determines (via research) whether an action is effective and should be continued. In addition, it's important to build research to illuminate the many unknowns in salmon recovery - the "critical uncertainties" - that make management decisions all the more difficult.

NMFS' guidance document presents a decision framework (Figure 8-1) that can guide the design of a RM&E plan. The framework contains: 1) questions regarding ESU/DPS status (biological viability criteria); 2) questions regarding statutory listing factors and factors limiting recovery (limiting factor and threats criteria). Evaluating a species for potential delisting requires an explicit analysis of both types of criteria.

The guidance document contains a more detailed discussion of the framework and identifies the specific questions necessary to evaluate ESU/DPS status. These specific questions take the form of a series of decision-question sets that address the status and change in status of a salmonid DPS and the risks posed by threats to the DPS. NMFS designed the decision-question sets to elicit the information it needs to make delisting decisions. For recovery planners, the framework can guide future decisions about management strategies and actions aimed at achieving recovery goals.

The White Salmon monitoring and evaluation program will build on existing programs designed for monitoring tributary habitat in the White Salmon. The White Salmon monitoring and evaluation program will provide 1) a clear statement of the metrics and indicators by which progress toward achieving goals can be assessed; 2) a plan for tracking such metrics and indicators; 3) a decision framework through which new information from monitoring and evaluation can be used to adjust strategies or actions aimed at achieving the Plan's goals.

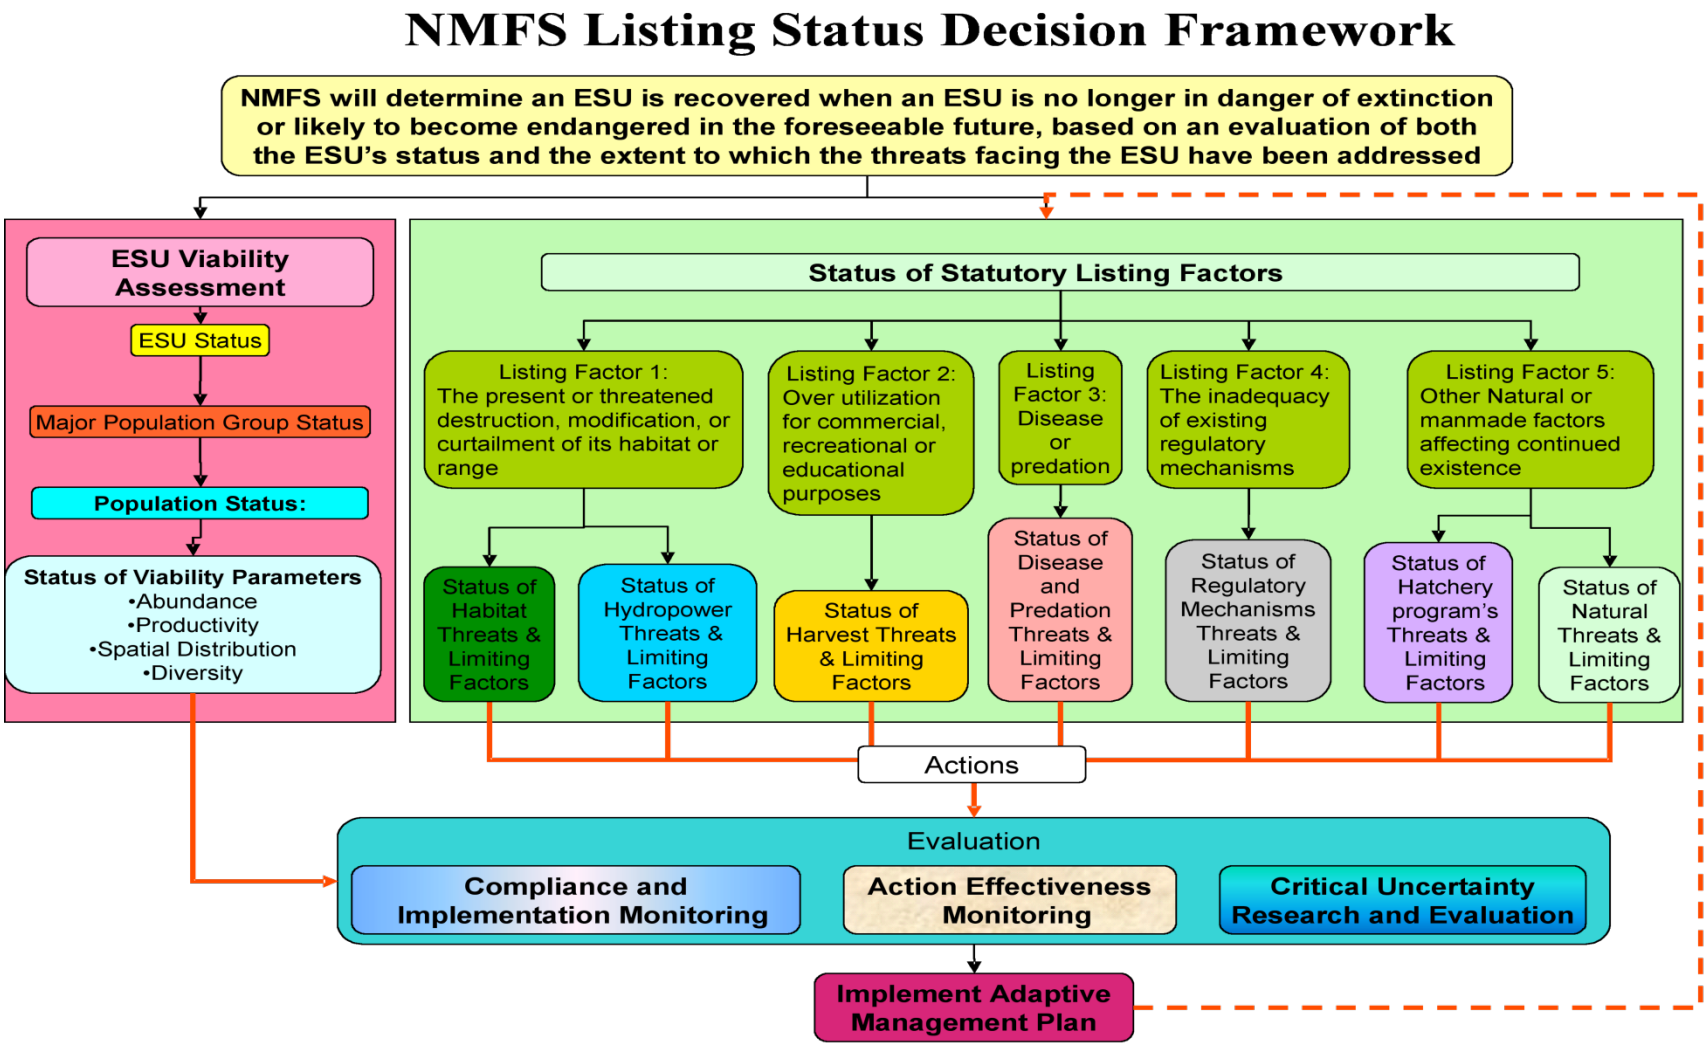

Figure 8-1. NMFS Listing Status Decision Framework

8.3 Critical Uncertainties

Data gaps important to recovery can be divided into two major categories: 1) those that deal with critical uncertainties; 2) gaps in knowledge about the linkages between specific actions and their effects on habitat factors and VSP parameters. Monitoring and evaluation will fill some of the data gaps; research will fill others.

Critical uncertainties, the unknown aspects of environmental conditions vital to salmonid survival, are a major focus of the RM&E program. To establish linkages between specific actions and resultant environmental effects will require monitoring. Those linkages are complex and often not well understood. Understanding them requires input from experts from various fields. It is important that the actions recommended in the Plan to benefit listed fish species in the White Salmon watershed be reviewed by fish ecologists, geologists, hydrologists, and other experts familiar with the recovery region.

The Plan expects that specific benchmark values for the VSP parameters will be refined during Plan implementation based on new information that addresses current uncertainties.

There are numerous out-of-basin uncertainties. The geographic areas that constitute the multiple ESU/DPSs encompass a large part of northern Oregon and a large part of southern Washington draining into the Columbia River. There are multiple populations across species. This context is significant in terms of uncertainties:

- Under the ESA, successful recovery of listed species as defined by NMFS requires achieving specific levels of productivity for populations within the entire ESU/DPS, not only acceptable productivity within any single basin that is a part of the ESU/DPS. Local communities in different watersheds/basins across local and state boundaries are dependent upon each other for successful delisting of these species.
- Of the seven necessary components of an ESA recovery plan, only three are the responsibility of in-basin parties - for which there is currently no collaborative governing board. The other components (e.g., hydropower operations, harvest, hatcheries, macro-economics, estuarine conditions), though significant to impacts on overall mortality, involve factors that are outside of the White Salmon watershed and actions taken within the watershed do not directly these factors. To measure the increases/decreases in productivity of the target populations before they migrate out of the watershed will require monitoring.

8.3.1 Research

As noted earlier, unknown aspects of environmental conditions vital to salmonid survival are termed “critical uncertainties.” Critical uncertainty research targets specific issues that constrain effective recovery plan implementation. This includes evaluations of cause-and-effect relationships between fish, limiting factors and actions that address specific threats related to limiting factors. Listed below are research actions to assess the effects of the uncertainties on recovery of listed fish species in the White Salmon watershed. Research actions address both in-basin and out-of-basin factors and are not all-inclusive. The

following lists in-watershed and out-of-watershed research needs. This list derives from a longer list identifying potential research needs for other basins within the ESUs and DPS.

8.3.2 In-Watershed Research Needs

- Determine fish abundance, origin, and production data after decommissioning of Condit Dam.
- Determine mainstem restoration needs after PacifiCorp's decommissioning plans have been implemented.
- Conduct habitat/population assessment work in Buck Creek.
- Track sediment downstream of Buck Creek through time.
- Monitor water quality after dam decommissioning.
- Assess impacts of dam removal on mainstem and tributary mouths above project area.
- Address potential issues at in-lieu fishing site after dam decommissioning.
- The White Salmon River is a thermal refuge. How important is this? What impact will this have on salmon and steelhead? Steelhead move into the White Salmon River to seek cold water refuge when mainstem Columbia River temperatures increase. What impact has dam-removal had on this condition?
- Increase understanding of linkages between physical and biological processes so that managers can predict changes in survival and productivity in response to selected recovery actions.
- Test assumptions and sensitivity of EDT and other model runs.
- Determine relative performance (survival and productivity) and reproductive success of naturally producing species.
- Assess population structure.
- Determine the effects of exotic species on recovery and the feasibility of actions to eradicate or control numbers of exotic species.
- Improve the understanding of the range of interactions between resident and anadromous forms of *O. mykiss*. The nature of the relationship is inherently complex and needs further evaluation, especially as recolonization begins to occur.
- Investigate instream flow needs for the mainstem White Salmon and tributaries that will support anadromous fish.

8.3.3 Out-of-Watershed Research Needs

- Monitor harvest levels.
- Develop better methods to estimate harvest of naturally produced salmon and steelhead and indirect harvest mortalities in freshwater and ocean fisheries.

- Assess the interactions between hatchery and naturally produced salmon and steelhead.
- Assess if hatchery programs increase the incidence of disease and predation on naturally produced fish.
- Evaluate increased predation risks from native and non-native fish, birds, and mammals.

These should be coordinated with NOAA's CR Estuary Recovery Plan Module (NMFS 2007) and the 2008 FCRPS Biological Opinion (NMFS 2008c).

8.4 Monitoring

The Plan includes direction for RM&E to: define unknown population characteristics, contribute to regional monitoring efforts, better direct efforts within the watershed, and assess the effectiveness of future actions.

Research and monitoring are designed to test implementation, validation, status/trend, and effectiveness. Implementation monitoring determines if the appropriate entities implemented the planned actions as intended and whether all implementation objectives are on schedule (section 8.1, Designing a Monitoring and Evaluation program to Support Adaptive Management). Status/trend monitoring determines the current conditions (status) of the populations and their habitats and their changes over time (section 8.2, Adaptive Management). Effectiveness monitoring focuses on whether the recovery actions changed the environment and/or the VSP parameters (section 8.3, Critical Uncertainties). Validation monitoring determines whether the fundamental ecological assumptions underlying the recovery plans are true. Prominent among these assumptions are the effects of specific environmental conditions on survival and abundance of listed fish species embodied in the EDT model. Researchers will determine which assumptions need testing once recovery planners fill the critical data gaps (section 8.3, Critical Uncertainties).

Conditions outside the watershed will affect and inform actions, research, and monitoring within the watershed. Out-of-basin conditions do and will have a significant effect on the success of recovery of species within the watershed. These factors include commercial harvest, sport and tribal harvest, conditions in the mainstem CR (including hydroelectric operations), and conditions in the estuary and ocean including short and longer term cycles in ocean conditions. The regional RM&E program developed under the FCRPS Biological Opinion will measure status, trends, and effectiveness of actions in this area.

A recently formed multi-agency Condit Technical Working Group (now White Salmon Working Group) met in early 2007 to discuss RM&E issues (and actions to resolve them) in light of the proposed removal of Condit Dam. The section "In-Watershed Research Needs" (below) the RM&E questions drafted during this meeting are detailed further.

Key Question #1: What is the source of colonizing salmon and steelhead?

Collect genetic samples after dam decommissioning and compare with samples collected prior to dam removal using genetic analysis.

Key Question #2: Has the abundance and origin of salmon, steelhead, and bull trout spawners changed between pre- and post- dam removal?

Compare pre-removal abundance of spring Chinook salmon, fall Chinook salmon, steelhead, and coho salmon with abundance post dam removal.

Key Question #3: Has smolt production increased after dam removal?

Compare smolt estimates pre-dam removal for Chinook salmon fry, and coho, Chinook salmon, and steelhead smolts (USGS) with smolt population estimates after dam removal.

Key Question #4: Has the habitat changed after dam removal?

Compare bathymetric surveys below Condit in the early 1990s with post-removal surveys. Conduct cross-sectional profiles just above reservoir and near mouth to document down-cutting and sediment transport.

Described below is a general framework for monitoring within the White Salmon watershed.

8.4.1 Implementation Monitoring

Effective RM&E requires implementation and compliance monitoring checks to determine whether action entities carried out the activities as planned and whether action entities met specified criteria as a direct result of an implemented action. Scientists will monitor recovery actions within the White Salmon watershed to assess whether action entities implemented the actions as planned. This monitoring will consist of an administrative review and will not require environmental or biological measurements.

Implementation monitoring will address the types, numbers, and locations of actions implemented and how much area or stream length each action affected. Indicators for implementation monitoring will include visual inspections, photographs, and field notes on numbers, location, quality, and area affected by an action. For example, if fencing is planned for 20 miles of stream corridor to keep livestock off the stream banks so that riparian vegetation will rebound, implementation monitoring would verify the presence of the fence. Compliance monitoring would take note of the presence or absence of livestock in the fenced-off area.

Comparing field notes with the specifications in the plans or proposals (detailed descriptions of engineering and design criteria) will determine success. Thus, design plans and/or proposals will serve as the benchmark for implementation monitoring. Evaluations will describe in detail any deviations from specified engineering and design criteria.

8.4.2 Status/Trend Monitoring

Status and trend monitoring is a compilation of data based descriptions of existing conditions. To be useful in decision-making, a scientist reduces the raw data, or metrics, to a more directly applicable form or indicator. For example, if the question is "What is the annual spawning population-size of steelhead in the White Salmon River?" The indicator would be total spawning numbers of steelhead over one season for the entire river basin. The metric, or directly measured thing, however, would be something quite different, perhaps

steelhead redds sighted on weekly passes over known spawning grounds. Thus, a scientist would process the metric to translate it from the metric data type (e.g., redds) into the indicator data type (e.g., spawners) and then summarize to generate the indicator required (e.g., from a list of weekly counts on spawning grounds to an annual total for the watershed).

A future collaborative board directing implementation will develop a program to monitor the status and trend of salmon and steelhead and their habitats throughout the White Salmon watershed. The program will utilize guidelines developed in the Pacific Northwest Aquatic Monitoring Partnership (PNAMP) and the Collaborative System-wide Monitoring and Evaluation Project (CSMEP).

8.4.3 Effectiveness Monitoring

Effectiveness monitoring specifically addresses cause-and-effect questions. Demonstrating the direct and indirect impact of management actions requires supporting all steps in a logical chain that connects the action to its expected impact. This chain is rarely short and usually contains several hypotheses. For this reason, it's better to build the effectiveness monitoring into the recovery action strategies with, for example, pilot-scale tests or other methods carefully thought out beforehand.

Not all recovery actions the Plan recommends need monitoring to determine effectiveness. However, it is important that scientists assess a sufficient number of replicates of each "type" of action to assess effectiveness. To the extent possible, monitoring for recovery action effectiveness will use the Before-After-Control-Impact design with stratified random sampling, as described in the Comprehensive Statewide Monitoring Strategy (Monitoring Oversight Committee 2002). This strategy describes in detail the approach, indicators, and protocols needed to assess effectiveness of habitat restoration classes. It is critically important to coordinate the effectiveness monitoring programs with status/trend monitoring and effectiveness monitoring within the hydro sector.

Monitoring and evaluation will only provide the answers to the questions the RM&E designs intended to address. They do not provide the framework for revising questions that are ill posed. Evaluating the assumptions upon which the recovery planners built their strategy or incorporated learning into future action and strategy decisions is the role of adaptive management.

8.5 Consistency with Other Monitoring Programs

This recovery plan will utilize existing monitoring programs to evaluate the status/trend and effectiveness of recovery actions within the White Salmon watershed. Specifically, this approach will incorporate strategies, indicators, and protocols described in the Yakima/Klickitat Fisheries Project, the upper Columbia Monitoring Strategy, the Comprehensive Statewide Monitoring Strategy, and CSMEP. The development of other regional monitoring programs may result in modifications to the monitoring programs used in the White Salmon watershed. These other programs, in various states of development, include such approaches as PNAMP. As these programs develop more fully, they will provide guidance on valid sampling and statistical designs, measuring protocols, and data management. Scientists may use this information to refine and improve the existing

monitoring and evaluation programs in the White Salmon watershed. The intent is to make monitoring and evaluation programs in the White Salmon watershed consistent with programs throughout the Columbia basin as well as the ESUs and DPS.

8.6 Coordination

Many entities have been or will be implementing recovery actions within and downstream of the White Salmon watershed. Monitoring programs to coordinate with include:

- Yakima/Klickitat Fisheries project
- YN Monitoring
- NOAA Fisheries RM&E program
- Washington SRFB program
- PACFISH/INFISH Monitoring program
- Pacific Northwest Interagency Regional Monitoring program
- USFWS, USGS, and Bureau of Reclamation (BOR), monitoring programs
- WDFW and Washington Department of Ecology monitoring programs
- Washington Department of Ecology Watershed Assessment and Management Process (Revised Code of Washington (RCW) 90.82)
- Local UCD monitoring

It is critical that recovery planners consult with these programs to emphasize utility, reduce redundancy, increase efficiency, and minimize costs.

8.7 Evaluation Schedule

While the White Salmon watershed currently has no collaborative regional board guiding work, a regional board for the Washington Gorge Management Unit could develop as a follow-up to recovery planning. An appropriate first check-in for the watershed is 3 years from the adoption of the Plan. At this time, the board or co-managers should review efforts within the watershed - whether or not they have obtained funding and initiated actions. At years 5, 8, and 12 further evaluations should occur in order to coordinate with other watersheds in the ESUs and the middle Columbia Steelhead DPS. Reviews at this time should start with funding and implementation effectiveness. If funding and implementation have taken place previously, the RM&E program should review their effectiveness and measure progress toward the overall implementation of projects within White Salmon. The evaluation should place progress, or the lack thereof, within context of all the ESUs and the DPS.

The first major step in the adaptive management program is to obtain 5-year implementation schedules from each of the partners that describe the tasks, schedules, priorities, and estimated cost to implement the recovery actions. The RM&E program will request that each of the Federal and state agencies, tribal and local governments, and non-governmental

partners prepare an implementation schedule for their recovery actions. A regional implementation schedule covering the entire White Salmon Management Unit will combine these individual schedules. The recovery partners will complete their initial schedules in the summer of 2010; they will prepare new schedules annually incorporating changes or modifications based on implementation and effectiveness evaluations. NOAA Fisheries 5-year ESA status reviews should coordinated with additional evaluations of the status of viability attributes limiting factors and new information critical uncertainties. The White Salmon Recovery Plan should incorporate the results of these programs into adaptive management and coordinate with other middle Columbia steelhead recovery plans, the recovery plan estuary, and harvest modules for the CR, as well as the 2008 FCRPS Biological Opinion.

8.8 Monitoring and Evaluation Plan

The information in this chapter provides a framework for the development of a salmonid RM&E and adaptive management plan for the White Salmon Basin. When NMFS finalizes the recovery plan's goals and objectives, a process will begin to fully develop a RM&E plan with the White Salmon Working Group and append it to the recovery plan when the recovery plan is completed. A multi-agency salmonid reintroduction plan for the White Salmon River will rely heavily on results of research guided by ongoing monitoring and evaluation.

Appendix I. Options for Salmon and Steelhead Reintroduction

The following are reintroduction plans for salmon and steelhead in the White Salmon River that were developed by the White Salmon Working Group, made up of Federal, state, and tribal fisheries managers, as well as representatives of the PacifiCorp (Condit Dam operators). The White Salmon Working Group developed a number of options for the reintroduction of salmon and steelhead into the White Salmon River in anticipation of the removal of Condit Dam in the fall of 2009. Each option developed for the various salmon and steelhead populations includes a description of the biological basis for the approach, operational and maintenance needs, and the monitoring and evaluation needs to support the approach. Each of the Plans and assorted options that were developed are listed below, with the preferred option highlighted in gray.

Tule Fall Chinook salmon

Salvage Effort Options within the White Salmon River in Preparation of Removal of Condit Dam.

1. Salvage adipose present CWT-negative tule fall Chinook salmon from White Salmon River in fall 2010 to start tule fall Chinook salmon restoration. Eggs collected and reared at Spring Creek NFH, juveniles acclimated and released at White Salmon Ponds.

a. Biological Basis

   i. Would emphasize collection of adult returns that presumably are natural progeny from previous spawning populations in the White Salmon.

   ii. The mass marking protocol used at Spring Creek NFH would allow for identification of "wild" fish on the spawning grounds.

      1. Hatchery fish would be either adipose-fin clipped or have a CWT present.

      2. Wild fish would have adipose-fins present and no CWT.

b. O&M (Operation and Maintenance) Needs

   i. Temporary weir construction at White Salmon Ponds.

      1. A salvage effort with fish wheel or active adult seining in Lower River to capture adipose present tule fall Chinook salmon could also be used in lieu of or in addition to weir.

         (a) Several options should be discussed for what efforts might be fiscally and logistically possible.

      2. New screens would be needed at the intake structure to comply with NOAA Fisheries or a waiver would be required to operate the ponds and weir during adult collections.

3. Potential need to coordinate with Condit Dam operations should flow manipulation need to occur for selected capture method.

ii. Eggs reared at Spring Creek NFH and transferred for acclimation at White Salmon Ponds for release in April or May per rotary trap timing of tule fall Chinook salmon.

1. Ponds need to be watered up and ready by spring following dam removal to be used for acclimation.

2. Potential upriver or alternative acclimation strategies could be used if White Salmon Ponds are not a viable option.

iii. Program Size

1. 1996 Columbia Basin Fish and Wildlife Authority (CBFWA) Document states 32,000 0+ juveniles for production and release. This translates into about 58 adults that will return based on SCNFH escapement estimates.

2. NMFS Draft White Salmon Recovery Plan states abundance recovery goal of 900 adults (TRT recommendations, pg 105).

3. White Salmon Subbasin Plan (using EDT analysis) estimates 792-995 for abundance estimation from historical through removal with PFC.

4. Based on adult escapement estimates for White Salmon, 500 to 600 adults might "fill out" escapement. The production goals would correlate to annual releases of 275,000 to 330,000.

5. Capacity at White Salmon ponds would be 300,000 for release.

iv. Need to revise HGMP from Spring Creek NFH

1. Would encompass tules and other stocks that may be acclimated at ponds (pending workgroup decisions).

c. RM&E Needs

i. Specific juvenile tagging of these fish is also needed to determine survival rates and evaluate the salvage action.

ii. Genetic analysis of adults collected for salvage effort in 2010.

1. Needed to properly assess success of salvage effort and also act as a baseline for monitoring hatchery/wild fish interactions on the spawning grounds for future years.

iii. Continuation of rotary trapping and genetic analysis to determine production of juveniles.

iv. Expansion of WDFW carcass surveys into areas above Condit dam in 2010 and beyond.

v. Some decision process to end production based on rotary trapping results of successful spawning abundance or on wild adult escapement estimates (might be easier to estimate).

2. Salvage adipose present tule fall Chinook salmon returning to Spring Creek NFH in fall 2009 to start restoration. Eggs collected and reared at Spring Creek NFH, with juveniles acclimated and released at White Salmon Ponds.

   a. Biological Basis

      i. Would emphasize collection of adult returns that presumably are natural progeny from previous spawning populations in the White Salmon.

      ii. Annual returns to Spring Creek NFH have some components that are presumed to be naturally produced fish.

         1. Fish that have their adipose fin and do not have a CWT.

         2. This would need to be verified by analysis of CWT return data in combination with scale analysis between CWT/adipose fin clipped fish and "wild" interceptions at the hatchery.

   b. O&M Needs

      i. Eggs reared at SCNFH and transferred for acclimation at White Salmon Ponds for release in April or May per rotary trap timing of tule fall Chinook salmon

         1. Ponds need to be watered up and ready by spring 2011, this should be 2010 if we are collecting in 2009, if going to be used for acclimation.

         2. Would need to modify screens or get a waiver from NOAA Fisheries.

         3. Potential upriver or alternative acclimation strategies could be used if White Salmon Ponds are not a viable option.

      ii. Program Size

         1. 1996 CBFWA Document states 32,000 0 + juveniles for production and release. This translates into about 58 adults that will return based on SCNFH escapement estimates.

         2. NMFS Draft White Salmon Recovery Plan states abundance recovery goal of 900 adults (TRT recommendations, pg 105).

         3. White Salmon Subbasin Plan (using EDT analysis) estimates 792-995 for abundance estimation from historical through removal with properly functioning conditions.

         4. Based on adult escapement estimates for White Salmon, 500 to 600 adults might "fill out" escapement. The production goals would correlate to annual releases of 275,000 to 330,000.

5. Capacity at White Salmon ponds would be 300,000 for release.

iii. Need to revise HGMP from Spring Creek NFH.

1. Would encompass tules and other stocks that may be acclimated at ponds (pending workgroup decisions).

c. RM&E Needs

i. Specific juvenile tagging of these fish is also needed to determine survival rates and evaluate the salvage action.

ii. Genetic analysis of adults collected for salvage effort in 2009.

1. Needed to properly assess success of salvage effort and also act as a baseline for monitoring hatchery/wild fish interactions on the spawning grounds for future years.

iii. Expansion of WDFW carcass surveys into areas above Condit dam in 2010 and beyond.

iv. Continuation of rotary trapping and genetic analysis to determine natural production of juveniles.

v. Some decision process to end production based on rotary trapping results of successful spawning abundance or on wild adult escapement estimates (might be easier to estimate).

3. No salvage effort in the White Salmon or at SCNFH

a. Biological Basis

i. Assumes natural colonization in the future.

ii. Would assume that sediment movement after dam removal would be large and allow for successful natural colonization immediately.

b. O&M Needs

i. None at SCNFH

c. RM&E Needs

i. Continuation of rotary trapping and genetic analysis to determine natural production of juveniles.

ii. Expansion of WDFW carcass surveys into areas above Condit dam in 2010 and beyond.

4. Outplant adults, adipose present, in 2010 above Condit Dam prior to removal.

a. Biological Basis

i. Assumes natural colonization and allows some spawning to occur above Condit Dam prior to removal.

ii. Would assume that sediment movement after dam removal would be large and allow for successful natural colonization in later years.

iii. Could be done in conjunction with any of the previous actions or for a number of years to allow for natural colonization.

b. O&M Needs

i. Radio-tagging and Peterson disc tagging of adults to determine movement to White Salmon.

c. RM&E Needs

i. Continuation of rotary trapping and genetic analysis to determine production of juveniles.

ii. Expansion of existing carcass surveys conducted by WDFW to monitor spawning above Condit Dam during 2009 and in 2010.

Spring Chinook salmon

1. Natural re-colonization - no active reintroduction efforts from outside sources.

a. Biological Basis

i. Probably very small number of returning native adults - may not be sufficient number to restart population.

ii. Concerns about Carson fish on spawning grounds?

b. O&M Needs - little to none

c. RM&E Needs

i. Monitor any natural spawner escapement.

ii. Monitor Carson fish on spawning grounds.

iii. Monitor smolt production.

2. Wild Klickitat spring Chinook salmon as brood source for juvenile release into the White Salmon River. Eggs collected and reared at Klickitat Hatchery, juveniles acclimated and released at White Salmon Ponds.

a. Biological Basis

i. Would emphasize collection of wild Chinook salmon from locally adjacent watershed, with similar geomorphologic characteristics and flow regime.

ii. No mass marking to minimize harvest to return as many spawners to White Salmon River as possible.

1. Hatchery fish would have unique CWT if determined that carcasses survey would be productive. More important to CWT after natural production is established.
2. Use PIT-tagging. Limited Wild fish would have adipose fins present and no CWT.

b. O&M Needs

i. New improved broodstock collection facility at Lyle Falls Fishway (~3 years out).

ii. Isolated spawning and rearing at Klickitat Hatchery - several options should be discussed for what efforts might be fiscally and logistically possible.

iii. White Salmon Pond rehabilitation and O&M.

iv. Juvenile transport at fry or smolt stage.

c. RM&E Needs

i. Monitor natural and hatchery escapement to spawning grounds.

ii. Monitoring natural escapement in Klickitat River (relatively low in recent years) and any impacts to natural population from broodstock collection.

3. Klickitat Hatchery spring Chinook salmon as brood source for juvenile release into upper White Salmon River, starting in spring 2010 (from Klickitat Hatchery thinning release or other surplus juveniles).

a. Biological Basis

i. Would emphasize use of hatchery Chinook salmon from locally adjacent watershed.

ii. Possible concerns about genetic mixing in Klickitat Hatchery stock of stream- and ocean-type Chinook salmon (see c.ii. below).

b. O&M Needs

i. Isolated spawning and rearing at Klickitat Hatchery - several options should be discussed for what efforts might be fiscally and logistically possible.

ii. Upper White Salmon release site identified/developed and O&M.

iii. Direct stream release locations identified/developed.

c. RM&E Needs

i. Fish Health monitoring (BKD concerns).

ii. Assessment of possible effects of use of genetically mixed Klickitat Hatchery stock (evidence of possible broodstock mixing of stream-type [spring-run] and ocean-type [summer-run] in Klickitat Hatchery stock).

4. Klickitat Hatchery integrated stock spring Chinook salmon as brood source for juvenile release into White Salmon River, in future years (broodstock source would be hatchery-reared offspring of wild fish).
    a. Biological Basis
        i. Would emphasize use of integrated stock Chinook salmon from locally adjacent watershed.
        ii. May alleviate concerns of broodstock mining effects on Klickitat wild population (pending success of program at Klickitat Hatchery).
        iii. Would likely alleviate concerns regarding use of current Klickitat Hatchery stock due to possible mixing of stream- and ocean-type Chinook salmon (see 3.c.ii above).
    b. O&M Needs - similar to Option 3 above.
    c. RM&E Needs - similar to Option 3 above (except for 3.c.ii).
5. Transport surplus Klickitat Hatchery adults to White Salmon starting in fall 2010.
    a. Biological Basis
        i. May be precluded by disease concerns resulting from out-of-basin transfer of adult fish.
        ii. Possible concerns about genetic mixing in Klickitat Hatchery stock of stream- and ocean-type Chinook salmon (see 3.c.ii. above).
    b. O&M Needs
        i. Trucking O&M.
        ii. Racking in of transported broodstock.
    c. RM&E Needs
        i. Radio-telemetry study.
        ii. Assessment of possible genetic effects (see 3.c.ii. above).
6. Trap and transport Klickitat wild adults to White Salmon.
    a. Biological Basis
        i. May be precluded by disease concerns resulting from out-of-basin transfer of adult fish.
    b. O&M Needs
        i. Trucking O&M.
        ii. Racking in of transported broodstock.

c. RM&E Needs

i. Monitor any natural re-colonization in interim (concerns about Carson fish?)

ii. Radio-telemetry study.

iii. Monitoring natural escapement in Klickitat River (relatively low in recent years) and any impacts to natural population from adult trap and transport.

7. Monitor natural escapement and production for 4-5 years then evaluate need and suitability of Option 4.

a. Biological Basis

i. Would determine if sufficient number of returning adults to restart population.

ii. Concerns about Carson fish on spawning grounds?

b. O&M Needs - little to none (unless Option 4 initiated).

c. RM&E Needs

i. Monitor any natural spawner escapement.

ii. Monitor Carson fish on spawning grounds.

iii. Monitor smolt production.

Coho salmon

1. Natural re-colonization - no reintroduction efforts from outside sources.

a. Biological Basis

i. Sufficient number of returning adults to restart population?

ii. Identification of coho benefits from EDT modeling efforts.

b. O&M Needs - little to none

c. RM&E Needs

i. Monitor natural spawner escapement.

ii. Monitor smolt production.

2. Juveniles from Washougal and/or Bonneville/Cascade hatcheries released into White Salmon River.

a. Biological Basis

i. Would use LCR coho stock for brood source (Washougal Hatchery, Lewis River, Type N, and/or Tanner Creek).

b. O&M Needs

i. Existing facilities at Washougal, Bonneville and Cascade hatcheries.

ii. For possible acclimation - White Salmon Pond rehabilitation and O&M.

iii. Juvenile transport at fry or smolt stage.

c. RM&E Needs

i. Monitor natural and hatchery escapement to spawning grounds.

ii. Monitor natural production.

iii. Fish health monitoring.

3. Collection of wild adult broodstock in Klickitat River with spawning and rearing at hatchery facility and juvenile release in White Salmon River.

a. Biological Basis

i. Would use nearby wild broodstock source.

b. O&M Needs

i. Identify suitable hatchery facilities for spawning and rearing.

ii. Adult capture facility at Lyle Falls Fishway on Klickitat River.

iii. For possible acclimation - White Salmon Pond rehabilitation and O&M.

iv. Juvenile transport at fry or smolt stage.

c. RM&E Needs

i. Monitor natural and hatchery escapement to spawning grounds.

ii. Monitor natural production.

iii. Fish health monitoring.

4. Collection of wild adult broodstock in White Salmon River with spawning and rearing at hatchery facility and juvenile release in White Salmon River.

a. Biological Basis

i. Would use local wild broodstock source.

b. O&M Needs

i. Identify suitable hatchery facilities for spawning and rearing.

ii. Adult capture facility - Weir or White Salmon Ponds rehabilitation.

iii. For possible acclimation - White Salmon Pond rehabilitation and O&M.

iv. Juvenile transport at fry or smolt stage.

c. RM&E Needs

i. Monitor natural and hatchery escapement to spawning grounds.

ii. Monitor natural production.

iii. Fish health monitoring.

5. Monitor natural escapement and production for 4-5 years then evaluate need and suitability of Options 2, 3 or 4.

a. Biological Basis

i. Would determine if sufficient number of returning adults to restart population.

ii. Identification of coho benefits from EDT modeling efforts.

b. O&M Needs - little to none (unless Options 2, 3, or 4 initiated).

c. RM&E Needs

i. Monitor natural spawner escapement.

ii. Monitor smolt production.

Chum salmon

1. Natural re-colonization - no reintroduction efforts from outside sources.

a. Biological Basis

i. Allows for natural colonization from populations within or below Bonneville pool.

b. O&M Needs

c. RM&E Needs

i. Continuation of either annual or every nth year chum surveys using revised chum specific "Patch" analysis or remote sensing techniques to monitor re-colonization efforts.

2. Active adult outplanting in years after Condit Dam Removal.

a. Biological Basis

i. Decreases timeframe of re-colonization and potentially provides better opportunity for multiple pairs of chum salmon to spawn in White Salmon.

ii. Most likely chum salmon are extirpated from White Salmon and chances for spawning to be occurring presently seem very unlikely.

iii. Accelerates building of chum population in White Salmon.

b. O&M Needs

i. Adults would have to be trapped in Bonneville Dam fishways or below Bonneville Dam (Ives Island, Duncan, Hardy and/or Multnomah Creek deltas) and trucked to release point in White Salmon River.

ii. Appropriate chum spawning channels could be constructed in suitable habitat within lower White Salmon River and adults transported into these channels.

c. RM&E Needs

i. Begin annual or every nth year surveys using chum specific "Patch analysis to monitor population dynamics.

ii. Identification of donor populations and determine both genetic and population fitness of these populations. (Below Bonneville stocks appear to be genetically best suited, and most easily obtained.)

iii. Identification of suitable spawning/outplanting locations and juvenile rearing habitat within White Salmon and lower tributaries.

iv. Potential PIT-tagging or Radio-tracking to determine spawning ground distribution and success or utilize remote sensing techniques.

3. Active stocking of juvenile chum salmon or outplanting of eggs in egg baskets and hatch boxes via WDFW's Washougal Hatchery or Willard NFH.

a. Biological Basis

i. Decreases timeframe of re-colonization and potentially provides better opportunity than natural re-colonization.

ii. O&M needs - yet to be determined but could involve infrastructure needs to Willard or Washougal hatcheries in addition to fish culture needs.

b. RM&E Needs

i. Continuation of either annual or every nth year surveys using chum specific "Patch analysis to monitor population dynamics.

ii. Identification of donor populations and determine both genetic and population fitness of these populations. (Bonneville fishway and or below Bonneville stocks appear most suitable and most easily obtained).

iii. Identification of suitable stocking locations and juvenile rearing habitat within the White Salmon River and lower tributaries.

iv. Potential PIT-tagging or Radio-tracking to determine distribution, timing and movement of chum salmon juveniles.

4. Initiate temporary hatchery program for chum salmon using existing USFWS hatcheries for subsequent outplanting using only chum captured at Bonneville Dam.

a. Biological Basis

i. Decrease risk to downstream donor stocks whose numbers are annually declining.

ii. Uses parent stock of chum salmon with fidelity to the Bonneville Reservoir and possible the White Salmon River.

iii. Decreases timeframe of re-colonization.

b. O&M Needs

i. Adults would have to be trapped in Bonneville Dam fishways.

ii. Adults would be held and spawned in Service Hatcheries.

iii. Eggs or juveniles would be outplanted in suitable habitat.

c. RM&E Needs

i. Survey and identify suitable habitats prior to outplanting.

ii. Evaluate success of any outplanted eggs.

iii. Continuation of either annual or every nth year surveys using chum specific "Patch analysis to monitor population dynamics.

iv. Potential PIT-tagging or Radio-tracking to determine distribution, timing and movement of returning adult chum salmon passing Bonneville Dam.

Steelhead

There are indications that the population of *O. mykiss* in the White Salmon River above Condit Dam is still producing smolts even though anadromy has been eliminated since the construction of Condit Dam and the end of passage in 1913. Pre-removal monitoring in the White Salmon River above Condit Dam has identified *O. mykiss* juveniles displaying smolt behavior and morphology, and PIT-tagged juveniles have been detected passing Bonneville Dam with one being recovered at the tern colony on East Sand Island (B. Allen, personal communication, 2007). In addition, a juvenile *O. mykiss* PIT-tagged above Condit Dam September of 2004 at 98 mm was detected ascending Bonneville Dam in July of 2006. Genetic analysis of juvenile *O. mykiss* collected in the upper watershed above Husum Falls are different from hatchery trout released in the basin, however additional samples are needed to confirm this finding (Allen et al. 2006). This information supports the theory that even though the population is functionally extirpated there is still the potential for re-establishing anadromous steelhead in the White Salmon River Basin.

Based on the potential to re-establish natural production of steelhead in the basin, the White Salmon Working Group decided that Option 1, the natural re-colonization approach, was the best suited for the status of *O. mykiss* in the basin. The key to the success of this option is to implement all of the proposed monitoring and evaluation activities, including screw trap operations and the installation of a weir on Rattlesnake Creek to monitor adult escapement, adult movement, and presence/absence of stray hatchery-origin steelhead. In the future, if the need arises, the weir could be used to exclude hatchery-origin adults creating a refuge for naturally produced steelhead. Another reason that the White Salmon Working Group

supported Option 1 was that the removal of Condit Dam provides a rare opportunity to study the natural re-colonization of newly available habitat without using hatchery intervention. Option 1 will be evaluated and an assessment made after 5 years to determine if the approach should continue or if the other proposed options should be considered.

1. Natural re-colonization - no reintroduction efforts from outside sources
    a. Biological Basis.
        i. Potentially a small number of returning native adults but may not be sufficient number to restart population.
        ii. Recent USGS studies identify PIT-tagged resident *O. mykiss* migrating from the White Salmon above Condit Dam. One PIT-tag collected at East Sand Island, and one detected passing back upriver through the Bonneville Dam fishway (steelhead life history may still be present in upper watershed).
    b. O&M Needs
        i. Maintenance of weir(s) in tributary stream(s).
    c. RM&E Needs
        i. Monitor all natural spawner escapements.
        ii. Monitor hatchery stray steelhead on the spawning grounds.
        iii. Juvenile fish surveys for abundance and growth (via PIT-tagging).
        iv. Rotary Screw Trap (both in lower river and above current reservoir site) to collect out migrants for DNA (deoxyribonucleic acid) analysis, and juvenile production.
        v. Adult and juvenile weir trap and/or instream PIT-tag detector for monitoring in Rattlesnake Creek.
        vi. Redd capping to conduct DNA analysis.
2. Wild donor from local watershed as brood source for juvenile release into the White Salmon River. Eggs collected and reared at suitable hatchery, juveniles acclimated and released at White Salmon Ponds.
    a. Biological Basis
        i. Would emphasize collection of wild steelhead from locally adjacent watershed, with similar geomorphologic characteristics and flow regime.
        ii. Marking to minimize harvest and still provide monitoring information on returning adults.
    b. O&M Needs
        i. White Salmon Pond rehabilitation and O&M.
        ii. Juvenile transport at fry or smolt stage.

iii. Possible identification and development of upriver acclimation site.

c. RM&E Needs

i. Monitor natural and hatchery escapement to spawning grounds.

ii. Monitoring natural escapement in brood source river and any impacts to natural population from broodstock collection.

3. White Salmon resident *O. mykiss* as brood source with locally suitable anadromous wild donor stock spawned for juvenile release into upper White Salmon River.

a. Biological Basis

i. Would emphasize both local (resident) and from locally adjacent watershed.

ii. Possible concerns of ESA status of new population.

b. O&M Needs

i. Upper White Salmon release site identified/developed and O&M.

ii. Possible identification and development of upriver acclimation site.

c. RM&E Needs

i. Fish Health monitoring (BKD/IHN concerns).

ii. Assessment of possible effects of use of genetically mixed local donor stock.

4. Develop White Salmon captive brood program using captured outmigrating juveniles.

a. Biological Basis

i. Capture genetically unique White Salmon steelhead for captive brood program development.

b. O&M Needs

i. Transport equipment.

ii. Spawning, incubation, rearing and adult holding facilities.

iii. Possible identification and development of upriver acclimation site.

c. RM&E Needs

i. DNA analysis to ensure White Salmon population.

5. White Salmon Steelhead Kelt Reconditioning. Recondition local spawners to enhance survival to repeat spawning stage.

a. Biological Basis

i. Maximize survival of White Salmon steelhead to bolster early stages of White Salmon re-colonization effort.

b. O&M Needs

i. Adult downstream weir trap to collect females.

ii. Holding area and feed.

iii. Direct stream release locations identified/developed (for release of reconditioned adults).

c. RM&E Needs

i. Monitoring holding/release methods (i.e. release below Bonneville, or release into White Salmon, hold and release into White Salmon just prior to spawning).

ii. PIT-tag adults for Bonneville Dam detection.

iii. Rotary Screw Trap (both in lower river and above current reservoir site) to collect out migrants for DNA analysis.

iv. Acoustic tag monitoring in White Salmon and Columbia plume to track kelt movement.

Appendix II. Current Efforts and Regulations Addressing and Protecting Population Productivity in the White Salmon Watershed

Population Enhancement and Habitat Restoration Actions

Positive change is underway to address limiting factors and threats to improve steelhead habitat conditions. A number of actions are proposed, being planned, or are already being implemented in the watershed to address these conditions and the affected populations.

Recent actions include:

- Planning for population introduction/reintroduction upstream of the former Condit Dam
- Plantings of trees in riparian zones to provide for future shade and LWD recruitment
- Assessment of habitat condition in Rattlesnake Creek to identify opportunities for future restoration actions
- Klickitat County expects to initiate the development of a White Salmon Watershed (WRIA 29b) Management Plan in the near future, pending the availability of funding

Regulatory Protection

Federal, state, county, and tribal regulatory mechanisms are in place to protect habitat from current and future threats posed to listed species through habitat loss and degradation caused by human land uses and development. Numerous voluntary programs are also available to address habitat conservation. In addition, some areas receive special protection through designation, such as Wild and Scenic River reaches, primitive areas, and wildlife refuges.

NOAA Fisheries and/or U.S. Fish and Wildlife Section 7 Consultations

Section 7 of the ESA directs all Federal action agencies to consult with NOAA's NMFS and the USFWS to ensure that all Federal actions/projects will not jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat. Actions include not only direct Federal actions, but also actions funded with Federal dollars. A Biological Assessment or Biological Evaluation is usually developed and submitted to NMFS for review prior to implementation of any project. The reader can find additional information regarding the consultation process at: http://www.nwr.noaa.gov/Salmon-Harvest-Hatcheries/Hatcheries/Sec-7-USFWS-Columbia.cfm (accessed April 19, 2012).

Clean Water Act

The Federal Clean Water Act addresses the development and implementation of water quality standards, the development of Total Maximum Daily Loads (TMDL), filling of wetlands, point source permitting, the regulation of stormwater, and other provisions related to protection of U.S. waters. The Clean Water Act is administered in the State of Washington by the WDOE with oversight by the EPA. State water quality standards are set to protect beneficial uses, which include several categories of salmonid use. Ecology has a

water quality certification program under which it reviews projects that will discharge dredged or fill materials into waters of the U.S. and issues certifications that the proposed action meets State water quality standards and other aquatic protection regulations, if appropriate. Ecology also issues National Pollution Discharge Elimination System (NPDES) permits, and develops water quality cleanup plans TMDL to address water quality limited streams.

National Environmental Policy Act (NEPA) Review

NEPA requires Federal agencies to consider the probable impacts of their proposed activities, programs, and projects (including funding of state, local, and private actions) on the quality of the human environment. NEPA reviews help agencies decide whether to undertake a proposed action. In most cases, the NEPA review requires the development of an Environmental Assessment or Environmental Impact Statement (EIS) that addresses the probable effects of a project and its alternatives on various elements of the environment, including soils, geology, landscapes, atmospheric conditions, vegetation, fish and wildlife, and cultural resources. Many Federal funding programs are covered under a general NEPA review completed when the funding program was developed.

Watershed Planning Act

In 1998 chapter 90.82 Revised Code of Washington (RCW) was amended with the passage of Engrossed Substitute House Bill (ESHB) 2514. This law is also known as the Watershed Planning Act. The Watershed Planning Act was established to address the diminishing water availability and quality, and the loss of habitat for fish in the State of Washington. The Watershed Planning Act provides a framework for local citizens, tribes, and state and local agencies to work together to develop and implement Watershed Management Plans for entire watersheds.

As part of the planning process, a watershed assessment is completed for each Water Resource Inventory Area (WRIA) to evaluate water supply and use. Once the watershed assessment is complete, a management plan, followed by a detailed implementation plan, is developed to address water quantity, water quality, and fish habitat issues identified in the assessment. The White Salmon River lies within WRIA 29b. Watershed planning activities are currently on hold due to the state's current budget shortfall.

State Environmental Policy Act (SEPA)

SEPA regulations require an environmental review of actions taken by the state and local agencies, including funding and permitting. Some actions, such as the construction of single-family dwellings, minor road repair, and issuance of business licenses, are exempt. A SEPA review evaluates the probable environmental effects of a proposed project. This information is used to determine if the action should be taken as proposed, if mitigation is necessary, or if the proposal should be rejected.

Forest & Fish Regulations (Washington State)

The Washington Forests & Fish Law, ESHB 2091, was signed into law in 1999 as part of The Washington State Forest Practices Act (Title 76.09 RCW), passed in 1974. The Forests

& Fish Law, based on the Forests & Fish Report, resulted in changes to forest practices rules to protect riparian and aquatic resources on more than eight million acres of private forestland. It is intended to meet the provisions of the Federal Clean Water Act concerning non-point source silvicultural practices. Changes to the law included:

- Updates of the stream typing system in the state to improve mapping of fish-bearing waters
- Increases in buffer widths along fish bearing and non-fish bearing streams,
- Changes in forest practices to protect against landslides
- Mandatory requirements to update the forest road system to hydrologically disconnect roads from streams and minimize sediment delivered to streams
- New regulations on pesticide applications to prevent or avoid drift of chemicals into streams
- Increased protection of wetlands
- Changes in enforcement
- Establishment of a scientifically based adaptive management and monitoring process for evaluating the impact of forest practices on aquatic resources
- Establishment of a process for amending the forest practices rules to incorporate new information as it becomes available
- Establishment of a small landowner office to assist non-industrial landowners

Additional information regarding the Forest Practices rules can be found at: http://www.dnr.wa.gov/BusinessPermits/ForestPractices/Pages/Home.aspx (accessed April 19, 2012).

The Washington Department of Natural Resources, on behalf of the State of Washington, submitted applications to NMFS and the USFWS for incidental take permits under section 10 of the ESA. Issuance of these permits would provide assurances that all forest practices activities in compliance with the state forest practices rules and administrative program will satisfy ESA requirements for aquatic species. The two services released the final HCP (habitat conservation plan), the final EIS, and implementing agreement in a ***Federal Register Notice*** on Jan. 27, 2006. This notice provides an opportunity for the public to review the final documents and the responses to public comments on the draft documents.

Klickitat County Shorelines Master Plan

In 1971 the Washington State Legislature passed the Washington Shoreline Management Act, adopted by public referendum in 1972. The purpose of the Act is "to prevent the inherent harm in an uncoordinated and piecemeal development of the state's shorelines" by requiring every county and many cities to develop a Shoreline Master Plan to govern development in shoreline area http://www.ecy.wa.gov/programs/sea/sma/st_guide/intro.html (accessed April 19, 2012). Klickitat County's Shorelines Master Plan (SMP) was first adopted in 1975 and has been updated periodically since then. The SMP and brochure on the shorelines permit program can be accessed from the Klickitat County Planning Department's website: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788 (accessed April 19, 2012).

The Klickitat County's SMP regulates "development" within the "shorelines" of the White Salmon River and other water bodies in Klickitat County's jurisdiction. "Development" is broadly defined as: construction or exterior alteration of existing structures; dredging; drilling; dumping; filling; removal of any sand, gravel or minerals; bulkheading; driving of piling; placing of obstructions; or any project of a permanent or temporary nature which interferes with the normal public use of the surface of the waters overlying lands subject to the SMP regulations at any state of water level. "Shorelines" are those lands extending landward for 200 feet in all directions as measured from the ordinary high water mark, floodways and contiguous floodplain areas landward 200 feet from such floodways; all wetlands and river deltas associated with the streams and lakes. The SMP applies to the shorelines of the mainstem of the White Salmon River as well as the shorelines of all tributaries with a mean annual flow of 20 cfs or more.

The SMP designates various shorelines of the White Salmon River and its tributaries as "environments", which determine the level of protection that is warranted. Much of the White Salmon River is designated either "Natural Environment" which prohibits most development within its shorelines or "Conservancy Environment", which allows a limited scope of development, subject to conditions (i.e., shoreline conditional use permit). Each development proposal is subject to review pursuant to the shoreline environment within which it is to be located. One or more shoreline permits must be secured prior to implementation: Substantial Development Permits are required for any development for which the total cost or fair market value exceeds $5,000, or any development which materially interferes with the normal public use of the water or shorelines; Shoreline Conditional Use Permits (CUP) are required for development types that warrant conditions to ensure consistency with the SMP; and Variances are issued to grant relief from specific bulk, dimensional, or performance standards of the SMP in order to avoid unnecessary hardship, provided that extraordinary circumstances are shown to exist and the public interest shall suffer no substantial detrimental effect. Some types of development, such as a single-family residence, normal maintenance and repair, or construction of a normal protective bulkhead for a single family residence, are exempt from the requirement of a substantial development permit, but are still subject to all other provisions of the SMP.

Existing structures and developments that were established prior to adoption of the SMP are considered legally established "non-conforming" uses. Since adoption of the SMP, the County and WDOE have reviewed all developments within shorelines, including modifications to non-conforming uses, to ensure compliance with the goals and requirements of the SMP.

The WDOE reviews the County's permit decisions and has final authority to approve or deny CUPs and Variances. Persons may appeal the final decision to the Shorelines Hearings Board.

Klickitat County Critical Areas Ordinance

Klickitat County adopted a Critical Areas Ordinance (CAO) in 2001 and, with the concurrence of WDFW, Community Trade and Economic Development, and Ecology, amended it in 2004. The CAO extends beyond the geographical scope of the County's SMP

to protect wetlands, critical fish/wildlife habitat, geologically hazardous areas, aquifer recharge areas, and frequently flooded areas. The CAO is, in effect, an overlay on existing land use regulations. The CAO provides for standard setbacks of 300' from Category I wetlands, 200' from Category II, and 75' from Category III and IV. The CAO provides for standard buffers of 200' from Type 1 & 2 waters; 150' from Type 3 waters; 50' from Type 4 waters; and 25' from Type 5 waters. A wildlife habitat management plan is required for new development that will likely impair salmonid habitat functions and values. As with the SMP, developments and uses that existed prior to the adoption of the CAO are considered legally established "non-conforming" uses. The CAO and brochures land use permit programs can be accessed from the Klickitat County Planning Department's website: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788 (accessed April 19, 2012)

Klickitat County Floodplain Management Ordinance

The Klickitat County Floodplain Management Ordinance (FPO) regulates all development and activities that may increase flood hazards. A permit is required for development within areas of special flood hazard (with at least one percent chance of flooding). The applicant for a non-residential structure must include a certification and flood analysis conducted by a professional engineer. In general, development that does not meet the specific criteria in the ordinance for development in these areas, to protect public health and safety, will be denied. The FPO and brochures land use permit programs can be accessed from the Klickitat County Planning Department's website: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788 (accessed April 19, 2012).

Klickitat County Zoning Ordinance

The Klickitat County Zoning Ordinance (CZO) was adopted in 1979 and has been amended over time. Much of the White Salmon River watershed is zoned by the CZO as "extensive agriculture" which requires a 20-acre minimum lot size for the purpose of dividing properties, and new development/uses are restricted to resource management uses/activities and other compatible uses. One permanent residential dwelling is allowed per lot. Some areas of the watershed are zoned for residential development. The allowable minimum lot size for new lots is either 1 or 2 acres; and one residential dwelling is allowed per lot. Other than residential development, most new development/uses in these zones is either prohibited or allowed per a zoning conditional use permit. The CZO and brochures land use permit programs can be accessed from the Klickitat County Planning Department's website: http://klickitatcounty.org/Planning/default.asp?fCategoryIDSelected=301427788 (accessed April 19, 2012).

Klickitat County Environmental Ordinance (CEO)

The Klickitat County Environmental Ordinance (CEO) was adopted pursuant to the SEPA. The CEO and SEPA require an analysis of probable significant adverse environmental impacts that may result from a proposed development. The CEO and SEPA require a threshold determination for each proposed development that is not exempt. The threshold determination is a determination that a project will or will not have probable significant

adverse environmental impacts. If a project has probable significant adverse impacts, and an EIS is prepared, any proposed development/use that is not specifically exempt in SEPA, chapter 43.21C RCW, or the SEPA rules adopted by the Department of Ecology, Chapter 197-11 Washington Administrative Code, is required to comply with SEPA. Klickitat County provides applicable state agencies and tribes, as well as the public, the opportunity to review threshold determinations and EISs.

Washington State Water Pollution Control Act (Chapter 90.48 RCW)

This act gives Ecology the authority to protect water quality in the state and to promulgate regulations as needed to achieve this goal. The Act makes discharges of pollutants into waters of the state unlawful and has provisions for enforcement of violations, including the authority and process for issuing compliance orders and civil penalties, and for seeking criminal penalties. The Act also provides for permitting processes, cooperation with other entities, water quality monitoring, grants, and numerous other subjects regarding management of water quality issues in the state.

Washington's Statewide Monitoring Program

In 2001, Substitute Senate Bill (SSB) 5637 was signed into law. This act related to monitoring of watershed health and salmon recovery. The Monitoring Oversight Committee developed a comprehensive statewide strategy that addresses the actions identified in SSB 5637. Among other things, the Plan is intended to provide information regarding trends in fish, water, and habitat conditions and assess effectiveness of actions taken to improve watershed health and provide for salmon recovery. The strategy includes documentation of fish population trends in some areas of the state; however, the White Salmon River watershed is not one of the areas included to date in that monitoring effort. The strategy is also monitoring the effectiveness of habitat restoration efforts funded by the state. The monitoring of project effectiveness follows the Monitoring and Evaluation Strategy (Washington SRFB 2003) that was developed in support of the Comprehensive Statewide Strategy. The Monitoring and Evaluation Strategy specified methods to assess a wide range of restoration and protection projects.

On-Site Sewage Systems

Chapter 246-272 of the Washington Administrative Code regulates the onsite disposal of sewage in the state. The law is applicable to septic systems as well as larger on-site systems. The rule addresses location of systems, site evaluations, design, installation, inspection, operation and maintenance, repair, abandonment, and other areas of concern. The rule helps to prevent the discharge of sewage into fish-bearing streams.

Hydraulic Code

Chapter 75.20 RCW governs construction projects within the waters of the State of Washington. The law requires hydraulic project approvals from the WDFW, Department of Fish and Wildlife for wharves, bulkheads, bridges, culverts, fish habitat restoration projects, and other construction activities within the ordinary high water mark. This regulation helps to protect fish and fish habitat during construction.

Regulation of Dairy Farms

Chapter 90.64 RCW, the Dairy Nutrient Management Act, includes a number of requirements designed to protect water quality from dairy operations. These are in addition to NPDES requirements in the Federal and state Clear Water Acts for concentrated animal feeding operations. The Act requires inspection of all dairy farms, implementation of dairy nutrient management plans, technical assistance and enforcement (including civil penalties) against significant polluters. The intent of the regulation is to protect water quality and, subsequently, fish habitat. The WDOE is the primary regulatory authority under this Act.

Other Rules and Regulations

There are over 100 additional rules and regulations applicable to the protection of water quality and fish habitat in the State of Washington. These rules cover a broad range of subjects such as groundwater quality standards, application of pesticides, well construction, motor oil disposal, utilities, solid waste disposal and recycling, water supply facilities, mining, energy facilities, dikes and levees, aquiculture, etcetera. Lists of applicable laws and rules and links to the specific requirements of those laws and rules can be found at: www.ecy.wa.gov/laws-rules.

Yakama Reservation Forest Management Plan

The YN has a variety of protective land use regulations in effect on reservation lands. One of these is the FMP. Under the 1993-2002 FMP, the Yakama Administrative Forest was divided into 11 Land Use Management Areas (LUMA). Each LUMA was managed for multiple uses with emphasis on dominant resource features and objectives. The draft FMP soon to be ratified changes the designation of LUMAs to Management Emphasis Areas (MEA), which will be managed within the forest habitat types (BIA and YN 2004). The forestry program is using historical species composition and stand densities as references for the desired future stand conditions. Just as with the health of aquatic systems, forest health describes the ability of a forest ecosystem to remain productive, to maintain a diversity of plants and animals, aesthetic appeal, and resource sustainability, and to withstand disturbances over time. In addition, a healthy forest is resilient to periodic disturbances such as drought, insects, diseases, fires, climatic change, and management practices.

The FMP prescribes the number of miles and density of roads allowed to be built for the purpose of harvesting timber from the Administrative Forest, and forest treatments such as thinning and prescribed burns are being put into place to move the forest vegetation more toward the historical condition of seral stands rather than dense, late successional forest cover. Streams are classified according to their flow, use for domestic purposes and use by fish for spawning, rearing and migration, and buffers and harvest restrictions are set accordingly. The objectives are the preservation of stream bank and riparian cover, water quality and flow maintenance and soil stabilization (BIA and YN 2004).

Fisheries Management and Evaluation Plan

Recent policy changes will reduce potential harvest impacts. A Fisheries Management and Evaluation Plan (FMEP) for tributary fisheries in the Washington portion of the LCR

Chinook salmon, steelhead, and chum salmon ESUs (WDFW 2002) has been approved by NMFS. WDFW has also requested NMFS approval on a proposed supplement to the FMEP that covers tributary fisheries impacts on listed LCR coho salmon. The agency has also submitted a FMEP for MCR steelhead to NMFS that includes management for recreational fisheries in the White Salmon River. The FMEP minimizes harvest impacts to listed steelhead through the use of selective fisheries that target marked hatchery steelhead and requires the release of all unmarked steelhead. The FMEP also includes management actions that limit impacts to juvenile steelhead through fishing seasons, area closures, and gear restrictions. NMFS is currently reviewing the FMEP to determine if it can be approved under the 4(d) rule limit 4 for MCR steelhead.

Hatchery and Genetic Management Plans

The USFWS submitted HGMPs to NMFS for approval under section 7 of the ESA. NMFS issued a section 7 Biological Opinion on November 27, 2007 for these hatchery programs (http://www.nwr.noaa.gov/Salmon-Harvest-Hatcheries/Hatcheries/Sec-7-USFWS-Columbia.cfm) (accessed April 19, 2012). . Many actions and measures in the HGMPs have already been implemented. These HGMPs cover programs that release fish into the LWS River and at the Spring Creek NFH. WDFW has also submitted an HGMP to NMFS for the releases of summer and winter steelhead into the White Salmon River. These programs may adversely affect listed populations in the White Salmon River and are being evaluated in a Biological Opinion. All of these programs are funded in whole or partially through the Mitchell Act, which is administered by NMFS. An EIS for NMFS' funding of the Mitchell Act and its hatchery programs is being drafted and will include evaluation of the programs listed above.

Special Land Use Areas

Several areas in the White Salmon drainage have received special Federal protection**.**

Columbia River Gorge National Scenic Area

"The National Scenic Area was created to protect and enhance the scenic, natural, cultural and recreational resources of the CR Gorge while encouraging economic development" (www.fs.fed.us/r6/columbia/). The White Salmon River downstream of Condit Dam, RM 3.3-mouth, is within the boundaries of the Gorge National Scenic Area. All new development and land uses must be reviewed in the National Scenic Area to determine if they are consistent with the Act and the implementing land-use ordinances. The development guidelines of the management plan are implemented through land-use ordinances that must be consistent with the management plan.

Wild and Scenic Rivers

The Wild and Scenic Rivers Act was created by Congress to preserve in a free-flowing condition selected rivers of the nation which, with their immediate environments, possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historical, cultural, or other similar values. The nine-mile reach from confluence of Gilmer Creek near BZ

Corner to Buck Creek is a Federal Wild and Scenic River. A twenty-mile stretch of the upper White Salmon and Cascade Creek received Senate approval for Wild and Scenic designation and awaiting presidential approval. The Act restricts the construction of any dam or other water resource project on or directly affecting a designated river or that would have a direct and adverse effect on the values for which such a river was established, such as its free-flowing nature. The Act directed the Forest Service to develop management plans for these portions. The Wild and Scenic Rivers Act on the White Salmon River does not supersede local Shoreline Management Plans.

Appendix III. Jewett Creek

Jewett Creek is a small creek located 2 miles to the east of the mouth of the White Salmon River. Geographically, the creek is located within the ICTRT-identified Klickitat independent population spatial distribution boundary, and is, therefore, within the Klickitat River recovery planning area. Jewett Creek is discussed here since it was not considered in the Klickitat Recovery Plan. Any steelhead found in Jewett Creek are most likely hatchery strays or strays from the Klickitat or other independent steelhead populations.

Jewett Creek does not meet the minimum criteria for consideration in the ICTRT's assessment of intrinsic habitat potential (ICTRT 2008) and is not considered a major or minor spawning area for the Klickitat independent population of the MCR Steelhead DPS. The creek does not have sufficient habitat to support a viable population, and the population has not been identified as contributing to the viability of the middle Columbia steelhead DPS (ICTRT 2004).

The lower portion of the creek runs through roughly 100 yards of pipe located under an existing industrial plant. The Bonneville Pool may back up water within the pipe. The creek daylights for approximately 0.9 miles between the railroad and Highway 14, and then passes under the highway. Another 0.8 miles of habitat is available upstream of the Highway. The gradient of the creek becomes impassable at the Gorge bluffs, located at roughly river-mile 0.35.

Local residents have indicated that fish have been seen up to the gorge bluffs. The entire area of stream, which is accessible to anadromous fish, is within the Bingen City limits. No information is available regarding the quality of the 1.7 miles of available habitat; however, monitoring and evaluation actions have been proposed to identify anadromous fish usage and habitat conditions. The ICTRT determined that at least 9.3 miles (15 km) of habitat is necessary to support a viable population of 500 fish (ICTRT 2004).

Appendix IV. White Salmon River Implementation Schedule: Summary of Actions and Potential Costs to Restore White Salmon River Anadromous Fish Populations and Their Habitat

The following table lists the recovery actions identified by the Washington Gorge Implementation Team to address salmon and steelhead recovery in the White Salmon River watershed. Actions addressing implementation of PacifiCorp's decommissioning plans, restoration of the reaches affected by the former Northwestern Lake and the former Condit Dam, and harvest practices potentially affecting the rate of recovery are priority actions.

Detailed cost breakdown by specific action.

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
	Chinook	Steelhead	Coho	Chum						
Species Reintroductions	x	x	x		Restore populations	Implement reintroduction plan for White Salmon salmonids	White Salmon Working Group	$0		$0
RM&E	x	x	x	x	Baseline Habitat Data Collection	Gather information needed to identify and prioritize habitat actions that will provide the greatest opportunity to contribute to recovery	PacifCorp, White Salmon Working Group	$131,000		$0
	x	x	x	x	Population Monitoring: - Monitor population abundance and productivity - Monitor proportion and origin of hatchery salmon and steelhead on the spawning grounds	Install & maintain large multiplexing PIT-tag detectors in the lower White Salmon mainstem, & in Buck & lower Rattlesnake Creeks. Report findings.	White Salmon Working Group	$176,000		$176,000

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species	Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
		proportion and origin of hatchery salmon and steelhead on the spawning grounds - Assess the resident trout contribution to smolts below Condit Dam; assess change in resident population after steelhead re-colonization/re-introduction					
			Implement population monitoring in the White Salmon River & Rattlesnake Creek.	White Salmon Working Group	$300,000		$300,000
			Install two small stationary in-stream PIT-tag detectors in the lower most portion of Spring Creek.	USGS	$20,000		$20,000
			Pit-Tag 3,000 juvenile salmonid each year above & below Condit Dam to track individual movement & seasonal growth rates.	USGS	$10,000		$10,000

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
						Conduct adult spawning ground surveys and monitor.	WDFW	$351,000		$351,000
						Create and maintain fish counts & biological database.	WDFW	$9,000		$9,000
						Mark adults for mark-recapture population estimates.	WDFW	$72,000		$72,000
						Derive estimates of salmonid population abundance & complete reporting	USGS & WDFW	$400,000		$400,000
					Population Monitoring: Genetic analses	Compare adult & smolt genetic analyses to ongoing adult salmon escapement estimates of WDFW & smolt outmigration estimates of USGS studies in the White Salmon River.	USFWS	$70,000		$70,000
Habitat	x	x	x		Restore channel, stabilize banks, replant banks, and restore habitat in inundated area currently occupied by the reservoir and habitats downstream of	Implement PacifiCorp's Decommissioning Management Plans.	PacifiCorp	$895,000 to 1,100,000+	$895,000 to 1,100,000+	$0

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
					Condit dam impacted by dam removal	Restore channel mainstream above Condit Dam.	YN, WDFW, UCD	$400,000-600,000	$400,000-600,000	$0
						Restore riparian condition.	UCD	$260,000		$260,000
						Dredge mouth of River if needed	ACOE	TBA		TBA
	x	x	x	x	Protect and conserve existing natural ecological processes	Protect existing habitat from future degradation though existing regulatory structure	Federal, state, county, and local governments			$0
						Protect existing habitat from future degradation though land management plans, conservation easements, acquisitions, reclassification of lands as natural areas	UCD, NRCS, Counties, Land Trusts, landowners	$260,000	$10,000	$250,000

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
	x	x	x		Restore vegetation along stream sections that exceed state standards for temperature	Identify stream segments that are excessively warm; within those areas, work with willing landowners to implement actions to increase density of riparian vegetation where sparse; implement programs to protect existing riparian vegetation, reduce sediment inputs to streams.	YN, WDFW, UCD, Mid-Columbia Regional Fishery Enhancement Group (MCRFEG), Klickitat Co.	$260,000		$260,000
		x	x		Restore passage and connectivity's to habitats blocked or impaired by artificial barriers	In cooperation with irrigation district and others, remove or replace barriers inhibiting upstream passage including dikes, culverts and irrigation structures, provide/upgrade screening of irrigation diversions.	YN, USFWS, WDNR, WDOT, Private landowners, USFS, UCD, or others	$700,000		$700,000
						Indian Creek culvert replacement.	UCD, USFWS, YN, Counties	$368,000	$118,000	$250,000
	x	x	x	x	Reduce nutrient inputs	Reduce runoff of nutrients from septic tanks, dairies, agricultural lands, and other sources.	UCD, WDOE, NRCS, landowners, Counties	$1,111,000	$10,000	$450,000

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
	x	x	x		Improve LWD abundance and recruitment	In cooperation with landowners plan, design and install stable wood and other large debris in steambeds and develop approaches to ensuring long-term LWD recruitment.	UCD, MCRFEG, YN, FS, WDFW, landowners	$715,000	$0	$715,000
						In cooperation with landowners develop grazing strategies that promote riparian recovery.	UCD, landowners	$80,000	$0	$80,000
						Eradicate invasive plant species from riparian areas.	County weed control board, USFS, landowners	$120,000	Unknown	$120,000
					Restore channel	With willing landowners, stabilize streambanks, restore natural channel form, reduce sediment inputs as needed from roads	UCD, landowners, MCRFEG, YN, USFWS, USFS, WDNR	80,000-120,000	$0	80,000-120,000
					Reduce anthropogenic effects on stream flow	Quantify anthropogenic effects on stream flow and identify priority actions	Counties	$200,000	$0	$200,000
						With willing landowners, Implement water conservation measures	Counties, UCD, WDOE	$1,500,000	$0	$1,500,000

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
						Improve irrigation conveyance and efficiency	UCD, landowners	$3,500,000	$0	$3,500,000
						Employ BMPs with willing landowners	Counties, WDFW, YN, USFS, landowners, UCD	$400,000	$0	$400,000
						Protect/restore springs with willing landowners	Counties, WDFW, YN, USFS, landowners, UCD, MCRFEG	$450,000	$0	$450,000
						Increase pool habitat	Counties, WDFW, YN, USFS, landowners, MCRFEG	$900,000	$0	$900,000
						With willing landowners restore wetlands	Counties, WDFW, YN, USFS, landowners, UCD, MCRFEG	$600,000	$0	$600,000
						Hydrologically disconnect roads from streams.	Counties, WDFW, YN, USFS, landowners	$1,500,000	$0	$1,500,000

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
						Control road/stream interactions by reducing erosion potential	Counties, WDFW, YN, USFS, landowners	500,000-700,000	$0	500,000-700,000
	x	x	x	x	Public Awareness	Public Awareness regarding restoration projects and importance of wood in streams and riparian areas	UCD, MCRFEG, WDFW, YN, USFWS,	30,000 to 40,000	$0	30,000 to 40,000
Harvest	x	x	x	x	Harvest Management	Manage harvest for low impact fisheries and rapid population growth	PFMC, U.S. v. Oregon Parties	TBD	**$0**	**$0**
	x	x	x	x	Harvest Management	Adjust tributary harvest regulations in areas where harvest significantly impacts salmon and steelhead population growth	WDFW, YN, Co-managers	$50,000	**$0**	$0
Hatcheries	x	x	x	x	Reintroduction - hatchery production	Rehabilitate White Salmon Ponds and update intake screen	Co-managers USFWS	$450,000	**$0**	**$450,000**
Hydrosystem and Mainstem Predation	x	x	x	x	Maintain or improve hydropower operations and facilities at Bonneville Dam to enhance salmon and steelhead survival	Decrease water travel time during smolt outmigration	BPA, ACOE	Costs addressed in Middle-Columbia River roll-up plan		

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
Hydrosystem and Mainstem Predation	x	x	x	x	Maintain or improve hydropower operations and facilities at Bonneville Dam to enhance salmon and steelhead survival	Improve operation of adult passage, maintain high standards of adult fish passage at Bonneville Dam	BPA, ACOE	Costs addressed in Middle-Columbia River roll-up plan		
Hydrosystem and Mainstem Predation	x	x	x	x	Reduce predation on salmonids	Reduce predation by pinnipeds, piscivores, cornorants, and Caspian terns	BPA, ACOE	Costs addressed in Middle-Columbia River roll-up plan		
Jewett Creek										
RM&E		x	x		Baseline data collection	Determine spatial distribution of salmonids in Jewett Creek.	MCFEG, YN, WDFW	$1,000		
RM&E		x	x		Baseline data collection	Complete gathering information on existing salmonid stocks: determine the status, life histories and genetic composition of fish in Jewett Creek	MCFEG, YN, WDFW,	$2,000		
RM&E		x	x		Baseline data collection	Assess fish passage and habitat conditions in lower Jewett Creek	MCFEG, YN, WDFW, landowners,	$5,000		

Recovery Strategies as Prioritized in Recovery Plan	Applicable Species				Action Type	Specific Action(s)	Potential Implementing Entity(s)	Total Estimated Cost ($)	Total Cost Secured	Funds Needed
Habitat		x	x			Restore riparian areas based on habitat assessment	MCFEG, YN, WDFW, landowners,	$75,000		
								$16,781,000	$1,873,000	$13,993,000
