Develop grazing strategies that promote riparian recovery	NRCS, AFS, USFS, BLM, SWCDs, ODFW, Watershed Councils, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, depending upon grazing plan adopted. Riparian corridor fencing and removal of riparian grazing has the fastest recovery rate.	High, based upon experience with existing grazing management and riparian recovery projects

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Indian and Murderers creeks, SF John Day below Izee Falls	No	Limited by resources.
SWCDs	Upland improvements, riparian improvements	Private lands on SF John Day and tributaries above and below Izee Falls. Act ive program on SF above Izee Falls		See State of Oregon programmatic review -- Appendix F.
Watershed Councils	Upland improvements, riparian improvements	Private lands on SF John Day and tributaries above Izee Falls	No	Resource limited.
USFS, BLM	Upland improvements, riparian improvements	Federal lands on SF John Day and tributaries above and below Izee Falls. Murderers and Wind creeks	Likely	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
NRCS	Upland improvements, riparian improvements	Indian Creek, SF John Day above Izee Falls	Yes	Program sufficient.
ODA	Agricultural Water Quality Management Program	SF John Day above Izee Falls		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Private lands on SF John Day and tributaries above and below Izee Falls in cooperation with SWCD and Watershed Council	Uncertain	Limited opportunities currently identified for this program.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

See discussion for Strategy 5, Lower Mainstem John Day River population.

In the last 20+ years ODFW, Watershed Councils, NRCS and Soil and Water Districts have implemented hundred of miles of riparian improvements on private lands, primarily through construction of riparian corridor fences that exclude livestock grazing, and development of off channel watering devices. Public land managers have implemented PACFISH standards for protection and restoration of USFS and BLM lands. Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management programs remains challenging in some locations. The Forest Services Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Primary constraints on implementing additional projects for more riparian improvements are funding and personnel needed for lanning, promotion, education of landowners, and implementation.

p

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	Mainstem South Fork John Day above Izee Falls (1); Murderers Cr between the lower USFS boundary up to Tex Cr (2); SF Murderers (1); Deer Cr, mouth to headwaters (1)	Altered hydrology, low flows, high temperatures	water withdrawals, land conversion on uplands, road network	Abundance, productivity	Primarily fry and 0+	The lower and upper mainstem South Fork John Day is used extensively for irrigation purposes, small diversions are present on Wind and Murderers crs
Improve irrigation conveyance and efficiency	South Fork John Day River below PW Schneider WMA boundary (1); Upper South Fork John Day River (1); Wind (2) and Murderers (2) crs	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Primarily fry and 0+	
Increase pool habitat (beaver ponds)	Lower South Fork John Day River (2); Upper South Fork John Day River (1); Wind (2); Deer (1); SF Murderers (1); and Murderers (1) crs	Habitat complexity		Abundance, productivity	Primarily fry and 0+	
Floodplain aquifer recharge		Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and 0+	
Lease or acquire water rights and convert to instream	Lower South Fork John Day River (2); Upper South Fork John Day River (1); Wind (2) and Murderers (2) crs	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and 0+	
Monitor/regulate water withdrawals	All MaSAs	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and 0+	
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD, watershed councils, NRCS	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights
Improve irrigation conveyance and efficiency	SWCD, OWEB, watershed councils, NRCS, landowners	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of	Immediate	High, if the saved water is protected from being appropriated to a

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
				projects		downstream user in areas with instream water rights
Increase pool habitat (beaver ponds)	SWCD, ODFW, CTWSRO, USFS, BLM	Ongoing	High dispersal downstream	Unknown	Immediate increase in instream flow	High
Floodplain aquifer recharge	CTWSRO, SWCDs	Planned, some ongoing	Potentially high dispersal from recharge project site downstream for many miles	Long term, although opportunities for pilot projects is dependent upon willing landowner	Immediate	High, if the additional water is protected from being appropriated to a downstream user in areas with instream water rights
Lease or acquire water rights and convert to instream	OWRD, FSA, OWEB, Oregon Water Trust, others	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and highly dependent upon landowner willingness to lease.	Immediate	High, if the leased water is protected from being appropriated to a downstream user in areas with instream water rights. FSA pays higher rates for CREP enrollment when water rights are leased for instream use.
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion downstream to mouth of John Day River	Long term, dependent upon OWRD enforcing the requirement to measure water usage	Immediate	High if water user reporting requirement and installation of measuring devices on diversions is implemented
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program, riparian improvements	Private land on SF John Day above Izee Falls, private and state lands on Murderers and Indian creeks	No	Limited by resources.
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	SF John Day and tributaries where irrigation withdrawals occur		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust and BOR	Leasing and Purchase of Water Rights	None currently identified, dependent upon cooperating landowner	No	No program currently active.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Soil and Water Conservation Districts	Improve irrigation efficiency, upland improvements, riparian improvements	Private lands on SF John Day and tributaries above and below Izee Falls		Could increase in scope.
Watershed Councils	Upland improvements, riparian improvements	SF John Day above Izee Falls	No	Needs expansion.
NRCS	Upland improvements, riparian improvements	SF John Day above Izee Falls	No	Needs expansion.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Approximately 22 miles of stream in the South Fork are protected with either existing or pending instream water rights. The instream water rights do not preclude further appropriation of water until flows in the affected reach drop down to the instream water rights as adopted by OWRD. Voluntary efforts restored 0.6 cfs instream in 2006. See Strategy 6, Lower Mainstem John Day River population for further discussion.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Increase riparian shading	Upper South Fork and tributaries above Izee Falls (1); Lower South Fork near the town of Dayville (2); Deer (2); SF Murderers (1); Murderers (2) crs	High water temperatures	Degraded riparian forests	Abundance, productivity	Primarily fry and 0+	Elevated water temperature is a pervasive water quality problem for the South Fork John Day River population, with 6 stream reaches listed as water quality limited. Additional reaches would probably be listed if water temperature data were available.
Manage return flow to reduce extreme stream temperatures	Upper South Fork and tributaries above Izee Falls (1); Lower South Fork near the town of Dayville (2); Wind (2) and Murderers (1) crs	High water temperatures	Water withdrawals	Abundance, productivity	Primarily fry and 0+	
Reduce chemical pollution and nutrient inputs	Upper South Fork and tributaries above Izee Falls (1); Lower South Fork near the town of Dayville (2)	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity	Primarily fry and 0+	Using more efficient irrigation methods, which reduces the amount of surface water returning to the stream, should result in fewer nutrients from pastures reaching the South Fork John Day River and tributaries. Reducing nutrient loads will contribute to increased water quality by reducing biological oxygen demand and algae blooms.
Apply BMPs to animal feeding operations	South Fork John Day River above Izee Falls (1)	Degraded water quality	Animal feed operations	Abundance, productivity	Eggs, fry, juveniles	
Continue TMDL monitoring	Upper South Fork and tributaries above Izee Falls (1) Lower South Fork near the town of Dayville (2)	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	Primarily fry and 0+	

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Increase riparian shading	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years	High
Manage return flow to reduce extreme stream temperatures	SWCDs, watershed councils	Ongoing	Water quality improvement would have high dispersal downstream	Less than 5 years, once the project has been identified	Immediate	High, reduced temperatures has been well documented
Reduce chemical pollution and nutrient inputs	ODEQ, others	Ongoing		Ongoing	Reduce chemical pollution immediately	High
Apply BMPs to animal feeding operations	ODA	Ongoing	Water quality improvement would have high dispersal downstream	Some treatments could be done immediately. There are few animal feeding operations within the subbasin, only one of which has been identified as a problem	5-15 years	High, once a treatment has been agreed upon
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Subbasin-wide	Ongoing	Immediate	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA	CREP, CRP	Private lands on SF John Day above Izee Falls	No	Could be expanded with additional funding.
ODA	Confined animal feeding operations (CAFO), AgWQM	SF John Day above Izee Falls		See State of Oregon programmatic review -- Appendix F.
ODEQ, ODA, SWCD, USFS	Sedimentation Monitoring (TMDL Development and Implementation)	Throughout SF John Day watershed		See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Low streamflows during the hottest part of the year exacerbate the already warm water temperatures. Opportunities for increasing streamflow through leasing of water rights, which often results in cooler water over a longer stream reach, are being pursued by Oregon Water Trust and US Bureau of Reclamation. Constraints for future projects include acceptance by landowners and a secure, long term funding source.

The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritization restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Reducing water temperatures through the use of improved riparian vegetation and more efficient methods of irrigation may take several years to provide measurable results. Many projects that improve water quality by reducing irrigation return water have been completed.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	**Geographic Locations (1-first priority, 2-second priority)**	**Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Restore native upland plant communities	South Fork mainstem above Izee Falls (1); Deer Cr (1); Murderers Cr (1)	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices, loss of water storage capacity	Abundance, productivity	Primarily fry and 0+	Upland improvements such as restoring native plant communities and controlling invasive weed species will improve precipitation infiltration rates and ultimately improve watershed health, including the hydrograph.
Upgrade or remove problem forest roads	Forest lands	Same as above	Road network	Abundance, productivity	Primarily fry and 0+	
Initiate upland improvement demonstration projects	South Fork mainstem above Izee Falls (1); Deer Cr (2); Murderers Cr (1)	Same as above	Upland land use practices	Abundance, productivity	Primarily fry and 0+	
Manage vegetation, including juniper removal	South Fork mainstem above Izee Falls (1); Deer Cr (2); Murderers Cr (1)	Altered hydrology, sediment routing	Invasive plants	Abundance, productivity	Primarily fry and 0+	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Throughout population	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	Primarily fry and 0+	

Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Restore native upland plant communities	SWCD, USFS, BLM	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term	5-15 years	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Upgrade or remove problem forest roads	USFS, ODF, ODOT	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff. Decommissioning may take many years	5-15 years	Moderate, although funding on public lands and landowner cooperation on private lands will

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
						determine rate of treatment
Initiate upland improvement demonstration projects	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed
Mange vegetation, including juniper removal	USFS, BLM, NRCS, SWCDs, Watershed Councils	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Juniper control can be done quickly, other strategies such as control of invasive plants may take more than 20 years	5-30 years	Moderate
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	SWCD, VSFS, ODA, CTWSRO, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of Agricultural Water Quality Management Plans	0-20,years, depending upon treatments applied	Moderate, dependent upon voluntary landowner participation

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
NRCS/Farm Service Agency	CRP	Private lands on SF John Day and tributaries above Izee Falls	No	Could be expanded.
SWCDs	Juniper control	Private lands on SF John Day and tributaries above and below Izee Falls		Could be expanded.
ODFW	Green Forage	Private lands on SF John Day and tributaries above Izee Falls, PW Schneider WMA	No	Very small program.
USFS, BLM	Forest Plan, PACFISH	Federal lands	Likely	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review--Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review--Appendix F.
ODA	Agricultural Water Quality Management Program	Private lands on SF John Day and tributaries above and below Izee Falls		See State of Oregon programmatic review--Appendix F.
CTWSRO	Watershed Restoration	Private lands on SF John Day and tributaries above Izee Falls in cooperation with SWCD and Watershed Council	Uncertain	Currently limited in scope.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
See discussion for Strategy 8, Lower Mainstem John Day River population. NRCS, SWCD and ODFW programs are relatively small, with the CRP program the largest and best funded. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Implementation of PACFISH standards and guides for Forest and BLM programs has been highly successful for passive upland restoration over most of this population's area. The limitations to all the programs are funding and, to a lesser extent, acceptance by landowners.

9.3.9 Habitat Strategies and Actions for Upper Mainstem John Day River Steelhead Population

Primary limiting factors: degraded channel structure and complexity (habitat quantity and diversity), degraded riparian areas and LWD recruitment, altered sediment routing, water temperatures, altered hydrology and degraded floodplain function and connectivity. Impaired fish passage is also a priority limiting factor in Beech and Laycock creeks.

Primary threats: agricultural practices, overgrazing by livestock, removal of large trees from the riparian corridor, wetland draining and conversion, stream channelization and diking, mining, and dredging.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition or conservation easements	EF and Middle Fork of Canyon Cr (1), tributaries draining the north side of Strawberry Wilderness (2), upper McClellan Cr (tributary to John Day River) (2), McClellan Cr (tributary to EF Beech Cr) (2), upper Fields Cr (2), John Day River above Blue Mt. Hot Springs (1) and tributaries Rail (1), Roberts (1), Reynolds (1), Deardorff (1), and Call (1) crs.	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing,	Many threats including livestock overgrazing of riparian area, channelization, stream bank armoring, agricultural practices (fertilizers, herbicides, sediments, changes in plant communities), water withdrawals, loss of beaver dams	Productivity, abundance	Primarily fry and 0+	Protecting base streamflows from further appropriations is a very important function of protecting existing high quality habitats. Protection of high quality habitats is the most cost effective way of ensuring fish have good quality habitat. Land acquisitions, easements, and cooperative agreements may also facilitate the implementation of active restoration projects.
Adopt and manage Cooperative Agreements	Grub Cr (2), John Day River between John Day and Blue Mt. Hot Springs (1), Indian Cr (2), Beech Cr (2), Cummings Cr (2), Canyon Cr (1)	Same as above	Same as above	Productivity, abundance	Primarily fry and 0+	
Special management designations in forest and BLM plans	Riparian Habitat Conservation Areas identified in existing Forest Plans	Same as above	Livestock overgrazing of riparian area, changes in plant communities	Productivity, abundance	Primarily fry and 0+	
Designate additional wilderness and wild and scenic status	Public lands identified in the Forest Plan Revision process	Same as above	Livestock overgrazing of riparian area, changes in plant communities	Productivity, abundance	Primarily fry and 0+	
Protect access to key habitats	Mainstem John Day River above Prairie City (1)	Passage barriers, altered hydrology, channel structure	Irrigation withdrawals, channelization	Productivity, abundance, distribution	Primarily fry and 0+	Thoroughly review projects that may block fish passage. Current ODFW policy is to grant exemptions from fish

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
						passage requirements only if mitigation meets or exceeds the loss of habitat. Exemptions must be approved by the Fish and Wildlife Commission.
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	Population-wide	All	Same as above	Productivity, abundance	All	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements	CTUIR, TNC, RMEF, John Day Basin Trust, SWCDs, USFS, CTWSRO, ODFW	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5-15 years with passive restoration approaches	High, based on previous cooperative agreements
Adopt and manage Cooperative Agreements	ODFW, SWCDs, FSA	Ongoing	Same as above	Agreements are for 10 to 15 years	Immediate	High, although not in perpetuity
Special management designations in forest and BLM plans	USFS, BLM	Ongoing as identified	Same as above	Many complete, potentially subject to change in Forest Plan revisions	Immediate	High, although subject to change from Forest Plan or mgmt plan revision
Designate additional wilderness and wild and scenic status	Public lands identified in Forest Plan Revision	Same as above	livestock overgrazing of riparian area, changes in plant communities	Long term	Long term	High
Protect access to key habitats	ODFW, SWCD, Oregon Water Resources	Ongoing	Population-wide	Long term	Long term	Moderate
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	NRCS, SWCDs, USFS, ODFW, ODF, DSL, BLM, ODOT, CTWSRO, ODA, FSA, private landowners	Ongoing	Population-wide	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS, BLM	Wilderness Areas, Wilderness Study Areas, Wild and Scenic River corridors, Special Management designations, PACFISH	Strawberry Mt. Wilderness, scattered BLM parcels and Malheur National Forest	Yes, PACFISH standards are good, but implementation is inconsistent between forests. See discussion below.	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODFW	Cooperative Agreements	Private lands on John Day River above John Day, Grub, Indian, Beech, and Canyon crs	No	The agreements are for only 10-15 years and need to be longer.
FSA	CREP	Private lands on John Day River above Dayville, Indian and Beech crs	No	The agreements are for only 10-15 years and need to be longer.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
NGOs	Lease or purchase of lands or instream water rights	Private lands on John Day River and tributaries above Dayville. Current conservation agreements exist on Dry and Widows creeks	Yes	Important to secure critical habitat and/or water rights as opportunities arise.
ODA	Agricultural Water Quality Management Program	Private lands on John Day River and tributaries above Dayville		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Forrest Ranch and private lands in cooperation with SWCD	Likely	Expand as opportunities arise.
ODF	Oregon Forest Practices Act	State and private timberlands		See State of Oregon programmatic review -- Appendix F.
Local Government	City and County Planning and Zoning	Private lands	Uncertain	
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Federally designated Wild and Scenic River reaches include the mainstem John Day from Tumwater Falls (RM 10) to Service Cr (RM 157). State designated reaches include the mainstem John Day from Tumwater Falls to Parrish Cr (RM 170). Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management program remains challenging in some locations. The CTWSRO owns a mitigation property (3,365 acres) on the Mainstem John Day River above Prairie City that is managed for the benefit of fish and wildlife. See Strategy 1, Lower Mainstem John Day River population for further discussion.				

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Remove or minimize use of push up dams	Warrens (2), Bridge (2), Birch (2), Belshaw (2), Fields (1), Moon (2), McClellan (2), Beech (1), Canyon (1), Strawberry (1), Dixie (1), Isham (2), Dads (2), and Reynolds (1) crs.	Impaired fish passage	Push up dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Push up dams are most common in the Upper John Day and tributaries. Annual maintenance and construction of push up dams contributes to onsite and downstream channel stability, loss of pools and other structure, and increased sediment loads.
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	Irrigation or water storage related issues: Warrens (2), Bridge (2), Birch (2), Belshaw (2), Fields (1), Moon (2), McClellan (2), Beech (1), Canyon (1), Strawberry (1), Dixie (1), Isham (2), Dads (2), and Reynolds (1) crs Culverts: Canyon Cr and tributaries (1), Reynolds Cr (1), John Day River above Blue Mt Hot Springs (2), and Fields Cr (2) A total of 120 culverts have been identified in this population as needing replacement (see Appendix G)	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure	Primarily adults and 0+ juveniles	Push up irrigation dams, concrete diversions, in-channel stock ponds, and road culverts are located throughout the entire subbasin. Passage problems at culverts are widespread throughout all subbasins

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Construct ladders over existing permanent concrete or earth fill dams	Beech Cr (1)	Impaired fish passage	Dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Concrete structures are located primarily in the Rock Cr. (Lower John Day) drainage although there are a number of structures scattered throughout other parts of the subbasin, including Beech Cr. and Reynolds Cr.
Provide screening at 100% of irrigation diversions	Dans (2), Jeff Davis (2), Strawberry (2), Pine (1), Ingles (2), Moon (1), Canyon (1), Cummings (1), Widows (2), Laycock (1) crs	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry, smolts	
Replace screens that do not meet criteria	Beech (1), Canyon (1), Dixie (2), Fields (1), Indian (1), Upper John Day River (1), Roberts (1) crs	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry	Most migration diversions are in the Upper John Day drainage and it has been the major emphasis for replacement of non-criteria screens.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove or minimize use of push up dams	SWCD	Ongoing	Provide access to upstream habitat	Ongoing, but all push up dams not expected to be corrected for at least 15 years. A comprehensive survey has not been completed	Immediate	High, if comply with fish passage design criteria
Remove or replace barriers blocking passage -- dams, road culverts and irrigation structures	USFS, BLM, watershed councils, SWCDs, ODOT	Ongoing	Access to upstream habitat	Ongoing, replacing all culverts blocking fish passage expected to take 20 years (see Appendix G)	Immediate	High, if comply with fish passage design criteria
Construct ladders over existing permanent concrete or earth fill dams	ODFW, SWCDs	Ongoing	Provide access to upstream habitat	Ongoing, providing passage at all diversion and pond barriers will take many years	Immediate	High if comply with fish passage design criteria
Provide screening at 100% of irrigation diversions	ODFW, SWCDs	Ongoing	At point of diversion	Approximately 39 diversions need to be screened	Immediate	High if comply with fish passage design criteria
Replace screens that do not meet criteria	ODFW	Ongoing	At point of diversion	Approximately 47 screens need to be replaced, should take many years	Immediate	High if comply with fish passage design criteria

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Soil and Water Conservation Districts	Irrigation dam improvements, culvert replacement or retrofits	Private lands on John Day R and steelhead bearing tributaries above Dayville		The Grant Soil and Water District is constrained by the construction window of opportunity.
ODFW	Fish Passage/Screening	Private lands on John Day R and steelhead bearing tributaries above Dayville	No	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding
USFS, BLM	Culvert replacement	Federal lands on Canyon Creek, Little Pine have been recently emphasized, others may be identified	Uncertain	See USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below. The BLM has no adult barriers at culverts. Monitoring is needed to determine if upstream passage for juveniles is an issue.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.				
Watershed Councils	Road Crossing Passage improvements, passage improvements	Private lands on John Day R and steelhead bearing tributaries above Dayville	No	Yes
ODOT	Culvert replacement or retrofit	Pine and Beech creeks, others may be identified		See State of Oregon programmatic review -- Appendix F.
BOR	John Day Basin Program	As identified by SWCD, ODFW, and others	Yes	No
CTWSRO	John Day Basin Program	Private lands on John Day R and steelhead bearing tributaries above Dayville in cooperation with SWCD	No	Yes, the tribe contracts with Soil and Water Districts to assist with consultation, permits, and monitoring

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Most of the mainstem passage problems have been addressed, but there are many tributaries where adult passage is blocked and more areas where juvenile passage problems occur. Irrigation dams, stock ponds, and road culverts are the primary causes of passage issues. In the Upper John Day subbasin, the Grant SWCD has implemented many passage improvement projects and currently has a waiting list of landowners who want them to correct passage problems at irrigation diversions on tributaries as well as the few remaining mainstem problem areas. The Grant SWCD is currently constrained by a relatively short in-water work period (4-6 weeks), so it will likely take another 10 years to address most of the tributary passage problems. Other Soil and Water Districts are also correcting passage at irrigation diversions and improperly installed culverts, but are constrained by funding and by personnel needed for construction oversight. An inventory of road crossings on state and county roads in 1999 indicated 14 culverts on state owned roads and 43 culverts on county owned roads within the Upper Mainstem John Day population boundaries did not meet fish passage criteria. Appendix G presents an inventory of culverts with known passage problems on state or county owned roads. Some of those culverts have been replaced with structures that do meet the fish passage criteria, but much work remains. Watershed councils and ODOT, who are the principal entities working on culverts are constrained primarily by funding. An inventory of road crossings on federal lands indicates juvenile passage problems are pervasive, particularly on National Forests, with approximately 54 culverts not meeting passage criteria in this population. The US Forest Service and BLM are constrained primarily by funding and the personnel needed for NEPA analysis. At the current rate of culvert replacements it will take over 50 years to correct all passage problems on National Forests, however, the Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) provides guidance that will help prioritize culvert replacements for this population. The BLM has no adult barriers at culverts. Monitoring is needed to determine if upstream passage for juveniles is an issue.Another constraint is that existing state laws do not require passage improvements at existing barriers unless there is a major change in the structure, such as reconstruction or significant modifications, so landowner cooperation is critical for improving passage throughout the subbasin.

See Strategy 2, Lower Mainstem John Day River population for further discussion.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Mainstem John Day River from Dayville to Blue Mt. Hot Springs (1)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily fry and 0+	Restoring channel migration processes will require a landowner willing to sacrifice irrigated pastureland. Opportunit ies may be limited to property owned by CTWSRO, above Prairie City.
Reconnect side channels and off-channel habitats to stream channels	Mainstem John Day River from Dayville to Blue Mt. Hot Springs (1), Canyon (1), Indian (2), and Pine (2) crs	Degraded floodplain, altered hydrology	Removal of side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity, spatial structure	Primarily fry and 0+	There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows.
Restore wet meadows	Canyon (2), EF Beech (2), Upper Belshaw (1)	Degraded floodplain, altered hydrology	Removal of wetlands	Abundance, productivity	Primarily fry and 0+	

Strategy 3. Maintain and restore floodplain connectivity and function.						
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	Canyon (1), Fields (1), Belshaw (2), Dixie (2), Strawberry (2)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity, spatial structure	Primarily fry and 0+	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain to channel	ODFW, watershed council, SWCD, USFS, BLM	Ongoing	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Reconnect side channels and off-channel habitats to stream channels	ODFW, watershed council, SWCD, USFS, BLM, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, because of widespread need	5-15 years, depending upon frequency and duration of channel altering flows	Moderate, depends upon how extensive the project is and frequency and duration of channel altering flows
Restore wet meadows	TNC, USFS, CTWSRO	Ongoing and planned	Benefits of improved channel morphology localized, improved water table and resulting increased streamflow and lower water temperatures have high dispersal downstream	Long term	5-15 years	Moderate
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	ODFW, CTWSRO, USFS, BLM	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, due to acceptance by landowners and widespread need	Within 5 years once the dams are built	Moderate-high, dependent upon acceptance by landowners

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Private lands on John Day River and tributaries above Dayville	No	Active measures used only if specific needs cannot be addressed by passive restoration techniques, program limited by funding.
USFS, BLM	Stream enhancement program	Federal lands on John Day River and tributaries above Dayville. Only when specifically identified that passive restoration is not working.	Yes in some areas, no in others due to limited funding	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. May need expansion. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	Private lands on John Day River and tributaries above Dayville	Dependent upon need and funding	Active measures used only if specific needs cannot be addressed by passive restoration techniques, limited by funding.
Soil and Water Conservation Districts	Watershed restoration	Private lands on John Day River and tributaries above Dayville		See State of Oregon programmatic review -- Appendix F.

Strategy 3. Maintain and restore floodplain connectivity and function.				
Nature Conservancy and other NGOs	Restoration projects	None currently identified, but conservation easement exist on Dry and Widows creeks	Yes	No actions currently underway, should seek new opportunities.
CTWSRO	Watershed restoration	Forrest Ranch and private lands in cooperation with SWCD	Uncertain	Dependent on funding availability.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Bank stabilization using some rock is still infrequently occurring after high water events in the Upper John Day River, primarily along irrigated pastures. These bank stabilization projects have historically relied on riprap and large rock, however in recent years the high economic and ecological cost of bank armoring with riprap and of channelization has been recognized, so the emphasis has shifted toward a more passive approach for stabilization, primarily through riparian vegetation improvements. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Mainstem John Day River from Dayville to Blue Mt. Hot Springs (1), Indian (1), Pine (1), lower Beech (1), lower McClellan (2), lower Moon (2), lower Laycock (2), middle Canyon (1), lower Fields (2), lower Strawberry (1), lower Dixie (2), lower Isham (2), lower Dans (2) crs	Degraded channel structure and complexity, habitat diversity, riparian area degradation, connectivity with floodplain, sediment routing, water temperature, flows	Stream channelization, bank armoring, large wood removal, beaver removal, removal of riparian vegetation, livestock overgrazing in riparian areas	Abundance, productivity	Primarily fry and 0+	Restoring channel migration processes will require a landowner willing to sacrifice irrigated pastureland. Opportunit ies may be limited to property owned by CTWSRO, above Prairie City.
Place stable wood and other large organic debris in streambeds	Mainstem John Day River from Dayville to Blue Mt. Hot Springs (2), Indian (1), Pine (1), lower Beech (1), lower McClellan (2), lower Moon (2), lower Laycock (2), middle Canyon (1), lower Fields (2), lower Strawberry (1), lower Dixie (2), lower Isham (2), lower Dans (2), crs	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal channelization	Abundance, productivity	Primarily fry and 0+	More active restoration techniques, such as rootwad placement or channel reconfiguration, may be appropriate in these reaches. Typical structures include rootwads, boulder clusters, whole trees, and rock weirs where appropriate.
Stabilize streambanks	Mainstem John Day River from Dayville to Blue Mt. Hot Springs (1), lower Beech (2), lower Indian (2),	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily eggs, fry and 0+	Some bank erosion is inevitable and beneficial. However, where erosion is actively taking place due to unnatural processes, stabilization may be needed to reduce fine sediments.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, USFS, BLM, watershed councils	Ongoing and planned	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Place stable wood and other large organic debris in streambeds	ODFW, USFS, watershed councils, BLM, SWCDs	As needed	For the immediate stream reach	Once identified, short term	Immediate	High
Stabilize streambanks	ODFW, USFS, watershed councils, BLM, SWCDs	Ongoing	For the treated stream reach, physical benefits dispersed downstream	Passive stabilization techniques are preferred and take longer to implement	With passive restoration the response may take 15 years	Medium to high, depending upon the extent of the treatments

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Private lands on John Day River and tributaries, once identified as deficient	No	Active measures used only if specific needs cannot be addressed by passive restoration techniques, program limited by funding.
USFS, BLM	Stream enhancement program	Federal lands on John Day River and tributaries, once identified as deficient. Only when specifically identified that passive restoration is not working.	Yes in some areas, no in others	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. PACFISH BMPs are generally sufficient for passive restoration but active restoration funds are limited. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	Population-wide	Uncertain	Limited resources.
Soil and Water Conservation Districts	Watershed restoration	Private lands on John Day River and tributaries, once identified as deficient		Active management, only if specific needs cannot be addressed by passive restoration techniques.
CTWSRO	Watershed restoration	Private lands on John Day River and tributaries, once identified as deficient in cooperation with SWCD	Uncertain	
NGOs	Watershed restoration	None currently identified	Uncertain	No actions currently planned.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Instream activities have not been identified as a high priority by the recovery planning team or the subbasin plan team except when identified as a need for specific sites. The planning team prefers that more passive approaches, such as riparian and upland improvements be emphasized. Typically, instream activities that would improve floodplain function and channel migration processes would include placement of rootwads, whole trees, or boulder clusters to improved habitat complexity and habitat diversity where those parameters are deficient and not expected to improve with passive restoration. Another structural activity would be to construct boulder or log weirs to raise the water table, but only where a passive approach has not worked.

The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	Some reaches of the upper mainstem John Day River (1) and Ingle (2), Harper (2), Beech (1), Bear (1), Birch (2), Dans (2), and Reynolds (2) crs; the lower reaches of Fields (1), Belshaw (1), Cummings (2), Moon (2), Riley (1), Strawberry (2), Pine (2), and Laycock (2) crs	Degraded riparian area, channel structure and complexity, floodplain degradation, altered hydrology, sediment, water quality	Overgrazing of riparian area, channelization, stream bank armoring, tree harvest in riparian areas, changes in plant communities (including invasive plants), loss of beaver dams	Abundance, productivity	Primarily fry and 0+	Primary methods of riparian enhancement include riparian corridor fences to exclude livestock, changes in grazing management that promote riparian recovery, and planting of native shrubs.
Develop grazing strategies that promote riparian recovery	Some reaches of the upper mainstem John Day River (1) and Ingle (2), Harper (2), Beech (1), Bear (1), Birch (2), Dans (2), and Reynolds (2) crs; the lower reaches of Fields (1), Belshaw (1), Cummings (2), Moon (2), Riley (1), Strawberry (2), Pine (2), and Laycock (2) crs	Same as above	Livestock overgrazing of riparian area	Abundance, productivity	Primarily fry and 0+	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, (see above)	High, based on experience with existing grazing management and riparian recovery projects
Develop grazing strategies that promote riparian recovery	NRCS, AFS, USFS, BLM, SWCDs, ODFW, Watershed Councils, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, depending upon grazing plan adopted. Riparian corridor fencing and removal of riparian grazing has the fastest recovery rate.	High, based on experience with existing grazing management and riparian recovery projects

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Private lands on John Day River and tributaries above Dayville	No	Limited by funds.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.				
SWCDs	Upland improvements, riparian improvements	Private lands on John Day River and tributaries above Dayville		
USFS and BLM	Upland improvements, riparian improvements	Federal lands on John Day River and tributaries above Dayville	Uncertain	PACFISH BMPs are generally sufficient for passive restoration, but active restoration funds are limited. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
NRCS	Upland improvements, riparian improvements	Private lands on John Day River and tributaries above Dayville	Yes	Program sufficient.
ODA	Agricultural Water Quality Management Programs	Private lands on John Day River and tributaries above Dayville		See State of Oregon programmatic review -- Appendix F.
CTUIR	Watershed restoration	Forrest Ranch property and private lands on John Day River and tributaries above Dayville in cooperation with SWCD	Uncertain	Program approach sufficient. Scope could be increased.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Overgrazing of riparian areas by livestock continues, however it is not as widespread as historically. Interest by private landowners and public land managers in riparian improvement remains high. See Strategy 5, Lower Mainstem John Day River population for further discussion. Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management program remains challenging in some locations. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	Fields (1), Indian (1), McClellan (2), Pine (1), Beech (1), Bear (2), Strawberry (1), Isham (2), Dean (2), Moon (2), Laycock (1), Dog (2), Ingle (2), and Riley (2)crs; John Day River, Dayville to Mt. Vernon (1)	Altered hydrology, low flows, high temperatures	water withdrawals, land conversion on uplands, road network	Abundance, productivity	Primarily, fry and 0+	Fields, Indian, McClellan, Pine, Beech, Bear, Strawberry, Isham, Dean, Moon, Laycock, Dog, Ingle, and Riley crs (all Upper John Day) have significantly less than naturally available flow or are either dry or intermittent in their lower reaches due to irrigation withdrawals. During low water years, the mainstem John Day River from Dayville to Mt. Vernon is intermittent.
Improve irrigation conveyance and efficiency	Fields (1), Indian (1), McClellan (2), Pine (1), Beech (1), Bear (2), Strawberry (1), Isham (2), Dean (2), Moon (2), Laycock (1), Dog (2), Ingle (2), and Riley (2)crs; John Day River, Dayville to Mt. Vernon (1)	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Primarily, fry and 0+	

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Increase pool habitat (beaver ponds)	Fields (2), Indian (1), McClellan (2), Pine (1), Beech (1), Bear (1), Strawberry (2), Isham (2), Dean (2), Moon (2), Laycock (1), Dog (2), Ingle (2), and Riley (1)crs				Primarily, fry and 0+	
Floodplain aquifer recharge		Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily, fry and 0+	
Lease or acquire water rights and convert to instream	Fields (1), Indian (1), McClellan (2), Pine (1), Beech (1), Bear (2), Strawberry (1), Isham (2), Dean (2), Moon (2), Laycock (2), Dog (2), Ingle (2), and Riley (2)crs; John Day River, Dayville to Mt. Vernon (1)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily, fry and 0+	The Upper John Day River does not meet requested in stream water right flows for all of August and the first half of September during irrigation season. Some tributaries are dry where they join the John Day River.
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily, fry and 0+	
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD, watershed councils, NRCS	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights
Improve irrigation conveyance and efficiency	SWCD, OWEB, watershed councils, NRCS, landowners	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights
Increase pool habitat (beaver ponds)	SWCD, ODFW, CTWSRO, USFS	Ongoing	High dispersal downstream	Unknown	Immediate increase in instream flow	High
Floodplain aquifer recharge	CTWSRO, SWCDs	Planned, some ongoing	Potentially high dispersal from recharge project site downstream for many miles	Long term, although opportunities for pilot projects is dependent upon willing landowner	Immediate	High, if the additional water is protected from being appropriated to a downstream user in areas with instream water rights
Lease or acquire water rights and convert to instream	OWRD, FSA, OWEB, Oregon Water Trust, others	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and highly dependent upon landowner willingness to lease.	Immediate	High, if the leased water is protected from being appropriated to a downstream user in areas with instream

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
						water rights. FSA pays higher rates for CREP enrollment when water rights are leased for instream use.
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion downstream to mouth of John Day River	Long term, dependent upon OWRD enforcing the requirement to measure water usage	Immediate	High if water user reporting requirement and installation of measuring devices on diversions is implemented
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program, riparian improvements	Private lands on John Day River and tributaries above Dayville	No	Limited in scope.
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Private lands on John Day River and tributaries above Dayville where irrigation withdrawals occur	Uncertain	See State of Oregon programmatic review–-Appendix F.
Oregon Water Trust and BOR	Leasing and Purchase of Water Rights	John Day River and above John Day and tributaries above Dayville. Leases currently exist on Dixie Creek and John Day River above Mt Vernon.	No	Sufficient where applied, program could expand with additional funding.
Soil and Water Conservation Districts	Improve irrigation efficiency, upland improvements, riparian improvements	Private lands on John Day River and tributaries above Dayville		See State of Oregon programmatic review – Appendix F.
NRCS	Upland improvements, riparian improvements	Private lands on John Day River and tributaries above Dayville	No	Limited in scope.
CTWSRO	Watershed restoration program	Forrest Ranch property and private lands on John Day River and tributaries above Dayville in cooperation with SWCD	Uncertain	Approach sufficient, scope is limited.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
Many landowners have converted from flood to sprinkler or gated pipe irrigation that makes more efficient use of the water and grows more palatable forage, but there has not been an effective mechanism to protect saved water from being used by another irrigator downstream. Water measuring devices are just beginning to be required on irrigation withdrawals and while progress is being made there is considerable resistance from irrigators, particularly in the Upper John Day. Flows are also improving because of projects that restore historical cover types by removing juniper, reintroducing fire, enrollment into CRP, and control of invasive/noxious plants. Primary constraints on implementing additional projects are funding, instream water rights that are junior to most irrigation rights, and water laws that sometimes conflict with conservation practices.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.
Approximately 120 miles of stream in the Upper Mainstem are protected with either existing or pending instream water rights. The instream water rights do not preclude further appropriation of water until flows in the affected reach drop down to the instream water rights as adopted by OWRD. US Bureau of Reclamation, as required in the Columbia River Biological Opinion, is required to identify and assist with passage improvement design and flow restoration. They have partnered with Oregon Water Trust on several water leases, most notably in Standard Creek, tributary to Dixie Creek.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Increase riparian shading	Mainstem John Day River (1), Beech (1), EF Beech (2), Canyon (1), Grub (2), Indian (1), Pine (1), Laycock (2), Belshaw (1), Fields (1), Strawberry (2), lower Dans (2), Riley (1), Ingle (1), Harper (1), and Bear (2) crs	High water temperatures	Degraded riparian forests	Abundance, productivity	Primarily fry, juveniles	Elevated water temperature is the most pervasive water quality problem for the Upper John Day River population, with 27 stream reaches listed as water quality limited. Additional reaches would probably be listed if water temperature data were available.
Manage return flow to reduce extreme stream temperatures	Mainstem John Day River, from South Fork to Blue Mt Hot Springs (1).	High water temperatures	Water withdrawals	Abundance, productivity	Primarily fry, juveniles	Many projects that improve water quality by reducing irrigation return water have been completed, particularly between the town of John Day and the National Forest Boundary above Blue Mt. Hot Springs.
Reduce chemical pollution and nutrient inputs	Mainstem John Day River from the South Fork to Blue Mt Hot Springs (1).	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity	Primarily fry, juveniles	Using more efficient irrigation methods, which reduces the amount of surface water returning to the stream, should result in fewer nutrients from pastures reaching the John Day River. Reducing nutrient loads will contribute to increased water quality by reducing biological oxygen demand and algae blooms.
Apply BMPs to animal feeding operations	John Day River between the South Fork and Blue Mt. Hot Springs (1)	Degraded water quality	Animal feed operations	Abundance, productivity	Primarily fry, juveniles	There are very few feedlots, but significant use of riverside meadows for winter feeding operations.
Continue TMDL monitoring	Temperature: Mainstem John Day River (1), Beech (1), EF Beech (2), Canyon (2), Grub (2), Indian (1), Laycock (1), Belshaw (2), Fields (2), and Bear (2) crs Sediment: Indian Cr (from burned area) (1)	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	Primarily fry, juveniles	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Increase riparian shading	ODFW, Watershed Councils,	Ongoing	Water quality benefits will have	Long term because of widespread	5-15 years	High

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
	SWCDs, USFS, BLM, CTUIR		high dispersal downstream from site	need		
Manage return flow to reduce extreme stream temperatures	SWCDs, watershed councils	Ongoing	Water quality improvement would have high dispersal downstream	Less than 5 years, once the project has been identified	Immediate	High, reduced temperatures has been well documented
Reduce chemical pollution and nutrient inputs	ODEQ, others	Ongoing		Ongoing	Reduce chemical pollution immediately	High
Apply BMPs to animal feeding operations	ODA	Ongoing	Water quality improvement would have high dispersal downstream	Some treatments could be done immediately. There are few animal feeding operations within the subbasin, only one of which has been identified as a problem	5-15 years	High, once a treatment has been agreed upon
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Basinwide	Ongoing	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA	CREP, CRP	Resource need is widespread, but acceptance is lacking	No	Limited by acceptance of landowners.
ODEQ	Mine Waste Program	None currently identified, although extensive gold mining has occurred on John Day River near the town of John Day, on Canyon Creek and Dixie Creek		See State of Oregon programmatic review -- Appendix F.
ODA	Confined animal feeding operations (CAFO), Agricultural Water Quality Management Program	None currently identified		See State of Oregon programmatic review -- Appendix F.
ODEQ, ODA, SWCD, USFS	Sedimentation Monitoring (TMDL Development and Implementation)	John Day River and tributaries above Dayville		See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Reducing water temperatures through the use of improved riparian vegetation and more efficient methods of irrigation may take several years to provide measurable results. Many projects that improve water quality by reducing irrigation return water have been completed. Opportunities for additional irrigation return water cooling projects exist above and below the town of John Day. Low streamflows during the hottest part of the year exacerbate the already warm water temperatures. Opportunities for increasing streamflow through leasing of water rights, which often results in cooler water over a longer stream reach, are being pursued by Oregon Water Trust and US Bureau of Reclamation. Constraints for future projects include acceptance by landowners and a secure, long term funding source.

The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	**Geographic Locations (1-first priority, 2-second priority)**	**Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Restore native upland plant communities	Bear (2), Grub (1), Beech (1), Belshaw (1), Cummings (1), Pine (2), Indian (2), Strawberry (2), and Laycock (2) crs	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices, loss of water storage capacity	Abundance, productivity	Primarily fry, juveniles	Upland improvements such as restoring native plant communities and controlling invasive weed species will improve precipitation infiltration rates and ultimately improve watershed health, including the hydrograph.
Upgrade or remove problem forest roads	Forest lands	Same as above	Road network	Abundance, productivity	Primarily fry, juveniles	
Initiate upland improvement demonstration projects	Bear (2), Grub (1), Beech (1), Belshaw (1), Cummings (1), Pine (2), Indian (2), Strawberry (2), and Laycock (2)crs	Same as above	Upland land use practices	Abundance, productivity	Primarily fry, juveniles	
Manage vegetation, including juniper removal	Bear (2), Grub (1), Beech (1), Belshaw (1), Cummings (1), Pine (2), Indian (2), Strawberry (2), and Laycock (2) crs	Altered hydrology, sediment routing	Invasive plants	Abundance, productivity	Primarily fry, juveniles	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Population-wide	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	Primarily fry, juveniles	

Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Restore native upland plant communities	SWCD, USFS, BLM	ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term		
Upgrade or remove problem forest roads	USFS, BLM, ODF, ODOT	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff. Decommissioning may take many years	5-15 years	Moderate, although funding on public lands and landowner cooperation on

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
						private lands will determine rate of treatment
Initiate upland improvement demonstration projects	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed
Manage vegetation, including juniper removal	USFS, BLM, NRCS, SWCDs, Watershed Councils	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Juniper control can be done quickly, other strategies such as control of invasive plants may take more than 20 years	5-30 years	Moderate
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	SWCD, USFS, ODA, CTWSRO, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of Agricultural Water Quality Management Plans	0-20,years, depending upon treatments applied	Moderate, dependent upon voluntary landowner participation

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
NRCS/Farm Service Agency	CRP	Private lands on John Day River and tributaries above Dayville	No	Limited in scope.
SWCDs	Juniper control	Private lands on John Day River and tributaries above Dayville		Needs expansion.
ODFW	Green Forage	Private lands on John Day River and tributaries above Dayville	No	Very small program.
USFS/BLM	Forest Plan, PACFISH, Resource Management Plan	Federal lands on John Day River above Forest boundary, and tributaries on Malheur National Forest	Yes, but highly dependent upon funding and monitoring	Particularly monitoring needs expansion. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
ODA	Agricultural Water Quality Management Program	Private lands on John Day River and tributaries above Dayville		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Forrest Ranch property and private lands on John Day River and tributaries above Dayville in cooperation with SWCD	Uncertain	Continued funding is uncertain.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
See discussion for Strategy 8, Lower Mainstem John Day River population. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Implementation of PACFISH standards and guides for Forest and BLM programs has been highly successful for passive upland restoration over most of this population's area. The limitations to all the programs are funding and, to a lesser extent, acceptance by landowners.

9.3.10 Habitat Strategies and Actions for Umatilla River Steelhead Population

Primary limiting factors: high water temperature, sediment routing, impaired fish passage, degraded channel structure and complexity and altered hydrology (low flow).

Primary threats: current land use practices that reduce habitat quality, quantity and disrupt ecosystem functions.

Table 9-2, behind the habitat strategy and action tables for the Umatilla, provides a cross reference of Geographic Areas and MaSAs/MiSAs. Table 8-35 identifies stream barriers to upstream steelhead passage in the Umatilla watershed.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition, conservation easements and cooperative agreements	North Fork Umatilla R (1); Umatilla R., Meacham Cr. to forks (1); Buck Creek (1); NF Meacham Cr. (1); E. Meacham Cr (1); Thomas Cr.(1); W. Birch Cr., Bear Cr. to headwaters (1); E. Birch Cr., California Gulch to headwaters (1); SF Umatilla R., mouth to Thomas Cr.(1); Umatilla R., Butter Cr. to Westland Dam and Stanfield Dam to McKay Cr.(2); Umatilla R., Three Mile Dam to Butter Cr. (2)	Loss of habitat quantity and diversity, channel stability, sediment, low flow and high temperatures	Cultivation, forestry, grazing, urban development	Abundance, productivity	All	Agreements (conservation easements, cooperative agreements, etc.) could be made with private landowners in areas where priority habitats exist to maintain the current habitat values. Agreements in areas with priority habitats may include: Putting in no-cultivation riparian buffers on agricultural lands that are currently cultivated up to the channel's edge, increasing riparian buffer widths associated with forested areas, protecting unstable areas, or changing other types of management in riparian areas.
Continue existing protections and/or increase protection of Federal lands; implement Forest Practices Act and PACFISH	North Fork Umatilla R (1); Umatilla R., Meacham Cr. to forks (1); Buck Creek (1); NF Meacham Creek (1); East Meacham Cr (1); Thomas Cr. (1); West Birch Cr., Bear Cr. to headwaters (1); E. Birch Cr., California Gulch to headwaters (1); SF Umatilla R., mouth to Thomas Cr. (1)	Same as above	Forestry, cultivation, grazing, urban development	Abundance, productivity	All	Current protections on USFS lands such as Riparian Habitat Conservation Areas should be continued and maintained. Protection on Federal lands may be increased through the NEPA process or ESA consultation. Aquatic habitat issues are addressed through both processes. Actions may include expanding riparian buffers, changing management within or near riparian areas, and identifying sensitive areas to avoid. All the options listed for added protection are directed through PACFISH program/management direction but would be considered "New" actions to be applied if/when the need is identified. Forest Plan management

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
						direction (landscape-scale) for roadless areas, wildlife management emphasis and Wilderness are unlikely to change significantly in the near future.
Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function	Umatilla R., Meacham Cr. to forks ; Thomas Creek (1); West Birch Cr., Bear Cr. to headwaters (1); Bear Creek (West Birch) and tribs (1); E. Birch Cr., mouth to headwaters (1); SF Umatilla R., mouth to Thomas Cr. (1); Umatilla R., Butter Cr. to Westland Dam and Stanfield Dam to McKay Cr (2); Umatilla R., Three Mile Dam to Butter Cr. (2); Birch Cr., mouth to forks (2); Umatilla R., Mission Br. To Meacham Cr. (1); Meacham Cr., mouth to North Fork (1); West Birch Cr., mouth to Bear Cr. (1); Buckaroo Cr (1); Meacham Cr., Sheep Cr. to headwaters (1)	Same as above	Same as above	Abundance, productivity	All	Setbacks could include: no-cultivation riparian buffers on agricultural lands that are currently cultivated up to the channel's edge, increasing riparian buffer widths associated with forested areas, protecting unstable areas, or changing other types of management in riparian areas.
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	Subbasin-wide	Same as above	Same as above	Abundance, productivity	All	To prevent degradation of existing habitat, Best management Practices and existing laws that protect aquatic habitat should be applied across the subbasin with emphasis on areas of very high quality.
Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues	Subbasin-wide	Same as above	Urban development	Abundance, productivity	All	Enforce existing land use laws that affect aquatic habitat and update laws that do not provide adequate protection.
Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance	Umatilla R., Meacham Cr. to forks (1); W. Birch Cr., Bear Cr. to headwaters (1); Bear Creek (West Birch) and tribs (1); E. Birch Cr., mouth to headwaters (1); Umatilla R., Butter Cr. to Westland Dam and Stanfield Dam to McKay Cr. (1); Umatilla R., Three Mile Dam to Butter Cr. (1); Birch Cr., mouth to forks (1); Umatilla R., Mission Br. To Meacham Cr. (1); Meacham Cr., mouth to North Fork (1); West Birch Cr., mouth to Bear Cr. (1); Iskuulpa Cr., Bachelor Cyn to headwaters(1); Buckaroo C (1); Meacham Cr., Sheep Cr. to headwaters(1)	Same as above	Urban development	Abundance, productivity	Abundance, productivity	Incorporating MCR steelhead priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance would allow the priority habitat areas to be protected while providing an expedient process for reviewing land uses.
Explore opportunities to incorporate priority areas into state legislation	NF Umatilla R (1); Umatilla R., Meacham Cr. to forks (1); Buck Creek (1); NF Meacham Cr (1); East Meacham Cr (1); Thomas Cr (1); West Birch Cr., Bear Cr.	Same as above	Rural and urban development	Abundance, productivity	All	Look for opportunities to make amendments that would incorporate increased protection for priority habitat areas.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
	to headwaters (1); E. Birch Cr., California Gulch to headwaters (1); SF Umatilla R., mouth to Thomas Cr. (1); Umatilla R., Butter Cr. to Westland Dam and Stanfield Dam to McKay Cr. (1); Umatilla R., Three Mile Dam to Butter Cr. (1)					
Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect high quality habitats through acquisition, conservation easements and cooperative agreements	CTUIR, ODFW, UBWC, TNC, RMEF, SWCDs	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5 years to decades with passive restoration approaches	High, based on previous cooperative agreements
Continue existing protections and/or increase protection of Federal lands; implement Forest Practices Act and PACFISH	USFS, ODF	Ongoing	Benefits accruing since 1995 for all streams in Umatilla subbasin on USFS lands, including priority GAs. Forest Practices Act applies to all commercial timber operations on private lands	Long term	Maintenance/improvement of existing conditions	High
Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function	CTUIR, ODFW, USFS, FSA, NRCS, SWCD	When need identified	Riparian areas associated with priority habitat areas	Long term	Immediate with continued improvement for up to 50 years. After 50 years habitat effectiveness will be maintained.	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	USFS, SWCDs, ODA, FSA, NRCS, CTUIR, ODSL, USACE	Ongoing	All priority areas within the Umatilla subbasin	Long Term	Maintenance of existing conditions	Moderate
Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues.	Municipalities	Unknown	Mid and lower subbasin; High dispersal downstream	Ongoing - unknown	Response is uncertain	It is unknown to what extent governments will address this need.
Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance	Umatilla County, CTUIR, ODFW	When possible	All priority areas within the Umatilla subbasin	Short term	Immediate with continued improvement for up to 50 years. After 50 years habitat effectiveness will be maintained.	Moderate, depends on implementation and enforcement

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Explore opportunities to incorporate priority areas into state legislation.	ODFW, CTUIR	When funding is available and amendment is possible	All priority areas within the Umatilla subbasin	Long term	Immediate with continued improvement for up to 50 years. After 50 years habitat effectiveness will be maintained.	Low

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTUIR	CTUIR Umatilla River Basin Anadromous Fish Habitat Enhancement Projects – Riparian Function	Birch Creek, Meacham Creek, Umatilla River	No	Yes, there is still potential for more conservation easements.
ODFW	Umatilla River Subbasin Fish Habitat Improvement Program, Fish Management Program	Birch Creek, Meacham Creek, Umatilla River	No	Yes, there is still potential for more conservation easements.
USFS	North Fork Umatilla River Wilderness and other specific Forest Plan management area allocations	Meacham Creek, North and South Fork Umatilla River and tribs	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
USFS	Land Exchange Program	Meacham Creek, North and South Fork Umatilla River and tribs, Pearson Creek (East Birch Creek)	No	See discussion below.
USFS	PACFISH/Umatilla Forest Plan	Meacham Creek, North and South Fork Umatilla River and tribs, West Birch Creek, Pearson Creek and other East Birch Creek tribs	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
USFWS	Umatilla Wildlife Refuge	Umatilla Wildlife Refuge	Yes	
US Army Corps of Engineers	Section 404/401 water alteration permitting	Subbasin-wide	No	Compliance validation and enforcement is inadequate due to lack of resources
ODSL	Waterway alteration permitting	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODA, SWCD	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
FSA, NRCS, SWCD	CREP, CCRP, CSP, EQIP	Subbasin-wide	No	The potential coverage of these programs has not been realized in Umatilla County.
CTUIR	Iskuulpa Creek	Iskuulpa Creek	Yes	Program meeting objectives.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

CTUIR and ODFW conservation easement programs have been effective at protecting and improving riparian habitat condition in the Umatilla subbasin. There is potential for considerable expansion of these programs. Emphasis should be placed on priority habitat areas for establishing easements. These agreements are typically 10 or 15 years in duration. Continuation of management and derived benefits are uncertain once agreements expire.

The Umatilla National Forest should emphasize protecting priority areas during project planning and implementation. Ongoing management actions sufficiently protect high priority aquatic habitats. These existing protections should be continued. PACFISH/Forest Plan Programs per se are sufficiently protective for lands in current ownership and require changing management or increasing buffers only when need is identified site-specifically ("New" actions). Most of FS lands (Meacham watershed, SF and NF Umatilla R. are already essentially fully protected under Forest Plan by protective management direction,- Roadless and Wilderness and Wildlife Emphasis Management Areas that prohibit road building and forest practices except in rare circumstances; PACFISH protections apply to all such activities. Meacham and Umatilla watersheds (FS) are essentially unroaded and unharvested, majority of existing road system is located on ridgetops, very little in stream bottoms. When/if needs are identified, additional aquatic habitat could receive increased protective status and a "new action". Adding additional wilderness areas and wild and scenic river segments would require designation by Congress. Priority areas for habitat protection as listed above that reside within the Umatilla National Forest should be assessed as to whether administrative designations apply to the areas that will support protection of these areas over the long term.

While permit processes implemented by the US Army Corps of Engineers are thorough and actions authorized are protective of aquatic resources, the program lacks personnel resources to insure that terms and conditions of permitted actions are followed. In addition, the agency lacks resources to adequately monitor waterways for non-permitted actions or act upon non-permitted situations reported by other agencies or private parties. See State of Oregon programmatic review -- Appendix F for comments on ODSL.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.
The USFS land exchange program has the potential to bring existing private lands under federal ownership and PACFISH protections. However, this program is completely voluntary on the landowner's part and the landowner would acquire public land and could very likely lower standards of resource protection. The land exchange is, however, a tool that could be used under very controlled circumstances to see increased protection of important aquatic habitats. But the purpose of the program is focused on consolidating land holdings and not necessarily protection of habitat. The Umatilla and Walla Walla Agricultural Water Quality Management (AgWQM) Area Rules require that management on agricultural lands allow the establishment, growth and maintenance of riparian or stream-side vegetation, consistent with site capability, to promote habitat and protect water quality by filtering sediment, stabilizing streambanks, naturally storing water, and providing shade. The AgWQM program is outcome-based rather than prescriptive, therefore allows landowners the flexibility to achieve water quality goals using available equipment, technology and innovation. The rules for each Management Area provide the enforceable backstop to the voluntary initiatives. The SWCDs are the local management agencies that provide the outreach, education and technical assistance. ODA is responsible for complaint investigations and enforcement actions. Technical and financial assistance is available through state and federal programs to landowners for establishing adequate riparian areas. The CREP program agreements are for durations of 10 or 15 years. There is no guarantee that the benefits and management actions will be continued beyond the duration of the agreements.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	Per Table 8-35 Priority (1) Butter Creek system priority (2) See Appendix G that identifies 25 culverts in need of replacement	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure, diversity	Primarily adults and 0+juveniles	See Table 8-35 for list of known passage barriers. The most serious passage barriers on the mainstem of the Umatilla River have been addressed. The watershed with the greatest need for passage remediation is Birch Creek.
Construct ladders over existing permanent concrete or earth fill dams	Per Table 8-35 Priority (1) Butter Creek system priority (2)	Impaired fish passage	Dams	Abundance, productivity, spatial structure, diversity	Primarily adults and 0+juveniles	
Provide screening at 100% of irrigation diversions	Unscreened diversions within current steelhead distribution (1); Butter Creek system priority (2)	Impaired fish passage	Irrigation diversions	Abundance, productivity	All	There is only one gravity flow diversion known to not have inadequate screening in areas that are occupied by steelhead. However, it is not known to what extent pump diversion are adequately screened.
Replace screens that do not meet criteria	Diversions within current steelhead distribution (1); Butter Creek system priority (2)	Impaired fish passage	Irrigation diversions	Abundance, productivity	All	
Operate and maintain fish passage facilities to meet criteria	Within current steelhead distribution (1); Butter Creek system priority (2)	Impaired fish passage and entrainment	Dams, culverts and irrigation diversions	Abundance, productivity, spatial structure, diversity	All	There are cooperative projects in place in the Umatilla subbasin to both physically maintain the facilities and provide biological oversight so they are operated to maintain optimum fish passage conditions.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove or replace barriers blocking passage such as	ODFW, CTUIR, SWCD, UBWC, USFS, ODOT, Umatilla County,	Ongoing	Access upstream of obstruction	Within 5 years	Immediate	High

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
dams, road culverts and irrigation structures	Municipalities, private landowners					
Construct ladders over existing permanent concrete or earth fill dams	ODFW, CTUIR, private landowners	Ongoing	Access upstream of obstruction	5-10 years	Immediate	High
Provide screening at 100% of irrigation diversions	ODFW, private landowners	Ongoing	Point of diversion	10-20 years	Immediate	High
Replace screens that do not meet criteria	ODFW, private landowners	Ongoing	Point of diversion	10-20 years	Immediate	High
Operate and Maintain fish passage facilities to meet criteria	CTUIR, ODFW, WID, private landowners	Ongoing	Facility site	Ongoing	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program, Fish Management Program	Subbasin-wide	No	More funding/implementation needed.
CTUIR	BPA Habitat Program	Subbasin-wide	No	More funding/implementation needed.
ODFW	Fish Screening Program	Subbasin-wide	Yes for gravity diversions	Need to inventory and address pump screening.
Westland Irrigation District	Fish facilities O and M	Lower Umatilla River	Yes	Program meeting objectives.
CTUIR/ODFW	Fish passage operations	Lower Umatilla River	Yes	Program meeting objectives.
USFS	Road Maintenance	Upper subbasin	No	More funding needed to address fish passage problems. Timeframe of implementation slow due to funding. See comments below.
SWCD, UBWC	Watershed Improvement	Subbasin-wide		See State of Oregon programmatic review – Appendix F.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

McKay, Butter and Willow creeks all historically supported summer steelhead, but steelhead are not currently present due to passage obstructions, inadequate screening and low flow problems. McKay Dam, constructed to store water for irrigation in the 1920's, completely blocks upstream passage of fish at RM 6 on McKay Creek. Unt il recent years, McKay Creek downstream of McKay Dam was completely de-watered when the reservoir was being filled. Butter Creek has a series of large diversion dams that block upstream passage throughout the subbasin. In addition, water withdrawal for irrigation is so severe that water flows out of the mouth for only a few days or weeks in any given year. Willow Creek Dam Was constructed in 1980 on Willow Creek just upstream of Heppner (RM 56) for flood control. Willow Creek Dam completely blocks upstream passage of fish. In addition, to Willow Creek Dam, numerous irrigation diversion dams throughout the Willow Creek watershed block passage. The lowest barrier in Willow Creek that blocks anadromous passage exists at RM 11. Steelhead are occasionally seen holding downstream of this dam. While the general condition of passage in these streams (McKay, Butter and Willow creeks) is understood, a thorough inventory and assessment is needed. This information can be used to pursue passage improvement for redband trout and to assess the feasibility of restoring passage for steelhead.

The USFS has identified passage barriers in addition to the ones listed in Table 8-35. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed within the ESU.

Screening of gravity-feed irrigation diversions within currently occupied steelhead habitat is thought to be adequate, with the exception of the lower six miles of McKay Creek and one site in the Birch Creek drainage that is known to not meet criteria. There is now documented use of steelhead juveniles in lower McKay Creek, but no efforts have been made in the past or present to screen water diversions there. It is not known to what extent pump-feed irrigation diversions are adequately screened. There is a critical need to inventory and screen all pump-feed irrigation diversions within currently occupied steelhead habitat. A comprehensive inventory of water diversions and screening needs has never been done in the Umatilla subbasin. Thus, while it is not likely that there are gravity feed diversions that are not screened, there exists the possibility, lacking a thorough assessment of the situation. A comprehensive inventory of all water diversions should be done and inspection of these diversions to ensure adequate screening.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Umatilla R., Mission Br. to forks (1); Meacham Cr., mouth to North Fork (1); Birch Creek (1); West Birch, mouth to gorge (1); East Birch Creek mouth to Pearson Cr. (1)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	All	Watershed scale problems and riparian management issues should be considered before active stream channel restoration is employed.
Reconnect side channels and off-channel habitats to stream channels	Umatilla R., Mission Br. to forks (1); Meacham Cr., mouth to North Fork (1); Birch Creek (1); West Birch, mouth to gorge (1); East Birch Creek mouth to Pearson Cr. (1)	Degraded floodplain, altered hydrology, habitat quantity and diversity	Removal of side channels, off-stream habitat	Abundance, productivity	All	Many streams in the subbasin are bordered by dikes and levies.
Remove dikes and levies	Umatilla R., Mission Br. to forks (1); Meacham Cr., mouth to North Fork (1)	Degraded channel structure and complexity	Stream channelization, bank armoring	Abundance, productivity	All	Many streams in the subbasin are bordered by dikes and levies.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain habitats	ODFW, UBWC,, SWCD, USFS, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Short term, once identified	Physical response will be immediate for some, others will develop over years to decades	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Remove dikes and levies	CTUIR, UBWC, CDs	When opportunity identified	Within the stream reach and reaches downstream for temp and sediment	10+ years	Improved stream and floodplain functions - some benefits will be realized immediately and others will develop over years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Reconnect side channels and off-channel habitats to stream channels	ODFW, UBWC, SWCD, USFS, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Short term, once identified	Physical response will be immediate for some, others will develop over years to decades	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes

Strategy 3. Maintain and restore floodplain connectivity and function.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Birch Creek, Meacham Creek, Umatilla River	No	Additional implementation needed
CTUIR	BPA Habitat Program	Birch Creek, Meacham Creek, Umatilla River	No	Additional implementation needed
SWCD, UBWC	Watershed Restoration	Subbasin-wide		Involvement is currently limited. See State of Oregon programmatic review – Appendix F.
Watershed Council	Watershed Restoration	Subbasin-wide	No	There is a continuing need for landowner assistance to insure that issues are dealt with appropriately.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Intensive land uses within Umatilla subbasin flood plains and upslope habitats have led to dramatic changes in waterway characteristics since arrival of Euro-American pioneers to the area during the middle 1800's (Nagel 1997, unpublished; Beschta 1994). Channel alterations in the Umatilla subbasin have resulted in 1) straight, incised channels with minimal woody riparian vegetation, and 2) wide channels with increased dynamics and minimal woody riparian vegetation. There is a need for continued implementation of measures to address limiting factors.				

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Umatilla River, Mission Br. to forks (1); Meacham Creek, mouth to North Fork (1); Birch Creek (2); West Birch Creek (1), mouth to Gorge; East Birch Cr. (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature, flows	Stream channelization, bank armoring, large wood removal, loss of beaver dams, removal of riparian vegetation, livestock overgrazing in riparian areas	Abundance, productivity	All	Stream channel reconstruction and instream structures can be designed to correct channel stability problems. Where appropriate, passive treatments are preferred.
Place stable wood and other large organic debris in streambeds	Umatilla River, Mission Br. to forks (1); Meacham Creek, mouth to headwaters (1); North Fork Meacham Cr. (1); Birch Creek (1); West Birch Creek, mouth to Gorge (1); East Birch Creek (1); Bear Cr. (West Birch) (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Removal of large wood, beaver, trees in riparian areas; channelization and streambank armoring, livestock grazing	Abundance, productivity	Fry to adult	Aside from riparian vegetation, removal of large woody debris is one of the most pervasive habitat deficiencies in the Umatilla subbasin, either from direct removal or from removal of vegetation from riparian zones and floodplains. In areas where direct and immediate benefits to viability parameters can be addressed, large wood should be placed to improve overall ecosystem function. In areas where the lack of large wood is in addition to other habitat deficiencies such as flow and water quality, then restoration should focus on these over riding factors first.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Stabilize and protect streambanks	Umatilla River, Mission Br. to forks (1); Birch Creek (1); W. Birch Creek, mouth to Gorge (1); East Birch Cr. (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, bank armoring, livestock grazing in riparian areas	Abundance, productivity	Eggs, fry and adults	Stream that have been altered by human activities such as grazing, removal of riparian vegetation, Channelization and bank armoring often have vertical and/or lateral erosion rates elevated above natural conditions, as well as coarse substrates that are not suitable for spawning.
Construct rock and log weirs to create pool habitats or elevate incised channels	Umatilla River, Mission Br. to forks (1); Meacham Cr, mouth to North Fork (1); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Creek (1); Bear Cr. (West Birch) (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Large wood removal, trees in riparian area	Abundance, productivity	Fry to adult	Pools should be constructed strategically where other alternatives are not likely to accomplish this need, or constraints will not allow natural processes to form them. Artificial enhancement of pools should only be performed in areas where other parameters, such as water quality, would allow immediate use/benefits to be realized.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, CTUIR, UBWC	Ongoing; some needs identified in ODFW/CTUIR five-year action plan	Within the stream reach and reaches downstream for temp and sediment	25 years	Improved riparian vegetation and associated attributes and improved stream and floodplain structure and function – response time immediate to 10 years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Place stable wood and other large organic debris in streambeds	ODFW, UBWC, CTUIR, SWCDs	Ongoing as needed	Reach affected	Short term	Improved instream channel habitat diversity - some benefits will be realized immediately and others will develop in 1-5 years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Stabilize and protect streambanks	ODFW, CTUIR, SWCD, UBWC, private landowners	Ongoing; when specific opportunity identified	Within the stream reach and reaches downstream for temp and sediment	10+ years	Improved water quality – response time 1-5 years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Construct rock and log weirs to create pool habitats or elevate incised channels	ODFW, CTUIR	Ongoing; current action planned for Meacham Cr.	Treatment site	25 years	Increased quantity of pool habitat and channel and floodplain function – response time immediate to 5 years	High over short term, however structures often require maintenance
Remove dikes and levies	ODFW, CTUIR, SWCD, UBWC	When specific opportunities identified	Within the stream reach and reaches downstream for temp and sediment	Once specific action planned, short term	Some benefits will be realized immediately and others will develop over years to decades	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Birch Creek, Meacham Creek, Umatilla River	No	Additional implementation needed
CTUIR	BPA Habitat Program	Birch Creek, Meacham Creek, Umatilla River	No	Additional implementation needed
SWCD	Watershed Restoration	Subbasin-wide		See State of Oregon programmatic review – Appendix F.
Watershed Council	Watershed Restoration	Subbasin-wide	No	There is a continuing need for landowner assistance to insure that issues are dealt with appropriately.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Intensive land uses within Umatilla subbasin flood plains and upslope habitats have led to dramatic changes in waterway characteristics since arrival of Euro-American pioneers to the area during the middle 1800's (Nagel 1997, unpublished; Beschta 1994). Channel alterations in the Umatilla subbasin have resulted in 1) straight, incised channels with minimal woody riparian vegetation, and 2) wide channels with increased dynamics and minimal woody riparian vegetation. There is a need for continued implementation of measures to address limiting factors.				

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	Umatilla River, Mission Br. to forks (1); Meacham Creek, mouth to headwaters (1); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Cr (1); Bear Cr. (West Birch) (1); Iskuulpa Cr. (1)	Degraded riparian area, channel stability, floodplain degradation, sediment, water temperature	Livestock grazing, channelization, stream bank armoring, cutting of trees in riparian areas, changes in plant communities (including invasive plants), loss of beaver dams	Abundance, productivity, diversity	All	Historically, bank armoring with rock and channelization were used to stabilize stream banks at the detriment of riparian vegetation growth. In the last 15 years the high economic and ecological cost of bank armoring with riprap and of channelization has been recognized, so the emphasis has shifted toward a more passive approach for stabilization, primarily through riparian vegetation improvements.
Develop grazing strategies that promote riparian recovery	Umatilla River, Mission Br. to forks (1); Meacham Creek, mouth to headwaters (1); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Cr (1); Bear Cr. (West Birch) (1); Iskuulpa Cr. (1)	Degraded riparian area, channel stability	Livestock overgrazing of riparian area	Abundance, productivity, diversity	All	Grazing strategies, other than exclusion, should be developed to achieve riparian recovery in the next 10-15 years. Permanent or temporary exclusion of livestock from riparian areas remains the surest way to achieve riparian restoration where livestock have been the primary impact.
Develop no-cultivation riparian buffer on agricultural lands and establish riparian setbacks for structures in	Umatilla River, Mission Br. to Meacham (1); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Cr (1); Bear Cr. (West Birch) (1)	Degraded riparian area, channel stability, floodplain degradation, sediment, water	Degradation of riparian areas and function; residential	Abundance, productivity, diversity	All	In areas where development is occurring, that development should be adequately set back from streams so as not to interrupt natural stream processes.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
areas where activities could upset riparian function		temperature	development and cultivation			
Maintain existing widths of RHCAs on USFS lands	Umatilla R. and tribs, Meacham Cr. to Forks (1); South Fork Umatilla and tribs (1); Buck Cr. and tribs (1); Thomas Cr. and tribs (1); North Fork Meacham and tribs (1); East Meacham and tribs (1); Butcher Creek and tribs (1)	Degraded riparian area, channel stability, floodplain degradation	cutting of trees in riparian areas, changes in plant communities	Abundance, productivity, diversity	All	
Riparian exclosure fencing	Umatilla River, Mission Br. to forks (1); Meacham Creek, mouth to headwaters (1); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Cr (1); Bear Cr. (West Birch) (1)	Degraded riparian area, channel stability	Livestock grazing	Abundance, productivity, diversity	All	Excluding livestock from riparian areas remains the most effective tool of mitigating livestock impacts.
Close, remove, and restore riparian road prisms	Umatilla River, Mission Br. to forks (1); Meacham Creek, mouth to headwaters (1); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Cr (1); Bear Cr. (West Birch) (1)	Degraded riparian area, channel stability, sediment	Roads	Abundance, productivity, diversity	All	In many areas of the Umatilla subbasin, riparian roads have reduced riparian vegetation, confined stream channels, and continue to deliver fine sediment to channels. Regular road maintenance, or road relocation or elimination will restore allow natural riparian processes.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities including vegetative planting	ODFW, CTUIR, NRCS/FSA , UBWC, SWCD, ODA, private landowners	Ongoing	High dispersal downstream from site	25 years	Improved riparian vegetation and associated attributes – response time 5 years to decades	Moderate – plant survival varies based on techniques used
Develop/implement grazing strategies that promote riparian recovery	ODA, NRCS, FSA, USFS, private landowners	Ongoing	High dispersal downstream from site	Long term	Improved riparian vegetation and associated attributes – response time 5 years to decades	Depends on diligence of management applications
Develop no-cultivation riparian buffer on agricultural in areas where activities could upset riparian function	CTUIR, landowners, FSA/NRCS, ODFW	Ongoing	Cultivated land in close proximity to priority habitat areas within the Umatilla subbasin	Long term	Immediate with continued improvement for up to 50 years or until easement ends and management changes. After 50 years habitat effectiveness will be maintained	High
Maintain existing widths of RHCAs on USFS land	USFS	Ongoing	Benefits accruing since 1995 for all streams in Umatilla subbasin on USFS lands, including priority GAs.	Long Term	Maintenance/improvement of existing conditions	High
Riparian exclosure fencing	ODFW, CTUIR, NRCS/FSA, Watershed Council, SWCD, private landowners	Ongoing	High dispersal downstream from site	25 years	Improved riparian vegetation and associated attributes – response time 5 years to decades	High
Close, remove, and restore riparian road prisms	USFS, ODOT, Umatilla County, private landowners	Ongoing	Riparian areas within the subbasin where potential for riparian road closure and removal exists	Based on opportunity and need	Improved water quality – response time immediate with continued response for up to 50 years	High

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODA, SWCD	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
FSA, NRCS, SWCD	CREP, CCRP, CSP, EQIP	Subbasin-wide	No	The potential coverage of these programs has not been realized in Umatilla County
ODFW, CTUIR	BPA Habitat Program		No	Many additional miles of stream to be treated
USFS	Grazing management	Upper subbasin	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
USFS	Vegetation management	Upper subbasin	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODEQ	TMDL	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
Municipalities	Land use planning ordinances	Subbasin-wide	No	Needs expansion.
USFS	Road management	Upper subbasin		See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODOT	Road maintenance	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODF	Forest Practices Act, Road management	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
Umatilla County	Road maintenance	Subbasin-wide	No	Needs expansion to better address water and sediment routing to waterways.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The Umatilla and Walla Walla AgWQM Area Rules require that management on agricultural lands allow the establishment, growth and maintenance of riparian or stream-side vegetation, consistent with site capability, to promote habitat and protect water quality by filtering sediment, stabilizing streambanks, naturally storing water, and providing shade. The AgWQM program is outcome-based rather than prescriptive, therefore allows landowners the flexibility to achieve water quality goals using available equipment, technology and innovation. The rules for each Management Area provide the enforceable backstop to the voluntary initiatives. The SWCDs are the local management agencies that provide the outreach, education and technical assistance. ODA is responsible for complaint investigations and enforcement actions. Technical and financial assistance is available through state and federal programs to landowners for establishing adequate riparian areas. The CREP program agreements are for durations of 10 or 15 years. There is no guarantee that the benefits and management actions will be continued beyond the duration of the agreements. Continued development adjacent to waterways is not suitable to the recovery of Mid. Columbia steelhead. Fish managers need to review the issue with Umatilla County and municipalities and identify ways to resolve problems with current regulations or their implementation.				

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement Umatilla Basin Project Phase I and II	Umatilla River from mouth to McKay Cr. (1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity	Parr to adult	Agricultural water diversions constructed on the lower Umatilla in the early 20th century lead to dewatering of the channel throughout the spring summer and fall. Implementation of the Umatilla Basin Water Exchange project has resulted in
Implement Umatilla Basin Project Phase III	Umatilla River from mouth to Thornhollow (1)	Flows, water temperatures, habitat	Water withdrawals	Abundance, productivity,	Parr to adult	

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
		quantity/diversity		diversity		restoration of flows in the mainstem of the Umatilla River so that migration and rearing of steelhead is better supported, but conditions are not fully restored. Continued implementation an maintenance of this project is critical for providing migration and rearing.
File for additional ISWRs	Butter Creek system (2); Bear Cr. (West Birch) (1); South Canyon Cr. (East Birch) (1); Westgate Canyon (East Birch) (1); East Fork Meacham Cr. (1); Twomile Cr. (2); Butcher Cr. (1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, spatial structure, diversity	Parr to adult	Most important spawning and rearing stream in currently utilized spawning and rearing habitat have instream water rights. However, no instream water rights exist in the Butter Cr. system
Implement agricultural water conservation measures	Butter Creek system (2); Umatilla River, Mission Br. to forks (2); Birch Creek (1); West Birch Creek, mouth to Gorge (1); East Birch Creek (1); Bear Cr. (West Birch)(1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity, spatial structure	All	The primary tributary streams where water withdrawals are affecting migration and rearing of steelhead include the Birch and Butter Creek watersheds. Dewatering and passage barriers are so severe in Butter Creek that steelhead are currently not documented to occur. B irch Creek continues to support steelhead, but water withdrawals are significantly impacting rearing and migration habitats.
Lease or acquire water rights and convert to instream	Butter Cr system (2); Umatilla River, Mission Br. to forks (2); Birch Cr (1); West Birch Cr, mouth to Gorge (1); East Birch Cr (1); Bear Cr. (W Birch) (1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity, spatial structure	Parr to adult	
Downstream water rights transfers	Umatilla River, Mission Br. to forks (2); Birch Creek (1); West Birch Creek, mouth to Gorge (1); East Birch Creek (1); Bear Cr. (West Birch) (1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity	Parr to adult	
Monitor/regulate water withdrawals	Subbasin-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Parr to adult	Many streams that historically flowed year long are now intermittent, creating fish passage barriers in the dewatered reach. Many of these due to water withdrawals
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement Umatilla Basin Project Phase I and II	BPA, BOR, OWRD, WEID, HID, SID, CTUIR, ODFW	Ongoing	From McKay Reservoir to mouth of the Umatilla River	Long Term	Improved water quality and flow – immediate response	High, but depends on continued BPA funding
Implement Umatilla Basin Project Phase III	BPA, BOR, OWRD, WEID, CTUIR, ODFW	In-planning	From McKay Reservoir to mouth of the Umatilla River	Long Term	Uncertain	Uncertain

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
File for additional ISWRs	ODFW	On hold	Specific to the stream reach	Unknown	Maintenance of existing conditions	High, depends on how resource managers implement protection
Implement agricultural water conservation measures	SWCDs	Ongoing	Depends on means used to protect instream flows	Short Term	Improved instream flow – response immediate	Moderate – depends on how saved water is protected, if any.
Lease or acquire water rights and convert to instream	OWRD., Oregon Water Trust, water right holders	Ongoing, when opportunities arise	From point of diversion downstream	Long term	Improved instream flow – response immediate	High, depending upon priority date of water right
Downstream water rights transfers	OWRD, private landowners	Ongoing	Reach between old and new point of diversion	Long Term	Improved instream flow – response immediate	High
Monitor/regulate water withdrawals	OWRD	Ongoing	From the point of diversion downstream to the mouth of the Umatilla River	Long term	Maintenance or improvement of existing conditions – response to regulation immediate	Moderate, staffing levels are inadequate
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
BOR/BPA	Umatilla Basin Project	Lower Umatilla River	No	Additional water is needed to meet target flows established for the basin project
OWRD	Streamflow Monitoring and Regulation, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust and BOR	Leasing and Purchase of Water Rights	Umatilla River, Birch Cr. system and Butter Cr. system	No	Additional implementation would help meet flow restoration needs
SWCD, ODFW, CTUIR, Watershed Council	Improve irrigation efficiency	Umatilla River, Birch Cr. system and Butter Cr. System	No	Additional implementation would help meet flow restoration needs
UBWC, SWCD, ODFW, CTUIR, NRCS	Upland improvements, riparian improvements	Subbasin-wide	Uncertain	Additional implementation would help meet flow restoration needs
Umatilla County	Noxious weed control	Subbasin-wide	Yes	
ODF	Forest Practices Act	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
USFS	Forest Management	Upper Subbasin	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Phase I and II of the Umatilla Basin Project are currently meeting critical flow needs in the mainstem of the Umatilla River. This program should be continued to support migration and rearing of steelhead. Target flows				

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.
for the Umatilla River mainstem were established as part of the Basin Project to the life history needs of Chinook and coho salmon and steelhead. The Basin Project as currently implemented does not provide adequate water to meet the target flows throughout the times needed by these species, and fails to provide any flow mitigation for a significant length of the river in July and August. BOR, CTUIR and WID are currently seeking to expand the Basin Project (Phase III) to better meet flow needs for migration and rearing. As Phase III of the Basin project is developed, priority should be given to providing additional flow at the time and locations to meet the needs of MCR steelhead.
Significant efforts have been made in the lower Umatilla subbasin to use more efficient means of applying water to agricultural crops. There has been less emphasis on irrigation efficiency in other areas of the subbasin. Efforts should be taken to improve irrigation efficiency in areas such as the Birch Creek watershed where flow is a primary limiting factor. There are approximately 238 stream miles protected by instream water rights in the Umatilla subbasin. Voluntary flow restoration projects restored 14.9 cfs instream during 2006.
The Oregon Water Trust has put significant effort into gaining instream water leases in the Umatilla subbasin, with limited success. While it is unlikely that this approach could make a significant difference on the lower Umatilla River, tributary habitats could benefit substantially from water leasing. The Oregon Water Trust should maintain a "presence" in the subbasin to be in a position to capitalize on opportunities as they arise.
While instream water rights have been established on many of the important spawning and rearing stream in the subbasin, some have not. Where important spawning and rearing streams have not been protected by instream water rights, appropriate instream flow studies should be conducted and instream water rights applied for. In addition, consideration should be given to protecting and restoring flows in the Butter Creek drainage, where steelhead are currently extinct.
Projects to improve summer and fall streamflow and temperature by recharging shallow aquifers have been proposed, but none have been implemented to date. These types of projects are highly experimental in nature and should be accompanied by rigorous monitoring and evaluation to determine the net benefits of the action.
The primary tributaries in need of flow restoration actions are Birch and Butter creeks.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Address point sources of water pollution	Umatilla River (1); Birch Creek (1)	Chemical pollution	Sewage, Pesticides, fertilizers, herbicides	Abundance, productivity	Egg to Smolt	Point sources of water pollution are direct impacts that should be corrected through implementation of the TMDL and associated water quality management plan.
Implement water quality management plans	Subbasin-wide	Degraded water quality, flows, sediment routing, water quality	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	All	The Umatilla River water quality management plan addresses many water quality problems in the drainage.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Address point sources of water pollution	ODEQ, others	Ongoing	Specific point location	Ongoing	Reduce chemical pollution immediately	High
Implement water quality management plans	ODA, SWCD, Municipalities, Umatilla County, USFS, ODF, Irrigation Districts, private landowners, Industry, ODEQ	Ongoing	High dispersal downstream	Ongoing	Immediate	Moderate – degree of implementation is uncertain

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA, NRCS, SWCD	CREP, CCRP, CRP, EQIP, CSP	Subbasin-wide	Uncertain	The potential coverage of these programs has not been realized in Umatilla County.
ODFW	BPA Habitat Program	Umatilla R. Birch Cr., Meacham Cr.	No	There is a need for additional buffers.
CTUIR	BPA Habitat Program	Umatilla R. Birch Cr., Meacham Cr.	No	There is a need for additional buffers.
ODEQ	TMDL, NPDES	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODF	Forest Practices Act	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
USFS	PACFISH	Upper Subbasin	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
SWCD	Landowner cost share programs for conservation farming practices	Subbasin-wide		More landowners could be included if funds were available. See State of Oregon programmatic review -- Appendix F.
Umatilla County	Noxious weed control	Subbasin-wide	Yes	Program sufficient.
US Army Corps of Engineers	Section 404/401 water alteration permitting	Subbasin-wide	No	Compliance validation and enforcement is inadequate due to lack of resources.
ODSL	Waterway alteration permitting	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODA, SWCD	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Although this threat is partially addressed by the Umatilla River Water Quality Management Areas Plan (WQMAP), the guidance provided to landowners on management of riparian areas is fairly general. There is also some uncertainty regarding the implementation of this plan's requirements, as enforcement is based on a complaint-driven system. There is a continuing need to establish more riparian buffers. Achievement of the TMDL targets is dependent of determination of system potential vegetation. During TMDL development, the best professional judgment of the team described the potential streamside shade-producing vegetation broadly, as continuous tree-belts on each side of the river.

The Umatilla and Walla Walla AgWQM Rules require control of sediment delivery to streams to acceptable levels, control of irrigation runoff, management of livestock grazing to prevent runoff of waste and sediment, and establishment and maintenance of riparian and streamside vegetation. Beginning in 2008, these land conditions will be enforceable by ODA. SWCD provides technical and financial assistance to private landowners.

The SWCD, in partnership from OSU Extension Service and NRCS, has been a leader in promoting adoption of high tech conservation farming practices. They have received grants to provide cost share for farmers to adopt direct seeding, variable rate fertilizer placement and selective weed control. This technology reduces tillage that results in less erosion and healthier soils, applies only the needed amount of fertilizer to crops and reduces the application of herbicides.

The CREP program agreements are for durations of 10 or 15 years. There is no guarantee that the benefits and management actions will be continued beyond the duration of the agreements.

While permit processes implemented by the US Army Corps of Engineers are thorough and actions authorized are protective of aquatic resources, this program lacks personnel resources to insure that terms and conditions of permitted actions are followed. In addition, the agency lacks resources to adequately monitor waterways for non-permitted actions or act upon non-permitted situations reported by other agencies or private parties. See State of Oregon programmatic review -- Appendix F for ODSL.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	**Geographic Locations (1-first priority, 2-second priority)**	**Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Restore native upland plant communities	Subbasin-wide	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices, loss of water storage capacity	Abundance, productivity	All	There are cooperative projects in place in the Umatilla subbasin.
Upgrade or remove problem forest roads	Subbasin-wide	Altered hydrology, sediment routing	Road network	Abundance, productivity	All	
Initiate upland improvement demonstration projects	Subbasin-wide	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	All	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Subbasin-wide	Altered hydrology, sediment routing	Upland land use practices	Abundance, productivity	All	

Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Restore native upland plant communities	SWCD, USFS, NRCS, private landowners	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term	Decades	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Upgrade or remove problem forest roads	BLM, ODF, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff. Decommissioning may take many years	5-15 years	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Initiate upland improvement demonstration projects	ODFW, USFS, CTUUIR, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	SWCD, USFS, ODA, CTUIR, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of water quality management plans and other plans	0-20,years, depending upon treatments applied	Moderate, dependent upon voluntary landowner participation

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA, NRCS, SWCD	EQIP, CRP, CREP, CCRP	Subbasin-wide	Uncertain	The potential coverage of these programs has not been realized in Umatilla County.
USFS	Forest Management	Upper subbasin	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODFW/CTUIR	BPA Habitat Program	Umatilla R., Birch Cr., Meacham Cr.	No	Additional implementation is needed.
SWCD, Watershed Council	Watershed Restoration, OWEB	Subbasin-wide		Additional implementation is needed.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
ODA, SWCD	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The degree to which upland vegetation management issues are being addressed has not been summarized subbasin-wide so sufficiency is currently not well understood.

The AgWQM Area Plan addresses upland conditions, both on rangeland and cropland that must be met to prevent and control erosion and improve overall watershed health to achieve water quality goals. The Area Rules require control of soil erosion to acceptable levels, allowing riparian and stream-side vegetation to establish for bank stability, filtering and shade, and management of livestock to prevent runoff of sediment and animal wastes. SWCD and NRCS programs are providing incentives to landowners to adopt farming practices that are more environmentally protective.

Implementation of PACFISH standards and guides for Forest programs has been highly successful for passive upland and riparian restoration in this population's area.

The CREP program agreements are for durations of 10 or 15 years. There is no guarantee that the benefits and management actions will be continued beyond the duration of the agreements.

Table 9-2. Umatilla Subbasin Geographic Areas

GA	Stream	Segment	MaSA	MiSA
1	Umatilla River	Mouth to Three Mile Dam		
2	Umatilla River	Three Mile Dam to Butter Creek		
3	North Hermiston Drain	All		
4	Butter Creek	Mouth to Madison diversion	Butter

39	Beaver Creek	All, including tributaries	Meacham	
40	Umatilla River	Meacham Creek to forks	Upper Umatilla	
41	Ryan Creek	All	Upper Umatilla	
42	North Fork Umatilla	Mouth to headwaters, including tributaries	Upper Umatilla	
43	South Fork Umatilla	Mouth to Thomas Creek	Upper Umatilla	
44	Buck Creek	All, including tributaries	Upper Umatilla	
45	Thomas Creek	All	Upper Umatilla	
46	South Fork Umatilla	Thomas Creek to headwaters, including Shimmiehorn Creek	Upper Umatilla	

Note: Minor spawning areas within the Umatilla Subbasin not represented include Cold Springs, Alkali, Speare, Mud Spring and Little McKay.

9.3.11 Habitat Strategies and Actions for Walla Walla River Steelhead Population

Primary limiting factors: high water temperature, sediment routing, impaired fish passage, degraded channel structure and complexity, degraded floodplain connectivity and function, and altered hydrology (low flow).

Primary threats: current land use practices that reduce habitat quality and quantity and disrupt ecosystem functions.

Several tables are included after the habitat strategies and actions for the Walla Walla River steelhead population. Tables 9-3 and 9-4 show priorities for steelhead habitat restoration and protection. This prioritization was developed by applying the Ecosystem Diagnosis and Treatment Model that determined limiting factors and the areas where the greatest increase in fish production could be realized from restoration and protection actions. Table 9-5 provides a cross reference of geographic areas and MaSAs/MiSAs.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition, conservation easements and cooperative agreements	SF Walla Walla, Elbow to headwaters (1); SF Walla Walla Tribs (1) ; NF Walla Walla Little Meadows to headwaters (1); Walla Walla, Dry Cr. to Mill Cr.(2); Yellowhawk mainstem (2); Couse Cr. drainage (2)	Loss of habitat quantity and diversity, channel stability, sediment, low flow and high temperatures	Cultivation, forestry, grazing, urban development	Productivity, abundance	All	Agreements (conservation easements, cooperative agreements, etc.) could be made with private landowners in areas where priority habitats exist to maintain the current habitat values. Agreements in areas with priority habitats may include: Putting in no-cultivation riparian buffers on agricultural lands that are currently cultivated up to the channel's edge, increasing riparian buffer widths associated with forested areas, protecting unstable areas, or changing other types of management in riparian areas.
Implement Forest Practices Act	SF Walla Walla, Elbow to headwaters; SF Walla Walla Tribs; NF Walla Walla Little Meadows to headwaters; All are first priority (1)	Same as above	Forestry	Productivity abundance	All	
Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function	SF Walla Walla, mouth to headwaters (1); SF Walla Walla Tribs (1); NF Walla Walla mouth to headwaters (1); Walla Walla, Dry Cr. to forks (1); Yellowhawk mainstem (1); Couse Cr. drainage (1); Little Walla Walla System (2)	Same as above	Same as above	Productivity, abundance		Setbacks could include: no-cultivation riparian buffers on agricultural lands that are currently cultivated up to the channel's edge, increasing riparian buffer widths associated with forested areas, protecting unstable areas, or changing other types of management in riparian areas.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Protect and conserve rare and unique functioning habitats	Upper South Fork Walla Walla (1)	Same as above	Same as above	Productivity, abundance	All	Priority areas can be identified and appropriate protective action can be taken.
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	Subbasin-wide	Same as above	Same as above	Productivity, abundance	All	To prevent degradation of existing habitat, Best management Practices and existing laws that protect aquatic habitat should be applied across the subbasin with emphasis on areas of very high quality.
Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues	SF Walla Walla, mouth to headwaters (1); SF Walla Walla Tribs (1); NF Walla Walla mouth to headwaters (1); Walla Walla, Dry Cr. to forks (1); Yellowhawk mainstem (1); Couse Cr. drainage (1); Little Walla Walla System (2)	Same as above	Urban development	Productivity, abundance	All	Enforce existing land use laws that affect aquatic habitat and update laws that do not provide adequate protection.
Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance	SF Walla Walla, mouth to headwaters (1); SF Walla Walla Tribs (1); NF Walla Walla mouth to headwaters (1); Walla Walla, Dry Cr. to forks (1); Yellowhawk mainstem (1); Couse Cr. drainage (1); Little Walla Walla System (2)	Same as above	Urban development	Productivity, abundance	Productivity, abundance	Incorporating MCR steelhead priority habitat areas into the Natural Area Overlay Zone provision of the county development ordinance would allow the priority habitat areas to be protected while providing an expedient process for reviewing land uses.
Explore opportunities to incorporate priority areas into state legislation.	SF Walla Walla, mouth to headwaters (1); SF Walla Walla Tribs (1); NF Walla Walla mouth to headwaters (1); Walla Walla, Dry Cr. to forks (1); Yellowhawk mainstem (1); Couse Cr. drainage (1); Little Walla Walla System (2)	Same as above	Rural and urban development	Productivity, abundance	All	Examine opportunities to amend laws that would increase protection for priority habitat areas.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect high quality habitats through acquisition, conservation easements and cooperative agreements	CTUIR, ODFW, WWBWC, WDFW,TNC, RMEF, SWCDs, CD's	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5 years to decades with passive restoration approaches	High, based on previous cooperative agreements
Implement Forest Practices Act and PACFISH	ODF, WDOE	Ongoing	Forest Practices Act applies to all commercial timber operations on private lands	Long term	Maintenance/improvement of existing conditions	High
Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function	CTUIR, ODFW, WDFW, WDOE, USFS, FSA, NRCS, SWCD, CD's, WWBWC	When need identified	Riparian areas associated with priority habitat areas	Long term	Immediate with continued improvement for up to 50 years. After 50 years habitat effectiveness will be maintained.	High

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Protect and conserve rare and unique functioning habitats	USFS, BLM	Protection ongoing	Affected area	Long term	Immediate – maintain existing high quality conditions where found; maintain or improve existing conditions elsewhere	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	USFS, BLM, SWCDs, WDOE, WDFW, ODFW, ODA, FSA, NRCS, CTUIR, ODSL, USACE, private landowners	Ongoing	All priority areas within the Walla Walla subbasin	Long term	Maintenance of existing conditions	High for federal lands; moderate elsewhere
Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues.	Municipalities, Counties	Unknown	Mid and lower subbasin; high dispersal downstream	Ongoing - unknown	Response is uncertain	It is unknown to what extent governments will address this need.
Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance	Counties, CTUIR, ODFW, WDFW	When possible	All priority areas within the Umatilla subbasin	Short term	Immediate with continued improvement for up to 50 years. After 50 years habitat effectiveness will be maintained.	Moderate, depends on implementation and enforcement
Explore opportunities to incorporate priority areas into state legislation.	ODFW, CTUIR, WDFW, WDOE	When funding is available and amendment is possible	All priority areas within the Umatilla subbasin	Long term	Immediate with continued improvement for up to 50 years. After 50 years habitat effectiveness will be maintained.	Low

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTUIR	CTUIR Walla Walla River Basin Anadromous Fish Habitat Enhancement Projects – Riparian Function		No	Yes, there is still potential for more conservation easements.
USFS	Roadless Areas		Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODF	Forest Practices Act			See State of Oregon programmatic review -- Appendix F.
BLM	South Fork Walla Walla ACEC		Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
USFS	PACFISH, Umatilla Forest Plan		Yes	Existing actions are adequate as implemented, but additional protection areas should be added as the need is identified.
CTUIR	Rainwater		Yes	Maintain current project.
USACE, ODSL	Waterway work permitting		No	Funding is not adequate.
ODA, SWCD	Walla Walla Ag.WQM rules			See State of Oregon programmatic review -- Appendix F.
SWCD/CDs/WWBWC/Tr-state Steelheaders	Watershed restoration		No	Programs have inadequate resources.
Municipalities	Land use ordinances		No	
Counties	Comprehensive plan		No	

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
FSA, NRCS, SWCD	CREP, CCRP, CSP, EQIP		Uncertain	The potential coverage of these programs has not been realized in Umatilla County.
OLCD	Statewide planning goals			See State of Oregon programmatic review -- Appendix F.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

CTUIR conservation easement programs have been effective at protecting and improving riparian habitat condition in the Walla Walla subbasin. There is potential for considerable expansion of this program. Emphasis should be placed on priority habitat areas for establishing easements.

The Umatilla National Forest should emphasize protecting priority areas during project planning and implementation. Ongoing management actions sufficiently protect high priority aquatic habitats. These existing protections should be continued. PACFISH/Forest Plan Programs per se are sufficiently protective for lands in current ownership and require changing management or increasing buffers only when need is identified site-specifically ("New" actions). Most of FS lands are already essentially fully protected under Forest Plan by protective management direction - Roadless and Wilderness and Wildlife Emphasis Management Areas that prohibit road building and forest practices except in rare circumstances; PACFISH protections apply to all such activities. When/if needs are identified; additional aquatic habitat could receive increased protective status and a "new action". Priority areas for habitat protection as listed above that reside within the Umatilla National Forest should be assessed as to whether administrative designations apply to the areas that will support protection of these areas over the long term. Adding additional wilderness areas and wild and scenic river segments would require designation by Congress.

Actions implemented under PACFISH on Federal lands allow for a near natural rate of recovery. An individual action may result in a short-term disturbance with minor effects. This assures that conditions are maintained over the long term.

While permit processes implemented by the US Army Corps are thorough and actions authorized are protective of aquatic resources, the program lacks personnel resources to insure that terms and conditions of permitted actions are followed. In addition, this agency lacks resources to adequately monitor waterways for non-permitted actions or act upon non-permitted situations reported by other agencies or private parties. See State of Oregon programmatic review -- Appendix F for ODSL.

The USFS land exchange program has the potential to bring existing private lands under federal ownership and PACFISH protections. However, this program is completely voluntary on the landowner's part and the landowner would acquire public land and could very likely lower standards of resource protection. The land exchange is, however, a tool that could be used under very controlled circumstances to see increased protection of important aquatic habitats. But the purpose of the program is focused on consolidating land holdings and not necessarily protection of habitat.

The Umatilla and Walla Walla Agricultural Water Quality Management (AgWQM) Area Rules require that management on agricultural lands allow the establishment, growth and maintenance of riparian or stream-side vegetation, consistent with site capability, to promote habitat and protect water quality by filtering sediment, stabilizing streambanks, naturally storing water, and providing shade. The AgWQM program is outcome-based rather than prescriptive, therefore allows landowners the flexibility to achieve water quality goals using available equipment, technology and innovation. The rules for each Management Area provide the enforceable backstop to the voluntary initiatives. The SWCDs are the local management agencies that provide the outreach, education and technical assistance. ODA is responsible for complaint investigations and enforcement actions. Technical and financial assistance is available through state and federal programs to landowners for establishing adequate riparian areas.

The CREP program agreements are for durations of 10 or 15 years. There is no guarantee that the benefits and management actions will be continued beyond the duration of the agreements.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Remove or replace barriers blocking passage such as dams, bridges, road culverts and irrigation structures	Priorities shown in Table 8-38. See Appendix G for the 22 culverts that need replacement.	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure, diversity	Primarily adults and 0+juveniles	A comprehensive on-the-ground survey of passage barriers in the Oregon portion of the subbasin has not been completed. All passage barriers in known steelhead habitat should be addressed in a prioritized fashion.
Construct ladders over existing permanent irrigation diversions	Priorities shown in Table 8-38	Impaired fish passage	Dams	Abundance, productivity, spatial structure, diversity	Primarily adults and 0+juveniles	
Operate and Maintain fish passage facilities	Diversions within current steelhead distribution are first priority (1)	Impaired fish passage and entrainment	Dams, culverts and Irrigation diversions	Abundance, productivity, spatial structure, diversity	All	There are cooperative projects in place in the Walla Walla subbasin to both physically maintain the facilities and provide biological oversight so they are operated to maintain optimum fish passage conditions.
Provide screening at 100% of irrigation diversions	Unscreened diversions within current steelhead distribution are first priority (1)	Impaired fish passage	Irrigation diversions	Abundance, productivity	All	In Oregon, all known gravity flow diversions are screened to NOAA criteria. It is not known to what extent that pump diversions are screened in the Oregon part of the subbasin. Pump diversions should be inventoried and addressed as soon as possible. The Little Walla Walla system is screened at the point of diversion, but diversions within this system where steelhead could be present, by swimming up the outlet in Washington, are not currently screened.
Replace screens that do not meet criteria	Diversions within current steelhead distribution are first priority (1)	Impaired fish passage	Irrigation diversions	Abundance, productivity	All	There are cooperative projects in place in the Walla Walla subbasin to maintain facilities and provide oversight so they are operated to maintain optimum fish passage conditions.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove or replace barriers blocking passage such as dams, bridges, road culverts	ODFW, CTUIR, WWBWC, CDs, TSS, road departments, private landowners	Ongoing	Fish access upstream of obstruction	Known issues addressed within 10 years	Immediate	High

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
and irrigation structures						
Construct ladders over existing permanent irrigation diversions	ODFW, CTUIR, WWBWC, CDs, TSS, private landowners	Ongoing	Fish access upstream of obstruction	Known issues addressed within 10 years	Immediate	High
Operate and Maintain fish passage facilities	CTUIR, ODFW, HBDIC, GFID,, private landowners	Ongoing	Facility site	ongoing	Immediate	High
Provide screening at 100% of irrigation diversions	ODFW, CTUIR, private landowners	Ongoing	Point of diversion	Status of most pump diversions unknown, remediation up to10-20 yrs	Immediate	High
Replace screens that do not meet criteria	ODFW, CTUIR, private landowners	Ongoing	Point of diversion	Status of most pump diversions unknown, remediation up to 10-20 yrs	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTUIR	BPA Fish Passage program		No	More funding needed.
ODFW	Fish Screening Program		Yes, for gravity diversions	Need to inventory and address pump screening.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

It is currently unknown to what extent pump diversions in the Oregon portion of the subbasin are adequately screened. Pump diversion should be inventoried to determine screening status and all diversions screened to NOAA criteria. Washington currently has an initiative underway to provide landowners with funding to screen their diversions. This effort should be continued until all diversions are adequately screened. There is also a need for a comprehensive inventory of screening needs throughout the Oregon portion of the basin as this has not been done to date.

Table 8-38 is a list of known passage barriers in the Walla Walla subbasin in the area occupied by the Walla Walla steelhead population. These barriers should be addressed in a prioritized manner.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn (2).	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	All	Watershed scale problems and riparian management issues should be considered before active stream channel restoration is employed.
Reconnect side channels and off-channel habitats to stream channels	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn (2); Little Walla Walla System (2); Yellowhawk System (2).	Degraded floodplain, altered hydrology, habitat quantity and diversity,	Removal of side channels, off-stream habitat	Abundance, productivity	All	Channel reconstruction, placement of instream structures and large woody debris in concert with riparian restoration can be used to restore functionality of stream channels. Watershed scale problems and riparian management issues should be considered before active stream channel restoration is employed. In areas where direct and immediate

Strategy 3. Maintain and restore floodplain connectivity and function.						
						benefits to viability parameters can be addressed, large woody should be placed to improve ecosystem function. In areas where other habitat deficiencies, such as flow and water quality, also exist, restoration should focus on these other factors first.
Remove dikes and levies	Walla Walla R., Mill Cr. to forks (1)	Degraded floodplain connectivity, channel structure and complexity	Stream channelization, bank armoring	Abundance, productivity	All	Many streams in the subbasin are bordered by dikes and levies.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	Subbasin-wide	Degraded floodplain connectivity, channel structure/complexity, flow, water quality, sediment	Loss of beaver dams	Abundance, productivity	all	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplains to channels	ODFW, WWBWC, SWCD, USFS, CTUIR, WDFW, BLM, Tri-state Steelheaders (TSS)	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Short term, once identified	Physical response will be immediate for some, others will develop over years to decades	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Reconnect side channels and off-channel habitats to stream channels	ODFW, WWBWC, SWCD, USFS, CTUIR, , WDFW, BLM, Tri-state Steelheaders	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Short term, once identified	Physical response will be immediate for some, others will develop over years to decades	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Remove dikes and levies	CTUIR, WWBWC, COE, private landonwers	When opportunity identified	Within the stream reach and reaches downstream for temp and sediment	10+ years	Improved stream and floodplain functions - Some benefits will be realized immediately and others will develop over years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	ODFW, WDFW, private landowners	Ongoing	Subbasin-wide	Long term	Undefined	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTUIR	BPA Habitat Program	Subbasin-wide	No	More funding needed.
SWCD, CD's, WWBWC/TSS	Watershed Restoration	Subbasin-wide	Uncertain	More funding/implementation needed.
ODOT, County road depts, Municipalities	Bridge maintenance	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
FSA, NRCS, SWCD, CD's	CREP, CCRP, CRP, EQIP	Subbasin-wide	Varies by program	Additional implementation needed.

Strategy 3. Maintain and restore floodplain connectivity and function.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
Intensive land uses within Walla Walla subbasin flood plains and upslope habitats have led to dramatic changes in waterway characteristics since arrival of Euro-American pioneers during the middle 1800's. The common outcomes of intensive land use activities in the subbasin include: 1) straight, incised channels with minimal woody riparian vegetation, and 2) wide channels with increased dynamics and minimal woody riparian vegetation. Site specific measures will be implemented within the context of an overall hierarchical strategy for prioritizing restoration actions. As implementation actions are planned, consideration will be first given to actions that address watershed processes and passive techniques, but artificial enhancement methods will be used where previous watershed assessment (2004) indicate that such work will lead to significant benefits for Mid-C steelhead and alternative approaches are not available.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature, flows	Stream channelization, bank armoring, large wood removal, loss of beaver damsl, removal of riparian vegetation areas	Abundance, productivity	All	Stream channel reconstruction and instream structures can be designed to correct channel stability problems. Where appropriate, passive treatments are preferred.
Place stable wood and other large organic debris in streambeds	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Removal of large wood, trees in riparian areas; channelization and streambank armoring, livestock grazing	Abundance, productivity	Fry to adult	Large, complex pools and riffle habitats with appropriate sized spawning gravels are missing within many areas. The preferred approach is to allow natural processes to restore these habitat elements. EDT has identified locations where significant benefit would occur if pools were introduced.
Stabilize and protect streambanks	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, bank armoring, livestock grazing in riparian areas	Abundance, productivity	Eggs, fry and adults	Incised or over steepened stream channels that reduce riffle habitat should be repaired through passive and active approaches where water quality is currently adequate to support spawning and rearing.
Construct rock and log weirs to create pool habitats or elevate incised channels	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	large wood removal, loss of recruitment trees in riparian area	Abundance, productivity	Fry to adult	Pools should be constructed strategically where other alternatives are not likely to accomplish this need, or constraints will not allow natural processes to form them. Artificial enhancement of pools should only be performed in areas where other parameters such as water quality would allow immediate use/benefit to be realized.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Implement bridge maintenance BMPs	Subbasin-wide	Degraded channel structure and complexity	Stream channelization, bank armoring	Abundance, productivity	All	Many streams in the subbasin are bordered by dikes and levies.
Educate landowners on importance of LWD	Subbasin-wide	Loss of pool habitat, channel structure and complexity	Large wood removal	Abundance and productive	all	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, CTUIR, WWBWC, CDs, WDFW, BLM	Ongoing; some needs identified in ODFW/CTUIR five-year action plan	Within the stream reach and reaches downstream for temp and sediment	25 years	Improved riparian vegetation and associated attributes and improved stream and floodplain structure and function; response time immediate to 10 years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Place stable wood and other large organic debris in streambeds	ODFW, WWBWC, CTUIR, CDs, WDFW, TSS, BLM	Ongoing as needed	Reach affected	Short term	Improved instream channel habitat diversity - Some benefits will be realized immediately and others will develop in 1-5 years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Stabilize and protect streambanks	ODFW, CTUIR, SWCD, CDs, WWBWC, BLM, private landowners	Ongoing; when specific opportunity identified	Within the stream reach and reaches downstream for temp and sediment	10+ years	Improved water quality – response time 1-5 years	High, but there is more risk with active restoration approaches in experiencing undesirable outcomes
Construct rock and log weirs to create pool habitats or elevate incised channels	ODFW, CTUIR, CDs, WWBWC, TSS	Ongoing; current action planned for Meacham Cr.	Treatment site	25 years	Increased quantity of pool habitat and channel and floodplain function – response time Immediate to 5 years	High over short term, however structures often require maintenance
Implement bridge maintenance BMPs	USFS, ODOT, WDOT, County road departments	Ongoing	Site specific	Long term	Improved LWD and water quality; slow response time	Moderate, depends on compliance with BMPs
Educate landowners on importance of LWD	Stellar, WWBWC, ODFW, BLM, CTUIR	Ongoing	Subbasin-wide	Long term	Variable lag time depending on actions	Moderate

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTUIR	BPA Habitat Program		No	More funding needed.
SWCD, CD's	Watershed Restoration		Likely	Involvement is currently limited. See State of Oregon programmatic review – Appendix F.
WWBWC/Tri-state Steelheaders	Watershed Restoration		No	There is a continuing need for landowner assistance to insure that issues are dealt with appropriately.
ODOT, County road depts.	Bridge maintenance			See State of Oregon programmatic review -- Appendix F.
FSA, NRCS, SWCD, CD's	CREP, CCRP, CRP, EQIP		Varies by program	Additional implementation needed.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

See discussion in Strategy 3, Walla Walla River population.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded riparian area, channel stability, floodplain degradation, sediment, water temperature	Livestock grazing, channelization, stream bank armoring	Abundance, productivity, diversity	All	Historically, bank armoring with rock and channelization were used to stabilize stream banks at the detriment of riparian vegetation growth. In the last 15 years the high economic and ecological cost of bank armoring with riprap and of channelization has been recognized, so the emphasis has shifted toward a more passive approach for stabilization, primarily through riparian vegetation improvements and bioengineering treatments
Develop grazing strategies that promote riparian recovery	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded riparian area, channel stability	Livestock overgrazing of riparian area	Abundance, productivity, diversity	All	Grazing strategies, other than exclusion, should be developed to achieve riparian recovery in the next 10-15 years. Permanent or temporary exclusion of livestock from riparian areas remains the surest way to achieve riparian restoration where livestock have been the primary impact.
Develop no-cultivation riparian buffer on agricultural lands and establish riparian setbacks for structures in areas where activities could upset riparian function	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded riparian area, channel stability, floodplain degradation, sediment, water temperature	Degradation of riparian areas and function; residential development and cultivation	Abundance, productivity, diversity	All	In areas where development is occurring, that development should be adequately set back from streams so as not to interrupt natural stream processes. Ordinances pertinent to fish habitat and water quality must be enforced.
Riparian exclosure fencing	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded riparian area, channel stability	Livestock grazing	Abundance, productivity, diversity	All	Excluding livestock from riparian areas remains the most effective tool of mitigating livestock impacts.
Close, remove, and restore riparian road prisms	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded riparian area, channel stability, sediment	Roads	Abundance, productivity, diversity	All	In many areas of the Walla Walla subbasin, riparian roads have reduced riparian vegetation, confined stream channels, and continue to deliver fine sediment to channels. Relocat ing roads outside riparian and sensitive areas or eliminating roads from riparian and sensitive areas has a positive effect on steelhead habitat by allowing natural riparian processes to be restored.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Protect high quality riparian habitats and unstable areas	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr. (1); NF Walla Walla R., mouth to Little Meadows Cyn. (1); Little Walla Walla System (2); Yellowhawk System (2)	Degraded riparian area, channel stability, floodplain degradation, sediment, water temperature	All	Abundance, productivity, diversity	All	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities including vegetative planting	CTUIR, NRCS/FSA, WWBWC, SWCD, CDs, TSS, private landowners	Ongoing	High dispersal downstream from site	25 years	Improved riparian vegetation and associated attributes – response time 5 years to decades	Moderate – plant survival varies based on techniques used
Develop grazing strategies that promote riparian recovery	ODA, NRCS, USFS, CDs, private landowners	Ongoing	High dispersal downstream from site	Long term	Improved riparian vegetation and associated attributes – response time 5 years to decades	Depends on diligence of management applications
Develop no-cultivation riparian buffer on agricultural in areas where activities could upset riparian function	CTUIR, ODFW, WWBWC, WDFW, WDOE, private landowners, TSS, FSA/NRCS	Ongoing	Cultivated land in close proximity to priority habitat areas within the Umatilla subbasin	Long term	Immediate with continued improvement for up to 50 years or until easement ends and management changes. After 50 years habitat effectiveness will be maintained.	High
Riparian exclosure fencing	CTUIR,ODFW, NRCS/FSA, WWBWC, SWCD, CDs, private landowners, TSS	Ongoing	High dispersal downstream from site	25 years	Improved riparian vegetation and associated attributes – response time 5 years to decades	High
Close, remove, and restore riparian road prisms	USFS, ODOT, WDOT, counties, private landowners	Ongoing	Riparian areas within the subbasin where potential for riparian road closure and removal exists	Based on opportunity and need	Improved water quality – response time immediate with continued response for up to 50 years	High
Protect high quality riparian habitats and unstable areas	CTUIR, ODFW, NRCS/FSA, BLM, SWCD, USFS, WWBWC, CDs	Ongoing	High dispersal downstream	Long Term	Depends on specific situation	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODA, SWCD	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
FSA, NRCS, SWCD, CD's, WWBWC	CREP, CCRP, CSP, EQIP	Subbasin-wide	Varies by program	Greater participation by landowners is needed in Oregon. Many more stream miles to be treated. See State of Oregon programmatic review -- Appendix F.
ODFW	Fish Management Program	Subbasin-wide	Yes	
CTUIR	BPA Habitat Program		No	Many additional miles of stream need to be treated.
ODEQ	TMDL			See State of Oregon programmatic review -- Appendix F.
ODF	Forest Practices Act			See State of Oregon programmatic review -- Appendix F.
USFS, BLM	Grazing management, Forest Plan, Resource Management Plan, PACFISH		Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
The Oregon Walla Walla River Water Quality Management Areas Plan (WQMAP) provides general guidance to landowners on management of riparian areas and there is some uncertainty regarding the implementation of this plan's requirements, as enforcement is based on a complaint-driven system. While there are ongoing programs to restore riparian vegetation, determination of limiting factors through use of the EDT model indicates that additional coverage is necessary. The Umatilla and Walla Walla AgWQM Area Rules require that management on agricultural lands allow the establishment, growth, and maintenance of riparian or stream-side vegetation, consistent with site capability, to promote habitat and protect water quality by filtering sediment, stabilizing streambanks, naturally storing water, and providing shade. The AgWQM program is outcome-based rather than prescriptive, therefore allows landowners the flexibility to achieve water quality goals using available equipment, technology and innovation. The rules for each Management Area provide the enforceable backstop to the voluntary initiatives. The SWCDs are the local management agencies that provide the outreach, education and technical assistance. ODA is responsible for complaint investigations and enforcement actions. Technical and financial assistance is available through state and federal programs to landowners for establishing adequate riparian areas. The CREP program agreements are for durations of 10 or 15 years. There is no guarantee that the benefits and management actions will be continued beyond the duration of the agreements.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Investigate feasibility of water storage or exchange to improve instream flows for steelhead	Walla Walla River, mouth to Little Walla Walla diversion (1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity	Parr to adult	
Close areas to appropriation of new water uses	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (2); NF Walla Walla R., mouth to Little Meadows Cyn (1). Little Walla Walla System (1)	Flows	Water withdrawals	Abundance, productivity, diversity	Parr to adult	Surface water flows are over appropriated in many areas of the Walla Walla subbasin. The various legal means available should be used to increase streamflows where assessments indicate that there is on-going take, or where steelhead production could be increased
File for additional ISWRs	Pine Cr. (2), Birch Cr. (1), Cottonwood Cr. (1), Walla Walla R. downstream of Little Walla Walla (1)	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity	Parr to adult	
Set criteria to protect flows for fish habitat from new appropriations	Subbasin-wide in Washington	Flows, water quality	Water withdrawals	Abundance, productivity	Parr to adult	High flow events are critical for maintaining quality instream habitat, and water quality. With increasing water demands for agricultural, industrial, municipal and domestic uses, the potential for mining of high flow increases. It is important that planners realize the importance of high flows for the maintenance of aquatic habitats and water quality, and that these flows are protected.
Improve irrigation conveyance and efficiency	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (2); NF Walla Walla R., mouth to Little Meadows Cyn (1); Little Walla Walla System	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity	All	
Enhance hyporheic flows and spring inputs	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (2); NF Walla Walla R.,	Flows, water temperatures, habitat	Water withdrawals	Abundance, productivity,	All	

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
	mouth to Little Meadows Cyn (1).	quantity/diversity		diversity, spatial structure		
Implement shallow aquifer recharge	Little Walla Walla system (1)	Flow, temperature	Water withdrawals	Abundance, productivity	All	While progress has been made, many streams t historically flowed year- long are now intermitten creating fish passage barriers in the dewatered reaches. Many of these are due to water withdrawals for agricultural, industrial, municipal and domestic uses.
Aquifer storage and recovery	Lower Mill Cr. (1)	Flow, temperature	Water withdrawals	Abundance, productivity	All	
Lease or acquire water rights and convert to instream	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (2); NF Walla Walla R., mouth to Little Meadows Cyn (1).	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity, spatial structure	Parr to adult	
Downstream water rights transfers	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (2); NF Walla Walla R., mouth to Little Meadows Cyn (1).	Flows, water temperatures, habitat quantity/diversity	Water withdrawals	Abundance, productivity, diversity	Parr to adult	
Monitor/regulate water withdrawals	Subbasin-wide (1)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Parr to adult	
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Investigate feasibility of water storage or exchange to improve instream flows for steelhead	USACE, CTUIR	Ongoing	Mid and lower Walla Walla	Uncertain	Improvements to flow depend on timing, magnitude and location of flow enhancement	Now in planning stage; actual implementation actions and potential funding are unknown
Close areas to appropriation of new water uses in Washington	WDOE	On hold	Affected reaches and downstream	Uncertain	Maintenance of existing conditions	High
File for additional ISWRs	ODFW, OWRD	On hold	Specific to the stream reach	Unknown	Maintenance of existing conditions	High, depends on how resource managers implement protection
Set criteria to protect flows for fish habitat from new appropriations	WDOE, WDFW	Ongoing	Affected reaches and downstream	Uncertain	Maintenance of existing conditions	Unknown
Enhance hyporheic flows and spring inputs	WWBWC, CTUIR, CDs	Ongoing	On site and downstream	Long term	Improved instream flow and water quality – response time depends on specific action	Depends upon specific approach used
Improve irrigation conveyance and efficiency	SWCD, WWBWC, private landowners, irrigation districts	Ongoing	Depends on means used to protect instream flows	Short term	Improved instream flow; response immediate	Moderate – depends on how saved water is protected, if any.
Implement shallow aquifer recharge	WWBWC, WDOE, HBDIC, GDID, WWRID, private landowners		Down gradient	Long term	Improved instream flow – uncertain response time	Undetermined

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Aquifer storage and recovery	City of Walla Walla	Ongoing	Downstream of Mill Creek POD	Long term	Improved instream flow – uncertain response time	Long term effectiveness is unknown
Lease or acquire water rights and convert to instream	OWRD, Oregon Water Trust, water right holders	Ongoing, when opportunities arise	Depends on means used to protect instream flows	10-15 years	Immediate	moderate, depending upon how saved water is protected
Downstream water rights transfers	OWRD, private landowners, irrigation districts	Ongoing	Reach between old and new point of diversion	Long term	Improved instream flow; response immediate	High
Monitor/regulate water withdrawals	OWRD, WDOE	Ongoing	From the point of diversion downstream to the mouth of Walla Walla River	Long term	Maintenance or improvement of existing conditions; response to regulation immediate	Moderate, staffing levels are inadequate
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USACE, CTUIR	Flow Restoration Feasibility Study	Lower Walla Walla	Unknown	
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust, BPA	Leasing and Purchase of Water Rights	Walla Walla River	No	Needs expansion.
SWCD, Watershed Council, WWRID, HBDIC, GFID	Improve irrigation efficiency	Walla Walla R., Mill Cr. to forks; SF Walla Walla mouth to Elbow Cr; NF Walla Walla R., mouth to Little Meadows Cyn.	Varies by program	Needs expansion.
NRCS, Watershed Council	Upland improvements, riparian improvements	Subbasin-wide	No	Needs expansion.
ODF	Forest Practices Act	Subbasin-wide	Likely	See State of Oregon programmatic review -- Appendix F.
BPA	Columbia Basin Water Transaction Prgm	Walla Walla R., Mill Cr. to forks; SF Walla Walla mouth to Elbow Cr.; NF Walla Walla R., mouth to Little Meadows Cyn.	No	Needs expansion.
WDOE	Water Management Initiative	Walla Walla R., Mill Cr. to forks		

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Significant progress has been made regarding flow issues on the mainstem Walla Walla River as a result of the Civil Penalty Agreement between the USFWS and three irrigation districts. However, significant flow issues remain along the Walla Walla River, NF Walla Walla R., Couse Cr., Dry and Pine creeks (Oregon) and Mill Creek. The Walla Walla subbasin has approximately 50 miles of stream protected by instream water rights. Voluntary flow restriction projects restored 4.4 cfs of flow in 2006.

The Walla Walla subbasin has approximately 50 miles of stream protected by instream water rights. Voluntary flow restoration projects restored 4.4 cfs of flow in 2006.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Address point sources of water pollution	Pine Creek (1), Walla Walla River (1)	Chemical pollution	Pesticides, fertilizers, herbicides	Abundance, productivity	All	Point sources of water pollution are direct impacts that should be corrected through implementation of the TMDL and associated water quality management plan.
Implement pest management plans for fruit growers	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (1); NF Walla Walla (1)	Water quality	Pesticides, fertilizers, herbicides	Abundance, productivity	All	
Improve municipal stormwater management and treatment	Walla Walla R., Mill Cr. to forks (1)	Water quality	Stormwater management	Abundance, productivity	All	
Permit waterway alteration activities and enforce rules	Subbasin-wide					
Implement water quality management plans	Walla Walla River (1)	Degraded water quality, flows, sediment routing, water quality	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	All	
Permit and enforce actions that could affect water quality	Subbasin-wide	Water quality	Land use practices,	Abundance, productivity, diversity	All	Directed actions at known sources of thermal pollution and sediment should be addressed through BMPs and improvement projects.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Address point sources of water pollution	ODEQ, WDOE	Ongoing	Subbasin-wide	Ongoing	Reduce chemical pollution immediately	High
Implement pest management plans for fruit growers	ODEQ, OSU, Ext. WWBWC, fruit growers	Ongoing	NF, SF, mainstem Walla Walla and Little Walla Walla system	Long Term	Reduced mortality of food items and issues with fish toxicology – minor response expected	Moderate
Improve municipal stormwater management and treatment	municipalities	Ongoing	Within city limits. High dispersal downstream	Long term	Improved water quality – immediate response	Uncertain
Permit waterway alteration activities and enforce rules	USACE, ODSL	Ongoing	Subbasin-wide	Ongoing	Variable lag time depending on actions	Moderate, current implementation of permit requirements are very specific and conservative
Implement water quality management plans	ODA, SWCD, Municipalities, CDs, USFS, BLM, ODF, Irrigation Districts, private landowners, Industry, ODEQ	Ongoing	High dispersal downstream	Ongoing	Immediate	Moderate – degree of implementation is uncertain

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Permit and enforce actions that could affect water quality	ODEQ, WDOE	Ongoing	Subbasin-wide	Ongoing	Variable lag time depending on actions	Ability of agencies to enforce water quality violations appears limited by staffing.

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODA, SWCD	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
FSA, NRCS, SWCD, CD, WWBWC	CREP, CCRP, CSP, EQIP	Subbasin-wide	Varies by program	Greater participation by landowners is needed in Oregon. Many additional miles of stream to be treated. See State or Oregon programmatic review – Appendix F.
CTUIR	BPA Habitat Program	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (2).; NF Walla Walla R., mouth to Little Meadows Cyn (1).	No	Many additional miles of stream to be treated.
USFS, BLM	Grazing management, Forest Plan, PACFISH	Upper Subbasin	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
USACE/ODSL	Waterway work permitting	Subbasin-wide	Uncertain	See State of Oregon programmatic review -- Appendix F for ODSL.
ODF	Forest Practices Act	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODEQ	Water Quality	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODEQ, EPA	Pesticides/Toxics	Subbasin-wide		See State of Oregon programmatic review -- Appendix F for ODEQ.
Municipalities	Public Works		No	

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

This threat is partially addressed by the Oregon Walla Walla River WQMAP, see discussion for Strategy in Section 5.

Implementation of PACFISH standards and guides for Forest and BLM programs, in conjunction with Forest Plan Management Area allocations, has been highly successful for passive upland restoration over most of this population's area.

The TMDLs set loading capacity to achieve water quality standards. To address high summer water temperatures, near stream vegetation disturbance, channel widening and low flows are the existing sources of increased solar radiation loading. Achievement of the TMDL targets is dependent of determination of system potential vegetation. During TMDL development, the best professional judgment of the team described the potential streamside shade-producing vegetation broadly, as continuous tree-belts on each side of the river.

While permit processes implemented by the US Army Corps of Engineers are thorough and actions authorized are protective of aquatic resources, the program lacks personnel resources to insure that terms and conditions of permitted actions are followed. In addition, this agency lacks resources to adequately monitor waterways for non-permitted actions or act upon non-permitted situations reported by other agencies or private parties. See State of Oregon programmatic review -- Appendix F for ODSL.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore native upland plant communities	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (1); NF Walla Walla R.,	Altered hydrology, sediment routing, channel stability,	Forestry, roads, overgrazing,	Abundance, productivity	All	

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
	mouth to Little Meadows Cyn (1).	floodplain and riparian area degradation, water quality	agricultural practices, noxious weeds			
Upgrade or remove problem forest roads	NF Walla Walla (1), SF Walla Walla (1)	Altered hydrology, sediment routing	Road network	Abundance, productivity	All	
Control noxious weeds through physical removal and chemical and biological agents	Subbasin-wide	Loss of native vegetation and watershed function	Noxious weed	Abundance, productivity	All	Control of noxious weeds is generally an issue that is not currently being addressed adequately at a regional scale.
Implement CREP and CCRP buffers	Walla Walla R., Mill Cr. to forks (1); SF Walla Walla mouth to Elbow Cr (1); NF Walla Walla R., mouth to Little Meadows Cyn (1)	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Agricultural practices	Abundance, productivity	All	
Initiate upland improvement demonstration projects	Subbasin-wide	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	All	
Conduct outreach to resource users and managers	Subbasin-wide	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	All	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Apply BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Subbasin-wide	Altered hydrology, sediment routing	Forestry, roads, overgrazing, agricultural practices, noxious weeds	Abundance, productivity	All	Upland land management practices affect the hydrologic function of the watershed, by causing rapid runoff rather than infiltration. BMPs should be implemented to insure that the watershed functions to its potential, given the anthropogenic influence in the watershed.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore native upland plant communities	SWCD, USFS, NRCS, BLM, ODF, Counties, private landowners	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term		
Upgrade or remove problem forest roads	BLM, ODF, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff.	5-15 years	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Control noxious weeds through physical removal and chemical and biological agents	County public works dept., public and private landowners, USFS, BLM	Ongoing	Subbasin-wide	Long term	Improvements to water quality expressed in decades	Uncertain. This is a broad landscape issue that is currently underfunded

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Implement CREP and CCRP buffers	FSA, NRCS, SWCD, CDs, private landowners	Ongoing, when opportunities available	High dispersal downstream	Depends on funding availability	5 years to decades	High
Initiate upland improvement demonstration projects	ODFW, WDFW, NMFS, USFWS, USFS, BLM, CTUIR, WWBWC, WDOE, SWCDs, CDs, TSS	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed
Conduct outreach to resource users, managers, general public	ODFW, WDFW, NMFS, USFWS, USFS, BLM, CTUIR, WWBWC, WDOE, SWCDs, CDs	Ongoing	Entire subbasin	Long term	Variable lag time depending on actions	Unknown
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Apply BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	NRCS, ODF, USFS, BLM, WDOE, SWCD, CDs, ODA, CTUIR, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term	Improvements to water quality expressed in years to decades; improvements in riparian vegetation and all associated attributes response time 5 years to decades	Moderate, depends on participation

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTUIR	Rainwater	Subbasin-wide	Yes	Maintain current project.
County Public Works	Weed Control	Subbasin-wide	No	Funding not adequate to meet the needs.
ODA	Agricultural Water Quality Management Program	Subbasin-wide		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
SWCD/CD's	Watershed restoration	Subbasin-wide	Uncertain	
FSA,NRCS, SWCD, CD's	CREP,CCRP,CRP,EQIP	Subbasin-wide	Varies	Needs more coverage. See State of Oregon programmatic review -- Appendix F for SWCD.
ODOT	Weed control	Subbasin-wide		Program reviewed in State assessment.
Municipalities	Public Works	Subbasin-wide	No	Additional improvements needed.
SWCD	Direct Seed Program			Additional landowner assistance needed.
USFS, BLM	Forest Plan, Resource Management Plan, PACFISH	Federal lands	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
Additional effort is needed to protect native plant communities and associated watershed functions. Vegetation management across the watershed varies in approach widely.

Table 9-3. Restoration Priority Geographic Areas from the Walla Walla Subbasin Plan (NPCC 2004).

GA	Description
27	Walla Walla River, Mill Cr. to East Little Walla Walla
31	Walla Walla River, East Little Walla Walla to Tumalum Bridge
35	Walla Walla River, Tumalum Bridge to Nursery Bridge
36	Walla Walla River, Nursery Bridge to Little Walla Walla Diversion
37	Walla Walla River, Little Walla Walla Diversion to forks
41	South Fork Walla Walla, mouth to Elbow Creek
39	North Fork Walla Walla, mouth to Little Meadows Canyon (plus Little Meadows Can.)
3	Coppei Drainage
4	Touchet River, Coppei to forks
10	South Fork Touchet Mainstem
11	South Fork Touchet Tribs
6	North Fork Touchet Mainstem
7	North Fork Touchet Tribs (excluding Wolf Fork)
8	Wolf Fork, mouth to Coates (plus Robinson and Coates)
9	Wolf Fork, Coates to access limit (plus Whitney)

Table 9-4. Protection Priority Geographic Areas from the Walla Walla Subbasin Plan (NPCC 2004).

GA	Description
	All Priority Restoration Geographic Areas
43	South Fork Walla Walla, Elbow to access limit
45	Skiphorton and Reser Creek Drainages
42	Lower SF Wall Walla Tribs (Flume Canyon, Elbow)
44	Upper SF Walla Walla Tribs (excluding Skiphorton and Reser)
40	North Fork Walla Walla, Little Meadows to access limit (plus Big Meadows)
5	Patit Drainage
17	Walla Walla River, Dry to Mill
32	Yellowhawk mainstem (mouth to source)
	Headwaters**
38	Couse Creek Drainage

**Headwaters is an assemblage of reaches covering the bull trout bearing (present or potential) waters upstream of the present reaches designated through the EDT process.

Table 9-5. Walla Walla Subbasin Geographic Areas.

GA	Stream	Segment	MaSA	MiSA
1	Walla Walla River	Mouth to Touchet River		
2	Touchet River	Mouth to Coppei Creek	NA	NA
3	Coppei Drainage	Mouth to presumed Steelhead access limit	NA	NA
4	Touchet River	Coppei to forks, including Whiskey Creek	NA	NA
5	Patit Drainage	Mouth to presumed steelhead access limit	NA	NA
6	North Fork Touchet	Mouth to presumed steelhead access limit	NA	NA
7	North Fork Touchet tribs	Rodgers, Jim, Weidman, Lewis and Spangler creeks; all from mouths to presumed steelhead access limit	NA	NA
8	Wolf Fork	Mouth to Coates Creek; also includes Robinson Cr and Coates Cr; mouths to presumed steelhead access limit	NA	NA
9	Wolf Fork	Coates Cr to presumed steelhead access limit; also includes Whiskey Cr mouth to presumed steelhead access limit	NA	NA
10	South Fork Touchet	Mouth to presumed steelhead access limit	NA	NA
11	South Fork Touchet tribs	Dry Fork SF Touchet, Griffin Fork, North Griffin Fork, Beaver Slide, Green Fork and Burnt Fork; mouths to presumed steelhead access limits	NA	NA
12	Walla Walla River	Mouth Touchet River to Dry Cr, including Mud Cr mouth to presumed steelhead access limit		
13	Pine Creek	Mouth to presumed steelhead access limit and Swartz Cr mouth to presumed steelhead access limit	Pine	

GA	Stream	Segment	MaSA	MiSA
14	Dry Creek Drainage (Pine)	Dry Cr (trib to Pine) mouth to presumed steelhead access limit	Pine	
15	Lower Dry Cr	Dry Cr (trib to Walla Walla), mouth to Sapolil Rd crossing	Dry	
16	Upper Dry Cr	Dry Cr (trib to Walla Walla). Sapolil Rd crossing to confluence of NF and SF Dry creeks	Dry	
17	Dry Cr tribs	Mud Cr (trib to Lower Dry Cr) , Mud Cr (trib to Upper Dry Cr, NF Dry Cr and SF Dry Cr; mouths to presumed steelhead access limit	Dry	
18	Walla Walla River	Dry Cr to Mill Cr		
19	West Little Walla Walla	West Little Walla Walla River Drainage and Walsh Cr drainage		
20	Mill Cr	Mouth to start of US Army Corps of Engineers project at Gose St near Walla Walla	Mill	
21	Mill Cr	Gose St to Bennington Dam	Mill	
22	Mill Cr	Bennington Dam to Blue Cr and Titus Cr drainage	Mill	
23	Blue Cr Drainage	Mouth to presumed steelhead access limit and Little Blue Cr mouth to presumed steelhead access limit	Mill	
24	Mill Cr	Blue Cr to City of Walla Walla water intake	Mill	
25	Middle Mill Cr tribs	Henry Canyon Cr, Webb Canyon Cr, Tiger Canyon Cr; mouth to presumed steelhead access limit	Mill	
26	Mill Cr	City of Walla Walla Water intake to presumed steelhead access limit	Mill	
27	Upper Mill Cr tribs	NF Mill Cr, Low Cr, Broken Cr, paradise Cr; mouth to presumed steelhead access limit	Mill	
28	Walla Walla River	Mill Cr to East Little Walla Walla River and McEvoy Cr and Springbranch		
29	Garrison Cr Drainage	Includes Bryant Cr and all Walla Walla Urban streams	Cottonwood	
30	Stone Cr Drainage	All	Cottonwood	
31	East Little Walla Walla Drainage	East Little Walla Walla Drainage; Unnamed Spring; Big Spring Cr, mouth to presumed steelhead access limit		
32	Walla Walla River	East Little Walla Walla To Tumalum Bridge	Walla Walla	
33	Yellowhawk mainstem	Yellowhawk drainage mouth to source	Cottonwood	
34	Cottonwood Cr Drainage	Including NF, MF and SF, mouth to presumed steelhead access limit	Cottonwood	
35	Birch Creek Drainage	Mouth to presumed steelhead access limit	Walla Walla	
36	Walla Walla River	Tumalum Br to Nursery Br	Walla Walla	
37	Walla Walla River	Nursery Br to Little Walla Walla Diversion	Walla Walla	
38	Walla Walla River	Little Walla Walla Diversion to forks	Walla Walla	
39	Couse Cr	Mouth to presumed steelhead access limit	Walla Walla	
40	North Fork Walla Walla	Mouth to Little Meadows Canyon and Little Meadows Canyon mouth to presumed steelhead access limit	Walla Walla	
41	North Fork Walla Walla	Little Meadows Canyon to Big Meadows Canyon and Big Meadows Canyon mouth to presumed steelhead access limit	Walla Walla	
42	South Fork Walla Walla	Mouth to Elbow Cr	Walla Walla	
43	Lower SF Walla Walla tribs	Flume Canyon Cr and Elbow Cr, mouth to presumed steelhead access limit	Walla Walla	
44	South Fork Walla Walla	Elbow Cr to presumed steelhead access limit	Walla Walla	
45	Upper South Fork Walla Walla tribs	Bear Cr, Kees Canyon Cr, Burnt Cabin Gulch, Swede Canyon, Table Cr, Husky Spring Cr, Bear Trap Springs; mouth to presumed steelhead access limit	Walla Walla	
46	Skiphorton & Reser Creek drainages	Mouth to presumed steelhead access limit	Walla Walla	

Note: Minor spawning areas within the Walla Walla subbasin not represented include: Woodward Canyon, Switzler, Vansyckle Canyon, Juniper, Spring Valley and Below Spring Valley.

9.4 Hydrosystem Strategies and Actions

Hydropower system operations and configurations on the mainstem Columbia remain a major factor limiting the viability of the Mid-Columbia River steelhead DPS. The ICTRT (2006) ranked the mainstem hydrosystem as one of the key limiting factors. Tributary dams that provide hydroelectric power also block and/or impair steelhead passage and habitats in several populations.

9.4.1 Mainstem Columbia River Hydropower Operations and Configurations

Recovery strategies and actions address both configurations and operations of the Columbia River hydroelectric system. Actions range from improving passage at particular dams to addressing flow and temperature issues. The following mainstem hydropower strategies and management actions include actions from the May 2008 Biological Opinion for the Federal Columbia River Power System (NOAA Fisheries 2008), as well as additional and alternative actions recommended by the State of Oregon. It is the position of the State of Oregon that additional or alternative actions should be taken in mainstem operations of the FCRPS for ESA-listed salmon and steelhead. Some additional or alternative actions recommended by Oregon, while considered, were not included in the FCRPS action agencies' proposed action or NOAA's FCRPS Biological Opinion. At the time this proposed recovery plan was being finalized, Oregon was a plaintiff in litigation against various federal agencies, including NOAA, challenging the adequacy of the measures contained in the current FCRPS Biological Opinion. Mainstem hydrosystem actions that improve survival are considered high priority because the survival benefits will be realized by all populations in the Mid-C DPS. We have provided a summary of strategies and reasonable and prudent alternatives (RPAs) taken directly from the FCRPS BiOp followed by the additional and alternative actions sought by the State of Oregon.

> *Hydropower Strategy 1*: Operate the FCRPS to provide flows and water quality to improve juvenile and adult fish survival.
>
> RPA 4: The action agencies will operate the FCRPS storage projects for flow management to aid anadromous fish.
>
> RPA 5: The action agencies will operate the FCRPS run-of-river mainstem lower Columbia River and Snake River projects to minimize water travel time through the lower Columbia and Snake rivers to aid in juvenile fish passage.
>
> RPA 6: In-season water management via water management plans and by the Regional Forum.
>
> RPA 7: To address forecasting and climate change/variability the action agencies will hold annual forecast performance reviews and report on effectiveness of experimental or developing/emerging technologies.
>
> RPAs 8-9: Manage for operations and fish emergencies.

RPAs 10-13: Columbia River Treaty and non-Treaty storage management, agreements, and coordination.

RPA 14: Manage flow during dry years to maintain and improve habitat conditions for ESA-listed species.

RPA 15: The action agencies will continue to update the Water Quality Plan for Total Dissolved Gas and Water Temperature temperature in the mainstem Columbia and Snake rivers, and implement water quality measures to enhance ESA-listed juvenile and adult fish survival and maintain spawning and rearing habitat.

Hydropower Strategy 2: Modify Columbia and Snake river dams to maximize juvenile and adult fish survival.

RPAs 18-21: The Corps will prepare, in cooperation with NOAA Fisheries and co-managing agencies, configuration and operational plans for the Bonneville Project (2008), The Dalles Project, John Day Project (2008) and McNary Project (2009).

RPA 27: The action agencies will operate turbine units to achieve best fish passage survival (currently within 1% of best efficiency at mainstem dams on the lower Columbia and lower Snake rivers.

RPA 28: The Corps will implement structural improvements to adult passage at the mainstem Columbia River and Snake River projects.

Hydropower Strategy 3: Implement spill and juvenile transportation improvements at Columbia River and Snake River dams.

RPA 29: The Corps and BPA will provide spill to improve juvenile fish passage while avoiding high TDG supersaturation levels or adult fallback problems.

RPA 30: Continue the juvenile fish transportation program toward meeting system survival performance metrics.

Hydropower Strategy 4: Operate and maintain facilities at Corps' mainstem projects to maintain biological performance.

RPA 32: The Corps will prepare annually a fish passage plan in coordination with NOAA and the Regional Forum. The Corps will operate its projects year around in accordance with the criteria in the fish passage plan.

At the time this proposed recovery plan was finalized, it was the position of the State of Oregon that additional or alternative actions should be taken in mainstem operations of the FCRPS for ESA-listed salmon and steelhead.

The State of Oregon recommends the following additional and alternative actions to better address survival and recovery needs of Mid-Columbia steelhead (see State of Oregon (2008) comments on Draft 2007 FCRPS Biological Opinion and State of Oregon's Supplemental Complaint-In-Intervention For Declaratory and Injunctive Relief (July 22, 2008) for detailed actions included here by reference).

- Draft storage reservoirs to meet lower Columbia summer flow and velocity equivalent objectives on a seasonal and weekly basis.
- Operate reservoirs at rule curves and seek additional flow augmentation volumes from Snake River and Canadian reservoirs to better meet spring and summer flow and velocity objectives.
- Operate John Day reservoir at minimum operating pool during spring and summer as long as barge transport and irrigation needs are met.
- Provide spill to total dissolved gas limits of water quality waivers or biological constraints at all dams, except maximize transportation at Snake River collector projects during lowest (10^{th} percentile) flow years.
- Maintain approximately 50/50 in-river and transportation proportions for spring and summer migrants in the Snake River by optimizing spill and surface-oriented routes of dam passage and transporting fish collected in the turbine screen bypass systems.
- Continue to provide spill and bypass all fish at McNary Dam at all flows during the spring migration period.
- Before reducing full spill, test removable spillway weirs and temporary spillway weirs to ensure they provide equal or better benefits than full spill.
- Establish more rigorous research, monitoring, and evaluation to assure that fish survival is increasing and to inform adaptive management.
- Identify and prepare contingency actions for implementation if necessary to meet fish performance standards linked to survival and recovery requirements of listed fish.

9.4.2 Tributary Hydropower Operations and Configurations

Hydropower development and operations affect the viability of four existing Mid-C steelhead populations in Oregon: Deschutes River Eastside, Deschutes River Westside, Umatilla River and Walla Walla River. The dams are also key factors affecting the potential recovery of now extinct steelhead populations in the Crooked River and Willow Creek systems.

Deschutes River Populations
The following strategies and actions are for the Deschutes Westside, Deschutes Eastside and extinct Crooked River populations. They focus on developing effective downstream collection and passage of steelhead smolts through the Pelton-Round Butte Complex on the Deschutes River. The passage strategy at the complex is to construct a Selective Water Withdrawal (SWW) and a Fish Collection Facility. The SWW is designed to modify flow patterns in the reservoir so that fish will be attracted to the entrance of the facility during their out-migration. The fish will them be enumerated, marked and transported to the lower Deschutes River, to continue their out-migration. The construction of the selective water withdrawal is scheduled for completion in 2009. The SWW will also have an intake near its bottom, so it can draw cold water during summer and fall to mix with warmer surface water. This will maintain appropriate downstream

temperatures in the lower Deschutes River. An adaptive management strategy will continue to be used to implement facility improvements based on monitoring and evaluation with the goal of achieving high passage efficiencies at the barrier.

Strategy 1: Restore sustainable natural steelhead production to blocked habitats in the Deschutes River Westside, Deschutes River Eastside, and the extinct Crooked River populations.

Management actions

1. Develop effective downstream collection and passage for smolts through the Pelton-Round Butte Complex.
2. Improve flow patterns through the reservoir to provide effective juvenile migration.
3. Modify Pelton-Round Butte Complex operating procedures to restore downstream water quality to meet State and Tribal water quality criteria.

Success in re-establishing runs of summer steelhead above Pelton-Round Butte Complex will depend substantially on the degree to which the new SWW and fish collection facility enable the steelhead to migrate effectively from the mouths of tributary streams and past Lake Billy Chinook during their out-migration. Adaptive fish management and improvements to altered streams above LBC will both be important, but effective fish passage through the reservoir will be a necessary prerequisite to any success in establishing runs that can sustain themselves. With this in mind, reintroductions of steelhead will occur in two phases. Phase 1 will emphasize introductions of pathogen-screened juveniles above Pelton-Round Butte Complex, to test the ability of the new SWW facility to change surface currents in LBC and collect out-migrant smolts. Actions taken during Phase 1 will also (1) begin to test recent estimates of fish production potential in habitat above Pelton-Round Butte Complex, (2) examine fish stock performance in the available habitat, (3) continue rehabilitating altered habitats, and (4) produce modest returns of adult fish. When smolt passage through LBC and into the fish collection facility meets agreed-upon measures of success[1], the reintroduction program will transition into Phase 2 in which adults returning to the upper basin (i.e., after rearing as juveniles above Round Butte Dam) are passed upstream and continued releases of pathogen-screened juveniles into the upper basin will use fish of the fittest lineages available. The exact timing and/or duration of shifts toward more or less intense releases of juvenile fish during this second phase of the reintroduction effort may differ for each subbasin.

Reintroduction Phase 1. During Phase 1 of the reintroduction effort for summer steelhead, the numbers of fish released into specific upper basin streams will be based on interactions between

[1] Measures of success include changes in reservoir surface currents, effective migration patterns of radio-tagged smolts (a biological response to the currents), and passage efficacy of about 50 percent for one or more species from one or more arms of the reservoir. The 50 percent reservoir survival target identified in the Settlement Agreement and in Table 4-1 of this Plan was originally intended to be a trigger for constructing permanent downstream passage facilities at Round Butte Dam, not as the single determining factor for permitting upstream adult passage at PRB. Consistent with adaptive management provisions included in the Settlement Agreement the decision to make the transition to upstream adult passage of known-origin fish will be based on numerous indicators and mitigating factors, and will be well-founded on sound biological principles. The indicators will include the 50 percent survival value, a value that modeling by Beamesderfer (2002) suggested was an approximate threshold for population sustainability.

statistical needs of fish passage studies (Skalski and Townsend 2007), habitat capability (Cramer and Beamesderfer 2006), and realistic assumptions about the opportunity to trap smolts after they have been produced in habitats above the reservoir. In the watersheds (Whychus Creek, and/or Crooked River) where it is reasonable to expect that adequate numbers of naturally-reared smolts could be produced, trapped, and marked prior to entering Lake Billy Chinook, fry releases will meet or exceed those estimated to be needed to produce the required numbers of marked naturally produced smolts for reservoir passage tests. Where fry releases into a particular major subbasin appear unlikely to provide enough naturally-produced smolts to meet the statistical demands of fish passage tests, releases will be less intense but sufficient to begin testing habitat suitability, begin evaluating fish performance, and (potentially) to produce small numbers of returning adults.

During Phase I there will also be direct releases into the upper basin of tagged hatchery-produced smolts that have been pathogen-screened. These fish will be given unique marks that can be distinguished from naturally-reared smolts , and released in numbers that will be large enough to meet the statistical demands of reservoir passage tests for smolts leaving each of the three major subbasins tributary to Lake Billy Chinook. Releases of hatchery smolts for reservoir passage tests will either provide information supplemental to that obtained from tests of naturally reared smolts or enable statistically meaningful passage tests where they would otherwise be infeasible.

Each naturally-reared smolt that successfully negotiates Lake Billy Chinook and leaves the upper basin via the SWW facility during Phase 1 will either be given a PIT-tag or will be marked with unique fin clips. The PIT-tags will allow additional data collection on fish as they migrate to and from the ocean. The tag or unique fin clips will allow managers to assure that the fish will (1) avoid directed harvest and therefore experience lower harvest rates as they pass through fisheries when returning as adults, and (2) be identified as having upper basin origins when they arrive as adults at the Pelton Trap. Naturally-reared adults arriving at the trap will be passed upstream during Phase 2.

Reintroduction Phase 2. The criteria for moving from Phase 1 to Phase 2 is when 50% of the smolts captured at one of the reservoir arms migrating through Lake Billy Chinook are subsequently recaptured at the SWW fish collection facility. Once this criteria is reached the reintroduction program will transition into Phase 2. In this phase adult fish returning to the Pelton Trap, after having reared as juveniles above Pelton-Round Butte Complex, will be passed into the upper basin, including those fish that reared in the upper basin during Phase 1. A small fraction of the returnees may be used as broodstock. Natural-origin fish will be used during Phase 2 if possible.

Fish releases above Round Butte Dam during this phase of the program will be intended to develop locally adapted populations, with the numbers of young fish released into specific upper basin areas reflecting information acquired on the developing anadromous runs. As an early approximation, releases of fry during the first fish generation of Phase 2 will be of magnitudes estimated to be sufficient by themselves to produce about 50 percent of the maximum smolt carrying capacity of a particular stream. If the number of returning adults and the anticipated progeny exceeds expectations, the percentage of fry released will be reduced. This first cycle of fry releases during Phase 2 will also be supplemented with releases of hatchery smolts produced

from natural-origin broodstock, if smolts can be produced from an appropriate group of parents. Fry releases after the first fish generation of Phase 2 will diminish as rapidly as can be justified, to avoid a situation in which an extended hatchery supplementation program works against natural selection processes. During Phase 2 of the reintroduction effort, fish releases into the upper basin will be consistent with the suitability and productive capacity of available habitat. If habitat in a particular area proves to have greater capacity than initially predicted, fish releases there might be adjusted upwards, depending on broodstock availability. If habitat has less capacity, greater emphasis will be placed in the near term on habitat rehabilitation efforts and fish releases may be adjusted downward until habitat improves.

Marking of smolts at the SWW facility will continue until disease or other concerns have been addressed sufficiently to allow all adult fish arriving unmarked at the Pelton Trap (those natural-origin fish that are either returning to the upper basin or migrating toward areas other than the spawning locations of their parents) to be passed upstream.

Umatilla River Population
The following strategy and actions address flow and passage problems due to hydrosystem operations and facilities at the Boyd Hydro Project between RM 9-10 on the Umatilla River.

Strategy: Improve hydrosystem operations and facilities at the Boyd Project to reduce impacts.

Management actions
1. If possible, bypass reach flows for the Boyd Hydro Project should be modified to mimic the instream water right.
2. Fish passage facilities associated with the dam should be modified to meet current ODFW and NMFS fish passage standards.
3. Implement timely removal of weir panels from the diversion dam during period of non-operation to facilitate upstream passage.
4. Conduct timely and thorough maintenance of trash racks during periods of non-operation.

Walla Walla River Population
The following strategy and actions improve operations at Twin Reservoirs Hydro Project in the Walla Walla drainage.

Strategy: Improve hydrosystem operations and facilities at Twin Reservoirs Project to reduce impacts.

Management action
1. Conduct an assessment of the fishway at the dam. If the fishway does not meet ODFW standards, then it should be modified to meet standards for passage of juvenile fish.

9.5 Estuarine and Plume Habitat Strategies and Actions

The complex relationships that exist between species and habitat conditions in the Columbia River plume, estuary, and lower mainstem are poorly understood. The Columbia River Estuary

Recovery Plan Module (LCREP 2006) identifies 23 management actions that, together, address the range of threats salmonids in the estuary face including: altered habitat-forming processes; altered habitat structure in the estuary; changes in the food web dynamics; and poor water quality. The Mid-C Expert Panel identified impacts of bird predation in the estuary as a secondary threat in the past and present land use threat category. Based on our guidance, actions in the estuary that provide survival benefits are considered high priority because the benefits would likely be realized by all populations in the Mid-Columbia River steelhead DPS. Actions addressing predation concerns are shown in Section 9.7.

Strategy: Restore degraded estuarine and plume habitats and associated ecological processes.

Management actions
The following management actions that were identified by the LCREP (2006) are considered important to the survival of Mid-C steelhead during their migration and residency in the estuary and plume.

1. Protect intact riparian areas in the estuary and its tributaries and restore riparian areas that are degraded.
2. Modify hydrosystem operations to reduce the effects of reservoir surface heating, or conduct mitigation measures.
3. Adjust the timing, magnitude and frequency of flows (especially spring freshets) entering the estuary and plume to provide better transport of sediments and access to habitats in the estuary, plume, and littoral cell.
4. Remove pile dikes that have low navigational value but high impact on estuary circulation and/or juvenile predation effects.
5. Protect remaining high-quality off-channel habitat from degradation through education, regulation, and fee simple and less-than-fee acquisition.
6. Breach or lower dikes and levees to improve access to off-channel habitats.
7. Identify and implement actions to reduce salmonid predation by pinnipeds.
8. Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.
9. Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.
10. Identify and reduce industrial, commercial, and public sources of pollutants.
11. Monitor the estuary for contaminants and/or restore contaminated sites.

9.6 Harvest Strategies and Actions

Harvest strategies and actions address threats to Mid-C steelhead from mainstem Columbia River and tributary fisheries. Few steelhead from any Columbia River populations are caught in ocean fisheries under current management regulations.

9.6.1 Mainstem Harvest

We have not proposed any actions related to mainstem harvest, which we considered a secondary threat to Mid-C steelhead. We have, however, identified a strategy that should be adopted within

the management regulation processes to implement actions in those fisheries that pose the most significant threats to Mid-C steelhead in Oregon. New harvest biological opinions will come into effect starting in 2008 and the following strategy should be considered.

Strategy: Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.

9.6.2 Tributary Harvest

The current level of impact of tributary sport fisheries in all populations is quite low, thus we have concluded that tributary fisheries do not pose a significant threat to viability of any Mid-C populations. Additional harvest management actions are recommended, however, to address threats from the straying of out-of-subbasin hatchery steelhead in the Deschutes River and John Day River populations.

Fifteenmile Creek Population
No additional harvest actions are necessary, as long as current regulations continue to be implemented.

Deschutes River Westside and Eastside Populations
Fishery impacts on adult and juvenile steelhead in the Deschutes River have been minimized under the fishing regimes established in the FMEP. The following harvest strategy addresses threats from out-of-subbasin hatchery steelhead strays.

Strategy: Utilize harvest to reduce the abundance and proportion of stray hatchery spawners.

Management action
1. Develop an educational outreach program to promote the use of selective recreational fisheries to reduce the number of out-of-subbasin hatchery strays. Action is designed to increase the removal of hatchery steelhead in the fisheries by promoting the increased retention of hatchery fish caught in the fisheries. Currently, many anglers release marked hatchery fish that have been hooked and landed. Fisheries managers should encourage retention of hatchery steelhead by developing an education outreach program describing the benefits to the natural populations from the retention of marked hatchery fish.

John Day River Populations
Overall, fishery impacts on adult and juvenile steelhead in the John Day River have been minimized under the fishing regimes established in the FMEP. Harvest is proposed as a tool to address the current threat from out-of-subbasin hatchery steelhead strays.

Strategy 1: Utilize harvest to reduce the abundance and proportion of stray hatchery spawners.

Management action
1. Develop an education outreach program to promote the use of selective recreational fisheries to reduce the number of out-of-subbasin hatchery strays. Action encourages

retention of all hatchery fish caught in the fisheries. Currently, a large number of anglers continue to release marked hatchery fish that have been hooked and landed. Fisheries managers should develop an education outreach program describing the benefits to the natural populations from the retention of marked hatchery fish.

Strategy 2: Reduce catch and release mortality on natural-origin fish.

Management action

1. Promote a voluntary curtailment of fishing at higher water temperatures (above 21° C) as a measure to reduce hook-and-release mortality. Action addresses potential fisheries impacts for steelhead in the John Day River subbasin when water temperatures are over 21° C. This may occur at the opening of the steelhead fishery in September primarily in the lower section of the river below Cottonwood Creek that is open year around.

Strategy 3: Improve quality of harvest and natural-origin fish.

Management action

1. Expand the creel surveys to monitor fisheries effort and catch in the areas from Tumwater upriver to the area deadline. In addition to the effort and catch data, creel surveys could be used to recover tagged hatchery steelhead and as a mechanism to communicate with the public regarding management actions 1 and 2 above. The surveys, in combination with increased marking of Columbia River Basin hatchery steelhead, should provide better data of location of recovery and origin of hatchery strays.

Umatilla River Population

Fisheries are believed to have a relatively small impact on steelhead in the Umatilla River as managed under regulations described in the FMEP and CTUIR regulations. Tributary fisheries are not considered a threat to viability of the Umatilla River steelhead population. Consequently, no additional harvest actions are proposed for the Umatilla River at this time.

Walla Walla River Population

Current fisheries are not considered a threat to viability of the Walla Walla River steelhead population as managed under the current FMEP and CTUIR fishing regulations. Because of the relatively small impact rate of the fisheries, no additional actions are recommended.

9.7 Hatchery Strategies and Actions

Strategies and actions address ecological and genetic effects resulting from current hatchery management programs in and outside the DPS.

9.7.1 Overall Hatchery Strategy and Actions

We are proposing a number of management actions that address impacts to Oregon Mid-C steelhead populations from hatchery programs outside the DPS that are providing the source of out-of-DPS strays. These management actions are common to all Mid-C populations and are therefore presented in this section. Unlike management actions for all the other H's, in some

cases the Sounding Board could not reach consensus on the proposed hatchery actions. We present all the alternatives that were considered and characterize each recommendation as either a consensus or non-consensus recommendation. In addition, we provide information related to concerns expressed by the Sounding Board members who could not support specific recommendations. Many of the proposed actions will require development of agreements within the Columbia Basin decision, management and funding processes, such as, US vs. Oregon, BiOp Remand, and the Lower Snake River Compensation Plan Program.

The Hatchery Scientific Review Group completed a review of Oregon's Mid-C steelhead population hatchery programs and released their recommendations on January 31, 2009 (HSRG 2009). The HSRG report was released after this recovery plan, including proposed management actions, was released for public comment in the Federal Register. We provide a comparison of the HSRG recommendations with the recovery plan proposed actions for each population to assess the degree of consistency.

Strategy: Reduce the uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish.

Management actions

1. Implement a representative coded-wire-tagging program so that all hatchery stocks have adequate CWT groups released on an annual basis. [This will improve the ability to determine origin of strays in all populations. This is a consensus recommendation.]
2. Mark all hatchery steelhead releases in the Columbia River Basin with, at a minimum, an adipose clip or other distinguishing mark. [This action would facilitate recognition of hatchery fish at weirs and on the spawning grounds providing for removal and better hatchery proportion estimates. This is a non-consensus recommendation.]
3. Recommend development of alternative broodstocks that will stray at lower rates for the hatchery programs that contribute significantly to the stray problem. [Currently, ODFW is evaluating an alternative broodstock approach for the Wallowa stock, which strays at high rates, to specifically reduce straying into Mid-C populations. If this alternative broodstock management strategy proves successful it should be considered for other Snake River steelhead hatchery programs. This is a consensus recommendation.]
4. Reduce the proportion of Snake River hatchery smolts that are transported from Lower Granite and Little Goose dams. [Recent evidence from Perry et al. (2006 unpublished data) indicates that transported smolts may stray at significantly higher rates than in-river migrants. There are limited data available to examine the relationship. This is a non-consensus action that the Sounding Board indicated should be examined in more detail when additional data are available.]

9.7.2 Tributary Hatchery Strategies and Actions

Out-of-subbasin hatchery strays were identified as a key threat to a number of Mid-C populations. In addition, hatchery fish escaping and spawning naturally in the Walla Walla population was also identified as a key threat. There is lesser concern regarding the impacts of the Round Butte Hatchery program and the Umatilla Hatchery Program on populations in these subbasins.

Fifteenmile Creek Population

There are no plans to use artificial propagation to support fisheries or enhance natural production in the Fifteenmile Creek subbasin. Consequently, the main hatchery-related threat to the Fifteenmile steelhead population is from out-of-DPS strays. However, since the source of most hatchery fish passing Fifteenmile Creek are summer steelhead, there is little chance of introgression. There was considerable uncertainty in the proportion of hatchery fish in the natural spawner estimates for viability assessment. The Mid-C Expert Panel did not identify this as major risk for Fifteenmile Creek winter and steelhead; however, it could become a factor in the future if improved water quality attracts stray hatchery fish into the subbasin.

Strategy: Reduce uncertainty in abundance and proportion of hatchery strays spawning naturally.

Management action

1. Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys.

   Additional surveys would increase the precision of the current estimates. Information gathered would be used to provide a better estimate of the hatchery fraction. This is a consensus recommendation.

The HSRG recommendations are entirely consistent with the proposed actions for the Fifteenmile Creek population.

Deschutes River Eastside Population

Actions are proposed within the Deschutes River subbasin to address hatchery-related threats resulting from stray out-of-subbasin hatchery steelhead.

Strategy 1: Reduce the abundance and proportion of stray hatchery fish that spawn naturally.

Management actions

1. Construct trapping facilities in Buck Hollow and Bakeoven creeks and conduct a study to determine the effects of hatchery strays on production, productivity, and life history. A detailed study proposal has been completed to conduct a control-treatment study in Buck Hollow and Bakeoven. Once the study is completed Facilities can be used to remove strays. This is a consensus recommendation.

2. Improve trapping facilities and expand trapping operations on Trout Creek to trap and remove all strays.

   This is a consensus recommendation.

3. Modify and operate the trap at Sherars Falls to collect and remove out-of-subbasin hatchery fish which will reduce the number of hatchery steelhead that could spawn naturally.

This action has substantial cost and would result in the handling of most of the Deschutes natural-origin fish. In addition, there are considerable social concerns of how best to deal with the trapped strays. The Sounding Board concluded that this action should be reconsidered at a later time after all the other hatchery actions in the Deschutes populations had been implemented and evaluated.

Strategy 2: Reduce uncertainty in abundance and proportion of hatchery strays spawning naturally.

Management action

1. Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys.

   Additional surveys would increase the precision of current estimates. This is a consensus recommendation.

   The HSRG recommendations are entirely consistent with the proposed actions for the Deschutes River Eastside population.

Deschutes River Westside Population

Hatchery actions for the Deschutes River Westside population aim to improve the Round Butte Hatchery summer steelhead program and address concerns regarding out-of-subbasin strays. The ICTRT and the Mid-C Expert Panel consider straying of out-of-DPS hatchery steelhead a key threat to steelhead in the Deschutes Westside population. In addition, we identified stray hatchery steelhead as a high risk for the diversity metric in the viability assessment. Strategy 1 and Strategy 2 are specific to the Westside population. Actions in Strategy 3 are proposed to support steelhead reintroduction above the Pelton-Round Butte Complex to restore sustained natural production.

Strategy 1: Reduce the genetic risks associated with the Round Butte Hatchery Program.

Management action

1. Investigate opportunities and risks associated with incorporating naturally produced Deschutes River summer steelhead into the RBH broodstock.

   The current practice of using only known RBH summer steelhead for broodstock has the potential for the RBH program steelhead to diverge from the naturally produced Westside steelhead population. This divergence can lead to potential adverse genetic effects from naturally spawning RBH summer steelhead. Methods to genetically identify Deschutes River origin steelhead will need to be developed to insure that only naturally produced steelhead from within the population are used in the broodstock. This is a consensus recommendation.

Strategy 2: Reduce the abundance and proportion of stray hatchery fish that spawn naturally.

Management action

1. Begin collecting and removing hatchery steelhead at the Shitike Creek Trap.

   The trap is currently used to monitor the reproductive success of hatchery spring Chinook salmon and evaluate bull trout life histories. The trap needs to be modified to support more efficient collection and removal of hatchery steelhead. The current trapping effort is planned to stop in a few years. There are concerns regarding the logistic feasibility and costs of building and operating a more permanent structure. This is a consensus recommendation.

Strategy 3: Restore natural production to blocked areas above Pelton-Round Butte Complex (for both Westside and Crooked River populations).

Management action

1. Develop and implement a comprehensive plan for the reintroduction of steelhead into the upper Deschutes River subbasin above the Pelton-Round Butte Complex.

   Hatchery production will play a crucial role during the initial phases of reintroduction. The hatchery will operate with dual objectives: (1) produce fish for harvest mitigation and (2) produce fish to achieve conservation objectives. Under the conservation objectives, (OAR 635-007-0545(11)), goals associated with reintroduction would aim to meet objectives for supplementation and restoration to areas upstream of the complex.

   Round Butte Hatchery stock steelhead will be used for initial steelhead releases due to their availability and to concerns with impacts of collecting native stock steelhead. Native stock steelhead will be used once it has been determined that passage efficiencies through the complex are suitable. A genetic assessment has been initiated to characterize Deschutes River steelhead and redband trout populations. Results from this work will be used to help identify appropriate broodstock for reintroduction. This approach, including a reduction of hatchery releases as naturally produced fish return, should lead to an adapted and productive natural steelhead stock.

   Steelhead fry or smolt releases will provide the primary means to re-establish adult returns to historical habitats during Phase 1 of reintroduction. Initial efforts to reintroduce steelhead will focus most strongly on productive habitats along Whychus Creek. Whychus Creek once supported steelhead runs in the range of about 500-1,000 adults, and was by far the strongest producer of these fish when passage efforts at Round Butte were abandoned in the late-1960s (ODFW and CTWSRO 2007). No steelhead will be released directly into the mainstem Deschutes River above the complex and in the Metolius subbasin because habitat in these areas is thought to be better suited to resident rainbow trout than to steelhead (Cramer and Beamesderfer 2006). Colonization of this habitat by steelhead, should it occur, will be a consequence of straying by naturally produced fish. Release sites are prioritized for key spawning and rearing areas downstream of significant passage barriers or unscreened surface water diversions.

The first steelhead smolt releases occurred in 2007. These releases were made in anticipation of the new surface intake and collection facilities becoming operational in the spring of 2009. Table 9-6 shows proposed release numbers and locations.

Downstream migrants will be collected and marked before release below the hydropower complex so they can be readily distinguished from unmarked out-of-subbasin strays. Returning adults from the outplants will be specifically identified as upper subbasin origin fish. Adults originating from upper Deschutes habitats will also be differentiated from other in-subbasin or out-of-subbasin stocks through the use of unique fin-clips, PIT tags, or other tags.

A comprehensive monitoring and evaluation plan will be implemented to assess the success of reintroduction and provide the critical information needed to make adaptive management changes.

Crooked River Population

The following strategy and action are designed to restore natural production in the Crooked River population.

Strategy: Restore natural production to blocked areas above Pelton-Round Butte Complex.

Management action

1. Develop and implement a comprehensive plan for the reintroduction of steelhead into the upper Deschutes River subbasin above the Pelton-Round Butte Complex.

   Hatchery production will play a crucial role during the initial phases of reintroduction. The hatchery will operate with dual objectives: (1) produce fish for harvest mitigation and (2) produce fish to achieve conservation objectives. Under the conservation objectives, (OAR 635-007-0545(11)), goals associated with reintroduction would aim to meet objectives for supplementation and restoration to areas upstream of the complex.

   Round Butte Hatchery stock steelhead will be used for initial steelhead releases due to their availability and to concerns with impacts of collecting native stock steelhead. Native stock steelhead will be used once it has been determined that passage efficiencies through the complex are suitable. A genetic assessment has been initiated to characterize Deschutes River steelhead and redband trout populations. Results from this work will be used to help identify appropriate broodstock for reintroduction. This approach, including a reduction of hatchery releases as naturally-produced fish return, should lead to an adapted and productive natural steelhead stock.

   Steelhead fry or smolt releases will provide the primary means to re-establish adult returns to historical habitats during Phase 1 of reintroduction. Initial efforts to reintroduce steelhead will focus on productive habitats in McKay and Ochoco creeks and the mainstem Crooked River between River Mile 51 and River Mile 56. McKay Creek contains some of the better steelhead habitat in the lower Crooked subbasin (i.e., below

Bowman and Ochoco Dams). Release sites are prioritized for key spawning and rearing areas.

Under the present schedule, the first steelhead fry and smolt releases occurred in 2008 and 2009 respectively. These releases were made in anticipation of the new surface intake and collection and handling facilities going operational in the spring of 2009. Table 9-6 shows proposed release numbers and locations.

Downstream migrants will be collected and marked before release into the Deschutes River below the hydropower complex so they can be readily distinguished from unmarked out-of-subbasin strays. Returning adults from the outplants will be specifically identified as upper subbasin origin fish. Adults originating from upper Deschutes habitats will also be differentiated from other in-subbasin or out-of-subbasin stocks through the use of unique fin-clips, PIT tags, or other tags.

A comprehensive monitoring and evaluation plan will be implemented to assess the success of reintroduction and provide the critical information needed to make adaptive management changes.

Table 9-6. Initial estimates of annual releases of summer steelhead to occur within specific areas of the drainage basin upstream of PRBC as the reintroduction effort moves forward. Parental origin (brood) is identified as being Hatchery (H), Mixed (M), or Natural (N; this category includes steelhead parents that are the first-generation, hatchery-reared offspring of natural-origin fish).

Species	Phase of reintroduction	Stream area	Fry		Smolts	
			Brood	Number	Brood	Number
Summer steelhead	Phase 1	Deschutes R.	---	0[a]	---	0[a]
		Whychus Cr.	H	286,000[b]	H	5,000[b]
		Crooked R. system	H	288,000 – 708,000	H	7,500[c]
		All	***H***	***574,000 – 994,000***	***H***	***12,500***
	Phase 2	Deschutes R.	---	0[a]	---	0[a]
		Whychus Cr.	N, M, H	100,000-596,000[d]	W	7,700[d] (one generation)
		Crooked R. system	N, M, H	222,000-1,417,000[d]	W	13,000[d] (one generation)
		All	***N, M, H***	***322,000 - 2,013,000***	***W***	***20,700***

[a] There will be no releases of steelhead directly into the Deschutes R., nor into the Metolius R. system. Habitat in these areas is believed to be better suited to resident than anadromous rainbow trout production (Cramer and Beamesderfer 2006), and colonization of this habitat by steelhead, should it occur, will be a consequence of straying by naturally-produced fish.

[b] Initial annual releases into Whychus Cr. will be intended to supply enough marked smolts (both naturally-produced and hatchery produced) to test fish passage effectiveness downstream through LBC and into the SWW fish collection facility. The releases of fry assume 10 percent of the smolts naturally produced in the stream will be trapped and reach the head of the reservoir bearing detectible marks, and have been increased by 20 percent above the minimum number estimated to be needed for adequate statistical precision in the fish passage tests (238,000). Initial fry releases will also test fish performance in the habitat above PRBC and produce the first generation of adult steelhead to have reared as juveniles in that habitat for about 40 years. Numbers of fry to be released assume smolt production only in suitable habitat below the TSID diversion dam and not above that dam.

[c] Initial annual releases into the Crooked R. system below Prineville will be intended to supply enough marked hatchery smolts to test fish passage effectiveness downstream, and to provide naturally produced smolts that can be marked and pooled with those from Whychus Cr. to potentially make fish passage tests based on naturally-produced smolts more robust. The releases of fry will also be intended to help test fish performance in the habitat above PRBC and to produce returning adults that reared as juveniles in that habitat. As currently envisioned, the scope of steelhead fry releases during Phase 1 will be relatively limited.

[d] Annual releases during Phase 2 will supplement natural fish production associated with returns of adult steelhead that reared as juveniles above PRBC. Releases of fry will initially be of a magnitude estimated to be sufficient by themselves to produce about 50 percent of the maximum number of smolts, including that in areas of Whychus Cr. above the TSID diversion dam, and will diminish through time (note: the percentage will be reduced very early in Phase 2 if the number of returning adults exceeds expectations and there is a potential that fry outplants might otherwise overwhelm the offspring of these adults). There may be exceptions to this basic pattern in the Crooked R. system, however. Actual annual releases of fry will depend on broodstock availability and, in the Crooked R. system early in Phase 2, anticipated post-release environmental conditions. Hatchery produced smolts derived from disease-screened natural-origin parents collected below PRBC will also be released into these areas for a 5-year period, if available, in numbers equivalent to 50 percent of maximum natural smolt production, so that adults returning from the releases can also begin to supplement the developing natural runs. Hatchery support of the natural runs will diminish through time and end as soon as the runs can sustain themselves. Barring unforeseen circumstances, it will not continue for more than three fish generations in a given subbasin before the fish are given an opportunity to sustain themselves without artificial support.

John Day Populations (Lower Mainstem, North Fork, Middle Fork, South Fork, Upper Mainstem)

The following strategy and action address threats to natural spawning steelhead populations in the John Day subbasin from straying hatchery steelhead from outside the subbasin.

Strategy: Reduce uncertainty in abundance and proportion of stray hatchery fish that spawn naturally.

Management action

1. Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys and other methods.

   There are currently two types of surveys conducted during steelhead spawning times, index counts and Environmental Monitoring and Assessment Protocol (EMAP) surveys. Index counts are done once and EMAP surveys done at least three times during the spawning time period. Of the two types of surveys conducted, the EMAP surveys provide the best opportunity to document stray hatchery steelhead. However, currently the 50 EMAP surveys are done at the subbasin scale. Better information would be gathered if more surveys were done at the population scale. Additional methods such as kelt trapping could also be used. This is a consensus recommendation.

The HSRG recommendations are entirely consistent with the proposed actions for all five John Day River populations.

Umatilla River Population

Although hatcheries were not identified as a key threat to the Umatilla River steelhead population, several management actions are proposed to reduce the risk of out-of-subbasin strays and the risks associated with ongoing hatchery programs in the subbasin.

Strategy 1: Reduce abundance and proportion of out-of-subbasin strays spawning naturally.

Management action

1. Uniquely mark Umatilla Hatchery steelhead and remove other hatchery strays at Three Mile Falls Dam to limit out-of-subbasin strays from reaching the spawning grounds.

   In recent years, out-of-DPS strays comprised a mean of 4.8% of steelhead returning to TMFD. These strays mostly originate from lower Snake River hatchery programs. Uniquely marking Umatilla hatchery steelhead would allow removal of out-of-subbasin stray steelhead at TMFD and eliminate the potential for outbreeding depression and impaired diversity. Major logistical constraints include the additional costs of applying an identification mark to 150,000 steelhead smolts. In addition, 100% of fish escaping past TMFD would need to be trapped and identified, as opposed to the current practice of enumerating a portion of the run through video analysis of adults swimming past the viewing window in the adult ladder. Due primarily to concerns related to additional stress of handling all fish at TMFD, this is a non-consensus recommendation.

Strategy 2: Re-establish natural production into historically utilized habitats.

Management action

1. Re-establish natural production in Little Butter and Butter creeks (MaSAs) and some minor spawning areas by outplanting adults and/or releasing juveniles into the tributaries after habitat, flow and passage is restored to a level that will support steelhead production.

   The loss of occupancy in the Butter Creek system was identified as a significant spatial structure gap. Re-establishing natural production in these historically occupied areas will lower the risk levels by expanding spatial extent/range and decreasing gaps between spawning areas. Re-establishing spatial extent and reducing gaps will reduce vulnerability to local catastrophes, enhance historical life history diversity, and enhance gene flow and the ability to recolonize extirpated areas. Any effort to re-establish production in formerly occupied areas should follow habitat restoration actions to address passage constraints, loss of instream flow, and degraded water quality and habitat. Once habitat, flow and passage are restored to the point that tributaries can again provide spawning and rearing habitat for steelhead, reintroduction can proceed. The benefits extend to the population in re-establishing the population across its historical range and decreasing gaps between spawning areas. The timeline for this action is dependent on the extent and rate of recovery of degraded habitat and successful removal or alteration of passage impediments. This is a consensus recommendation.

Strategy 3: Reduce the genetic influence of hatchery fish in hatchery broodstock.

Management action

1. Eliminate the use of hatchery produced adults in the broodstock to reduce potential for divergence in genetic and phenotypic traits between hatchery and natural-origin steelhead.

   Sufficient natural-origin adults have been available in all years to meet broodstock needs; however, hatchery fish are used in some years. Implementing this action will eliminate the use of adults that have undergone domestication selection and reduce genetic and phenotypic divergence from the natural-origin stock. A potential downside of this management action would be further reducing the abundance of natural-origin steelhead spawners and increasing abundance of hatchery steelhead on the spawning grounds. This is a non-consensus recommendation.

Strategy 4: Reduce interactions between residual hatchery steelhead and natural steelhead to limit competition with and potential predation on natural steelhead juveniles.

Management action

1. Conduct volitional releases steelhead smolts and remove the fish that do not migrate.

   Reducing interactions between hatchery and natural steelhead reduces the threat that natural juveniles rearing in the Umatilla River will experience reduced survival or

mortality from competition with hatchery smolts. To further reduce competition between natural and hatchery juveniles, smolts remaining in the acclimation ponds after the volitional release period could to retained rather than forced into the Umatilla River. This technique has been used in other subbasins (e.g., Tucannon, Grande Ronde, Imnaha), usually according to guidelines on the sex ratio and numbers of smolts remaining in the acclimation pond. Research on the Tucannon River, Washington demonstrates that juveniles remaining in acclimation ponds after volitional release periods are predominantly male and few exhibit smolt characteristics and that retaining these fish reduced the abundance of residuals in the river (Viola and Schuck 1995). The management action could be implemented at the two existing acclimation facilities on the Umatilla River. This is a non-consensus recommendation due to logistical concerns expressed by Facility operators.

Strategy 5: Reduce potential negative ecological interactions between coho salmon and natural steelhead.

Management action

1. Reduce the number of hatchery coho released in the Umatilla River and relocate releases downstream to areas not currently important for steelhead production.

   Currently, approximately 1.5 million coho salmon smolts are released into the Umatilla River annually from the Pendleton Acclimation Facility. These coho salmon smolts have the potential to compete with juvenile steelhead for prey resources or space. This competition may reduce survival or result in direct mortality of steelhead juveniles, affecting productivity and abundance. Several steps could be taken to reduce potential interactions between coho salmon and steelhead smolts. Actions range from eliminating the Umatilla coho salmon program to changing the numbers, locations or methods of release of coho salmon. Because steelhead rearing habitat occurs downstream of McKay Creek where the colder water released from McKay Reservoir enters the Umatilla River, one potential solution would be to release coho salmon downstream of steelhead rearing habitat in the lower Umatilla River. Pendleton is the most downstream acclimation facility, so implementing this action would require either direct stream releases of coho salmon or construction of another acclimation facility on the lower Umatilla River. If implemented, the action would affect rearing habitat in the lower Umatilla River between Pendleton, where coho salmon are currently released, and the new release location. The largest logistical constraint would be locating and funding a new acclimation facility on the lower Umatilla River. No logistical constraints would exist for directly releasing coho salmon into the lower Umatilla River. There was consensus on reducing the number of coho released annually to at least 1 million. However, changing location of release was not a consensus recommendation.

The HSRG had no recommendations for the Umatilla population and related hatchery programs.

Walla Walla River Population

Several hatchery management actions and proposals to manage and reduce hatchery risks to the Walla Walla summer steelhead population were developed and are presented below. Consensus could not be reached to identify a preferred alternative.

Strategy: Reduce the abundance and proportion of non-local-origin hatchery strays spawning naturally.

Management actions

1. Eliminate adult hatchery strays above Nursery Bridge Dam by resuming trapping operations and removing hatchery fish.

   Removing hatchery strays above NBD would eliminate the threats and resulting diversity risk caused by introgression of hatchery steelhead into the natural population. Sorting and removing hatchery produced adults at NBD would greatly reduce or eliminate these threats. However, resumption of trapping activities would cause handling stress on natural-origin adults and may result in a small amount of mortality. This is a non-consensus recommendation due to concerns of handling natural-origin fish and associated risks.

2. Alter the release strategy of Lyons Ferry Hatchery smolts released into the lower Walla Walla River from direct stream to acclimated releases and implement trap and removal near the acclimation site.

   Changing the release strategy of smolts in the lower Walla Walla River from a direct stream to an acclimated release has the potential to reduce wandering of returning hatchery adults into the upper Walla Walla River. If lower stray rates were realized, it would reduce risks. The action would require construction of an acclimation facility on the lower Walla Walla River to hold smolts in natural stream water before release. While the action would be implemented on the lower Walla Walla River, effects could be realized throughout the subbasin. There was considerable concern expressed about the costs of this action as well as the logistics of separating natural-origin and hatchery-origin fish in the adult trapping component. This is a non-consensus recommendation.

3. Develop local broodstock to replace Lyons Ferry stock for use in the current harvest augmentation program.

   Developing local broodstock for use in the current program would reduce the risks to the natural population because the hatchery fish that stray and spawn naturally would have similar genetic characteristics to the natural fish. However, the initial stages of broodstock development would require mining natural-origin fish from the natural population reducing the effective number of spawners. This is a non-consensus recommendation due to concerns of removing natural-origin fish to initiate the broodstock.

4. Develop local broodstock to replace Lyons Ferry stock and initiate a natural production supplementation program.

   Develop local broodstock from natural-origin fish collected at Nursery Bridge Dam. Move the smolt release location upriver someplace near the Oregon-Washington state line. Allow hatchery fish to intentionally escape into natural production areas and spawn naturally. This action would potentially reduce the genetic risks because hatchery fish would have similar genetic characteristics as natural fish. However, hatchery fish will comprise a much larger proportion of natural spawners than under current scenarios. Considerable concern was expressed about this action due to lack of demonstrated success of supplementation, the number of studies demonstrating negative viability affects of hatchery fish, and the fact that current abundance and productivity are very near viable criteria. This is a non-consensus recommendation.

5. Maintain current Lyons Ferry harvest augmentation program and initiate endemic local broodstock supplementation program in upper mainstem Walla Walla River and Mill Creek.

   This proposal maintains the 100,000 Lyons Ferry direct stream smolt release into the mainstem Walla Walla River. In addition, local broodstock would be collected at Nursery Bridge to initiate a supplementation program. An initial target of 35 pairs would be collected to produce 100,000 smolts annually. The smolt production would be split for release with 50,000 direct stream into Mill Creek and 50,000 direct stream into the upper Walla Walla River near the North Fork. This action would result in an increased proportion of hatchery fish in the natural spawners because of the additional hatchery spawners produced from the endemic supplementation program. The overall benefits and risks to viability are dependent on a number of performance factors for which the outcomes are uncertain. This is a non-consensus recommendation due to concerns of increased hatchery proportions and lack of demonstrated success of supplementation.

Some elements of the HSRG recommendations are consistent with the proposed management actions and some are inconsistent. The HSRG recommended to "Eliminate the annual importation and release of out-of-basin fish and develop within basin adult collection to promote locally adapted hatchery broodstock." Management actions numbers three and four are consistent with this recommendation. The HSRG also recommended "Under any scenario, facilities to acclimate and release juveniles and recapture returning adults will need to be developed." Management actions numbers one and two are consistent with this HSRG recommendation.

Development and implementation of a preferred alternative will require co-manager agreements developed through the Columbia Basin decision processes, such as US v. Oregon, Columbia Basin Fish and Wildlife Program, the Lower Snake River Compensation Plan, as well as, state and tribal planning processes.

9.8 Predation and Competition Strategies and Actions

Predation strategies and actions are discussed below. No actions are currently proposed to address potential competition related threats.

9.8.1 Predation Strategies and Actions

Predation by pinnipeds, birds, and piscivorous fish in the mainstem Columbia River has become a contributing factor affecting the viability of the Mid-Columbia River steelhead DPS. We present the following strategies and management actions to address predation concerns. These include actions from October 2007 Proposed Action for the Federal Columbia River Power System (NOAA Fisheries 2007a), as well as, additional actions being considered that would contribute to improving survival. Presentation of the BiOp proposed actions in no way implies endorsement of the adequacy of the actions for recovery.

Predation by Pinnipeds
The following actions will reduce predation by Pacific harbor seals, Steller sea lions, and California sea lions on salmon and steelhead in the lower Columbia River.

Strategy: Reduce the seasonal abundance of pinnipeds at Bonneville Dam.

Management actions
1. Continue with hazing program at Bonneville Dam to reduce pinniped seasonal abundance and predation near the dam.
2. Provide and improve sea lion excluder devices (SLEDs) to prevent pinnipeds from entering fishways.
3. Maintain acoustic devices to move pinnipeds away from fishway entrances, project facilities, and navigation locks.
4. Pursue authorization under Section 120 of the MMPA to remove problem California sea lions.

Predation by Avian Predators
The following actions are proposed to reduce predation by native bird species, such as Caspian terns and double-crested cormorants, in the Columbia River estuary.

Strategy 1: Relocate Caspian tern colonies in the Columbia River away from corridors that increase the vulnerability of juvenile salmon and steelhead out-migrants.

Management actions (actions in addition to those in the FCRPS proposed actions are presented in italics)
1. Maintain habitat conditions on Rice Island unsuitable or undesirable for nesting terns.
2. Reduce nesting habitat on East Sand Island and relocate most of the Caspian tern colony to areas outside of the Columbia River Subbasin.
3. Develop and implement an avian management plan to address predation from the Caspian tern colony on Crescent Island.
4. Modify dredge spoil disposal practices to avoid creating habitat suitable for Caspian tern nesting.

5. Modify hydropower operations to provide sufficient river flow to decrease travel times and water clarity for migrating juvenile salmonids.
6. Implement rearing practices that would enhance predator avoidance behavior in hatchery salmonids.

Strategy 2: Begin to address predation by double-crested cormorants in the Columbia River estuary and mid-Columbia.

Management actions
1. Continue to conduct research on predation impacts of double-crested cormorants on migrating juvenile salmonids, bioenergetics modeling, and habitat/population management strategies.
2. Develop an avian management plan to address predation by double-crested cormorant colonies on East Sand Island and Foundation Island (mid-Columbia).

Strategy 3: Deny predation opportunities to other avian predators such as California gulls.

Management action
1. Implement and improve deterrent devices and activities (e.g. bird wire, water cannons, hazing) at dams to keep avian predators away from bypass outfalls and other areas of juvenile salmonid concentration.

Predation by Piscivorous Fishes
The following actions are proposed to reduce predation by northern pikeminnow and a wide variety of introduced species (such as walleye, smallmouth bass, and channel catfish) that prey on juvenile salmonids in the Columbia River.

Strategy 1: Continue to implement the NPMP with exploitation rates at 10-20% to maintain reduced predation rates on juvenile salmonids.

Management actions (actions in addition to those in the FCRPS proposed actions are presented in italics)
1. Implement the sport-reward program with increased rewards similar to the enhanced reward structure in 2001 and 2004-2006.
2. Evaluate the effectiveness and relative efficiency of a hook-and-line fishery at select dams on the mainstem Columbia to remove northern pikeminnow in areas inaccessible to sport-reward anglers.

Strategy 2: Begin to address the management of non-indigenous piscivores as a means of reducing predation on juvenile salmonids.

Management actions (actions in addition to those in the FCRPS proposed actions are presented in italics)
1. Organize a workshop to review and evaluate predation by non-indigenous species (consumption rates and abundance), and develop strategies to reduce predation.
2. Implement transplant or removal programs in select areas.

3. Adopt regulatory changes that encourage harvest of target species.
4. Implement hydro-operation changes to reduce recruitment of non-indigenous predators.

9.8.2 Competition Strategies and Actions

As discussed in Section 8, steelhead abundance and capacity in the Deschutes Westside population may be significantly reduced by competition with resident rainbow trout. However, no management actions are proposed because a reduction in steelhead capacity due to resident trout abundance is considered a potential natural interaction effect. If, in the future, additional studies confirm this reduction in capacity in waters with abundant larger rainbow trout, then the abundance criteria for the Deschutes River Westside steelhead should be reevaluated.

Section 10 Management Action Effectiveness

This section presents an analysis of the effects of actions on the performance of Oregon populations in the Mid-Columbia River steelhead DPS. Projected levels of effectiveness in improving abundance and productivity for the actions described in the previous section are analyzed using modeling tools. Results are expressed as changes to population abundance and productivity parameters, as they were defined by the ICTRT for baseline conditions for each population (Section 6). The analysis was performed in sequential steps, first by projecting outcomes for tributary actions alone, then sequentially adding in hatchery fish genetic effects, then types of out-of-subbasin actions, and finally actions to manage stray hatchery fish. Results of each of these steps provide a means of comparing relative benefits of the proposed actions and assessing the overall benefits of the combined actions. We recognize that there is uncertainty associated with many of the input parameters and model assumptions used in our assessment of management action effectiveness. The models we used do not have the capability to characterize statistical certainty. We examined combinations of different temporal response periods, alternative tributary habitat action implementation priority scenarios, and alternative ocean conditions in an attempt to characterize the range of potential population responses to the management actions. The results of our effectiveness analyses should not be viewed as predicted responses, rather as ranges of potential outcomes. We were not able to assess spatial structure/ diversity effectiveness in a quantitive manner. Therefore, we assess the spatial structure/ diversity effectiveness by describing how the specific actions which target gaps will improve status.

The section is presented in four parts:

1. Methods.
2. Results of the abundance/productivity analysis of tributary habitat actions.
3. Results of the abundance/productivity analysis of all other actions by integrating effectiveness across actions, including tributary actions.
4. Results of the spatial structure/diversity effectiveness.

10.1 Methods

We performed our analysis of action effectiveness for abundance and productivity using two modeling platforms that have been widely applied in the Columbia basin: EDT and All-H Analyzer (AHA). These modeling approaches are discussed below. Action effectiveness for spatial structure and diversity was assessed qualitatively by describing the specific actions and how the actions are expected to address the spatial structure/diversity impairments.

10.1.1 Approach

EDT and AHA address different life stages in the life cycle and thus the different limiting factors that affect salmonid population performance (Figure 10-1). We incorporated several refinements to the modeling procedures for each platform as they are usually employed in the region to improve application for our objectives. For EDT, we formulated an auxiliary tool for defining action effectiveness to better ensure that we considered the distinct elements of effectiveness

consistently between actions and subbasins, and we incorporated an implementation timeframe element. For AHA, we disaggregated the life cycle into more segments than used in the standard AHA in order to completely incorporate the effects of habitat conditions in the juvenile life stages following emigration from the subbasin through the adult life stages, until return to the subbasin. We also formulated a module for AHA to provide an efficient way of processing the large number of action combinations—both in tributaries and the mainstem Columbia—of interest to this analysis. In addition, we modified the default settings in AHA for genetic fitness to produce results that appear to be more consistent with how the populations of interest are currently performing.

We used the modeling results to assess relative changes in population performance due to management actions compared to performance under a baseline set of conditions (both within and out of subbasin). We then applied these relative changes to the baseline performance measures as derived empirically for each population by the ICTRT. In applying the results in this way, we assume that each modeling platform provides a useful and appropriate assessment of how actions can be expected to affect performance relative to the baseline. We avoid the question of how well EDT output parameters represent actual performance levels if measured accurately over a sufficient period of time (e.g., as addressed by Rawding 2004[2]).

The EDT model was used to analyze the potential benefits of tributary habitat actions. The model is designed to estimate salmonid population performance based on characteristics of the aquatic habitat (Mobrand et al. 1997; Blair et al. *in press*). While it considers conditions at all life stages—producing population parameters for the entire life cycle—it was originally built to address factors that affect freshwater survival. In the Columbia basin, it has been used to focus on habitat conditions within subbasins, being applied in nearly every subbasin that currently supports anadromous salmonids. It was the principal modeling tool used to formulate many of the recently completed subbasin plans, including those that support the populations in the Mid-Columbia River steelhead DPS. The EDT analyses for these subbasins provide one part of the limiting factors assessment of subbasin habitat conditions described in Section 8 of this plan. The stream reach and habitat characterizations used in those analyses were applied as part of the baseline conditions for the analysis presented herein.[3]

The EDT model is particularly well suited for analyzing effects of habitat actions on salmonid population performance. As part of its setup, it requires characterizations of both historical and existing habitat conditions for all stream reaches used by the population of interest (see Lichatowich et al. 1995). This provides a simple, logical framework for considering the effectiveness of future habitat actions. The Scenario Builder tool, one of the suite of EDT modeling tools, is then used to explicitly define the extent that an action might be expected to

[2] / Rawding (2004) compared EDT model output with observed data for several salmon and steelhead populations in the lower Columbia River. He concluded that spawner-recruit performance results were comparable between observed data and EDT outputs when recruits were measured as smolts (EDT does not incorporate variation in marine survival).

[3] / All of the data inputs completed as part of the subbasin planning process were unchanged for the analysis reported herein with two exceptions. It was discovered that the population age structure for Fifteenmile winter steelhead was incorrect, requiring an update to this input. Secondly, the spawning distributions specified for the Deschutes Eastside and Westside populations were not consistent with those defined by the ODFW steelhead distribution database and ICTRT. These inputs were updated to reflect ODFW and ICTRT information.

move reach-specific habitat characteristics back toward the pre-development state (Thompson et al. *in press*). Scenario Builder also allows for defining actions that represent future watershed development, as would occur over time with human population growth. In this case, the tool can be used to identify the extent that reach characteristics move further away from the pre-development state and toward a fully developed one. This aspect of the tool is used extensively as part of recovery planning in areas where human population growth is rapidly increasing, such as in the Puget Sound region (Thompson et al. *in press*), but it was not applied here. Growth is expected to be relatively slow in the subbasins of interest here and patterns of future development are not well defined. Actions intended to give protection against further habitat loss can be analyzed with Scenario Builder when habitat loss actions are also defined.

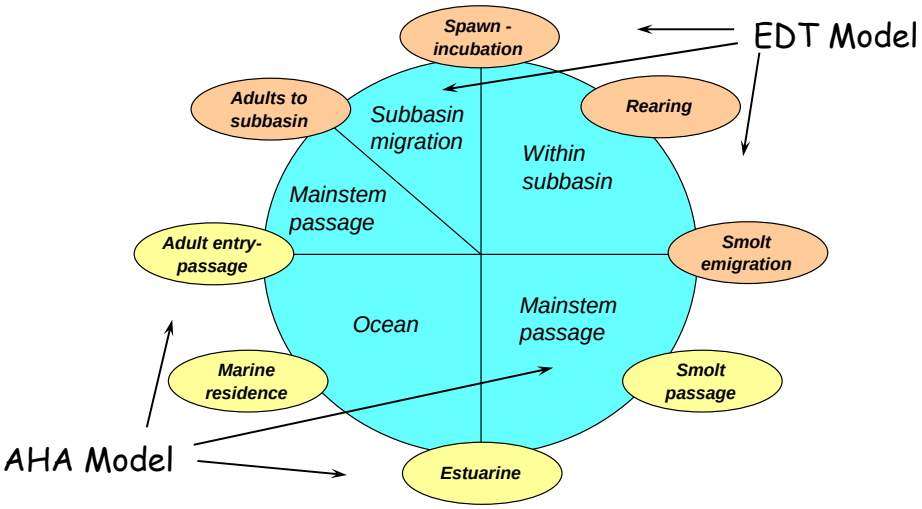

Figure 10-1. Use of EDT and AHA modeling platforms for different segments of steelhead life cycle. The EDT model covers the life stages from adults to subbasin through smolt emigration and AHA covers smolt passage through adult entry.

Four scenarios were modeled using the EDT model, reflecting two priorities for where actions would be implemented at two future times:

1. High priority action areas only at 25 years in the future;
2. High priority action areas only at 100 years in the future;
3. All priority action areas at 25 years in the future; and
4. All priority action areas at 100 years in the future.

Each scenario for each population consisted of a large number of diverse actions aimed at improving habitat conditions for the affected population (see Section 9). In addition to these four scenarios, the Deschutes Westside population was modeled with and without passage at the Pelton-Round Butte Complex to illustrate the added benefit of passage and restoration of natural production in the blocked areas..

The standard output from EDT consists of Beverton-Holt population parameters for smolt yield (leaving subbasin during smolt migration window) and spawners (virgin spawners successfully

spawning). The parameters are productivity (progeny per parent at low density), carrying capacity, and equilibrium abundance (i.e., average). Repeat steelhead spawners are not computed in the model, but repeat spawning is known to be very small (<5%; Busby et al. 1996) for Mid-Columbia steelhead. Parameter values produced for each scenario were used to compute the percent change in the parameter compared to the baseline. We used these relative changes to characterize the potential benefits to population performance corresponding to each scenario. Another EDT output is referred to as life history diversity and is a measure of the distribution of life cycle pathways through time and space determined to be successfully completed within the modeled environment. The model creates a multitude of diverse time-space pathways (or trajectories) through the environment consistent with the species' known life history patterns (incorporating seasonal movement patterns, rates of movement, and age structure), computing life cycle productivity and capacity parameter values for each pathway under each scenario. The percentage of pathways that are able to be completed successfully (i.e., having a productivity ≥1) of the entire set of modeled pathways is reported in the output as the % life history diversity. A value of 100% means that all modeled pathways would be expected to support completed life histories over the entire life cycle. In contrast, for example, a value of 20% would mean that only 20% of the pathways would support successful life histories—indicating that 80% of the pathways encountered such poor conditions for survival at some times or places (or were blocked by barriers) that life history condition was not possible. Typically, modeling of the undeveloped environment (historical condition) produces values for this metric at or near 100%. Modeling of severely degraded environments yields values much reduced—in severe cases <20% of the pathways might be successful. A large reduction in this metric compared to the undeveloped state usually means that significant portions of habitat no longer support sustainable production and, in the case of steelhead, older aged life history patterns have become less productive. The underlying concept of the metric is that it will reflect a real change in diversity of life history pathways relative to the undeveloped state that can be supported under the habitat conditions being modeled. Applying it to action analysis, if the current condition scenario yields a value of 20% for this metric, then how much does the metric change under a prospective action scenario? In this case, a large increase in the metric associated with an action scenario would mean that a significant expansion has occurred in life history distribution with improved habitat.

We report the results for this life history diversity metric to reflect only one aspect of how life history diversity would be expected to change due to an action set. The ICTRT is concerned about life history diversity at a larger scale than represented in the EDT measure, where patterns of distribution, movement, and age structure are considered. The EDT metric is not an equivalent measure, even though it reflects all of these higher scale patterns to some extent. We are currently exploring how information from the EDT results can be summarized to reflect changes in these patterns at the ICTRT criteria scale as a result of tributary actions.

The relative restoration benefit is determined by comparing current conditions to restored conditions resulting from implementation of proposed tributary habitat actions. We assessed restoration benefit for two scenarios for each population: 1) priority 1 actions only after 100 years; and 2) priorities 1 and 2 actions after 100 years.

The relative restoration benefit was determined based on the ranking of the amount of change in the consideration of all three previously decribed population performance measures (abundance,

productivity, diversity). All reaches or geographic areas were assigned a rank based on the change for each performance measure. The reach with the largest change was assigned higher values unless there was a tie. The three performance measure ranks for each reach were then summed and a simple average was computed. The reaches were then re-ranked so that the reach with the lowest average was giving a value of 1 (highest restoration benefit); all other reaches were assigned higher values.

Following the completion of the integrated ranking procedure, reaches were grouped and placed into four categories including: high, moderate, low, or very low, restoration benefit. The very low restoration benefit category includes reaches where zero restoration benefit is achieved. Results of the restoration benefit analyses are presented in maps in this section, as well as, in tables in Appendix H.

The AHA model was used to link the analyses of tributary habitat actions to prospective recovery actions involving hatchery fish and the mainstem Columbia River and to explore a few simple alternative ocean assumptions. The output from EDT, expressed in terms of Beverton-Holt population parameters, was an input to the AHA model. The AHA model was developed to give managers a tool for examining different ways of balancing habitat restoration, hatchery practices, harvest, and hydroelectric facilities operation (Mobrand – Jones & Stokes Associates 2005). It is particularly adapted to addressing the effects of hatchery operations, having been created by the Hatchery Scientific Review Group[4] to consider genetic interactions between hatchery and natural stocks. Model features incorporate theoretical concepts about these interactions based on Ford (2002) and Lynch and O'Hely (2001), and as further discussed by Mobrand et al. (2005).

Linking the two models provides a way of assessing benefits measured at the end of the life cycle for a wide range of potential actions, regardless of what life stage an action affects. The AHA platform integrates the effects of various types of actions over the full life cycle (Figure 10-2A). The output from AHA, also expressed as Beverton-Holt population parameters, represents the expectation for population performance when all actions are integrated together. Here, these parameters were then converted to the percent change in each parameter value compared to baseline conditions and multiplied by the ICTRT's baseline population measures to compute expected ICTRT-equivalent parameter values reflecting the effects of all actions (Figure 10-2B). The two parameters of interest here are population intrinsic productivity (recruits per spawner at low population density) and equilibrium spawner abundance. These parameters, whether estimated by EDT/AHA modeling or empirically as done by the ICTRT, are identical in meaning though they can differ in actual value for the same population due simply to different ways of estimation. Therefore, a conversion to an "ICTRT parameter equivalent" was necessary to allow for a direct comparison of output to the ICTRT baseline values. It was concluded that this simple multiplication procedure is the appropriate mathematical conversion to compute the change in ICTRT parameter values from EDT/AHA output.

[4] / The Hatchery Scientific Review Group is an independent scientific panel established and funded by Congress to provide an autonomous and credible evaluation of hatchery reform as part of the Hatchery Reform Project. The objective of the HSRG is to assemble, organize, and apply the best available scientific information and to provide guidance to the policymakers and technical staff who are implementing hatchery reform. The project is being applied in most areas of the Pacific Northwest, including within the Columbia Basin.

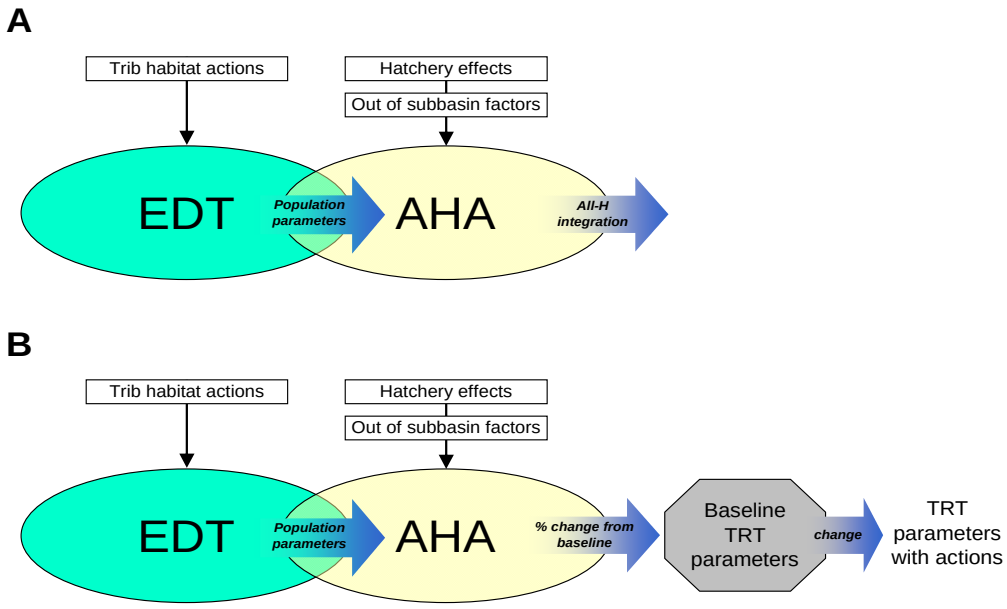

Figure 10-2. Action integration components.

The AHA model is principally used in the region to help evaluate hatchery programs and makes broad comparisons involving other strategy types. In the analysis presented herein, a strong focus is placed on integrating actions that not only involve hatcheries and out-of-subbasin actions, but detailed subbasin habitat restoration plans. The standard AHA model uses a simplified approach in integrating across such a range of actions by treating the effects of out-of-subbasin actions on population productivity and capacity as multipliers on parameter values produced by EDT, hence it assumes simple multiplicative effects. In doing so, effects of performance parameters for the final life stages (pre-spawning and spawning) are not fully incorporated, which can bias spawner estimates from the model high.[5] Therefore, the AHA platform was modified by first disaggregating output into life stage segments as described in Beverton and Holt (1957) and Mousalli and Hilborn (1986), then linking AHA inputs to the appropriate segment and re-computing end of spawning population parameters by reaggregating across the full life cycle (Mobrand et al. 1997). This modification provided a way of producing essentially unbiased parameter estimates.[6]

[5] / All life stages affect the performance of a salmonid population when measured at the end of the life cycle. Both habitat quality and quantity can affect fish performance during each life stage, and therefore, also affect population performance measured at the completion of the life cycle (end of spawning). Hence, benefits of actions affecting intermediate life stages, such as outmigrating smolts or returning adults within the mainstem Columbia River, do not proportionally translate into performance benefits when measured at the end of spawning in the subbasins. This is clearly evident in examining the Beverton-Holt function disaggregated into life stage segments.

[6] / The AHA model is to be updated formally to address this computational need (Lars Mobrand, personal communication). The procedure used in our analysis involved the use of a supplemental EDT output called the Hits file, which contains detailed results for each life history trajectory. These results were disaggregated to life stage, then used to compute weighted average performance parameter values for each life stage. This step was necessary for just the baseline model run, giving an analytical reference that could then be used to compute final adult life stage values for each action scenario.

A set of scenarios was modeled using AHA representing baseline conditions, current conditions, and combinations of actions aimed at tributary habitat, mainstem Columbia River factors, and hatchery fish management. Baseline conditions represent average conditions for the migration years 1980 to 2001 which represents the time period that recruit-per-spawner data were used for the ICTRT viability assessments. Current conditions are intended to generally reflect recent years (2002 to 2006) measures implemented for mainstem Columbia hydrosystem predation, estuary, and harvest. The benefits of these actions are not represented in the baseline abundance and productivity estimates. Population parameter estimates derived by the ICTRT in Section 6 reflect baseline conditions. Prospective actions to be taken in the mainstem Columbia River and estuary that were modeled include:

- Predator management – aimed at reducing predation rates caused by avian and northern pikeminnow;
- Downstream juvenile passage improvements – measures to improve survival at each of the mainstem dams;
- Columbia estuary habitat improvements – measures to enhance habitat conditions within the Columbia estuary; and
- Harvest – regulatory measures to reduce or hold harvest impacts in the mainstem Columbia River to current levels.

Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, then adding in actions sequentially, each being added to the previous scenario. The effects of hatchery steelhead programs on genetic fitness—hence performance—of natural-origin fish were incorporated for each scenario using AHA.

Actions that would control the number of stray hatchery fish in subbasins where feasible were modeled as part of another set of scenarios. In this case, the full set of scenarios aimed at tributary habitat and mainstem factors was modeled with and without these actions.

The effects of potential changes in marine survival were also modeled with a few alternatives. All of the scenarios described above were modeled using an average marine survival rate corresponding to the average during both the baseline and current periods. We then modeled two more scenarios, which consisted of all actions combined, using marine survival rates set to +/- 25% of the average applied to the other scenarios. This range is consistent with how average marine survival appears to vary between periods of years for Mid-Columbia River steelhead.[7] These results are intended to reflect outcomes of implementing recovery actions under alternative possible future marine survival regimes that might either decline or improve compared to the baseline average.

As noted previously, we formulated a module for AHA that enabled us to efficiently analyze the various combinations of tributary and mainstem action scenarios, in conjunction with hatchery management actions.

[7] / Inter annual variability in marine survival can be incorporated into AHA but estimates of population parameters are then made in a way that represents the average marine survival over the years used in modeling. We simplified the analysis by just applying an average marine survival to represent the modeled outcome within a period of years.

Table 10-1 lists the various combinations of actions and effects that were modeled for each population using AHA.

Table 10-1. Combinations of actions and effects modeled for each steelhead population using the AHA model. See text for definitions of baseline and current. Action groups are listed in columns, corresponding to where they would be implemented. Hatchery effects are those associated with modeled changes in genetic fitness of natural-origin fish due to hatchery strays. Codes are: B – baseline condition, C – current condition, B/C – baseline/current condition (assumed to be the same for both), A – actions implemented.

Scenario	Tributary		Mainstem Columbia				Ocean
	Trib habitat	Hatch effects	Pred control	Hydro pass	Est habitat	Harv regs	Marine surv
Baseline	B/C	B/C	B	B	B	B	B/C
Current	B/C	B/C	C	C	C	C	B/C
Trib habitat actions	A	B/C	C	C	C	C	B/C
Mainstem actions	A	B/C	A	C	C	C	B/C
- add more	A	B/C	A	A	C	C	B/C
- add more	A	B/C	A	A	A	C	B/C
- add more	A	B/C	A	A	A	A	B/C
Hatch fish actions	A	A	A	A	A	A	B/C
Alter marine surv	A	A	A	A	A	A	+/- 25%

In addition to these scenarios, the Deschutes Westside population was modeled with and without passage at the Pelton-Round Butte Complex to illustrate the added benefit of providing passage and re-establishing natural production.

10.1.2 Tributary Habitat Effectiveness

Details of how action effectiveness was modeled are described below.

Non-Passage Actions
The EDT Scenario Builder tool is used to capture assumptions about the effectiveness of an action in altering attributes of habitat within a river system. EDT habitat characterizations consist of ratings of 46 environmental attributes (flow, sediment, temperature, etc.) that describe the conditions of each stream reach delineated within a river system (see Lestelle et al. 2004). The characterizations are meant to represent an average state of conditions within a time period, i.e., current period, pre-development period, or a future period corresponding to the outcome of one or more habitat actions.

The Scenario Builder can be inefficient and awkward to use with large numbers of actions, multiple watersheds, large numbers of stream reaches, and multiple time lags in evaluating action effects. This can result in inconsistencies in how actions are defined with respect to their effectiveness. To minimize potential inconsistencies, an auxiliary tool (Action Mapper) was formulated for this project to define effectiveness through a set of systematic steps for all actions. The tool—built in Excel—helped ensure that action effectiveness was being formulated

consistently across populations by providing more transparency in defining effectiveness assumptions and giving improved documentation.

A total of 93 distinct actions within eight strategy types were assembled from Section 9 into a library of actions for processing. (Aspects of some actions overlapped with others, which required some consideration in assigning effectiveness values to reduce redundancy and overestimation of action benefits.) The action library is listed in Table 10-2 showing which actions were applied in each of the five subbasins. Although we summarize the library at the subbasin scale, actions are actually applied at the individual population scale, as well as, all areas downstream of the population boundary in the subbasin that are used for rearing and migration.

The Action Mapper was used to derive the effectiveness values for all action-stream reach-attribute combinations applicable to the analysis, which were then loaded into the Scenario Builder for input into EDT. The derivation consisted of two parts:

1. Part 1 - Mapping the precise geographic distributions of stream reaches that would be affected by the actions within each population, and
2. Part 2 - Quantitatively defining the various elements used to compose action effectiveness in the analysis.

The steps associated with each part provided a consistent process for deriving effectiveness values for each action.

Table 10-2. Tributary habitat actions modeled in each subbasin.

Strategy and action	Fifteenmile	Deschutes	John Day	Umatilla	Walla Walla
1. Protect/conserve ecological processes

Outreach to upland users					x

Part 1 for deriving action effectiveness asks: *What stream reaches will be affected by each of the actions?* The stream system in each of the five subbasins is delineated into a large number of reaches in EDT, each reach being precisely defined in how it is connected both upstream and downstream. In addition, reaches are aggregated into population units using the ICTRT population boundaries. The number of reaches in each subbasin that actions could potentially affect is listed below:

Subbasin	No. reaches
Fifteenmile	49
Deschutes	206
John Day	1,158
Umatilla	331
Walla Walla	220
Total	1,964

The planning teams identified the stream, and in many cases portions of streams, where each action would be targeted. They also designated which streams, or portions thereof, would be given high priority (priority 1) for action implementation or a lower priority (priority 2) for treatment (see Section 9).

Some actions would involve the direct manipulation of conditions within a stream reach, such as by riparian fencing along the reach, while others would act in areas removed from the stream (such as in the uplands) but would then affect reaches draining the affected area. In both cases, there would be one or more stream reaches affected within an area of highest influence by the action, with the potential for a dispersal of effects then moving downstream to other reaches. The Action Mapper was used to map the assumed distribution of effects associated with each action, as streams and reaches designated for action implementation were described in Section 9. A linear form of mapping is used in how reaches are shown arranged in the tools, lending itself to doing this task efficiently. For many actions, effects were assumed to not continue downstream beyond the area of direct influence due to the many factors that would need to be taken into account, such as other influences affecting downstream conditions. Generally, actions meant to affect flow and the hydrograph were extended downstream the furthest, as these actions would presumably be designed for that purpose.

The second part of deriving action effectiveness consisted of explicitly defining distinct elements—or factors—that are used to compose the overall effectiveness value applied in the analysis. Five elements of action effectiveness were recognized (Figure 10-3), each acting as a scalar to determine how effective an action would be in moving an attribute's current baseline rating back toward the undeveloped state. Combined, these scalars produce the realized effectiveness $REffect$ for action i, at lag time t, for attribute a used in modeling the action as follows:

$$REffect_{i,t,a} = Effect_i \times Intensity_i \times Lag_{i,t} \times Schedule_{i,t} \times Attribute_{a,i}$$

where $Effect_i$ is the potential effectiveness of action *i*

$Intensity_i$ is a scalar for defining the scale at which action *i* is to be applied

$Lag_{i,t}$ is a scalar that defines how much of the potential effectiveness of action *i* will be achieved at time *t* in the future (25 or 100 years in the future)

$Schedule_{i,t}$ is a scalar that defines an implementation schedule effect, i.e., whether implementation is delayed to some point in the future, whereby the amount of the potential effectiveness of action *i* would be reduced at time *t* in the future (25 or 100 years out)

$Attribute_{a,i}$ is a scalar that defines whether the potential effectiveness of action *i* for attribute *a* is the full amount (scalar of 1) or reduced due to an attribute effect. A scalar of 0 would indicate that the attribute is not affected by action *i*.

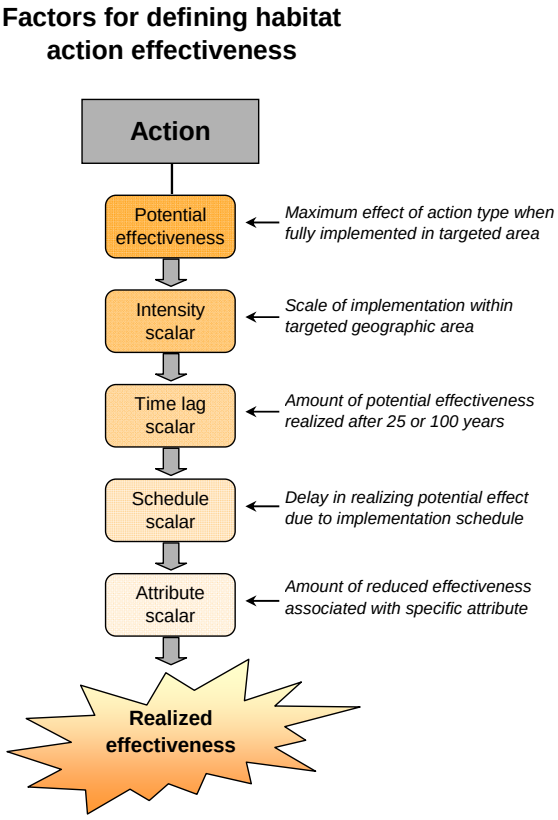

Figure 10-3. Action effectiveness elements.

An action's potential effectiveness ($Effect_i$) identifies the magnitude of effect that might reasonably be expected when the action would be implemented as fully as feasible within a geographic area. For example, how much of a stream reach 5 miles in length might reasonably be treated with a riparian restoration action (called Restore Riparian Communities in Table 10-2) if the action was focused on that reach—and, in turn, to what extent would the action restore attributes largely tied to the riparian condition in the pre-altered state? If the action remained in effect until its full benefit was to be realized—for this action perhaps 100 years—what would be its measured effectiveness at that time? In this case, we could reasonably argue that the full 5 miles could be treated and that after 100 years certain attributes (e.g., temperature, wood loading) might be restored completely (100%) to their pre-altered state. We assumed for the riparian restoration action a somewhat more conservative assumption—for this action, we applied an effectiveness value of 80%.

The potential effectiveness defines the maximum, yet reasonable, extent of effectiveness that might occur for the action of that type. Considering this aspect of an action's effectiveness provides a straightforward way of identifying a base effectiveness, to which the other scalars can then be applied. The potential effectiveness value assigned to each action is an assumption, since there are usually limited empirical data for defining the value with high degree of certainty. The assignment of effectiveness values to actions in recovery planning is often done through a team effort, either by consensus or as an average of values from different individuals (Mobrand Biometrics Inc 2003; Thompson et al. *in press*). Here, in this recovery planning process, the values were developed by one person using values from many previous efforts and who has facilitated a wide variety of team-oriented approaches in the Pacific Northwest.[8] This provided a consistent means of assigning effectiveness values for the entire set of actions considered across the five subbasins. To simplify the task of assigning potential effectiveness values, selections were made from 6 different levels, ranging between no effect to very high (Table 10-3) (See Appendix H for details).

Table 10-3. Potential effectiveness levels assigned to actions.

Effectiveness level	Definition	Effect
1	Very high	0.80
2	Moderately high	0.56
3	Moderate	0.32
4	Low	0.08
5	Negligible	0.01
6	No effect	0.00

[8] / Effectiveness modeling here was performed by Larry Lestelle, one of the principal architects of EDT, who has facilitated numerous EDT analyses in many watersheds of the Pacific Northwest. The perspective gained and actual effectiveness values used in those recovery planning efforts, in which the extent and causes of habitat degradation were assessed from pre-development conditions, gave an informed, consistent way of considering effectiveness of moving habitat conditions back toward their prior state.

The intensity scalar ($Intensity_i$) defines the average scale at which an action would actually be expected to be applied to the areas identified for treatment. In most cases, we would not expect actions to be applied at the maximum extent possible, given constraints imposed by land ownership patterns, various on-going land uses, and costs. The planning teams identified streams, and in many cases portions of streams, where specific actions would be targeted. They did not identify the extent that the actions would be applied within each of the targeted streams.

Continuing with the example of a five-mile reach where a riparian action would be applied, what portion of the reach would actually be expected to be treated? It would be reasonable to expect that some reaches might be treated in their entirety, while others would be treated at a much lower rate due to land ownership issues or other constraints imposed by on-going land uses. Actual project planning for implementing the tributary habitat actions will involve identification of opportunities and constraints and closely working with local stakeholders and planning entities.

Lacking some detailed planning information, we assigned an assumed level of intensity for each action, depending on action type and our understanding of how such actions have been implemented in the past. Initially, we considered varying the intensity scalar by the size of the subbasin (less intensity to larger subbasins). However, the larger subbasins also support multiple steelhead populations. We concluded that the analysis should be comparable between populations and applied identical intensity values between subbasins for the same action. Differences in how the actions would be applied in actuality are assumed to be reflected in the distributions of actions identified by the planning teams. To simplify the task of assigning intensity values, we chose from five different levels of intensity, ranging between negligible to very high (Table 10-4)(See Appendix H for details.)

Table 10-4. Intensity levels assigned to actions.

Intensity level	Definition	Scalar
1	Very high	0.85
2	High	0.40
3	Moderate	0.15
4	Low	0.05
5	Negligible	0.02

The lag scalar ($Lag_{i,t}$) defines how much of the potential effectiveness of an action will be achieved after a period of some number of years into the future. The full effectiveness of some actions would be realized immediately upon implementation (e.g., barrier removal), while others would require a lengthy time period to realize full effectiveness, such as riparian restoration. Two time lags were analyzed: 25 and 100 years into the future. All actions were assumed to be fully effective (lag scalar = 1) after 100 years, whereas the scalar was <1 at 25 years for those actions requiring a longer period to achieve full effectiveness. (See Appendix H for details.) Actions that would mature in effectiveness over time are those associated with maturing of

native vegetation, channel and floodplain reformation and stabilization, and the gradual restoration of more normative hydrographs as best management practices are instituted and realized.

The implementation schedule scalar ($Schedule_{i,t}$) defines how the schedule for implementing an action—relative to what might be considered year 0 of a recovery program—would affect realized effectiveness in either year 25 or year 100 of the program. Use of this scalar in the analysis recognizes that the recovery programs will be long-term in implementation due to their very extensive scope. Only a small fraction of the program can be expected to be implemented in the first year of the program. The scalar accounts for the reduced number of years an action might be operating between year 0 of the program and year 25 or year 100 considered in the analysis. The scalar $Schedule_{i,t}$ can be computed as:

$$Schedule_{i,t} = \frac{Y_t - Y_{imp}}{Y_t}$$

where Y_t is the number of years in the future of interest, here either 25 or 100 years

Y_{imp} is the year number into the program when action *i* is implemented.

If, for example, an action's potential effectiveness is 80% with a lag scalar of 50% at year 25, but it is implemented in year 10 of the program instead of year 0, then it's realized effectiveness in year 25 would be (ignoring intensity and attribute scalars):

Potential effectiveness	0.8
Lag scalar at 25 years	0.5
Schedule scalar at year 25	=15/25 = 0.6
Realized effectiveness at 25 years	= 0.8 x 0.5 x 0.6
	= 0.24

The planning teams for each subbasin generally identified how many years it would take before each action could be expected to be fully implemented in the subbasin. Actions were classified as being implemented immediately or in the short term (taking between 0-3 years from the start of the program to fully implement), or over an intermediate term (taking 4-14 years from program start to complete), or over a longer term (taking 15-25 years to complete). We approximated the implementation year for each action by taking the midpoint of the appropriate interval of years for completing the action and dividing by two (hence the median year by when half of the action would be expected to have begun).

The attribute scalar ($Attribute_{a,i}$) defines whether the potential effectiveness of an action will be the full amount (scalar = 1) or reduced due to an attribute effect. Some actions will have no effect on some attributes (scalar = 0). For each action, attributes were identified as being affected or not affected. We assigned the scalar to be 1 for any attribute that would be affected except for those that characterize some aspect of sediment, flow, and temperature. We set the

scalar for these to be 0.75, recognizing that these attributes are broadly affected by watershed conditions and can be more difficult to influence than attributes driven mainly by site-specific conditions. It is noted, however, that the distributions of many actions were identified by the planning teams to extend well into the headwater areas of streams. (See Appendix H for details.)

The example shown above is extended below to include all of the scalars, here shown with a moderate intensity of application as applied to the attribute maximum water temperature:

Potential effectiveness	0.8
Intensity scalar	0.15
Lag scalar at 25 years	0.5
Schedule scalar at year 25	0.6
Temperature attribute scalar	0.75
Realized effectiveness at 25 years	= 0.8 x 0.15 x 0.5 x 0.6 x 0.75
	= 0.027

In this example, the resulting realized effectiveness is calculated to be 0.027, meaning here that in the affected stream reach the maximum water temperature rating would be moved 2.7% of the distance between the current and the pre-altered ratings.[9]

Fish Passage Actions

The planning teams identified actions to provide for fish passage at sites known or assumed to be full or partial physical barriers to fish migration. Restoration of fish passage at each of these sites was modeled if the barrier had been identified and incorporated into the EDT database when the reach characterization was completed during the subbasin planning process. In some cases, these barriers had not been incorporated. In those instances, our analysis assumed that the problem had already been resolved.[10] Except in the case of the Pelton-Round Butte Complex in the Deschutes system, we modeled passage actions as providing full (100%) passage for both upstream and downstream migrations.

The Pelton-Round Butte Complex is the most significant barrier to fish migration addressed in the analysis. Passage around this hydro-electric project on the mainstem Deschutes River was terminated in 1968, blocking anadromous fish from returning to major spawning areas in that river. Work is currently underway to restore both upstream and downstream passage at the

[9] / To illustrate the effect, the current condition for maximum water temperature within a stream reach might have a rating of 3.5, which is equivalent to peak temperatures reaching 22-25 C on multiple occasions during a month. If the historic temperature—given what can reasonably be assumed about riparian condition, wet meadows, flow, etc—was much cooler, here having a rating of 1.0 meaning that temperatures normally did not exceed 16 C during the month, then the action would result in a rating of 3.43 ((3.5 – 1) x (1 – 0.027) + 1= 3.43), a very slight improvement from the current condition. The ratings for each attribute are used in the EDT rules to compute survival effects by life stage and species (see Lestelle et al. 2004).

[10] / We left the reach characterizations intact as they had been formulated during the subbasin planning process. If a barrier had not been incorporated in that process, it suggests that a passage problem had already been rectified at the time that the planning process was performed or there is uncertainty about the true state of the potential barrier. Regardless, our modeling in such case was performed assuming that a barrier did not exist if it had not been identified in the EDT database.

facilities. Uncertainty exists about how effective passage will be due to the nature of conditions within Lake Billy Chinook. In our analysis, we applied passage assumptions provided by Don Ratliff with Portland General Electric (personal communication), listed below:

Upstream passage effectiveness	99%
Downstream passage effectiveness	75%

As part of the action to restore passage at the Pelton-Round Butte Complex, we also incorporated an option to restore passage at water diversion sites within Whychus Creek. This aspect had not been explicitly called for in actions provided by the planning team. However, Whychus Creek provides the greatest amount of potential spawning habitat for the Deschutes Westside steelhead population upstream of the Pelton-Round Butte Complex—it is logical to assume that barriers in that stream would be addressed.

10.1.3 All-H Integration Across Life Cycle

The AHA model was used to incorporate potential effects of hatchery programs on the genetic fitness of the naturally-produced populations.

Genetic Fitness Effects
The AHA model incorporates key concepts and assumptions about the effects of genetic interactions between hatchery and natural fish built on the work of Lynch and O'Hely (2001) and Ford (2002), with further development of those ideas by geneticists working with the Hatchery Scientific Review Group (Mobrand – Jones & Stokes 2005). Fitness is computed in the model using Ford's (2002) modeling equations.

Ford (2002) used a quantitative genetic model to examine how the combined effects of selection in two environments, hatchery and wild, can influence the distribution of a phenotypic trait and the fitness of a salmon population. The model incorporates assumptions about the strength of selection in hatchery and wild environments, the rate of exchange between the two populations, the maximum reproductive rates of the population in each environment, and the duration of hatchery influence. Modeling results showed that when the hatchery population is closed to gene flow from the natural population, even low levels of gene flow from the hatchery population to the natural population will shift the natural population's mean phenotype so that it approaches the optimal phenotype in the hatchery. If the hatchery population receives gene flow from the natural population, such as by incorporating natural fish into the brood stock, the shift in the natural population's mean phenotype is reduced. While the fitness consequences of such shifts depended on model assumptions, a decline of over 30% in fitness occurred over a broad range of parameter values. When selection was assumed to be relatively strong, the fitness of the natural population was reduced by 80% or more if the hatchery population was closed to immigration from the natural population. The natural population was protected from such fitness decline only when gene flow from the hatchery to the natural population approached zero. Weaker selection produced less dramatic fitness loss, but even very weak selection could produce large reductions in fitness if the hatchery population was closed to immigration from the natural population.

The HSRG concluded (Mobrand et al. 2005) on the basis of AHA modeling that stray hatchery-origin fish from genetically-segregated populations can have a significant genetic influence on natural-origin populations after several generations when their proportion of the total naturally spawning population exceeds 5%. Consequently, they have recommended that hatchery-origin spawners from segregated programs not be allowed to exceed 5% of the natural-origin spawners as an upper-limit guideline. The HSRG is using the AHA model to evaluate potential genetic interactions between hatchery and natural fish associated with hatchery programs in much of the Pacific Northwest, including within the Columbia Basin. In most cases, the model is applied using the HSRG's default parameter settings for the model (Lars Mobrand, personal communication).

In examining genetic effects associated with default model settings, we concluded that one modification was needed. The default setting for what Ford (2002) defines as the optimal trait value in the hatchery environment results in a rapid and severe decline in the natural-origin population's fitness (recruits per spawner) as the proportion of strays exceeds about 5% (dashed line in Figure 10-4). As the proportion of strays continues to increase, equilibrium fitness bottoms out at approximately 20% of the natural-origin population unaffected by strays. (The dashed line in Figure 10-4 corresponds to the line in Ford's Figure 3A associated with a theta of -20, which can be seen there as having a very severe effect relative to other possibilities.) We find this level of severity to be unrealistic as it would have already caused extinction to several Mid-C steelhead populations. Lars Mobrand (personal communication) reports that the HSRG has reached the same conclusion, though they address these by truncating the effect on fitness at 50%, which they suggest is a likely worst case effect. Truncation in this manner results in a very precipitous decline in fitness at relatively low levels of strays, then an abrupt floor on fitness effect when 50% is reached. The 50% effect occurs with about 7-8% of the natural spawning population consisting of strays.

We assume that a 50% floor on fitness effect is reasonable and have applied it in our modeling. However, we modified the optimal trait value in the hatchery such that a floor of 50% would be attained while providing for a smooth transition across a relatively wide range of strays (solid line in Figure 10-4). This setting for the hatchery optimal trait value also provides a less precipitous decline in fitness though it still results in a very strong effect when strays are 10% or more of the naturally spawning population.

In our analysis of genetic effects of hatchery fish, we applied the AHA model primarily to consider interactions of stray hatchery fish with the natural-origin populations being analyzed. The average proportions of strays in the naturally spawning populations for the baseline and current time periods used in the analysis are identified in Appendix B in the spawner composition SS/D metric for each population. These proportions would decline with increased natural-origin run sizes for scenarios involving tributary habitat actions, since numbers of strays would be unchanged.

Prospective actions to manage the numbers of strays were analyzed for the two Deschutes populations. Although there are no significant proposed actions to reduce strays in the John Day River populations, we do plan to model reductions in the future for reference information. The numbers of strays in the natural spawning populations would be reduced to 5% of the number

entering the spawning areas, such as by using weirs. We assumed that the ratio of Round Butte hatchery strays to out-of-DPS hatchery strays would remain unchanged from the baseline ratios. The number of strays that enter a subbasin could increase above baseline levels, however, due to improved survival in the mainstem Columbia River associated with actions to improve survival.

We also used the model to incorporate genetic effects for the within-population hatchery program associated with the ten populations analyzed, that being the Umatilla supplementation hatchery program. Potential genetic effects of that program were incorporated into our analysis by using the modeling inputs for the program as being applied by the HSRG.

We used the default parameter settings in AHA to analyze fitness except as noted above.

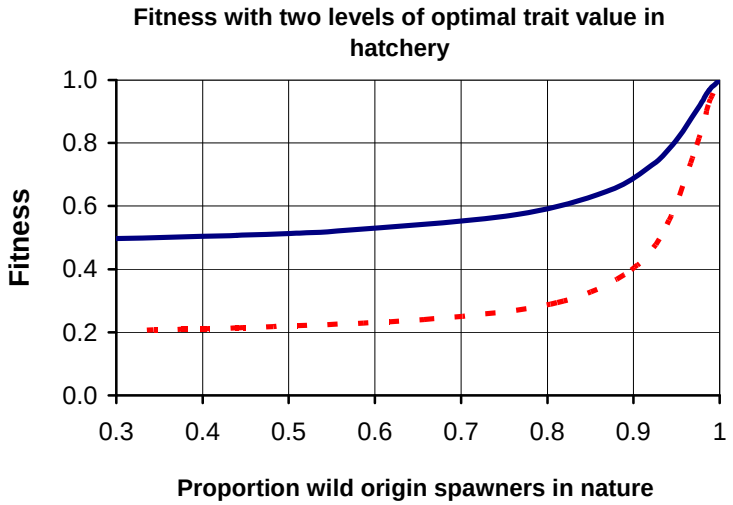

Figure 10-4. Change in fitness in relation to proportion of strays used in AHA modeling. Dashed line represents the default AHA settings based on Ford (2002). The solid line represents the relationship used for modified AHA in these analyses.

Out-of-Subbasin Factors and Actions

Out-of-subbasin actions were modeled using projected survival improvements as presented in Table 10-5. Projected survival improvements are consistent with values given in the most recent Biological Opinion issued by NOAA Fisheries on October 30, 2007. Use of the BiOp survival improvement values in no way implies endorsement of the validity of the estimates or the adequacy of the actions for recovery. At this time, the BiOp survival improvement estimates for the hydrosystem, predation, and estuary actions are the only estimates available for these proposed actions.

Scenarios were run in a stepwise fashion, starting with baseline, then current condition, then adding in actions sequentially, each being added to the previous scenario. The effects of hatchery steelhead programs on genetic fitness—hence performance—of natural-origin fish were incorporated for each scenario using AHA.

Table 10-5. Out-of-subbasin survival improvements for Mid-C steelhead populations. Improvement factors are expressed as multipliers on survival and are derived as ratios of estimated survival in one period divided by the previous period.

Mainstem river survival factor	Affected populations	Current/base ratio	Future/current
Hydro			
1 dam	Fifteenmile	1.031	1.002
2 dam	Deschutes	1.064	1.051
3 dam	John Day, Umatilla	1.103	1.100
4 dam	Walla Walla	1.143	1.122
Predation			
Avian	All	0.997	1.034
Pikeminnow	All	1.000	1.010
Estuary	All	1.003	1.057
Harvest	All	1.040	1.000

10.2 Analysis of Tributary Habitat Action Effectiveness

Results of the tributary action analysis are presented for each population below. Changes in performance measures associated with each action scenario are presented for intrinsic productivity, equilibrium (or average) abundance, and life history diversity, as these metrics were described earlier in this section.

For each population, the following results are presented in tabular and/or graphic form:

- Summary of level of action coverage, reporting
  - Stream miles within the subbasin relevant to the population
  - Number of actions applied;
  - Cumulative miles of stream potentially affected by all actions (ignoring intensity of application);
  - Ratio of cumulative miles potentially affected by stream miles relevant to population;
  - Average action effectiveness applied, weighted by the number of stream miles potentially affected per each action;
  - Average adjusted effectiveness, weighted by the number of stream miles potentially affected, where effectiveness is adjusted for all scalars (such as intensity of treatment) except the attribute scalar (therefore the actual adjusted effectiveness is lower for some attributes); and
- Summary of estimated percent changes in population performance for each population due to the tributary habitat actions for each scenario; and
- Estimated amounts of tributary habitat potential achieved by population performance measures resulting from tributary habitat actions. Habitat potential here is assumed to be equal to the population performance that would have occurred associated with the pre-

development condition in the subbasin. Performance for habitat potential is computed with baseline (i.e., post-development) out-of-subbasin conditions in place; and

- Maps illustrating geographic areas that are currently in protected status (wilderness areas, proposed wilderness areas, and municipal watersheds, USFS 2009 personal communication); stream reaches where priority 1 and priorities 1 and 2 protection actions are proposed; and, restoration benefits from priority 1 and priorities 1 and 2 restoration actions for all reaches.

Genetic effects to populations due to hatchery-origin fish spawning with natural-origin fish are not considered in this part of the analysis. Genetic effects are incorporated as part of the all-H integration.

10.2.1 Fifteenmile Creek Winter Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions in the Fifteenmile subbasin is greater than for any of the coverage amounts for the other populations analyzed. The ratios of cumulative miles potentially affected by actions to total stream miles available exceed 20 for both Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-6 summarizes tributary habitat action coverage and average action effectiveness values applied to the Fifteenmile Creek winter steelhead population.

Table 10-6. Summary of tributary habitat action coverage and average action effectiveness values applied to the Fifteenmile Creek winter steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar.

Population:	Fifteenmile Creek	
Total stream miles in subbasin:	134	
	Priority 1	Priority 1 & 2
No. of actions:	39	39
Cum miles affected by actions:	2,799	2,987
Ratio cum miles affected to total miles:	20.9	22.4
Weighted ave potential action effectiveness 1/:	0.253	0.270
Weighted ave adjusted action effectiveness 1/:	0.050	0.051

1/ Weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Fifteenmile Creek winter steelhead from tributary actions are shown in tables 10-7 and 10-8, and figures 10-5 and 10-6. Estimated increases in population performance resulting from tributary habitat actions are relatively large for each performance measure for both 25 and 100 year scenarios (Figure 10-5). Between 50-70% of habitat potential (i.e., historical potential) for both abundance and productivity is estimated to be achieved for the four scenarios considered (Figure 10-6). Nearly 100% of habitat potential would be achieved as expressed by the life history diversity metric. It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays (fitness loss is assumed to be zero for this population).

Table 10-7. Estimated percent changes in population performance of Fifteenmile Creek winter steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag	
		25 yr	100 yr
Abundance	Priority 1	108%	134%
	Priority 1 & 2	119%	147%
Productivity	Priority 1	48%	90%
	Priority 1 & 2	55%	100%
Diversity index	Priority 1	166%	175%
	Priority 1 & 2	180%	185%

Table 10-8. Estimated amounts of tributary habitat potential achieved by population performance measures resulting from tributary habitat actions applied to Fifteenmile Creek winter steelhead. Habitat potential is assumed equal to performance associated with the pre-development condition in the subbasin. Performance for habitat potential is computed with baseline (i.e., post-development) out-of-subbasin conditions in place.

Performance measure	Scenario	Time period		
		Base/Curr	25 yr	100 yr

	Priority 1 & 2		55%	71%
Diversity index	Baseline	34%		
	Priority 1		91%	95%
	Priority 1 & 2		96%	98%

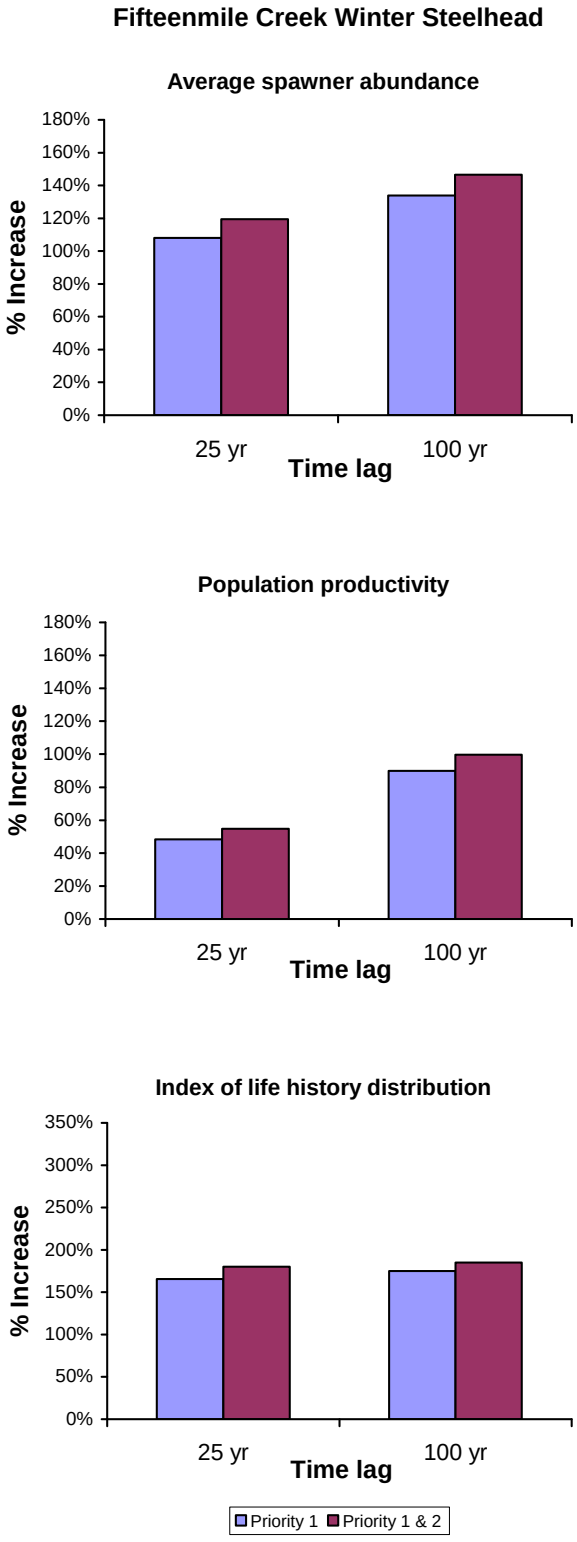

Figure 10-5. Estimated percent changes in population performance of Fifteenmile Creek winter steelhead due to tributary habitat actions.

Figure 10-6. Estimated amounts of tributary habitat potential achieved by population performance measures resulting from tributary habitat actions applied to Fifteenmile Creek winter steelhead. Habitat potential is assumed equal to performance associated with the pre-development condition in the subbasin.

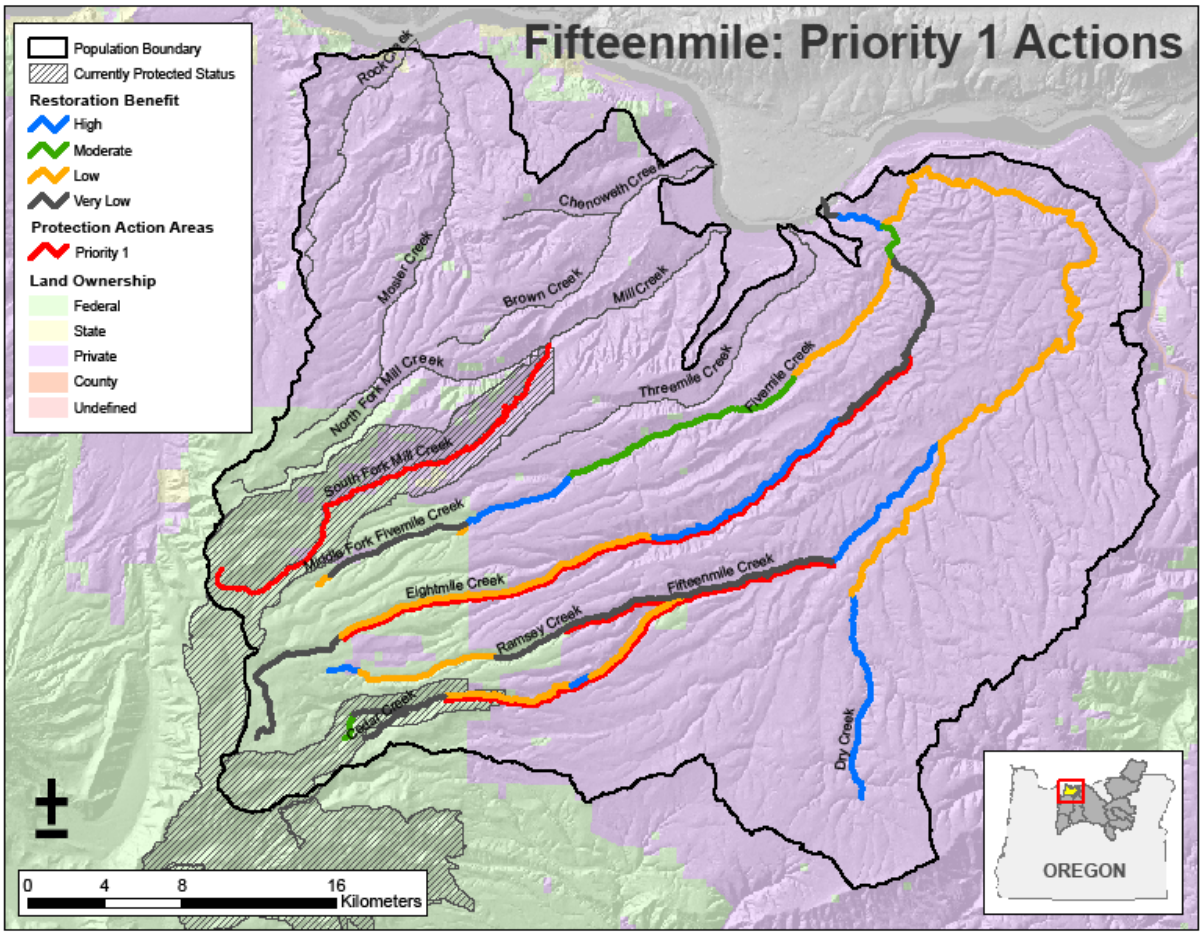

Figure 10-7. Map of the Fifteenmile Creek steelhead population showing geographic areas that are currently in protected status, reaches identified as high priority for proposed protection management actions, and relative restoration benefit from high priority (priority 1) proposed restoration actions for all reaches. Restoration benefits are only shown for the Fifteenmile Creek watershed because no effectiveness modeling was completed for the other watersheds in the population.

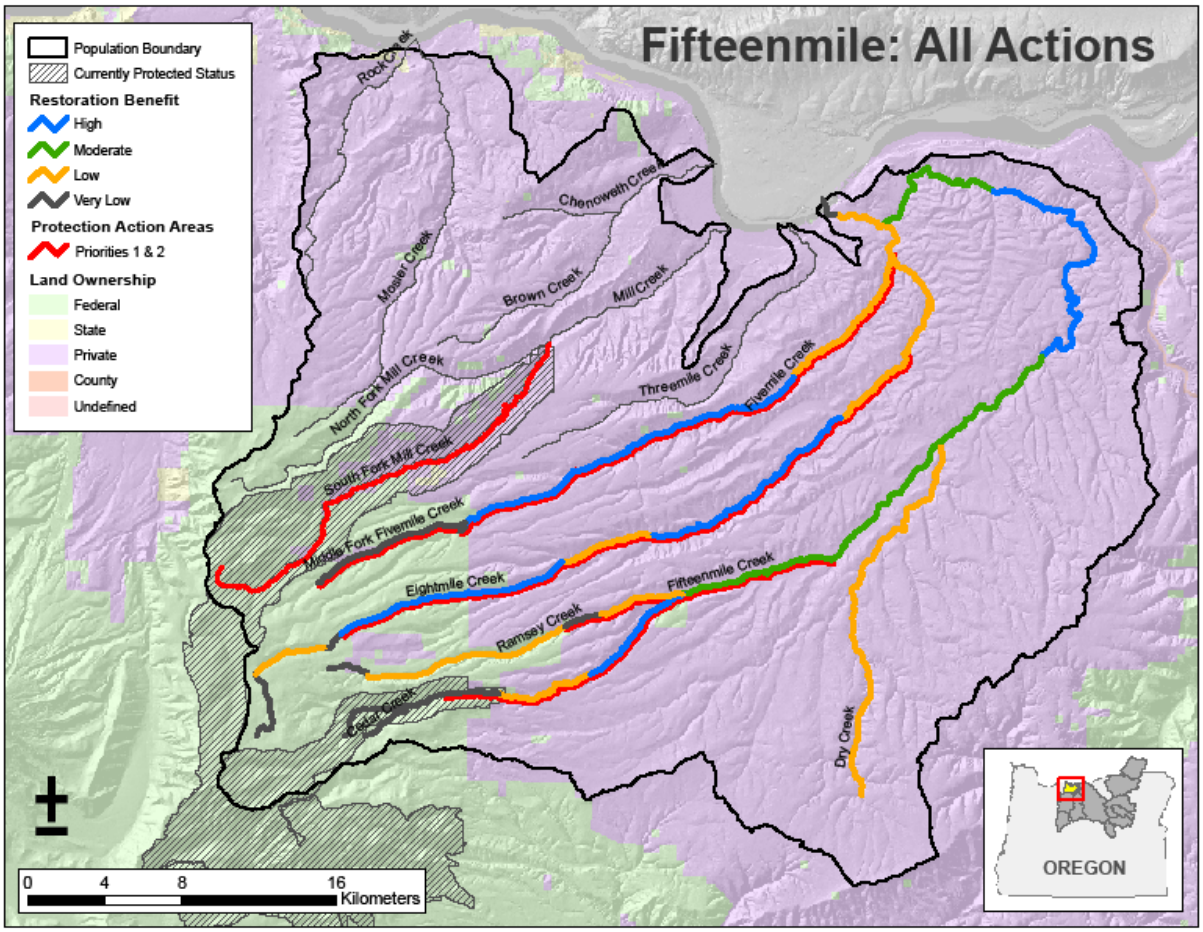

Figure 10-8. Map of the Fifteenmile Creek steelhead population showing geographic areas that are currently in protected status, reaches identified for proposed protection management actions (priority 1 and priority 2), and reaches with high, moderate, low and very low restoration benefit from all (priority 1 and priority 2) proposed restoration actions. Restoration benefits are only shown for the Fifteenmile Creek watershed because no effectiveness modeling was completed for the other watersheds in the population.

10.2.2 Deschutes River Eastside Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the Deschutes River Eastside population is comparable to the coverages applied to most of the other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are approximately 10 for both Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-9 summarizes tributary habitat action coverage and average action effectiveness values applied to the Deschutes River Eastside summer steelhead population.

Table 10-9. Summary of tributary habitat action coverage and average action effectiveness values applied to the Deschutes River Eastside summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar. Effectiveness values shown apply to the entire Deschutes subbasin.

Population:	Deschutes River Eastside	
Total stream miles in Deschutes subbasin:	802	
	Priority 1	Priority 1 & 2
No. of actions:	38	38

Cum miles affected by actions:	3,363	4,145
Ratio cum miles affected to total miles:	9.3	11.5
Weighted ave potential action effectiveness 1/:	0.136	0.170
Weighted ave adjusted action effectiveness 1/:	0.038	0.043

1/ Value shown is for entire Deschutes subbasin; weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Deschutes River Eastside summer steelhead from tributary actions are shown in tables 10-10 and 10-11, and figures 10-9 and 10-10. Estimated increases in population performance resulting from tributary habitat actions are relatively large for both 25 and 100 year scenarios (Figure 10-9). Between approximately 50-70% of habitat potential (i.e., historical potential) for abundance is estimated to be achieved for the four scenarios considered (Figure 10-10). The amount of habitat potential reached in productiviy is somewhat less, roughly between 25-45% of potential. These results indicate that

the habitat actions would have a greater effect on habitat quantity, since abundance is affected by both the quantity and quality of habitat, and productivity is primarily affected by habitat quality. Increases in water flow and opening of fish passage barriers would tend to affect habitat quantity more than quality characteristics on the whole. The largest amount of habitat potential regained by the actions would occur for the life history diversity measure. This measure of diversity reflects how much of the habitat could support sustainable life histories. The increase in diversity indicates that habitat quality and removal of barriers is sufficient to result in a substantial expansion of sustainable distribution within the geographic area of interest.

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-10. Estimated percent changes in population performance of Deschutes River Eastside summer steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag	
		25 yr	100 yr
Abundance	Priority 1	69%	107%
	Priority 1 & 2	102%	139%
Productivity	Priority 1	48%	98%
	Priority 1 & 2	79%	143%
Diversity index	Priority 1	137%	188%
	Priority 1 & 2	174%	219%

10.2.3 Deschutes River Westside Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the Deschutes River Westside population is comparable to the coverages applied to most of the other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are approximately 10 or slightly greater for both Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-12 summarizes tributary habitat action coverage and average action effectiveness values applied to the Deschutes River Westside summer steelhead population.

Table 10-12. Summary of tributary habitat action coverage and average action effectiveness values applied to the Deschutes River Westside summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar. Effectiveness values shown apply to the entire Deschutes subbasin.

Weighted ave adjusted action effectiveness 1/:	0.038	0.043

1/ Value shown is for entire Deschutes subbasin; weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Deschutes River Westside summer steelhead from tributary actions are shown in tables 10-13 and 10-14, and figures 10-13 and 10-14. Estimated increases in population performance resulting from tributary habitat actions are modest for both 25 and 100 year scenarios in the absence of passage at the Pelton-Round Butte Complex (Figure 10-13). Estimated increases in spawner abundance associated with habitat actions are <20%, even after 100 years of action maturation. Estimated increases in productivity are larger, being between 35-55% greater at the 100 year time period in the absence of passage.

Increases in the life history diversity metric are smaller (<12%). With passage at Pelton-Round Butte Complex (and including passage at barriers in Whychus Creek), performance measures for abundance and life history diversity are markedly increased. In contrast, productivity is reduced slightly when passage occurs. A reduction in productivity can occur with passage due either to the opening of poorer quality habitat than below the barrier or to a toll on survival associated with fish passing the barrier. In this case, the slight drop in survival is apparently due to migration survival loss associated with passage (juvenile passage effectiveness was assumed to be 75%).

Without fish passage at Pelton-Round Butte Complex, less that 50% of the habitat potential (i.e., historical potential) for abundance is estimated to be achieved for the four scenarios considered (Figure 10-14). The amounts of potential for these scenarios are only slightly greater than the baseline level. These modest increases toward regaining lost habitat potential, given the extent of actions being applied, suggest that much of the historical potential that existed historically downstream of Pelton-Round Butte is already being achieved. This further suggests that one or more other factors are constraining the actual population's performance besides that determined by habitat condition. One factor, loss in genetic fitness due to hatchery strays, is addressed as part of the All-H integration later in this section. We hypothesize that a second factor is interaction with the resident life history form of *O. mykiss*. Our analysis, including both our detailed tributary action assessment and the All-H integration, does not address how the resident form of *O. mykiss*, may be constraining the performance of the anadromous population.

Table 10-13. Estimated percent changes in population performance of Deschutes River Westside summer steelhead due to tributary habitat actions. Results are shown with and without passage at the Pelton-Round Butte Complex. The passage scenarios also include passage at water diversion barriers on Whychus Creek.

Performance measure	Scenario	No passage		Passage	
		Time period lag			
		25 yr	100 yr	25 yr	100 yr

10.2.4 Lower Mainstem John Day River Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the Lower Mainstem John Day River population is comparable to the coverages applied to most of the other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are approximately 10 or less for Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-15 summarizes tributary habitat action coverage and average action effectiveness values applied to the Lower Mainstem John Day River summer steelhead population.

Table 10-15. Summary of tributary habitat action coverage and average action effectiveness values applied to the Lower Mainstem John Day River summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar. Effectiveness values shown apply to the entire John Day subbasin.

Population:	Lower Mainstem John Day River	
Total stream miles in John Day subbasin:	2,936	
	Priority 1	Priority 1 & 2
No. of Lower John Day actions:	37	37
Total stream miles in Lower John Day:	1,026	1,026

Ratio cum miles affected to total LowJD miles:	7.6	10.5
Weighted ave potential action effectiveness 1/:	0.145	0.146
Weighted ave adjusted action effectiveness 1/:	0.034	0.032

1/ Value shown is for entire John Day subbasin; weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Lower Mainstem John Day River summer steelhead from tributary actions are shown in tables 10-16 and 10-17, and figures 10-17 and 10-18. Estimated increases in population performance resulting from tributary habitat actions are relatively moderate to large, depending on the performance measure (Figure 10-17). The smallest percentage increases occur for productivity. Even with these increases, performance for both productivity and abundance achieve only approximately 30-40% of habitat potential

with actions. Amounts of potential for the baseline are only approximately 20% or less for these metrics. (Figure 10-18). The largest amount of habitat potential regained by the actions would occur for the life history diversity measure. Between 40-60% of potential associated with this metric would be achieved with habitat actions. The life history diversity metric reflects how much of the habitat could support sustainable life histories. An increase in diversity indicates that habitat quality and removal of barriers (when present) is sufficient to result in a substantial expansion of sustainable distribution within the geographic area of interest.

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-16. Estimated percent changes in population performance of Lower Mainstem John Day River summer steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag	
		25 yr	100 yr
Abundance	Priority 1	64%	113%
	Priority 1 & 2	97%	177%

10.2.5 North Fork John Day River Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the North Fork John Day River population is least in the range of coverages applied to the other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are in the range of 5-6 for Priority 1 and Priority 1 & 2 scenarios. One reason for low coverage in this geographic area is due to the presence of the North Fork Wilderness Area. The adjusted weighted average action effectiveness values also show that actual treated areas well less than values suggested by these ratios. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-18 summarizes tributary habitat action coverage and average action effectiveness values applied to the North Fork John Day River summer steelhead population.

Table 10-18. Summary of tributary habitat action coverage and average action effectiveness values applied to the North Fork John Day River summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar. Effectiveness values shown apply to the entire John Day subbasin.

Population:	North Fork John Day River	
Total stream miles in John Day subbasin:	2,936

Weighted ave adjusted action effectiveness 1/:	0.034	0.032

1/ Value shown is for entire John Day subbasin; weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of North Fork John Day River summer steelhead from tributary actions are shown in tables 10-19 and 10-20, and figures 10-21 and 10-22. Estimated increases in population performance resulting from tributary habitat actions are relatively moderate for this population (Figure 10-21). Amounts of habitat potential for the abundance and productivity performance measures reach approximately 45-55%. Amounts of

potential for the baseline for these performance measures are approximately 35-40% (Figure 10-22).

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-19. Estimated percent changes in population performance of North Fork John Day River summer steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag	
		25 yr	100 yr
Abundance	Priority 1	23%	39%
	Priority 1 & 2	26%	44%
Productivity	Priority 1	15%	29%
	Priority 1 & 2	18%	35%
Diversity index	Priority 1	20%	32%
	Priority 1 & 2	23%	35%

Map of the North Fork John Day River steelhead population showing geographic areas that are currently in protected status, reaches identified for proposed protection management actions (priority 1 and priority 2), and reaches with high, moderate, low and very low restoration benefit from all (priority 1 and priority 2) proposed restoration actions.

10.2.6 Middle Fork John Day River Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the Middle Fork John Day River population is on the lower end of the range of coverages applied to the other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are in the range of 7-9 for Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-21 summarizes tributary habitat action coverage and average action effectiveness values applied to the Middle Fork John Day River summer steelhead population.

Table 10-21. Summary of tributary habitat action coverage and average action effectiveness values applied to the Middle Fork John Day River summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar. Effectiveness values shown apply to the entire John Day subbasin.

Population:	Middle Fork John Day River	
Total stream miles in John Day subbasin:	2,936

Weighted ave adjusted action effectiveness 1/:	0.034	0.032

1/ Value shown is for entire John Day subbasin; weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Middle Fork John Day River summer steelhead due to tributary actions are shown in tables 10-22 and 10-23, and in figures 10-25 and 10-26. Estimated increases in population performance resulting from tributary habitat actions are relatively moderate for this population (Figure 10-25). Amounts of habitat potential for the abundance and productivity performance measures with actions reach approximately 40-55%.

Amounts of potential for the baseline for these performance measures are approximately 30-35% (Figure 10-26).

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

1/ Value shown is for entire John Day subbasin; weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of South Fork John Day River summer steelhead from tributary actions are shown in tables 10-25 and 10-26, and figures 10-29 and 10-30. Estimated increases in population performance resulting from tributary habitat actions are relatively small to moderate for this population (Figure 10-29), depending on performance measure. Amounts of habitat potential for the abundance and productivity performance measures with actions reach approximately 40-55%. Amounts of potential for the baseline for these

performance measures are approximately 30-35% (Figure 10-30). Small increases were projected for the life history diversity metric.

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-25. Estimated percent changes in population performance of South Fork John Day River summer steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag

10.2.8 Upper Mainstem John Day River Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the Upper Mainstem John Day River population is on the lower end of the range of coverages applied to the other Mid-Columbia Oregon steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are in the range of 7-10 for Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-27 summarizes tributary habitat action coverage and average action effectiveness values applied to the Upper Mainstem John Day River summer steelhead population.

Table 10-27. Summary of tributary habitat action coverage and average action effectiveness values applied to the Upper Mainstem John Day River summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. 1/ Value shown is for all actions in the John Day subbasin; weighted by miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Upper Mainstem John Day River summer steelhead from tributary actions are shown in tables 10-28 and 10-29, and figures 10-33 and 10-34. Estimated increases in population performance resulting from tributary habitat actions are relatively moderate to large, depending on the performance measure (Figure 10-33). With these increases, performance for both productivity and abundance achieve only approximately 35-55% of habitat potential (Figure 10-34).

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-28. Estimated percent changes in population performance of Upper Mainstem John Day River summer steelhead due to tributary habitat actions.

10.2.9 Umatilla River Summer Steelhead

Level of Action Coverage

The level of treatment coverage by habitat actions for the Umatilla River population is on the upper end of the range of coverages applied to the other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are in the range of 13-14 for Priority 1 and Priority 1 & 2 scenarios. The adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios, however. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River. Table 10-30 summarizes tributary habitat action coverage and average action effectiveness values applied to the Umatilla River summer steelhead population.

Table 10-30. Summary of tributary habitat action coverage and average action effectiveness values applied to the Umatilla River summer steelhead population. 	Priority 1	Priority 1 & 2
No. of actions:	38	38
Cum miles affected by actions:	9,055	9,664
Ratio cum miles affected to total miles:	13.3	14.2
Weighted ave potential action effectiveness 1/:	0.255	0.247
Weighted ave adjusted action effectiveness 1/:	0.048	0.046

1/ Weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Umatilla River summer steelhead due to tributary habitat actions are shown in tables 10-31 and 10-32, and figures 10-37 and 10-38. Estimated increases in population performance resulting from tributary habitat actions are relatively moderate to large, depending on the performance measure (Figure 10-37). The increase in productivity is less for Priority 1 & 2 actions (i.e., all actions) compared to just Priority 1 actions. This is the result of a Priority 2 action opening habitat blocked by a barrier—habitat upstream of the barrier is relatively low in quality. The effect is that productivity is reduced while overall habitat capacity, hence spawner abundance, is increased (more habitat open to be used).

Between approximately 45-70% of habitat potential (i.e., historical potential) for abundance, productivity, and the life history diversity measure is estimated to be achieved for the four scenarios considered (Figure 10-38).

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-31. Estimated percent changes in population performance of Umatilla River summer steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag	
		25 yr	100 yr
Abundance	Priority 1	67%	93%
	Priority 1 & 2	82%	112%
Productivity	Priority 1	71%	116%
	Priority 1 & 2	62%	101%
Diversity index	Priority 1	53%	72%
	Priority 1 & 2	61%	96%

10.2.10 Walla Walla River Summer Steelhead

Level of Action Coverage

The number of actions applied in the analysis of the Walla Walla River population was substantially more than used to analyze any of the other Oregon Mid-C steelhead populations that were modeled. While the distribution of treatment for some of these actions was described in Section 9 as occurring within both Oregon and Washington, we modeled the actions as occurring only within Oregon. (Downstream effects of actions were still incorporated.) Table 10-33 summarizes tributary habitat action coverage and average action effectiveness values applied to the Walla Walla River summer steelhead population.

The level of treatment coverage by habitat actions applied to the Walla Walla River population is roughly in the middle of the range of coverages applied to other Oregon Mid-C steelhead populations. The ratios of cumulative miles potentially affected by actions to total stream miles available are in the range of 10-12 for Priority 1 and Priority 1 & 2 scenarios. However, the adjusted weighted average action effectiveness values show that actual treated areas would be far less than suggested by these ratios. The reader should note that the cumulative miles affected by the actions include stream miles outside the population's boundaries as defined by spawning distribution—encompassing miles within the migration corridor and downstream rearing areas down to the confluence of the subbasin with the mainstem Columbia River.

Table 10-33. Summary of tributary habitat action coverage and average action effectiveness values applied to the Walla Walla River summer steelhead population. Total stream miles are those modeled in EDT. Cumulative miles affected are the total miles targeted for actions without considering intensity of treatment by actions. Average potential and adjusted effectiveness values are weighted by stream miles targeted by each action. Average adjusted action effectiveness values incorporate all action scalars except the attribute scalar.

Population:	Walla Walla River

Weighted ave potential action effectiveness 1/:	0.134	0.131
Weighted ave adjusted action effectiveness 1/:	0.047	0.043

1/ Weighted by stream miles affected per action

Projected Changes to Population Performance

Estimated percent changes in population performance of Walla Walla River summer steelhead due to tributary habitat actions are shown in tables 10-34 and 10-35, and figures 10-41 and 10-42. Results presented here reflect the result of actions applied only to waters within Oregon,

though effects to habitat characteristics continue downstream into Washington waters. Estimated increases in population performance resulting from tributary habitat actions are relatively moderate to large, depending on the performance measure (Figure 10-41).

Between approximately 40-60% of habitat potential (i.e., historical potential) for abundance and productivity is estimated to be achieved for the four scenarios considered (Figure 10-42). However, the amount of habitat potential expressed through life history diversity (i.e., distribution within the drainage) reaches only about 20%. This is apparently due to effects of barriers or poor quality conditions in reaches downstream of reaches in Oregon.

It should be noted that these measures of performance for this part of the analysis do not include any loss in performance that might be associated with genetic fitness loss due to strays.

Table 10-34. Estimated percent changes in population performance of Walla Walla River summer steelhead due to tributary habitat actions.

Performance measure	Scenario	Time period lag	
		25 yr	100 yr
Abundance	Priority 1	97%	119%
	Priority 1 & 2	99%	121%
Productivity	Priority 1	54%	70%
	Priority 1 & 2	54%	69%
Diversity index	Priority 1	82%	91%
	Priority 1 & 2	90%	112%

Table 10-35. Estimated amounts of tributary habitat potential achieved by population performance measures resulting from tributary habitat actions applied to Walla Walla River summer steelhead. Habitat potential is assumed equal to performance associated with the pre-development condition in the subbasin. Performance for habitat potential is computed with baseline (i.e., post-development) out-of-subbasin conditions in place.

10.3 All-H Integration Analysis

Results of All-H integration analysis are presented for each population below. Changes in performance measures associated with each action scenario are presented for intrinsic productivity and equilibrium spawner abundance, as these metrics were described earlier in this section. The results are comparable to population metrics presented in Section 6 for baseline performance, as derived empirically by the ICTRT, and to minimum productivity (at the threshold abundance level) and abundance viability thresholds at the 5% risk level (see Table 5-3 in Section 5). Thresholds represent one combination of abundance and productivity needed to achieve a 95% probability of persistence over 100 years. The threshold levels are specific to population size and are based on estimates of historical capacity.

Scenarios were run in a stepwise fashion, starting with baseline, then current condition, then adding in actions sequentially, each being added to the previous scenario. The effects of hatchery steelhead programs on genetic fitness—hence performance—of natural-origin fish were incorporated for each scenario using AHA.

To facilitate an understanding of how estimated performance levels compare to viability thresholds, we computed the ratio of scenario performance/viability threshold level for both abundance and productivity (referred to here as the threshold ratio). Values >1 indicate that performance is expected to achieve the viability threshold criterion for a 5% risk. The amount that the ratio exceeds 1 provides a relative measure of risk—with risk diminishing as the ratio increases. Ratio values <1 suggest a risk level >5%. Table 10-36 provides a list of abbreviations used in the tables and figures.

Table 10-36. Abbreviations used in tables reporting All-H integration results.

Area and abbreviation	Definition
Tributary	
B	Baseline condition
P1-25	Priority 1 actions at 25 yrs
P12-25	Priority 1 and 2 actions at 25 yrs
P1-100	Priority 1 actions at 100 yrs
P12-100	Priority 1 and 2 actions at 100 yrs
Mainstem and estuary	
B	Baseline condition
C	Current condition
Hyd	Hydro action
Pred	Predation plus hydro actions
Est	Estuarine, predation, hydro actions
Har	Harvest, Estuarine, predation, hydro actions
All	All actions (same as Har)
Ocean	
B/C	Baseline and current (assumed same)
-25%	75% of average marine survival
25%	125% of average marine survival

10.3.1 Fifteenmile Creek Winter Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. By far, the largest contribution to performance improvements is estimated to be due to tributary habitat actions. Relatively small increases are estimated to occur as a result of mainstem actions.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. Most scenario combinations result in threshold ratios >2, suggesting a very low risk of extinction over 100 years.

Estimated changes in population performance (productivity and equilibrium abundance) of Fifteenmile Creek winter steelhead associated with combinations of tributary and out-of-subbasin actions are shown in Table 10-37 and Figure 10-45.

Table 10-37. Estimated population performance (productivity and equilibrium abundance) of Fifteenmile Creek winter steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

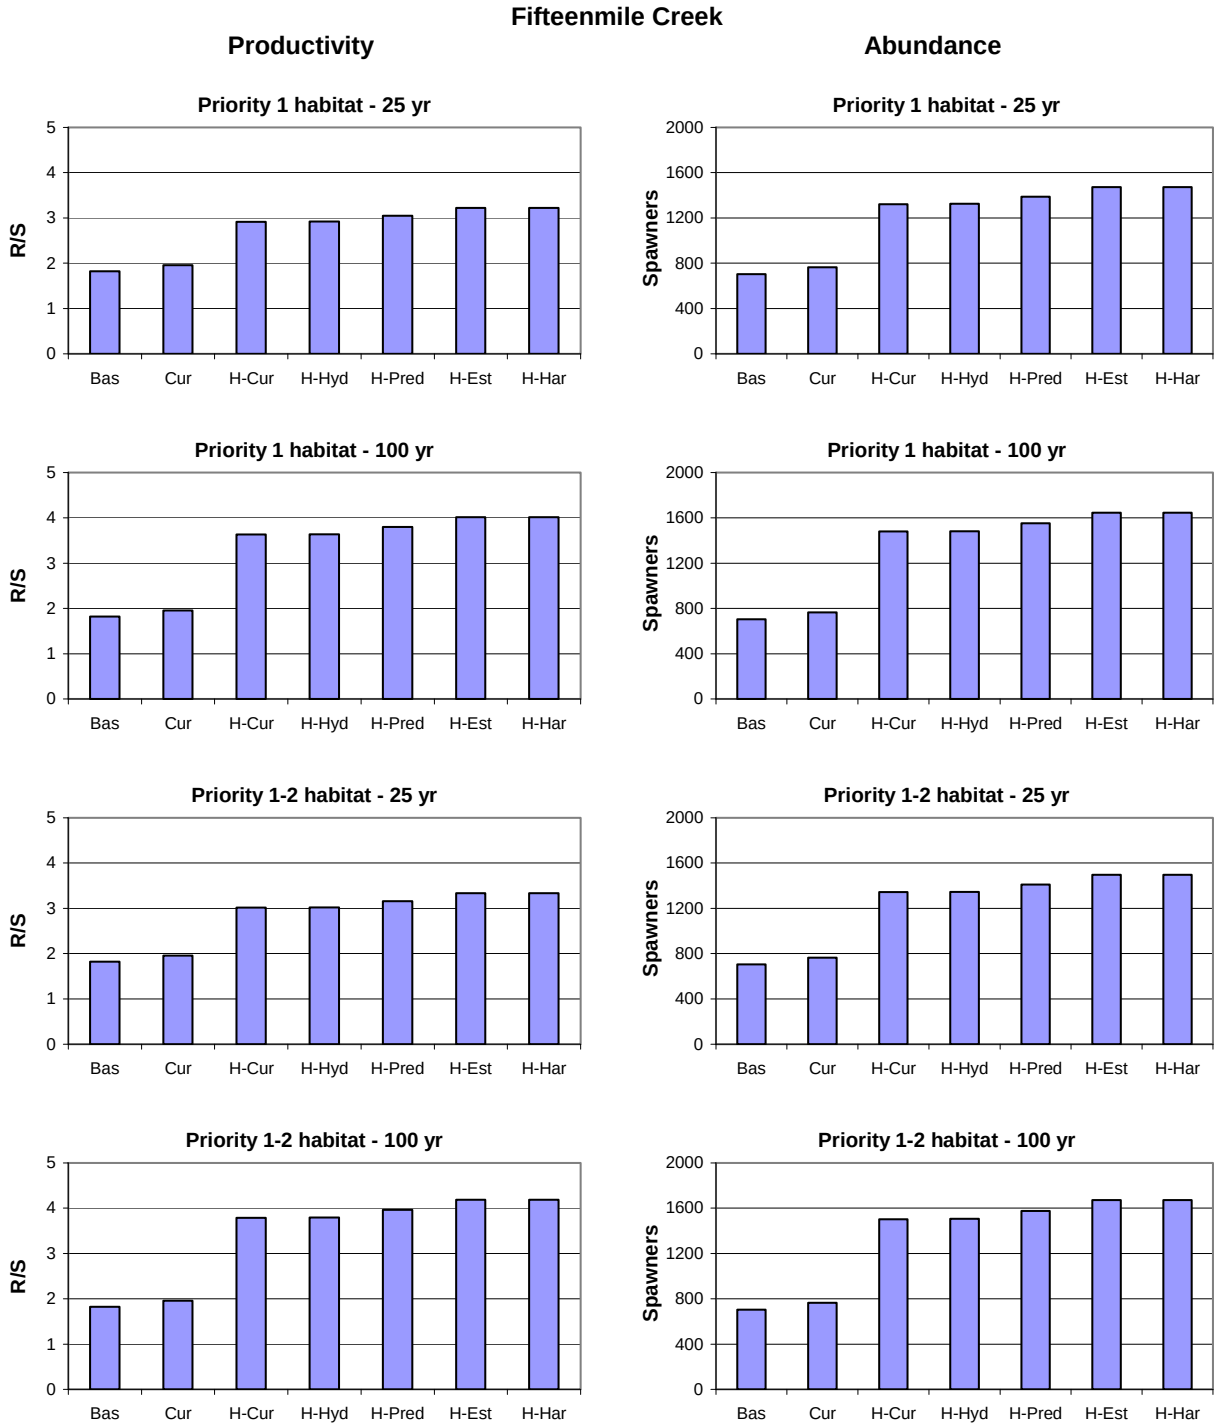

Figure 10-45. Estimated population performance (productivity and equilibrium abundance) of Fifteenmile Creek winter steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.2 Deschutes River Eastside Summer Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements is estimated to be due to tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of action measures. Very substantial benefits to both population productivity and natural-origin spawner abundance also occur as a result of reducing the number of stray hatchery fish that spawn with natural-origin fish.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. All scenario combinations result in threshold ratios >2 for both productivity and abundance, suggesting a very low risk of extinction over 100 years. Reductions in stray hatchery fish produce threshold ratios >4 and >7 for all scenario combinations for productivity and abundance, respectively.

Table 10-38 and figures 10-46 and 10-47 show estimated changes in population performance of Deschutes River Eastside population associated with tributary and out-of-subbasin actions.

Table 10-38. Estimated population performance (productivity and equilibrium abundance) of Deschutes River Eastside summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without action to reduce the number of hatchery strays by 95% of those expected to enter the relevant area for the scenario. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

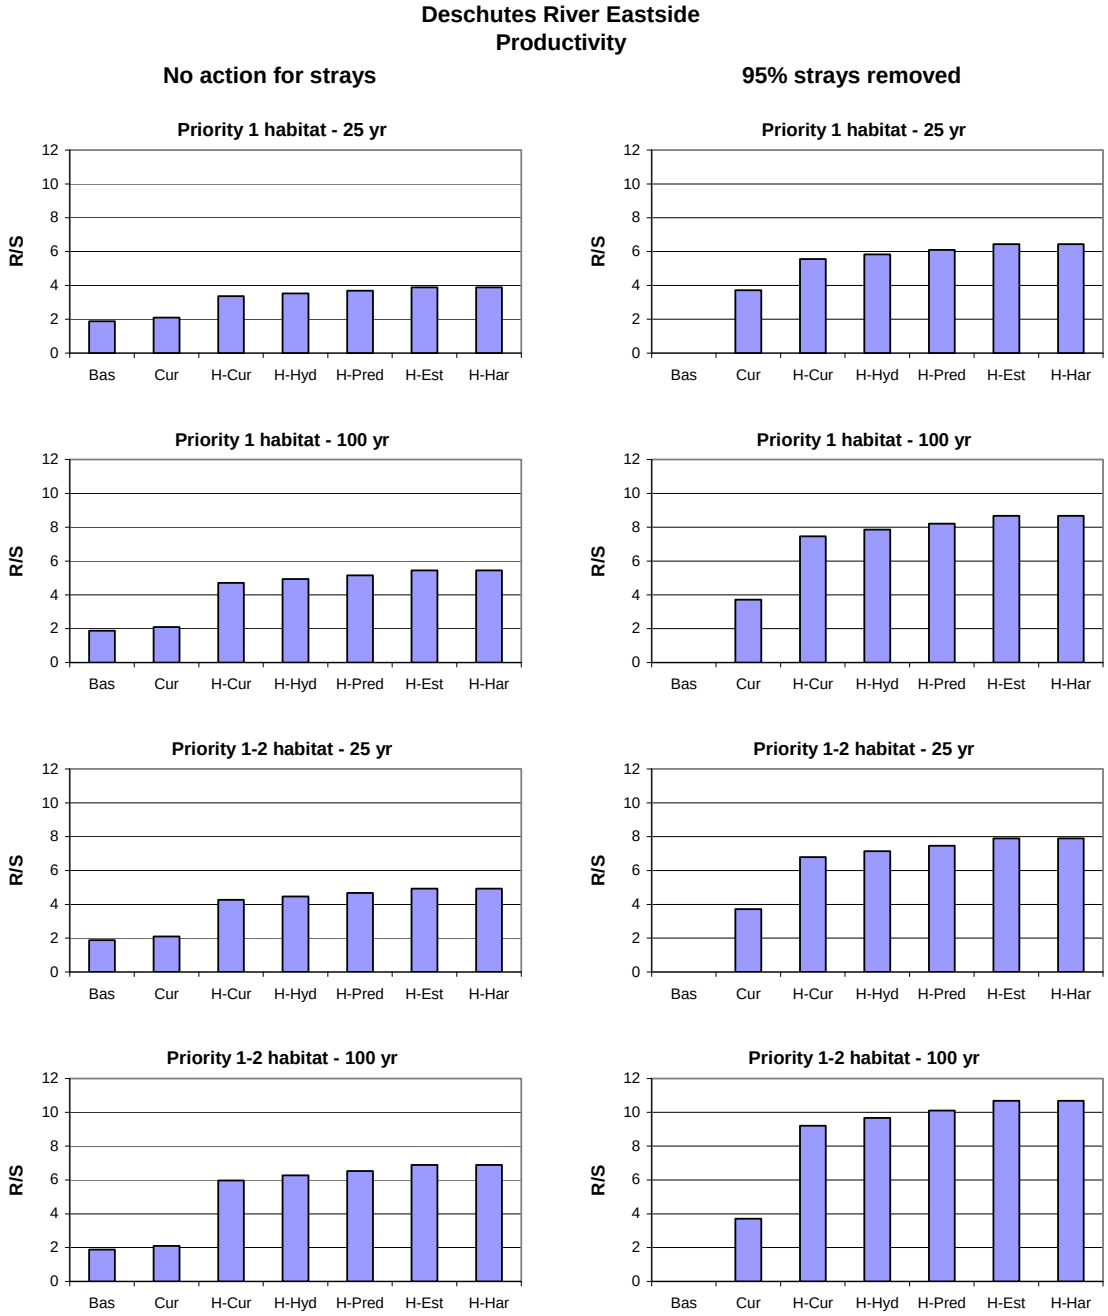

Figure 10-46. Estimated population productivity of Deschutes River Eastside summer steelhead associated with combinations of tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without action to reduce the number of hatchery strays by 95% of those expected to enter the relevant area for the scenario. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

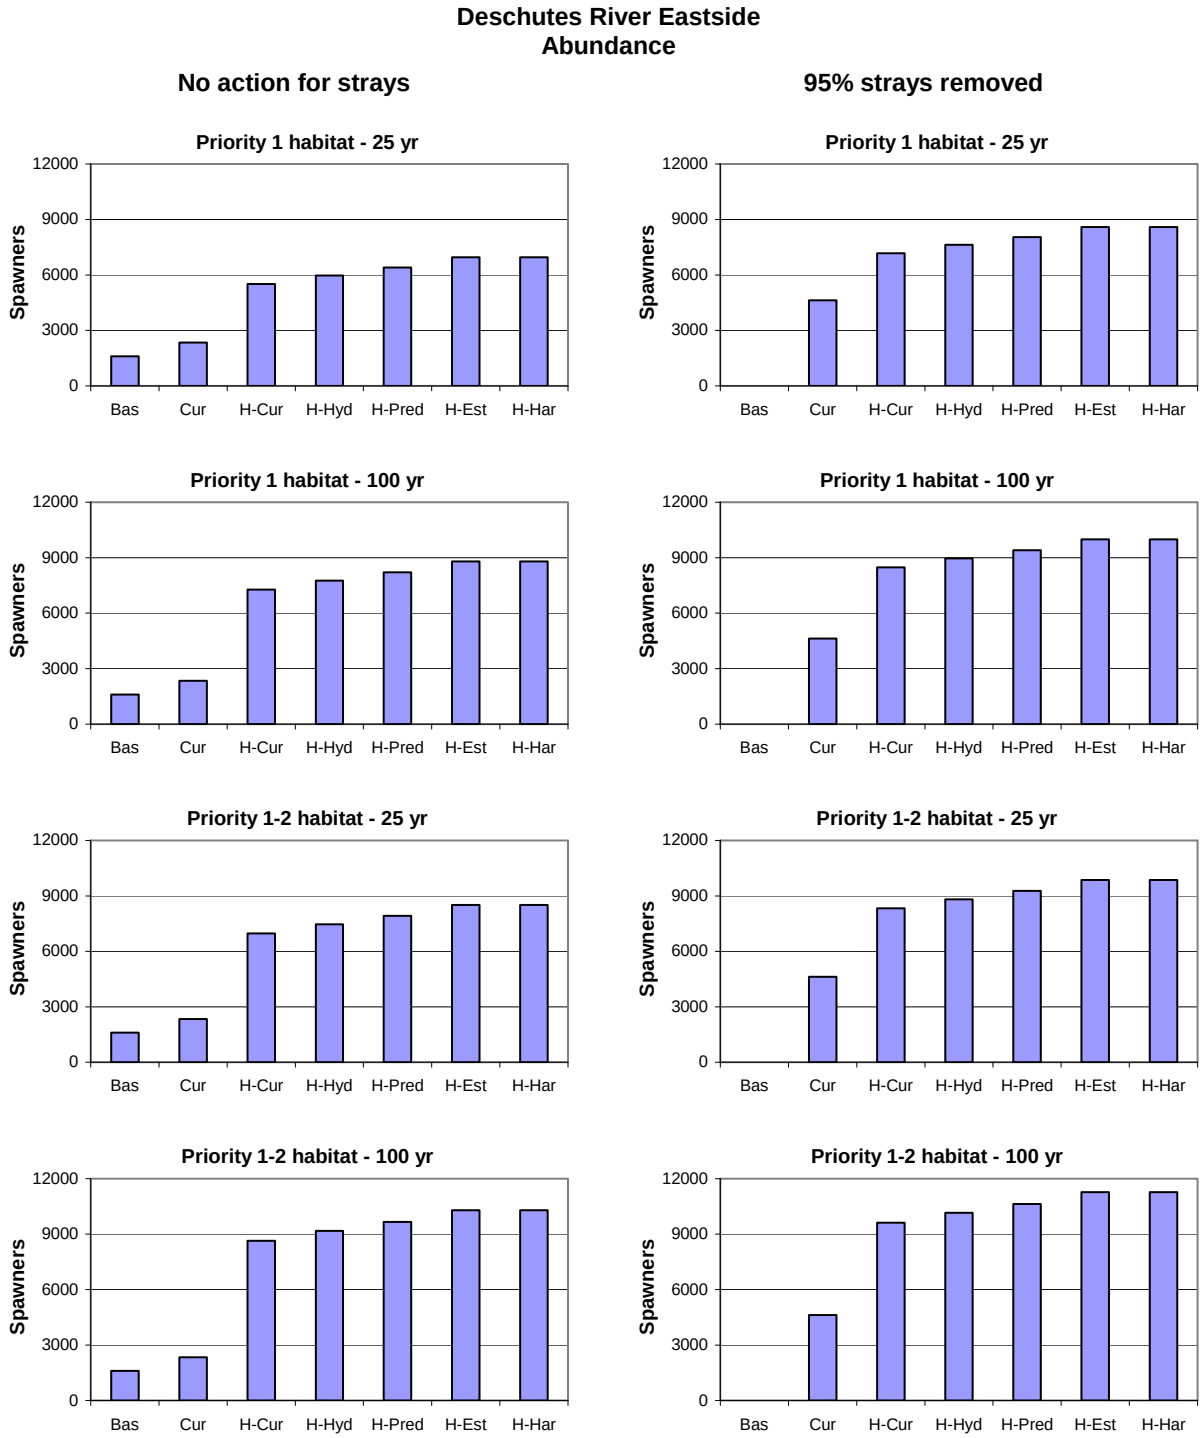

Figure 10-47. Estimated population equilibrium abundance of Deschutes River Eastside summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without action to reduce the number of hatchery strays by 95% of those expected to enter the relevant area for the scenario. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.3 Deschutes River Westside Summer Steelhead, Projected Changes to Population Performance

The largest increases in population performance associated with the range of scenario combinations analyzed occur as a result of decreasing the number of stray hatchery fish and/or by providing passage at the Pelton-Round Butte complex (includes passage at Whychus Creek barriers). In the absence of the removal of strays or passage, benefits are much reduced. For those scenario combinations lacking removal of strays and passage, beneficial effects of tributary actions are greatest, though beneficial cumulative effects of adding in mainstem actions are clearly evident. The more modest benefits associated with tributary actions than found for the Deschutes Eastside population are due to the much better condition of tributary habitat in general compared to that on the east side of the subbasin (as reflected in how habitat conditions were characterized in EDT). We also hypothesize that performance of anadromous *O. mykiss* in west side tributaries is constrained in part by the significant presence of the resident form of *O. mykiss* in these streams.

The viability threshold for productivity is exceeded for all action scenarios, including ones associated with a 25% decrease in marine survival (threshold ratio >1 in all cases). It is noted however that the productivity threshold is tied to the minimum abundance threshold, which for this population, is not exceeded for any scenario combination considered. This suggests that the population would remain at significant risk of extinction despite the full range of actions considered. Only with all actions implemented and a 25% improvement in marine survival is the abundance threshold ratio of 1 approached (but still remaining <1). We hypothesize that this is, at least in part, due to a constraining influence of the presence of resident *O. mykiss* on abundance.

Table 10-39 and figures 10-48, 10-49 and 10-50 show changes in population performance of the Deschutes River Westside population associated with tributary and out-of-subbasin actions.

Table 10-39. Estimated population performance (productivity and equilibrium abundance) of Deschutes River Westside summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without passage at Pelton-Round Butte Complex and with and without action to reduce the number of hatchery strays by 95% of those expected to enter the relevant area for the scenario. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without action to reduce the number of hatchery strays by 95% of those expected to enter the relevant area for the scenario. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

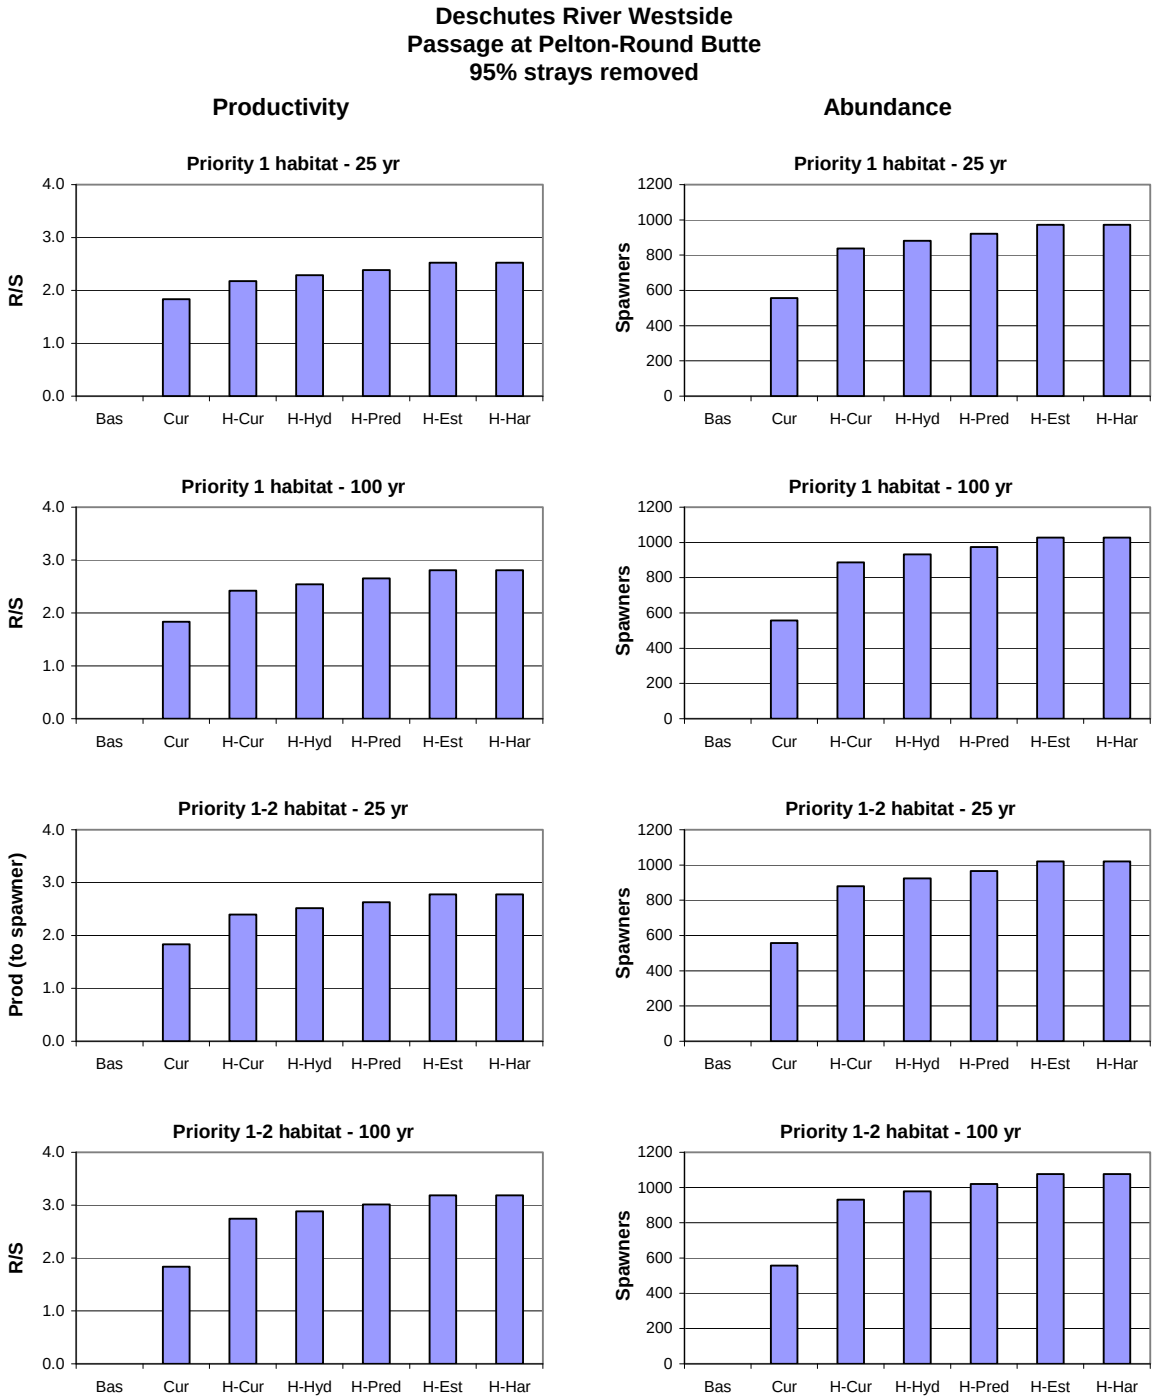

Figure 10-50. Estimated population performance measures (productivity and equilibrium abundance) of Deschutes River Westside summer steelhead associated with combinations of tributary and out-of-subbasin actions and with passage at Pelton-Round Butte Complex. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with action to reduce the number of hatchery strays by 95% of those expected to enter the relevant area for the scenario. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.4 Lower Mainstem John Day River Summer Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements is estimated to be due to tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. All scenario combinations result in threshold ratios >4 (approximately) for productivity and >2 for abundance, suggesting a very low risk of extinction over 100 years.

Table 10-40 and Figure 10-51 show projected changes in estimated population performance of Lower Mainstem John Day River summer steelhead associated with combinations of tributary and out-of-subbasin actions.

Table 10-40. Estimated population performance (productivity and equilibrium abundance) of Lower Mainstem John Day River summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

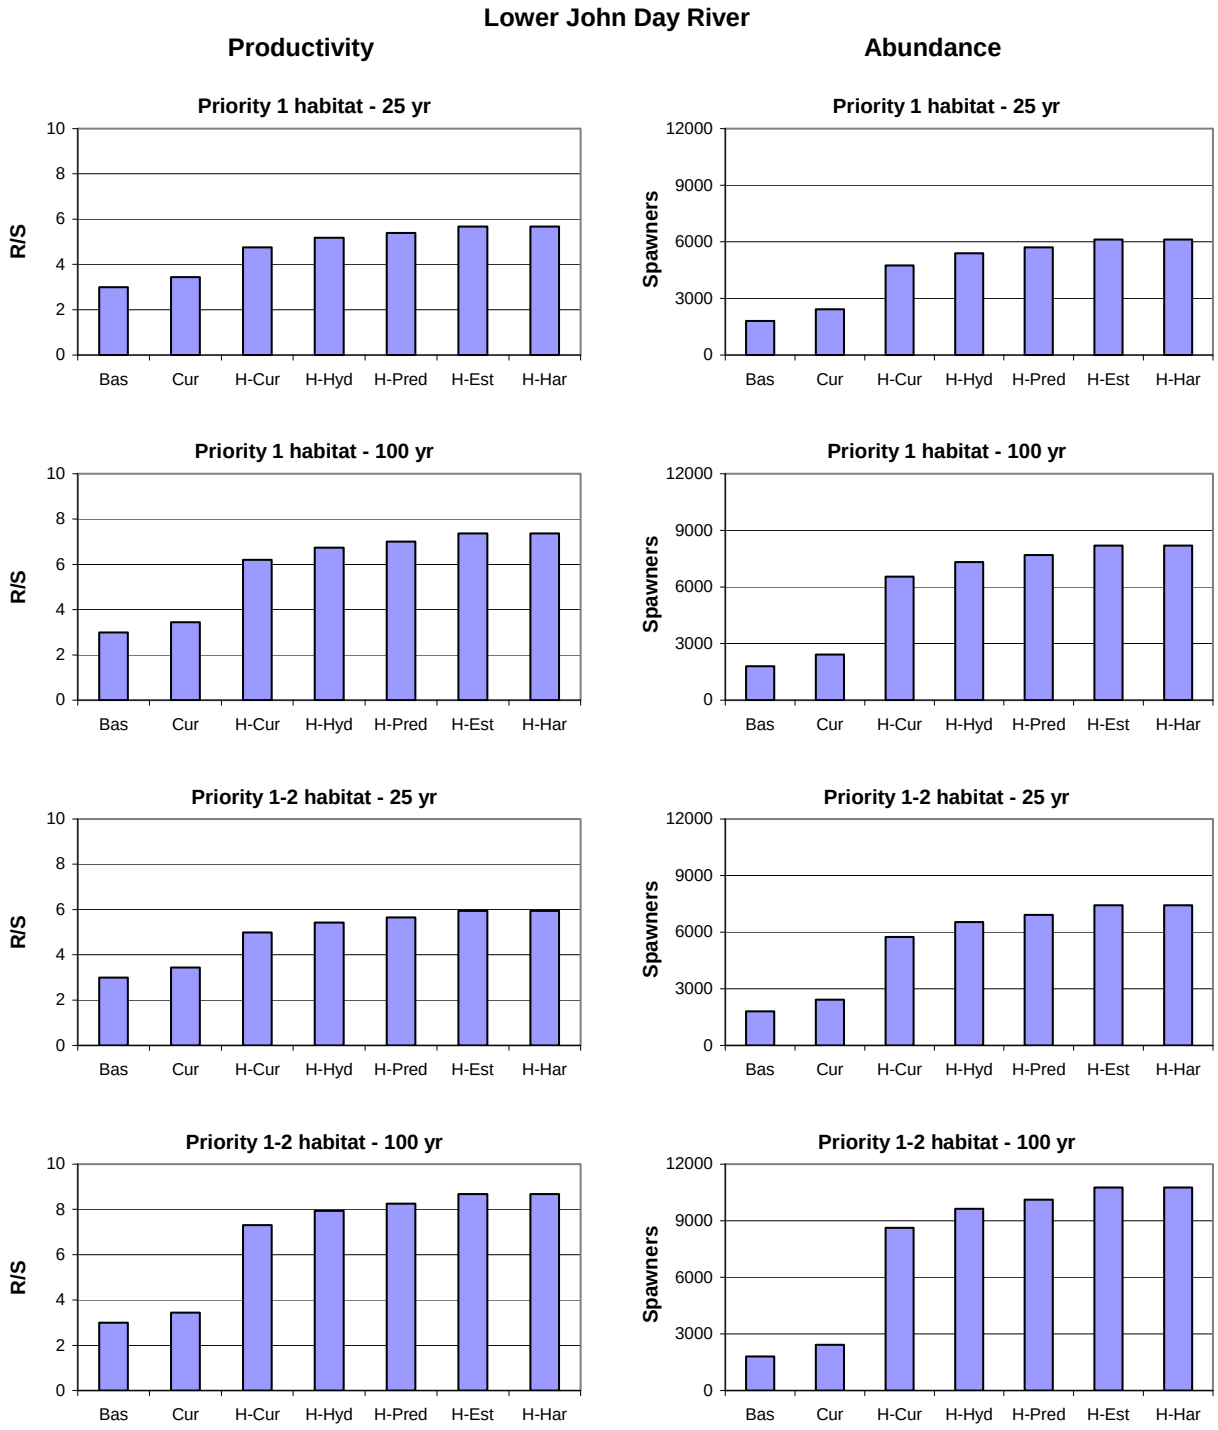

Figure 10-51. Estimated population performance measures (productivity and equilibrium abundance) of Lower Mainstem John Day River summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.5 North Fork John Day River Summer Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements is estimated to be due to tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. Most scenario combinations result in threshold ratios >3 for productivity and >2 for abundance, suggesting a very low risk of extinction over 100 years.

Table 10-41 and Figure 10-52 show projected changes in population performance of North Fork John Day River summer steelhead associated with tributary and out-of-subbasin actions.

Table 10-41. Estimated population performance (productivity and equilibrium abundance) of North Fork John Day River summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.6 Middle Fork John Day River Summer Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements is estimated to be due to tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. Most scenario combinations result in threshold ratios >3 for productivity. Threshold ratios for abundance across the range of scenario combinations are lower, generally between values of 1-2.

See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.7 South Fork John Day River Summer Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements is estimated to be due to tributary habitat actions, with greatest benefits accruing for the 100 year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions.

The viability threshold for productivity is exceeded for all action scenarios, including ones associated with a 25% decrease in marine survival (threshold ratio >1 in all cases). It is noted however that the productivity threshold is tied to the minimum abundance threshold, which for this population, is not exceeded for approximately half of the scenario combinations considered. Only at 100 years, after some tributary habitat actions have fully matured, in combination with addition of mainstem actions, does the threshold ratio for abundance >1. The abundance ratio with all actions implemented, even after 100 years of maturation, drops to <1 when marine survival is reduced to 75% of the current average.

Table 10-43 and Figure 10-54 show projected changes in population performance of South Fork John Day River summer steelhead associated with tributary and out-of-subbasin actions.

Table 10-43. 10.3.8 Upper Mainstem John Day River Summer Steelhead, Projected Changes to Population Performance

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements is estimated to be due to tributary habitat actions, with greatest benefits accruing for the 100 year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. All scenario combinations result in threshold ratios between 2 and 5 for productivity. Most scenario combinations result in abundance threshold ratios between 1 and 2. These abundance threshold ratios are, however, markedly higher than the current ratio value.

Table 10-44 and Figure 10-55 show projected changes in population performance of Upper Mainstem John Day River summer steelhead associated with tributary and out-of-subbasin actions.

Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.3.10 Walla Walla River Summer Steelhead, Projected Changes to Population Performance

We ran two sets of model runs for the Walla Walla River population. The first set included tributary habitat actions described in this plan, most of which were within the geographic boundaries of the state of Oregon. The second set of model runs included the tributary habitat actions identified in this plan, and in addition included the tributary habitat action scenarios modeled in the subbasin planning process within the boundaries of the state of Washington. For both sets of model runs, we used the out-of-subbasin survival improvements previously described in this section.

Action Effectiveness for Action Analysis Used in the Subbasin Plan
The approach used to model action effectiveness within the Washington Walla Walla subbasin planning process (carried forward into the Washington Walla Walla steelhead recovery plan) was less rigorous and less specific to actual proposed actions than the Oregon planning process.

Formulation of action strategies and effectiveness modeling in the subbasin planning process was done in three steps or components: working hypotheses, biological objectives, and strategies. Working hypotheses were the conclusions derived through the EDT diagnostic analysis about limiting factors. The second step was to establish restoration objectives for each of the limiting factors targeted for the analysis. These objectives were set for individual areas of the subbasin based on what the subbasin planning team assumed about what might be realistically attainable. For example, the percentage of pool habitat within a section of the mainstem river had been characterized to be 10% of the wetted surface area. The historical condition was hypothesized to be 20% of the wetted surface area. The biological objective for restoration in this case was set to be 20%. In other reaches, or for other habitat attributes, the objective was set to be intermediate between current condition and historical condition as it was hypothesized to exist. These biological objectives then prescribed a level of action effectiveness needed to achieve each objective, where the action represented whatever kinds of strategies might be employed to achieve the attribute specific objectives. Therefore, action effectiveness was not actually defined by the team, but became a by-product of first setting the objectives for targeted habitat attributes. Based on the targeted biological objectives that had been set, the subbasin planners then defined suites of strategies (or action types) that might be employed to achieve the objectives.

In contrast to ODFW's approach, the Walla Walla subbasin planning approach in 2004 only considered action effects at a 10-15 year time horizon. The action set for areas within Washington was comprised of the full suite of actions—including barrier removal (i.e., provisions for passage were made)—that were assembled for the subbasin plan. Because the Washington Walla Walla recovery plan only identified actions for a 10-15 year time horizon, we only modeled the response to actions for the 25 year timeframe and not for the 100 year timeframe.

Population performance as measured by both productivity and spawner abundance is increased markedly for all scenario combinations identified in this recovery plan, as well as, the aggregate actions of this plan and the Washington recovery plan. Relatively small differences exist between scenario results at 25 and 100 years. The largest contribution to performance

improvements is estimated to be due to tributary habitat actions. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions.

Viability thresholds are exceeded for all scenarios, including ones associated with a 25% decrease in marine survival. All scenario combinations result in threshold ratios between 1-3 for both productivity and abundance, suggesting a low risk of extinction over 100 years.

Table 10-46 and Figure 10-57 show projected changes in population performance of Walla Walla River summer steelhead populations associated with tributary and out-of-subbasin actions. Table 10-47 and Figure 10-58 show actions identified in this recovery plan. Projected changes in population performance of the Walla Walla River summer steelhead population associated with the tributary actions identified in this recovery plan and the Washington Walla Walla River steelhead recovery plan and out-of-subbasin actions.

Table 10-46. Estimated population performance (productivity and equilibrium abundance) of Walla Walla River summer steelhead associated with combinations of tributary and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. The results represent tributary actions that are described in this recovery plan and do not represent actions described in the Washington Walla Walla recovery plan area. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

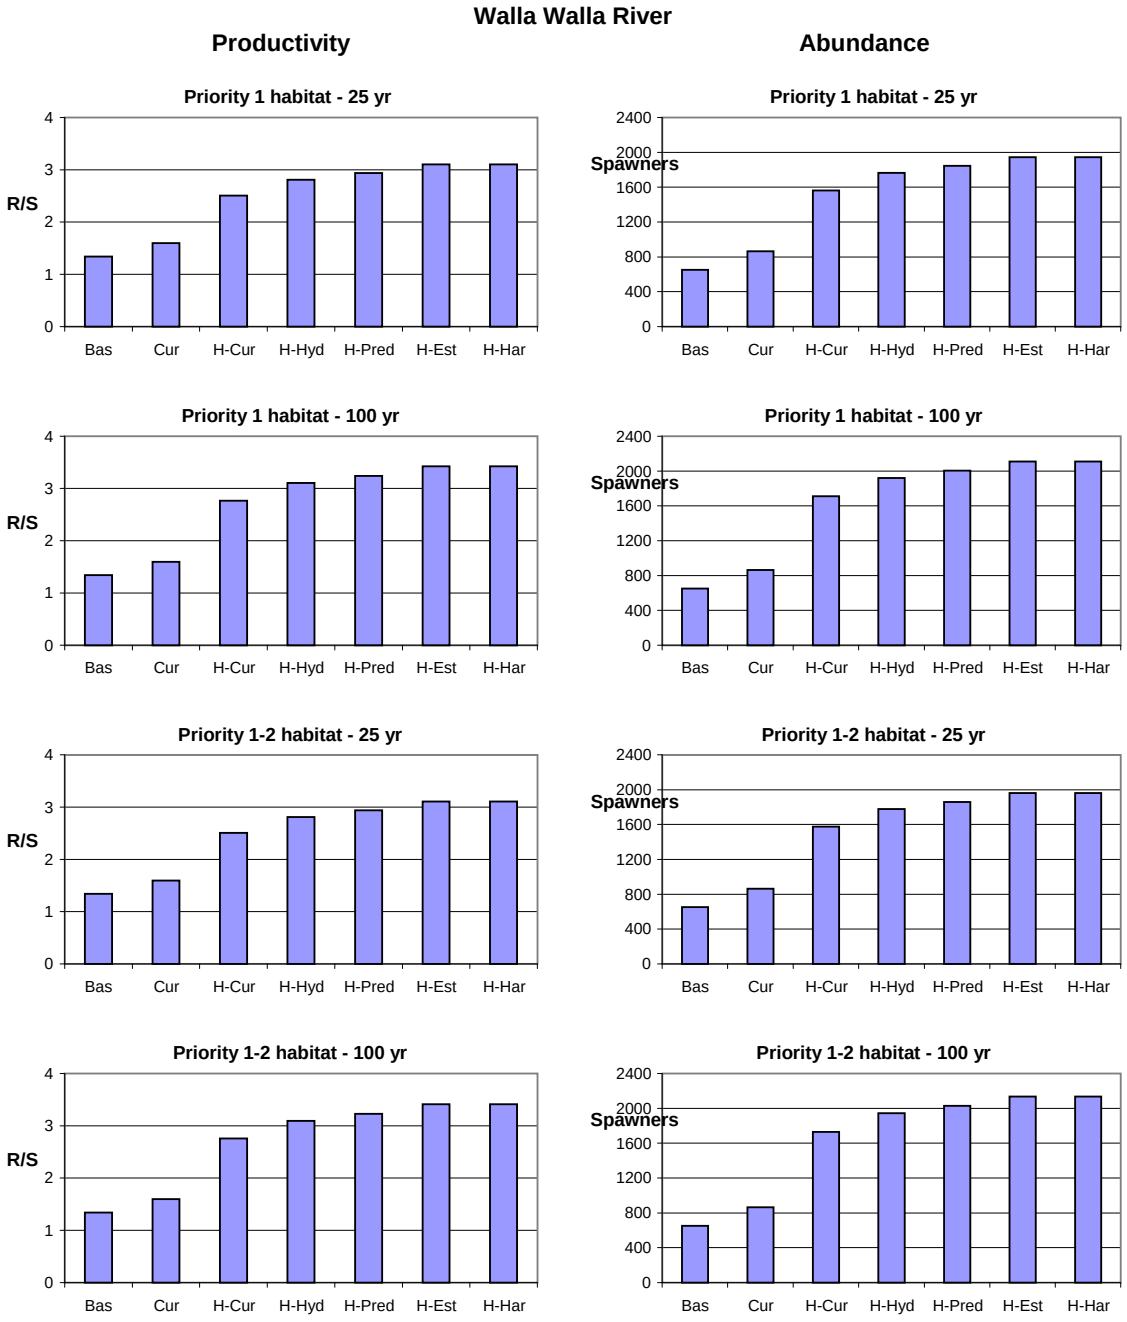

Figure 10-57. Estimated population performance measures (productivity and equilibrium abundance) of Walla Walla River summer steelhead associated with combinations of tributary actions identified in the Oregon recovery plan and out-of-subbasin actions. See Table 10-36 for abbreviation definitions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

Table 10-47. Estimated population performance (productivity and equilibrium abundance) of Walla Walla River summer steelhead associated with combinations of tributary and out-of-subbasin actions. Results are shown for actions performed on just Oregon lands (P12Ore) and with actions combined on Oregon and Washington lands (P12OreWa). Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. The threshold ratio is the ratio of the performance measure/ viability threshold level at the 5% level.

Scenario combination			Performance		Threshold ratio

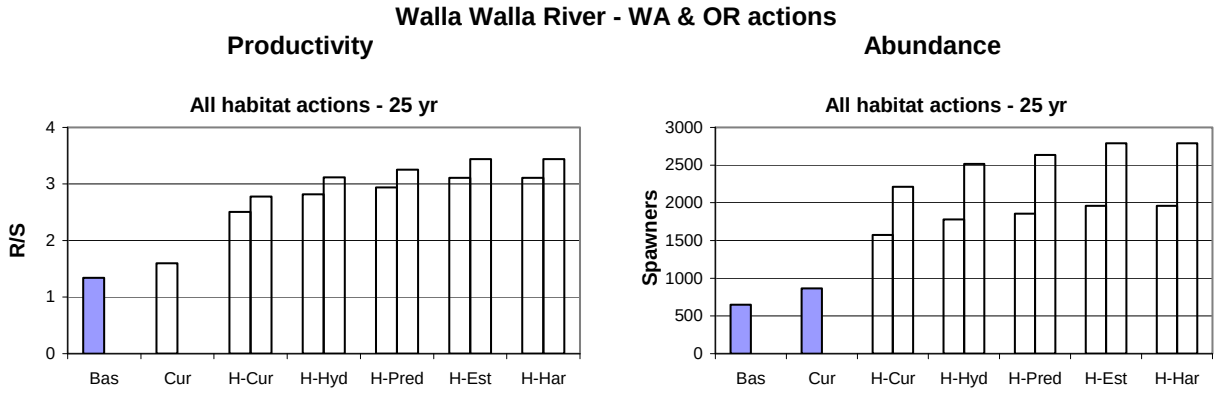

Figure 10-58. Estimated population performance measures (productivity and equilibrium abundance) of Walla Walla River summer steelhead associated with combinations of tributary and out-of-subbasin actions. Results are shown for actions performed on just Oregon lands (blue) and with actions combined on Oregon and Washington lands (red). Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Baseline, current, and combinations of tributary habitat scenarios (shown as H) with out-of-subbasin factors (Hyd, Pred, Est, Har) are shown.

10.4 All-H Management Action Effectiveness Analyses for Spatial Structure/Diversity

Fifteenmile Creek Population
There are no spatial structure or diversity gaps for the Fifteenmile Creek population. However, priority tributary habitat actions focus on restoring the natural hydrograph and reducing stream temperatures which are considered limiting factors. Improving these environmental conditions will allow for expansion of spawning distribution and expression of greater juvenile life history diversity, thus improving spatial structure and diversity status.

Deschutes River Eastside Population
Diversity is significantly impaired with gaps for phenotypic variation and spawner composition metrics. Reduced variability in both adult and juvenile migration patterns have likely occurred due to flow and temperature changes in Bakeoven, Buck Hollow, and Trout creeks, all of which are important production areas. Tributary habitat management actions target restoring the natural hydrograph and reducing stream temperatures. Restoring more normative flow patterns and reducing temperature will provide opportunity for more natural expression adult and juvenile migration patterns thus reducing risk ratings and improving viability.

Abundance of out-of-DPS stray hatchery spawners is a significant diversity impairment creating a high risk rating for the spawner composition metric. Management actions to reduce the abundance of stray hatchery spawners in this population include expansion of trapping and removal of hatchery fish in Trout Creek and initiation of trap and removal of stray hatchery fish in Bakeoven and Buck Hollow creeks. These actions are expected to significantly reduce the

proportion of spawners that are hatchery-origin fish in the population resulting in a lower risk rating for the spawner composition metric in the future.

Deschutes River Westside Population
The Deschutes River Westside population has gaps in both spatial structure and diversity. Spatial structure is significantly impaired because a substantial proportion of the spawning habitat is blocked by the Pelton-Round Butte Complex. This blockage results in spatial structure gaps for multiple metrics including spatial extent/range of spawning and increase in gaps between spawning aggregates. Management actions are underway to provide passage upstream and downstream at the dam complex and to reintroduce steelhead using Westside Deschutes stock to re-establish sustained natural production throughout the historic distribution. These actions, if successful, will result in reducing the risk ratings and improving viability.

Abundance of out-of-DPS stray hatchery spawners and genetic variation are significant diversity impairments. The high proportions of hatchery spawners results in a high risk rating for the spawner composition metric and genetic samples show moderate to low differentiation from outside-basin hatchery samples. Management actions to reduce abundance of out-of-basin hatchery spawners include continuation of trap and removal of strays at Warm Springs hatchery and initiation of trap and removal at Shitike Creek. These actions are expected to significantly reduce abundance of hatchery spawners and improve the diversity metric ratings in the future.

Lower Mainstem John Day River Population
Life history diversity, genetic variation and spawner composition are all metrics that have gaps for this population. Juvenile life history diversity has been reduced as a result of flow and temperature changes. Abundance of out-of-DPS spawners has resulted in a high risk rating for spawner composition. There are many tributary habitat actions that target restoring natural processes and improving both flow and temperature for the long term. These actions are expected to provide opportunity for expression of broader life history diversity. There are no specific actions proposed within this population to reduce abundance of out-of-DPS hatchery strays. However, we expect that if transportation of Snake River hatchery smolts is reduced in the future, and if some alternative broodstock are used for Snake River hatchery programs in the future, that the number of hatchery strays in this population will be reduced.

North Fork John Day River Population
The spatial structure/diversity gap for the North Fork population is spawner composition. Although there is a high degree of uncertainty associated with the proportion of hatchery spawners in this population this metric was rated high risk. No within-population actions are proposed to reduce out-of-basin hatchery stray abundance; however, reduced transportation of Snake River hatchery smolts and broodstock reform in Snake River hatchery programs may reduce abundance of strays in the future.

Middle Fork John Day River Population
All spatial structure/diversity metrics were rated low except spawner composition which was high risk due to abundance of out-of-DPS strays. No within-population management actions are proposed to reduce stray abundance. See the Lower Mainstem description of potential Snake River transportation and hatchery actions that may reduce strays.

South Fork John Day River Population
All spatial structure/diversity metrics were rated low except spawner composition which was high risk due to the proportion of out-of-DPS stray hatchery spawners. No within-population management actions are proposed to reduce the abundance of stray hatchery fish. See the Lower Mainstem description of potential Snake River transportation and hatchery actions that may reduce strays.

Upper Mainstem John Day River Population
Life history diversity and spawner composition are metrics that have gaps for this population. Juvenile movement patterns and reduced summer rearing distribution have likely resulted from altered tributary and mainstem habitats. There are many tributary habitat actions that target restoring natural processes with focus on reducing temperature, improving riparian condition, and increasing flow. These actions are expected to improve habitat conditions and result in opportunity for greater life history expression. The spawner composition metric was rated high risk due to abundance of out-of-DPS hatchery strays. No within-population management actions are proposed to reduce stray abundance. See the Lower Mainstem description of potential Snake River transportation and hatchery actions that may reduce strays.

Umatilla River Population
The Umatilla River population, along with the Walla Walla River population, has the greatest extent of spatial structure/diversity impairment of all Oregon's Mid-C populations. Both spatial structure and diversity have multiple metrics with substantial gaps. The current spawner distribution is significantly reduced from historical due to loss of spawning in Butter Creek and McKay Creek watersheds. Tributary habitat management actions in the Butter Creek watershed target improvement of passage, temperature and flow conditions which are the key limiting factors. These efforts, in the long term, will restore conditions and provide the potential for production in the future.

Four diversity metrics have gaps including life history, phenotypic variation, spawner composition and selective change in natural processes. Tributary management actions that target restoration of natural processes including reducing temperatures, improving the hydrograph, and improving riparian conditions will allow for broader expression of life history diversity including more normative adult and juvenile migration characteristics. These actions are expected to significantly reduce the diversity gaps. There are no Columbia River mainstem hydrosystem management actions proposed that will reduce the selectivity impacts of the hydrosystem.

Walla Walla River Population
The Walla Walla River population is one of Oregon's Mid-C populations with the greatest spatial structure/diversity impairments. Both spatial structure and diversity have multiple metrics with significant gaps. The current spawner distribution is reduced from the historic distribution due to loss of spawning in the Pine Creek watershed. Tributary management actions target restoration of natural processes and conditions, and actions within Pine Creek that focus on improving flow and water quality are considered high priority. Although, we expect that it will take a long time to restore Pine Creek to a condition that will allow sustained natural production. Restoration of sustained natural production in Pine Creek will significantly improve spatial structure with the population.

Four diversity metrics have gaps including life history, phenotypic variation, spawner composition and selective change in natural processes. Tributary habitat management actions target restoration of natural processes and include specific focus on the limiting factors causing diversity impairments. Actions focus on improving temperature, restoring natural hydrograph, and improving passage. These actions, although they will take a long time, will improve conditions and allow for more natural expression of life history diversity and phenotypic traits, such as adult and juvenile migration characteristics. There are no Columbia River mainstem hydrosystem management actions proposed that will reduce the selectivity impacts of the hydrosystem.

Section 11 Time and Cost Estimates

The ESA section 4(f)(1) requires that recovery plans include "estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal" (16 U.S.C. 1531-1544, as amended). This section and Appendix I are intended to meet this ESA requirement, and will be used by NMFS to estimate the total recovery costs for the Mid-Columbia steelhead DPS in its draft Mid-Columbia Steelhead DPS Plan.

11.1 Cost Estimates

The Oregon Department of Fish and Wildlife, together with its Recovery Planning Team, Management Action Teams, and the Oregon Mid-Columbia River Sounding Board have developed an extensive list of projects needed to recover the Oregon populations in the Mid-Columbia steelhead DPS. These projects are intended to address the recovery of ESA-listed Mid-Columbia River steelhead. This project list was developed using the most up-to-date assessment of Mid-Columbia steelhead recovery needs, without consideration of cost or potential funding. This section summarizes cost estimate findings and Appendix I provides cost estimates for recovery projects where available information was sufficient to do so. These draft cost estimates were prepared by a NMFS economist at the Northwest Fisheries Science Center in Seattle using a regional recovery cost database, together with input and review from ODFW, regional experts, and the Mid-Columbia Sounding Board in 2007.

Cost estimates for proposed recovery projects were developed using the unit cost method described in Appendix I. This involved: (1) grouping proposed recovery actions in Section 9 by project type; (2) determining the scale for each action; (3) developing unit costs for each project type and then calculating the total cost estimate for each project; and (4) the resulting total cost estimate by project was multiplied by 1.6 to reflect the additional costs of project planning, coordination, engineering, permits and other administrative needs. The multiplier was estimated after consulting with ODFW and other parties experienced in habitat restoration project implementation.

Table 11-1, Recovery Costs Summary Table, summarizes the total estimated cost for each strategy by population. The estimates are based on cost estimates in Appendix I, Table I-1 (*All Actions by Population, Strategy and Category*) that summarizes estimated total costs that can currently be identified for recovery actions in each Oregon population and strategy. No cost estimates are provided for (1) baseline actions (programs that are already in existence and would occur regardless of this recovery plan, or voluntary actions) that are listed as Not Applicable (N/A); and (2) for actions that need costs to be developed, need unit costs, and/or need project scale estimates, which are listed as To Be Determined (TBD). ODFW will work with regional experts to identify costs, scale or unit costs for actions that need more information during the public comment period. Appendix I will be updated with this new information for the final recovery plan.

The total estimated costs shown in Table 11-1 are by strategy and are either the Priority 1 and 2 estimated total stream mile costs or the estimated project costs in Appendix I, Table I-1. There are several cautions that must be highlighted regarding these summary costs, because many of these estimates may be incomplete until actions are better defined. For example, costs for potentially expensive projects such as land and water acquisition, water leasing, and RM&E have not yet been estimated for many populations. For other projects, unit cost estimates or determination of project scale may also still need to be calculated. Therefore, Table 11-1 presents preliminary summary costs, which will increase when unit cost estimates, scale of projects, and costs for actions are determined, for recovery of these populations.

The estimated total recovery costs in Table 11-1 range widely from relatively less expensive fish passage projects to more expensive projects such as restoring stream channel structure and complexity. The Lower John Day ($116,192,806) and Deschutes River Westside ($114,110,501) populations have the most expensive estimated total project costs, while the South Fork John Day ($8,656,103) and Fifteenmile ($28,358,906) populations have the smallest total costs. These total cost differences may be due to many factors such as size of the population's watershed, extent to which current conditions need to be improved, scale of projects, number of projects identified, and the availability of recovery action cost information by population at this time. The overall total cost estimate for all proposed actions where costs are available for all populations is $512,843,328.

Table 11-1. Recovery Costs Summary Table.

Population and Strategy	Total Estimated Cost
Fifteenmile Creek Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$480,000
3. Maintain and restore floodplain connectivity and function.	$7,760,314
4. Restore degraded and maintain properly functioning channel structure and complexity.	$17,090,583
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions	$2,852,009
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
Fifteenmile Total	**$28,358,906**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, Orchard Ridge and Wolf Run diversion piping, and upland vegetation management.	
Deschutes River Eastside Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$160,000
3. Maintain and restore floodplain connectivity and function.	$17,795,520
4. Restore degraded and maintain properly functioning channel structure and complexity.	$18,539,341
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$7,046,854
6. Restore natural hydrograph to provide sufficient flow during critical periods.	$197,702
7. Improve degraded water quality and maintain unimpaired water quality.	

Population and Strategy	Total Estimated Cost
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
Deschutes River Eastside Total	**$43,915,417**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, and upland vegetation management.	
Deschutes River Westside Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	
3. Maintain and restore floodplain connectivity and function.	$50,499,360
4. Restore degraded and maintain properly functioning channel structure and complexity.	$52,808,352
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$10,626,789
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
Deschutes River Westside Total	**$114,110,501**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, and forest road upgrading/removal.	
Lower Mainstem John Day River Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers.	$7,600,000
3. Maintain and restore floodplain connectivity and function and maintain unimpaired conditions.	$42,164,092
4. Restore degraded and maintain properly functioning channel structure and complexity.	$44,623,665
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$17,121,854
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	$4,507,195
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
Lower Mainstem John Day Total	**$116,192,806**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, push up dam removals, grazing management, and forest road upgrading/removal.	
North Fork John Day River Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$16,120,000
3. Maintain and restore floodplain connectivity and function.	$6,728,300
4. Restore degraded and maintain properly functioning channel structure and complexity.	$6,288,402
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$3,116,517
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	$1,704,357
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	$707,200

Population and Strategy	Total Estimated Cost
North Fork John Day Total	**$34,840,776**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, push up dam removal, and mine discharge management.	
Middle Fork John Day River Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$18,880,000
3. Maintain and restore floodplain connectivity and function.	$12,034,700
4. Restore degraded and maintain properly functioning channel structure and complexity.	$11,847,511
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$5,262,030
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	$1,489,614
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	$1,060,800
Middle Fork John Day Total	**$50,750,655**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, and push up dam removal.	
South Fork John Day River Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$5,680,000
3. Maintain and restore floodplain connectivity and function.	$551,660
4. Restore degraded and maintain properly functioning channel structure and complexity.	$481,353
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions	$1,234,920
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	$532,170
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
South Fork John Day Total	$8,656,103
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, push up dam removal, and forest road upgrading/removal.	
Upper Mainstem John Day River Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$12,240,000
3. Maintain and restore floodplain connectivity and function.	$11,891,318
4. Restore degraded and maintain properly functioning channel structure and complexity.	$15,855,724
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$5,731,272
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	$2,324,475
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	$104,000
Upper Mainstem John Day Total	**$48,322,789**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, and push up dam removal.	
Umatilla River Population	
1. Protect and conserve natural ecological processes.	$176,000

Population and Strategy	Total Estimated Cost
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$5,280,000
3. Maintain and restore floodplain connectivity and function.	$11,191,348
4. Restore degraded and maintain properly functioning channel structure and complexity.	$12,176,285
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$5,855,134
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
Umatilla Total	**$34,678,767**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, point source water pollution management, the Umatilla Basin Project, and forest road upgrading/removal.	
Walla Walla River Population	
1. Protect and conserve natural ecological processes.	$176,000
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	$3,520,000
3. Maintain and restore floodplain connectivity and function.	$9,786,240
4. Restore degraded and maintain properly functioning channel structure and complexity.	$14,696,304
5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	$4,838,064
6. Restore natural hydrograph to provide sufficient flow during critical periods.	
7. Improve degraded water quality and maintain unimpaired water quality.	
8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	
Walla Walla Total	**$33,016,608**
Totals do not include actions with potentially significant costs to be determined later, including habitat acquisition, water right purchases, point source water pollution management, and forest road upgrading/removal.	
Grand Total	**$512,843,328**

Information on current expenditures and expected five-year budget amounts for habitat projects by a wide range of local, state, federal agencies and non-governmental organizations (NGOs) is provided in Appendix I, Table I-2 (*Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead*). This table provides context for the estimated costs of recovery actions and provides a basis for estimating possible levels of funding for recovery plan implementation over a given period of time. Total expected average expenditures over the next five years vary by population. For example, the Fifteenmile Creek population had the lowest expected total five-year expenditure ($3,550,000), while the Lower Mainstem John Day River population had the highest expected total five-year expenditure ($15,095,000). The total expected five-year expenditures for all populations is $103,537,000.

11.2 Time Estimate

NMFS estimates that recovery of the Mid-Columbia steelhead DPS, like recovery for most of the ESA-listed Pacific Northwest salmon and steelhead, could take 50 to 100 years. While this

recovery plan contains an extensive list of actions that need to be undertaken to recover Oregon's Mid-Columbia steelhead populations, there are many uncertainties involved in predicting the course of recovery and in estimating total costs. These include uncertainties regarding biological and ecosystem responses to recovery actions, as well as uncertainties regarding long-term and future funding. While continued programmatic actions in the management of habitat, hatcheries, hydro and harvest will warrant additional expenditures beyond the first 10 years, Oregon believes it is impracticable to estimate all projected actions and costs over 50 to 100 years, given the large number of economic, biological, and social variables involved. NMFS has a policy recommendation to focus on the first 10 years of implementation, with the proviso that before the end of this first implementation period, specific actions and costs will be estimated for subsequent years, to achieve long-term goals and to proceed until a determination is made that listing is no longer necessary.

Given the uncertainties in developing recovery cost estimates described above, Oregon is not able to estimate total or 10-year costs to recover Oregon's populations in the Mid-Columbia steelhead DPS. Table I-2, however, provides current average expenditures on habitat projects expected expenditures during the next five years. These projected five-year habitat project expenditures in Table I-2 total approximately $102 million.

In early 2008, Oregon will develop a plan for recovery project implementation, which will include project cost estimates, and identify how recovery plan implementation will be coordinated. This process is already underway as the Sounding Board discusses its future role in recovery plan implementation. Recovery costs will be revised in the future as specific project budgets are completed. The implementation plan will identify what entity or individual will carry out the recovery actions and the timeline for implementation.

Section 12 Implementation and Adaptive Management

12.1 Implementation

The successful implementation of the Oregon Mid-Columbia steelhead recovery plan recovery actions, research, monitoring and evaluation, and adaptive management process will require significant funds and the coordinated work of ODFW, State agencies, tribes, counties, irrigation districts, agriculture and private forest land managers, NMFS, U.S. Forest Service, BLM, other Federal agencies, local residents, citizen groups, utilities, other agencies, and individuals. ODFW, in coordination with the Oregon Governor's Office and NMFS, has taken the lead in developing this recovery plan; all will continue to be instrumental in its implementation. This section describes the overall framework for coordinated and cohesive implementation of the plan, including tracking, monitoring and reporting, as well as implementation of an adaptive management process.

The recovery plan identifies recovery strategies and actions using the best available science to address limiting factors and threats and recover Mid-C steelhead in Oregon. The NMFS interim recovery planning guidance (NMFS 1996) acknowledges that recovery plans are not regulatory documents, and that it is not a requirement of the ESA for any entity to implement the recovery strategy or specific actions in a recovery plan unless otherwise legally mandated. Consequently, this recovery plan is based primarily on voluntary implementation of proposed recovery actions as well as existing laws, regulations and agreements.

Many of the organizations which are currently implementing, and will implement recovery actions in the future, are not obligated to participate. The identification of an entity in the recovery actions does not necessarily require the identified party to implement the action(s) or to secure funding for implementing the action(s). It is anticipated that these organizations will choose to participate to advance their missions, as part of funding and contractual agreements, and in response to public education and outreach. In fact, there are many examples of voluntary recovery actions already being taken that support steelhead recovery. It is also acknowledged that there may be alternative actions to those proposed in this plan that may also attain recovery strategies. Actions to achieve a specific recovery strategy may vary due to logistics, funding constraints, or an organization's authorities and administrative processes.

Because of this large reliance on voluntary implementation of actions, public outreach and education will be a critical component of engaging citizens and communities to contribute to species recovery needs. Outreach and education will be conducted at all levels within the implementation framework, but will be most important at the local implementation level, specifically with watershed councils and soil and water conservation districts. Recovery plan outreach will be coordinated with outreach efforts under the Oregon Plan for Salmon and Watersheds. The public will also be invited to participate in meetings associated with recovery plan implementation. Without public interest, engagement and stewardship, the goals of this plan will not be achieved.

Oregon's recovery plan implementation framework is intended to provide a collaborative approach to implementation, science guidance and policy direction, as well as facilitate information exchange and coordination from local-level action entities to upper level decision makers and provide linkage to state, DPS and regional forums. Existing forums, groups, partnerships and involved citizens make this implementation structure possible, but additional resources and funding will be needed to make it work effectively and successfully. The basic components of Oregon's implementation framework include a Recovery Team, an Implementation Coordinator, an Implementation Team, a Technical Team, and Watershed Teams (Figure 12.1). These teams will interface with and potentially strengthen the various state agency teams associated with the Oregon Plan for Salmon and Watersheds that provide for policy, management, and monitoring of interagency Oregon Plan programs for the conservation and restoration of habitat, water quality, and salmon (http://www.oregon.gov/OPSW/). In addition, these teams will function to coordinate within the DPS implementation and adaptive management framework (Figure 12.2). The implementation framework will adapt and change as necessary to adjust to funding, available resources, and implementation needs. The roles of each of these implementation teams and the coordinator are described below.

Recovery Team: The Recovery Team provides oversight and vision to recovery plan implementation, in a similar role as the Mid-C Sounding Board served in the plan development process. This team is the responsible entity for reporting to NMFS and shares accountability for species recovery in this MU. The Recovery Team coordinates at state, federal and regional levels; makes decisions and acts on policy, funding and legislative needs; provides overall guidance to the recovery plan teams and coordinates with other domain teams and the Oregon Plan Core Team (interagency policy forum); and serves as the state's representative at the bi-state Mid-C Forum. Members of this team include representatives from the Oregon Governor's Natural Resources Office, ODFW (including the Implementation Coordinator), and the Oregon Watershed Enhancement Board. Additional membership will include interested parties from counties, tribes and federal agencies. While the Recovery Team serves a unique purpose and function, members of this Team will also be members of the Implementation Team.

Implementation Coordinator: An ODFW implementation coordinator will serve as Oregon's "MU lead" for recovery plan implementation, under the advice and guidance of the Recovery Team. The Coordinator will be a key connector to the various teams, groups, subgroups and individual entities. The Implementation Coordinator will work in conjunction with the Implementation Team and Watershed Teams to plan, schedule, track and report on action implementation, and in coordination with the Technical Team to develop, track and report on RM&E activities. The Implementation Coordinator will also be a member of the Recovery Team and a participant in the DPS Implementation and Outreach subgroups. If necessary, the Coordinator will communicate with local, state, federal or tribal hatcheries and other entities and agency staff that perform work related to anadromous fish in the MU. The Implementation Coordinator will lead the Implementation Team in its deliberations and actions, coordinate and lead annual implementation plan development and adaptive management processes, coordinate and communicate with Watershed Teams (or individual implementation entities) and the Oregon Plan Regional Management Teams (interagency regional manager forum). This MU lead will also integrate with regional forums for hydro, harvest and hatchery issues, including the FCRPS BiOp, US v OR, Northwest Planning and Conservation Council, and Columbia Basin Fish and

Wildlife Authority, through linkage with ODFW staff representatives in these forums. Actions and decisions within these forums are important for achieving successful plan implementation and recovery of Mid-C steelhead.

Implementation Team: The Implementation Team provides advice, recommendations and support to the Implementation Coordinator (chair). This Team assists in the communication and coordination with Watershed Teams or local implementation groups, development, tracking and reporting of annual implementation plans, and tracking and reporting of research and monitoring. The Implementation Team also facilitates gathering and exchange of information, identifies and pursues funding sources, and provides for public participation, education and outreach.

Team Members include members of the Mid-C Sounding Board (irrigation districts, utilities, conservation groups, federal and tribal representatives, watershed councils, SWCDs) and other local stakeholders, interest groups and governments. This diverse group represents differing perspectives, missions, and geographic areas, with the overall objective of collectively and synergistically working together to achieve and advance recovery plan goals. The Implementation Team will be staffed by a facilitator and a NMFS representative.

Technical Team: The Technical Team provides advice and guidance on technical and science issues related to monitoring, research and evaluation, data analysis, and adaptive management that supports and strengthens effective implementation of recovery plan actions. The Team will provide the framework for data and dataset gathering from diverse sources and the data management and analysis necessary for threats and viability assessments of the MPG populations. The Oregon Plan Monitoring Team (interagency monitoring forum) will interface with the Technical Team. The Technical Team will be an important MU link to the Mid-C Forum RM&E subgroup, participating in DPS status reviews and ensuring consistency in monitoring. A member of the Technical Team will serve on the Implementation Team. Members of the Technical Team will include members of the recovery plan Planning Team and Expert Panel, as well as other key state, federal, tribal, utility and private scientists and biologists, consultants, and university staff. A voluntary chair will facilitate team operations until funding can be obtained to provide remuneration.

Watershed Teams: Watershed Teams are comprised of the various local entities implementing local restoration and conservation actions via their respective authorities, mandates, missions, and work plans, and include watershed councils, SWCDs, federal and state agencies, local governments, tribes, conservation groups, and utilities. Watershed Teams will be encouraged and facilitated to form on a voluntary basis for a specific watershed, or will be collaborative partnership forums already in existence. In many cases, watershed councils currently serve this function with representation from a diversity of interest and action groups. Team chairs will be voluntary and teams will be self-directed. Collaborative teams will facilitate coordination and prioritization of actions and exchange of information within the watershed. They will provide project information to the Implementation Coordinator (or members of the Implementation Team) to support development of annual implementation schedules, plans, and reports. Collectively or individually, Watershed Teams will promote public involvement through outreach, education, and volunteer opportunities.

The Watershed Teams represent the Major Population Groups in the Oregon Mid-C MU, to include the Cascade Eastern Slopes MPG, the John Day MPG, and the Umatilla/Walla Walla MPG. However, each MPG will include two or more teams representing various populations in the MPG.

Cascade Eastern Slopes MPG: Deschutes Westside (to include Fifteenmile Creek) and Deschutes Eastside populations
John Day MPG: Lower Mainstem, North Fork, Middle Fork, South Fork, and Upper Mainstem John Day populations.
Umatilla/Walla Walla MPG: Umatilla and Walla Walla populations.

If Watershed Teams are not formed, the Implementation Coordinator and members of the Implementation Team will work with individual action entities in the watershed, as necessary.

Oregon will participate in the newly formed bi-state steelhead DPS-level Mid-Columbia Forum to ensure Oregon steelhead implementation activities are coordinated with recovery work in the other steelhead DPS management units in Washington, which are coordinated by local recovery boards (i.e., Yakima and Snake River). Oregon's Recovery Team (through its leads) and Washington's recovery boards (through their executive directors or leads) will be responsible for reporting progress to the Mid-Columbia Forum and NMFS on an annual basis, including progress in management, conservation, and research, monitoring and evaluation actions, and trends in habitat health and salmonid viability.

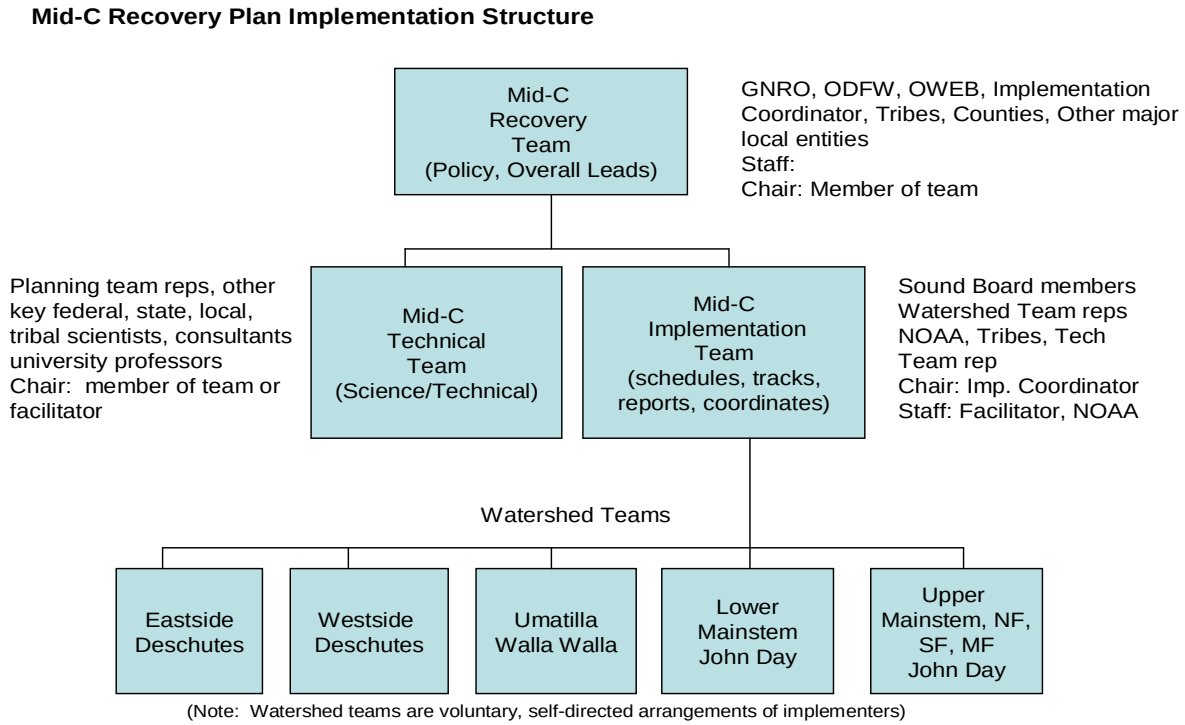

Figure 12.1. Implementation and adaptive management organizational chart for Oregon's Mid-C Steelhead Recovery Plan.

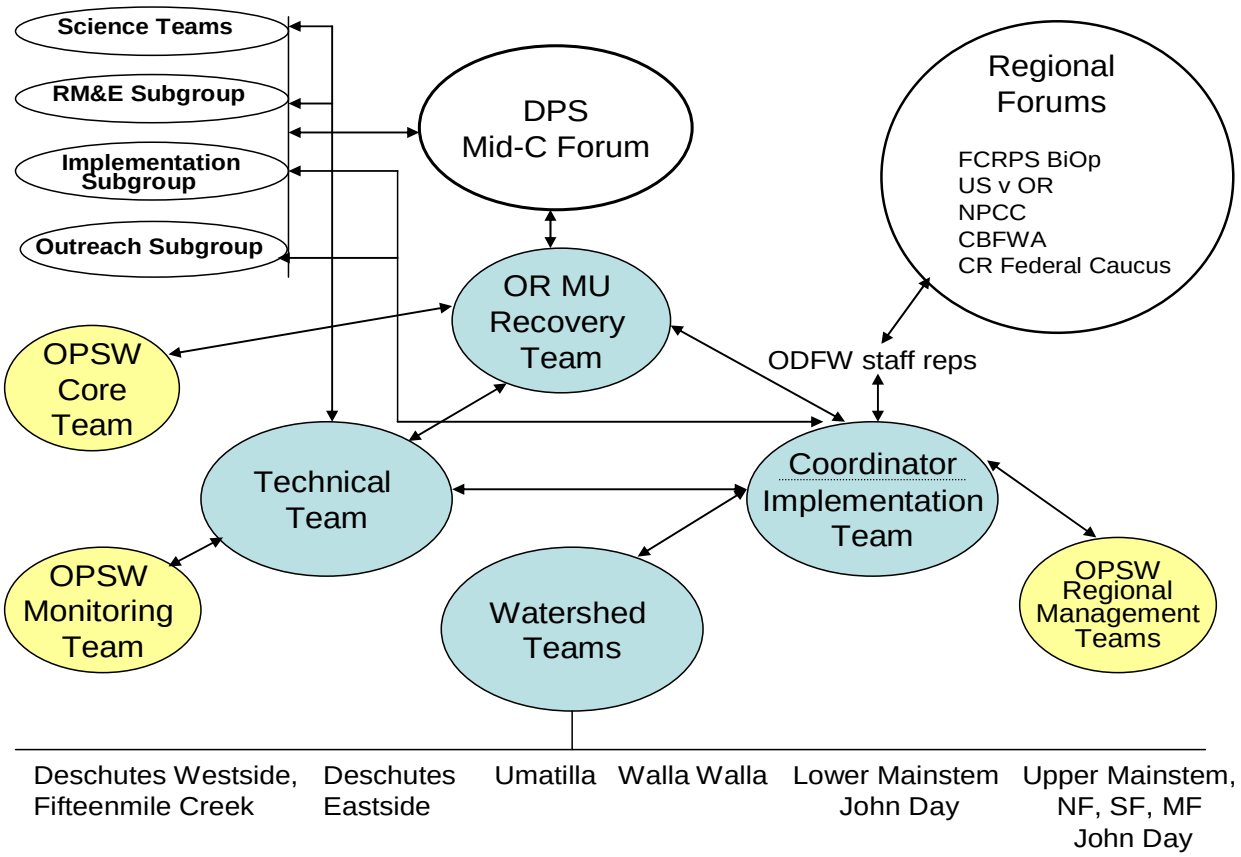

Figure 12.2. Implementation and adaptive management organizational chart for the Mid-C DPS Steelhead Recovery Plan including the Oregon components.

Oregon and NOAA will produce an implementation plan with a schedule to satisfy the requirement under the ESA. The detailed implementation plan will serve as the guidance document that describes the time-specific implementation of actions for all programs. The implementation plan will serve as the benchmark of expected milestones that allows for tracking of progress in recovery plan action implementation.

An ESA implementation plan identifies the following:

- recovery actions,
- priority for completing the actions,
- timeline and duration for completion of the actions,
- lead agency/entity to implement each action, and
- estimated cost for each action over a specified period of time.

Many of the elements of the detailed implementation plan are already covered in this recovery plan including actions, priorities, and program responsibility. The principle element that is missing is the program by program description of actions that will be completed on an annual basis. A detailed implementation schedule and plan will be completed in 2009 after Oregon and NMFS have refined and finalized the proposed recovery actions and recovery costs based on

public comments and the recovery plan is adopted in 2009. In developing this implementation plan, Oregon and NMFS will work with Oregon's Implementation Team, and in close association with the Oregon Plan Regional Management Teams (Central Regional Management Team and Eastern Regional Management Team), to identify who is responsible for carrying out recovery actions and when. Federal agencies will also need to identify how they will be involved in recovery plan implementation.

12.2 Adaptive Management

Mid-C steelhead have a complex life cycle that traverses habitats from high elevation tributaries to the open ocean. Life history strategies and life stage specific habitat requirements are complex. There are many limiting factors and threats that influence the viability of Oregon's Mid-C steelhead at all life stages. The suite of proposed management actions to address primary limiting factors and threats across the entire life cycle is extensive and diverse. Although the limiting factors and threats, as well as the management actions, have been developed based on the best available science, there remains considerable uncertainty regarding the outcomes and effectiveness of the proposed management actions as well as the status of the populations. It is this uncertainty which generates the essential need for an effective adaptive management process.

A successful adaptive management process requires that we understand how and why steelhead and their associated habitats respond to the management actions we take to address key limiting factors and threats. In addition, success requires a decision framework and process which considers new information in the development and implementation of future management actions.

One of the great challenges facing the development and implementation of an effective adaptive management strategy for Oregon's Mid-C steelhead is the extensive number of organizations that implement management actions, as well as the complexity in jurisdictional and management decision authority. There are many different organizations including state agencies, tribes, counties, irrigation districts, agriculture and private forest land managers, NOAA, U.S. Forest Service, BLM, other federal agencies, local residents, citizen groups, utilities and others that implement management actions.

Along with this implementation complexity is a parallel level of jurisdictional, management decision authority, and process complexity. There is no one single decision body that holds decision authority for management actions across all the H's. Decision authority for management actions resides across many entities including state, tribal, federal, county as well as others. Those diverse decision frameworks and processes, many independent of others, create coordination and collaboration challenges. We acknowledge that it is unreasonable to expect centralization and integration of all authorities and decision processes into a single decision framework. Our approach is to develop a collaboration and coordination process that uses the implementation structures and allows for sharing of information and decisions that influence recovery of Mid-C steelhead.

Integration of the many adaptive decision processes will occur within the adaptive management framework illustrated in Figure 12.1. The Recovery Team and the Implementation Team will serve key roles in incorporating new knowledge into future management guidance and direction. These teams will not only provide input for adaptive implementation of tributary habitat actions, they will also provide input into other regional decision forums through the Mid-C Forum and State of Oregon representatives.

In the following text, we provide a description of the various management decision processes and associated adaptive management plans that influence management actions for tributary habitat, mainstem hydrosystem, harvest and hatcheries.

12.2.1 Tributary Habitat

There is a variety of funding sources and implementing entities responsible for tributary habitat restoration actions. In all cases the funding sources and implementing entities have adaptive decision processes for prioritizing actions. It is beyond the scope of this document to present all of the processes used, thus, we provide a few examples illustrating the major ongoing decision processes, followed by a description of how the recovery plan adaptive management framework will address adaptive management for tributary habitat protection and restoration.

The Oregon Watershed Enhancement Board (OWEB) is a state agency that supports Oregon's efforts to improve water quality, strengthen ecosystems and restore salmon runs. OWEB coordinates the Oregon Plan for Salmon and Watersheds, which is an essential element of tributary habitat restoration for the recovery plan. OWEB administers grant funding programs from Oregon lottery proceeds and from federal Pacific Coastal Salmon Recovery Funds (PCSRF). These grant programs fund cooperative salmon habitat restoration for a wide variety of implementers. OWEB's strategic plan describes how the board will achieve watershed restoration. OWEB focuses on projects that approach natural resource management with a whole-watershed perspective through investments and partnerships. Priority watershed concerns addressed by grants include:

- Instream Process and Function
- Fish Passage
- Urban Impact Reduction
- Riparian Process and Function
- Wetland Process and Function
- Upland Process and Function
- Water Quantity/Irrigation Efficiency
- Road Impact Reduction

An essential element of the OWEB strategy is active implementation of adaptive management. Adaptive management is implemented in a variety of ways through strategic guidance, project review, selection and prioritization processes and emphasis on monitoring and evaluation. Review team members score and discuss applications to determine which projects to recommend for funding.

Monitoring information from the complement of different types of project monitoring efforts (e.g., baseline, compliance, status and trend, effectiveness, and validation monitoring) and the cooperative interagency Monitoring Team is used to help measure project progress and effectiveness. Oregon is able to document watershed conditions, track changes in critical habitat and species over time, and evaluate the effectiveness of conservation and restoration efforts. This diversity of monitoring approaches is essential to understanding watershed health, tracking the success of projects, and setting restoration priorities.

As a critical element in the grant funding process, the OWEB Board is kept apprised of new and emerging issues in the natural resources arena to help guide their decisions. As an example, the Board has received many presentations on climate change and its potential impacts to watersheds and salmon. This information helps to shape the decision framework within which the Board operates and its final recommendations. The OWEB Board has provided general recommendations as guidance for grant funding and overall action implementation in the watershed to strengthen the Oregon Plan for Salmon and Watersheds:

- Promote citizen involvement in the Oregon Plan
- Build creative partnerships to focus on significant ecological outcomes
- Streamline and expedite permitting for restoration projects
- Support strong leadership, interagency communication, and coordination
- Develop and implement shared priorities for restoration
- Track restoration and recovery trends and improve information accessibility
- Develop a coordinated strategy that demonstrates ways habitat restoration actions reduce the growing risk of climate change

The Northwest Power and Conservation Council's Columbia Basin Fish and Wildlife Program provides extensive funding to many habitat protection and restoration implementers in all of Oregon's Mid-C steelhead populations. The Fish and Wildlife Program was established to mitigate the effects of the Columbia River federal power system. On a periodic basis (typically every three years), the NPCC solicits and evaluates proposals for on-the-ground monitoring and evaluation projects to meet the goals and objectives of the program. Proposed projects undergo a rigorous scientific review and revision process to ensure implementation of sound and effective high priority projects that are based on best available science and use state-of-the-art restoration strategies and approaches. Integral to this process is the review of each individual proposal by the Independent Science Review Panel (ISRP). Each project is evaluated, in part, based on the project's role in contributing to an effective adaptive management process. The review process has resulted in significant changes through time in implementation strategies and actions for most habitat restoration projects.

SWCDs, Watershed Councils, and other habitat restoration implementation entities all have prioritization and adaptive change processes that are used in deciding which projects to implement. New monitoring and evaluation information is used within each of these decision frameworks to decide on priority actions, geographic locations, and specific applications. Within these processes the consideration of high priority recovery actions is important.

Although OWEB, NPCC, SWCDs, tribes, states, NGOs and others have prioritization processes and elements of adaptive management, there is a clear need for a more integrated and coordinated adaptive management approach for tributary habitat restoration. Previously in this section we described an implementation and adaptive management framework for this recovery plan. We do not envision this new framework and process to replace the other processes that are currently used, but rather a mechanism to improve collaboration, coordination and sharing of essential information for decision making. Under the guidance of the Recovery Team and the Implementation Team, the Technical Team and Implementation Coordinator will function as the core for tributary habitat adaptive management. New information, including successes and failures, will be shared throughout the framework from the watershed and technical teams upwards to the Recovery Team to allow for better decisions regarding priority actions, geographic focus areas, and application techniques. The Oregon Plan Regional Management teams play an important role in this adaptive process as they hold responsibility for managing the implementation and prioritization of many critical restoration actions.

12.2.2 Mainstem Hydrosystem

Implementation Plans and Reporting Requirements
The FCRPS BiOp requires the federal Action Agencies to continue collaboration with states and tribes in the implementation of Reasonable and Prudent (RPA) actions, progress reporting, and adaptive management using regional fora such as the Regional Implementation Oversight Group. RPA Actions 1 through 3 identify the general requirements governing the federal Action Agencies' development of implementation plans and reporting requirements. The federal Action Agencies must submit implementation plans to NOAA Fisheries in December of 2009, 2013, and 2016 that detail commitments to implement RPA actions - during subsequent years - for hydro, habitat, hatcheries, harvest, and predation (RPA Actions 4-49), and RPA actions (50-73) for Research, Monitoring, and Evaluation (RM&E).

The federal Action Agencies are required to submit Annual Progress Reports to NOAA Fisheries September 2009 through 2018 which cover hydro operations, status of physical or biological metrics monitoring, and actions implemented in the previous year, except in 2013 and 2016.

In June of 2013 and 2016, the federal Action Agencies are required to submit Comprehensive RPA Evaluation Reports to NOAA Fisheries. These reports shall review all implementation activities through the end of the previous year (as covered in the Annual Progress Reports) and compare them to scheduled completion dates in the BiOp or as modified through the Implementation Plans in 2009, 2013, and 2016. The Comprehensive RPA Evaluation will also describe the status of the physical and biological factors identified in the RPA, and compare these with the expectations in the survival improvements identified in the Comprehensive Analysis or Supplemental Comprehensive Analysis. Physical and biological factors will include new information on climate change and its effects on listed salmon and steelhead. The Comprehensive Evaluation will include a discussion of the Action Agencies' plan to address any shortcomings of current estimated survival improvements as compared to the original survival estimates identified in the Comprehensive Analysis referenced in the 2008 FCRPS BiOp.

RM&E Requirements

The 2008 FCRPS BiOp includes some research, monitoring, and evaluation (RM&E) requirements (Reasonable and Prudent Alternative Actions 50 through 73) for the federal Action Agencies (U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, and Bonneville Power Administration). These RM&E requirements are designed to provide information needed to support planning and adaptive management and demonstrate accountability related to the implementation of FCRPS ESA hydropower and offsite actions for all ESA-listed species (Evolutionarily Significant Units or Distinct Population Segments). Considerably more detail in the RM&E plans needs to be developed in the early stages of BiOp implementation. The 24 RPA actions can be categorized into nine broad strategies:

1. Monitor Status of Selected Fish Populations Related to FCRPS Actions
2. Hydropower RM&E
3. Tributary Habitat RM&E
4. Estuary and Ocean RM&E
5. Harvest RM&E
6. Hatchery RM&E
7. Predation Management RM&E
8. Coordination and Data Management
9. Project Implementation and Compliance Monitoring

Regional Implementation and Oversight Group and Technical Committees

Regional Implementation and Oversight Group (RIOG)

As described in the BiOps and related documents, the RIOG is established to provide a high level policy forum for discussion and coordination of the implementation of the FCRPS and related BiOps between the federal agencies on the one hand and states and affected tribes on the other hand. The overall purpose of the group is to inform federal, state and tribal agencies that are actively engaged in salmon recovery efforts regarding implementation issues from each sovereign's perspective. In doing so, the RIOG will serve as a forum where Basin-wide policy issues and concerns related to the implementation of the BiOps, including impacts on other Basin-wide basin programs and interests may be discussed in a collaborative manner, and to provide a forum for enhanced accountability and transparency.

The RIOG will consist of designated senior policy representatives of each of the following:

- five regional federal agencies: NOAA, BPA, Reclamation, Corps and the US Fish and Wildlife Service;
- four state governors: Montana, Idaho, Washington and Oregon; and
- Colville, Spokane, Kootenai, Warm Springs, Umatilla, Yakama, Nez Perce, Kalispel and Salish-Kootenai tribal governments (all Columbia Basin Tribes are invited to participate).

However, no agency or sovereign is compelled to participate in the RIOG because participation is by interest and choice. Some sovereigns may not have enough interest in implementation of the BiOps to warrant participation.

All decisions under the authority of the federal government will continue to be made by the appropriate federal agency with the statutory authority to make such decisions. The RIOG is a forum for interagency coordination and does not supplant existing federal, state or tribal decision-making authorities.

Technical Committees

The RIOG will be supported (groups should form in 2009) by Senior Technical Teams for hydro, habitat, hatcheries, and RM&E integration (the latter as needed) and by additional Technical Teams. The Technical Teams will include groups that have been used in the past (Technical Management Team, System Configuration Team, Water Quality Team, Corps of Engineers workgroups, etc.), as well as, new teams (geographically based Habitat and Hatchery Teams and a Predation Management Team) that will be formed in 2009. Technical information and recommendations will flow "upward" from the Technical Workgroups to the Senior Technical Workgroups to the RIOG (for adaptive management and dispute resolution) and policy guidance and technical assignments will flow "downward" from the RIOG to the Senior Technical and Technical level groups.

Together, these RIOG and Technical Committees will attempt to assure that actions required by the 2008 FCRPS BiOp are effectively implemented, performance standards are achieved, disputes are resolved, and other regional processes (NOAA Fisheries' recovery plans, US v. Oregon, Northwest Power and Conservation Council's Fish and Wildlife Program, etc.) are fully considered during the 10-year implementation of the 2008 FCRPS BiOp.

12.2.3 Harvest

Mainstem Columbia River

The parties to the *2008-2017 United States v. Oregon Management Agreement* recognize that a vigorous research and monitoring program is essential to the continued implementation and adaptive management of the harvest regimes that are envisioned in the agreement. The objective of the proposed research and monitoring is to improve the accuracy and precision of harvest management. Specific monitoring and research needs to provide information which is essential for adaptive management are identified in the agreement, and include:

- Fisheries sampling for stock composition including impacts to natural-origin fish
- Fishery effort accounting
- Natural spawning escapement enumeration including enhancements over current sampling efforts
- Run reconstruction and forecasting
- Observer programs and test fisheries
- Dam passage sampling
- PIT tag sampling
- Increased sampling effort to maintain necessary fishery sampling rates
- Evaluation of genetic stock identification methods to further improve stock identification

A Technical Advisory Committee (TAC), comprised of fishery biologists from state, federal and tribal management agencies, is established by the agreement to develop, analyze, and review data pertinent to the agreement and to make reports and technical recommendations regarding harvest management.

The parties to *US v. Oregon* agreed to work together to maintain funding for current research and monitoring programs, and to seek additional funding that are considered essential to increase certainty in the conservation effectiveness of the harvest strategies contained within the agreement. The parties also agreed to seek funding sources to assist TAC and its representatives in the performance of their functions.

Additional monitoring, evaluation and adaptive management of harvest is provided by the Endangered Species Act Section 7(a)(2) Consultation Biological Opinion and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Consultation on Treaty Indian and Non-Indian Fisheries in the Columbia River Basin Subject To the 2008-2017 *US v. Oregon* Management Agreement (hereafter, Fisheries Biological Opinion). The Fisheries Biological Opinion was approved by NOAA Fisheries on May 5, 2008. Section 13.4 of the Biological Opinion specifically identifies several Reasonable & Prudent Measures that emphasize in-season management actions that will ensure that incidental take of ESA-listed species, including of listed steelhead, remain consistent with the Biological Opinion. These measures specifically require that:

- Harvest impacts on listed species shall be monitored using the best available measures;
- In-season management actions taken during the course of fisheries managed pursuant to the 2008 *US v. Oregon* Agreement shall be consistent with the level of take specified in the Incidental Take Statement in the Fisheries Biological Opinion;
- NOAA Fisheries shall consult with the states and tribes to account for the catch of ESA-listed steelhead in the action area as these occur through the season; and
- NOAA Fisheries will track the results of these monitoring activities, and in particular, any anticipated or actual increases in the incidental take from those expected preseason.

Recreational Fisheries Regulation Processes (ODFW)
The procedures for promulgation of angling regulations in accordance with Oregon Revised Statute 496.162 are described in Oregon Administrative Rule 635-011-0050. This rule states that "Department staff shall continually monitor the status of fish, shellfish, and marine invertebrates and report promptly to the Director and Commission any serious or abnormal changes in health or abundance of the resource." There are three basic rule making processes used to develop angling regulations which are described below.

The "Public Process" solicits proposals for new or modified angling regulations from the public and considers these proposals for adoption along with ODFW staff proposals. The public process takes place on a four-year cycle, with the last Public Process completed for the 2009 Oregon Sport Fishing Regulations. The Public Process takes over a year to execute with staff proposals solicited 16 months before rule adoption.

During the "Interim Years" angling regulation changes are adopted without substantive changes, but there are opportunities to make rule changes to meet conservation needs, and to make any corrections or clarifications. Rules developed as part of Fish Management Plans are also considered during Interim Years. The "Interim Year" process normally begins in late April when Fish Division Staff solicit rule changes from Fish District Biologists and Fish Division Management. Rules are then adopted in August and take effect January 1 of the following year.

Angling regulations can also be changed by "Temporary Rules" (often referred to as emergency rules) which are put in place to: protect or preserve a fish species or stock experiencing depletion or drastic decline in health or abundance, or to allow anglers to harvest stocks of fish that become more abundant than expected. Temporary Rules are approved by the ODFW Director and can be put in place within 24 hours. The Commission must reaffirm the Temporary Rules at the next scheduled Commission meeting. Temporary Rules are good for up to 6 months, but any temporary rule needing to be in place longer should be adopted as a permanent rule prior to the 6-month time period.

Fisheries Management and Evaluation Plans

Under Limit 4 of the 4(d) rule (U.S. Office of the Federal Register 2000), take prohibitions do not apply to activities associated with fishery harvest activities, provided that the fisheries are managed in accordance with a NMFS-approved Fisheries Management and Evaluation Plan (FMEP) that is implemented in accordance with a letter of concurrence from NMFS. The FMEP, to be approved, must meet a number of specified criteria described in the rule. A template has been adopted for development of FMEPs that meet the required criteria (NMFS 2000).

To provide for adaptive management, Section 3.5 of the FMEP template requires the applicant to include a schedule and process for reviewing and modifying fisheries management under the FMEP (NMFS 2000). The FMEP template calls for two evaluation review processes to be identified in the FMEP (1) a regular review of fisheries (e.g., annually) and (2) a comprehensive assessment of the overall effectiveness of the FMEP (e.g., every one or two full brood cycles, depending on the listed species). The FMEP evaluation must assess the effectiveness of the FMEP in accomplishing the stated objectives over a longer period of time. This evaluation would take into account any new information that may require revisions in assumptions or management strategies (NMFS 2000).

The FMEP shall describe the process and schedule that will be used on a regular basis (annually) to evaluate the fisheries, and revise management assumptions and targets if necessary. The annual evaluation should provide (1) summaries of mortality, effort, escapement, and biological data, and (2) how well management performed in meeting the desired management targets by population (or management unit). Specific annual reporting requirements are described in the concurrence letter from NMFS to the applicant (NMFS 2000).

The FMEP shall also include a description of the process and schedule that will occur every 5 years (or one or two brood cycles), to evaluate whether the FMEP is accomplishing the state objectives. The conditions under which revisions to the FMEP will be made and how the revisions will likely be accomplished are to be included in this section. The FMEP

comprehensive evaluation must provide (1) summaries of population or management unit status relative to delisting and broad sense recovery goals at the beginning and end of the period under review; (2) a summary of the status of the ESU/DPS at the beginning and end of the period under review; (3) performance review of each element of the FMEP relative to its specific existing and any subsequent newly defined standards; (4) estimates of precision and confidence for the analyses conducted above; and (5) recommendations pertaining to management objectives, strategies, and actions including possible modification or termination of existing measures and addition of new ones (NMFS 2000).

In addition to the processes described above, NMFS requires that the fisheries managers notify and provide to NMFS any proposed fishery regulation changes that affect fisheries within the FMEP. NMFS will evaluate the proposed changes to determine if they constitute additional impacts that were not contemplated during the review and evaluation of the submitted FMEP. Depending on the species and fishery involved, these regulation changes can occur annually or in-season.

12.2.4 Hatcheries

Hatchery Scientific Review Group (HSRG)
The HSRG completed review and recommendations for all populations and hatchery programs in the Oregon portion of the Mid-Columbia Steelhead DPS. In Section 9, we characterized the HSRG recommendations and the consistency between the recovery plan actions and HSRG recommendations. In all cases, the HSRG recommendations were consistent with what had been proposed in the 2007 draft recovery plan released for public comment.

Hatchery and Genetics Management Plans
Under Limit 5 of the 4(d) rule (65 FR 42422 July 10, 2000), take prohibitions do not apply to activities associated with artificial propagation programs, provided that a Hatchery and Genetics Management Plan (HGMP) has been approved by NMFS as meeting a list of criteria that are specified in the rule. To provide for adaptive management, the HGMPs need to provide adequate monitoring and evaluation to detect and evaluate the success of the hatchery program and any risks potentially impairing the recovery of the listed ESU/DPS. Furthermore, the HGMPs need to provide for the evaluation of the monitoring data and include the potential to revise the assumptions, management strategies, or objectives that data show are needed. As part of the letter of concurrence, NMFS will describe the implementation process and reporting requirements, including annual production reports and the evaluation of monitoring data.

Limit 5 of the 4(d) rule requires NMFS to evaluate on a regular basis the effectiveness of the HGMP in protecting and achieving a level of salmonid productivity commensurate with the conservation of the listed salmonids. If the HGMP is not effective, NMFS will identify to the operators ways in which the program needs to be altered or strengthened.

The evaluation of the effectiveness of the HGMPs could lead to the reinitiation of the hatchery consultation if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the hatchery actions that may affect listed species or critical habitat in a manner or to an extent not considered in the consultation; (3) the hatchery actions are subsequently

modified in a manner that causes an effect on the listed species or critical habitat not considered in the consultation; or (4) a new species is listed or critical habitat designated that may be affected by the action.

Among other considerations, NMFS may reevaluate the HGMP if there is information indicating that genetic or ecological impacts, beyond those considered in the consultation, are occurring from the operation of the proposed artificial propagation programs. Additionally, NMFS may seek to reinitiate consultation if the HGMPs are modified based upon information: (1) developed during any subsequent review of the HGMPs that are the basis for these programs; (2) any of the other ongoing hatchery review processes such as the Mitchell Act EIS, the Columbia River Hatchery Scientific Review Group analysis; and (3) other processes such as recovery planning, and *US v. Oregon* negotiations.

12.2.5 Implementation Progress and Status Check-ins

Evaluating a species for potential delisting requires an explicit analysis of population or demographic parameters (the biological criteria) and also of threats under the five ESA listing factors in ESA section 4(a)(1) (listing factors (threats)criteria). Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B). NMFS' Middle Columbia Steelhead Recovery DPS Plan summarizes the biological criteria and threats criteria that will be used to evaluate the DPS for potential delisting.

ESA Requirements for Species Status Reviews
Section 4(c)(2) of the Endangered Species Act requires that NMFS conduct a status review of Middle Columbia steelhead at least once every five years to evaluate the status of the DPS and determine whether it should be removed from the list or changed in status. Guidance for these reviews, developed jointly by NMFS and the U.S. Fish and Wildlife Service in 2006, is on the NMFS website at: http://www.nmfs.noaa.gov/pr/pdfs/laws/guidance_5_year_review.pdf. In addition, ESA section 4(g) requires that once a species has been de-listed that monitoring must be conducted in cooperation with the states for at least five years to ascertain the de-listing action.

The joint NMFS and U.S. Fish and Wildlife Service Guidance identifies the following key components of the status review process:

- a summary and analysis of available information on a given species;
- the tracking of a species' progress toward recovery;
- the recording of a deliberative process used to make a recommendation on whether or not to reclassify a species; and
- a recommendation on whether reclassification of the species is indicated.

The NMFS Northwest Regional Office will coordinate the five-year status review process with scientists from the Northwest Fisheries Science Center. Publication of a Federal Register notice announcing those species under active review is required. This notifies the public that the review is underway and requests information to assist in the review. As recovery plans are completed in the Northwest Region, there is now a need to conduct status reviews in the context of the

biological viability criteria and threats criteria described in the respective recovery plans. Addressing this need and identifying a process and methodology for carrying out the status reviews in the context of recovery planning is a high priority for NMFS.

In 2008, the Northwest Fisheries Science Center carried out a "test" status review for a selected ESU to evaluate how to best carry out the status review and what information is needed to support a robust review and status determination. Based on this preliminary status review exercise and on-going discussions between state, federal, local and tribal monitoring experts, the NMFS Northwest Region is producing a 2009 *Guidance for Monitoring Recovery of Salmon and Steelhead* listed under the ESA. This Guidance will provide recommendations for monitoring that addresses all of the viable salmonid population (VSP) criteria and the listing factors and threats. This draft Guidance is currently being finalized and will be made available to all state, Tribal, local and other entities involved in recovery plan monitoring and adaptive management programs for listed salmon and steelhead species.

NMFS has previously provided three documents describing the need for various kinds of information for determining the status of salmon and steelhead listed under the ESA:

- viable salmonid populations were described in NOAA Technical Memorandum NOAA Fisheries-NWFSC-42 (McElhany et al. 2000);
- additional guidance mainly directed toward habitat restoration monitoring has been given to states and tribes through the Pacific Coastal Salmon Recovery Fund "Performance Goals, Measures, and Reporting Framework (NMFS, December 2006); and
- the initial framework for developing monitoring is described in "Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance" (NMFS, May 2007).

Three types of monitoring are needed to collect the most important information for the status review process. These include: (1) status and trend monitoring, (2) implementation (compliance) monitoring, and (3) effectiveness monitoring. The Middle Columbia steelhead Science Team, in coordination with NMFS, will work with all appropriate parties within the Middle Columbia steelhead DPS to design an appropriate monitoring and evaluation plan to ensure appropriate data is collected to track and evaluate DPS viability status and threats criteria.

NMFS scientists conducting the five-year status review will work closely with the Middle Columbia River steelhead Management Unit coordinators, DPS Science Team, and the Oregon Technical Team formed to provide science input and advice on Middle Columbia River steelhead actions, strategies, research designs, and RM&E priorities to implement the Middle Columbia River Steelhead DPS Recovery Plan. The Recovery Plan Science Team's input will be critical to ensure the most recent monitoring and evaluation data is used during the status review.

For the NMFS Middle Columbia River steelhead status review, the following information will be taken into account, as well as, other relevant information available at the time of the review:

- The biological recovery criteria (ICTRT 2007a) and listing factor (threats) criteria described in the DPS Recovery Plan
- Previous status reviews (including ICTRT 2008)
- The management programs in place to address the threats, including an evaluation of what progress these programs have made on implementing recovery strategies identified in the recovery plan. For example, how many miles of riparian restoration have been carried out relative to specific populations needing viability improvements to meet overall MPG or DPS viability goals?
- Principles presented in the Viable Salmonid Populations paper (McElhany et al. 2000)
- Best available information on population and DPS status and new advances in risk evaluation methodologies
- Other considerations, including: the number and status of extant spawning groups; the status of the major spawning groups; linkages and connectivity among groups; the diversity of life history and phenotypes expressed; and considerations regarding catastrophic risk

The Puget Sound Shared Strategy's Monitoring and Adaptive Management Plan (MAMA) for Chinook salmon provides an example for how to develop effectiveness monitoring metrics. Similar to the MAMA we will use the following questions to assist in tracking progress under major recovery strategies. Effectiveness monitoring metrics are designed to answer the following specific management questions:

- What are the key hypotheses supporting each major strategy in the Recovery Plan?
- What are the expected physical, biological changes and timeframes for those changes?
- What is the overall effectiveness of recovery actions? Is quality habitat being restored faster than it is being lost?
- Are there certain categories of recovery actions that are consistently failing or succeeding?

Effectiveness monitoring is broadly defined to encompass what is often called validation monitoring, and will address effectiveness of key strategies identified in the Middle Columbia River Steelhead Recovery Plan. The RM&E Plan addresses the following key questions:

- To what extent have strategies and actions been implemented and are they effective at meeting their objectives?
- Are recovery actions at the site, watershed *(MaSA, huc6 or other assessment scale as appropriate)* or programmatic scale producing the desired physical and biological changes?
- Are there categories of salmon recovery actions that are consistently more successful than others at meeting their objectives?

Modifying and Updating the Middle Columbia Steelhead Recovery Plan

According to NMFS' Interim Endangered and Threatened Species Recovery Planning Guidance (NMFS Recovery Guidance) (NMFS 2006), immediately following the five-year species review, an approved recovery plan should be reviewed in conjunction with implementation monitoring, to determine whether or not the plan needs to be brought up to date.

NMFS Recovery Guidance provides three types of plan modifications: 1) an update; 2) a revision; or 3) an addendum. An update involves relatively minor changes. An update may identify specific actions that have been initiated since the plan was completed, as well as, changes in species status or background information that do not alter the overall direction of the recovery effort. An update does not suffice if substantive changes are being made in the recovery criteria or if any changes in the recovery strategy, criteria, or actions indicate a shift in the overall direction of recovery; in this case, a revision would be required. Updates can be made by the Salmon Recovery Division which will seek input from the local stakeholder group prior to making any update. An update would not require a public review and comment period.

NMFS expects that updates will result from implementation of the adaptive management program for this plan. Adaptive management depends on the flow of information from the field staff to review managers and planners; hence, it requires frequent updates from monitoring and research on the effectiveness of recovery actions and the status and trends of the listed species. It may be most efficient to keep the recovery plan current by updating it frequently enough to forego the need for major revisions.

A revision is a substantial rewrite and is usually required if major changes are required in the recovery strategy, objectives, criteria, or actions. A revision may also be required if new threats to the species are identified, when research identifies new life history traits or threats that have significant recovery ramifications, or when the current plan is not achieving its objectives. Revisions represent a major change to the recovery plan and must include public review and comment period.

An addendum can be added to a recovery plan after the plan has been approved and can accommodate minor information updates or relatively simple additions, such as implementation strategies or participation plans, by approval of the field office or Regional Administrator. More significant addenda – adding a species to the recovery plan, for example – should undergo public review and comment before being attached to a plan. Addenda are approved on a case by case basis because of the wide range of significance of different types of addenda. NMFS will seek input from stakeholders on minor addenda.

For the Middle Columbia Steelhead Recovery Plan, NMFS will work with each Management Unit lead, the Mid-C Forum and Science Team to identify any changes, amendments or modifications to the Management Unit Plan which will need to be reflected in the DPS Plan. NMFS will coordinate any public notification and review of substantial changes to the Management Unit and DPS Plans with the Management Unit leaders.

State of Oregon Adaptive Management Process

The State of Oregon's Native Fish Conservation Policy identifies elements related to adaptive management that must be included in a state conservation plan. The policy states that a conservation plan will include "a process for modifying corrective strategies based upon the monitoring, evaluation and research results." The policy also identifies that a conservation plan will include "annual and long-term reporting requirements necessary to document data, departures from the plan, and evaluations necessary for adaptive management, in a format available to the public." The elements outlined previously in this chapter are designed to meet the requirements in the NFCP related to adaptive management and the successful implementation of this recovery plan. The State of Oregon will work cooperatively with NOAA to conduct implementation progress and status updates and to report the results of progress and status.

Section 13 Research, Monitoring, and Evaluation

This research, monitoring, and evaluation (RM&E) plan covers the Oregon portion of the Mid-C steelhead DPS. It describes the RM&E recommended for assessing the status and trends in population viability and for evaluating the success of management actions implemented to recover these steelhead populations. In addition, the types of monitoring approaches that are needed, current efforts underway, and additional RM&E needs are presented. Logistical and monetary limitations are understood to exist. However, this comprehensive plan will help to focus efforts towards the common goal of assessing success in population and DPS recovery.

To help identify needed monitoring and evaluation efforts, local managers were queried to identify critical uncertainties which, in their opinion, currently limit our ability to make informed management decisions. Within the context of ESA listing status, monitoring and evaluation should focus on providing measures needed for the critical evaluation of the status and trends of these populations that are informative for their recovery.

This plan is based in part on principles and concepts laid out in the NMFS guidance document, *Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance (May 1, 2007)* http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf. This plan also borrows from RM&E plans that were developed for Mid-Columbia subbasins and other Columbia Basin regions.

NMFS's guidance document provides a listing status decision framework (Figure 13-1), which is a series of decision-questions that address the status and change in status of a salmonid ESU/DPS, and the risks posed by threats to the ESU/DPS. Consistent with this framework, Oregon's approach focuses on providing key information to determine the condition or status of the populations for each of the four VSP parameters, and the effects of factors (and actions) on the condition or status of the populations.

The plan also follows the principles of adaptive management, the process of adjusting management actions and/or directions based on new information. Adaptive management is considered crucial for salmonid recovery programs because of the length and complexity of the salmonid life cycle, and the uncertainties involved in improving salmonid survival and status. The plan addresses adaptive management by linking monitoring and evaluation to biological and physical responses, and using these results to better design and implement of management actions.

We acknowledge repetition of objectives and methods between MPGs and populations. We expect that in some cases this comprehensive RM&E plan will be separated by MPG and population for use by managers and researches responsible for securing funding and implementing local RM&E efforts. We have developed the plan so that, when separated, the individual MPG plans will be useful as stand alone documents.

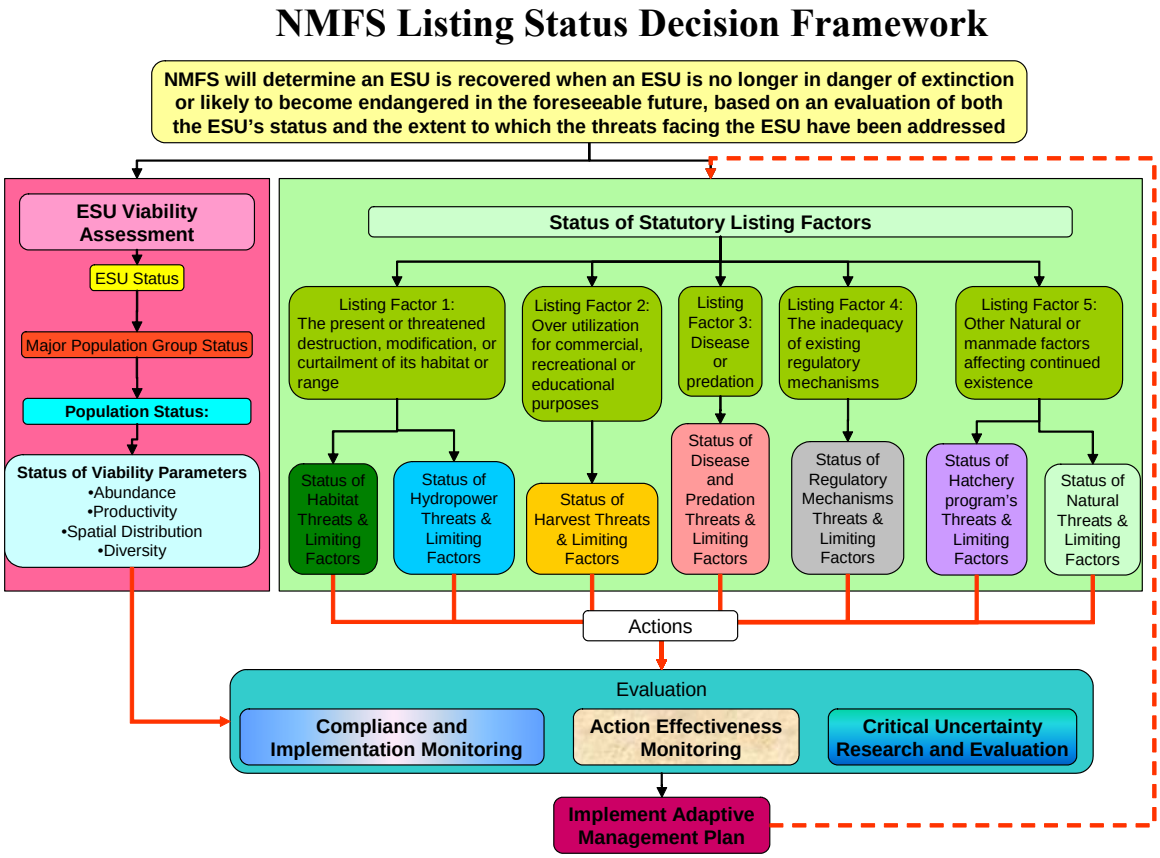

Figure 13-1. NMFS Listing Status Decision Framework.

13.1 Types of Monitoring Efforts

Several types of monitoring are needed to support adaptive management and to allow managers to make sound decisions:

- **Status and Trends Monitoring.** Status monitoring includes measures of the current state or condition of the population at any given time. Trend monitoring tracks these conditions to provide a measure of the increasing, decreasing, or steady state of a status measure through time. Status and trends monitoring includes the collection of standardized basic information used to monitor broad-scale trends over time in the status of fish populations, habitat conditions, and other ecosystem factors affecting fish. This information is the basis for evaluating the cumulative effects of management actions on fish and the aquatic and terrestrial ecosystem.

- **Action Effectiveness Monitoring.** Action effectiveness monitoring involves project-scale monitoring of local conditions to determine if implemented actions were effective in creating the desired proximate change. Action effectiveness monitoring typically is used to determine whether project- or program-specific goals were met. This type of monitoring also includes post-project monitoring to see whether the actions continue to

function as they were designed or intended. Note that status and trend monitoring may be appropriate for fulfilling these needs but that project effectiveness monitoring generally requires focused evaluations of more specific parameters directly associated with actions. Specific indicators and metrics need to be developed in plans for each category of action. Specific plans will include measurable variables or parameters to address each objective, study design (spatial and temporal scale, tests and controls, statistical criteria, etc.), data collection methods and reference examples, and analyses and decisions in response to results.

- **Implementation and Compliance Monitoring.** Implementation and compliance monitoring involves monitoring of management actions to determine if they were implemented as planned and meet established benchmarks. This monitoring is typically conducted by the groups implementing the management and restoration actions.

- **Uncertainties Research.** Uncertainties research includes scientific investigations of critical assumptions and unknowns that constrain effective recovery plan implementation. Uncertainties include unavailable pieces of information required for informed decision making as well as studies to establish or verify cause-and-effect and identification and analysis of limiting factors.

The following sections address each major population group separately. In some cases we provide specific objectives at the population scale to characterize unique monitoring needs. Specific approaches are presented that address each objective. A brief sampling design, including the spatial and temporal scale of application, is provided for each objective. Measurement variables, protocols and a description of the analysis are presented. Ongoing efforts and needed changes and enhancements are discussed for each objective. Existing and potential funding sources are identified and finally, implementation and coordination details are discussed. The techniques described for each population are not necessarily exhaustive, but are meant to be representative of those actions considered to have potential while recognizing logistical and monetary constraints.

13.2 John Day River MPG

Most of the monitoring and evaluation for the John Day River MPG is currently conducted by ODFW. Current status and trends monitoring includes spawner escapement, smolt-to-adult returns (SAR), juvenile abundance, productivity, distribution, and habitat condition. Not all populations are equally monitored but could be assessed with inference through ongoing monitoring of neighboring populations or with expansion of ongoing efforts in the populations that have inadequate monitoring. Limited rigorous effectiveness monitoring occurs and is closely tied to implementation and compliance monitoring of the numerous restoration projects. One of the critical uncertainties for this MPG is hatchery-related threats from out-of-basin hatchery fish that stray into the basin.

The five populations within this MPG (Lower Mainstem, Upper Mainstem, South Fork, Middle Fork, and North Fork) are similar in many respects and are therefore often monitored and evaluated collectively. Further, information collected from M&E efforts within one population

are often applicable to the other four. Where efforts or circumstances differ significantly among populations, differences are noted below within each objective.

Critical Uncertainties

Six critical uncertainties for the John Day River MPG that currently limit the ability to make informed management decisions have been identified by local area managers. We combined these uncertainties with those identified during the recovery planning process to produce the RM&E objectives that are addressed herein by our recommended RM&E efforts. They include:

1. Determine the current status and trend in the abundance and productivity of natural-origin spawners and compare to viability abundance criteria for each John Day population.
2. Determine the status of the spatial structure of each population based on current and historically utilized habitat.
3. Determine the status and trend in conditions of current and historically utilized habitat within each population.
4. Determine the freshwater productivity of each population relative to viability criteria and identify primary habitat factors limiting freshwater production.
5. Determine the current status and change in future status of life history and phenotypic diversity for each population.
6. Determine the effects of disease and predation on the abundance, productivity, diversity and spatial structure of the natural populations.
7. Determine the effects of hydropower on the abundance, productivity, diversity and distribution of the natural populations.
8. Determine the effects of habitat degradation and habitat restoration actions on the abundance, productivity, and spatial structure of the natural populations.

While any of these objectives can be applied to monitoring the recovery of most populations, we will identify details specific to the John Day populations and to the unique circumstances of the five John Day populations in the following recommended approaches. Circumstances and management typically do not differ greatly among the John Day populations, and therefore M&E needs are quite similar across the populations. Some of these objectives (e.g., the out-of-basin influences of hydropower and ocean environment) will remain consistent across all populations in this MPG.

Much of the information needed to monitor the status of John Day River steelhead is currently collected under the ODFW monitoring and evaluation program (Wiley et al. 2005; Wilson et al. 2005b). This plan will describe and supplement the existing programs so that the status and trend of the steelhead populations can be compared with recovery criteria. The following approaches follow those described in the evaluation framework and monitoring guidance set forth in the Adaptive Management for ESA-Listed Salmon and Steelhead Recovery draft document (NOAA 2006) and PNAMP management guidelines.

13.2.1 Lower Mainstem, North Fork, Middle Fork, South Fork, Upper Mainstem John Day Rivers Populations

Objective 1: Determine the current status and trend in the abundance and productivity of natural-origin spawners and compare to viability criteria for each John Day population.

The status of a population is determined by estimating the VSP parameters previously described in this recovery plan. These parameters include adult abundance, population productivity and growth rate, spatial structure, and diversity. The status of these parameters is compared to the population-specific recovery criteria resulting in an overall determination of the status of the population, MPG, and DPS. This is a highest priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- Is the 10-year geometric mean (GM) of naturally-produced steelhead spawners in each John Day River population greater than or equal to the recovery criterion for natural spawners?
- What are the current spawner abundance and five-year trend in abundance?
- What are the current and trend in the 20-year population growth rate?
- What are the current and trend in recruits/spawner compared to the delisting goal?

Performance metrics: Spawner abundance, recruits/spawner.

Approach: Tracking the abundance of adults is an important first step in population monitoring because it integrates the entire life cycle influences on status and trends. No weirs are operated or planned in the John Day River subbasin with the exception of a small temporary weir for research on Bridge Creek in the Lower Mainstem population area. Redd surveys are therefore the only alternative to estimate annual adult abundance for recruits/spawner and trend analyses. The recommended survey design includes a spatially balanced site selection process and a rotating panel design for temporal selection (environmental monitoring and assessment protocol (EMAP) approach; Stevens and Olsen 2004). ODFW currently uses this approach to estimate annual spawner escapement to the entire John Day River subbasin. Redds are counted bi-weekly on 2-km reaches selected by using a four-year rotating panel design with 50 randomly selected reaches sampled per year in the John Day River MPG. Ideally, sampling using this design would also be conducted at the population scale which would require additional samples to achieve greater accuracy and precision. In addition, index areas specific to the population that were established in 1966 are sampled annually by ODFW managers. These index data were originally used to estimate viability criteria and continue to provide valuable long-term trend information. A census redd count of a representative population outside of the basin is also conducted to establish a fish/redd ratio. Redd count surveys are currently conducted by walking and/or floating all streams within the index (one-time annual counts) and randomly selected reaches (bi-weekly counts, ≥ 3 counts/year). A fish/redd ratio is estimated by counting spawners passed above a weir (outside of the John Day River subbasin) and subsequent spawning ground redd

surveys, of similar design to those conducted in the John Day, of all known utilized habitat above the counting weir.

Analysis: Estimate the number of naturally produced spawners using proportions of observed naturally produced fish (unmarked) and hatchery (fin clipped) fish, total number of redds, expansion factor of surveyed stream length/available stream length, and fish/redd ratio. Calculate 10-year GM for abundance of naturally produced fish. Calculate recruits/spawner based on redd counts and estimated spawner age structure. Analyze as a time series (trend analysis).

Status: BPA currently funds the sampling of randomly selected reaches for spawning surveys at the MPG scale. LSRCP and NOAA currently fund spawner and redd counts (for fish/redd ratio) on a reference stream in the Grande Ronde River basin. State of Oregon funds index spawning ground surveys. Field work is currently implemented and coordinated primarily by the ODFW and ISEMP. Population-level sampling has been conducted for the South Fork population during 2006 and 2007 and may be rotated annually to other populations. However, additional funding would be required to conduct population-level sampling for the larger populations (Lower Mainstem, North Fork) within the MPG. Population-scale monitoring for the Middle Fork population will be initiated in 2008 as part of the intensively monitored watershed (IMW) approach. This IMW work is funded by NOAA through OWEB. Much of the Upper Mainstem population is within private property where access is limited, and therefore population-scale spawner surveys are logistically very difficult there. Similarly, private property dominates the Lower Mainstem population area and the low density stream network coupled with remote access for several major tributaries and more frequent turbid water further complicates sampling and logistics of redd surveys.

Objective 2: Determine the status of the spatial structure of each population based on current and historically utilized habitat.

This is a highest priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:
- What is the spatial distribution of spawning within each population?
- What is the current spatial extent and distribution of rearing habitat used by juvenile steelhead within each population?

Approach: The same EMAP of all known spawning and rearing areas as used for determining abundance of spawners is recommended and currently implemented by ODFW for refining the known spatial extent of both adult and juvenile steelhead in the John Day MPG. Fifty sites within the John Day MPG are sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. All observed adult spawners and redds are geographically referenced using handheld GPS units for inclusion in a GIS. Juvenile steelhead are sampled using snorkeling or electrofishing techniques. This approach is refining current knowledge of steelhead spatial

distribution throughout the John Day River subbasin. Current sampling efforts in the South Fork population are adequate and the future sampling associated with the Middle Fork IMW will provide information needed for this population. Expanded sampling in the Lower Mainstem, North Fork, and Upper Mainstem populations will be required to get adequate population specific information.

Analysis: Data are currently analyzed as distribution data in a GIS format. The known distribution of steelhead is modified when previously unknown blockages to migration are discovered. Juvenile steelhead are evaluated as fish/pool in each study reach.

Status: BPA currently funds the sampling of randomly selected reaches for spawning surveys. BPA has eliminated funding for juvenile distribution work after 2007. Additional funding may be procured from OWEB. Field work is currently implemented and coordinated primarily by the ODFW and ISEMP. ISEMP is developing contracts with ODFW to reinstate habitat and juvenile distribution monitoring that will address sampling at population spatial scales. Additional work on juvenile fish is conducted by the USFS PACFISH Biological Opinion project on federally owned lands and by CTWSRO on tribal managed properties. The same limitations indicated above in Objective 1 are relevant here as well.

Objective 3: Determine the status and trend in conditions of current and historically utilized habitat within each population.

This is a highest priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- What is the status and trend in habitat quantity and quality throughout the John Day MPG area?
- What is the status and trend in habitat quantity and quality for each of the populations in the John Day MPG?

Approach: The same EMAP of all known spawning and rearing areas as used for determining abundance of spawners is recommended for sampling the known spatial extent and status and trend of steelhead habitat in the John Day MPG. Fifty sites within the John Day MPG are sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. Habitat variables follow ODFW Aquatic Inventories design (Moore et al. 2002) and are measured at the unit and reach scale.

Analysis: Data are currently analyzed as distribution data in a GIS format. Sample sites can be associated to specific populations but sample draw was conducted to represent MPG level. Database and GIS formatting of data allow associations with land use, land vegetation coverage, and many other attributes at watershed and population scales. The survey effort needs to be expanded to provide monitoring at the population level. Current and future planned efforts are adequate for the South Fork and Middle Fork populations but not the other three.

Status: BPA has eliminated funding for basin-wide habitat work after 2007. Work is currently unfunded for most populations. Habitat monitoring will continue for Middle Fork population using NOAA/OWEB funding as part of the Middle Fork IMW. ISEMP is developing contracts with ODFW to reinstate habitat and juvenile distribution monitoring that will address sampling at population spatial scales.

Objective 4: Determine the freshwater productivity of each population relative to viability criteria and identify primary habitat factors limiting freshwater production.

This is a highest priority objective.

Type of monitoring effort: Long term status and trend monitoring for productivity and uncertainties research for limiting factors.

Monitoring questions:
- What are the current and trend in freshwater productivity measured as smolts/redd?
- What are the primary habitat factors limiting freshwater production of steelhead?

Approach: The ratio of smolts/adult is one recommended measure of freshwater productivity. Smolts are typically counted using traps as they migrate out of their natal habitat. If weirs are not present to count adults, then redd counts can act as a surrogate measure. Freshwater productivity is measured as smolts/redd or smolts/adult. Trapping with rotary screw traps (RSTs) and mark-recapture are currently used to estimate smolt abundance for significant portions of three populations (South Fork, Middle Fork, Upper Mainstem) in the John Day MPG. Similar efforts have been attempted for the North Fork population with limited success due to physical constraints. The structure of the watershed for the Lower Mainstem population precludes effective sampling of smolts with traps because the tributaries are disperse and enter the Mainstem where it has very large discharge during seasonal flow events. Redd counts are estimated using the previously mentioned approach and an EMAP sampling framework. Sample draws for redd surveys need to be directed at the population segments above smolt trapping locations. Actual freshwater productivity estimates are derived estimates not direct measures. For example, egg-to-smolt survival requires an estimate of the number of eggs deposited by individual females or deposited in each redd. Parr-to-smolt survival can be estimated by capturing a representative number of parr in their rearing habitat, PIT tagging them, and then monitoring their recapture at the downstream smolt traps. Migration survival can similarly be estimated by monitoring detections of PIT-tagged individuals as they pass through PIT tag detection facilities.

Identification of factors limiting freshwater production by RM&E efforts provides much needed direction for restoration efforts and is best explored using an uncertainties research approach. Several physical and biological factors can potentially limit production. Therefore, a multivariate or hierarchical approach may be appropriate for identifying factors. For example, data from habitat surveys can be combined with data from long-term monitoring of discharge and temperature and fish growth and distribution information to identify factors potentially limiting productivity. Often, simple presence/absence

information of parr or adults can be examined in the context of existing habitat information and used to initially deduce and explore more complex predictive relationships.

Analysis: Smolt abundance is estimated using RSTs and mark/recapture techniques (Thedinga 1994, Steinhorst 2004). Survival and productivity measures are calculated ratios of abundance from one life stage to another.

Status: BPA currently funds trapping of smolts and spawning surveys for redd counts. NOAA and OWEB will fund future work for identifying limiting factors under the IMW approach for the Middle Fork John Day River. With current efforts there will be estimates for the South Fork and Middle Fork populations. Efforts will have to be expanded to collect information for the other populations. Similar efforts, funded by NOAA and BPA, to estimate freshwater productivity are planned for an IMW on Bridge Creek, a tributary of the Lower John Day River. Smolts-redd estimate are not logistically feasible for the Lower Mainstem and North Fork populations. Outflowing waters are too large for efficient trapping of smolts using RSTs and commingling of smolts from other populations would introduce additional complications for unique identification. It may be feasible to monitor a representative portion of the North Fork population (above Desolation Creek, for example) if additional funds become available.

Objective 5: Determine the current status and change in future status of life history and phenotypic diversity for each population.

This is a high priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- What proportion of steelhead spawners in the John Day MPG are out-of-basin hatchery strays?
- What is the origin of out-of-basin strays?
- What is the population-level genetic composition of the John Day MPG and of individual populations?

Approach: The John Day River basin lacks facilities to capture adult steelhead. Determination of out-of-basin strays will therefore rely on identification of hatchery-marked adults observed on spawning ground surveys, in creel surveys, from incidental catches, and from detections of PIT tags at PIT tag antenna arrays. See also Objective 6 for harvest monitoring.

To determine population-level genetic composition for the MPG, genetic data that allow an objective determination of population structure are required. Age-0 *O. mykiss* from four representative streams in each population segment have been sampled for three consecutive years beginning in 2005. A minimum of three cohorts were sampled using non-lethal fin tissue for DNA analysis. Populations will be characterized using a suite of nuclear DNA markers, including both microsatellite loci (variable-number simple-sequence repeats) and

non-coding single nucleotide polymorphisms (SNPs), or base substitutions assayed via restriction enzyme analysis (Moran et al. 1997).

An EMAP of all known spawning areas is currently employed in the entire John Day River MPG. Fifty sites within the John Day MPG are sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. ODFW managers also continue to annually visit pre-determined and long-standing index sites for spawners. These index surveys continue a long-term trend dataset that was initiated in the 1960's. The number of marked (adipose fin clip) and unmarked (presumably natural-origin) fish are visually identified on all spawner surveys. All observed carcasses marked with a fin clip are sampled for coded-wire tags to determine the presence of a coded-wire tag and hatchery origin. Expanded sampling efforts are recommended to provide population specific hatchery fraction information.

Because there are no permanent weirs in the John Day River basin, the operation of semi-permanent PIT tag antenna arrays is critical for the identification of the origin of hatchery strays. PIT tag monitoring should be accomplished near the downstream extent of watersheds, near RSTs, to monitor the passage of tagged adults. These antennas can serve a dual purpose by also aiding in the determination of the capture efficiency of RSTs.

Analysis: Estimating the proportion of out-of-basin strays is a simple comparison of the number of marked and unmarked spawners and carcasses observed. Direct comparisons can then be made with recovery criteria. DNA tissue samples are analyzed by NMFS using known microsatellite markers. Microsatellite loci are analyzed using pairwise FST comparisons to estimate levels of gene flow and to identify geographic areas that contain genetically differentiated populations. Genetics monitoring is conducted under the NMFS Columbia Basin-wide steelhead genetics monitoring program.

Status: Spawning ground surveys are implemented and coordinated primarily by the ODFW with input from ISEMP participants. BPA currently funds spawning ground surveys for EMAP reaches and state funds are used for index surveys. Genetic analysis is implemented and coordinated collaboratively between ODFW and NMFS Northwest Science Center. Federal funds are used for genetic stock analysis.

There are currently no creel surveys conducted in the John Day River subbasin. Current evidence suggests that out-of-basin hatchery strays is a particular problem for the Lower Mainstem population. There appears to be a negative correlation between distance from the mouth of the John Day River and presence of hatchery strays. The scope of surveys is currently inadequate to make population specific estimates of the proportion of spawners that are hatchery origin.

As of 2009, semi-permanent antenna arrays are operated at McDonald Ford on the Lower John Day River, on the South Fork John Day River, Middle Fork John Day, and on Bridge Creek. The latter three are operated as part of the ongoing IMW studies by ISEMP and ODFW. The McDonald Ford array is operated by Biomark, Inc. in cooperation with NOAA and ODFW.

Objective 6: Determine the effects of disease and predation on the abundance, productivity, diversity and distribution of the populations.

This is a moderate priority objective.

Type of monitoring effort: Status and trend monitoring.

Monitoring questions:

- What is the prevalence of whirling disease in the John Day River basin and what is its influence on the natural steelhead populations?
- What is the predation rate and predatory impact of introduced fishes in the John Day River on juvenile steelhead?
- What is the effect of predation from piscine predators in the Columbia River migration corridor on juvenile steelhead originating from the John Day River?
- What is the effect of predation from avian predators in the Columbia River migration corridor on juvenile steelhead originating from the John Day River?

Approach: The current distribution and influence of whirling disease on wild steelhead populations is not fully understood. Representative sentinel stations should be established and monitored through time for each population to measure prevalence and intensity of infection rates of the disease. Infection, or the presence of *Myxobolus cerebralis* DNA, is detected by polymerase chain reaction (PCR) analysis. A logical place to locate initial sentinel tests would be in locations where hatchery strays are known to be prevalent because they are a known vector of transmission from infected watersheds in northeast Oregon (Sollid et al. 2004). Sentinel stations should then be placed near the mouths of important tributary and mainstem habitats occupied by fry and parr life history stages of steelhead. While all populations in the John Day have some susceptibility to disease, the prevalence of hatchery strays and habitat conditions in the Lower Mainstem population area likely make this population more vulnerable than those upstream. The initial focus of study should be in the Lower Mainstem population.

ODFW currently conducts annual collections of smallmouth bass *Micropterus dolomieui* in the John Day River using angling techniques. Collected stomach samples are analyzed for the presence of juvenile salmonids. These data could be incorporated into a bioenergetics model to derive a population-level consumption estimate imposed by introduced fishes. Sampling of predatory fish diets should occur during times and locations when and where their distribution overlaps with juvenile steelhead. Interpretation of the predatory impact in the migration corridor should be conducted from methods established in published literature (Ward et al. 1995, Fritts and Pearsons 2006).

To evaluate avian predation, colonies are monitored for presence of PIT tags originating from specific populations (Collis et al. 2001). Bioenergetics models are used to expand tag recoveries at colonies to population-level impacts (Antolos et al. 2005). We acknowledge that both the Columbia River mainstem piscine predator and avian predator monitoring needs are outside the scope of this plan. However, we encourage adequate monitoring of these limiting factors and threats.

ODFW currently PIT tags 4,000 juvenile steelhead migrants each year in the John Day River basin for estimation of SAR. Determining the fate of PIT tags in this database should be utilized for examining the influences of migration corridor predation.

Analysis: The proportion of SAR attributable to predatory mortality could be estimated from the predation bioenergetics modeling results. Infection rates of sentinel fish from disease would provide some indication of the potential impacts of whirling disease.

Status: ODFW currently tests opportunistically for the presence of diseases in juvenile salmonids submitted as mortalities from rotary screw traps and other sampling operations from the John Day River basin. PIT tagging of juvenile steelhead is currently completed by the ODFW with funding from the BPA. The whirling disease foundation, whirling disease initiative, and Oregon Sea Grant are potential funding sources for whirling disease investigations. Investigations of predation in the migration corridor have been conducted by many agencies with various funding sources including BPA and USACE. We encourage the continuation of the piscine and avian predation monitoring.

Objective 7: Determine the effects of hydropower on the abundance, productivity, diversity and distribution of the natural populations.

This is a high priority objective.

Type of monitoring effort: Long term status and trends.

Monitoring questions:

- What is the effect of Columbia River hydropower operations on juvenile steelhead outmigrating from the John Day River populations?
- What is the effect of Columbia River hydropower operation on returning adult steelhead originating from the John Day River populations?

Approach: PIT tags have been used successfully to measure the influence of hydropower operations on migrating salmonids (Berggren et al. 2006, Schaller et al. 2007). ODFW has cooperated with the CSS study by PIT tagging steelhead smolts as they migrate out of the John Day River Basin. These PIT-tagged fish are subsequently monitored for detections at FCRPS facilities along the migration corridor at both juvenile and adult life stages using Data Access in Real Time (DART) and PIT Tag Information System (PTAGIS) databases. Detection probabilities of juvenile salmonids migrating downstream at FCRPS facilities are modeled using the Survival Under Proportional Hazards (SURPH) analytical tool (Lady et al. 2003). Adult detection (purportedly 100%) is currently available at ladders on several dams, including Bonneville and McNary, and is expected in the near future at The Dalles and John Day dams.

Analysis: Juvenile survivals at each FCRPS facility can be estimated using the SURPH model. Adult survival between facilities will soon be possible by comparing detections at adult ladder facilities along the migration corridor. Rates can be expanded to population-level impacts using the relative number of fish PIT tagged and smolt abundance estimates

generated from mark-recapture at RSTs. Adult detections within the John Day River basin, subsequent to those in the Mainstem Columbia River, will be used to determine the relative proportion of successful migrants from each migration strategy outside of the basin.

Status: ODFW currently PIT tags emigrating smolts and monitors their detections at mainstem hydropower facilities. Coordination with comparative survival studies (CSS) occurs with the Fish Passage Center. Currently, juvenile steelhead are PIT tagged representing three populations (South Fork, Upper Mainstem, and Middle Fork) in the John Day. Estimates derived for these populations would be representative for the remaining John Day populations. NMFS and Biomark operate a developmental PIT tag antenna array on the Lower John Day River. This array will allow partial detection of PIT-tagged fish migrating through the lower John Day River.

Objective 8: Determine the effects of habitat degradation and habitat restoration actions on the abundance, productivity, and spatial structure of the natural populations.

This is a high priority objective.

Type of monitoring effort: Status and trend monitoring; implementation and compliance monitoring; effectiveness monitoring.

Monitoring questions:

- Status & Trend Monitoring—What is the current status and trend of steelhead habitat?
- Implementation and Compliance Monitoring—Has the management action been implemented in the prescribed manner and achieved its objectives?
- Effectiveness Monitoring—Have the management actions significantly influenced the viability of John Day River steelhead populations?

Approach: Status and trend monitoring at the subbasin and population scale is best conducted by using a spatially explicit sampling approach such as the EMAP approach developed by the EPA. Measured habitat variables vary depending on the specific question addressed but are directed at those closely related to salmonid requirements, targeted for restoration, or identified as limiting recovery. Remote sensing (e.g. thermal infrared (TIR) imagery; light detecting and ranging, (LIDAR); and spatially referenced color imagery) is also appropriate and typically addresses spatial scales at watershed or larger landscapes. We typically use ODFW aquatic inventories which include riparian, within channel and physical properties.

Compliance monitoring of restoration projects incorporates record keeping and reporting of activities. Compliance monitoring should be primarily conducted by the implementing party and should include any parameters indicated in related work statements. Although some compliance monitoring is currently underway, there is need to expand at the project scale and for aggregation to assess at the population scale.

Effectiveness monitoring can be approached at the watershed and project spatial scales. IMWs are currently used in some places for the watershed scale. Effectiveness monitoring should preferably be directed at measures of abundance, survival, growth, etc. of steelhead or

abiotic or biotic factors limiting their recovery. A modified before-after-control-influence (BACI) design (including spatial replication) is recommended for measuring the effectiveness of active restoration activities (Jones & Tonn 2004). For passive restoration activities, a BACI design that monitors trends through time may be appropriate. If comparisons are made to reference or control sites, they should be under similar environmental conditions experienced by the treatment site but outside the influence of treatment activities. Restoration action implementing entities must coordinate with monitoring groups prior to scheduled activities—preferably years in advance to allow measurement of pre-treatment variables. Temporal scales must account for delays due to life history and life cycle timeframes.

Analysis: Direct comparisons of measured parameters with recovery criteria can be made. Otherwise, measures at smaller scales will need to be scaled up to determine if they would have desired responses at the population level.

Status: Implementation monitoring is currently conducted by the groups that implement the activities (e.g. ODFW, CTUIR, CTWSRO, watershed councils, etc.). ODFW currently conducts limited effectiveness monitoring of selected restoration projects within the John Day River basin. IMWs were established in the Middle Fork John Day River and Bridge Creek on the Lower John Day River in 2007. Remote sensing is typically conducted by professional consultants. Funding from BPA, OWEB, NOAA, and other sources has supported past and current activities. There is limited implementation monitoring underway and a significant need to compile information across projects for assessment at the population scale.

13.3 Umatilla/Walla Walla Rivers MPG

Steelhead restoration activities in the Umatilla subbasin include supplementation of the endemic steelhead population, harvest management, and habitat, flow, and passage improvement projects. The "Comprehensive Research, Monitoring, and Evaluation Plan for Umatilla Subbasin Summer Steelhead and Chinook Salmon" (Umatilla RM&E plan; CTUIR and ODFW 2006) is a detailed plan for obtaining information needed to assess the performance and evaluate the effectiveness of these habitat restoration, harvest management, and hatchery programs. The RM&E aspects of this plan are designed to assess the current efforts and test new strategies for the supplementation and restoration of steelhead and the establishment and enhancement of commercial and recreational fisheries. Due to the lack of pre-treatment data, managers rely primarily on status and trend data and comparison to out-of-subbasin reference populations to assess the success or failure of management strategies and to make adaptive management decisions.

Most of the monitoring and evaluation for the Umatilla/Walla Walla Rivers MPG is currently conducted by ODFW and CTUIR. Status monitoring is performed for all projects in the Umatilla subbasin, including natural production, hatchery evaluation, and juvenile outmigration and survival. Proposed natural production status monitoring includes abundance indices for juveniles (parr and smolts), adult abundance, recruits per spawner, estimated redd numbers, life history characteristics, as well as flow, temperature, and habitat data to assess the success of flow augmentation and stream restoration work. Hatchery evaluations include the monitoring of

smolt-to-adult returns, smolt-to-adult survival, catch contribution, catch distribution, and straying rates. Juvenile outmigration monitoring (which was discontinued in 2007 due to BPA budget cuts, then re-started in 2009) includes abundance of outmigrating smolts, travel timing, and survival rates to downstream dams. In addition, the fishery is monitored using creel surveys and marine fishery observations to estimate the contribution of Umatilla River fish to the commercial and recreational fisheries. RM&E for the two Oregon populations within this MPG are addressed separately below.

13.3.1 Umatilla River Population

Critical Uncertainties
Seven critical uncertainties for the Umatilla River population that currently limit the ability to make informed management decisions have been identified by local area managers.

1. What are the status and trends of steelhead and their habitat in the Umatilla basin?
2. What are appropriate and effective rearing and release strategies for summer steelhead reared at Umatilla Fish Hatchery?
3. Will the historical summer steelhead fishery be sustained by hatchery releases of summer steelhead?
4. To what extent will hatchery summer steelhead released in the Umatilla contribute to out-of-subbasin fisheries?
5. To what extent will supplementation alter the genetic diversity and life history characteristics of the native steelhead population?
6. To what extent will supplementation enhance natural production of summer steelhead?
7. How will habitat protection and enhancement actions influence abundance, productivity, life history diversity, and long-term sustainability of Umatilla steelhead?

We used these uncertainties and others identified during the recovery planning process to produce the monitoring and evaluation objectives and the recommended M&E efforts. We list the priority level of each objective from highest to low, with a monitoring and evaluation focus on the highest priority activities. This does not mean that criteria ranked as moderate or low are not important to monitor. Rather, it means that limited resources will be applied to monitoring those aspects of recovery that are most important. Monitoring of moderate and low priority criteria will occur as resources are available. This plan does offer possible metrics and methods for monitoring medium and low priority criteria. Monitoring objectives listed as highest or high priority address population and environmental status, natural production, the hatchery program, flow, passage, and other habitat actions and fisheries.

We combined the aforementioned uncertainties with those identified during the recovery planning process to produce the RM&E objectives that are addressed herein by our recommended efforts. Not all objectives are associated with each population segment. The objectives include:

1. Monitor and assess the status and trends of abundance and productivity of natural- and hatchery-origin adult steelhead.

2. Determine the status of the spatial structure of the population based on current and historically utilized habitat.
3. Monitor and assess the abundance, timing, life history characteristics, and in-stream survival of out-migrating steelhead.
4. Determine the current status and change in status of life history and genotypic diversity in the population.
5. Identify and assess factors limiting viability of Umatilla River steelhead.
6. Determine the status and trend of current and historically utilized steelhead habitat in the Umatilla subbasin.
7. Determine the influence of the current hatchery supplementation program on the natural population.
8. Monitor and assess the impact of flow enhancement on steelhead survival, habitat, and migration.
9. Determine the effect of mainstem hydropower operations and operational improvements on viability of Umatilla River steelhead population.
10. Determine the effect of harvest on the abundance, productivity, diversity, and distribution of the natural population.
11. Determine the effect of predation on the abundance, productivity, diversity, and distribution of the natural population.
12. Monitor production, survival, harvest and spawning of hatchery-origin steelhead.
13. Determine the transmission and effect of disease on the abundance, productivity, diversity and distribution of the natural population.

Some of the information needed to monitor the status of Umatilla summer steelhead is currently collected under the ODFW and CTUIR monitoring and evaluation program as described in the Umatilla RM&E plan, while limited monitoring activities that address the effectiveness of irrigation screening are also conducted by the Bureau of Reclamation. The research, monitoring, and evaluation objectives and approaches that follow are primarily from the Umatilla RM&E plan (CTUIR and ODFW 2006). Some of these objectives have been supplemented so that the status and trend of the steelhead population can be compared with recovery criteria. More detailed information on approaches and analysis is contained in the Umatilla RM&E plan.

Objective 1: Monitor and assess the status and trends of abundance and productivity of natural- and hatchery-origin adult steelhead.

Adult returns to Three Mile Falls Dam (TMFD) are critical for monitoring the status and long-term trends of steelhead in the Umatilla subbasin (Critical Uncertainty No. 1). Monitoring trends in productivity metrics will be critical to assessing the performance of the Umatilla subbasin fish restoration program. These measures will also be used in stock-recruitment models to estimate natural production capacity of the subbasin. This is considered a highest priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What are the annual abundance and time-series trends in abundance?

- Is the 10-year GM of naturally-produced steelhead spawners in the Umatilla subbasin greater than or equal to the recovery criterion for natural spawners?
- What are the current and trend in the 20-year population growth rate?
- What are the current and trend in smolts/spawner?
- What are the current and trend in adult recruits per spawner?

Performance metrics: Number of natural- and hatchery-origin adult returns to the Umatilla River, run timing of natural- and hatchery-origin adult returns, smolts-per-spawner, adult recruits per spawner.

Approach: Numbers of adult natural- and hatchery-origin returns are currently enumerated by trap counts and video monitoring at the TMFD (RM 3.7) fish ladder. A complete count of escapement past TMFD is obtained, as all returning adults must use this fish ladder. During trapping, fish are routed into a sorting complex. During sorting, data, disposition, and number trapped by sex, age class (classified by fork length), and marks are collected. Fish are also examined for presence of coded-wire tags. Additional age, length, and CWT information is obtained when broodstock collected at TMFD are spawned and from snouts collected in the Umatilla River fishery. The natural origin of unmarked steelhead is cross-checked by examining scale patterns on all unmarked fish collected for broodstock or sampled in fisheries and on the spawning grounds. Harvest is monitored below TMFD to obtain an estimate of returns to the mouth of the Umatilla River. A roving creel survey is used to count and contact anglers in the steelhead fishery. During video enumeration, total counts of steelhead are obtained from review of the video tapes. During the video review, about 50% of steelhead can be classified as hatchery or natural by the presence or absence of an adipose fin, respectively. Origin of the unidentified steelhead, and age, sex, and mark composition of video monitored steelhead are estimated as their mean percent composition from trapping periods immediately before and after the video period.

Analysis: Counts of adult returns to TMFD plus estimated harvest below TMFD are combined to estimate the number of natural- and hatchery-origin fish that return to the mouth of the Umatilla River. Counts of adults in combination with other measures are used to estimate key metrics of survival (smolt-to-adult survival, pre-spawn mortality) and productivity (smolts-per-spawner, adult recruits-per-spawner ratios). In-basin freshwater productivity has been estimated as the number of smolts-per-spawner from spawner abundance estimates and smolt abundance estimates collected by the BPA-funded Umatilla Smolt Outmigration and Survival Project. Adult-to-adult productivity is measured as recruits-per-spawner ratios using spawner abundance data and estimates of total adult spawner production resulting from each brood year.

Status: Adult and smolt estimates are currently funded. BPA currently funds counts at TMFD, creel surveys, and harvest estimates. Returns have been enumerated at TMFD using an electronic fish counter from 1966-1983 and mark-recapture methods from 1983-1987, after which a trapping and collection facility was constructed. All returning adults were trapped until the 1999 return year, after which alternating trapping-video enumeration was implemented. Funding for smolt abundance was discontinued in 2007, then re-started in 2009.

Objective 2: Determine the status of the spatial structure of the population based on current and historically utilized habitat.

Spawners can escape differentially to each watershed due to habitat conditions, pre-spawn mortality, and stochasticity. The production of juveniles can vary among watersheds due to spawner abundance, spawner productivity, habitat quality, habitat quantity, egg mortality, fry mortality, or parr mortality. An understanding of spatial and temporal variance in both spawner and juvenile distribution is therefore necessary to address several of the critical uncertainties. This is a highest priority objective.

Type of monitoring effort: Long-term status and trends monitoring.

Monitoring questions:

- What is the spatial arrangement of the occupied spawning areas within the population boundaries?
- What is the distribution and density of spawners on the spawning grounds?
- What is the current spatial extent and distribution of rearing habitat used by juvenile steelhead?
- What is the distribution of juveniles on the rearing grounds?

Performance metrics: Spawner distribution, redd distribution, spawn timing, rearing distribution, juvenile density and distribution.

Approach: Sampling will be conducted throughout all known spawning and rearing habitat. Sample site selection design will follow an EMAP protocol (Stevens and Olsen 2003, 2004; www.epa.gov/emap). Redds are enumerated using multiple-pass visual surveys of the selected sample reaches. The location of each redd will be georeferenced. Although few carcasses are recovered, carcasses will be measured and weighed, and a scale sample will be collected for age, growth and origin analysis.

Enumeration of juvenile out-migrants on Meacham Creek, a major tributary to the Umatilla River, started with a mark-recapture project in 2009. Habitat restoration conducted under CTUIR's Meacham Creek Habitat Enhancement Project will be evaluated for effectiveness using smolt production ratios as performance measures. It is hypothesized that Meacham Creek smolt production will make up a larger proportion of the Umatilla Basin's total smolt production as habitat restoration efforts come to fruition.

Juvenile survey reaches will be randomly selected within watersheds using the same EMAP protocol. Sampling will be stratified by increasing intensity in watersheds that are receiving supplementation, flow, or habitat treatments. At least thirty juvenile sites will be surveyed annually. This sample size approaches the practical maximum for field efforts, surpasses the sample size required to detect geographic patterns in community structure related to and independent of habitat variability, far exceeds the sample size needed to detect habitat changes in each watershed (Roper et al. 2003), and should be sufficient to detect a 20-50% change in salmonid densities per annum at the watershed scale.

Analysis: Annual estimates of density will be produced for each life-history stage and watershed. A geostatistical analysis will be conducted using population and habitat data to estimate fish-habitat relationships and to produce a geostatistical stock assessment of spawners and juveniles. Associative, trend, and descriptive analyses will be used to monitor changes in spawner and juvenile populations across space and time. Detailed analysis to be conducted is located in the detailed methods section of the Umatilla RM&E Plan.

Status: Spawner abundance data are collected by the Umatilla Natural Production Project. Spawner monitoring is funded by BPA and is ongoing. Trapping to enumerate juvenile out-migrants on Meacham Creek began in 2009. Summer steelhead index sites have been surveyed in the Umatilla for more than 10 years.

Objective 3: Monitor and assess the abundance, timing, life history characteristics, and in-stream survival of out-migrating steelhead.

An estimate of smolt abundance for natural-origin steelhead in the lower Umatilla River is essential to answering critical uncertainties related to natural production capacity and within subbasin productivity. In addition, an understanding of migration success and survival is necessary to identify in and out-of-subbasin limiting factors (including environmental conditions, flow, fish habitat, hatchery rearing and release strategies, predation, and passage difficulties) and estimated loss by life stage for natural- and hatchery-origin steelhead. This objective addresses Critical Uncertainties numbers six and seven. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What are the abundance, timing, and in-stream survival of out-migrating steelhead?
- What are the life history characteristics of out-migrating steelhead?

Performance metrics: Migration parameters, abundance, survival, and life history characteristics (including age, size and condition) of emigrating smolts.

Approach: Smolt abundance will be estimated for naturally-reared steelhead emigrating from Meacham Creek to TMFD, and for smolts from the lower Umatilla River, using fish collection and trapping efficiency on lower Meacham Creek and at TMFD. Smolt survival and migration parameters (timing, duration and travel speed) will be monitored for naturally- and hatchery-reared species using PIT tags and remote interrogation at Three Mile Falls and lower Columbia River dams. Juvenile life history characteristics including smolt outmigration timing, length, age, condition and smolt status will be collected.

An incline plane trap set in West Extension Canal is currently utilized to capture emigrating juvenile salmonids in the lower Umatilla River. The trap is located within the juvenile bypass facility off TMFD. Trapping is conducted between February and June, and coincides with the primary smolt emigration period. Fish are enumerated by species, race and origin (natural or hatchery). Scales are collected on a subsample of natural summer steelhead for age analysis and developmental (smoltification) stage for all species is assessed by visible

brightness and the presence or absence of parr marks. All smolts captured during fish sampling are interrogated for PIT tags. To improve total outmigration estimates, CTUIR's Natural Production Monitoring and Evaluation Project will enhance PIT tag detection rates at TMFD by installing improved detectors on the smolt bypass structure on the west side of the dam and in the adult fish ladder on the east side of the dam.

Analysis: Smolt survival estimates have previously been calculated using the Migrant Abundance Method (Burham et al. 1987 and Dauble et al. 1993) and the SURPH 2 model (http://www.cbr.washington.edu/). Environmental variables including water discharge, flow, temperature and water clarity in the lower river will be monitored and relationship to smolt survival and/or migration success will be assessed using regression and correlation analyses. Associative and trend analyses will be used to evaluate outmigration.

Status: Smolt abundance estimates for the Umatilla River basin were provided by the BPA-funded Umatilla Smolt Outmigration and Survival Project until 2007, when funding was discontinued. Funding was re-established for that project in 2009. Funding was obtained by CTUIR from BPA to estimate Meacham Creek smolt abundance and survival beginning in 2009.

Objective 4: Determine the current status and change in status of life history and genotypic diversity in the population.

Natural steelhead production in the Umatilla River basin is supplemented by hatchery-raised fish that spawn in natural environments. However, the artificial propagation of fish and manipulation of breeding structures includes genetic risks that may compromise the goal of supplementation (Currens and Schreck 1995). It is important to monitor the genetic characteristics of natural and hatchery-produced fish to insure that the artificially produced fish resemble the wild population genetically, that adequate effective population sizes are maintained to prevent catastrophic genetic drift, and that outbreeding depression does not reduce the reproductive success of the entire population. This objective addresses Critical Uncertainties numbers five and six. This is a high priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- What proportion of steelhead spawners are out-of-basin hatchery strays?
- What is the origin of out-of-basin strays?
- What are the population-level genetic characteristics of the Umatilla River steelhead population?
- What is the status of life history patterns and variation in the Umatilla steelhead population?

Approach: Numerous life history metrics are monitored in the natural- and hatchery-origin steelhead populations: adult and juvenile migration timing, growth rates, age structure, sex ratios and size at age. A subsample of natural-origin juveniles is PIT-tagged on the spawning

grounds for outmigrant detection at TMFD and Columbia Mainstem facilities. Scales of natural-origin juveniles can be sampled during EMAP surveys and lower river trapping.

We will collect genetic samples from 100 returning adults of both natural- and hatchery-origin collected at TMFD. In addition, juvenile samples have been collected for three years (2005-2007) from multiple locations in the basin. Genetic samples will consist of fin clips, which will be immediately preserved in alcohol. Sampling will be initially conducted for five years to determine changes in the performance metrics over a generation and assess the periodicity of additional sampling.

Analysis: Migration timing and age structure are assessed by distribution comparisons. Age and growth analysis will be conducted and associative models will be used to evaluate growth of natural- and hatchery-origin fishes from each release site and watershed.

The genetic samples will be analyzed using microsatellite and/or allozyme analysis to determine the genetic diversity among returning natural- and hatchery-origin adults, the genetic distance between natural- and hatchery-origin adults, and the effective population size of the natural-origin adults within the Umatilla subbasin.

Status: Monitoring of hatchery-origin steelhead that stray into the Umatilla River is conducted by the BPA-funded Umatilla Hatchery Monitoring and Evaluation Project. Genetics samples are collected by the Umatilla Natural Production Project, with samples processed by Columbia River Inter-Tribal Fish Commission fish geneticists.

Objective 5: Identify and assess factors limiting viability of Umatilla River steelhead.

Limiting factors analysis is the process by which factors affecting population productivity, capacity, diversity and spatial structure are identified. As conditions are improved through management actions, and limiting factors are addressed, it is essential to re-assess limiting factors to guide future actions. This objective addresses Critical Uncertainty number seven. This is a high priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- What environmental factors limit steelhead productivity in the Umatilla subbasin?

Approach: We have developed an improved version of EDT and AHA (All-H Analyzer) which is more representative of Oregon's Mid-C steelhead. The revised EDT model will be updated in the future as habitat actions begin to improve conditions and additional data are available. We will use the EDT model to re-assess limiting factors.

Analysis: Limiting factors and the capacity of the Umatilla subbasin will be analyzed every five years as part of regular evaluation activities. A multi-factor spatially explicit model (EDT and improved AHA) of the Umatilla subbasin will be used to estimate mortality in Umatilla, Columbia, and marine life-history stages.

Status: Ongoing, but will need additional funding for the future.

Objective 6: Determine the status and trend of current and historically utilized salmonid habitat in the Umatilla subbasin.

This recovery plan identifies a set of management actions that will increase natural production and harvest opportunities in the Umatilla subbasin through habitat restoration and protection, flow augmentation, passage restoration, and hatchery supplementation. There are a number of habitat-based RM&E information needs that must be addressed if the benefits of these management actions are to be effectively detected with sufficient power. Information from this objective addresses Critical Uncertainty number seven. This is a high priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- What is the status and trend in steelhead habitat quantity and quality throughout the Umatilla subbasin?
- What are the spatial distribution and quantitative features of Umatilla subbasin steelhead habitat?

Approach: A variety of complementary habitat monitoring activities are regularly conducted in the Umatilla subbasin to capture variance in physical, biological, and chemical conditions. The sampling regime of these activities has varied from continuous monitoring of flow and temperature, to decadal monitoring of riparian conditions. Monitoring has focused on factors that are not primarily controlled by upstream conditions so that measurable improvements can be detected in important elements of salmon habitat. Habitat recovery will primarily be measured in terms of regrowth of the riparian vegetation, vegetation and channel structure, and in-stream cover. In addition, vegetative recovery is related to improvements in bank stability and channel morphology, therefore geomorphic characteristics will also be monitored. These broader parameters, though not useful for project specific monitoring, are more important when tracking comprehensive subbasin-wide recovery. The spatially explicit sampling approach (EMAP) of all known spawning and rearing areas is recommended for sampling the known spatial extent and status and trend of steelhead habitat in the Umatilla subbasin. Representative sites within the subbasin are sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. Habitat variables follow ODFW Aquatic Inventories design (Moore et al. 2002) and are measured at the unit and reach scale.

Analysis: Data are analyzed as distribution data in a GIS format. Sample sites are associated to specific major spawning and rearing areas. Database and GIS formatting of data allow associations with land use, land vegetation coverage, and many other attributes at watershed and population scales.

Status: BPA currently funds two Umatilla River Anadromous Fish Habitat projects; one managed by ODFW to improve and monitor habitat and the other managed by CTUIR to

increase our understanding of the spatial arrangements of physical processes that create and maintain critical habitats for Pacific Salmon in the Umatilla River basin and nearby basins.

Objective 7: Determine the influence of the current hatchery supplementation program on the natural population.

The reproductive success and genetic characteristics of hatchery-reared fish can be different from those of naturally-reared individuals or populations (Reisenbichler and McIntyre 1977). These differences stem in part from the environment of hatcheries, and in part from the artificial selection associated with the hatchery environment. The problem can in theory impact population growth (productivity of the natural-origin population) even when endemic stock is used and traditional stock domestication is avoided (Chilcote 2003; Reisenbichler et al. 2003). This objective provides information that addresses Critical Uncertainty numbers five and six. This is a high priority objective.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- Does supplementation alter the life history or genetic characteristics of the natural steelhead population?
- To what extent will supplementation enhance natural production of summer steelhead?
- Are residualization rates of hatchery releases greater than those of naturally-spawned fishes?
- Do the ecological relationships of hatchery-reared steelhead negatively impact naturally-reared steelhead?

The goal of supplementation is to enhance natural production by increasing survival of hatchery-origin fish, resulting in an increase the number of spawners in natural environments. However, the artificial propagation of fish and manipulation of breeding structures includes genetic risks that may compromise the goal of supplementation (Currens and Schreck 1995).

The hatchery supplementation program is managed to minimize potential unintended impacts on the life history characteristics of the native steelhead population. It is assumed that the use of natural-origin fish for broodstock will result in hatchery fish that mimic the behavioral characteristics of native fish, thus minimizing potential unintended impacts of the supplementation program. Since no pre-supplementation life-history information is available for pre- and post-supplementation comparisons, managers need to rely on long-term monitoring to detect shifts in native steelhead life history. However, the challenge of this approach is distinguishing whether these shifts are attributable to natural variability or hatchery supplementation.

Hatchery-origin fish are usually released at sizes and conditions which differ from their natural-origin counterparts. Sexually mature residualized fish can compete with returning anadromous adults for mates, and can compete with resident fish or pre-migrant juveniles for ecological resources. Recent studies by the Yakima-Klickitat Fisheries Program suggest that hatchery practices can be modified to decrease residualization rates if problems are detected.

Similar work should be conducted to determine the extent and impacts of hatchery fish residuals on the natural population.

Potential unintended negative impacts of hatchery supplementation to the life history and genetic characteristics of the endemic steelhead population in the Umatilla subbasin is a primary management concern. The management strategy for reducing risk of unintended impacts to the natural-origin steelhead population is to implement hatchery production protocols that maximize life history and genetic diversity of hatchery-origin steelhead. If protocols achieve their goal, smolt migration and adult life history characteristics expressed by hatchery-origin steelhead should mimic those of natural-origin steelhead, and reduce the risk of unintended impacts to the natural-origin steelhead population when hatchery-origin steelhead spawn naturally.

Ideally, assessing whether hatchery supplementation negatively impacts life history and genetic characteristics of the naturally population is best accomplished by a pre/post supplementation comparison of these characteristics. However, no pre-supplementation data are available to provide a baseline for pre/post comparisons. Therefore, the approach should be to monitor life history characteristics and assess whether smolt and adult life history and genetic characteristics expressed by hatchery-reared steelhead are similar to those expressed by naturally-reared steelhead and detect changes if they occur. These data can be used to assess population viability by measuring life history diversity.

The Umatilla Fish Hatchery has used endemic steelhead stock for more than a decade. Nonetheless, it is not possible under the current RM&E approach to validate the long-term success of hatchery-origin fishes, or to estimate the relative reproductive success of hatchery- or natural-origin individuals. Due to increasing concern for the welfare of endemic populations, the reproductive success and genetic characteristics of Umatilla steelhead remains a critical uncertainty. Pedigree studies are being used in a variety of subbasins to answer a number of questions. These endeavors are costly and resource intensive, but may provide essential management information. Pedigree studies can demonstrate the relative productivity of natural and hatchery fish in the environment and aid in determining the effectiveness of a supplementation program.

Approach: Polymorphic microsatellite loci have been used in a variety of studies to determine parentage and population structure (O'Reilly et al. 1998; Bernatchez and Duchesne 2000; Letcher and King 2001; Eldridge et al. 2002). The technique and its application have been thoroughly reviewed (Wilson and Ferguson 2002). Microsatellite analysis can be used to estimate the relative reproductive success of natural- and hatchery-origin steelhead, the long-term reproductive success of hatchery-origin steelhead, and the genetic characteristics of both stocks.

Two parallel studies have been proposed for the evaluation of long-term reproductive success at the watershed level. A weir is planned for the mouth of Iskuulpa Creek to sample returning adult steelhead. Adult anadromous returns, resident redband trout, and juvenile progeny will be sampled and genotyped for 16 microsatellite markers. This sampling regime will be followed for ten years, the completion of two full steelhead generations. This

pedigree analysis will be used to assess and compare the relative and long-term reproductive success of hatchery x hatchery (H x H), hatchery x natural (H x N), and natural x natural (N x N) crosses from Umatilla Mid-C summer steelhead.

In addition the testing of a new technique for the evaluation of progeny parentage is currently proposed. Hatchery-origin female returns will be injected with strontium chloride hexahydrate ($SrCl2 \cdot 6H2O$) in solution. This will serve as a mark of hatchery female parentage. These injections have been shown to elevate progeny Sr/Ca ratios in the otolith primordia. A subsample of progeny above the weir would be sacrificed, and their otoliths extracted. The proportion of "elevated" vs. normal Sr:Ca ratios would be used to estimate the fraction of offspring from hatchery- vs. natural-origin mothers.

We have completed an initial analysis to assess if nearby unsupplemented populations in the John Day Basin can serve as reference populations for the Umatilla supplementation monitoring. There is a high degree of correlation in the pre-hatchery treatment time period between Umatilla steelhead and the John Day populations for both abundance and productivity. We will use the John Day populations as reference populations to assess changes in abundance and productivity that result from the long-term hatchery supplementation program.

Residualized steelhead are currently planned to be sampled during EMAP surveys. Residuals would be classified based on the presence of a fin clip or wire tag for hatchery fish. Their distribution and abundance should be measured across the Umatilla watershed.

We will monitor and compare smolt and adult migration timing, ocean residency age structure, and adult sex ratios of natural- and hatchery-origin steelhead. Migration timing of steelhead smolts will be monitored via detection of PIT-tagged fish at TMFD, John Day, and Bonneville dams. Adult run timing of steelhead to the Umatilla River will be monitored by trap and video enumeration at TMFD and in-subbasin creel surveys below TMFD. Ocean residency age structure and adult sex ratios of steelhead will be monitored during adult trapping and handling operations at TMFD.

Ocean residency age and sex ratios of natural- and hatchery-origin adult steelhead are monitored during trapping at TMFD. Migration timing of natural- and hatchery-origin steelhead smolts is compared by calculating the percent of the run that passes TMFD, John Day, and Bonneville Dams on a weekly basis, and testing for a statistically significant difference. The same method is used to compare migration timing of natural- and hatchery-origin adult steelhead that pass TMFD. The proportions of the natural- and hatchery-origin runs that were one- and two-year ocean residents, male and female, and male and female by ocean age will also be compared.

Analysis: Umatilla adult steelhead samples are analyzed by the Columbia River Inter-Tribal Fisheries Commission cooperative genetics program at the Hagerman Fish Culture Experiment Station using microsatellite loci that have been optimized for steelhead studies. Juvenile samples are analyzed by NOAA Fisheries as a part of the Columbia basin-wide genetic monitoring program. Samples are analyzed for each brood and return year.

Genotypes are assembled using 16 microsatellite markers. Parentage is estimated using a variety of exclusion, likelihood, pair-wise relatedness, and genetic similarity algorithms (Wilson and Ferguson 2002). The relative and long-term reproductive success of hatchery x hatchery (H x H), hatchery x natural (H x N), and natural x natural (N x N; including steelhead x steelhead and steelhead x redband trout) crosses will be evaluated in the controlled escapement experiment in Iskuulpa Creek.

Status: Partially funded by BPA and implemented by CTUIR and ODFW.

Objective 8: Monitor and assess the impact of flow enhancement on steelhead survival, habitat, and migration.

Considerable effort and resources are directed at flow restoration in the Umatilla River. Umatilla flow management programs are considered a Columbia Basin success story due to the cooperative efforts between CTUIR, BLM, and the various water-rights managers in the subbasin. However, some of the direct benefits to fish have not been quantified. While the relationships between flow restoration and trap-and-haul work are comparatively straightforward, the relationship between increased flow and increased spawning and rearing habitat has not been directly studied. Additional flow restoration activities including the Phase III flow exchange project are receiving considerable attention. Baseline effectiveness monitoring is needed to understand the added benefits to fish that these future flow programs would bring to the subbasin. This objective provides information that addresses Critical Uncertainty number seven. This is a high priority objective due to the cost and scale of the flow enhancement efforts.

Type of monitoring effort: Effectiveness monitoring.

Monitoring questions:

- What is the impact of flow enhancement on steelhead survival and frequency of steelhead transport?
- What is the effect of flow enhancement on the availability of spawning and rearing habitat?
- What is the effect of flow enhancement on steelhead migration?

A major passage restoration project is planned for the Umatilla Mainstem at Feed Canal (Harza Engineering Company 1999). Experience has shown that not all passage restorations are successful, so project effectiveness monitoring is warranted upon completion of construction and beginning of operations. The efficacy of two additional fish passage facilities, the Boyd Hydro and Maxwell Dams, is uncertain due to a lack of data associated with these recently renovated structures. Passage at these facilities needs to be evaluated.

Adult and juvenile fish passage facilities at irrigation diversions in the Umatilla mainstem were reconstructed from 1988 to 1994. Effectiveness of the updated facilities has previously been evaluated. Juvenile passage evaluation was conducted by ODFW (Knapp and Ward 1990; Knapp 1992; Cameron and Knapp 1993; Cameron et al.1994, 1995, 1997; Walters et al. 1994), adult passage evaluation was conducted by CTUIR (Kutchins 1990; Kissner 1992,

1993; Volkman 1994, 1995; Contor et al. 1996, 1997), and Nigro and Ward (1986) evaluated channel modification below Three Mile Falls Dam. These studies identified two passage impediments in the Umatilla mainstem and recommended potential corrective measures.

Performance metrics: Percent of juvenile and adult returns which pass through the lower river volitionally, during enhanced flows, and those requiring transport, survival from TMFD to spawning, and spawning distribution.

Approach: We will monitor and report the percent of juvenile and adult returns which pass through the lower river volitionally, during enhanced flows, and those requiring transport. This computation will include an adjustment to account for transit time from enumeration at TMFD to when their migration through the flow-enhanced river reach is completed. These adjustments will be based on estimates of juvenile and adult migration speeds available from adult radio tracking studies conducted from 1994-1996 (Volkman 1994 and 1995, Contor et. al 1996 and 1997) and smolt migration monitoring from the recently funded smolt outmigration and monitoring project..

Logistical difficulties impede assessment of survival benefits from flow enhancement for smolts migrating through the lower Umatilla River. A potential approach for assessing benefits to smolt migrants is a tier III treatment and control experiment, where the treatment is smolts volitionally migrating past the juvenile trapping and transport facility at RM 27 during flow enhancement and the control is smolts trapped at RM 27 and transported to the river mouth (simultaneous to tagging of treatment fish).

Juvenile habitat utilization and summer steelhead spawning will be monitored in the Umatilla mainstem during annual EMAP surveys. Summer stream temperatures will be monitored in collaboration with BOR and CTUIR water quality programs. Habitat quantity will be monitored continuously as a function of stream flow throughout the supplemented reaches of the Umatilla River.

Adult steelhead could be collected and radio-tagged at TMFD using standardized handling techniques. Fixed site radio telemetry receivers would be placed at key passage barriers to monitor migration around these obstructions. Baseline estimates of passage and delay are available for various flow regimes (Contor et al. 1995, 1996, 1997, 1998).

Analysis: Habitat potential will be modeled regularly using a spatially explicit model of habitat quality and quantity such as EDT, facilitating the evaluation of the relative impacts of various flow management regimes, including the implementation of Phase III flow exchange.

The benefits of flow augmentation will be analyzed based on comparative performance of the lower and middle Umatilla mainstem reaches as indicated by habitat, rearing, and spawning metrics. Data collected will be compared to the baseline data to evaluate the effectiveness of the passage restoration projects.

Status: BPA funds the CTUIR managed Umatilla Fish Passage Operations project, which collects data on juvenile and adult steelhead passage in relation to flow. BPA also funds the

ODFW managed Umatilla Smolt Outmigration and Survival Project. Monitoring of adult steelhead migration past potential barriers, using radio telemetry, occurred in 2008 and 2009, Funding is needed to investigate relationships between flow and juvenile habitat use.

Objective 9: Determine the effect of mainstem hydropower operations and operational improvements on viability of Umatilla River steelhead population.

This is a high priority objective.

See John Day MPG for *Timeline, Monitoring Questions, and Approach*.

Objective 10: Determine the effect of harvest on the abundance, productivity, diversity, and distribution of the natural-origin population.

Restoring and optimizing fishery opportunities are a primary goal of local and regional fishery managers. However, this can be a challenging due to changes in fishing effort, run sizes, catch and harvest that are likely to occur as environmental and anthropogenic conditions vary and the fisheries restoration program matures. In addition, fisheries are also managed to keep unintended impacts to natural and hatchery production and non-target species within acceptable limits. This objective addresses Critical Uncertainty number four. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What is the annual harvest rate that occurs outside of the Umatilla River subbasin?
- Do summer steelhead return at a level of abundance adequate to support annual fisheries?
- What is the annual harvest rate that occurs within the Umatilla River subbasin?
- What is fishing effort, catch, and harvest for tribal and non-tribal fisheries in the Umatilla River?
- Are harvest goals met and do management actions optimize fishing opportunities while meeting production and population objectives?

Much of the impetus for the Umatilla supplementation and reintroduction programs are tribal and non-tribal harvest mitigation. Steelhead fisheries take place throughout most of the mainstem Umatilla River using a diversity of fishing gear. Tribal fisheries mostly occur upstream within the CTUIR Reservation and consist of a subsistence fishery using gaffs or dipnets and a recreational fishery using rod-and-reel. Non-tribal fisheries occur from Pendleton downstream to the river mouth using rod-and-reel, with most effort, catch, and harvest concentrated below TMFD. Creel data provide information needed to determine whether harvest goals are achieved or exceeded, enumerate fish removed from the run below TMFD, and assess how to optimize fishing opportunities through adaptive management. Accurate run size predictions allow managers and program staff to plan appropriate broodstock collection, harvest, spawning escapement, and CWT recovery strategies in advance. Run predictions are integrated into co-management of the Umatilla Subbasin Fishery Program through the development of an annual plan for hatchery and subbasin

operations. Harvest estimates for Umatilla subbasin-origin fish in out-of-subbasin fisheries provide essential data to track status and trends of fish populations, provide a full accounting of all hatchery production and rearing strategies, compare recruits-per-spawner ratios of natural- and hatchery-origin fish, and evaluate alternative hatchery production and release strategies.

Approach: Out-of-basin harvest contributions are currently grouped by three main fishery areas: ocean, Columbia River, and in-subbasin fisheries. The number of adults harvested by individual hatchery groups and the total number for all hatchery groups by run year are reported. A database of recoveries by brood year contributions is also maintained.

Annual out-of-subbasin harvest is reported for tribal and non-tribal ocean, Columbia River, and subbasin fisheries. In out-of-subbasin fisheries that are selective for hatchery-origin fish, harvest of hatchery-origin fish are estimated from CWT recoveries reported on the Pacific States Marine Fisheries Commission CWT database. In out-of-subbasin fisheries, which are not selective for hatchery-origin fish, harvest of natural-origin fish is estimated based on exploitation rates of hatchery-origin fish.

Tribal fisheries are monitored using roving creel surveys, phone surveys, and volunteer fishing journals. Non-tribal fisheries are monitored using a combination of stratified roving creel surveys and "punchcard" data from anglers who turn in their salmon and steelhead harvest cards. Harvest estimated from creel surveys is used to monitor the developing fisheries in the Umatilla River to assess harvest potential and whether annual harvest goals are met. Overall harvest goals are listed in Table 2 of the Umatilla RM&E plan, and harvest goals for varying run sizes are currently under development. Creel information on spatial and temporal patterns of fishing effort, catch, and harvest are used to assess whether fisheries are optimized within the constraints of natural production and population objectives.

Creel surveys in the non-tribal fishery are composed of three main components: 1) angler counts, 2) interviews to obtain information on catch rate, harvest rate, gear types, and angler demographics, and 3) collection of biological, mark, and CWT information from catch. A roving creel survey is used to count and contact anglers in the steelhead fishery. The lower river is surveyed from September 15 to April 15, and the upper river from January until April 15. Fishing effort is typically very low in the lower river from February through April.

Correlation models have been developed for preseason prediction of steelhead run size to the Umatilla River. Correlations for steelhead ($r = 0.87$) run size to the Umatilla River are based on forecasted steelhead run sizes to Bonneville Dam (Upriver A-run for steelhead). The steelhead model is updated in early-September after the Upriver A-run to Bonneville Dam has been counted.

Analysis: Ratios between punchcard and creel data are used to estimate harvest in the river reach from TMFD upstream to about RM 37 that is logistically difficult to access and survey. Geographically and temporally stratified variance in the tribal and non-tribal catch and harvest estimators are based on the variances of the fishing effort and catch and harvest rates. Effort, catch, and harvest are estimated monthly for steelhead.

Analysis follows Malvestuto (1996) for the field work and Cochran (1977) for creel survey data by expanding subsamples by sample strata and proportional coverage rates. Similar expansions are used to extrapolate tribal wide harvest estimates based on postseason interviews. Catch-per-unit-effort is estimated directly from interview responses and fishing journals. Total fishing effort is estimated based on time period, week period, and site encounter probabilities.

Status: Partially funded by BPA. ODFW has monitored the non-tribal steelhead fishery on the Umatilla River since 1992, and the out-of-subbasin harvest estimates are determined by the hatchery M&E project.

Objective 11: Determine the effect of predation on the abundance, productivity, diversity, and distribution of the natural-origin population.

The objective is moderate priority because predation has not been identified as a key limiting factor.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring question:

- What are the predation rate and predatory impact of introduced fishes in the Umatilla River on juvenile steelhead?

Approach: Annual collections of smallmouth bass and other piscine predators in the Umatilla River could be conducted using angling techniques. Collected stomach samples would be analyzed for the presence of juvenile salmonids. These data could be incorporated into a bioenergetics model to derive a population-level consumption estimate imposed by introduced fishes. Sampling of predatory fish diets should occur during times and locations when and where their distribution overlaps with juvenile steelhead.

Analysis: Interpretation of the predatory impact in the migration corridor should be conducted from methods established in published literature (Ward et al. 1995, Fritts and Pearsons 2006). The proportion of total mortality (e.g. SAR) attributable to predatory mortality could be estimated from bioenergetics modeling results.

Status: Currently unfunded and not implemented.

Objective 12: Monitor production, survival, harvest and spawning of hatchery-origin steelhead.

Monitoring survival and disposition of all hatchery fish through all life stages provides fundamental information required to assess what changes may be needed if management objectives are not met. Information on the magnitude of losses at each life stage also assists managers to determine priorities for changes. Adaptive management actions may involve aspects of the hatchery program or changes to fish restoration programs, harvest regulations, and hydrosystem management within or outside of the Umatilla subbasin.

In 1994, following ESA section 7 consultations concerning the effects of straying by non-native hatchery-origin fish, NMFS set an interim standard to limit stray, non-native hatchery-origin fish to 5% of any naturally spawning population (Grant 1997). To achieve this management standard and provide the necessary information needed to develop risk containment strategies for straying, all hatchery production which has the potential to stray into spawning areas of ESA-listed populations needs to be adequately marked, and monitoring programs must be present in ESA areas to recover marked fish. In addition, adaptive management of the Umatilla subbasin fisheries restoration program may have potential to reduce straying by adjustments in the timing of flow enhancement, and increased capabilities for flow enhancement if Phase III water exchange is implemented. This M&E objective is focused on providing information needed to monitor standard hatchery production goals, adaptive management of the Umatilla subbasin hatchery program, and straying of hatchery production fish into areas with ESA-listed steelhead populations.

Release sites for smolts in a hatchery steelhead supplementation program are typically located high in a subbasin, in or near tributary streams that are targeted for supplementation. In contrast, harvest oriented hatchery programs typically release steelhead smolts in lower mainstem reaches of a subbasin. In the case of the Umatilla subbasin steelhead supplementation program, hatchery smolt releases in Meacham Creek are intended to provide the Meacham Creek spawning aggregate with additional hatchery-reared spawners. Hatchery smolt releases into the Umatilla mainstem lower in the subbasin at Minthorn (RM 64) and Pendleton (RM 56) have a dual harvest-supplementation intent. They are intended to enhance fisheries in the upper Umatilla mainstem while providing "Middle Umatilla" tributaries with additional hatchery-origin spawners.

The Birch Creek watershed is managed as a native steelhead sanctuary. Adult escapement was monitored for a number of years by CTUIR and ODFW, and fraction was consistently less than 5%. Periodic monitoring of spawning escapement to Birch Creek is warranted to determine if straying and the hatchery fraction remain at low rates. This is a high priority objective because of the assumed benefits and high degree of uncertainty in the management action.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- Are hatchery returns achieving the goals of the comprehensive plan?
- Are recruits-per-spawner ratios higher for hatchery-origin compared to natural-origin steelhead?
- What is the number of hatchery-origin returns that stray?
- What percent of returns stray into the Snake and upper Columbia River basins?
- Does hatchery supplementation result in increased natural production of steelhead?
- What proportion of steelhead spawners in the Umatilla subbasin is derived from the hatchery program, and what is their distribution?

Performance metrics: For all hatchery production and release strategies: annual numbers of smolts produced, smolt-to-adult survival by brood year; number of adults produced by brood

year, annual number of adult returns, and annual and brood year harvest and number of natural spawners.

Approach: Routine in-hatchery production and survival is monitored by hatchery staff and reported to the statewide ODFW hatcheries database. This M&E objective primarily describes monitoring activities conducted outside of the hatchery. Survival of hatchery-origin fish during the smolt migration life stage is currently monitored by detection of PIT-tagged smolts in the lower Umatilla River and at John Day and Bonneville dams in the Columbia River. Adult production, SAS, harvest, and straying of all hatchery production and release groups are monitored using CWTs. Adult returns to the Umatilla subbasin for all hatchery production and release groups are monitored using CWTs recovered within the subbasin.

Repeated spawning ground surveys could provide a future measure of the presence of hatchery (fin-clipped) steelhead in the Birch Creek watershed during the spawning season. While actual fish observations may be low, repeat spawning ground surveys on the John Day River have demonstrated that visual surveys are feasible. This approach is much more logistically and financially feasible compared to the operation of a new weir and adult trap.

Rearing and release history of hatchery steelhead returns to the Umatilla subbasin is monitored using CWTs recovered from all locations within the subbasin. Of particular regional interest is the identification of non-Umatilla origin hatchery groups that enter the Umatilla River in spring that will likely spawn with ESA listed Umatilla steelhead.

Recruits-per-spawner ratios of hatchery-origin steelhead over time must be substantially higher than those of natural-origin steelhead for hatcheries to be a viable tool for fisheries restoration. If this is not the case, more adult production will be realized by leaving hatchery broodstock in the river to spawn naturally. The number of additional adults produced by hatchery programs also must be great enough to overcome potentially lower productivity (reproductive success) when they spawn naturally compared to natural-origin fish.

Numbers of adult parents will be known from spawning records for hatchery-origin fish, but will require estimation for natural-origin steelhead. Spawning information is documented in annual reports produced by the CTUIR Umatilla Hatchery and Satellite Facilities O&M Project (BPA Project # 83-435). Numbers of natural-origin parents are from counts at TMFD. Adult progeny from a brood will return over multiple years. Number of progeny per brood for hatchery-origin fish is estimated from abundance and age information acquired by CWT recoveries. Number of progeny per brood for natural-origin steelhead that return to TMFD is estimated by collecting scales for age analysis to apportion adult returns by brood year. Numbers of natural-origin steelhead harvested in non-selective fisheries is estimated by creel surveys for Umatilla subbasin fisheries and by using CWT recoveries of harvested hatchery-origin fish as a surrogate for harvest of their natural-origin counterparts in out-of-subbasin fisheries. For out-of-subbasin harvest, it is assumed that the age classes of the natural-origin fish harvested out-of-subbasin are equal to the age composition of returns to the Umatilla River. Monitoring straying of adult steelhead from the Umatilla subbasin

hatchery is conducted by marking steelhead with a CWT and analyzing out-of-subbasin CWT recovery data.

Analysis: Up until 2004, in-basin survival of hatchery salmonids was estimated using the Migrant Abundance Method (Burham et al. 1987 and Dauble et al. 1993). Commencing in 2005, in-basin and out-of-basin survival for natural and hatchery steelhead was estimated using the CRISP and SURPH models. The Umatilla Outmigration and Survival study is no longer funded, thus these estimates are not currently available.

Testing for significant differences in survival rates is conducted annually and over five-year periods. Smolt survival estimates generated by SURPH include a point estimate and associated variance.

Relative survival of PIT tagged groups from valid comparisons to TMFD, and John Day and Bonneville Dams were compared in the past. PIT tag information is currently submitted and recovery data obtained from the PSMFC database. Number, travel time, and length at PIT-tagging are recorded for each release group at all reporting observation sites.

To determine number of adult progeny produced per brood for natural- and hatchery-origin steelhead, calculate P:P ratios for both natural- and hatchery-origin fish as total number of adult progeny produced divided by total number of adult parents that spawned.

Numbers of adults which are recovered at terminal locations outside of the Umatilla subbasin (spawning grounds, hatcheries, and adult traps) can be reported for the following areas: Snake River Basin, Columbia River Basin above McNary Dam, Columbia River Basin below McNary Dam, and all other locations. No steelhead with CWTs have been recovered at out-of-subbasin terminal locations to date.

Status: Partially funded by BPA.

Objective 13: Determine the transmission and effect of disease on the abundance, productivity, diversity and distribution of the natural-origin population.

The overall goal of the fish health program is to release fish into the Umatilla subbasin that are known to have a healthy disease history during rearing to minimize impacts on naturally- and other hatchery-reared fish. This is a low priority objective because disease effects have not been identified as a limiting factor.

Type of monitoring effort: Long-term status and trend monitoring.
Monitoring questions:

- What are the prevalence and level of pathogens in natural- and hatchery-origin steelhead?
- What are the magnitude and pathways of disease transmission between hatchery- and natural-origin steelhead?
- What is the prevalence of whirling disease in the Umatilla River basin, and what is its influence on the natural steelhead populations?

Performance metrics: Pathogen prevalence and levels in natural- and hatchery-origin steelhead.

Approach: The health of hatchery-origin fish should be monitored starting with broodstock and continuing through rearing and release of juveniles. Natural fish health is assessed on mortalities encountered during parr, smolt, and spawner monitoring activities. If possible, all sampling, diagnostic, and statistical analyses will conform to the Integrated Hatchery Operations Team and the Pacific Northwest Fish Health Protection Committee guidelines. All monitoring is consistent with the ODFW fish health policy and the native fish conservation policy.

All raceways of each species and stock at Umatilla Hatchery are monitored monthly for fish health. Monthly monitoring consists of examining five fresh-morbid or moribund fish from each raceway for systemic and gill bacteria on TYE-S agar. In addition, monthly inspections include microscopy of gill tissue and body scrapings for parasites and gill condition from a minimum of five fish. Sixty fish are tested annually for *Myxobolus cerebralis,* the causative agent of whirling disease. Within four weeks of transfer from the hatchery, tissues from grab-sampled fish are examined for virus on cell cultures from a minimum of 10 fish per raceway. Gill and body scrapings are examined by microscopy from a minimum of three fish per lower raceway at Umatilla Hatchery. In addition, prior to their liberation from acclimation facilities most groups of fish are examined from each acclimation pond as in the monthly monitoring protocols described above.

A minimum of 60 broodstock fish are examined for culturable viruses as per fish health section bluebook methods. This includes ovarian fluid and pyloric caeca/kidney/spleen samples from all broodstock for this program. All broodstock mortalities are examined for culturable systemic viruses using TYE-S agar.

Currently, fish health personnel examine naturally-reared fish that are submitted for analysis. Submissions consist of mortalities from naturally-reared juveniles obtained from smolt traps and parr collected during juvenile fish sampling. Disease examinations include testing for *M. cerebralis,* IHNV, and other culturable viruses.

Analysis: Analysis of samples will follow standard protocols defined in the latest edition of the American Fisheries Society "Fish Health Blue Book" (Procedures for the Detection and Identification of Certain Fish Pathogens).

Status: Partially funded by BPA, partially implemented.

13.3.2 Walla Walla River Population

Summer steelhead are currently the only natural population of anadromous fish in the Walla Walla subbasin. Steelhead restoration and management programs in the Walla Walla subbasin include hatchery actions, harvest management, and habitat, flow, and passage improvement projects. Artificial production programs for steelhead include a Lyons Ferry Hatchery steelhead harvest mitigation program and an experimental endemic steelhead mitigation program in the

Touchet River population. The "Comprehensive Aquatic Research, Monitoring and Evaluation Plan" (RM&E plan, Appendix AD3 in the Walla Walla Subbasin Plan) outlines a strategy for obtaining information needed to assess the performance and evaluate the success of these restoration programs.

The research, monitoring, and evaluation objectives and approaches that follow are from the RM&E section of the Walla Walla Subbasin Plan (2004). To date, a comprehensive Walla Walla subbasin RM&E plan, including critical uncertainties, has not been agreed upon by all agencies, however research priorities are listed in the Subbasin Plan and in this report. Some of the monitoring and evaluation activities described in this plan are ongoing. However, several currently unfunded activities are proposed in this plan to address key information gaps and improve ongoing efforts. These proposed activities include modification of ongoing monitoring, critical uncertainty research, and innovative study approaches.

Status monitoring is performed at multiple scales for summer steelhead in the Walla Walla subbasin. Natural production status monitoring includes abundance indices for juveniles (parr and smolts), number of returning adults, estimated redd numbers, as well as flow, temperature, and habitat data to assess the success of flow augmentation and stream restoration work. Hatchery and natural production evaluations include the monitoring of smolt-to-adult returns, smolt-to-adult survival, catch contribution, catch distribution and straying rates, and experimental releases of juveniles and spawners. Juvenile outmigration monitoring includes the number of outmigrating smolts, travel timing, and survival to downstream dams. In addition, the fisheries are monitored using creel surveys and marine fishery observations to estimate the contribution of Lyons Ferry Hatchery fish to all commercial, subsistence and recreational fisheries.

The objectives of status monitoring are to describe existing habitat conditions and population status, and to assess trends over time. The NOAA Fisheries RM&E plan (NOAA 2003) calls for status monitoring to document progress toward recovery of listed populations. Repeated measurements (temporal replicates) are taken over time to quantify change. Existing population conditions are compared to performance standards as established in the appropriate recovery or master plans.

The Walla Walla EDT model was parameterized during the subbasin planning process without extensive empirical data for the subbasin. In all cases, empirical data were used if available. However many habitat attributes were rated based on local knowledge and best scientific judgment. It is clear that there is significant uncertainty in how well the data represent habitat and fish assemblage conditions. Improving the quality of habitat data is an important step in improving future modeling efforts. Improved data quality can be achieved by collecting additional empirical data and future efforts should focus on the following recommended attributes.

1) Those attributes with the greatest importance in EDT model results (e.g. maximum width, gradient, habitat type inventories, large wood, bed scour).
2) Those that are within the priority protection or restoration stream reaches identified in Section 9.

3) Data that are limited for attributes which have a broad (subbasin wide) effect on population or habitat status (passage at obstructions, water quality, others).
4) Attributes identified as primary limiting factors in Section 8.

The general M&E framework for the Walla Walla subbasin is guided by the need to fill data gaps and establish a better understanding of the baseline habitat conditions including the characteristics of passage, flow, substrate and ecological interactions which most directly impact the production of steelhead. The overall goal of monitoring and evaluation efforts will be to address, at a minimum, those critical areas for VSP analysis as described by NOAA Fisheries. Specific performance measures were identified for the four VSP areas:

1) *Adult abundance*: Run size to the basin (this can be greatly impacted by out-of-subbasin effects but is critical to monitoring population status). Estimates or enumeration of escapement to the spawning grounds including hatchery fish and harvest within the subbasin (hatchery harvest and incidental hooking mortality of natural-origin fish). Out-of-basin harvest and mortality may limit recovery.

2) *Juvenile:* Smolt production at the population scale to reflect freshwater survival and production within the basin. It will be critical in modeling population response to habitat restoration actions.

3) *Diversity:* Genetic characterization, phenotypic diversity, life history pathways (juvenile and adult), and artificial propagation effects (hatcheries).

4) *Spatial Structure:* Distribution of juveniles and adults within the population, habitat limiting factors by life stage.

5) *Productivity:* Population growth rate or potential – smolts per spawner, natural-origin recruits-per-spawner, and population growth rate.

Monitoring of these key VSP parameters and their various performance metrics is described in the RM&E objectives that follow.

Objective 1: Monitor and assess the status and trends of abundance and productivity of hatchery- and natural-origin steelhead.

Adult abundance estimates to the Walla Walla River population are a critical metric for monitoring the status and long-term trends of this steelhead population. Monitoring trends in the performance metrics listed below will be critical to assessing the performance of the Walla Walla subbasin fish restoration program. These measures will also be used in viability analyses to estimate productivity and natural production capacity. Adult monitoring in the Walla Walla River is limited by the absence of a trap or ladder near the mouth of the river. Therefore, total returns to the Walla Walla River population are estimated from counts at Nursery Bridge and expansions of these counts to unsurveyed areas in the remainder of the population. Expansions are based on habitat capacity relationships and there is considerable uncertainty. Traps exist in

the middle-upper reaches of each drainage. Facilities at the Bennington Dam fish ladder require improvements to function for effective fish enumeration. This is a highest priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What is the annual steelhead spawner abundance in the Walla Walla and Mill Creek watersheds?
- Is the 10-year GM of natural-origin steelhead spawners in the Walla Walla population greater than or equal to the recovery criteria for natural-origin spawners?
- What are the current and trend in the 20-year population growth rate?
- What are the current and trend in smolts/spawner?
- What are the current and trend in adult spawner-to-spawner ratios?

Performance metrics: Number of hatchery- and natural-origin adult spawners in the Walla Walla population, run timing of hatchery- and natural-origin adult returns, smolts-per-spawner, adult spawner-to-spawner ratios.

Approach: Numbers of adult hatchery- and natural-origin returns will be enumerated by trap counts, as well as by visual redd surveys. Current traps/monitoring stations in the basin include Nursery Bridge, Bennington Dam ladder, and the Yellowhawk fish weir. A complete count of escapement past these locations could be obtained, but several of the facilities require improvement.

CTUIR will sponsor a design investigation to study the feasibility and technical requirements of placing a video-sonar adult monitoring system at or near the mouth of the Walla Walla. The study will cover design and maintenance requirements for a system, and will recommend best-available technology for such a system. If implemented the system would greatly aid management in understanding total abundance of adult returns to the Walla Walla, run timing and environmental correlates of migration in the lower river. In addition, CTUIR will work with USACE to improve fish monitoring equipment and protocols on Bennington Dam as described by Tice (2004). Improvements may include the use of visual, sonar, and lasers to acquire a more complete count of fish passing the facility.

Analysis: Counts of adult returns in combination with other metrics described in later M&E objectives (harvest, straying, spawner abundance, and smolt outmigrant abundance) will be used to estimate key metrics of abundance, survival (smolt-to-adult survival, pre-spawn mortality) and productivity (smolts-per-spawner, adult spawner-to-spawner ratios).

Status: Partially funded, ongoing.

Objective 2: Monitor and assess the distribution and density of spawners and juveniles.

An understanding of spatial and temporal variance in both spawner and juvenile production and productivity is necessary to estimate a variety of performance measures. Improved accounting of adults into the upper Mill Creek is needed. This is a highest priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What are the annual distribution and abundance of spawners and redds in each watershed?
- What are the spatial distribution of the occupied spawning areas and density of spawners within the population boundaries?
- What are the current spatial extent and distribution of rearing habitat used by juvenile steelhead?
- What are the relative abundance and distribution of juvenile steelhead, by age, seasonally throughout the basin?

Performance metrics: Spawner spatial distribution, spawn timing, and rearing distribution.

Approach: Sampling will be conducted for steelhead within their spawning and rearing habitat. The sampling design will follow a modified EMAP protocol. Spawner surveys will be randomized by tributary and reach for randomly selected reaches. Index reaches have been established for most of the subbasin. Juvenile surveys will be randomized by watershed, or stratified where randomization is undesirable. Annual estimates of density will be produced for each life-history stage, watershed, and at the population-scale.

Electrofishing, seining, and trapping will be used to quantify the abundance of juvenile salmonids at the reach scale. The sampling universe for juvenile surveys will be the EDT reaches developed for subbasin planning. We will use these reaches and watershed delineations to allocate sampling across the subbasin.

Instead of attempting to populate traditional statistical models, we will use a geostatistical estimator of population variance to project juvenile stock assessments across watersheds based on annual juvenile fish surveys. We will survey permanent index sites in each target watershed using multiple pass depletion electrofishing, snorkeling, and seining between barrier nets. Habitat conditions of the index sites will be estimated every 3 to 10 years, and the wetted width and volume of each site will be determined annually. An additional 2-5 sites will be randomly selected using a spatially balanced algorithm (Stevens and Olsen 2003, 2004). Within each reach sampling sites will be distributed randomly where possible, but will conform to landowner requests and trespassing laws. Fish communities and habitat information will be sampled at each randomly selected site. A draft site selection is currently under development and review by EPA's EMAP laboratory for the Walla Walla subbasin. Thirty permanent index sites and at least an additional thirty randomly selected sites will be sampled each year. This sample size approaches the practical maximum for field efforts, surpasses the sample size required to detect geographic patterns in community structure related to habitat variability, far exceeds the sample size needed to detect changes in each watershed (Roper et al. 2003), and should be sufficient to detect a 50% change in salmonid densities per annum at the watershed scale. Approximately five to ten percent of the catch will be PIT-tagged for survival and outmigration monitoring. This will provide a sample for the assessment and monitoring of within-subbasin survival of salmonids using detections at Columbia River PIT-tag detectors and the within-subbasin rotary screw traps.

Spawner surveys will be conducted during the appropriate spawning and holding season. Effort will be allocated using a stratified randomization of EDT reaches based on known and historical spawning habitat. Redds will be enumerated as an index of spawner abundance using multiple-pass visual surveys of the spawning grounds. The location of each redd will be georeferenced. The condition of each redd and any observed spawner activity will be noted. Each observed redd will be flagged by marking tape on adjacent vegetation to avoid re-sampling.

Steelhead survey efforts will be stratified using index sites that have five- to ten-year datasets. Each site will be visited annually and receive at least three passes each year. An additional two to six randomly selected reaches will be surveyed annually using multiple-pass visual observations. The co-managers are currently working to develop a rolling panel or continuous survey methodology for summer steelhead and bull trout.

Analysis: A geostatistical analysis will be conducted using population and habitat data to estimate fish-habitat relationships and to produce a geostatistical stock assessment of spawners and juveniles. Associative and trend analyses will be used to monitor changes in spawner and juvenile populations.

Status: Spawner monitoring is funded and ongoing; juvenile surveys are funded and implemented.

Objective 3: Monitor and assess the abundance, timing, life history characteristics, and in-stream survival of out-migrating steelhead.

An estimate of smolt abundance for natural-origin steelhead in the lower Walla Walla River is essential to answering critical uncertainties surrounding natural production capacity and within-subbasin productivity. In addition, an understanding of migration success and survival is necessary to identify in and out-of-subbasin limiting factors (including environmental conditions, flow, fish habitat, hatchery rearing and release strategies, predation, and passage difficulties) and estimate loss by life stage for hatchery- and natural-origin fish. This is a highest priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What are the abundance, timing, and in-stream survival of out-migrating steelhead?
- What are the life history characteristics of out-migrating steelhead?

Performance metrics: Migration parameters, abundance, survival, and life history characteristics (including age, size and condition) of emigrating smolts or migrants.

Approach: Total population smolt abundance will be estimated for natural-origin steelhead emigrating from the Walla Walla River using a rotary screw trap. In addition, estimates of outmigrant abundance will be obtained for the upper Walla Walla and Mill Creek rivers using rotary screw traps. The Bootstrap method with 1,000 iterations will be used to derive a

variance. Smolt survival and migration parameters (timing, duration and travel speed) will be monitored for hatchery- and natural-origin fish using PIT tags and remote interrogation at the lower screw trap and Columbia River dams.

Environmental variables including water discharge, flow, temperature, and water clarity in the lower river will be monitored. Juvenile life history characteristics including smolt emigration timing, length, age, health, condition and smolt status will be collected.

Analysis: Smolt survival estimates will be calculated using the Migrant Abundance Method (Burham et al. 1987 and Dauble et al. 1993) and the SURPH 2 model (http://www.cbr.washington.edu/). The binomial test will be used to test for significant differences in detection between comparable release groups of hatchery-reared fish. The relation of environmental variables to smolt survival and/or migration success will be assessed using regression and correlation analyses. Associative and trend analyses will be used to evaluate outmigration.

Status: Partially funded, modification and expansion of ongoing activities are needed.

Objective 4: Monitor and assess the residualization of hatchery- and natural-origin steelhead.

Hatchery-reared fish are released at sizes and conditions that differ from their naturally-reared counterparts. Sexually mature residualized fish can compete with returning anadromous adults for mates, and can compete with resident fish or pre-migrant juveniles for ecological resources. Recent studies suggest that hatchery practices can be modified to decrease residualization rates if problems are detected. The purpose of this work will be to determine the extent and impacts of residualism, whether hatchery practices produce greater-than-natural residualization rates, and to provide some potential corrective measures. This is a moderate priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What is the distribution and relative abundance of hatchery steelhead residuals?
- Are residualization rates of hatchery releases greater than those of natural-origin fishes?

Performance metrics: Residualization rates.

Approach: The WDFW Snake River Lab and Fish Management have annually surveyed (electrofishing) the juvenile production areas of the Touchet River since 2001. Hatchery-origin summer steelhead have been captured and identified (Lyons Ferry stock or Touchet Endemic stock), and residual population estimates have been derived to assess the overall impacts. Juvenile surveys will continue into the future to monitor the residualism rates and their distribution within the watersheds to describe interactions with natural salmonids. In the Walla Walla and Mill Creek system, residualized steelhead will be sampled during juvenile surveys. Residuals will be classified based on the presence of a fin clip or wire tag for hatchery fish, and using outlier analysis for the juvenile population. Resident redband

trout populations will be similarly noted, but are recognized as part of the steelhead population (Currens and Schreck 1995; Kostow 2003).

Status: Work is funded and is currently being implemented, expansion to Walla Walla and Mill creeks is needed.

Objective 5: Monitor and assess the distribution, condition and utilization of essential salmonid habitat in the Walla Walla population.

At the macro- and micro-scales land use and riparian conditions are strongly related to in-stream conditions (Crispin et al. 1993; Stednick and Kern 1994; Chen et al. 1998). These features directly impact water quality conditions, and can alter salmonid production through ecological mechanisms (Torgersen et al. 1999; Ebersole 2002). Habitat impacts are detectable at multiple scales, and can result in decreased survival and production of juveniles (Paulsen and Fisher 2001) and decreased recruitment of spawners (Regetz 2003) at the subbasin scale.
The EMAP of all known spawning and rearing habitats is recommended for sampling the known spatial extent and status and trend of steelhead habitat in the Walla Walla subbasin. Representative sites within the subbasin are sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. Habitat variables could follow ODFW Aquatic Inventories design (Moore et al. 2002) and are measured at the unit and reach scale. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What are the spatial distribution and quantitative features of the Walla Walla population essential fish habitat?
- What is the status and trend in habitat quantity and quality throughout the Walla Walla population?

Performance metrics: Quantity, quality, and utilization of essential fish habitat.

Approach: The Walla Walla Subbasin Plan identifies a set of desired future conditions that may increase natural production and harvest opportunities in the Walla Walla subbasin through habitat restoration and protection, flow augmentation, passage restoration, and hatchery supplementation. There are a number of habitat-based RM&E information needs that must be addressed if the benefits of these management actions are to be effectively detected with sufficient power. For example, the availability and distribution of quality essential fish habitat will be used to define the sampling universe of juvenile and spawner surveys. The adequacy of habitat representation in EDT will need to be evaluated. The condition and importance of several EDT habitat variables, especially bedscour and sediment load, need to be investigated.

Analysis: Spatial and numerical relationships among the habitat and salmonid variables will be used to estimate the degradation or restoration through time of essential fish habitat associated with both natural and anthropogenic disturbance; to estimate the absolute

abundance and distribution of juveniles and spawners using geostatistical expansions; to estimate the effectiveness of habitat restoration and flow augmentation projects; and, to estimate the quantitative relationship between habitat and production. Physical, biological, chemical and ecological habitat conditions will be monitored throughout the subbasin using a variety of techniques.

Status: Not funded, not implemented.

Objective 6: Identify and assess factors limiting production of Walla Walla River steelhead.

Limiting factor analysis is the process by which impairments to population viability are determined. As conditions are improved through management actions, and population limiting factors and threats are influenced, it is essential to re-assess limiting factors to guide future actions. Section 8 of this plan has a detailed limiting factors assessment. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What environmental factors limit steelhead viability in the Walla Walla population?

Approach: Limiting factors and the capacity of the Walla Walla subbasin will be analyzed every five years as part of regular evaluation activities. A multi-species spatially explicit model of the Walla Walla subbasin, such as the ICTRT matrix model and EDT-AHA, will be used to analyze life stage specific survival in Walla Walla, Columbia, and marine life-history stages.

Analysis: Analyses will be conducted with EDT-AHA and ICTRT matrix models.

Status: Not funded.

Objective 7: Assess the impact of habitat improvement and protection on steelhead viability in the Walla Walla subbasin.

Considerable resources are invested in habitat improvement measures. Most habitat improvement projects conduct some monitoring and evaluation at the project scale to determine successful project implementation. However, typically only the cumulative impacts of watershed restoration can be directly linked to increased steelhead production. The connection between Tier 1 habitat project implementation monitoring and Tier 2 effectiveness monitoring must be addressed across the spatial hierarchy of reaches and watersheds. This is a high priority objective. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring Questions:

- Status & Trend Monitoring—What is the current status and trend of steelhead habitat?

- Implementation and Compliance Monitoring—Has the management action been implemented in the prescribed manner and achieved its objectives?
- Effectiveness Monitoring—Has the management action significantly influenced the viability of the Walla Walla River steelhead population?

Performance metrics: Habitat conditions, egg, fry, juvenile, and smolt production and survival, and smolts-per-spawner or per female. Comparison with information on survivals and smolts-per-spawner with other subbasins.

Approach: Status and trend monitoring at the subbasin and population scales is best conducted by using a spatially explicit sampling approach, such as the EMAP approach. Measured habitat variables will be the same as previously described for the John Day populations. Remote sensing (e.g. TIR; LIDAR; and spatially referenced color imagery) is also appropriate and typically addresses spatial scales at watershed or larger landscapes.

Compliance monitoring of restoration projects incorporates record keeping and reporting of activities. Compliance monitoring will be primarily conducted by the implementing entities and will include any parameters identified in related work statements.

Effectiveness monitoring can be approached at the watershed or project spatial scales, and should preferably be directed at measures of abundance, survival, growth, etc. of steelhead or abiotic or biotic factors limiting their recovery. A BACI design (including spatial replication) is recommended for measuring the effectiveness of active restoration activities (Jones & Tonn 2004). For passive restoration activities, a BACI design that monitors trends through time may be appropriate. If comparisons are made to reference or control sites, they should be under similar environmental conditions experienced by the treatment site but outside the influence of treatment activities. Restoration implementing entities must coordinate with monitoring groups prior to action implementation—preferably several years in advance to allow measurement of pre-manipulation variables. Temporal scales must account for timelags related to life history and life cycle. Derived variables include proportion of population-level parameter (e.g. abundance, production, survival) influenced by restoration activity.

Analysis: If at the appropriate scale, direct comparisons of measured parameters with recovery criteria can be made. Otherwise, measures at smaller scales will need to be combined to determine if they have the desired responses at the population level.

Status: Evaluation is partially funded; habitat monitoring is not funded and not implemented. Some projects currently conduct compliance monitoring; however, there is no ongoing effort to aggregate results at the population scale.

Objective 8: Determine the effect of disease and predation on the abundance, productivity, diversity, and distribution of the natural-origin population.

This objective is moderate priority.

Type of monitoring effort: Uncertainties research.

Monitoring questions:

- What is the prevalence of whirling disease in the Walla Walla subbasin and what is its influence on the natural steelhead populations?
- What is the predation rate and predatory impact of introduced fishes in the Walla Walla subbasin on juvenile steelhead?
- What is the effect of predation from piscine predators in the Columbia River migration corridor on juvenile steelhead originating from the Walla Walla subbasin?
- What is the effect of predation from avian predators in the Columbia River migration corridor on juvenile steelhead originating from the Walla Walla subbasin?

Approach: The current distribution and influence of whirling disease on wild steelhead populations is not fully understood. Representative sentinel stations could be established and monitored through time for each population to measure prevalence and intensity of infection rates of whirling disease. Infection, or the presence of *Myxobolus cerebralis* DNA, is detected by PCR analysis. A small incomplete survey was conducted in the late 1980's and a more complete survey is needed.

Collections of smallmouth bass and other potential predators in the WallaWalla River could be conducted using angling techniques. Collected stomach samples are analyzed for the presence of juvenile salmonids. These data could be incorporated into a bioenergetics model to derive a population-level consumption estimate imposed by introduced fishes. Sampling of predatory fish diets should occur during times and locations when and where their distribution overlaps with juvenile steelhead. Interpretation of the predatory impact in the migration corridor should be conducted from methods established in published literature (Ward et al. 1995; Fritts and Pearsons 2006).

To evaluate avian predation, colonies are monitored for presence of PIT tags originating from specific populations (Collis et al. 2001). Bioenergetics models are then used to expand tag recoveries at colonies to population-level impacts (Antolos et al. 2005).

Analysis: The proportion of total mortality attributable to predatory mortality could be estimated from bioenergetics modeling results.

Status: The whirling disease foundation, whirling disease initiative, and Oregon Sea Grant are potential funding sources for whirling disease investigations. Investigations of predation in the migration corridor have been conducted by many agencies with various funding sources including BPA and USACE. This work should continue to effectively evaluate the benefits of the proposed actions.

Objective 9: Determine the effect of mainstem hydropower operations and operational improvements on viability of the Walla Walla River steelhead population.

See John Day MPG for *Timeline, Monitoring questions, and Approach*.

Status: Specific estimates for Walla Walla population are unfunded.

Objective 10: Monitor straying of adult steelhead from the Walla Walla subbasin hatchery programs.

Adult trapping provides substantial data annually on stray fish entering the upper Walla Walla River. Currently, natural spawners in the Walla Walla River include returns originating from naturally spawning adults and from out-of-DPS strays which originate from Lyons Ferry Hatchery releases in the lower Walla Walla River. Hatchery strays were removed at Nursery Bridge Dam by trapping until 1999. Trapping was discontinued after 1999 and replaced with video monitoring. Hatchery fish currently pass above Nursery Bridge Dam to spawn naturally. Continuation of monitoring is needed to assess the annual hatchery fraction and to determine if management changes result in increases or decreases in the hatchery fraction. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring question:

- What is the number and proportion of hatchery fish in the Walla Walla population?

Performance metrics: Number of hatchery fish and proportion of hatchery fish that spawn naturally in the Walla Walla population; percent of Lyons Ferry Hatchery releases that stray

Approach: WDFW monitors the return of summer steelhead throughout southeast Washington through adult trapping (Tucannon River, Lyons Ferry Hatchery, Lower Granite Reservoir, Touchet River, Cottonwood Creek), and spawning ground and creel surveys (sport harvest and CWT expansions can be used to estimate the number that would have returned to the project area)—all of which provide CWT recoveries of marked fish for evaluation purposes. Trapped and/or spawned broodstock fish and carcasses provide data concerning origin, stray rates, sex ratios, age composition, and mean fecundity of each year's run. Spawning ground surveys in Mill Creek provide numbers of redds, spawn timing, and distribution of fish. These surveys provide some measure of the presence of hatchery strays on spawning grounds by noting the presence of fin clips on spawners. This technique has shown some success on the surveys conducted on the John Day River subbasin. A more complete census of natural- and hatchery-origin spawners could be conducted using a weir and trap similar to that previously conducted at Nursery Bridge Dam.

Analysis: Estimating the proportion of out-of-basin strays is a simple comparison of the number of marked and unmarked spawners and carcasses observed within and outside of targeted areas for hatchery returns.

Status: Partially funded, modify and enhance existing monitoring.

Objective 11: Monitor and assess the effect of flow on the availability of spawning and rearing habitat in the mainstem Walla Walla.

Considerable effort and resources are directed at flow restoration in the Walla Walla. However, some of the direct benefits to fish have not been quantified. The relationship between flow restoration and trap-and-haul work is comparatively straightforward: proper flow through

structures and reaches allows for easy passage and a reduction in the need to trap and haul fish. However, the relationship between increased flow and increased spawning and rearing habitat has rarely been directly studied. The IFIM was used to study optimal flow conditions for a number of reaches in the Walla Walla subbasin, and these results are currently being used to guide flow restoration programs. Baseline effectiveness monitoring is needed to understand the added benefits to fish that these future flow programs would bring to the subbasin, and to determine the accuracy of IFIM in predicting habitat use under various flow conditions for priority reaches. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring, uncertainties research.

Monitoring questions:
- What is the effect of flow on the availability of spawning and rearing habitat in the mainstem Walla Walla?
- Are flows suitable for spawning and rearing of steelhead for each reach?

Performance metrics: Spawning and rearing habitat utilization, effectiveness of flow restoration programs.

Approach: Juvenile habitat utilization will be monitored in the Walla Walla mainstem during annual juvenile fish surveys by the CTUIR. Flow will be monitored in these mainstem reaches during fish surveys using a handheld flow meter. Habitat potential will be modeled using a spatially explicit model of habitat quality and quantity such as IFIM or life-cycle analysis, facilitating the evaluation of the relative impacts of various flow management regimes, including the implementation of flow exchange programs and climatological variability.

Analysis: The results of IFIM studies will be compared with results obtained in the field to evaluate the accuracy of the modeled flow recommendations and suggest changes when necessary.

Status: Partially funded, partially implemented.

Objectives 12: Develop models for pre-season estimation of Walla Walla River returns to facilitate management of subbasin fisheries.

Accurate run size predictions allow managers and program staff to plan appropriate broodstock collection, harvest, spawning escapement, and CWT recovery strategies in advance. In addition, models describing return timing can be used in the evaluation of flow management regimes in-season. These models are relatively simple to develop, but require datasets that cover several years or even many decades to be relatively accurate. In general the results of much of the long-term monitoring work will be used to produce these models. This is a low priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What is the annual estimated run size of summer steelhead to the Walla Walla River mouth?
- Can the run size of steelhead be estimated accurately prior to adult returns, and how can the predictor be improved?

Performance metrics: Run size forecast.

Approach: Correlation models have been developed for preseason prediction of steelhead run size to the Columbia River. Local models must be constructed to predict the timing and size of anadromous runs to the Walla Walla. A variety of metrics (including marine conditions, flow conditions, outmigrant abundance, etc.) are collected as part of regular status and trend monitoring or out-of-basin monitoring. These variables can be used to develop run predictors for all steelhead. Detailed methods for this exercise are under development, and are not discussed below.

Analysis: We use multivariate regression analyses to develop predictive models.

Status: Funded, ongoing.

Objective 13: Quantify fishing effort, catch, and harvest for tribal and non-tribal fisheries in the Walla Walla River.

Much of the impetus for the Walla Walla supplementation and reintroduction programs and the WDFW sponsored steelhead hatchery programs is tribal and non-tribal harvest mitigation. Creel or catch-card data are needed to provide information to determine whether steelhead harvest goals are achieved or exceeded, to enumerate fish removed from the run, and to assess how to optimize fishing opportunities through adaptive management. A properly designed creel survey can also provide data for determining the impact of fisheries on the natural-origin fish. This is a moderate priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What are the fishing effort, catch, and harvest by gear type, and location for tribal and non-tribal fisheries in the Walla Walla River?
- What is the annual fishing mortality rate that occurs within the Walla Walla River subbasin?

Performance metrics: Fisher hours, catch, and harvest.

Approach: WDFW utilizes catch cards and a limited creel to monitor harvest. The need to expand these efforts is currently being investigated. Tribal harvest appears minimal and is currently not being monitored.

Analysis: Statistical analyses of creel survey information.

Status: Partly funded; modify and enhance existing monitoring.

13.4 Cascades Eastern Slope Tributaries MPG

The Cascades Eastern Slope Tributaries MPG includes seven steelhead populations in both Oregon and Washington. In Oregon, the populations are the Fifteenmile Creek, Deschutes West, Deschutes East, and the extirpated Crooked River (Deschutes River subbasin) populations. The MPG is unique in a number of ways compared to the others of the Mid-C steelhead DPS. It includes the uppermost expression of an adult winter-run life history (Fifteenmile Creek) in the Columbia River Basin. Impacts to survival of adult winter run steelhead can be expected to differ from the summer run fish during upstream migration through different hydro conditions and fisheries. Smolts from all populations in this MPG migrate through shorter reaches of the Columbia hydrosystem and pass fewer dams. Portions, or all, of the spawning habitat of the three populations in the Deschutes River subbasin have been blocked by hydroelectric development in the subbasin. The sampling methods used to obtain some of the VSP information for this MPG that was used in the recovery plan's viability analyses (see Section 6) are more varied and the management entities that conduct monitoring are diverse.

The most systematic population-level monitoring in the Oregon portion of the Cascades Eastern Slope Tributaries MPG has been through spawning ground surveys conducted by CTWSRO, ODFW, and USFS. This information was used to develop spawner abundance estimates for each population. These surveys had neither been conducted explicitly to represent the spatial distribution of the populations as defined by the ICTRT nor to collect the types of information ideally used to assess each population's viability and to compare current status to the desired population recovery criteria. Nonetheless, the current monitoring routines represent the foundation on which to build future status and trends monitoring that will fill information gaps identified in the viability analyses, allow future changes in VSP criteria to be tracked, and in some cases, function in part as action effectiveness monitoring. Monitoring infrastructure currently exists or has been deployed in the past in the MPG that could inform future VSP status and trend assessments including the following:

- Abundance of adult progeny on the spawning grounds (for productivity expressed as recruits-per-spawner ratios)
- Trends in abundance of juveniles and SARs
- Spatial distribution of spawners
- Diversity of life history characteristics of both adults and juveniles including differences, similarities, or changes in genetic traits

This plan describes and supplements the existing monitoring activities so that the status and trend of the steelhead populations can be compared with recovery criteria. It is not exhaustive, but generally builds on the strengths of existing monitoring efforts that could be used to update the viability assessments that were conducted and adapt existing efforts to fill missing information. A balance between an ideal monitoring effort and what is sufficient relative to costs and resources is considered. Wherever possible, attempts to integrate status and trends monitoring with action effectiveness monitoring are made.

Critical Uncertainties

Critical uncertainties for the population group that currently limit the ability to make informed management decisions have been identified by local area managers. We combined these uncertainties with those identified during the recovery planning process to produce the RM&E objectives that are addressed herein by our recommended M&E efforts. Not all objectives are associated with each population segment. For example, there is no within-basin harvest for the Fifteenmile Creek population. The objectives include:

1. Determine the current status and trend in the abundance and productivity of natural-origin spawners and compare to viability abundance criteria for each population.
2. Determine the status of the spatial structure of each population based on current and historically utilized habitat.
3. Determine the effects of out-of-basin strays on the productivity of each population relative to viability criteria.
4. Determine the status and trend in conditions of current and historically utilized habitat within each population.
5. Determine the freshwater productivity of each population relative to viability criteria and identify primary habitat factors limiting freshwater production.
6. Determine the effects of disease and predation on the abundance, productivity, diversity and spatial structure of the natural populations.
7. Determine the effect of hydropower on the abundance, productivity, diversity and distribution of the natural populations.
8. Determine what effects habitat degradation and habitat restoration actions have on the abundance, productivity, and spatial structure of the natural populations.
9. Determine the influence of in-basin harvest on the abundance and productivity of natural-origin spawners.

13.4.1 Fifteenmile Creek Population

Objective 1: Determine the status and trend in the abundance of natural-origin spawners relative to viability abundance levels.

The status of a population is determined by estimating the VSP parameters described in the recovery plan. The VSP parameters include adult abundance, population productivity or growth rate, population spatial structure, and diversity. This is a highest priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- Is the 10-year GM of natural-origin steelhead spawners in the Fifteenmile Creek subbasin greater than or equal to the recovery criterion for natural spawners?
- What are the current spawner abundance and five-year trend in abundance?
- What are the current and trend in the 20-year population growth rate?
- What are the current and trend in recruits/spawner compared to the recovery goal?

Performance Metrics: Spawner abundance, recruits/spawner.

Approach: Currently, abundance of adult spawners in the Fifteenmile Creek system is estimated based on observations of redds from three-pass spawning ground surveys conducted annually within each MaSA. The present sampling is statistically representative of spawning activity allowing inference to the total Fifteenmile Creek spawning population and allows annual monitoring of the distribution of spawners in each of the population's MaSAs. The sample design is a stratified random survey where each MaSA is divided into five-mile sections that cover the currently known spawning habitat. A one-mile reach is randomly selected each year from the five one-mile sections in each five-mile stratum and surveyed by foot once per week three times during spring.

Analysis: The total season's abundance of redds is estimated by summing individual redds observed in each five-mile section and expanding by the surveyed/unsurveyed proportion (approximately five-fold). A fish/redd ratio is presently estimated by counting spawners passed above a weir (outside of the DPS) and results of subsequent multiple complete area census spawning ground redd surveys.

To estimate abundance of progeny (spawning recruits), age structure is assumed to be similar to wild winter steelhead in the downstream Hood River.

Status: Currently implemented.

Objective 2: Determine the status of the spatial structure of the population based on current and historically utilized habitat.

Spatial and seasonal distribution of juveniles, their habitat use, and density within the MaSAs and MiSAs, particularly in Mill and Chenoweth creeks, are not presently well known. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What is the spatial distribution of the occupied spawning areas within the population boundaries?
- What is the current spatial extent and distribution of rearing habitat used by juvenile steelhead?

Approach: An EMAP sampling approach of all known spawning and rearing areas could be used to refine the known spatial distribution of both adult and juvenile steelhead for the Fifteenmile Creek population. Representative sites within the watershed would be sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. All observed adult spawners and redds would be geographically referenced using handheld GPS units for inclusion in a GIS. Juvenile steelhead would be sampled using snorkeling or electrofishing techniques. This approach would refine current knowledge of steelhead spatial distribution for this population segment.

Analysis: Data would be analyzed as distribution data in a GIS format. The known distribution of steelhead will be modified when previously unknown blockages to migration or newly inhabited reaches are observed. Juvenile steelhead densities are determined in each study reach.

Status: Not currently implemented.

Objective 3: Determine the abundance of out-of-basin strays in the Fifteenmile Creek population relative to viability criteria.

The proportion of spawning steelhead in Fifteenmile Creek that are hatchery-origin fish is assumed to be very low, but is not known. To monitor the presence of hatchery-origin fish, additional effort during spawning ground surveys will be necessary to observe sufficient numbers of fish to develop annual estimates of hatchery fraction and hatchery fish abundance. This is a high level priority.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What proportion of steelhead spawners in the Fifteenmile Creek population is derived from out-of-basin hatchery stocks?
- What is the origin of out-of-basin strays?
- What is the population-level genetic composition of the Fifteenmile Creek population?

Approach: The Fifteenmile Creek basin lacks facilities to capture adult steelhead. Determination of out-of-basin strays will therefore rely on identification of hatchery-marked adults observed on spawning ground surveys, and from incidental catches. To determine population-level genetic composition, genetic data that allow an objective determination of the population(s) structure are required. Age-0 *O. mykiss* from several representative streams in the population segment are currently sampled annually. Collection of juveniles from a minimum of four cohorts will be sampled. The population will be characterized using a suite of nuclear DNA markers, including both microsatellite loci (variable-number simple-sequence repeats) and non-coding SNPs, or base substitutions assayed via restriction enzyme analysis (Moran et al. 1997). The current monitoring program is conducted as part of the Columbia Basin-wide steelhead genetics monitoring.

Analysis: Estimating the proportion of out-of-basin strays is a simple comparison of the number of marked and unmarked spawners and carcasses observed. Direct comparisons can then be made with recovery criteria. DNA tissue samples are analyzed by NMFS using known microsatellite markers. Microsatellite loci are analyzed using pairwise FST comparisons to estimate levels of gene flow and to identify geographic areas that contain genetically differentiated populations.

Status: Spawning ground surveys are implemented and coordinated. Genetics analysis is implemented and coordinated collaboratively between ODFW and NMFS Northwest Science Center. Federal funds (NMFS) are used for genetics stock analysis.

Objective 4: Determine the status and trend of current and historically utilized habitat.

This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What are the status and trend in habitat quantity and quality throughout the population area?

Approach: The same EMAP sampling approach of all known spawning and rearing areas, as described above is recommended for sampling the known spatial extent and status and trend of steelhead habitat. Habitat variables would be monitored as defined by ODFW Aquatic Inventories design (Moore et al. 2002) and are measured at the unit and reach scale.

Analysis: This type of data are analyzed as distribution data in a GIS format. Database and GIS formatting of data allow associations with land use, land vegetation coverage, and many other attributes at the population and smaller scales.

Status: Not implemented.

Objective 5: Determine the freshwater productivity of the population relative to viability abundance levels and identify primary factors limiting freshwater production.

Trapping juvenile outmigrants will help provide estimates of smolt production for the watershed, allow estimation of smolt-to-adult survival rates, and provide life history diversity information including timing, age, size, and genetic variation. This expanded monitoring effort will allow for assessment of the cumulative benefits of the habitat protection, enhancement, and restoration actions on juvenile survival and abundance in the Fifteenmile Creek population.

The Fifteenmile Creek subbasin plan identifies an "ideal" monitoring scenario where returning adults would be trapped and enumerated and a juvenile outmigrant trap would be operated near the mouth of Fifteenmile Creek. This scenario could represent a second tier to more comprehensively monitor the population. Its benefits would need to be weighed against the implementation costs. This is a highest level priority.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What are the current and trend in freshwater productivity measured as smolts/redd?
- What is/are the primary factor(s) limiting freshwater production of steelhead?

Approach: The ratio of smolts/adult is the principle measure of freshwater productivity. Smolt abundance will be determined using traps. If we do not obtain adequate funding for a weir to count adults, then redd counts will be used. Freshwater productivity will be assessed as smolts/redd or smolts/adult. Trapping with RSTs and mark-recapture will be used to

estimate smolt abundance. Egg-to-smolt survival requires an estimate of the number of eggs deposited by individual females or deposited in each redd. Parr-to-smolt survival will be estimated by capturing a representative number of parr in their rearing habitat, PIT tagging them, and then monitoring their recapture at the downstream smolt traps. Migration survival can similarly be estimated by monitoring detections of PIT-tagged individuals as they pass through PIT tag detection facilities.

Analysis: Smolt abundance will be estimated using mark/recapture techniques (Thedinga 1994; Steinhorst 2004). Survival and productivity measures are simple proportions and ratios from one life stage to another.

Status: Operation of smolt and adult traps are not currently implemented.

Objective 6: Determine the effect of disease and predation on the abundance, productivity, diversity, and distribution of the natural-origin population.

This is a moderate priority objective.

Type of monitoring effort: Long-term status and trend monitoring and short-term research.

Monitoring questions:

- What is the prevalence of disease in the basin and what is its influence on the natural steelhead populations?
- What is the effect of predation from piscine predators in the Columbia River migration corridor on juvenile steelhead originating from Fifteenmile Creek?
- What is the effect of predation from avian predators in the Columbia River migration corridor on juvenile steelhead originating from Fifteenmile Creek?

Approach: The current distribution and influence of whirling disease on natural steelhead populations is not fully understood. Representative sentinel stations would be established and monitored through time for this population to measure prevalence and intensity of infection rates of whirling disease. Infection, or the presence of *Myxobolus cerebralis* DNA, is detected by PCR analysis.

To evaluate avian predation, colonies are monitored for presence of PIT tags originating from specific populations (Collis et al. 2001). Bioenergetics models are used to expand tag recoveries at colonies to population-level impacts (Antolos et al. 2005). This method requires the collection and PIT tagging of smolts originating from the Fifteenmile Creek population. The piscine and avian predation monitoring is outside the scope of this RM&E plan. However, we encourage the ongoing monitoring programs to continue their efforts to address these limiting factors and threats.

Analysis: The proportion of total mortality (e.g., SAR) attributable to predatory mortality could be estimated from bioenergetics modeling results. Infection rates of sentinel fish from disease would need to be related to actual mortality rates experienced in the natural population. If this were determined then mortality rates resulting from disease could be

estimated as a proportion of freshwater mortality (i.e., egg to smolt mortality) although some delayed mortality may also occur (Sollid et al. 2004).

Status: Not implemented at the population level.

Objective 7: Determine the effect of hydropower on the abundance, productivity, diversity, and distribution of the Fifteenmile Creek population.

This is a moderate priority objective because the population resides above only one dam.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What is the effect of Columbia River hydropower operations on Fifteenmile Creek steelhead smolts?
- What is the effect of Columbia River hydropower operation on returning Fifteenmile Creek adult steelhead originating from Fifteenmile Creek?

Approach: PIT tags have been used successfully to measure the influence of hydropower operations on migrating salmonids (Berggren et al. 2006; Schaller et al. 2007). PIT-tagged fish are monitored for detections at FCRPS facilities along the migration corridor at both juvenile and adult life stages using DART and PTAGIS databases. Detection probabilities of juvenile salmonids migrating downstream at FCRPS facilities are modeled using the SURPH analytical tool (Lady et al. 2003). Adult detection (purportedly 100%) is currently available at ladders on several dams including Bonneville, and is expected in the near future at The Dalles.

Analysis: Juvenile survivals at each FCRPS facility can be estimated using the SURPH model. Adult survival between facilities will soon be possible by comparing detections at adult ladder facilities along the migration corridor. Rates can be expanded to population-level impacts using the relative number of fish PIT tagged and abundance estimates generated from mark-recapture at RSTs.

Status: This method would require the collection and PIT tagging of smolts originating from the Fifteenmile Creek population. Systematic PIT tagging of juveniles in Fifteenmile Creek is not implemented.

Objective 8: Determine the effect of habitat degradation and habitat restoration activities on the abundance, productivity, and distribution of the Fifteenmile Creek population.

This is a highest priority objective.

Type of monitoring effort: Long-term status & trend monitoring, implementation and compliance monitoring, and effectiveness monitoring.

Monitoring questions:

- Status & Trend Monitoring—What are the current status and trend of steelhead habitat?
- Implementation and Compliance Monitoring—Has the management action been implemented in the prescribed manner and achieved its objectives?
- Effectiveness Monitoring—Have the management actions significantly influenced the viability of the Fifteenmile Creek steelhead population?

Approach: Status and trend monitoring at the subbasin and population scale are best conducted by using a spatially explicit sampling approach, such as the EMAP approach developed by the EPA. Measured habitat variables will be the same as previously described for the John Day populations. Remote sensing (e.g., TIR imagery, LIDAR, and spatially referenced color imagery) is also appropriate and typically addresses spatial scales at watershed or larger landscapes.

Compliance monitoring of restoration projects incorporates record keeping and reporting of activities. Compliance monitoring will be primarily conducted by the implementing entity and will include parameters identified in related work statements. Effectiveness monitoring can be approached at the watershed or project spatial scales. IMWs are one example of the watershed approach. Effectiveness monitoring should preferably be directed at measures of abundance, survival, growth, etc. of steelhead or abiotic or biotic factors limiting their recovery. A modified BACI (Smith 2002) design (including spatial replication) is recommended for measuring the effectiveness of active restoration activities (Jones & Tonn 2004). For passive restoration activities, a BACI design that monitors trends through time may be appropriate. If comparisons are made to reference or control sites, they should be under similar environmental conditions experienced by the treatment site but outside the influence of treatment activities. Restoration implementing entities must coordinate with monitoring groups prior to action implementation—preferably several years in advance to allow measurement of pre-manipulation variables. Temporal scales must account for timelags related to life history and life cycle.

Analysis: If collected at the appropriate scale, direct comparisons of measured parameters with recovery criteria can be made. Otherwise, measures at smaller scales would need to be scaled up to determine if they would have desired responses at the population level.

Status: Implementation monitoring is currently conducted by the groups that implement restoration activities.

Objective 9: Determine the effect of in-basin harvest on the abundance, productivity, and diversity of the Fifteenmile Creek population.

Under current fisheries regulations, adult steelhead cannot be legally retained in any of the minor Columbia River tributaries (Fifteenmile, Mill or Chenoweth creeks). Further, Fifteenmile Creek is closed to all recreational winter steelhead fishing, including catch and release. The Fifteenmile Creek population is subject to target and incidental fishery impacts in sport, commercial, and tribal fisheries occurring in the mainstem of the lower Columbia River and in Bonneville Reservoir. Passage rates of winter steelhead through mainstem fisheries, past the dams, and through the reservoirs are not known with any certainty at a population level. Run

timing of Bonneville Reservoir and upstream summer steelhead populations can overlap with winter run populations. This is a moderate priority objective.

Type of monitoring effort: Long term status and trends

Monitoring questions:

- What is the stock composition of adult steelhead populations in the mainstem Columbia River during winter and early spring?
- What is the annual fishing mortality rate that occurs outside of the Fifteenmile Creek subbasin?

Approach: Passive monitoring of representatively PIT-tagged steelhead ascending Bonneville Dam and The Dalles Dam will help monitor run timing and stock composition. Enhanced stock composition monitoring using GSI methods will also add valuable information. Enhancing catch sampling in the fisheries will aid in partitioning harvest rates among mixed-DPS and MPG populations across the winter and early spring seasons.

Analysis: See Objective 8.

Status: Not implemented at the population level.

13.4.2 Eastside and Westside Deschutes River Populations

Major spawning areas of two populations, Deschutes River Eastside and Deschutes River Westside, are routinely monitored for abundance and spatial distribution of spawning adults (redd counts from spawning ground surveys). Abundance of steelhead in the Westside MaSAs in the Warm Springs River is determined based on a count at the Warm Springs NFH barrier. The extirpated Crooked River population is not addressed in this RM&E plan; however, monitoring was previously discussed in Section 9. Both extant populations use the mainstem of the Deschutes River for spawning and rearing, and the area delineation separating the two is the mainstem Deschutes River near the mouth of Trout Creek. Portions of both populations' historical range are blocked by the Pelton-Round Butte Complex. Round Butte Hatchery produces a Deschutes-origin hatchery stock of steelhead to mitigate for the blocked habitat. Recent FERC hydropower re-licensing negotiations have resulted in the beginning of an effort to restore steelhead upstream of Round Butte Dam focusing particularly on Whychus Creek. Significant numbers of hatchery steelhead from outside the subbasin enter the Deschutes River annually and some are known to remain within the Deschutes and its tributaries to spawn, but the actual rate or numbers are not known with certainty. The Deschutes River and its tributaries (particularly those of the Deschutes Westside steelhead population) support large numbers of resident redband trout (*O. mykiss*), and a blue ribbon trout fishery is a major attraction to the Deschutes River.

These subbasin characteristics present unique challenges to monitoring the VSP parameters for each of the two steelhead populations. The monitoring activities which provided the data used to assess the viability of each population (see Appendix B) are described briefly below, including recommended improvements needed for better status and trends monitoring of viability

parameters specific to each population. Because steelhead status and trend monitoring in the subbasin is so interrelated with gaining insight to critical uncertainties and tracking the effectiveness of major recovery actions, this monitoring overview addresses population status and trend monitoring, action effectiveness monitoring, and critical uncertainties research in combination. The main monitoring issues identified in order of priority by local fisheries managers include:

1. Straying: What is the cause and origin of strays in the Deschutes? Has introgression with strays impacted the genetic characteristics of natural-origin steelhead in the Deschutes? How many strays are overwintering in the Deschutes, entering spawning tributaries, spawning in the main stem Deschutes, and what are the effects on fitness? What is the fall back rate for non-Deschutes hatchery and natural fish that pass above Sherars Falls?
2. Population structure of Eastside vs. Westside: Is their a difference in the two populations and the stock-recruit function?
3. Reintroduction: Which stocks should be used as broodstock (Eastside vs. Westside)? What would be the effects on the founding population? What will the effect of competition of juvenile *O. nerka* and *O. mykiss* be? If sockeye are successful in the reintroduction, what will be the effect of large numbers of juvenile sockeye in the lower Deschutes? How successful will the steelhead reintroduction be?
4. Resident *vs.* anadromous: What is the relationship between the two, causative mechanism for either life history, and is competition an issue? What influence does the abundant resident population have on the steelhead populations?

Objective 1: Determine the status and trend in the abundance of natural-origin spawners and compare to viability abundance criteria for the Deschutes River populations.

The critical uncertainties in characterizing the abundance of each spawning population and abundance of adult progeny (recruits) returning to spawn to estimate abundance and productivity (spawner to spawner ratio) are threefold:

1. The unknown abundance of fish that spawn in the mainstem Deschutes River and their relative contribution to the Westside and Eastside populations.
2. The abundance and origin of hatchery steelhead that spawn naturally and the inability to enumerate adult progeny and assess the degree of risk from out-of-MPG hatchery spawners.
3. Annual population-specific information on freshwater and saltwater adult age at return is unavailable to partition natural-origin spawners into broodyear of origin.

Presently, all of the major spawning areas of the two populations in the Deschutes River are surveyed annually for presence of steelhead adults and redds with varying degrees of spatial coverage. In addition, adult weirs are fished on most major spawning tributaries. Observations from these surveys and weir counts are used to estimate the abundance of redds in each major spawning area and to characterize the degree of occupancy (spatial distribution). These surveys are neither statistically designed nor conducted systematically and inferences are made to unsurveyed areas. This approach has weaknesses because there is no validation of the

relationship of spawner density in surveyed and unsurveyed areas. Modifying the present spawning ground surveys is needed to assure observations of redds are statistically based.

Alternatively, a stratified random spawning ground survey similar to that used in the Fifteenmile Creek subbasin could be conducted in the MaSAs of Buckhollow, Bakeoven, Trout, and Shitike creeks. If the present surveys are changed, appropriate fixed sites could be maintained to allow for calibrating historical data, and allow flexibility for local project-level action effectiveness monitoring such as for habitat improvement actions. Intensity of present single pass spawning ground survey effort could possibly be redistributed to multiple passes over a smaller proportion of the spawning area than is presently surveyed. To monitor spawning activity in the mainstem of the Deschutes River, spawning ground surveys would need to be conducted either by air or boat. To date, only two single pass aerial surveys of spawning steelhead have been conducted. This is a highest level priority.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- Is the 10-year GM of natural-origin steelhead spawners in the Westside and Eastside populations greater than or equal to the recovery criterion for natural spawners?
- What are the current spawner abundance and five-year trend in abundance?
- What are the current and trend in the 20-year population growth rate?
- What are the current and trend in recruits/spawner compared to the recovery goal?

Performance metrics: Spawner abundance, recruits/spawner.

Approach: Where weirs are absent, redd surveys are the only alternative to estimate annual adult abundance for recruit/spawner and trend analyses. The recommended survey design is a spatially balanced site selection and a rotating panel design for temporal selection (EMAP approach; Stevens and Olsen 2004). Ideally, sampling using this design would also be conducted at the population scale which would require a separate sample draw and additional samples. Redd count surveys would be conducted by walking and/or floating all streams within the index (one-time annual counts) and randomly selected reaches (bi-weekly counts, $\geq$ 3 counts/year).
Analysis: Estimate the number of naturally produced spawners using proportions of observed naturally produced fish (unmarked) and hatchery (fin clipped) fish, total number of redds, expansion factor of surveyed stream length/available stream length, and fish/redd ratio. Calculate 10-yr GM for abundance of naturally produced fish. Calculate recruits/spawner based on redd counts and estimated spawner age structure. Analyze as a time series (trend analysis).

Status: State of Oregon funds index spawning ground surveys. An EMAP approach for spawning ground surveys has been previously proposed by ODFW and approved by the ISRP and NPCC, but BPA failed to fund the proposed monitoring.

Objective 2: Determine the status of the spatial structure of each population based on current and historically utilized habitat.

This is a highest level priority.

Type of monitoring effort: Long term status and trend monitoring

Monitoring questions:

- What is the spatial distribution of the occupied spawning areas within the population boundaries?
- What is the current spatial extent and distribution of rearing habitat used by juvenile steelhead?

Approach: The same EMAP sampling protocol of all known spawning and rearing areas as used for determining abundance of spawners is recommended for refining the known spatial extent of both adult and juvenile steelhead. Representative sites within the subbasin will be sampled annually using a three-panel rotating panel design. Panels include annual, every four years, and one-time visit selections. All observed adult spawners and redds are geographically referenced using handheld GPS units for inclusion in a GIS. Juvenile steelhead are sampled using snorkeling or electrofishing techniques.

Analysis: Data would be analyzed as distribution data in a GIS format. The known distribution of steelhead is modified when previously unknown blockages to migration are discovered. Juvenile steelhead are evaluated as fish/pool in each study reach.

Status: Not implemented nor funded. The same limitations indicated above in Objective 1 are relevant here.

Objective 3: Determine the effects of out-of-basin strays on the productivity of each population.

Hatchery strays, especially from out-of-subbasin hatcheries, pose a significant threat to wild summer steelhead populations in the Deschutes subbasin. The large influx of out-of-subbasin stray summer steelhead may contribute maladapted genetic characteristics to the wild summer steelhead populations in the Deschutes River subbasin. While Round Butte Hatchery origin summer steelhead contribute to this problem, their abundance is much less and they are genetically more similar than the large number of out-of-subbasin strays. The cumulative effect of this genetic introgression may contribute to reduced productivity of the wild populations.

ODFW completed and submitted a comprehensive study plan to investigate the impact of strays. Implementing ODFW's study plan to investigate the reproductive success of stray hatchery and wild steelhead in the lower Deschutes River would address uncertainties of the magnitude of straying, its actual effect on wild populations in the Deschutes River, as well as provide a tool to exclude hatchery steelhead from either Buckhollow or Bakeoven creeks in the future. Completion of ODFW's study objectives would determine the number of stray hatchery steelhead entering Bakeoven and Buckhollow creeks, degree of introgression between hatchery and natural fish, relative reproductive success, and the influence of hatchery fish on natural productivity.

Improved monitoring of stray hatchery fish in the Deschutes River has regional significance in the Columbia Basin. For example, efforts underway in the Snake River Basin through the Lower Snake River Compensation Plan to decrease and monitor stray rates of Snake River hatchery steelhead will require both knowledge of which fish stray, at what rates, and whether efforts taken to modify stray rates are effective. The management and operation of the FCRPS, specifically barging, may be increasing the rate of straying of salmon and steelhead originating upstream of the Mid-C steelhead DPS. Quantifying this potential effect and monitoring effectiveness of efforts to reduce straying will require continued monitoring of straying into the Deschutes, as well as the ability to identify outmigrating juveniles in the mainstem Columbia and their migration experience (in river or barged). Implementing the Columbia Basin Fish and Wildlife Program's Comparative Survival Study plan for steelhead tagging would contribute significantly to improving information related to straying.

A coalition of Deschutes River fisheries managers has been working together to address a number of population identification issues using genetics techniques. Continuing this effort will greatly help to inform population structure and genetic characteristics of summer steelhead in the Deschutes River subbasin. A recent draft of a project plan outlines the scope of future work (personal communication, D. Hand, USFWS, CRFPO). In FY2002, the U.S. Fish & Wildlife Service obtained funding for part of the Federal Columbia River Power System biological assessments, opinion and hatchery operations. In FY 2004, the Columbia River Fisheries Program Office (CRFPO) secured additional funding for population monitoring. This "add-on" was to lend additional support to on-going monitoring & evaluation projects as well as help answer additional questions associated with hatchery operations and impacts to the Deschutes basin native fish community. On-going evaluations include: 1) population dynamics and genetics of hatchery- and natural-origin spring Chinook salmon in the Warm Springs River and Shitike Creek; 2) evaluating the reproductive success of hatchery spring Chinook salmon outplanted into Shitike Creek; 3) evaluating the ecological interactions between hatchery- and natural-origin fish; and, 4) assessing the population structure of summer steelhead trout in the Deschutes River and potential impact from out-of basin hatchery strays.

Additional unanswered questions were developed by the ICTRT (2003). In identifying independent populations of listed steelhead in the Interior Columbia River Basin, they noted that limited information existed to evaluate genetic differences between steelhead occupying the tributaries on the east and west sides of the lower Deschutes River below the Pelton-Round Butte Dam complex. Concurrently, the Pelton-Round Butte Fish Reintroduction Committee expressed interest in developing a better understanding of steelhead population structure in the lower Deschutes in order to determine the best donor stock for reintroduction above the dam complex. A series of meetings among ODFW, CTWSRO, CRFPO, and the Abernathy Fish Technology Center identified a variety of issues and information needs regarding steelhead in the Deschutes. In response to the various discussions, the CRFPO and the Pelton-Round Butte Fish Reintroduction Committee organized a meeting to bring together all interested parties and identify issues of concern. This group agreed on a set of overall study objectives and drafted a phased implementation approach:

1. Augment existing information to develop an understanding of the population structure and genetic variability among steelhead occupying tributaries and the mainstem Deschutes River downstream of the Pelton-Round Butte Complex;
2. Evaluate the effect of out-of-basin strays on the Deschutes River populations (rate of strays and reproductive contribution of strays); and,
3. Provide information pertinent to brood stock selection that would assist with efforts to reintroduce steelhead to currently inaccessible portions of the middle and upper basin.

As adult fish begin returning from reintroduction efforts upstream of Round Butte Dam, they too will need to be distinguished from the Deschutes RBH stock and the Westside and Eastside wild populations. Studies may need to be implemented to assure the fidelity of these reintroduced fish to their parent stream. A draft reintroduction plan (personal communication, M. Gauvin, CTWSRO) includes key metrics to monitor fish passage above Round Butte Dam and the reintroduction effort. This monitoring should be integrated with monitoring of the other populations including Round Butte Hatchery steelhead, with emphasis on smolt-to-adult return rates, harvest rates (or impacts) in the Deschutes River, counts of returning adults by species and sex at Round Butte Dam, spawn timing and success (redd counts) by species and subbasin; and adult recruits per spawner. This is a highest level priority.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What proportion of steelhead spawners in the Deschutes subbasin are out-of-basin hatchery strays?
- What is the origin of out-of-basin strays?
- What is the population-level genetic composition of the Deschutes populations?

Approach: Presence of hatchery fish by origin is monitored at trapping facilities in the Deschutes subbasin. Steelhead ascending Sherars Falls are sampled routinely and tagged for run-to-the river population abundance estimates. Hatchery-origin fish are captured, removed, and examined for hatchery of origin at Bakeoven, Buckhollow, Trout and Shitike creeks, and at Pelton trap and Warm Springs NFH. Fish can also be examined in creel surveys. All observed fish marked with a fin clip can be sampled for the presence of a coded-wire or PIT tag to determine hatchery origin. Where spawning ground surveys are conducted, the number of marked (adipose fin clip) and unmarked (presumably natural-origin) fish will be visually identified and enumerated. This information is important to monitor the potential magnitude and origin of hatchery straying. The rate at which fish observed at Sherars Fall eventually fall back and leave the Deschutes River system and continue migrating to their parent stream remains unknown. Although funding is not available, there is a need to conduct a radio telemetry project to assess fall back rates.

A number of recent and future actions will allow better monitoring of the magnitude of straying into the Deschutes River and the effectiveness of actions to control stray rates. The Sherars Falls trap is now equipped with PIT tag detection capability and will allow adult detection of both fish PIT-tagged as juveniles and released in the Deschutes River subbasin and those tagged and released outside of the Deschutes. If sufficient numbers of hatchery

summer steelhead were representatively tagged throughout the Columbia Basin, a better understanding of the rate at which out-of-population hatchery fish descend Sherars Falls could be developed. Implementing the Columbia Basin Fish and Wildlife Program's Comparative Survival Study plan for steelhead tagging would contribute to monitoring stray rates in the Deschutes. The recent effort to representatively PIT tag all LSRCP hatchery steelhead will greatly enhance the ability to estimate fall back. Fish that pass above Sherars Falls and are later detected migrating up the Columbia River above the Deschutes will provide better estimates of fall back rates. Repeating Columbia River mainstem radio telemetry studies, with additional effort to track steelhead that enter the Deschutes River further upstream and longer throughout the winter and possibly spring, would help to quantify the stray rate upstream of Sherars Falls.

To determine population-level genetics composition for the MPG, genetics data which allow an objective determination of the population(s) structure are required. Age-0 *O. mykiss* from several representative streams in each population segment have recently been sampled. Collection of juveniles from a minimum number of cohorts (3-4) is recommended using non-lethal fin tissue for DNA analysis. Population genetics will be characterized using a suite of nuclear DNA markers, including both microsatellite loci (variable-number simple-sequence repeats) and non-coding SNPs, or base substitutions assayed via restriction enzyme analysis (Moran et al. 1997).

Analysis: Estimating the proportion of out-of-basin strays is a simple comparison of the number of marked and unmarked spawners observed. Direct comparisons can then be made with recovery criteria. DNA tissue samples are analyzed by USFWS using known microsatellite markers. Microsatellite loci are analyzed using pairwise FST comparisons to estimate levels of gene flow and to identify geographic areas that contain genetically differentiated populations.

Status: Ongoing or planned, but efforts need to be enhanced.

Objective 4: Determine the status and trend in conditions of current and historically utilized habitat for each population.

This is a high level priority.

Type of monitoring effort: Long term status and trend monitoring.

Monitoring questions:

- What is the status and trend in habitat quantity and quality in the Deschutes Eastside and Westside populations?

Approach: Similar to other watersheds, we would use an EMAP sampling protocol as previously described for the John Day populations. Habitat variables follow ODFW Aquatic Inventories design (Moore et al. 2002) and are measured at the unit and reach scale.

Analysis: Data will be analyzed as distribution data in a GIS format. Database and GIS formatting of data allow associations with land use, land vegetation coverage, and many other attributes at watershed and population scales.

Status: Not implemented and currently unfunded.

Objective 5: Determine the freshwater productivity of each population relative to viability criteria and identify primary habitat factors limiting freshwater production.

No quantitative time series of smolts per adult or smolt-to-adult survival rates have been developed to represent Deschutes River populations across multiple generations. This type of information is important to monitor productivity and segregate tributary productivity from the migration and ocean life stages. This metric allows for better understanding of the productive potential of steelhead in the Eastside and Westside populations. Productivity appears to be inherently low in the Westside population relative to other Columbia Basin summer steelhead populations (see Section 7). It is hypothesized that interactions with the abundantly naturally occurring resident *O. mykiss* may limit steelhead production. Presently, juvenile outmigrants are trapped annually in the Warm Springs River and near the mouth of Trout Creek. With a more accurate method of determining spawner abundance in Trout Creek and smolt abundance estimates from the Warm Springs River, an index of smolts/adult or smolts/redd would be available for each population. This is a highest priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:
- What are the current and trend in freshwater productivity measured as smolts/redd?
- What are the primary factors limiting freshwater production of steelhead?

Approach: The ratio of smolts/adult is a recommended measure of freshwater productivity. Smolts are typically counted using traps as they migrate out of their natal habitat. If weirs are not present to count adults, then redd counts can act as a surrogate. Freshwater productivity will be measured as smolts/redd or smolts/adult. Trapping with RSTs is currently being conducted on the Trout Creek tributary. Egg-to-smolt survival requires an estimate of the number of eggs deposited by individual females or deposited in each redd. Parr-to-smolt survival can be estimated by capturing a representative number of parr in their rearing habitat, PIT tagging them, and then monitoring their recapture at the downstream smolt traps. Migration survival can similarly be estimated by monitoring detections of PIT-tagged individuals as they pass through PIT tag detection facilities.

Analysis: Smolt abundance would be estimated using mark/recapture techniques (Thedinga 1994, Steinhorst 2004).

Status: Partially implemented at the tributary level. Current PIT tagging efforts on Trout Creek need to be coordinated with efforts to estimate escapement.

Objective 6: Determine the effect of disease and predation on the abundance, productivity, diversity, and distribution of the Deschutes River populations.

Out-of-subbasin strays also pose a threat to steelhead population health. About 5% of the hatchery stray steelhead have tested positive for whirling disease (Engleking 2002). This is a high level priority.

Type of monitoring effort: Disease is short term research; predation long term status and trends.

Monitoring questions:

- What is the prevalence of whirling disease in the Deschutes subbasin and what is its influence on the natural steelhead populations?
- What is the effect of predation from piscine predators in the Columbia River migration corridor on juvenile steelhead originating from the Deschutes River?
- What is the effect of predation from avian predators in the Columbia River migration corridor on juvenile steelhead originating from the Deschutes River?

Approach: The current distribution and influence of whirling disease on wild steelhead populations is not fully understood. Representative sentinel stations could be established and monitored through time for each population to measure prevalence and intensity of infection rates of whirling disease. Infection, or the presence of *Myxobolus cerebralis* DNA, is detected by PCR analysis. A logical place to locate initial sentinel tests would be in locations where hatchery strays are known to be prevalent because they are a known vector of transmission from infected watersheds in northeast Oregon (Sollid et al. 2004). Sentinel stations should then be placed near the mouths of important tributary and mainstem habitats occupied by fry and parr life history stages of steelhead.

To evaluate avian predation, colonies are monitored for presence of PIT tags originating from specific populations (Collis et al. 2001). Bioenergetics models can then be used to expand tag recoveries at colonies to population-level impacts (Antolos et al. 2005).

Analysis: The SAR attributable to predatory mortality could be estimated from bioenergetics modeling results. Infection rates of sentinel fish from disease would need to be related to actual mortality rates experienced in the natural population. If this were determined then mortality rates resulting from disease could be estimated as a proportion of freshwater mortality (i.e., egg to smolt mortality) although some delayed mortality may also occur (Sollid et al. 2004).

Status: The whirling disease foundation, whirling disease initiative, and Oregon Sea Grant are potential funding sources for whirling disease investigations. Universities, through graduate student projects, are often used for this type of research and monitoring.

Objective 7: Determine the effect of hydropower on the abundance, productivity, diversity, and distribution of the Deschutes River populations.

MPG-specific SARs and migration survival rates need to be developed for the Mid-C steelhead DPS. The Deschutes River subbasin has the infrastructure to contribute PIT-tag groups of natural-origin steelhead to this need. Recently, approximately 1,400 steelhead smolts per year have been PIT tagged and released at the Trout Creek outmigrant trap (personal communication, Tom Nelson, ODFW, Madras). The Columbia Basin Fish and Wildlife Program's Comparative Survival Study plan for PIT-tagging steelhead includes a mark group for the Warm Springs River, but it has not been implemented. Implementing the Warm Springs tagging, and supplementing Eastside PIT-tagging with juveniles from the Buckhollow-Bakeoven hatchery influence study would result in a mark group from both populations that yields statistically robust annual SARs and migratory survivals through FCRPS facilities. PIT-tag based SAR estimates are a valuable information source to partition subbasin survival rates from survival rates through the Columbia mainstem migration corridor, during estuary and early ocean life, and for returning adults to Bonneville Dam and Sherars Falls.

No quantitative time series of smolts per adult or smolt-to-adult survival rates have been developed to represent wild Deschutes River populations across multiple generations. This type of information is important to monitor the productivity. This metric would help greatly to better understand the comparative productivity of Westside and Eastside populations. This is a high priority objective.

Type of monitoring effort: Long-term status and trend monitoring.

Monitoring questions:

- What is the effect of Columbia River hydropower operation on steelhead smolt survival for the Deschutes River Eastside and Westside populations?
- What is the effect of Columbia River hydropower operation on returning adult steelhead originating from the Deschutes River Eastside and Westside populations?
- What are SAR rates for the Deschutes River Eastside and Westside populations?

Approach: PIT tags have been used successfully to measure the influence of hydropower operations on migrating salmonids (see Berggren et al. 2006; Schaller et al. 2007). ODFW has cooperated with the CSS study by PIT tagging steelhead smolts as they migrate out of the John Day River Basin. These PIT-tagged fish are subsequently monitored for detections at FCRPS facilities along the migration corridor at both juvenile and adult life stages using DART and PTAGIS databases. Detection probabilities of juvenile salmonids migrating downstream at FCRPS facilities are modeled using the SURPH analytical tool (Lady et al. 2003). Adult detection (purportedly 100%) is currently available at ladders on several dams including Bonneville and are expected in the near future at The Dalles dam.

Analysis: Juvenile survivals at each FCRPS facility can be estimated using the SURPH model. Adult survival between facilities will soon be possible by comparing detections at adult ladder facilities along the migration corridor. Rates can be expanded to population-

level impacts using the relative number of fish PIT tagged and abundance estimates generated from mark-recapture at RSTs.

Status: ODFW currently PIT tags emigrating smolts on Trout Creek. Presently, juvenile outmigrants are also trapped annually in the Warm Springs River by CTWSRO. Detections of these tagged fish at FCRPS facilities are automatically logged into the PTAGIS database. The number of smolts tagged will need to be increased.

Objective 8: Determine the effect of habitat degradation and habitat restoration activities on the abundance, productivity, and distribution of the Deschutes River populations.

This is a high priority objective.

Type of monitoring effort: Long term status and trend; long term implementation and compliance; long term effectiveness monitoring.

Monitoring questions:

- Status & Trend Monitoring—What is the current status and trend of steelhead habitat?
- Implementation and Compliance Monitoring—Has the management action been implemented in the prescribed manner and achieved its objectives?
- Effectiveness Monitoring—Have the management actions significantly influenced the viability of the Deschutes River steelhead populations?

Approach: Status and trend monitoring at the subbasin and population scale is best conducted by using a spatially explicit sampling approach such as the EMAP approach developed by the EPA. Measured habitat variables will be the same as previously described for the John Day populations. Remote sensing (TIR, LIDAR, and spatially referenced color imagery) is also appropriate and typically addresses spatial scales at watershed or larger landscapes.

Compliance monitoring of restoration projects incorporates record keeping and reporting of activities. Compliance monitoring will primarily conducted by the implementing entity and will include parameters identified in related work statements.

Effectiveness monitoring can be approached at the watershed or project spatial scales, and should preferably be directed at measures of abundance, survival, growth, etc. of steelhead or abiotic or biotic factors limiting their recovery. A modified BACI design (including spatial replication) is recommended for measuring the effectiveness of active restoration activities (Jones & Tonn 2004). For passive restoration activities, a BACI design that monitors trends through time may be appropriate. If comparisons are made to reference or control sites, they should be under similar environmental conditions experienced by the treatment site but outside the influence of treatment activities. Restoration implementing entities must coordinate with monitoring groups prior to action implementation—preferably several years in advance to allow measurement of pre-manipulation variables. Temporal scales must account for time lags related to life history and life cycle. Derived variables include

proportion of population-level parameter (e.g., abundance, production) influenced by restoration activity.

Analysis: If at the appropriate scale, direct comparisons of measured parameters with recovery criteria can be made. Otherwise, measures at smaller scales will need to be scaled up to determine if they would have desired responses at the population level.

Status: Implementation monitoring is ongoing for some programs, however, roll-up to the population level is not ongoing and some programs have limited monitoring.

Objective 9: Determine the effect of harvest on the abundance, productivity, and diversity of the Deschutes River populations.

Since 1979, recreational angling regulations have stipulated that all wild fish be released unharmed. Tribal harvest of wild steelhead since 1998 has also been restricted at Sherars Falls, where most tribal summer steelhead harvest occurs. From 1993 to 2003, the annual harvest of wild steelhead in this subsistence fishery averaged 34 fish, with a range from 0 to 135 per year (French and Pribyl 2004). Significant tribal harvest of steelhead continues to occur in the mainstem Columbia; however, the number of Deschutes origin fish harvested in this fishery is unknown.

During the past ten years (1993 to 2002) the average catch of wild steelhead in the recreational fishery from the mouth upstream to, but not including the Sherars Falls area, averaged 3,268 fish, with a range of 1,192 to 6,525 fish. Recreational angling regulations stipulated that all wild fish had to be released unharmed. During the same period the catch of hatchery origin steelhead for the same river reach averaged 2,665 fish, with a range from 779 to 5,120 fish. Most tribal summer steelhead harvest occurs in the dipnet/set net subsistence fishery concentrated at Sherars Falls. During the 10-year period from 1993 to 2003, tribal fishers at Sherars Falls had tribal regulations restricting the harvest of wild steelhead. The annual harvest of wild steelhead in this subsistence fishery averaged 31 fish, with a range from 0 to 135 per year (French and Pribyl 2004). Some limited hook and line harvest of wild summer steelhead by Tribal members does occur in areas upstream of Sherars Falls, primarily during the winter months. The number of wild summer steelhead harvested by tribal fishers in this fishery is not known. This is a high level priority.

Type of monitoring effort: Long term status and trends.

Monitoring questions:

- What is the annual fishing mortality rate that occurs outside of the Deschutes River subbasin?
- What is the annual fishing mortality rate that occurs within the Deschutes River subbasin?

Approach: Reinstating an expanded creel survey of the recreational fishery within the Deschutes River subbasin would enable an estimate of the effects of the fishery on the wild populations. Examine all fish for fin clips and external tags. Origin of out-of-basin hatchery

strays will be determined by collecting and identifying any coded-wire tags from fin-clipped fish. Fish will be scanned for coded-wire and PIT tags using portable detectors. If tags are detected, snouts from fish with coded-wire tags and those that are ventral-clipped should be removed for tag identification.

Analysis: The number of fin-clipped and natural-origin fish caught by interviewed anglers will be totaled and be used for an expanded estimate of the number of fin-clipped and natural-origin fish caught throughout season. Estimate of the incidental and/or directed fishing mortality on natural-origin steelhead will be calculated using published literature values. Proportion of total mortality imposed by fishing mortality will be estimated when combined with additional mortality information.

Status: Voluntary returns of tags from cooperating anglers have occurred sporadically over the past several years. ODFW should provide lead with aid of tribal agencies where jurisdiction overlaps.

Appendix B

Oregon Mid-Columbia Steelhead Viability Assessments

Viability assessments following the format provided by the ICTRT for the following populations:

Fifteenmile Creek Winter Steelhead
Deschutes River Eastside Summer Steelhead
Deschutes River Westside Summer Steelhead
Crooked River Summer Steelhead
Lower Mainstem John Day River Summer Steelhead
North Fork John Day River Summer Steelhead
Middle Fork John Day River Summer Steelhead
South Fork John Day River Summer Steelhead
Upper Mainstem John Day River Summer Steelhead
Umatilla River Summer Steelhead
Walla Walla River Summer Steelhead

Fifteenmile Creek Winter Steelhead Population

The Fifteenmile Creek winter steelhead population (Figure 1) is one of five extant populations in the Cascades Eastern Slope Tributaries MPG within the Mid-Columbia steelhead DPS. The Fifteenmile Creek population is the only population in the DPS that is classified as an entirely winter life history type.

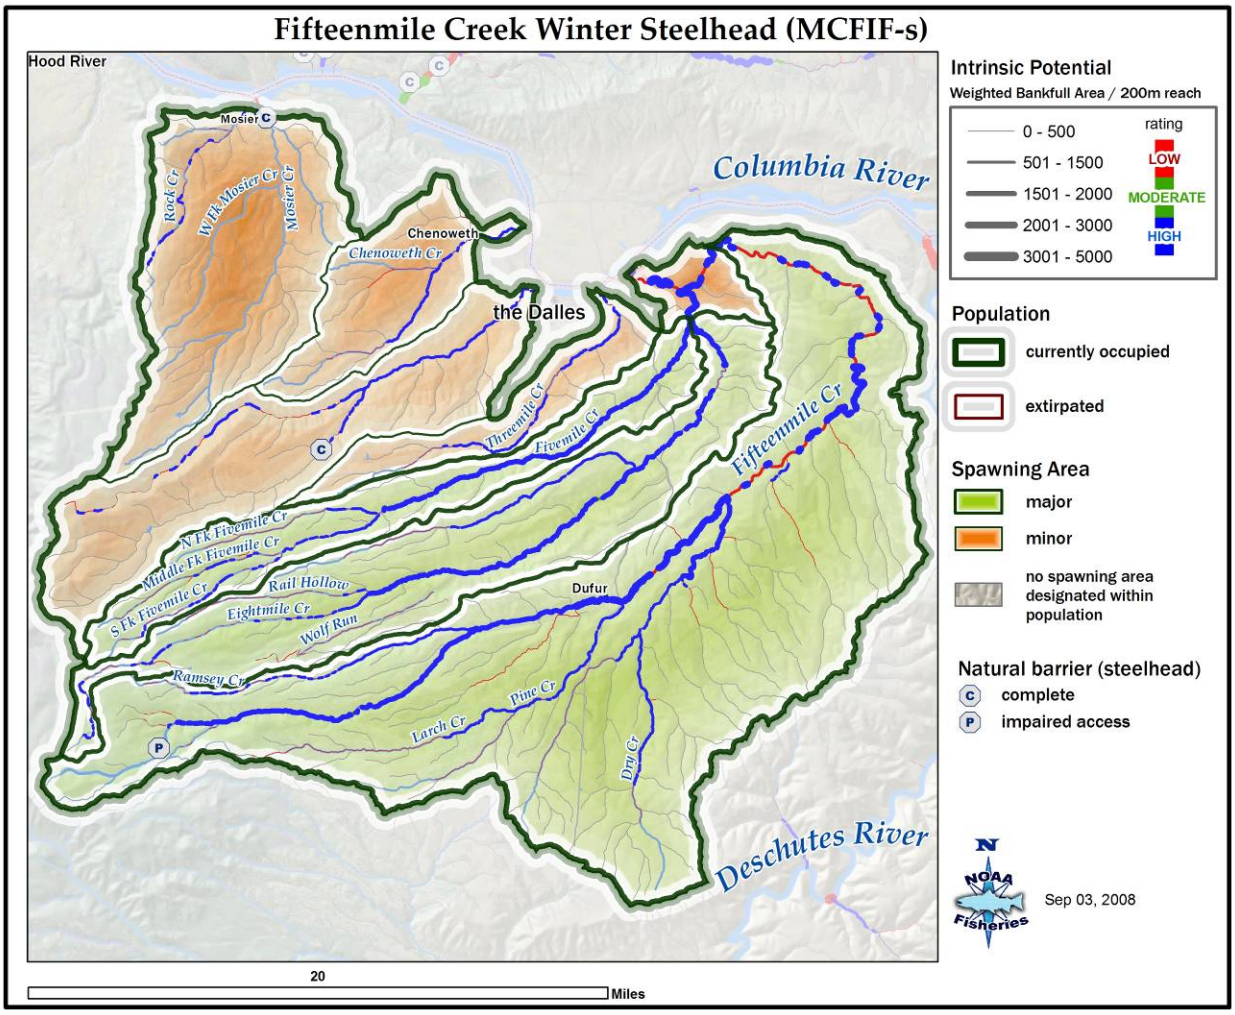

Figure 1. Fifteenmile Creek winter steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Fifteenmile Creek population as "basic" in size and complexity (Table 1). A steelhead population classified as basic has a mean minimum abundance threshold of 500 natural-origin spawners with sufficient intrinsic productivity (≥ 1.56 recruits per spawner at the abundance threshold level) to achieve a 5% or less risk of extinction over a 100-year timeframe. In order for the Fifteenmile Creek population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 2.00 recruits per spawner at the minimum abundance threshold.

Table 1. Fifteenmile Creek winter steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	1,420
Stream lengths km (total) [a]	638
Stream lengths km (below natural barriers) [a]	495
Branched stream area weighted by intrinsic potential (km^2)	1.816
Branched stream area km^2 (weighted and temp. limited) [b]	1.384
Total stream area weighted by intrinsic potential (km^2)	2.006
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	1.423
Size / Complexity category	Basic / "C" (trellis pattern)
Number of major spawning areas (MaSAs)	3
Number of minor spawning areas (MiSAs)	5

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

Current (1985 to 2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 231 in 1998 to 1,922 in 2004 (Figure 2). Estimates of abundance of adult steelhead spawners in the Fifteenmile Creek subbasin are based on redds observed during single pass spawning ground surveys conducted annually by the Oregon Department of Fish and Wildlife (ODFW) and U.S. Forest Service (USFS) personnel in selected survey units in upper Fifteenmile, Ramsey, and Eightmile creeks from 1985 through 2002. Since 2003, spawning ground surveys have been conducted in three passes over the duration of annual spawning activity in one-mile survey sites selected randomly from five-mile survey units stratified across the currently known spawning habitat in Fifteenmile, Ramsey, Eightmile, and Fivemile creeks. For this analysis, observations of redds and the locations of surveys have been compiled from DePinto et al. (2003), Glenney et al. (2004) and unpublished data (R. French, ODFW, personal communication 2005). Prior to 2003, we used redd densities in surveyed reaches to estimate redd densities in unsurveyed reaches. The ICTRT intrinsic potential analyses (ICTRT 2007) were used to estimate redds per weighted m^2 in surveyed reaches. To estimate total redds in the population, we multiply the number of redds per weighted m^2 in surveyed reaches by the total weighted m^2 of currently used habitat in the drainages where reaches were surveyed (ICTRT 2007). Historical intrinsic potential is estimated using a simple GIS-based model that accounts for differences across stream reaches (in terms of stream width, gradient, and valley width) and is further weighted by habitat quality.

For the 2003 and later years, observations of redds were expanded by the sample rate, both temporally and spatially, to estimate each season's total redds (redds/total spawning area/year). For years when streams in the Fifteenmile Creek subbasin were not surveyed (most notably Fivemile Creek prior to 2003) assumptions were made that spawning activity in unsurveyed streams was generally evenly distributed and synchronous with the entire population. Average proportional relations relative to the Fifteenmile Creek mainstem were used to estimate spawning activity in unsurveyed streams (Fivemile Creek redds represent approximately 15% of the Fifteenmile Creek mainstem redds).

The 2003-2005 multiple pass surveys have shown that spawning times can vary across years. Because the spawning ground surveys prior to 2003 were conducted once per season, variability in the time of spawning may be masked. However, spot checks were conducted to monitor the

level of spawning activity to determine when to conduct the surveys and recent investigations have shown that redd life (the length of time new redds remain visible) is sufficiently long to ensure that the observations from the historic single-pass surveys represent total spawning activity for each season (R. French, personal communication). Conversion of an annual total redd count to the adult population from 1985 to present assumes there are 2.1 fish per redd. This estimate was developed based on data from Deer Creek, a tributary to the Wallowa River (R. Carmichael, ODFW, personal communication,).

To estimate the abundance of adult progeny on the spawning grounds each season, consideration of removals of natural-origin fish for hatchery broodstock and natural spawning hatchery-origin fish must be accounted for. However, no steelhead hatchery program exists in the Fifteenmile Creek subbasin and hatchery steelhead are not released in steelhead habitat (Anonymous 2004). Further, hatchery strays in the Fifteenmile Creek subbasin have rarely been observed and the proportion is near 0%. Consequently for this analysis, the fraction of hatchery fish in the spawning population was assumed to be very low and mathematically assigned a value of zero.

Virtually no spawning steelhead in the Fifteenmile Creek subbasin have been sampled for age-at-return and no population specific information exists to assign natural-origin spawning fish into cohorts to estimate abundance of progeny. Therefore, age-at-return information from the closest natural-origin steelhead population with similar winter run traits was used to apportion Fifteenmile Creek steelhead spawners into brood years. Year specific age-at-return data for Hood River natural-origin winter steelhead sampled at Powerdale Dam were used. For those years with inadequate sample sizes, an average age-at-return by spawning year was applied.

Recent year natural spawners include only natural-origin fish. Hatchery strays in the Fifteenmile Creek population have rarely been documented.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 703 (Table 2). During the period 1985-1999, recruits per spawner (R/S, in terms of spawner to spawner) in the Fifteenmile Creek population ranged from 0.37 in 1987 to 5.58 in 1998. The annual R/S estimates were adjusted to reflect average smolt-to-adult return rates (SAR). The 15-year (1985-1999) geometric mean productivity was 1.82 R/S, adjusted for SAR and delimited at 75% (375 spawners) of the abundance threshold.

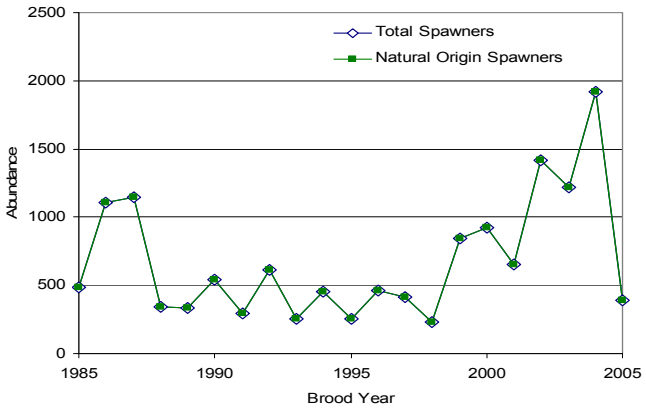

Figure 2. Fifteenmile Creek winter steelhead population spawner abundance estimates (1985-2005).

Table 2. Fifteenmile Creek winter steelhead population abundance and productivity estimates.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	703	(231-1,922)	
Proportion: natural-origin spawners (10-year geometric mean, range)	1.0	No obs. strays	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (15-year R/S, SAR adjusted and delimited) [a]	1.82	(1.23-2.68)	0.20
Productivity (15-year Beverton-Holt fit, SAR adjusted)	n/a		(n/a)
Trend Statistics (1985-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	1.03	(0.98-1.15)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	1.03	(0.83-1.28)	0.65
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.03	(0.83-1.28)	0.65

a. Delimited productivity excludes any recruit/spawner pair where the spawner number exceeds 75% of the abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Fifteenmile Creek winter steelhead population is at **Low Risk** based on current abundance and productivity. The point estimate for abundance and productivity resides above the 1% risk curve, but the population is not considered to be at very low risk since the 98% confidence interval (CI) extends below the 25% risk curve (Figure 3). However, since the 90% CI is above the 25% risk curve, the population is rated at low risk. Results should be viewed cautiously, as estimates are based on only 15 years of data.

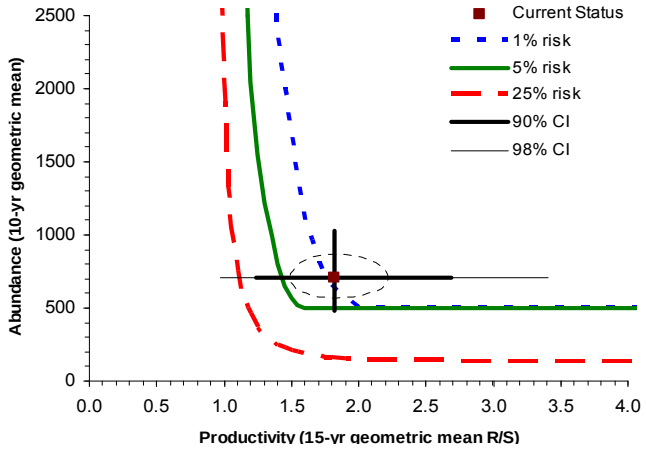

Figure 3. Fifteenmile Creek winter steelhead population current abundance/productivity (A/P) compared to DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A, 90% and 98% CIs for P (point estimate >1% risk curve; the uncertainty test is <1% probability the combined A/P is at high risk).

Both of the recent abundance trend metrics for this population indicate an average annual increase of approximately 3% per year over the period, driven largely by a relatively steady increase from 1999 through the 2004 return (Figure 2, Table 2). Abundance in 2005 decreased to similar levels observed from 1988 through 1998.

Spatial Structure and Diversity

The ICTRT has identified three major spawning areas (MaSAs) and five minor spawning areas (MiSAs) within the Fifteenmile Creek population boundaries. The population boundary extends outside the Fifteenmile Creek subbasin to encompass the Rock Creek, Mill Creek, and Threemile Creek drainages which directly enter the Columbia River downstream from Fifteenmile Creek (Figure 4). These drainages account for four of the five MiSAs. Current spawning distribution is similar to historic with major production areas in Fifteenmile, Ramsey, Eightmile and Fivemile creeks.

Spawners within the Fifteenmile Creek population include only natural-origin fish. Very few strays have been observed in the population and there is no hatchery program operated within the population. Additionally, there are few sources of winter steelhead strays in the interior Columbia River basin.

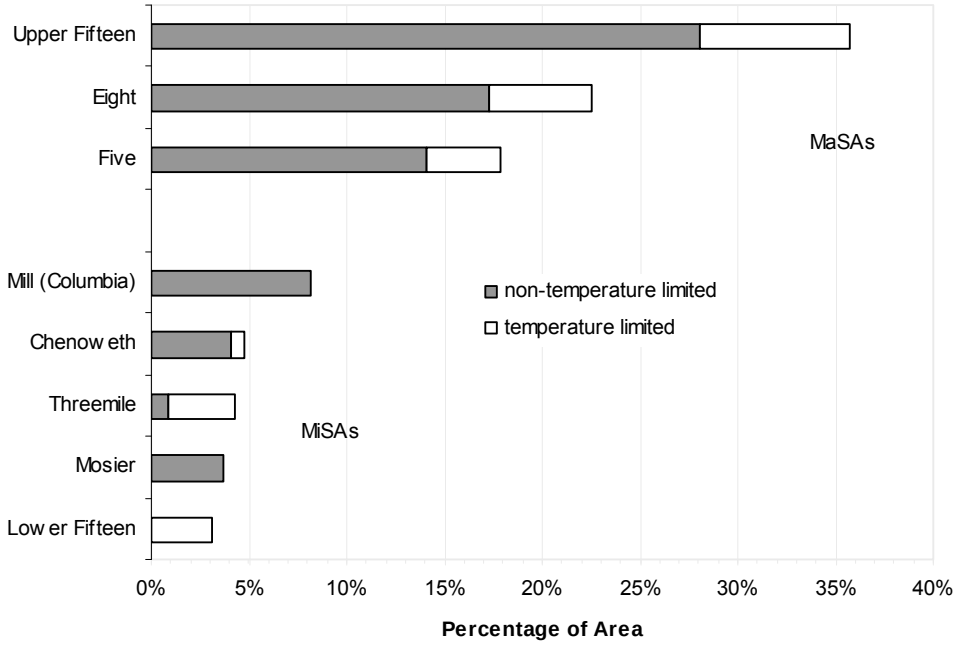

Figure 4. Fifteenmile Creek winter steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs). White bars represent current temperature limited areas that could potentially have had historical temperature limitations

Factors and Metrics

A.1.a Number and spatial arrangement of spawning areas

The Fifteenmile Creek population has three MaSAs and five MiSAs distributed in a trellis pattern. Historic major production areas included Fifteenmile, Ramsey, Eightmile and Fivemile creeks. Based on the ODFW current spawning distribution database, all three MaSAs and all five MiSAs are now occupied. Current distribution is similar to the historic intrinsic potential distribution, with reductions primarily in the southeast tributaries of the Fifteenmile MaSA. The Fifteenmile Creek population rates at **very low risk** because it has three occupied MaSAs and five MiSAs that equate to greater than 75% of one MaSA.

A.l.b. Spatial extent or range of population

The current spawner distribution mirrors the historic distribution with all MaSAs currently occupied (Figure 5). The rating for this metric is **very low risk** because the current spawning distribution mirrors the historic distribution. Spawning ground survey data are available for Fifteenmile, Ramsey, and Eightmile creeks for 1985-2005. We will conduct additional analyses at a later date to assess occupancy based on this recent survey data.

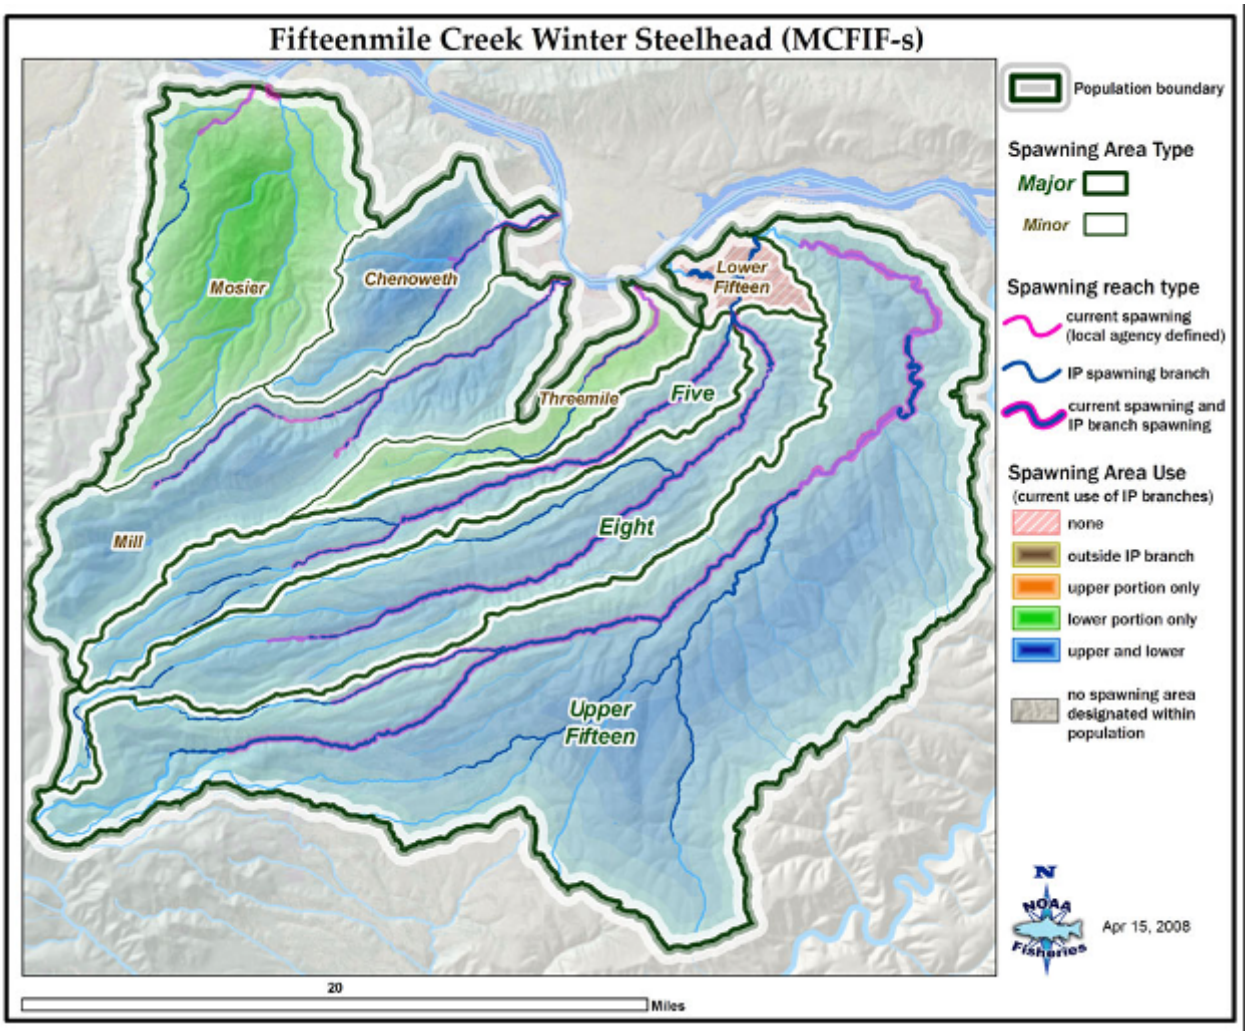

Figure 5. Fifteenmile Creek winter steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There has been little change in gaps between current and historical distribution. The population is rated at **very low risk** because all historical MaSAs are occupied, gap distance and continuity has changed little, and there has been no increase in distance between this population and other populations in the Mid-Columbia DPS.

B.1.a. Major life history strategies

There are limited data to allow any direct comparisons between historic life history strategies and current strategies. Flow and temperature changes have likely influenced movement pathways and continuity of habitat for juvenile steelhead. Some middle and lower mainstem reaches become uninhabitable during low flow summer periods. We infer that these habitat changes have truncated spawn timing and somewhat limited juvenile rearing diversity. Although these changes have had some influence on life history strategies, they have not likely influenced major strategies. The anadromous form of *O. mykiss* currently persists in the population and the winter

run characteristics have been maintained. We hypothesize that all historic major life history pathways are present, although the mean and variability may have shifted slightly. The rating is **low risk** for this metric.

B.1.b. Phenotypic variation

We have no direct evidence for loss or substantial change in phenotypic traits. However, changes in flow patterns and temperature profiles within Fifteenmile Creek subbasin have likely reduced variation in both juvenile migration timing and adult spawn timing. We hypothesize that low flows and elevated water temperatures result in a narrower window for successful smolt out-migration as well as truncation of adult spawn timing. However, the magnitude of the changes is likely small. Based on inference from habitat changes we have rated the Fifteenmile Creek population at **low risk**.

B.1.c. Genetic variation

Genetics data consist of samples from two locations within the Fifteenmile Creek population—Eightmile and Fifteenmile creeks. This genetics information indicates that the Fifteenmile Creek population is well differentiated from other populations in the Cascades Eastern Slope Tributaries MPG. Samples within the population from Eightmile Creek are also substantially differentiated from Fifteenmile Creek indicating within-population variation. We have rated this metric as **low risk**. Additional samples collected in 2005 from multiple locations within the population will provide a more robust dataset to assess this metric in the future.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners:* Out-of-DPS winter steelhead strays would originate from the Hood River hatchery program, from releases into the White Salmon River, and from other hatcheries downstream of Hood River. We have documented very few strays, thus the rating is **low risk**.

(2) *Out-of-MPG spawners from within the DPS:* There are no out-of-MPG within-DPS winter hatchery programs, thus the rating is **very low risk**.

(3) *Out-of-population spawners from within the MPG:* The only source of out-of-population within-MPG strays would be from the Klickitat River winter steelhead hatchery program. Since very few strays have been documented and their source is unknown, we have rated this metric as **low risk**.

(4) *Within-population hatchery spawners:* There is no within population hatchery program. This metric rated **very low risk**.

The overall spawner composition rating is **low risk**.

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution encompassed four ecoregions, of which three accounted for 10% or more of the distribution (Figure 6). Although there have been reductions in the proportional distribution of the Umatilla Plateau ecoregion, these reductions were not substantial. The population rates at **low risk**.

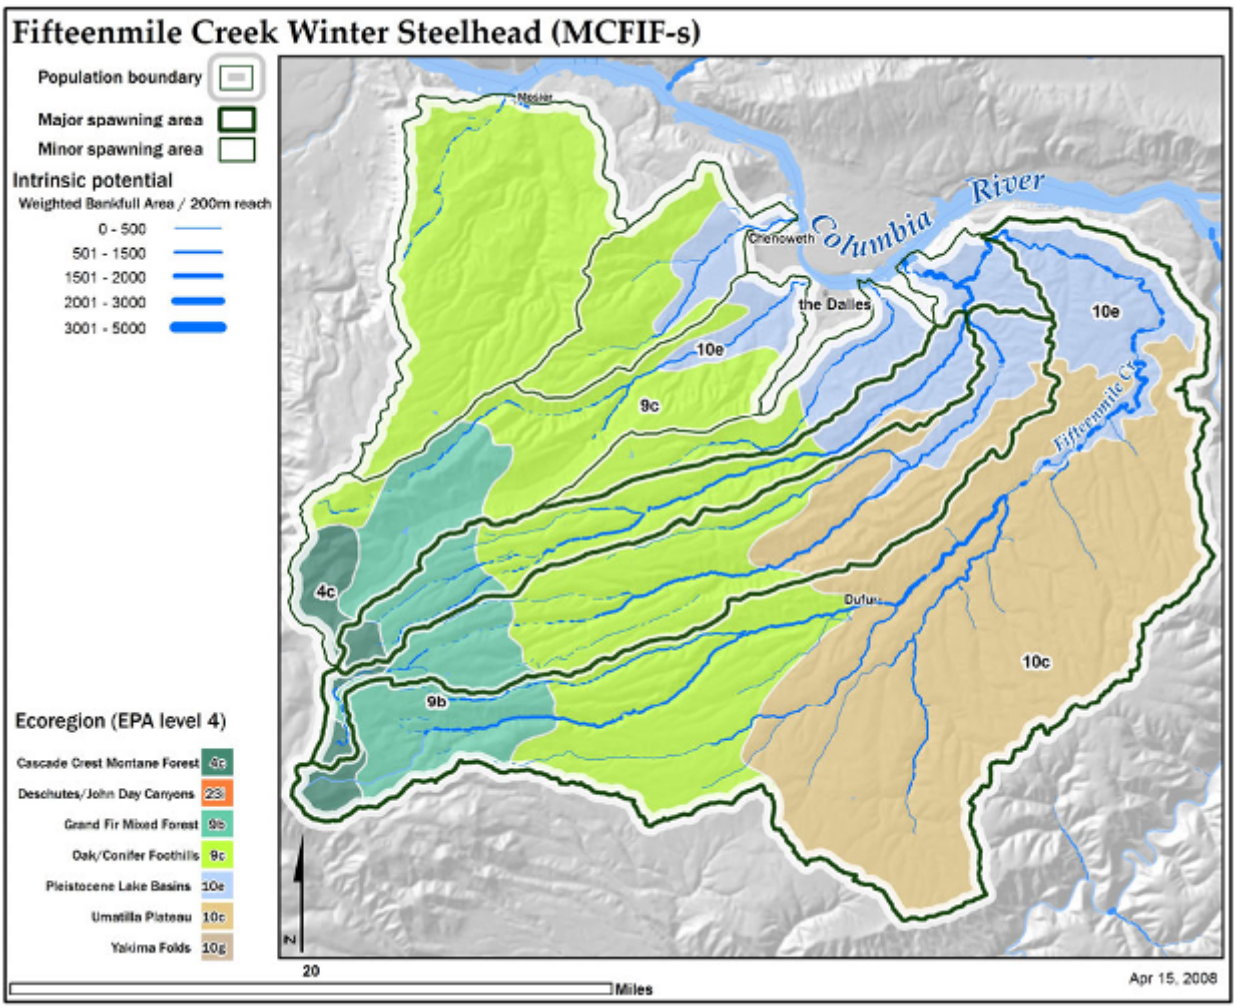

Figure 6. Fifteenmile Creek winter steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Fifteenmile Creek winter steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Grand Fir Mixed Forest	7.8	4.1
Oak/Conifer Foothills	36.4	41.2
Pleistocene Lake Basins	32.6	39.7
Umatilla Plateau	23.3	15.0

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes one dam in its seaward and spawning migrations, thus impacts on this population are relatively low. No traits are selectively affected by hydropower activity to the degree that they raise the risk level for this population. The rating is **low risk** for all traits.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be some very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery. While heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is no recreational fishery in the subbasin. No phenotypic traits appear to be at risk as a result of harvest activity and the rating is **low risk**.

Hatcheries: There are no steelhead hatchery programs operated within the population, therefore, there are no selective effects. The rating is **very low risk**.

Habitat: Altered flow profiles and increased temperatures in tributary spawning and rearing areas, which have been in place for many generations and are ongoing, likely impose some selection on juvenile and adult migration timing. However, the magnitude of the impact on any trait is negligible, thus the rating is **low risk** for all traits.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that is felt most strongly by the large steelhead smolts. The rate of predation is highest in May during nesting season. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selection is **low risk**.

No single trait has a moderate risk rating for any selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Low Risk** (Table 4) for the Fifteenmile Creek population. There has been little change in distribution relative to the historic distribution. The absence of major reductions in distribution resulted in a rating of very low risk for spatial structure metrics. We hypothesize that there have been minor reductions in life history diversity and phenotypic variation, but these changes are not severe enough to raise risk levels to moderate. There are few hatchery fish in the population resulting in low risk for spawner composition.

Table 4. Fifteenmile Creek winter steelhead population spatial structure and diversity risk rating.

Metric	Risk Assessment Scores

Overall Viability Rating

The Fifteenmile Creek winter steelhead population currently meets ICTRT viability criteria and is rated as a **VIABLE** population (Figure 7). Overall abundance and productivity is rated at **Low Risk.** The 10-year geometric mean abundance of natural-origin spawners is 703, which exceeds the minimum abundance threshold of 500. The 15-year geometric mean productivity (1.82 R/S; Table 6) exceeds the 1.56 R/S required at the minimum abundance threshold. Overall spatial structure and diversity is also rated at **Low Risk.** A relatively small increase in productivity and a substantial reduction in the CI are required to move this population into "highly viable" status. Additional data will likely decrease the standard error and move the 98% CI out of the high risk region. These results should be viewed with caution, as abundance and productivity estimates for the Fifteenmile Creek population are based on only 15 years of R/S data. Monitoring should be continued to allow analysis of a longer time series.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V** **Fifteenmile Creek**	**V**	**M**
	Moderate (6 – 25%)	**M**	**M**	**M**	**HR**
	High (>25%)	**HR**	**HR**	**HR**	**HR**

Figure 7. Fifteenmile Creek winter steelhead population risk ratings integrated across the four viable salmonid population (VSP) metrics. ***Viability Key: HV – Highly Viable; V – Viable; M – Maintained; HR – High Risk; Shaded cells - does not meet viability criteria (darkest cells are at greatest risk).***

Data Summary – Fifteenmile Creek Winter Steelhead Population

Data type: Expansions from multiple pass surveys in major tributary spawning reaches. Annual index area counts expanded to total population abundances using ratio of total to index area weighted intrinsic habitat (ICTRT 2007, Appendix C). Assumed 2.1 fish per redd.

SAR: Mid-Columbia steelhead composite series (see *Methods* section).

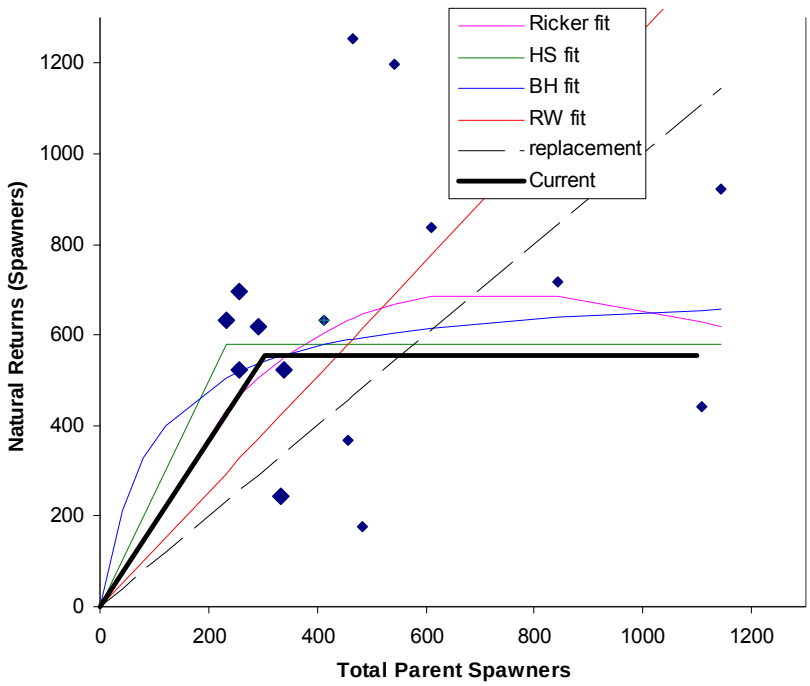

Figure 9. Fifteenmile Creek winter steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Deschutes River Eastside Summer Steelhead Population

The Deschutes River Eastside summer steelhead population (Figure 1) is one of five extant populations in the Cascades Eastern Slope Tributaries MPG within the Mid-Columbia steelhead DPS.

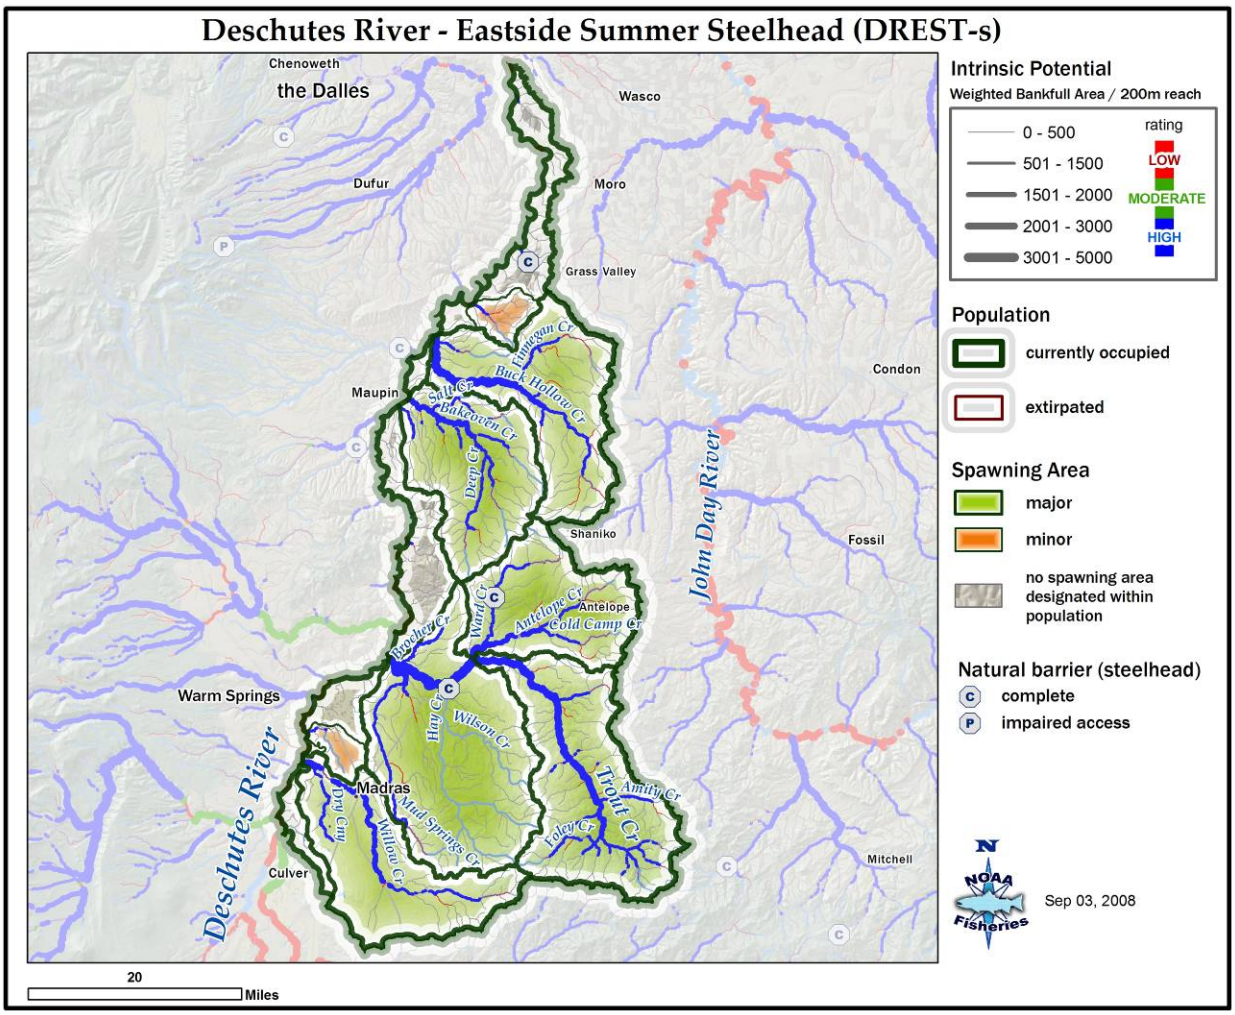

Figure 1. Deschutes River Eastside summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Deschutes River Eastside population as "intermediate" in size and complexity (Table 1). A steelhead population classified as intermediate has a mean minimum abundance threshold of 1,000 natural-origin spawners with a sufficient intrinsic productivity (≥ 1.35 recruits per spawner at the abundance threshold level) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the Deschutes River Eastside population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.64 recruits per spawner at the minimum abundance threshold.

Table 1. Deschutes River Eastside summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	3,889
Stream lengths km (total) [a]	974
Stream lengths km (below natural barriers) [a]	884
Branched stream area weighted by intrinsic potential (km^2)	2.780
Branched stream area km^2 (weighted and temp. limited) [b]	1.772
Total stream area weighted by intrinsic potential (km^2)	4.082
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	2.253
Size / Complexity category	Intermediate / "B" (dendritic structure)
Number of major spawning areas (MaSAs)	6
Number of minor spawning areas (MiSAs)	2

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

Current (1990 to 2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 583 in 1993 to 9,801 in 2001 (Figure 2). Current abundance of natural-origin adult spawners ranged from 299 in 1993 to 8,274 in 2001 (Figure 2). We examined two approaches for estimating the abundance of natural-origin and hatchery-origin steelhead in the Deschutes River Eastside population and selected one for this viability assessment. The first approach is similar to that used by Chilcote (2001) who conducted stock recruitment analyses for the combined Deschutes River Eastside and Westside populations. This method used the following information: estimated number of steelhead that pass above Sherars Falls (from mark-recapture estimates); the number of fish recovered in fisheries and traps above Sherars Falls; and estimated fall back rate for hatchery fish. We conducted similar analyses for the Deschutes River Eastside population with the additional step of subtracting out the Westside population abundance estimates. We found that this approach yielded, what appeared to be, extremely high abundance estimates of both natural-origin and hatchery-origin spawners for the Deschutes River Eastside population. Using this method resulted in a high number of spawners in the mainstem Deschutes River that was not consistent with the two years of redd observations data. We were unable to adequately quantify Sherars Falls fallback rates for natural-origin and hatchery-origin fish. The Sherars Falls mark-recapture subtraction approach is very sensitive to the fall back estimates, so in the absence of accurate estimates, we chose to use an alternative approach.

We chose to assess abundance and productivity based on estimates of spawners in the tributary production areas including Buck Hollow, Bakeoven, and Trout creeks. We acknowledge that this approach does not account for mainstem abundance and productivity. However, we believe this approach provides a better representation of the abundance and productivity for the Deschutes River Eastside population.

Estimates of the abundance of steelhead in the tributary production areas of the Eastside population are based on single pass index spawning ground surveys in the major spawning areas (MaSAs) of Trout, Bakeoven, and Buck Hollow creeks. Annual observations of redds begin with the 1990 spawning year in Bakeoven and Buck Hollow creeks, and 1993 in Trout Creek (excluding 1994). Spawning also occurs in the mainstem, but only two surveys have been conducted in the mainstem downstream of Trout Creek and this portion of the Eastside population is not included in this assessment.

To estimate spawning abundance, observed redd densities (redds/m^2) were extrapolated to unsurveyed areas of currently occupied spawning habitat. Variability in spawning habitat quality and capacity are incorporated in the abundance estimate by using the ICTRT's historical intrinsic potential (ICTRT 2007) to expand redd observations per unit survey area to unsurveyed areas. The number of redds per weighted m^2 of intrinsic habitat in the index survey areas are multiplied by the total m^2 of weighed intrinsic habitat within each tributary production area. Total redds are determined as the sum of redds in Bakeoven, Buck Hollow, and Trout creeks. In Trout Creek in 1990-1992 and 1994, when surveys were not conducted, the Trout Creek abundance was assumed to be 1.44 times the sum of the Buck Hollow and Bakeoven Creek abundance estimates, based on the proportion of spawning habitat in Trout Creek relative to all three tributaries. Redds are expanded to fish by multiplying total redds by 2.1 fish per redd (R. Carmichael, Oregon Department of Fish & Wildlife, personal communication). This estimate was derived for summer steelhead in Deer Creek, a tributary of the Wallowa River.

Abundance of progeny by spawning year was estimated by apportioning the total spawning abundance estimate into hatchery and natural-origin fish. For years when at least ten fish were examined for the presence of adipose fins in each stream, the marked fish proportion was used for the hatchery fraction. Field observers believe that these estimates may be biased low because of difficulties observing adipose fins on live fish at a distance (R. French, Oregon Department of Fish & Wildlife, personal communication). For years when fewer than ten fish were observed, the hatchery fraction was estimated based on the average ratio of the percentage of hatchery fish at Sherars Falls and the percentage of hatchery fish on the spawning grounds in Buckhollow and Bakeoven Creeks across all years. For Trout Creek we used the relationship of hatchery fraction between Trout Creek and Warm Springs National Fish Hatchery.

Virtually no spawning steelhead in the Deschutes River Eastside population have been sampled for age-at-return and no population specific information exists to assign natural-origin spawning fish into cohorts to estimate the abundance of progeny (Anonymous 2004). Age structure information used to estimate progeny by brood year was based on the average of a two-year sample of scales from natural-origin adult steelhead (N=100) collected in the lower Deschutes River (Olsen et al. 1991).

Recent year natural spawners include returns originating from naturally spawning parents, strays from the Deschutes Subbasin Round Butte Hatchery program, and a significant number of out-of-DPS hatchery strays from the Snake River basin. Origin of strays is based on recovery of coded-wire tagged fish in fisheries and at traps in the Deschutes River subbasin. Spawners originating from naturally spawning parents have comprised an average of 66% of naturally spawning fish since 1990. The percentage of natural-origin spawners has ranged from 21% to 88%.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 1,599. During the period 1990-1999, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Deschutes River Eastside population ranged from 0.24 in 1991 to 3.97 in 1996. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 10-year (1990-1999) geometric mean productivity was 1.89 R/S, adjusted for SAR and delimited at the median number of spawners (1,312; Table 2).

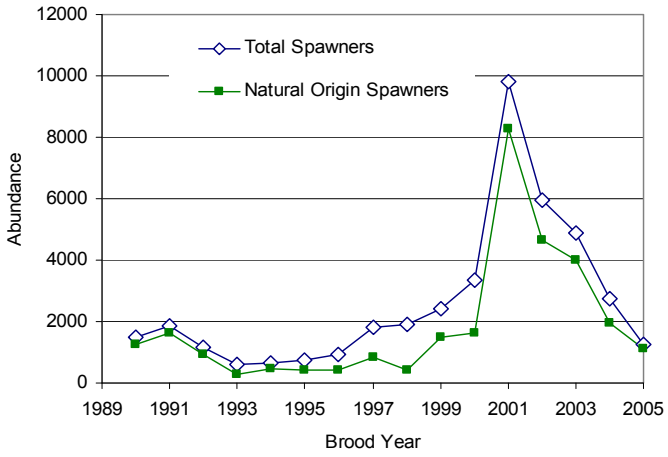

Figure 2. Deschutes River Eastside summer steelhead population spawner abundance estimates (1990-2005).

Table 2. Deschutes River Eastside summer steelhead population abundance and productivity estimates.

Abundance/Productivity Statistics	**Estimate**	**(Range)**	
Abundance: natural-origin spawners (10-year geometric mean, range)	1,599	(583-9,801)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.62	(0.21-0.88)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (10-year R/S, SAR adjusted & delimited) [a]	1.88	(1.10-3.26)	0.24
Productivity (15-year Beverton-Holt fit, SAR adjusted)	3.94		3.83
Trend Statistics (1990-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	1.11	(1.01-1.23)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	0.98	(0.53-1.79)	0.44
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.09	(0.55-2.15)	0.68

a. Delimited productivity excludes any recruit/spawner pair where the spawner number exceeds the median escapement. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Deschutes River Eastside population is at **Low Risk** based on current abundance and productivity. The point estimate for abundance and productivity resides above the 1% risk curve, but the population is not considered to be at very low risk since the lower end of the 98% confidence interval (CI) for productivity extends below the 25% risk curve. The 90% CI is above the 25% risk curve and the population is rated at low risk (Figure 3).

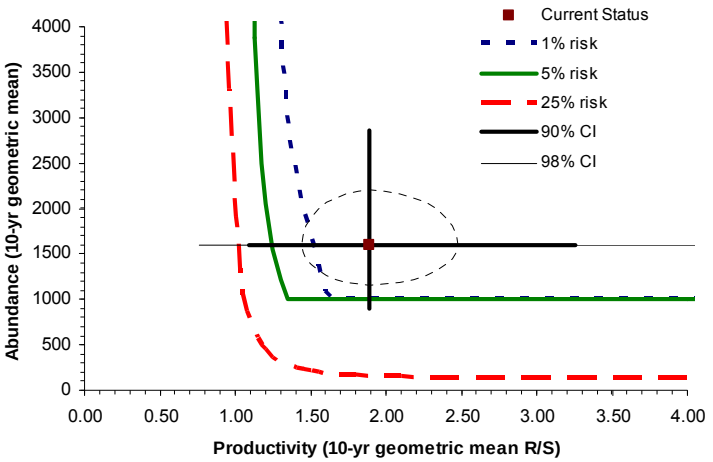

Figure 3. Deschutes River Eastside summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A, 90% and 98% CIs for P (point estimate >1% risk curve, therefore the uncertainty test results in <1% probability the combined A/P is at high risk).

On average, the trend in annual spawners (Table 2) has been positive since 1990, the first year data were available to generate estimates for this population. Both hatchery-origin and natural-origin returns showed similar patterns over the time period (Figure 2). Relatively high numbers of spawners in return years 2001-2003 contributed significantly to the average trend. In more recent years, annual spawning estimates have generally been at the levels observed in the initial years of the series. Under the assumption that hatchery and natural-origin parents were equally effective in contributing to natural production for this population (hatchery effectiveness = 1.0), the point estimate of population growth rate (λ) was below 1.0, with a 40% chance that the actual estimate exceeded 1.0. The relative effectiveness of hatchery-origin spawners in the Deschutes River Eastside population is not known. An estimate of the population growth rate was calculated assuming that hatchery returns did not effectively contribute to natural production (hatchery effectiveness = 0.0; Table 2). The estimated population growth rate assuming that hatchery spawners are not contributing to natural production was 1.09 (78% probability of exceeding 1.0).

Spatial Structure and Diversity

The ICTRT has identified six major spawning areas (MaSAs) and two minor spawning areas (MiSAs) within the Deschutes River Eastside steelhead population (Figure 4). The population boundaries extend above the Pelton Reregulation Dam, and therefore include areas that are currently inaccessible. One MaSA (Willow Creek) and one MiSA (Campbell) exist in the inaccessible area. The intrinsic potential analysis rated most of the Deschutes River mainstem spawning habitat as low potential because of the width and confinement, although steelhead spawning has been observed in the mainstem. Spawning is distributed broadly throughout the population boundaries. Steelhead production is concentrated in Buck Hollow, Bakeoven and Trout creeks, with some spawning in the mainstem from Trout Creek to Buck Hollow Creek. Spawners within the Deschutes River Eastside population include natural-origin returns, hatchery returns from Deschutes River origin fish produced from Round Butte Hatchery, and out-of-DPS hatchery strays primarily from the Snake River basin. Hatchery-origin fish comprise a significant proportion of the natural spawners.

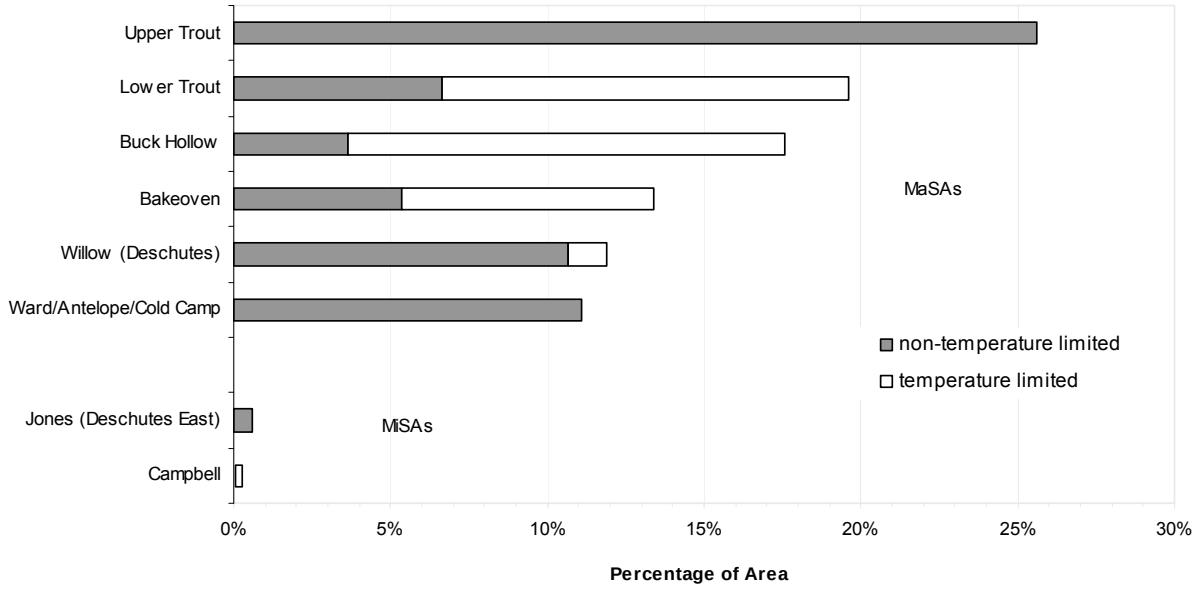

Figure 4. Deschutes River Eastside summer steelhead population distribution of intrinsic potential habitat across major and minor spawning areas. White bars represent current temperature limited areas that could potentially have had historical temperature limitations.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Deschutes River Eastside population has six MaSAs and two MiSAs distributed in a dendritic pattern (Figure 5). The primary production areas include Buck Hollow, Bakeoven, and Trout creeks. Historically, Willow Creek was also a significant production area. Based on the Oregon Department of Fish and Wildlife (ODFW) current spawner distribution database, five of the six MaSAs and neither of the two MiSAs are currently occupied. The MaSA that does not meet the occupancy criteria is Willow Creek. This MaSA is unoccupied because it is inaccessible. The Deschutes River Eastside population rates at **very low risk** for this metric because it has five MaSAs occupied in a non-linear configuration.

A.l.b. Spatial extent or range of population

The current spawner distribution is restricted somewhat from the historical distribution. The Willow Creek MaSA is unoccupied because it is inaccessible. There is also loss of spawning in the Jones and Campbell MiSAs (Figure 5). The population is rated at **low risk** for this metric because greater than 75% (but less than 90%) of the historic MaSAs are currently occupied.

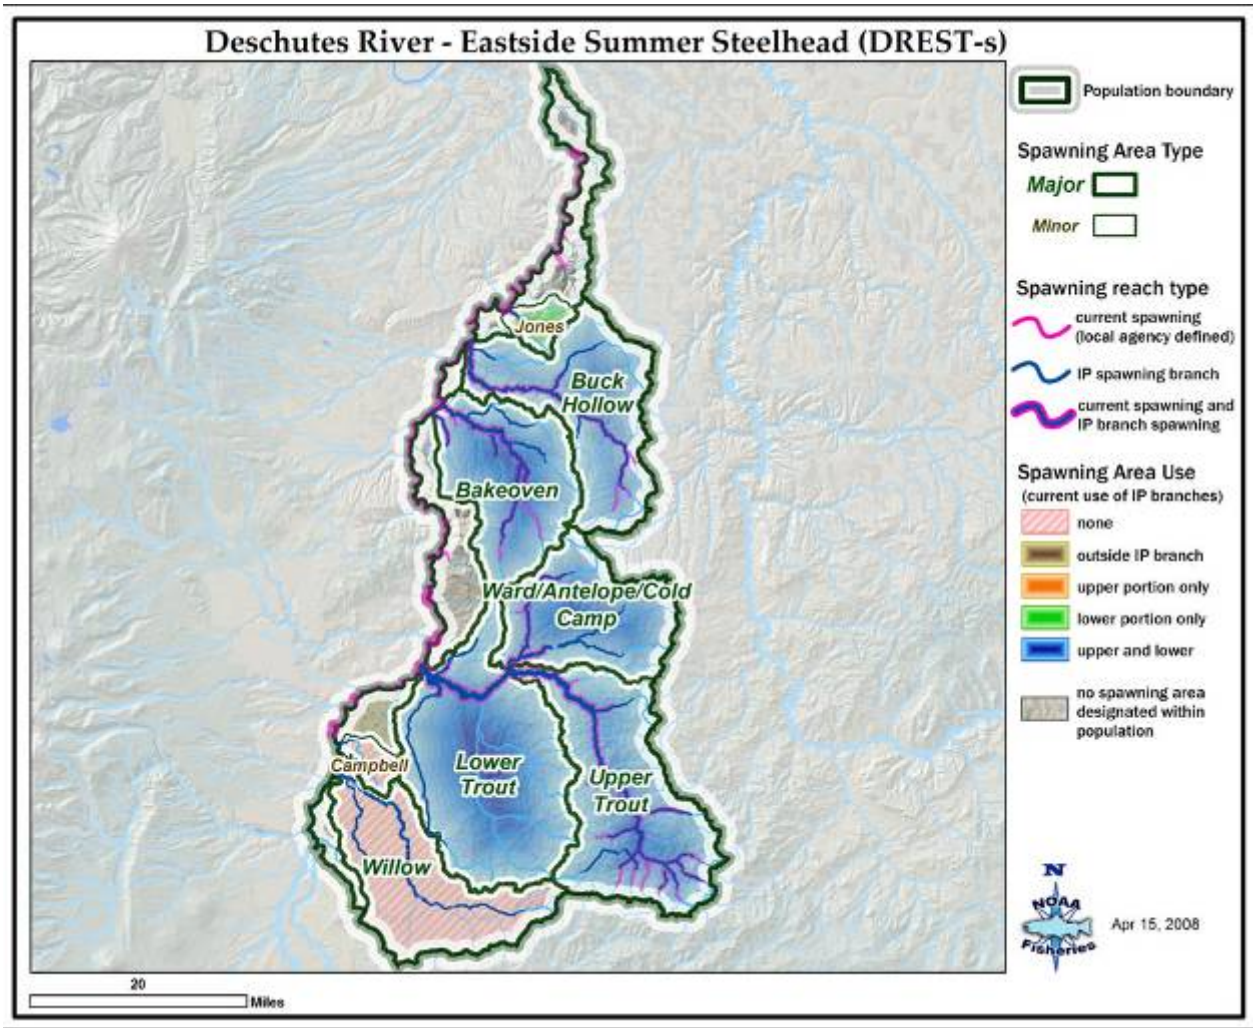

Figure 5. Deschutes River Eastside summer steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

The loss of spawning in the Willow Creek drainage has caused a significant increase in the gap distance between the uppermost spawning in the population and the middle production areas in Trout Creek. Currently, with the exception of the gap created by loss of spawning in Willow Creek, there is little difference in gaps and continuity between the historic and current distributions. We have rated the population at **low risk** for this metric.

B.1.a. Major life history strategies

There are no data to allow any direct comparison of historic and current major life history patterns, thus we must infer from habitat information. Flow and temperature changes within the major spawning tributaries have changed significantly relative to historic conditions with lower summer flows and higher temperatures. These changes have resulted in shifts in juvenile rearing patterns, with less summer rearing capacity in the tributaries and mandatory movement into either the mainstem or upper reaches for periods of summer rearing. Adult migration and spawn timing have likely been impacted by flow and temperature changes. Based on scale analyses of Deschutes River fish collected from the mainstem, the population demonstrates multiple ages at smolt migration and ocean residence time as well as repeat spawning. The habitat conditions, with mainstem rearing opportunities, do provide for opportunity for diverse life history strategies. We have rated the population at **low risk** for this metric.

B.1.b. Phenotypic variation

We have no direct observations to assess loss or substantial change in phenotypic traits, thus we must infer from habitat conditions and habitat changes through time. The flow and temperature changes in the tributaries have likely influenced both adult and juvenile migration timing and patterns. The loss of summer rearing opportunities forces juveniles to move downstream into the mainstem. Adult run-timing through the tributaries, as well as spawn timing, have likely been narrowed to some degree. We have rated this metric at **low risk** because two or more traits have likely changed and have reduced variability.

B.1.c. Genetic variation

There are limited genetics data for the Deschutes River Eastside population. The lower East Folley Creek samples were not significantly differentiated from other Eastside, Westside, or Round Butte Hatchery samples. However, the remaining samples from eastside tributaries show levels of differentiation between each other and between other populations that are consistent with a relatively unchanged structure. As a result of these data the population is rated at **low risk** for this metric. The ongoing genetics study that the U.S. Fish and Wildlife Service (USFWS) and co-managers are undertaking will yield additional and better information to assess this metric in the future.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners*: There are a significant number of out-of-DPS strays spawning naturally in the Deschutes River Eastside population. Estimates for stray hatchery proportions are derived from observations in Buck Hollow, Bakeoven, and Trout creeks. Since 1990, we estimated that hatchery strays have comprised from 12-90% of the spawners in this population, with a mean of 34.4% annually. We have no direct estimate of the proportion of out-of-DPS and Round Butte Hatchery strays for this population. Assuming the same proportion of out-of-DPS strays as we did for the Deschutes River Westside population (based on observations at Warm Springs National Fish Hatchery), we estimate that an average of 29% of the spawners in the Deschutes River Eastside population were out-of-DPS strays. Given this proportion and the duration of the influence we have rated the population at **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS*: There have been few out-of-MPG within-DPS strays recovered in the Deschutes River. The only source of this type of stray steelhead is from the Umatilla Hatchery program. We have rated this metric as **very low risk** due to the low proportion.

(3) *Out-of-population spawners from within the MPG*: Strays originating from the Round Butte Hatchery program are considered out-of-population within-MPG strays because their origin includes fish captured at the Pelton Reregulation Dam ladder and at Sherars Falls. The broodstock source likely includes both Westside and Eastside populations. Based on a total average hatchery proportion of 34.4% and the average proportion that Round Butte Hatchery strays make up of the total strays at Warm Springs National Fish Hatchery (15.5%), we estimated that Round Butte Hatchery strays comprise 5.4% of the naturally spawning fish annually. We have rated this metric as **moderate risk**.

(4) *Within-population hatchery spawners*: There are no within-population hatchery fish produced, thus we have rated this metric as **very low risk**.

The overall spawner composition rating is **high risk** due to the high proportion of out-of DPS strays that spawn naturally in this population.

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution encompassed five ecoregions of which three accounted for greater than 10% of the distribution. The current distribution is not significantly reduced from the historic distribution (Figure 6, Table 3). We have rated this metric at **low risk** because there were three historic ecoregions occupied and no substantial reductions.

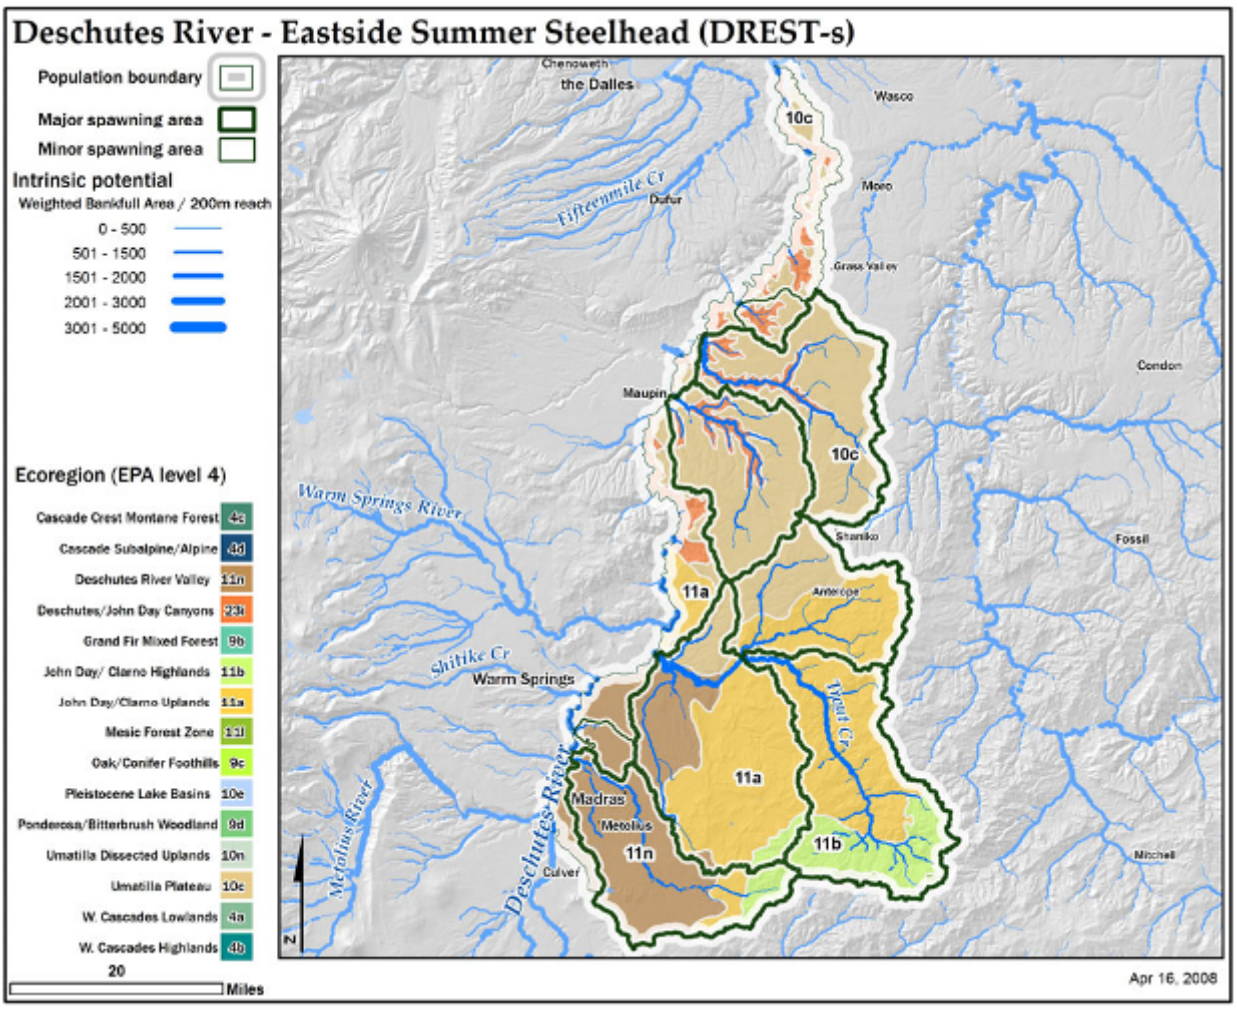

Figure 6. Deschutes River Eastside summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Deschutes River Eastside summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Deschutes River Valley	23.5	10.4
Deschutes / John Day Canyons	35.0	42.3
John Day Clarno Highlands	4.2	4.2
John Day Clarno Uplands	28.4	34.3
Umatilla Plateau	9.0	8.8

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes two dams in its seaward and spawning migrations, thus impacts on this population are relatively low. No traits are selectively affected by hydropower activity to the degree that they raise the risk level for this population. The hydropower rating is **low risk** for all traits.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is no selective impact of the recreational fishery. No phenotypic traits appear to be at risk as a result of harvest activity and the rating is **low risk** for all traits.

Hatcheries: There are no steelhead hatchery programs operated within the population; therefore, the hatchery rating is **very low risk**.

Habitat: Altered flow profiles and increased temperatures in tributary spawning and rearing areas, which have been in place for many generations and are ongoing, likely impose some selection on juvenile and adult migration timing, as well as spawn timing. However, the magnitude of selective mortality is likely negligible; therefore the habitat rating for all traits is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selection is **low risk**.

No single trait has a moderate risk rating for any selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** for the Deschutes River Eastside population (Table 4). The rating for Goal A (allowing natural rates and levels of spatially mediated processes) was **low risk**. Although the overall rating for this goal was low, spawning distribution is reduced significantly from the historic distribution with loss of spawning in the Willow Creek drainage being the primary factor. The population remains broadly distributed with little change in gaps and good continuity within the currently accessible habitat.

The rating for Goal B (maintaining natural levels of variation) was **moderate risk**. Habitat changes in key tributary production areas have likely resulted in limitations to life history diversity and reduction in phenotypic expression. In addition, a significant proportion of natural spawners are out-of-DPS strays which resulted in a high risk rating for the spawner composition metric. Additional genetics information is needed to assess differentiation within and between populations, as well as to improve our understanding of the degree of introgression of out-of-DPS strays. The ongoing genetics work of the USFWS and co-managers will provide the information needed to better assess the genetic health of this population.

Overall Viability Rating

The overall rating for the Deschutes River Eastside summer steelhead population currently meets ICTRT viability criteria for **VIABLE** status (Figure 7). Overall abundance and productivity is rated at **Low Risk.** The 10-year geometric mean abundance of natural-origin spawners is 1,599, which is well above the minimum abundance threshold of 1,000. The 10-year geometric mean productivity (1.89 R/S; Table 6) exceeds the 1.35 R/S required at the minimum abundance threshold and puts the population into the very low risk region; however the 98% CI extends well below the 25% risk level. This wide standard error results in a low risk level for abundance/productivity. Overall spatial structure and diversity is rated at **Moderate Risk**. This is primarily a result of the influence of habitat changes on life history and phenotypic expression as well as the influence of out-of-DPS hatchery spawners.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V**	**V** **Deschutes River Eastside**	**M**
	Moderate (6 – 25%)	**M**	**M**	**M**	**HR**
	High (>25%)	**HR**	**HR**	**HR**	**HR**

Deschutes River Eastside summer steelhead population risk ratings integrated across the four viable salmonid population (VSP) metrics. ***Viability Key: HV – Highly Viable; V – Viable; M - Maintained; HR – High Risk; Shaded cells - does not meet viability criteria (darkest cells are at greatest risk).***

Data Summary – Deschutes River Eastside Summer Steelhead Population

Data type: Expansions from single pass surveys in major tributary spawning reaches. Annual index area counts expanded to total population abundances using ratio of total to index area weighted intrinsic habitat (ICTRT 2007, Appendix C). Assumed 2.1 fish per redd.

SAR: Mid-Columbia steelhead composite series (see *Methods* section).

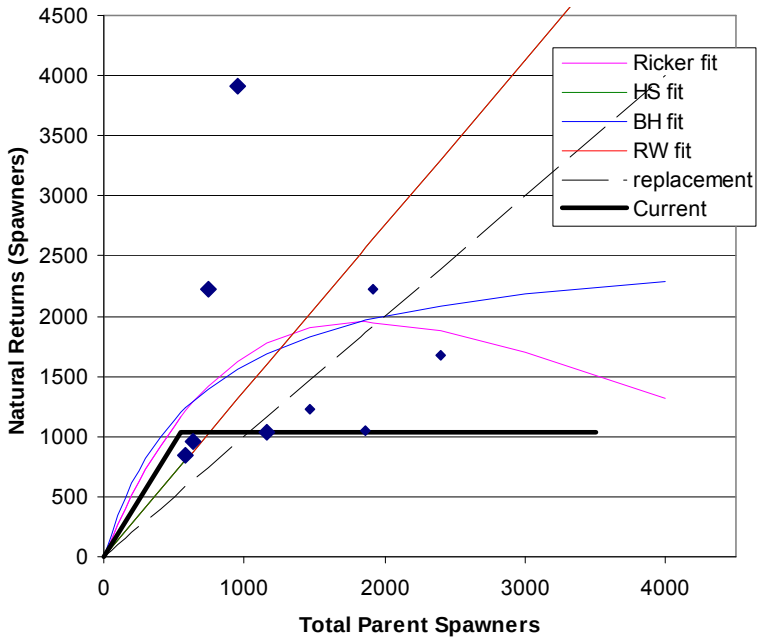

Figure 9. Deschutes River Eastside summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Deschutes River Westside Summer Steelhead Population

The Deschutes River Westside summer steelhead population (Figure 1, Figure 2) is one of five extant populations in the Cascades Eastern Slope Tributaries MPG within the Mid-Columbia steelhead DPS.

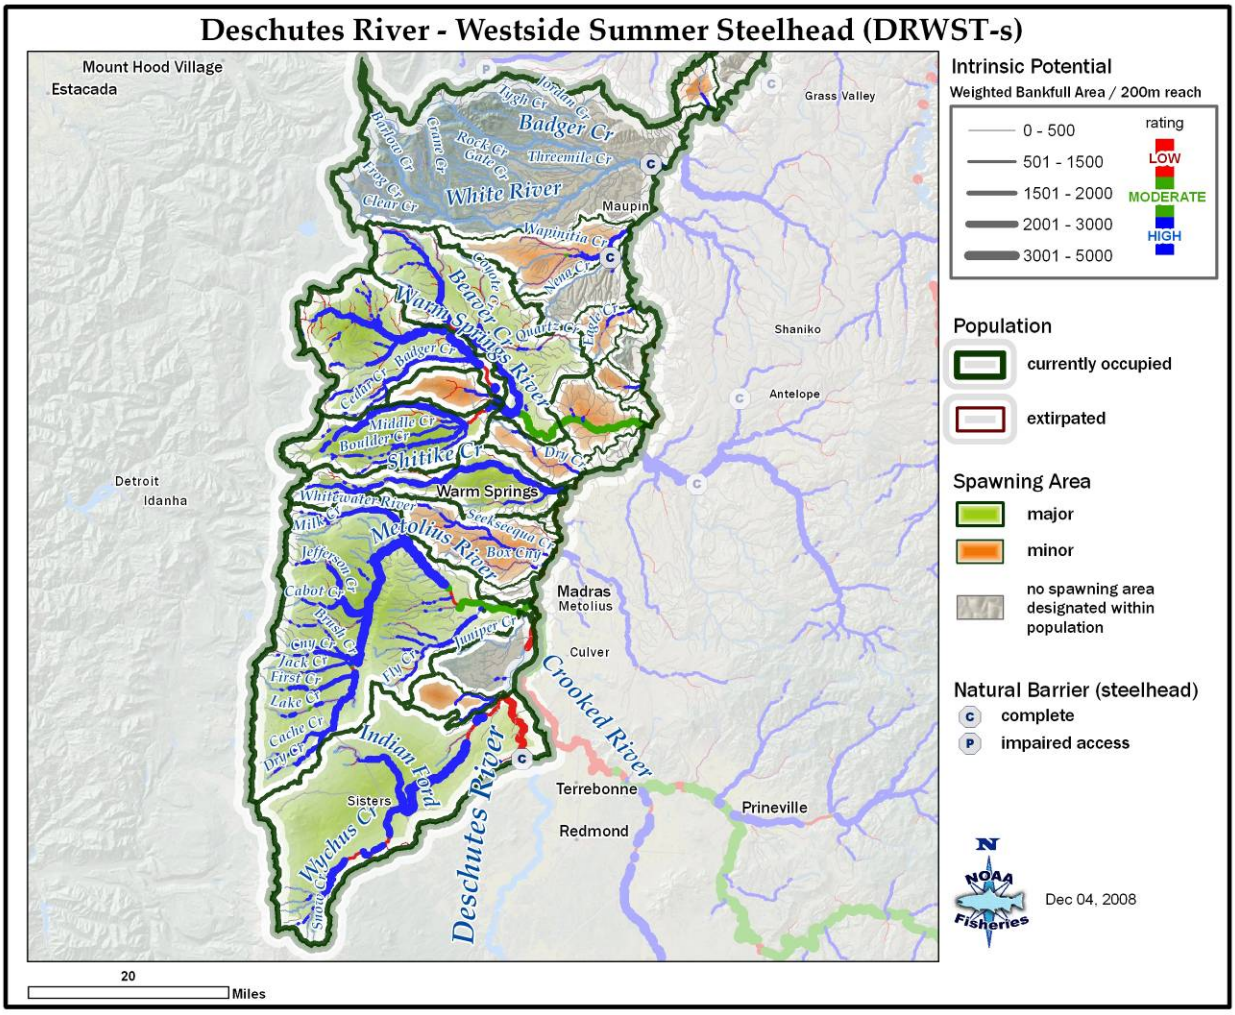

Figure 1. Deschutes River Westside summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas - currently accessible population areas.

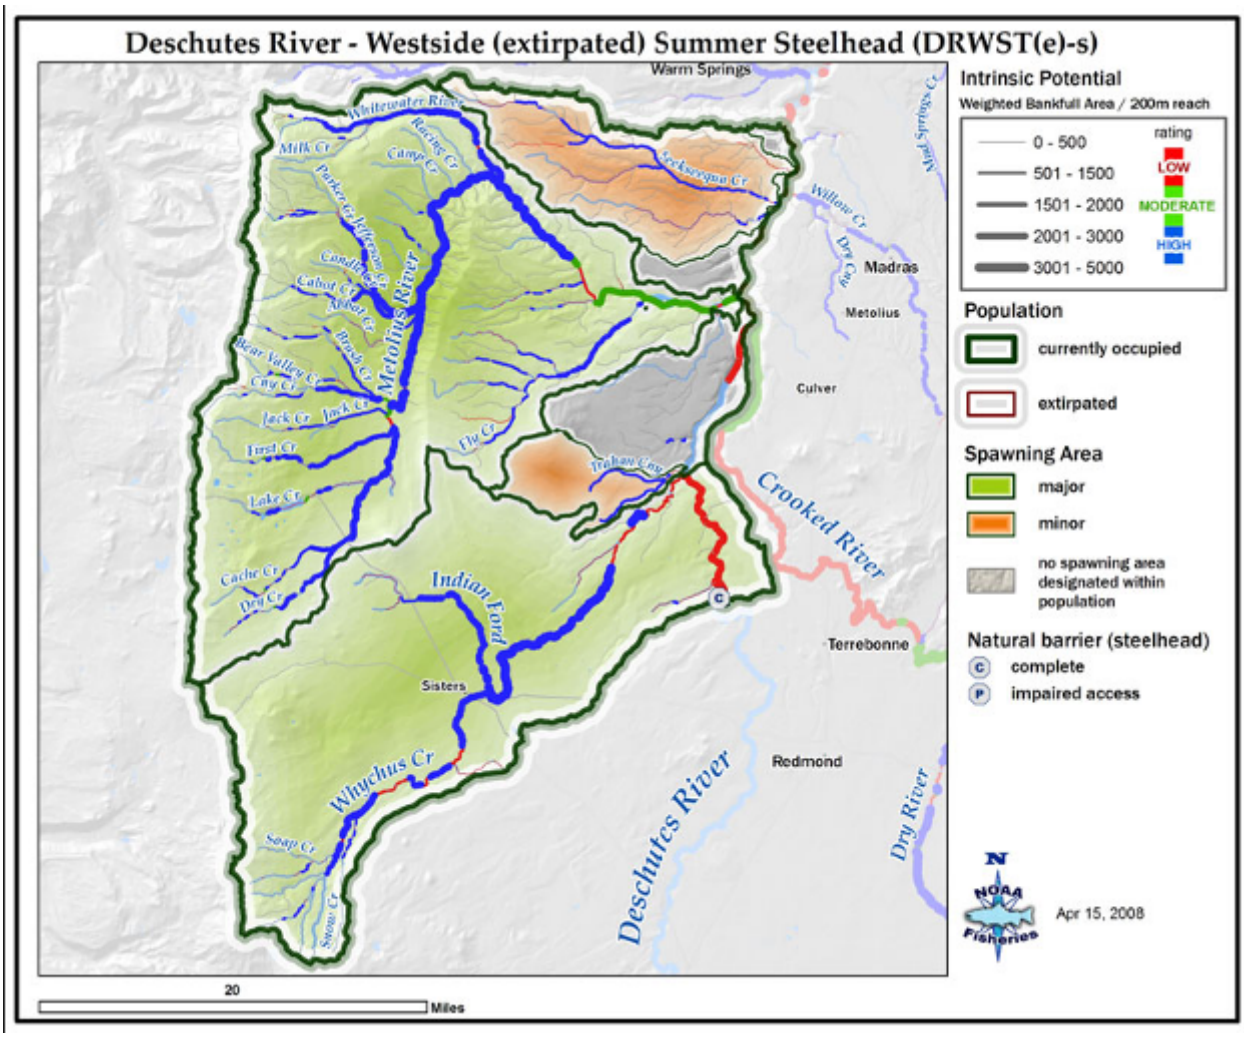

Figure 2. Deschutes River Westside summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas - historically accessible areas.

The Deschutes River Westside population can be classified as either "large" or "intermediate" in size and complexity depending on whether the classification is based on historically accessible habitat or currently accessible habitat. These size category options exist because access to a considerable amount of habitat is blocked by the Pelton-Round Butte dams within the population, with current spawning only below the barrier (Table 3.1.3-1). A steelhead population classified as large has a mean minimum abundance threshold of 1,500 natural-origin spawners with sufficient intrinsic productivity (≥ 1.26 recruits per spawner at the abundance threshold level) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. Alternatively, a steelhead population classified as intermediate has a mean minimum abundance threshold of 1,000 natural-origin spawners with sufficient intrinsic productivity (≥ 1.35 recruits per spawner at the abundance threshold) to achieve a 5% risk of extinction over 100 years. In this assessment we evaluate the population with the abundance/productivity (A/P) criteria for an intermediate sized population that assesses only the habitat below the Pelton Reregulation Dam. However, for the spatial structure/diversity (SS/D) assessment we evaluated the population based on the historic distribution and characteristics. Viable status for this population could not be

achieved using A/P criteria for a large population because current capacity is not adequate to meet abundance criteria.

Table 1. Deschutes River Westside summer steelhead population basin statistics and intrinsic potential analysis summary.

Metric	All areas	Currently Accessible areas
Drainage area (km^2)	6,060	3,619
Stream lengths km (total) [a]	2,230	1,511
Stream lengths km (below natural barriers) [a]	1,474	937
Branched stream area weighted by intrinsic potential (km^2)	5.51	2.65
Branched stream area km^2 (weighted and temp. limited) [b]	5.01	2.24
Total stream area weighted by intrinsic potential (km^2)	8.25	4.56
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	6.61	3.18
Size / Complexity category	Large / "B" (dendritic)	Intermediate / "B" (dendritic)
Number of major spawning areas (MaSAs)	6	4
Number of minor spawning areas (MiSAs)	9	7

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22°C.

Current Abundance and Productivity

Current (1978 to 2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 154 in 1996 to 1,548 in 2003 (Figure 3). Current abundance of natural-origin adult spawners ranged from 108 in 1996 to 1,283 in 2003 (Figure 3). Abundance estimates for the Deschutes River Westside population of adult spawning steelhead are the sum of abundance estimates for three components of the population:

- natural-origin fish upstream of the Warm Springs National Fish Hatchery (NFH) barrier dam at river kilometer (rkm) 16 in the Warm Springs River
- natural-origin and hatchery fish that ascend Shitike Creek
- natural-origin and hatchery-origin fish that remain in the mainstem Deschutes River and spawn from above the mouth of Trout Creek upstream to Pelton Reregulation Dam

The data series begins in the 1978 spawning year with census counts at Warm Springs NFH and in the 1982 spawning year with single pass spawning ground surveys in Shitike Creek index survey units in that cover 67% of the currently used spawning habitat. For the mainstem, single pass aerial surveys were conducted in 1995 and 2001 (Pribyl 1995 and 2001), and multiple pass surveys were conducted in 1996 and 1997 (Zimmerman and Reeves 2000).

To estimate spawning abundance in Shitike Creek, observed redd densities ($redds/m^2$) in surveyed reaches were used to estimate redd densities in unsurveyed areas. Variability in habitat quality and capacity throughout reaches in Shitike Creek is accounted for by using the ICTRT's historical intrinsic potential. The ICTRT intrinsic potential analyses were used to estimate redds per weighted m^2 of habitat in surveyed reaches. To estimate total redds in the population we multiplied the number of redds per weighted m^2 in surveyed reaches by the total weighted m^2 of currently occupied habitat in Shitike Creek (ICTRT 2007). Historical intrinsic potential is

estimated using a simple GIS-based model that accounts for differences across stream reaches in terms of stream width, gradient, and valley width that are further weighted by habitat quality. An expansion of 2.1 fish per redd was used to estimate annual spawner abundance (R. Carmichael, Oregon Department of Fish & Wildlife, personal communication). This estimate was derived for summer steelhead in Deer Creek, a tributary of the Wallowa River. For the 1978-1981 spawning years when spawning ground surveys were not conducted in Shitike Creek, the Shitike Creek abundance was assumed to represent 1.6% of the Sherars Falls escapement based on the average proportional relation between Shitike Creek and Sherars Falls escapement from 1982 to present.

Abundance estimates for the mainstem Deschutes River upstream of Trout Creek also assume 2.1 fish per redd. For years when spawning ground surveys were not conducted in the mainstem, an average relative proportion of observed spawning activity per number of fish escaping above Sherars Falls was applied to the Sherars Falls escapement (1.2%).

Abundance of progeny by spawning year is estimated by apportioning the total spawning abundance estimate into hatchery- and natural-origin fish. The proportion of hatchery fish entering Shitike Creek to spawn and hatchery fish remaining in the mainstem upstream of Trout Creek is assumed to be identical to the proportion of hatchery fish observed at the Warms Springs NFH barrier.

Virtually no spawning steelhead in the Deschutes River Westside population have been sampled for age-at-return, and no population specific information exists to assign natural-origin spawners into cohorts to estimate abundance of progeny (Anonymous 2004). Age structure information used to estimate progeny by brood year is based on the average of a two-year sample of scales from natural-origin adult steelhead (N=100) collected in the lower Deschutes River (Olsen, et al., 1991).

Recent year natural spawners include returns originating from naturally spawning parents, strays from the Deschutes Subbasin Round Butte Hatchery program, and a significant number of out-of-DPS hatchery strays from the Snake River. Natural-origin spawners have comprised an average of 82% of naturally spawning fish since 1978. The percentage of natural-origin spawners has ranged from 57% to 97%.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 456 (Table 2). During the period 1980-1999, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Deschutes River Westside population ranged from 0.24 in 1987 to 3.72 in 1996. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 20-year (1979-1998) geometric mean productivity was 1.05 R/S, adjusted for SAR and delimited at 75% (750 spawners) of the minimum abundance threshold (Table 2).

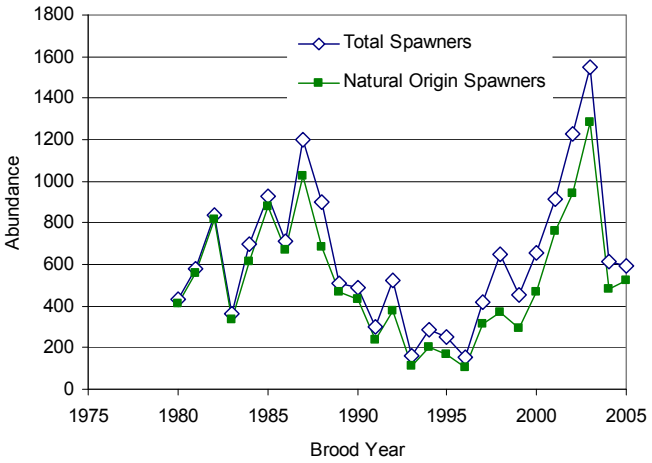

Figure 3. Deschutes River Westside summer steelhead population spawner abundance estimates (1978-2005).

Table 2. Deschutes River Westside summer steelhead population abundance and productivity estimates.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	456	(108-1283)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.75	(0.57-0.97)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (20-year R/S, SAR adjusted & delimited) [a]	1.05	(0.81-1.37)	0.15
Productivity (20-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	0.99	(0.96-1.17)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	0.97	(0.78-1.20)	0.35
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.02	(0.81-1.29)	0.58

a. Delimited productivity excludes any recruit/spawner pair where the spawner number > 75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Deschutes River Westside population is at **High Risk** based on current abundance and productivity. The point estimate for abundance and productivity resides below the 25% risk curve (Figure 4). The upper end of the 90% confidence interval (CI) for productivity extends slightly above the 25% risk curve but is not significant enough to lower the risk rating.

The average trend in abundance over the most recent 20 years has been just below 1.0 based on both the trend in ln(natural-origin spawner abundance) and the population growth

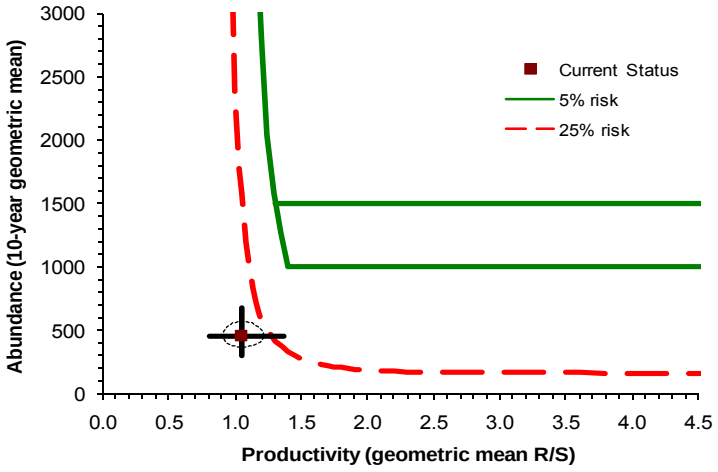

Figure 4. Deschutes River Westside summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

rate metric (λ) with no adjustment for relative hatchery-origin spawner effectiveness (Table 2). The pattern in returns from 1991 through 2005 is similar to the pattern for several other Mid-Columbia DPS steelhead populations, including the Deschutes River Eastside; an increasing trend beginning in 1996 followed by an abrupt decrease to levels observed in the early 1990s. The estimated proportion of hatchery-origin spawners has been relatively constant at 25% over this time period (Table 2). The relative effectiveness of hatchery-origin spawners in contributing to natural production in this population is not known. The estimated population growth rate calculated for this population is sensitive to the input value for relative hatchery effectiveness. Setting the value to 0.0, the opposite extreme from 1.0, results in an estimated annual growth rate of 1.02 (0.58 probability of exceeding 1.0).

Spatial Structure and Diversity

The ICTRT has identified six major spawning areas (MaSAs) and nine minor spawning areas (MiSAs) in the historically accessible habitat within the Deschutes River Westside steelhead population (Figure 5). In the currently accessible habitat there are four MaSAs and seven MiSAs (Figure 6). The Metolius River is identified as a MaSA in the historically accessible habitat; however there is considerable uncertainty regarding the magnitude of historical steelhead production in this river. Recent conclusions reached by Cramer and Beamsderfer (2001) suggest that the primary *O mykiss* life history form in the Metolius River was resident and it is likely that little steelhead production occurred. When we conducted the spatial structure/diversity assessment, we did not consider the Metolius River as a MaSA due to the uncertainty in historical use. Current distribution is reduced significantly from the historic distribution as a result of loss of accessibility to the Whychus Creek drainage.Spawning is currently concentrated in the Warm Springs River and Shitike Creek, as well as in the mainstem Deschutes River between Trout Creek and Pelton Reregulation Dam.

Spawners within the Deschutes River Westside population include natural-origin returns, hatchery returns of Deschutes River origin fish produced from Round Butte Hatchery, and out-of-DPS hatchery strays primarily from the Snake River basin. Hatchery-origin fish comprise a significant proportion of the natural spawners in Shitike Creek and the Deschutes River mainstem. Hatchery fish are removed from returns to the Warm Springs River at Warm Springs NFH, which reduces the proportion of naturally spawning hatchery fish in the population.

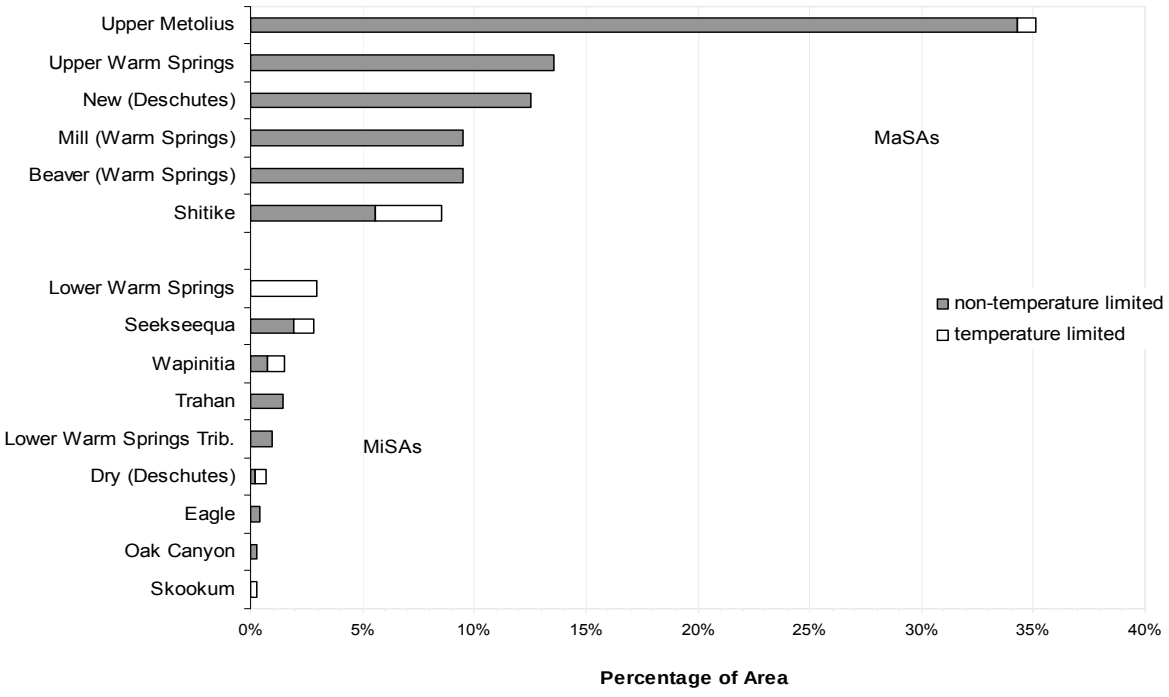

Figure 5. Deschutes River Westside summer steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs). White bars represent current temperature limited areas that could potentially have had historical temperature limitations. This figure is based on *historically* accessible areas within the population.

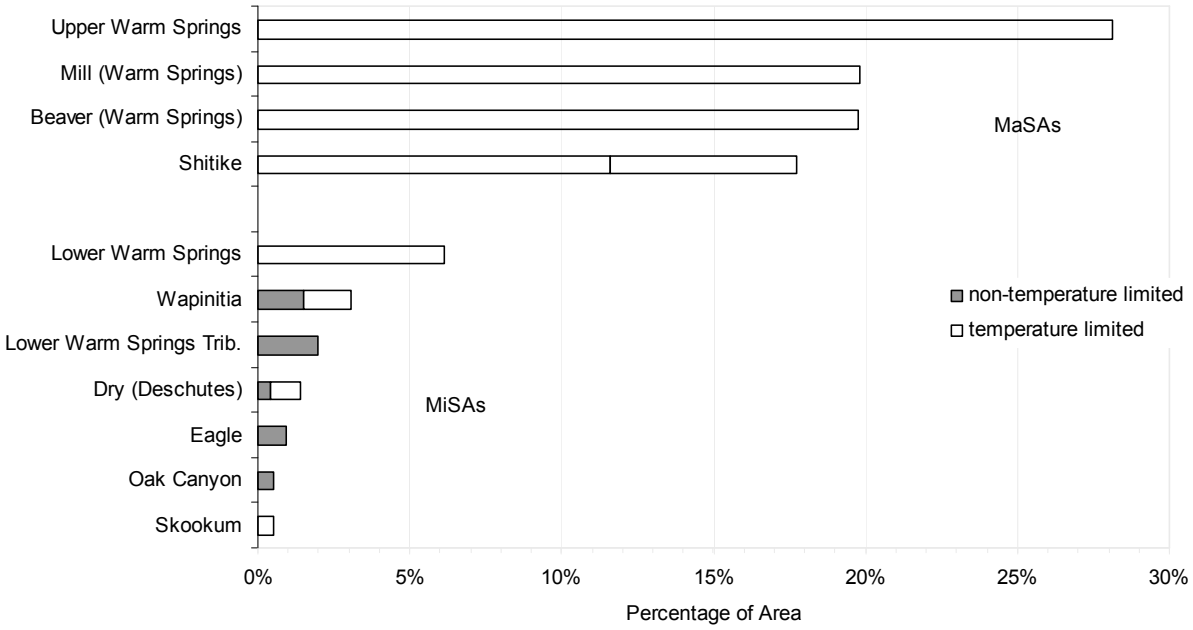

Figure 6. Deschutes River Westside summer steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs). White bars represent current temperature limited areas that could potentially have had historical temperature limitations. This figure is based on *currently* accessible areas within the population.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Deschutes River Westside population has five MaSAs and nine MiSAs distributed in a dendritic pattern. The historic primary production areas include the Warm Springs River, Shitike Creek, Whychus Creek, and the Deschutes River mainstem. Based on the Oregon Department of Fish and Wildlife (ODFW) current spawner distribution database, four of the five historic MaSAs are currently occupied and four of the nine MiSAs are occupied. The Deschutes River Westside population is rated at **very low risk** for this metric.

A.I.b. Spatial extent or range of population

The current spawner distribution is reduced substantially from the historic intrinsic distribution. One of the five historic MaSAs (Whychus) is currently unoccupied. In addition, only four of the nine MiSAs are occupied (Figures 7 and 8). The population is rated at **low risk** because 80% of the MaSAs are occupied. There are index spawning surveys conducted in the Warm Springs River drainage and the Shitike Creek drainage. Results of these surveys will be evaluated for future viability assessments.

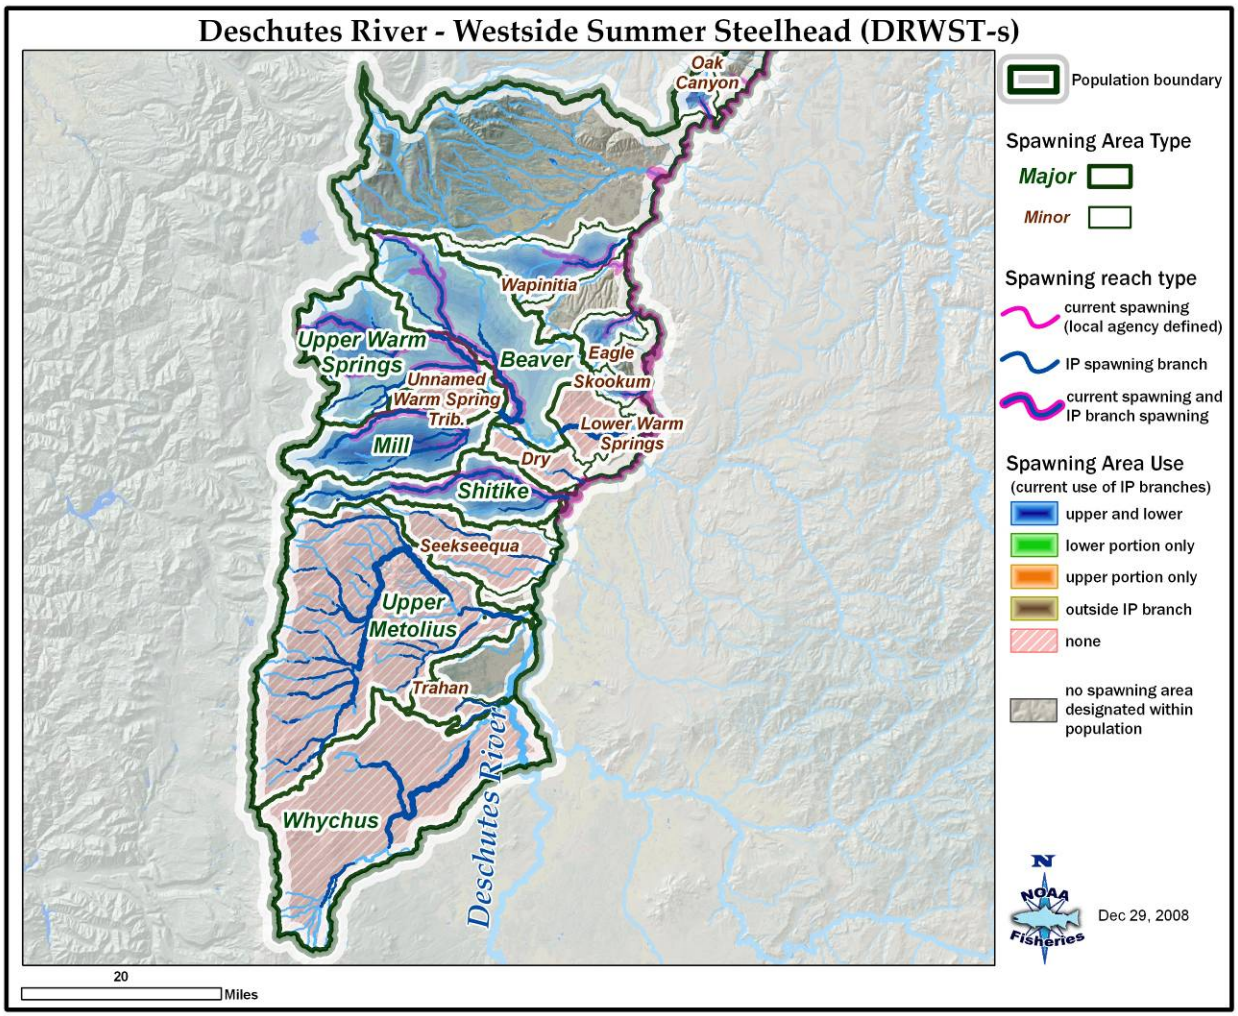

Figure 7. Deschutes River Westside summer steelhead population current spawning distribution and spawning area occupancy designations. This figure is based on currently accessible areas.

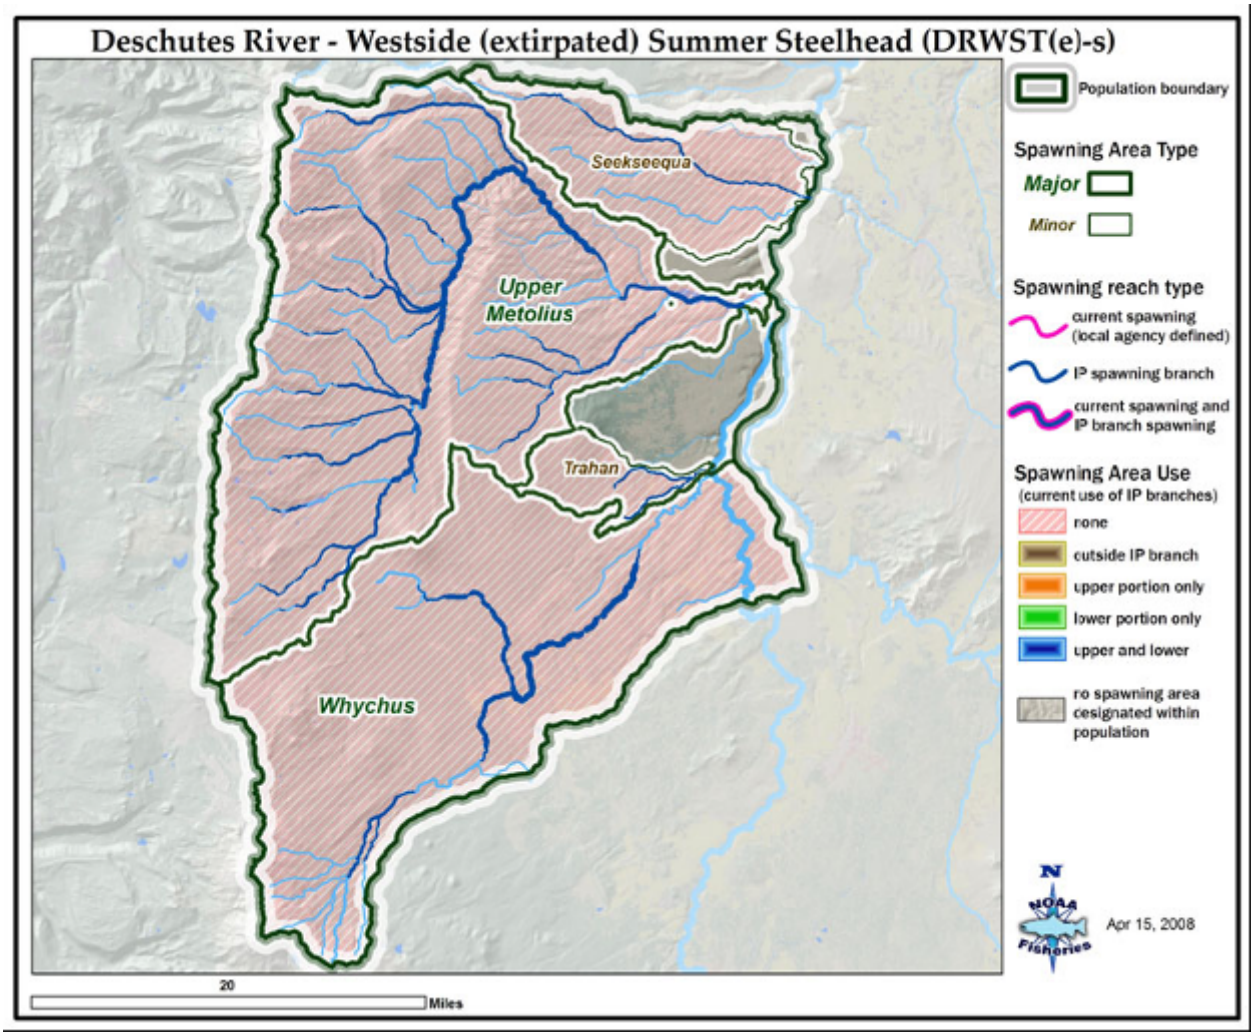

Figure 8. Deschutes River Westside summer steelhead population current spawning distribution and spawning area occupancy designations. This figure is based on historically accessible areas.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There has been a substantial change in gaps between, and continuity within, the spawning areas in the Deschutes River Westside population. The loss of occupancy in the Whychus MaSA has resulted in loss of production in the entire upper area of the population. The population is rated at **moderate risk** for this metric.

B.1.a. Major life history strategies

There are limited data to allow any direct comparisons of historic and current major life history strategies. Current habitat conditions are such that the potential for diverse juvenile life history patterns, such as movement between tributary and mainstem, as well as tributary and mainstem rearing, are possible. The population demonstrates multiple ages of smolt migration and ocean residence time. It does not appear likely that any loss in variability or change in major life

history strategies has occurred for this population. Thus, the population rated at **very low risk** for this metric.

B.1.b. Phenotypic variation

We have no direct observations to assess loss or substantial changes in phenotypic traits, therefore we must infer from habitat conditions. However, there does not appear to be the level of habitat changes within the basin that would result in loss of any major traits or substantial shifts in the mean of multiple traits. It is likely that flow and temperature changes in the mainstem Columbia River, as well as temperature changes within the Deschutes River subbasin, have influenced adult migration timing as well as smolt migration timing to a small degree. Thus, we have rated the population at **low risk** for this metric.

B.1.c. Genetic variation

There are only a few samples available from the Deschutes River Westside population, and those that are available are from a small tributary, Nena Creek. These samples show similarity to both the Deschutes River Eastside population samples and to out-of-population hatchery samples. Primarily on the basis of limited information and apparent similarity to the out-of-population hatchery samples, we have rated the population at **moderate risk** for this metric. Additional tissue samples have been collected and will be analyzed in the near future. The genetics variation metric will be reassessed for this population following the completion of analyses of the recent samples.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners*: A significant number of out-of-DPS strays spawn naturally in the Deschutes River Westside population. Estimates of strays are derived from stray hatchery proportions and stray origin data collected at the Warm Springs NFH trap and expanded to unsampled areas in the population. Hatchery fish are removed at the Warm Springs NFH, thus the overall hatchery proportion in the population is less than the proportion observed at Warm Springs NFH. The majority of stray hatchery fish at Warm Springs NFH are out-of-DPS strays. We estimated that hatchery strays have comprised 18% of the natural spawners in the population since 1978. Of the 18%, about 15.2% were estimated as out-of-DPS strays, primarily from the Snake River basin. We were unable to acquire stray origin data for the most recent years, thus we will update the risk rating when the data are received. Given the high proportion and the length of time that out-of-DPS hatchery strays have been present in this population, the rating is **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS*: There have been few out-of-MPG within-DPS strays recovered in the Deschutes River. The only source for this type of stray fish is from the Umatilla Hatchery program. This metric rated at **low risk** due to the low proportion of strays.

(3) *Out-of-population spawners from within the MPG*: There have been no observed strays originating from hatchery programs operated outside the Deschutes River subbasin but within the MPG. The rating is **very low risk**.

(4) *Within-population hatchery spawners:* The Round Butte Hatchery program operates as a harvest augmentation program within the Deschutes River subbasin and does not use best management practices as described for supplementation programs. Round Butte Hatchery fish are present in the naturally spawning population at low levels with an average of 2.8% since 1978. We have rated the metric at **moderate risk** because of the low proportion of hatchery fish in the natural spawning population.

The overall spawner composition rating is **high risk** due to the high proportion of out-of-DPS strays that spawn naturally in this population.

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution within historically accessible habitat encompassed seven ecoregions (Figures 9 and 10), of which four accounted for 10% or more of the distribution (Table 3). There has been no substantial shift in ecoregion distribution from the historic intrinsic to the current distribution (Table 3). The population rated as **very low risk** because there are four ecoregions with no substantial change in proportional distribution.

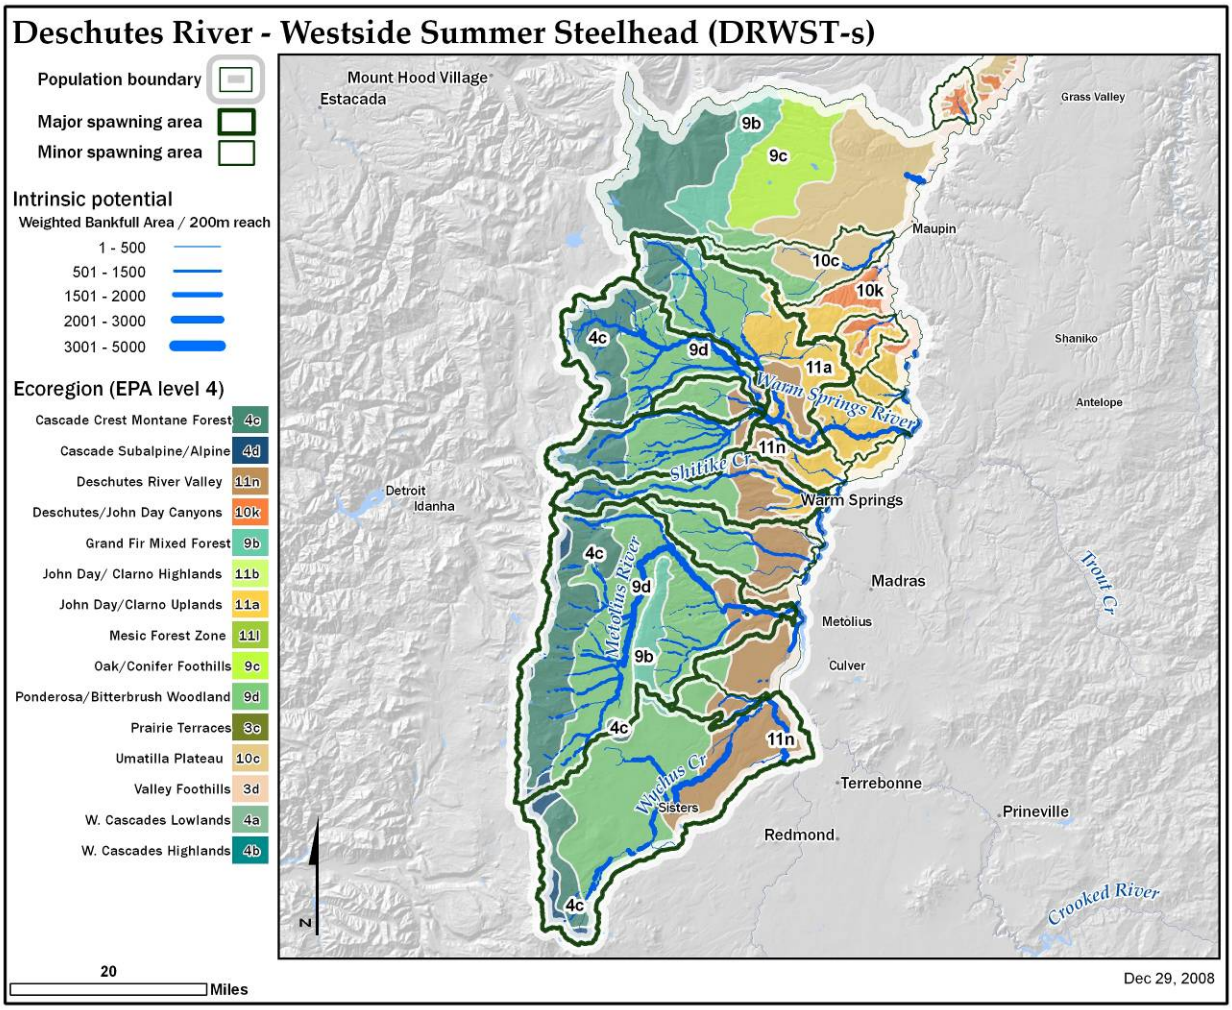

Figure 9. Deschutes River Westside summer steelhead population spawning distribution across EPA level IV ecoregions. This figure is based on currently accessible areas.

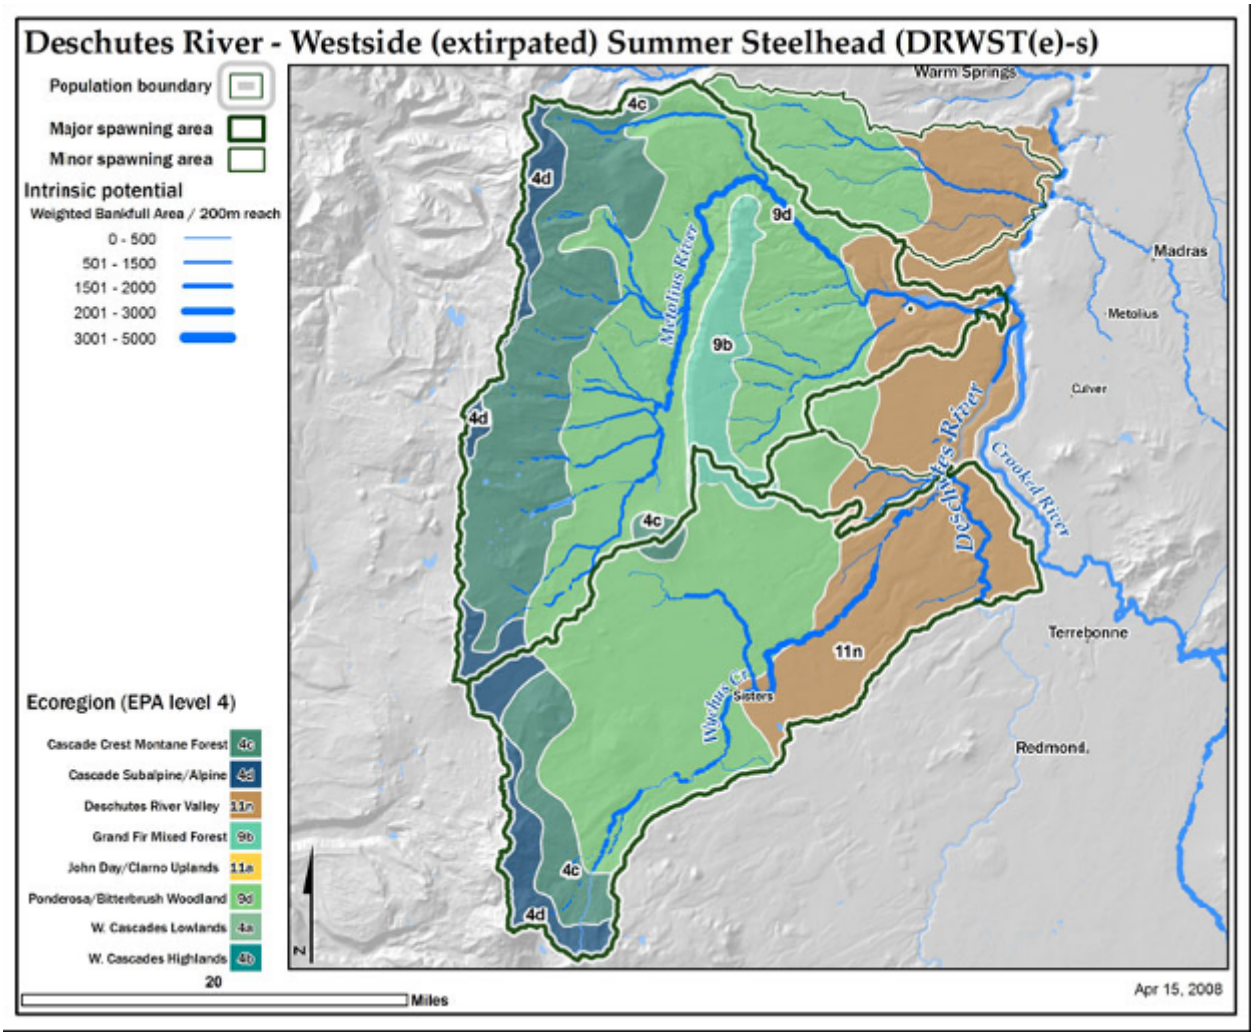

Figure 10. Deschutes River Westside summer steelhead population spawning distribution across EPA level IV ecoregions. This figure is based on historically accessible areas.

Table 3. Deschutes River Westside summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of *historical* spawning area (non-temp. limited) ALL AREAS	% of *currently* occupied spawning area (non-temp. limited) ALL AREAS	% of *historical* spawning area (non-temp. limited) CURRENTLY OCC. AREAS	% of *currently* occupied spawning area (non-temp. limited) CURRENTLY OCC. AREAS
Umatilla Plateau	1.7	4.0	3.0	4.0
Deschutes/John Day Canyons	10.9	27.4	19.6	27.4
John Day / Clarno Uplands	13.0	19.3	23.4	19.3
Deschutes River Valley	18.3	7.3	7.1	7.3
Cascade Crest Montane Forest	8.2	4.7	10.1	4.7
Grand Fir Mixed Forest	0.3	0.5	0.6	0.5
Ponderosa Pine / Bitterbrush Woodland	47.6	36.8	36.1	36.8

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes two dams in its seaward and spawning migrations, thus impacts on this population are relatively low. No traits are selectively affected by hydropower activity to the degree that they raise the risk level for this population. The hydropower rating is **low risk** for all traits.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is no selective impact of the recreational fishery. No phenotypic traits appear to be at risk as a result of harvest activity and the rating is **low risk** for all traits.

Hatcheries: There is a hatchery program operated within this population. Hatchery broodstock are collected at Pelton Dam and no natural-origin fish are collected. Broodstock are collected in a manner which results in no selective impact for any adult phenotypic traits. The population is rated at **very low risk** of selective hatchery actions for all traits.

Habitat: Altered flow profiles and increased temperatures in tributary spawning and rearing areas, which have been in place for many generations and are ongoing, likely impose some selection on juvenile and adult migration timing, as well as spawn timing. However, the magnitude of selective mortality is likely negligible; therefore the habitat rating for all traits is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food

availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selection is **low risk**.

No single trait has a moderate risk rating for any selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** for the Deschutes River Westside population (Table 4). The population rates at moderate risk for one of the spatial distribution metrics (Goal A: **low risk** overall) because the current distribution is substantially reduced from the historic intrinsic distribution due to blocked passages to areas above the Pelton-Round Butte Complex. Ratings for two diversity metrics resulted in a **moderate risk** rating for Goal B (maintaining natural patterns of variation). Genetic variation rated moderate due to limited data and the lack of differentiation between the Deschutes River samples and outside-basin hatchery samples. Samples collected in 2005-2006 will better inform the risk associated with genetic variation. The proportion of out-of-DPS hatchery strays resulted in a high risk rating for spawner composition. Most of these strays originate from the Snake River basin.

Overall Viability Rating

The Deschutes River Westside steelhead population does not currently meet the ICTRT recommended viability criteria and the overall viability rating is considered **HIGH RISK** (Figure 11). Overall abundance and productivity is rated at **High Risk.** The 10-year geometric mean abundance of natural-origin spawners is 456, which is only 46% of the minimum abundance threshold of 1,000. The 20-year geometric mean productivity (1.05 R/S; Table 6) is below the viability minimum of 1.35 R/S required for an intermediate sized population. A substantial increase in productivity will be required to raise the productivity value to the low risk level. The overall spatial structure and diversity rating is at **Moderate Risk**. The genetics information that is currently being collected will better inform the genetics variation risk level in the future. A reduction in the proportion of naturally spawning out-of-DPS hatchery strays will be needed to reduce the risk rating for the spawner composition metric.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**

Data Summary – Deschutes River Westside Summer Steelhead Population

Data type: Expansions from single pass surveys, Warm Springs weir count. Annual index area counts expanded to total population abundances using ratio of total to index area weighted intrinsic habitat (ICTRT 2007 Appendix C). Assumed 2.1 fish per redd.

SAR: Mid-Columbia steelhead composite series (see *Methods* section).

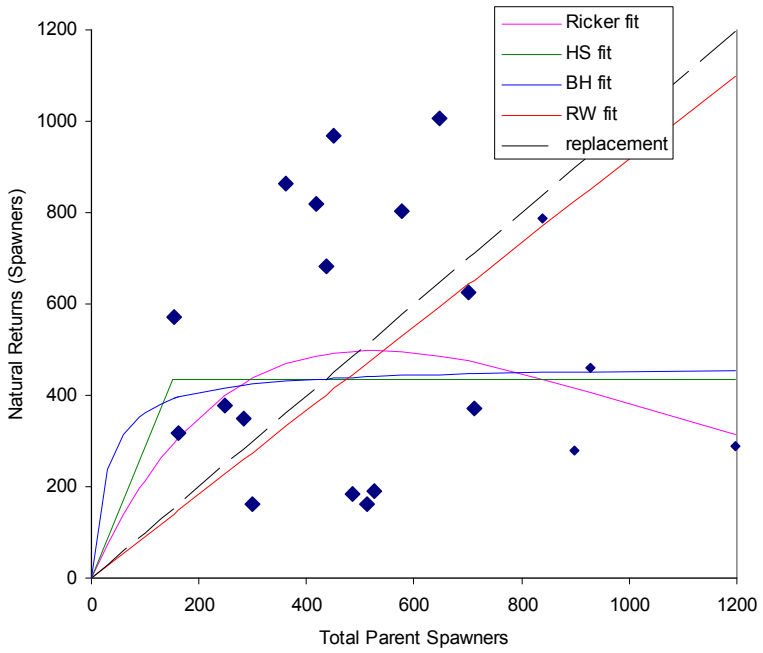

Figure 12. Deschutes River Westside summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were not adjusted for marine survival.

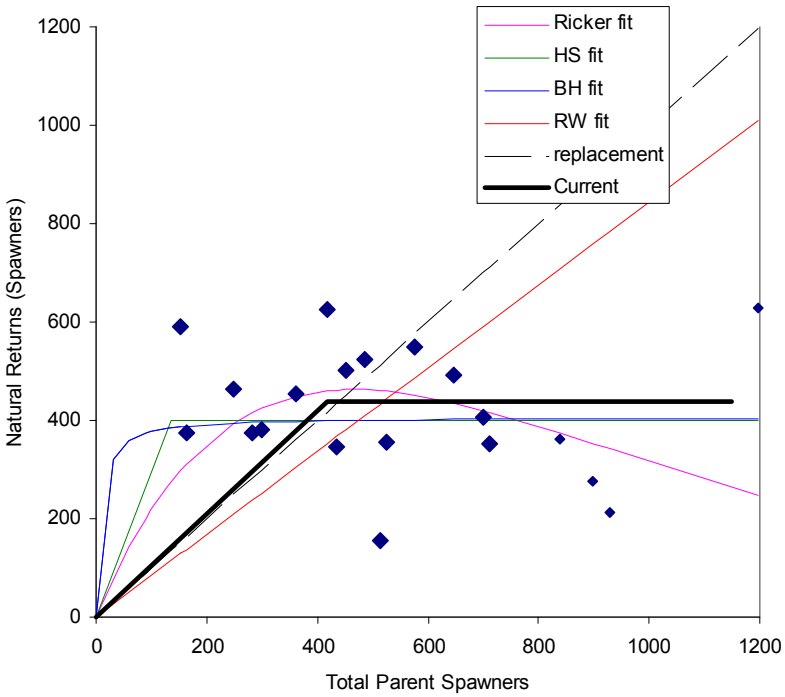

Figure 13. Deschutes River Westside summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Crooked River Summer Steelhead Population

The functionally extirpated Crooked River summer steelhead population (Figure 1), located entirely above the Pelton Reregulation Dam in the Deschutes River subbasin, was historically part of the Cascades Eastern Slope Tributaries MPG within the Mid-Columbia steelhead DPS.

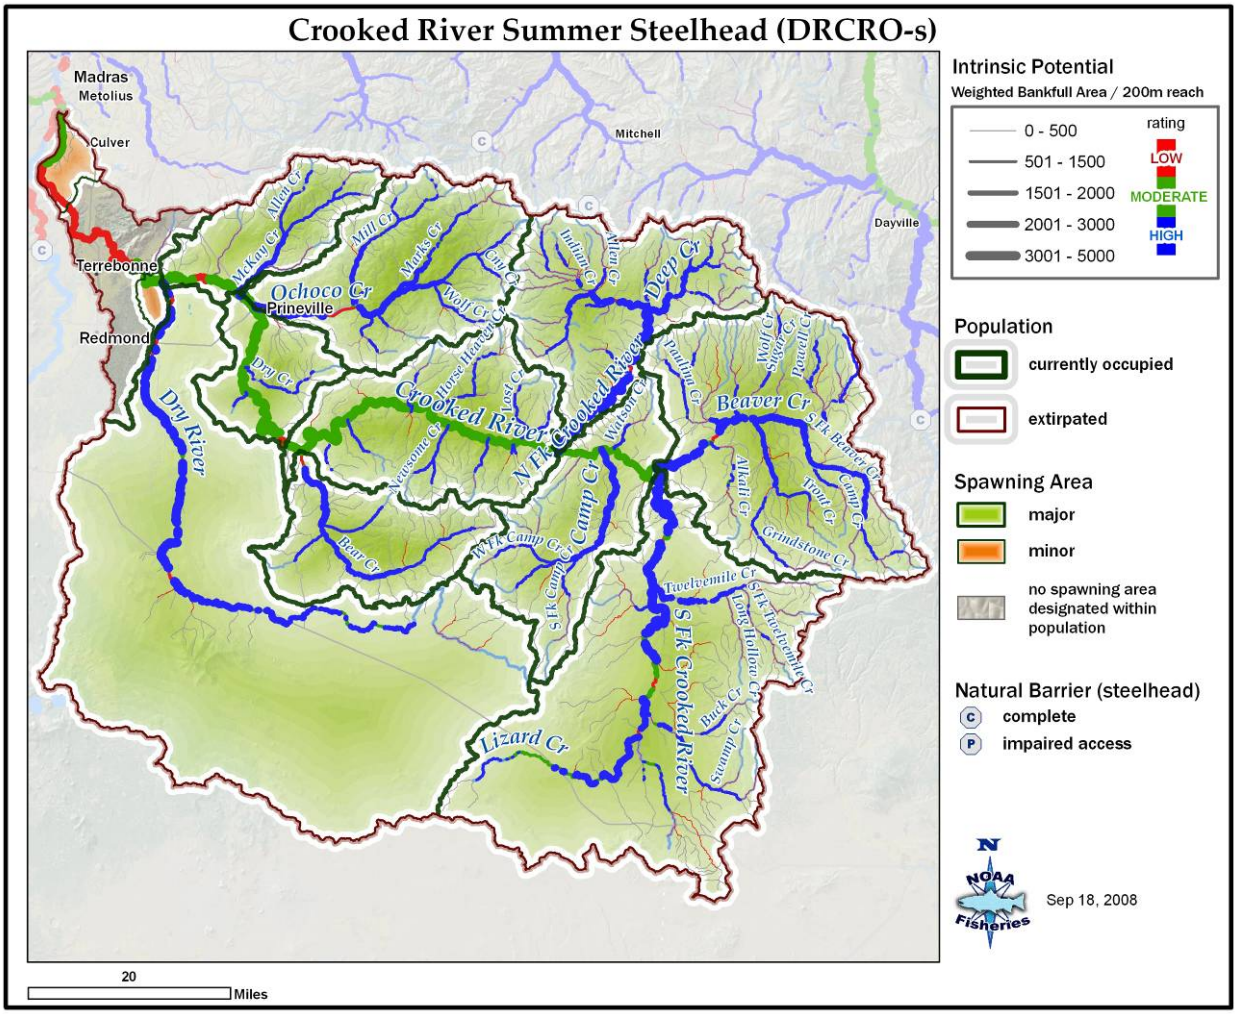

Figure 1. Crooked River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Crooked River population as "very large" in size and complexity (Table 1). A steelhead population classified as very large has a mean minimum abundance threshold of 2,250 natural-origin spawners with sufficient intrinsic productivity (≥ 1.19 recruits per spawner at the abundance threshold level) to achieve a 5% or less risk of extinction over a 100-year timeframe. In order for the Crooked River population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 14 recruits per spawner at the minimum abundance threshold.

Table 1. Crooked River summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	11,832
Stream lengths km (total) [a]	2054

a. All stream segments ≥3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

The Crooked River steelhead population is currently extirpated. Steelhead distribution was restricted in Crooked River by construction of Ochoco Dam at RM 10 in 1921 and further by Bowman Dam (RM 70) constructed in 1961. Access to habitat above RM 100 on the mainstem Deschutes River was blocked entirely by 1968 due to inadequate passage at the Pelton and Round Butte dams, thus terminating access to the Crooked River drainage.

Spatial Structure and Diversity

The ICTRT has identified ten major spawning areas (MaSAs) and two minor spawning areas (MiSAs) within the Crooked River steelhead population (Figure 3.1.7–2). The population boundaries are completely above the Pelton Reregulation Dam and, therefore, all areas are currently inaccessible.

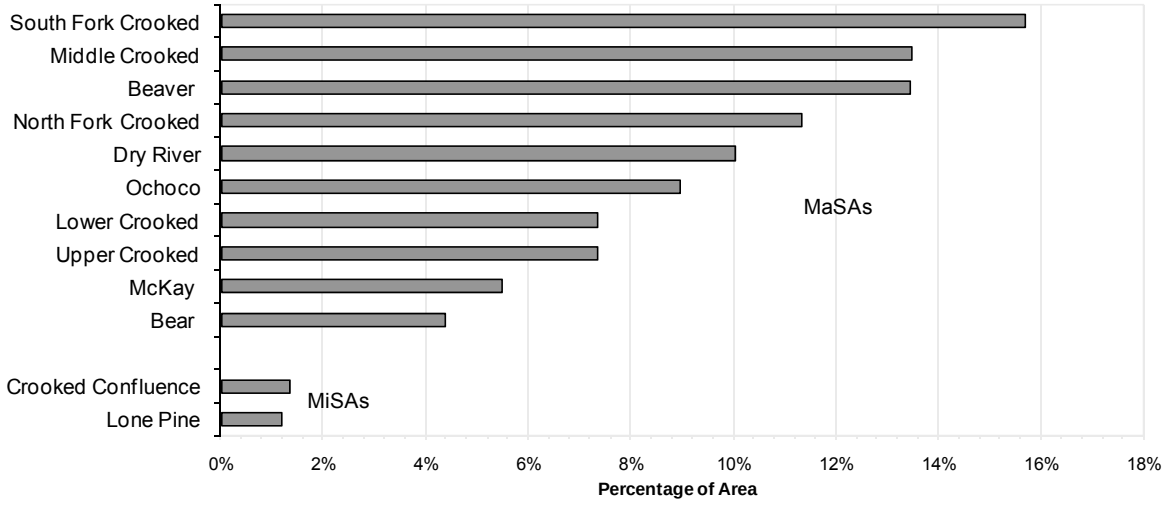

Figure 3.1.7– 2. Crooked River summer steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor (MiSAs) spawning areas. There are no areas in this population that could potentially have had historical temperature limitations.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Crooked River population has ten MaSAs and two MiSAs distributed in a dendritic pattern. All areas within this population have been extirpated due to the Pelton Reregulation Dam. Reintroduction of steelhead into the Crooked River subbasin is currently being planned.

A.l.b. Spatial extent or range of population

There is no current spawner distribution. All areas above the Pelton Reregulation Dam, including the Crooked River population, have been extirpated (Figure 3).

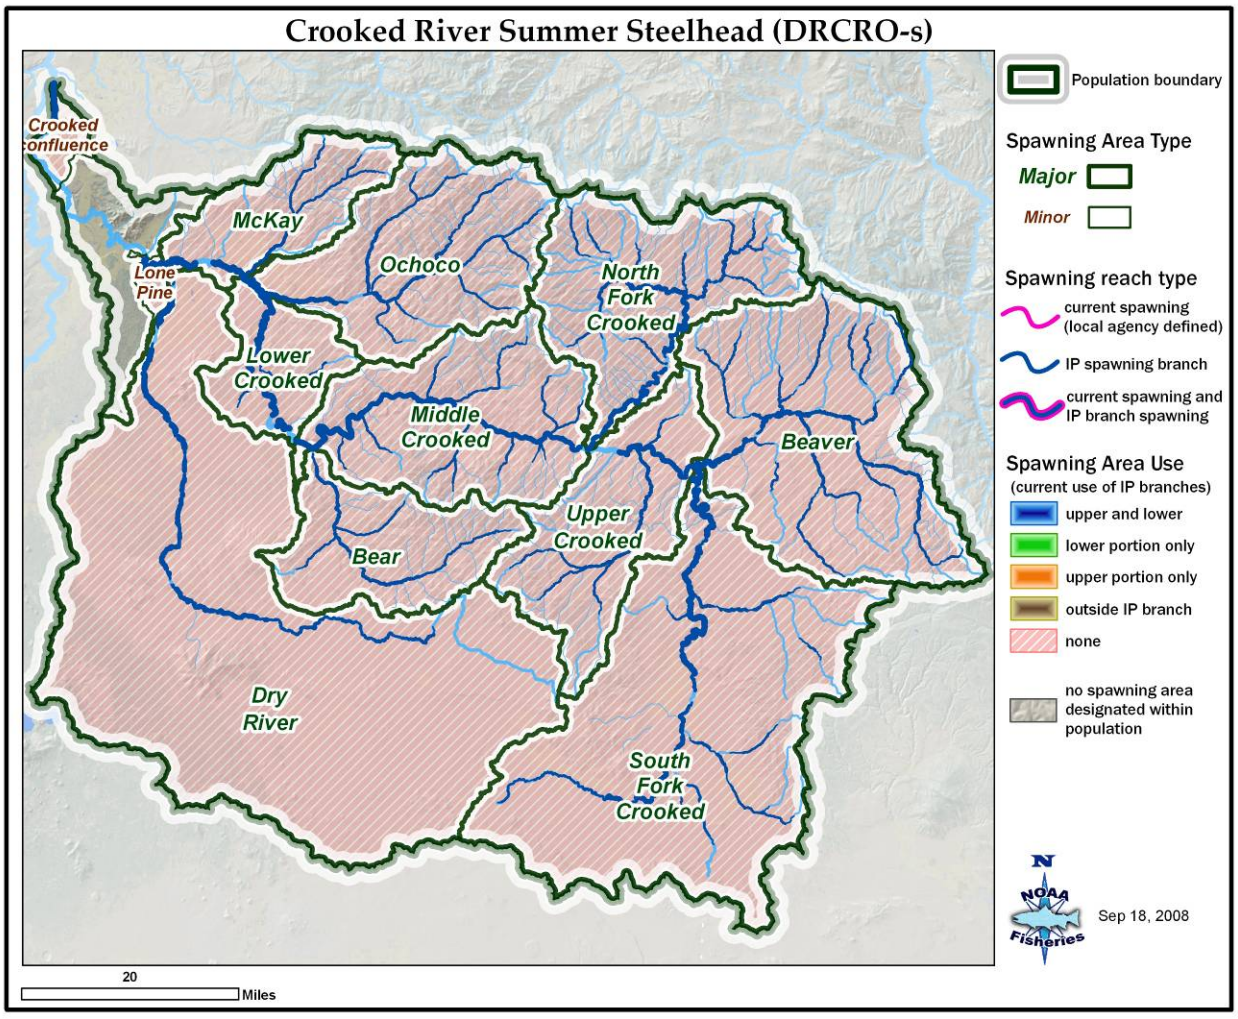

Figure 3. Crooked River summer steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

This population is functionally extirpated and is therefore not rated.

B.1.a. Major life history strategies

There are no data to allow any direct analyses of historic major life history patterns. This population is functionally extirpated and is therefore not rated.

B.1.b. Phenotypic variation

We have no direct observations to assess historic phenotypic traits. This population is functionally extirpated and is therefore not rated.

B.1.c. Genetic variation

There are no genetics data for the Crooked River population. This population is functionally extirpated and is therefore not rated.

B.2.a. Spawner composition

This population is functionally extirpated and is therefore not rated.

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution encompassed eight ecoregions, of which three accounted for greater than 10% of the distribution (Figure 4). The Crooked River steelhead population is extirpated and therefore no ecoregions are currently occupied.

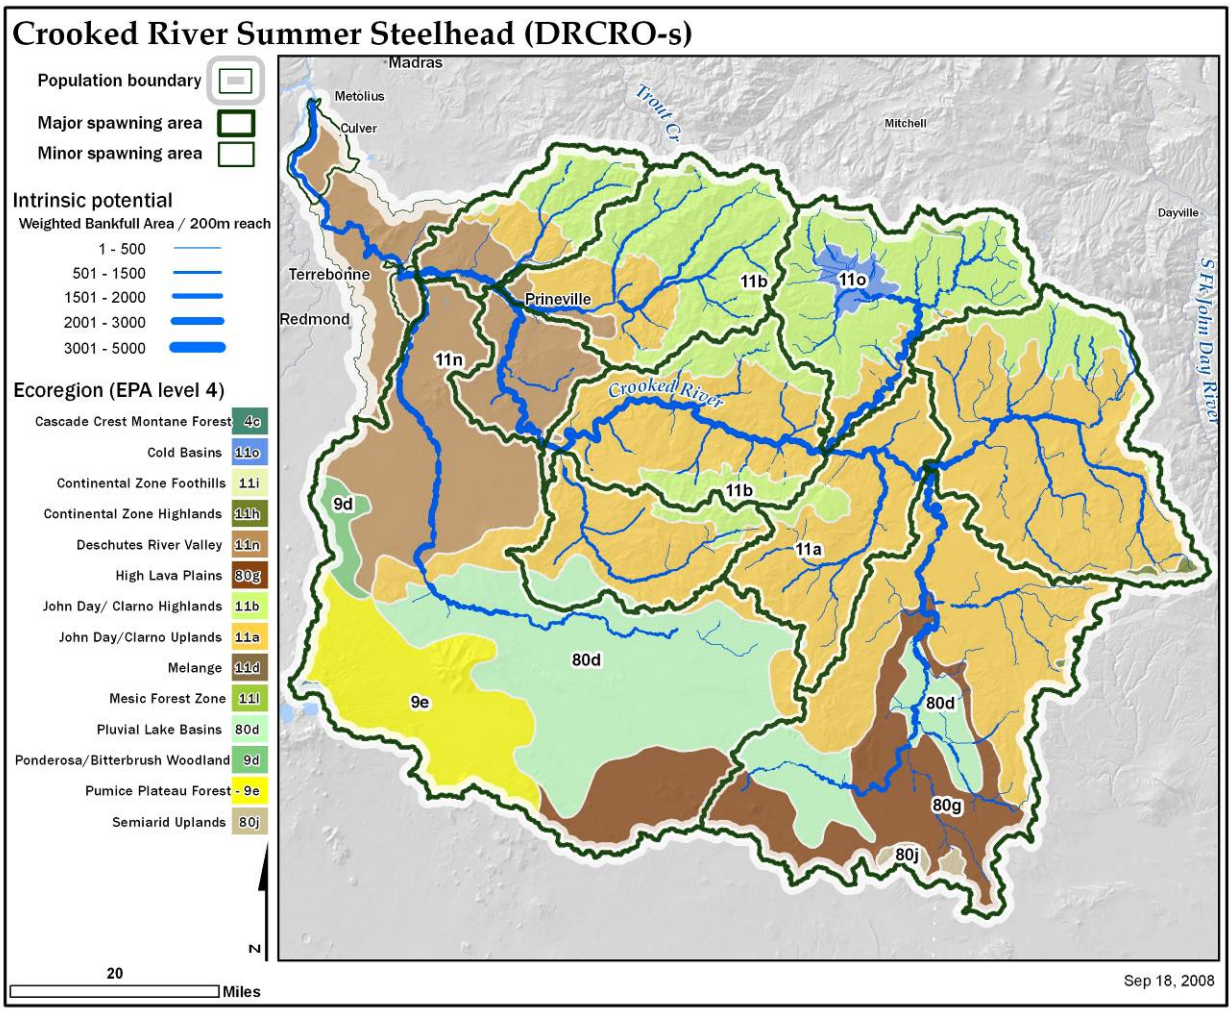

Figure 4. Crooked River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 2. Crooked River summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
John Day Clarno Uplands	46.7	0
John Day Clarno Highlands	13.2	0
Continental Zone Highlands	0.03	0
Mesic Forest Zone	0.04	0
Deschutes River Valley	22.53	0
Cold Basins	2.11	0
Pluvial Lake Basins	7.45	0
High Lava Plains	4.98	0

B.4.a. Selective change in natural processes or selective impacts

This population is functionally extirpated and is therefore not rated.

Spatial Structure and Diversity Summary

The Crooked River summer steelhead population is not rated for spatial structure and diversity since it is considered to be functionally extirpated.

Overall Viability Rating

The Crooked River summer steelhead population does not have an overall viability rating since it is considered to be functionally extirpated.

Lower Mainstem John Day River Summer Steelhead Population

The Lower Mainstem John Day River summer steelhead population (Figure 1) is one of five populations in the John Day River MPG within the Mid-Columbia steelhead DPS. All five populations in the John Day River MPG are summer run.

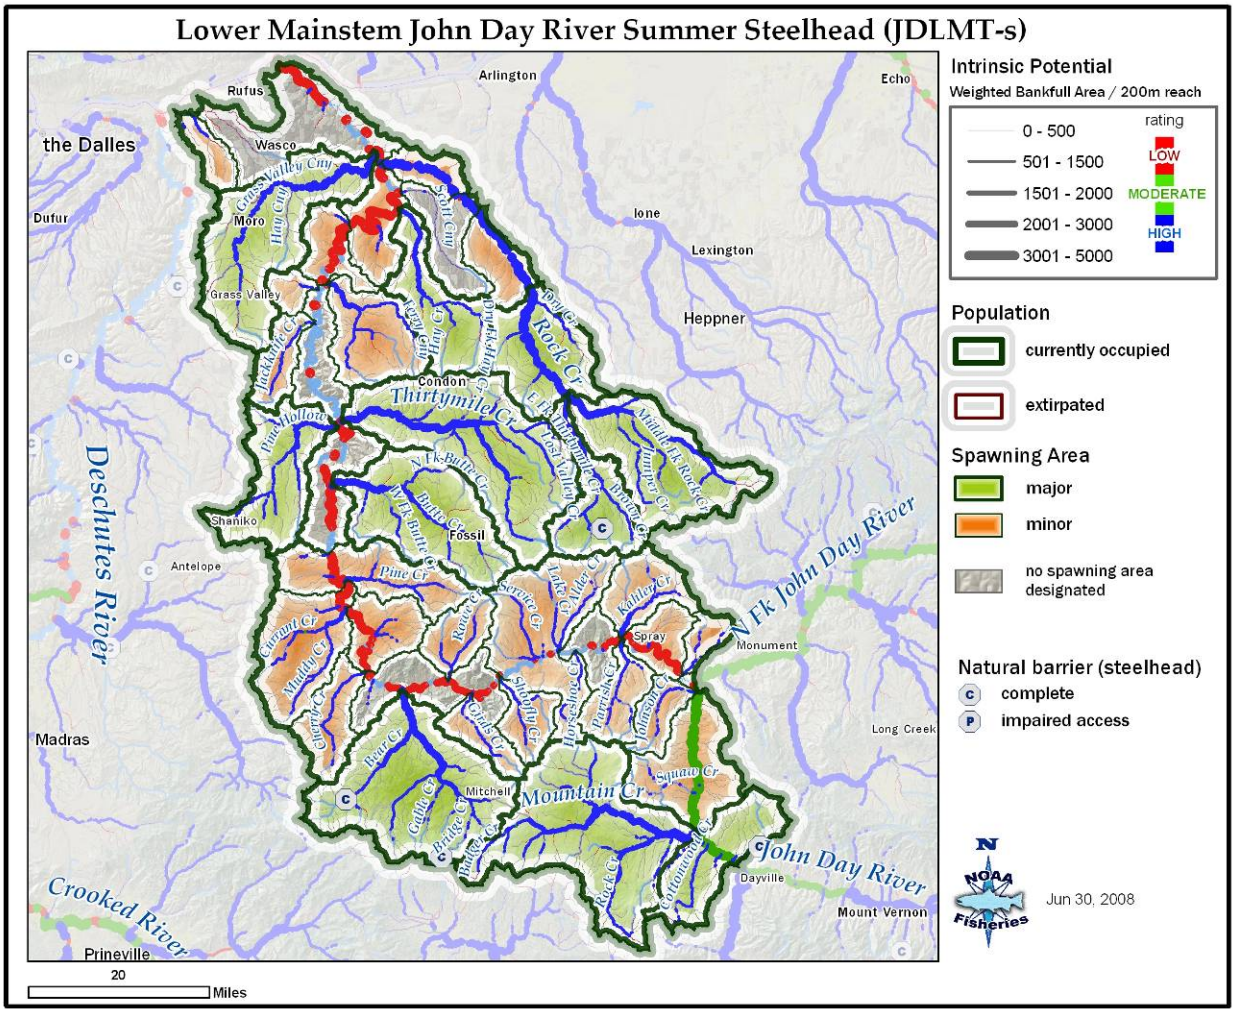

Figure 1. Lower Mainstem John Day River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Lower Mainstem John Day River population as "very large" in size and complexity (Table 1) based on historical habitat potential (ICTRT 2007). A steelhead population classified as very large has a minimum abundance threshold criteria of 2,250 natural-origin spawners with sufficient intrinsic productivity (≥ 1.19 recruits per spawner at the threshold abundance level) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the Lower Mainstem population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.41 recruits per spawner at the minimum abundance threshold.

Table 1. Lower Mainstem John Day River summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	9,857
Stream lengths km (total) [a]	2,455
Stream lengths km (below natural barriers) [a]	2,411
Branched stream area weighted by intrinsic potential (km^2)	6.778
Branched stream area km^2 (weighted and temp. limited) [b]	5.065
Total stream area weighted by intrinsic potential (km^2)	11.754
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	6.433
Size / Complexity category	Very Large / "B" (dendritic structure)
Number of major spawning areas (MaSAs)	11
Number of minor spawning areas (MiSAs)	19

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

Current (1965-2005) total abundance (number of adult spawners in natural production areas) for this population has ranged from 111 in 1979 to 10,557 in 1987 (Figure 2). Abundance estimates are based on expanded redd counts. Index surveys of steelhead redds from the Oregon Department of Fish and Wildlife (ODFW), John Day District, were used for the historical dataset. We used index surveys that showed relatively consistent visitation through all years. Survey data from Bear, Kahler, Parrish, Pine, and Thirtymile creeks were used in the analyses. The current spawning distribution was used for the miles of available habitat within each population's range. The index redd densities were then multiplied by a correction factor to estimate the annual redd densities for the entire spawning distribution, based on the ratio of index redd densities to redd densities in 2004-2005 derived from the Environmental Monitoring and Assessment Program (EMAP); the ratio was consistent for these years (0.36, 0.35). The estimated redd density for the entire spawning area (0.355 x index density) was multiplied by the total miles of spawning habitat currently utilized. Total annual redds were converted to fish by multiplying the total annual number of redds by the number of fish per redd. Fish per redd ratios were developed from survey data on Deer Creek in the Grande Ronde River basin and are an average from four years of data from complete and repeated redd surveys (censuses) above a weir where we have a complete fish count; the calculated average fish per redd estimate was 2.1.

The hatchery-origin/natural-origin composition of spawners was computed separately for the Lower Mainstem John Day River and combined for all other populations in the MPG. Data included observations of positively identified fin-clipped spawners (1992-present) from spawning surveys. Evidence from the Deschutes River indicates that hatchery straying was substantially lower before 1992; because the source of strays in the John Day River basin is the same as the Deschutes River, we assumed a similar trend. No other data are available for earlier years so the hatchery fraction was set at zero. Age composition was derived from scale readings of creel sampled unmarked fish collected during the 1980s above Tumwater Falls.

Recent natural spawners include returns originating from naturally spawning parents and a small fraction of strays from Snake and Columbia River hatchery programs. Spawners originating from naturally spawning parents have comprised an average of 92% of the spawners since hatchery strays began being documented in 1992. Since that time, the percentage of natural spawners has ranged from 82%-99%.

Abundance in recent years has been highly variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 1,800 (Table 2). During the period 1975-1997, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Lower Mainstem population ranged from 0.14 in 1987 to 17.5 in 1979. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 19-year (1980-1998) geometric mean productivity was 2.99 R/S, adjusted for SAR and delimited at 75% (1,688 spawners) of the abundance threshold.

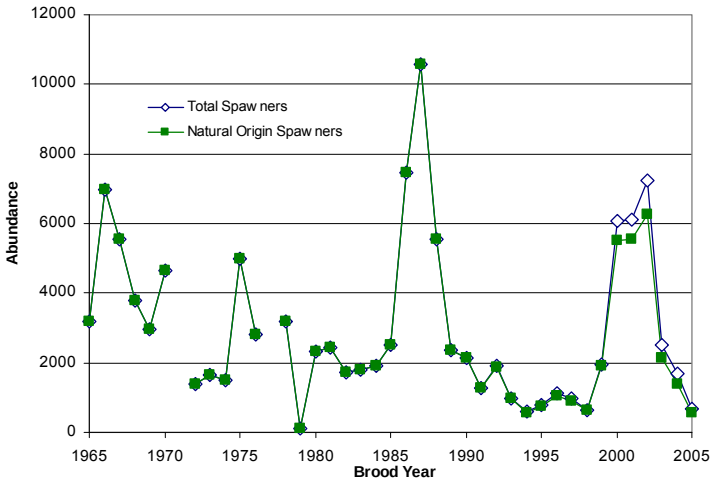

Figure 2. Lower Mainstem John Day River summer steelhead population spawner abundance estimates (1965-2005).

Table 2. Lower Mainstem John Day River summer steelhead population abundance and productivity estimates.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	1,800	(563-6,257)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.90	(0.82-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (19-year R/S, SAR adjusted & delimited) [a]	2.99	(1.91-4.67)	0.24
Productivity (19-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	0.98	(0.94-1.14)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	1.00	(0.71-1.41)	0.50
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.01	(0.71-1.43)	0.53

a. Delimited productivity excludes any recruit/spawner pair where the spawner number >75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Lower Mainstem John Day River population is at **Moderate Risk** based on current abundance and productivity. The productivity is at very low risk because the point estimate is above very low risk and the lower end of the adjusted standard error is above the 5% risk level. The abundance is at moderate risk because it resides between the 5% and 25% risk levels (Figure 3).

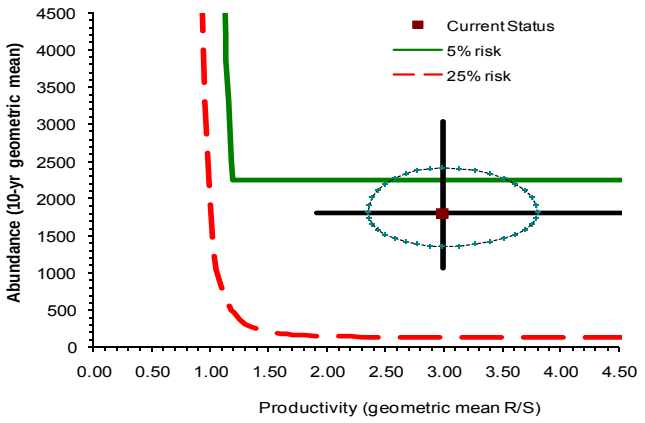

Figure 3. Lower Mainstem John Day River summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

The average trend in natural-origin spawner abundance over the most recent 20 years has been just below 1.0; the

population growth rate metric (λ), calculated with relative hatchery effectiveness set to 1.0, was 1.00 for the same period (Table 2). The pattern in returns from 1991 through 2005 is similar to the pattern for several other Mid-Columbia DPS steelhead populations, including the Deschutes River Eastside—an increasing trend beginning in 1996 followed by an abrupt decrease to levels observed in the early 1990s. The estimated proportion of hatchery-origin spawners has averaged approximately 10% for the period. The relative effectiveness of hatchery-origin spawners in contributing to natural production in this population is not known. Setting the value to 0.0, the opposite extreme from 1.0, results in an estimated annual growth rate of 1.01 (0.53 probability of exceeding 1.0).

Spatial Structure and Diversity

The ICTRT has identified 11 major spawning areas (MaSAs) and 19 minor spawning areas (MiSAs) within the Lower Mainstem John Day River population (Figure 4). Spawning is distributed broadly across the landscape in numerous watersheds that flow into the lower mainstem of the John Day River. Moderately large drainages such as Rock, Thirtymile, Bridge, Service, Mountain and Butte creeks comprise a substantial proportion of the production area. In addition, multiple smaller drainages support production. Spawners within the Lower Mainstem population are predominantly natural-origin; however, outside-DPS hatchery fish, primarily from Snake River stocks, are present in significant proportions in some years.

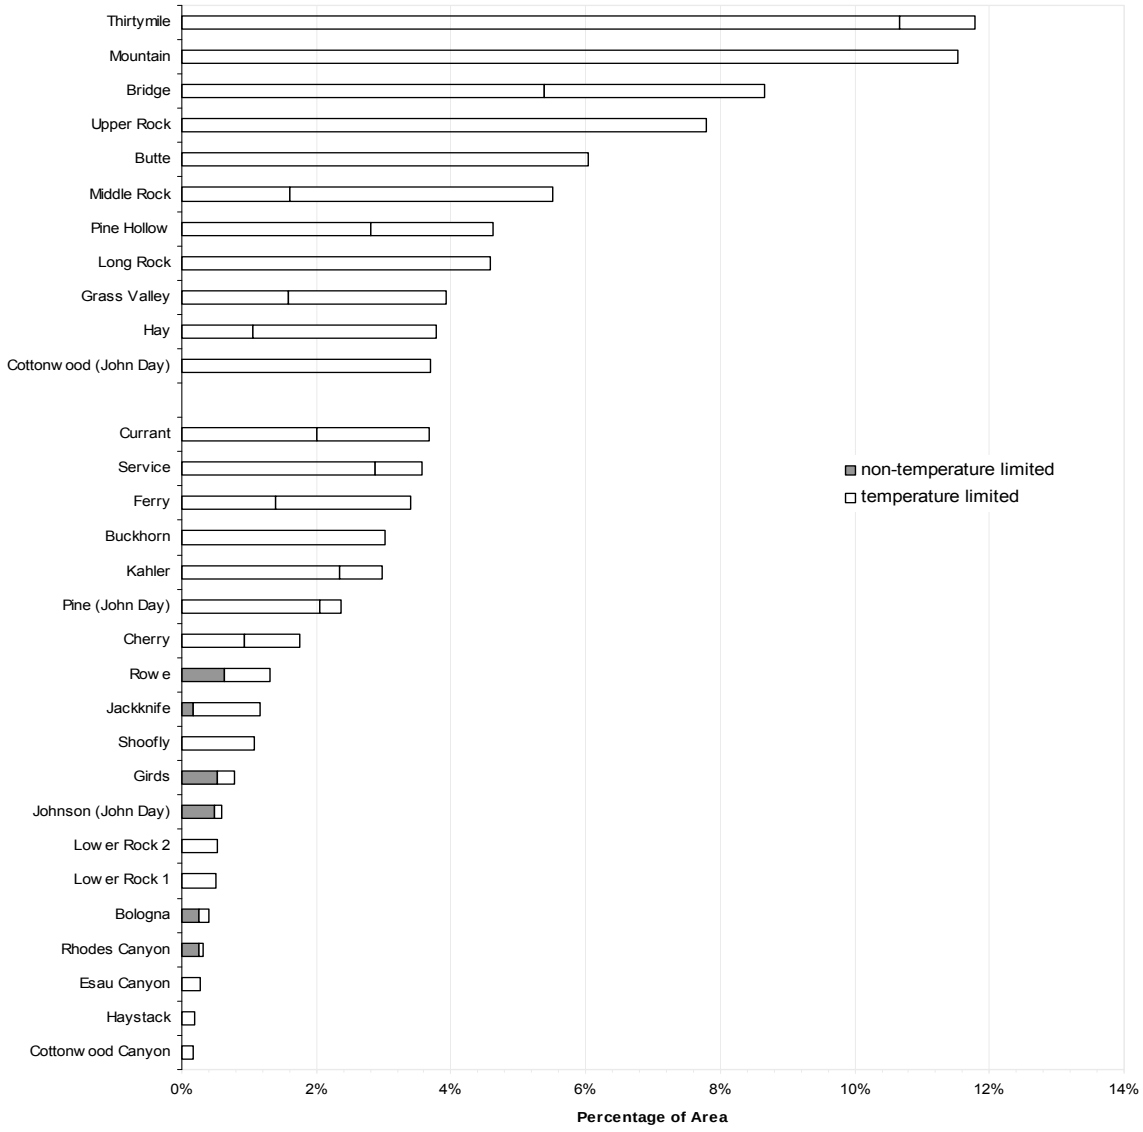

Figure 4. Lower Mainstem John Day River summer steelhead population distribution of intrinsic potential habitat across major and minor spawning areas. White bars represent the area that could potentially have had historical temperature limitations.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Lower Mainstem population has 11 MaSAs and 19 MiSAs distributed in a very complex dendritic pattern. Intrinsic potential is distributed relatively evenly across the 11 MaSAs. Based on the ODFW spawner distribution database all 11 of the MaSAs are currently occupied (except for the upper portion of the Cottonwood MaSA) and 11 of the 19 MiSAs are occupied (Figure 5). A total of 1,197 km of habitat is presently used for spawning. The Lower Mainstem population rates at **very low risk** for this metric.

A.l.b. Spatial extent or range of population

The current spawner distribution closely resembles the intrinsic potential distribution. All of the MaSAs are currently occupied except the upper portion of Cottonwood, and 11 of the 19 MiSAs are also occupied. The unoccupied MiSAs are scattered throughout the population, and, therefore, do not result in a change in extent and range of distribution. The rating is **very low risk**. There are six index spawning survey sites in the Lower Mainstem population.

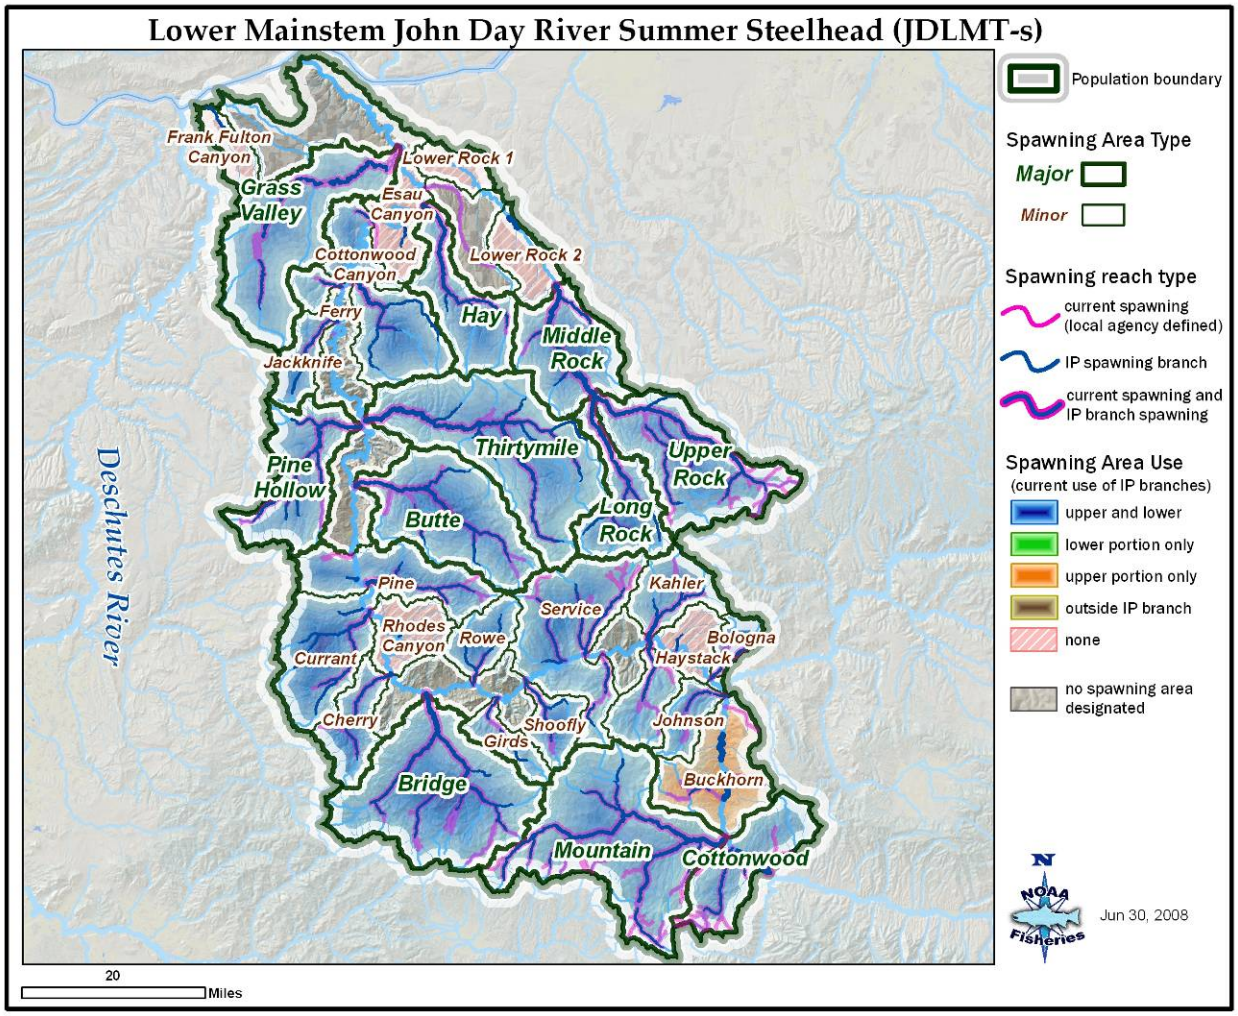

Figure 5. Current spawning distribution and spawning area occupancy designations of the Lower Mainstem John Day River summer steelhead population.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There has not been any significant increase in gaps relative to historic intrinsic distribution. Although 8 of the 19 MiSAs are not currently occupied, the remaining occupied spawning areas (11 MaSAs and 11 MiSAs) provide good continuity between spawning areas throughout the population as well as relatively unchanged gaps. The Lower Mainstem population rating is **very low risk** for this metric.

B.1.a. Major life history strategies

The Lower Mainstem population is an A-run population that migrates to the ocean at multiple ages and returns after spending one or two years in the ocean (based on ages of natural-origin angler caught fish). These life history patterns are consistent with other A-run steelhead. There are limited data available to evaluate changes in life history patterns for this population; thus, they must be inferred based on habitat changes. This population is very large and inhabits a broad geographic area with habitat quality ranging from good to poor. Although current habitat conditions provide opportunity for expression of diverse life history strategies, habitat changes (particularly temperature) have likely reduced movement patterns and summer rearing distribution. This population rates at **moderate risk** for this metric because of the loss of tributary habitat rearing due to flow and temperature.

B.1.b. Phenotypic variation

There are no data to directly assess if any phenotypic traits have been substantially changed or lost, thus, they must inferred from habitat data. We hypothesize that there has been some reduction in variability of traits, such as adult entry and migration timing through the Columbia and John Day rivers, as well as juvenile migration timing. Although the distribution of these types of traits has likely been altered, the magnitude has likely not been substantial. Habitat conditions and absence of significant major phenotypic selective pressures indicate this population is at **low risk**.

B.1.c. Genetic variation

There are limited genetic data for John Day River populations, and no samples have been analyzed for the Lower Mainstem population. The major concern regarding genetic variation within the Lower Mainstem population relates to the spawner composition and potential genetic effects of out-of-DPS hatchery strays. There are no past population bottlenecks or intentional hatchery practices that would influence genetic variation. Due to the high proportion of hatchery strays and the lack of genetic data for this population, we have rated this metric as **moderate risk.** Samples were collected in 2005 and 2006 to provide an assessment of the genetic characteristics of the Lower Mainstem population. These data will allow for a more informed assessment of the genetic variation in the future.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners:* Based on coded wire tags (CWTs) recovered primarily from recreational fisheries, the proportion of out-of-DPS hatchery spawners in the Lower Mainstem John Day River population has ranged from 0.1 in the early 1990s to 0.18 in 2004, with a mean

of 0.07. The trend from the early 1990s to 2005 has shown a consistent increase in hatchery proportion through time. The hatchery fish originate primarily from the Snake River Basin. Due to the combined effects of the high hatchery fraction, the increasing trend through time, and the origin of the strays, this population rates at **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS*: There have been a total of four CWTs recovered from fish in the John Day River from out-of-MPG within-DPS origin. Three originated from the Umatilla Hatchery program and one from the Deschutes Hatchery program. It appears very few within-DPS hatchery fish stray into the John Day River, thus the rating is **low risk** for this metric.

(3) *Out-of-population spawners from within the MPG:* There are no steelhead hatchery programs operated within the John Day River basin; therefore, this metric is rated as **very low risk**.

(4) *Within-population hatchery spawners:* There are no steelhead hatchery programs operated within the John Day River basin; therefore, this metric is rated as **very low risk.**

The overall spawner composition rating is **high risk** due to the high proportion of out-of-DPS strays that potentially spawn in this population**.**

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution of the Lower Mainstem John Day River population encompassed seven ecoregions (Figure 6), although only two had values greater than 10%. There has been little change in distribution among ecoregions and no substantial reductions. All ecoregions that had significant use historically remain in use currently (Table 3). The rating is **low risk** for this metric.

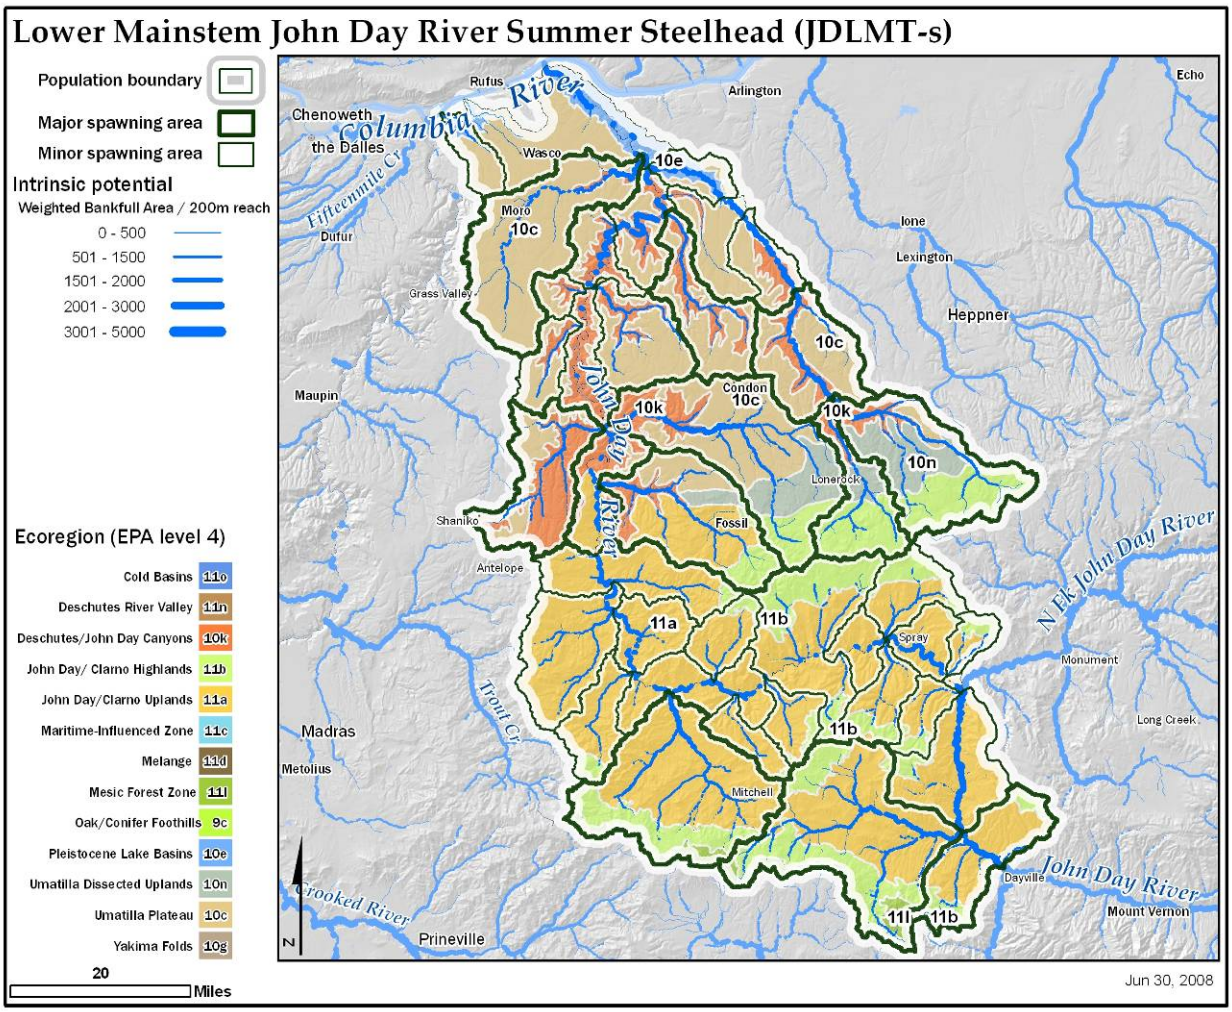

Figure 6. Lower Mainstem John Day River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Proportion of current spawning areas across EPA level IV ecoregions of the Lower Mainstem John Day River summer steelhead population.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Deschutes/John Day Canyons	32.0	35.4
John Day Clarno Highlands	5.2	7.9
John Day Clarno Uplands	46.6	42.7
Mesic Forest Zone	0.2	0.4
Pleistocene Lake Basins	6.1	0.1
Umatilla Dissected Uplands	2.7	4.7
Umatilla Plateau	7.2	8.9

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes three dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Adult migration timing:* The dams create a thermal barrier in the reservoirs that delays and potentially induces some mortality of migrating adults. This barrier is diminished later in the migration season. Because the timing of the barrier varies from year to year and does not develop in some years, and the degree of differential survival is likely low although not well-understood, we rate the selection intensity as low. Heritability of this trait is high; thus, the hydropower rating for this trait is **moderate risk**.

Harvest: Harvest has the potential to affect migration timing, maturation timing, and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts would be negligible. There is very limited tribal harvest of natural-origin fish within the John Day River subbasin. Impacts from the recreational fishery are incidental to the harvest of hatchery-origin fish and are not selective. No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: There are no steelhead hatchery programs operated within the population; therefore, the hatchery rating is **very low risk** for all traits.

Habitat: Altered flow and increased temperatures in spawning, rearing, and the mainstem migration corridor, which have been in place for many generations and are ongoing, likely impose some selection on juvenile and adult migration timing.

> *Adult migration timing:* Low flows in the late summer and early fall in the John Day River likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable, but a negligible proportion of the population is likely subject to these effects. Thus, the impact of habitat changes on this trait is **low risk.**
>
> *Juvenile migration timing:* Late spring and early summer temperatures are elevated relative to historical conditions. There has likely been some affect on juvenile migration timing as late spring and early summer river temperatures can reach stressful levels in some years in the John Day River mainstem. Selection intensity is considered negligible and the heritability of this trait is moderate to low. The impact of habitat changes on this trait is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective

predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

There is only one trait that has a moderate rating for one selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** for the Lower Mainstem John Day River population (Table 4). The rating for Goal A (allowing natural rates and level of spatially mediated processes) was **very low risk**. The current spawner distribution is similar to historic with all MaSAs occupied. The MiSAs that are currently unoccupied have little influence on gaps and continuity, and spawners are spread over a very broad geographic area.

The rating for Goal B (maintaining natural levels of variation) was **moderate risk**. This rating was a result of moderate risk for life history and genetic variation and high risk for spawner composition out-of-DPS hatchery strays. The magnitude and trend in out-of-DPS hatchery strays are of significant concern. Analysis of genetic information will yield considerable insight into the genetic characteristics of this population. The extent of hatchery introgression will be useful information for future spatial structure/diversity risk assessments.

Table 4. Spatial structure and diversity risk rating of the Lower Mainstem John Day River summer steelhead population.

Overall Viability Rating

The Lower Mainstem John Day River summer steelhead population does not meet viability criteria. However, the population does meet criteria to be rated as **MAINTAINED** (Figure 7). Overall abundance and productivity is rated at **Moderate Risk.** The 10-year geometric mean abundance of natural-origin spawners is 1,800, which is 80% of the minimum abundance threshold of 2,250. The 19-year geometric mean productivity (2.99 R/S; Table 6) exceeds the minimum required productivity of 1.19 R/S at the abundance threshold. Overall spatial structure and diversity is also rated at **Moderate Risk.** To achieve a viable rating, this population must improve in both abundance/productivity and spatial structure/diversity. Out-of-DPS spawners are the most influential factor on diversity risk. Additional data are needed to better quantify spawner composition to reduce the uncertainty associated with this risk metric.

Abundance/ Productivity Risk	Spatial Structure/Diversity Risk: Very Low	Low	Moderate	High
Very Low (<1%)	HV	HV	V	M
Low (1-5%)	V	V	V	M
Moderate (6 – 25%)	M	M	M Lower Mainstem John Day River	HR
High (>25%)	HR	HR	HR	HR

Figure 7. Lower Mainstem John Day River summer steelhead population risk ratings integrated across the four viable salmonid population (VSP) metrics. ***Viability Key: HV – Highly Viable; V – Viable; M – Maintained; HR – High Risk; Shaded cells – does not meet viability criteria (darkest cells are at greatest risk).***

Data Summary – Lower Mainstem John Day River

Data type: Redd count expansion - Index area redd counts expanded to total population estimate by applying ratio of average redd densities (samples across all areas to samples from index reaches) from EMAP surveys. Assumed 2.1 fish per redd.

Smolt-to-Adult Return rate (SAR): Mid-Columbia composite series (see *Methods*).

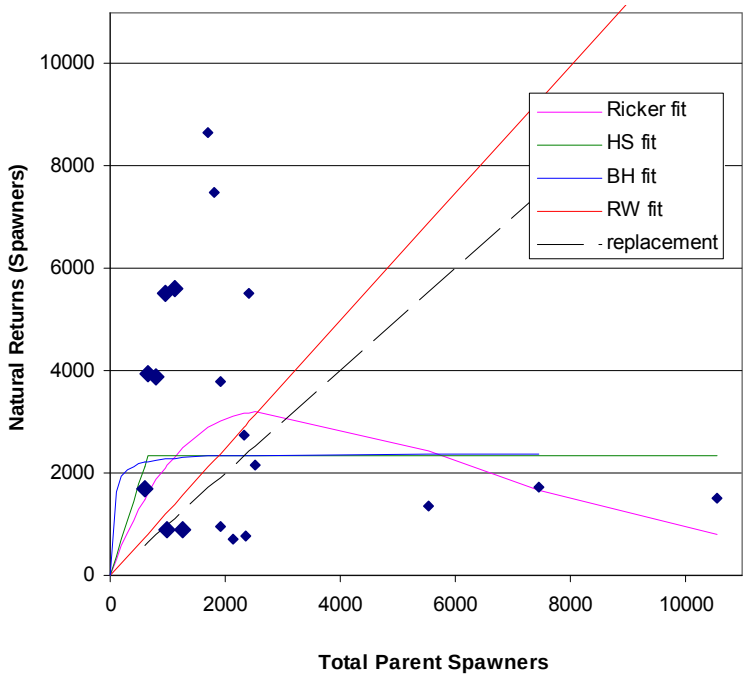

Figure 8. Lower Mainstem John Day River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were not adjusted for marine survival.

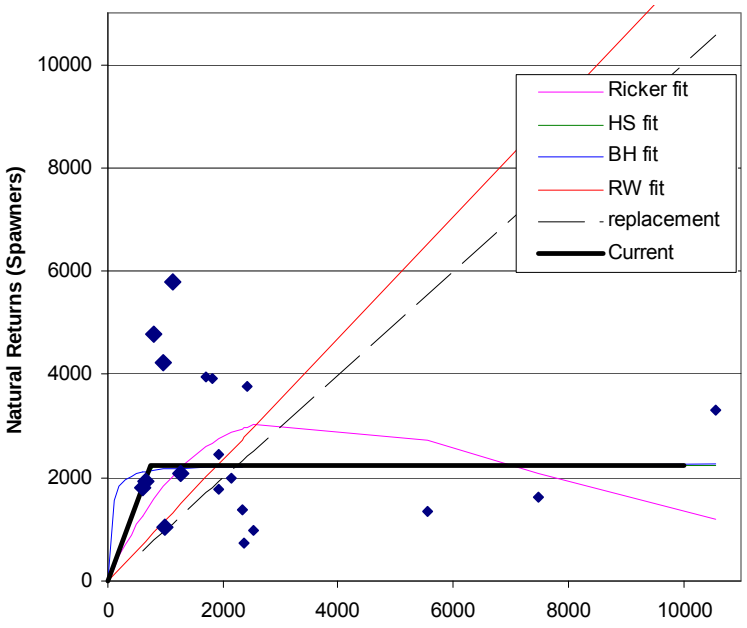

Figure 9. Lower Mainstem John Day River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

North Fork John Day River Summer Steelhead Population

The North Fork John Day River summer steelhead population (Figure 1) is one of five populations in the John Day River MPG within the Mid-Columbia steelhead DPS. All five populations in this MPG are summer run.

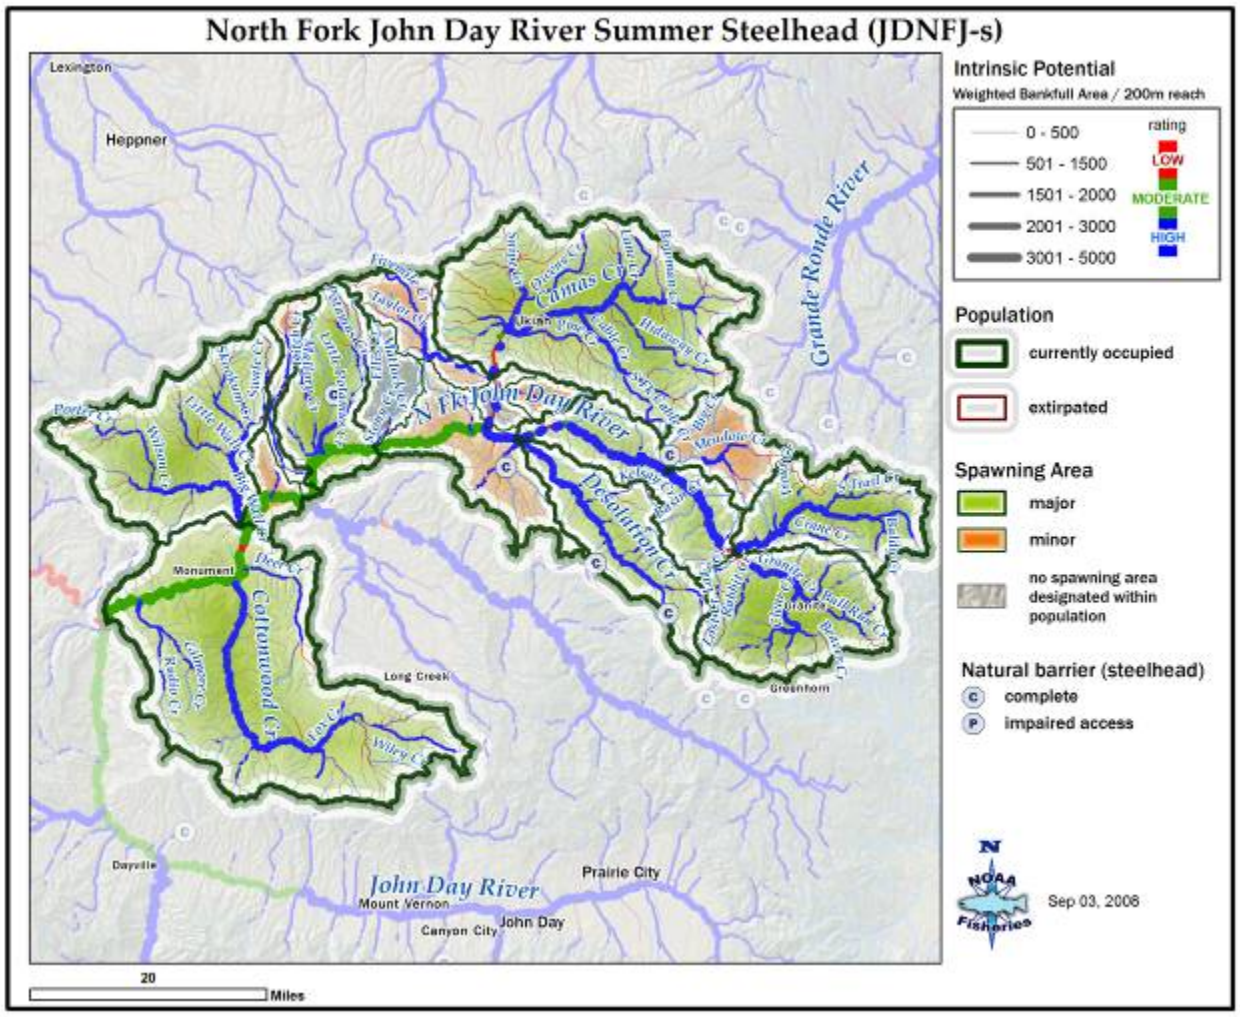

Figure 1. North Fork John Day River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the North Fork population as "large" in size and complexity (Table 1) based on historical habitat potential (ICTRT 2007). A steelhead population classified as large has a mean minimum abundance threshold criteria of 1,500 natural-origin spawners with sufficient intrinsic productivity (≥ 1.26 recruits per spawner at the abundance threshold level) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the North Fork John Day River population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.53 recruits per spawner at the minimum abundance threshold.

Table 1. North Fork John Day River summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	4,788
Stream lengths km (total) [a]	1,823
Stream lengths km (below natural barriers) [a]	1,678
Branched stream area weighted by intrinsic potential (km^2)	5.221
Branched stream area km^2 (weighted and temp. limited) [b]	4.917
Total stream area weighted by intrinsic potential (km^2)	6.867
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	6.474
Size / Complexity category	Large / "B" (dendritic)
Number of major spawning areas (MaSAs)	8
Number of minor spawning areas (MiSAs)	7

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

Current (1965-2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 369 in 1990 to 10,235 in 1965 (Figure 2). Abundance estimates are based on expanded redd counts. Index surveys of steelhead redds from the Oregon Department of Fish and Wildlife (ODFW), John Day District, were used for the historical dataset. We used index surveys that showed relatively consistent visitation through years. Survey data from Beaver, Fox, North Fork Trail, Middle Fork Trail, Wall and Wilson creeks were used in the analyses. The current spawning distribution was used for the miles of available habitat within the population's range. The index redd densities were then multiplied by a correction factor based on the ratio of index densities to EMAP (Environmental Monitoring and Assessment Program) densities for 2004-2005; this ratio was consistent for these years (0.36, 0.35). The estimated redd density for the entire spawning area (0.355 x index density) was multiplied by the total miles of currently utilized spawning habitat. Total annual redds were converted to fish by multiplying the total annual number of redds by the number of fish per redd. Fish/redd ratios were developed from survey data on Deer Creek in the Grande Ronde River basin. The ratio is an average from four years of data of complete and repeated surveys (censuses) of redds above a weir where we have a complete count; the calculated average fish per redd estimate was 2.1.

The hatchery-origin/natural-origin composition of spawners were computed separately for the Lower Mainstem John Day River population and combined for all other populations in the MPG. Data used to represent the North Fork population included observations of positively identified fin-clipped spawners (1992-present) from spawning survey observations in the four populations above the Lower Mainstem, and observations from rotary screw trap and seine collections of adults (2000-present). There is evidence from the Deschutes River that hatchery straying was substantially lower before 1992, and since the source of strays in the John Day River basin is the same as the Deschutes River, we are assuming a similar trend. No other data are available for earlier years so the hatchery fraction was set at zero. Age composition was derived from scale readings of creel sampled unmarked fish collected during the 1980s above Tumwater Falls.

Recent year natural spawners include returns originating from naturally spawning parents, and a small fraction of strays from the Snake and Columbia River hatchery programs. Since documentation of hatchery strays began in 1992, spawners originating from naturally spawning parents have comprised an average of 93% of the spawners, ranging from 87-99%.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 1,740 (1,898 total spawners; Table 2). During the period 1979-1998, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the North Fork John Day River ranged from 0.10 in 1985 to 3.07 in 1991. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 20-year (1979-1998) geometric mean productivity was 2.41 R/S, adjusted for SAR and delimited at 75% (1,125 spawners) of the abundance threshold (Table 2).

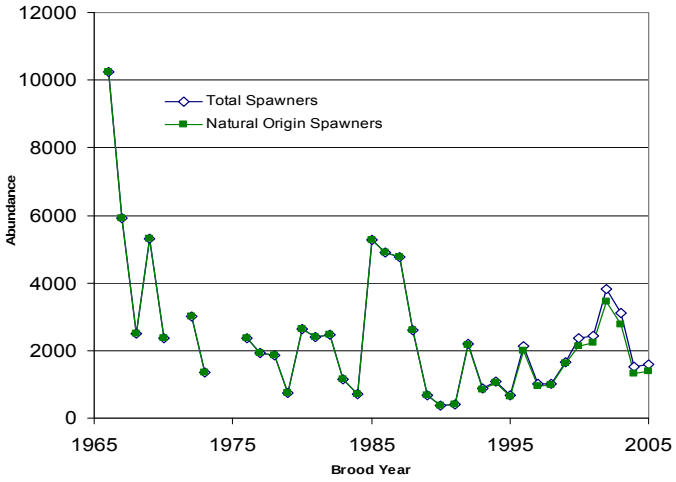

Figure 2. North Fork John Day River summer steelhead population spawner abundance estimates (1966-2005).

Table 2. North Fork John Day River summer steelhead population abundance and productivity estimates.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	1740	(369-10,235)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.93	(0.87-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (20-year R/S, SAR adjusted & delimited) [a]	2.41	(1.31-4.42)	0.22
Productivity (20-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	0.99	(0.95-1.16)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	1.00	(0.79-1.25)	0.48
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.00	(0.80-1.26)	0.51

a. Delimited productivity excludes any recruit/spawner pair where spawner number >75% of population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The North Fork John Day River population is at **Very Low Risk** based on current abundance and productivity. The point estimate for abundance and productivity is above the 1% risk curve (Figure 3) and the lower end of the 98% confidence interval (CI) for productivity is above the 25% risk curve.

The abundance of natural-origin spawners in the North Fork population has fluctuated substantially over the recent 20-year period. The average trend in natural-origin spawner abundance has been 0.99; the

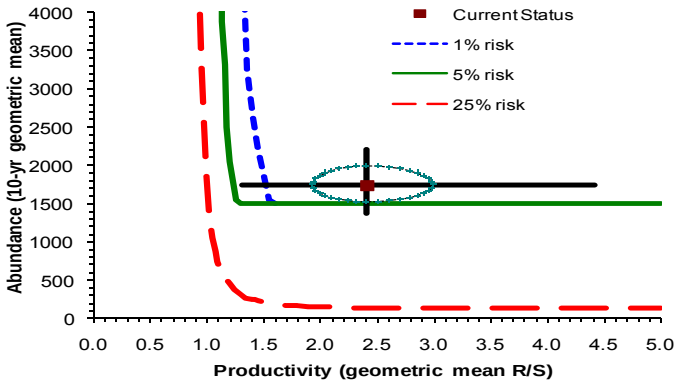

Figure 3. North Fork John Day River summer steelhead population current abundance and productivity (A/P) compared to DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A, 98% CI for P (if point estimate >1% risk curve, the uncertainty test is <1% probability the combined A/P is at high risk).

population growth rate metric (calculated with relative hatchery effectiveness set to 1.0) was 1.00 for the same period (Table 2). The pattern in returns from 1991 through 2005 is similar to the pattern for several other Mid-Columbia DPS steelhead populations, including the Deschutes River Eastside—an increasing trend beginning in 1996 followed by an abrupt decrease to levels observed in the early 1990s. The estimated proportion of spawners of hatchery-origin has averaged approximately 7% for the period. The relative effectiveness of hatchery-origin spawners in contributing to natural production in this population is not known. Setting the value to 0.0 did not change the point estimate of the average population growth rate for the period, although the probability of exceeding 1.0 increased slightly from 0.48 to 0.51.

Spatial Structure and Diversity

The ICTRT has identified eight major spawning areas (MaSAs) and seven minor spawning areas (MiSAs) within the North Fork John Day River steelhead population (Figure 4). Spawning is distributed broadly throughout the population boundaries including many tributaries and mainstem areas of Cottonwood, Camas, Desolation, and Granite creeks and the upper North Fork John Day River. Spawners in the North Fork John Day River are primarily natural-origin fish; however, outside-DPS hatchery fish, primarily from Snake River stocks, are present in the North Fork population.

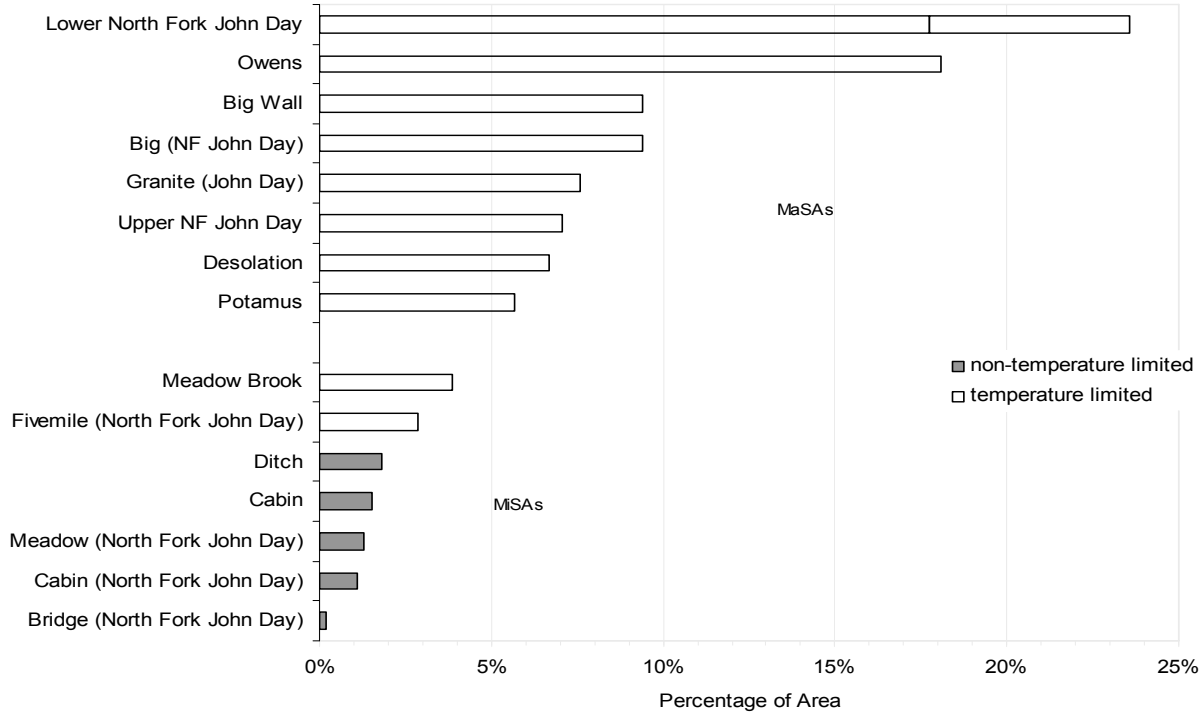

Figure 4. North Fork John Day River summer steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs). White bars represent areas that could potentially have had historical temperature limitations.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The North Fork John Day River population has eight MaSAs and seven MiSAs which are distributed in a complex dendritic pattern. Based on the ODFW spawner distribution database all eight MaSAs and seven MiSAs are currently occupied and a total of 1,194 km are presently used for spawning (Figure 5). The North Fork population rates at **very low risk** for this metric because it has more than four MaSAs occupied in a dendritic configuration.

A.l.b. Spatial extent or range of population

The current spawner distribution mirrors the historical distribution represented by the intrinsic potential analyses. All MaSAs and MiSAs are currently occupied (Figure 5). The current spatial extent and range criteria rating for the North Fork population is **very low risk**. Index area spawning surveys are conducted in six spawning tributaries in the North Fork population.

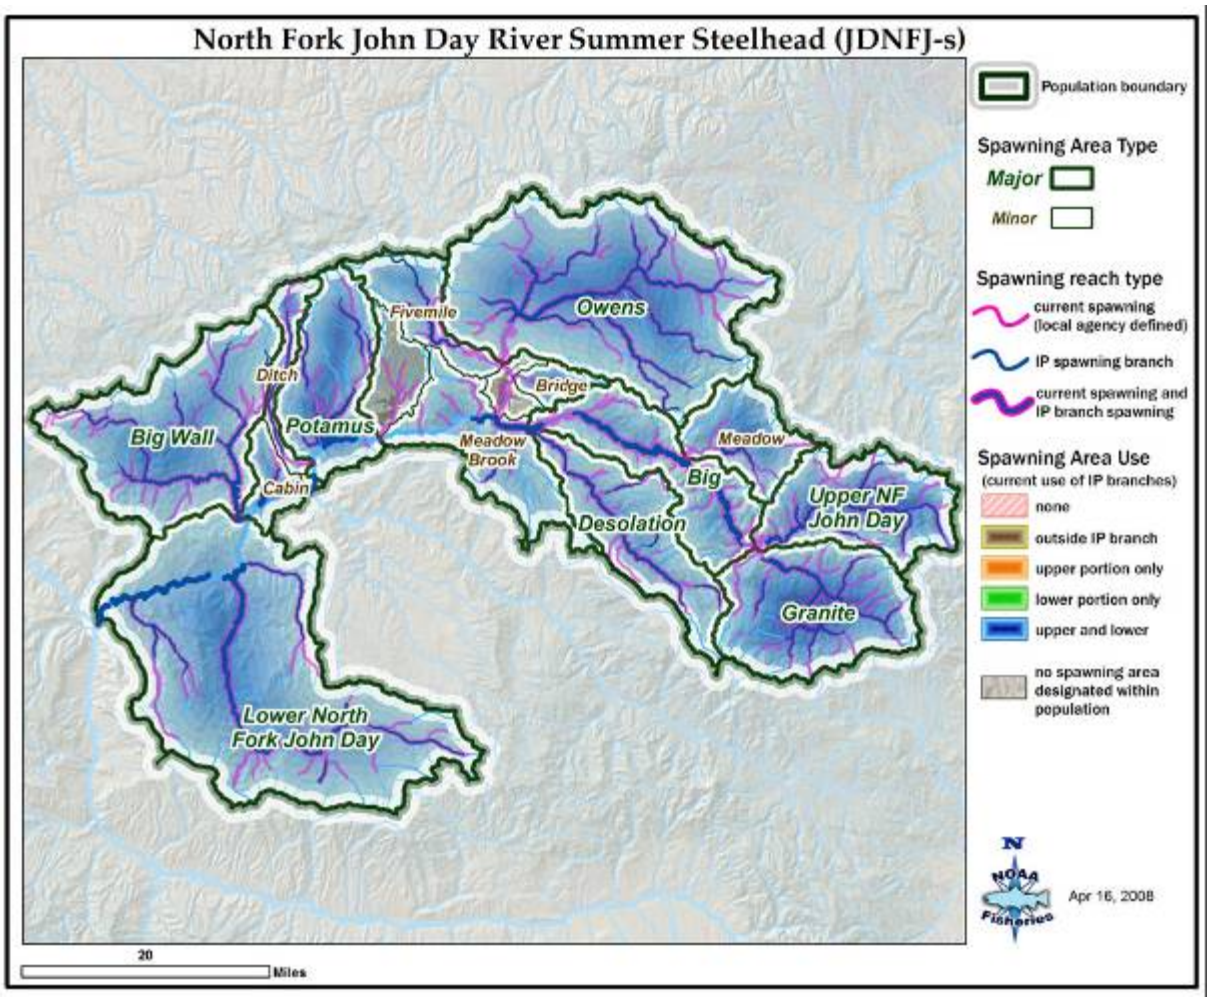

Figure 5. North Fork John Day River summer steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There have been no significant increases in gaps between spawning areas. Connectivity between historic spawning areas has remained relatively unchanged. The North Fork population rates at **very low risk** for gaps.

B.1.a. Major life history strategies

There are limited data for evaluating specific life history patterns of North Fork John Day River steelhead, and therefore we use habitat information to infer changes in life history strategies. A

significant proportion of the North Fork population resides in wilderness area with habitat conditions that are relatively unaltered. Habitat conditions throughout the population do theoretically provide the opportunity for expression of all historic life history strategies. The North Fork John Day River population is an A-run population with ocean migration occurring predominantly at age 2 and age 3, and adults returning after one or two years in the ocean. These life history patterns are consistent with what we observe for most A-run populations. We have no evidence of loss of major life history strategies, thus the rating is **very low risk** for this metric.

B.1.b. Phenotypic variation

Data were not available to evaluate if any phenotypic traits have been lost. We used habitat information to infer potential changes in phenotypic traits. Relatively unaltered habitat conditions across a significant proportion of the population results in the absence of significant phenotypic selective pressures, thus the population is at **very low risk** for loss of phenotypic traits.

B.1.c. Genetic variation

There are limited genetic data for John Day River steelhead populations, with only one sample from the North Fork population. The populations within the John Day MPG are not well differentiated from one another. There is no biological basis to explain why the samples did not show normal differentiation. There are no past events, such as severe population bottlenecks or hatchery outplanting that would explain these results. There are out-of-DPS strays in the John Day River basin but the degree of introgression is unknown, and the past genetic samples, which were collected in the 1980s, were taken at a time when stray proportions were likely lower than in recent years. We have assigned a rating of **low risk** for this metric. This rating is driven by the balance between apparent similarity within and between populations and the relative degree of differentiation. Samples were collected in 2005 that will better inform the risk assessment for genetic variation in the future.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners:* Available data were inadequate to estimate the out-of-DPS hatchery fraction specifically for the North Fork population. The estimates derived were based on data from a composite of the four populations (South Fork, Middle Fork, Upper John Day, and North Fork) in the John Day River MPG that are above the Lower Mainstem population. These estimates were calculated from observations from spawning surveys and kelt collections seined from the mainstem. Since 1992, the estimated hatchery fraction ranged from 0.01-0.13. The mean hatchery fraction was 0.067. Based on coded wire tags (CWTs) recovered primarily from recreational fisheries, the majority of stray hatchery fish originate from Snake River hatcheries. Given that the hatchery fraction of out-of-DPS strays is estimated to be greater than 0.05 for two or more generations, the rating is **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS:* There have been four fish with CWTs recovered in the John Day River from out-of-MPG within-DPS origin. Three originated from

the Umatilla Hatchery program and one from the Deschutes. It appears very few within-DPS hatchery fish stray into the John Day River, thus the rating is **low risk** for this metric.

(3) *Out-of-population spawners from within the MPG:* There are no steelhead hatchery programs operated within the John Day River basin, therefore this metric is rated **very low risk**.

(4) *Within-population hatchery spawners:* There are no steelhead hatchery programs operated within the John Day River basin, therefore this metric is rated as **very low risk**.

The overall rating for the spawner composition metric is **high risk** due to the high proportion of out-of-DPS strays that spawn naturally in this population**.**

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution of the North Fork John Day River summer steelhead population encompassed six ecoregions, with the John Day Clarno Highlands and Mesic Forest zone comprising slightly over 60% of the distribution (Table 3). There are four ecoregions that comprise greater than 10% of the historic distribution. There has been little change in ecoregion distribution between intrinsic and current distribution with all six ecoregions currently occupied at nearly identical proportions as the intrinsic distribution (Figure 6). There have been no substantial reductions in any of the ecoregions. The rating for this metric is **very low risk**.

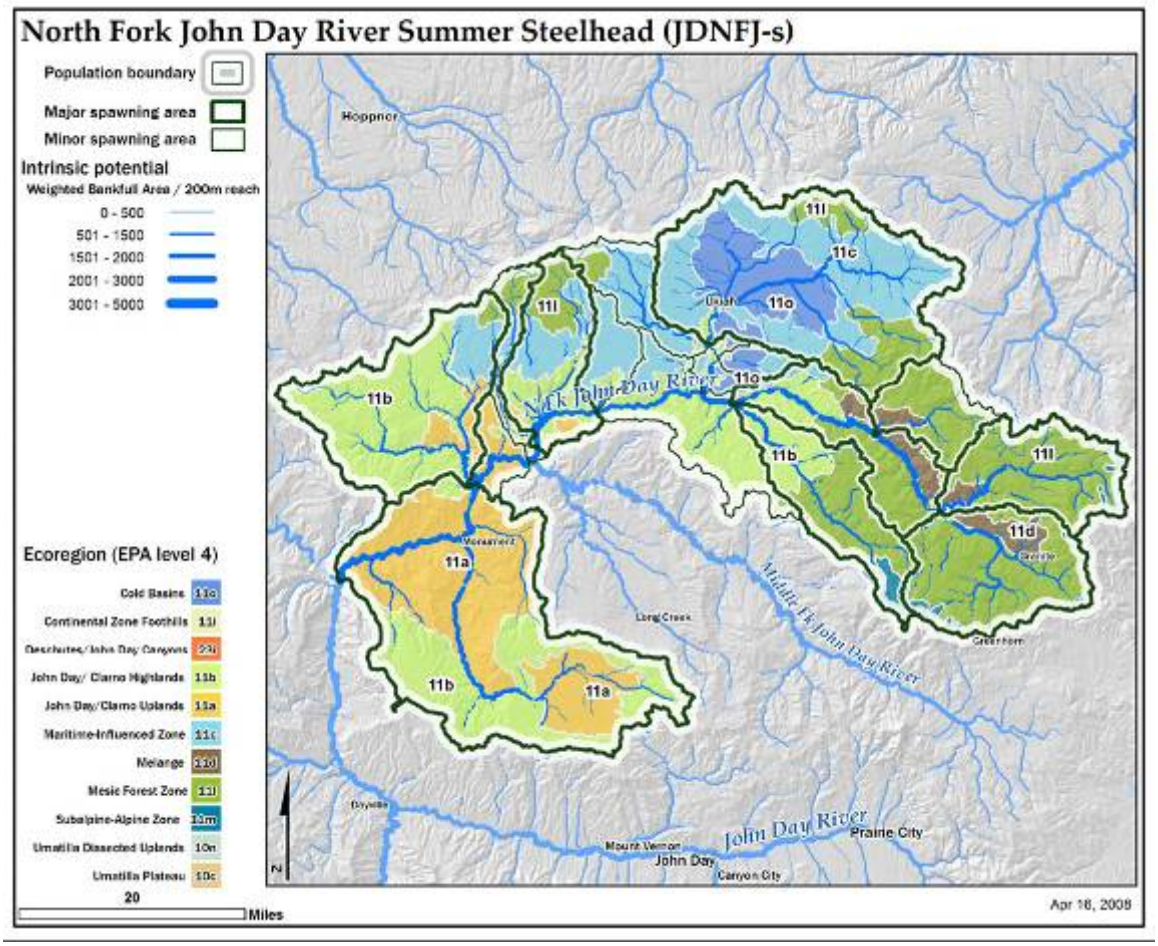

Figure 6. North Fork John Day River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. North Fork John Day River summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Cold Basins	8.3	10.4
John Day Clarno Highlands	27.0	26.4
John Day Clarno Uplands	26.6	16.9
Maritime-Influenced Zone	10.4	11.9
Melange	2.4	3.3
Mesic Forest Zone	25.3	31.2

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population crosses three dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Adult migration timing:* These dams establish a thermal barrier in the reservoirs that delays and potentially induces some mortality of migrating adults. This barrier is diminished later in the migration season. Because the timing of the barrier varies from year to year and does not develop in some years, and the degree of differential survival is likely low and not well-understood, we rate the selection intensity as low. Heritability of this trait is high, thus the hydropower rating for this trait is **moderate risk**.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is very limited tribal harvest of natural-origin fish within the John Day River subbasin; impacts from the recreational fishery are incidental to hatchery-origin fish harvest and are not selective. No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: There are no steelhead hatchery programs operated within the population; therefore, the hatchery rating is **very low risk** for all traits.

Habitat: Little change in flow profile and temperature has occurred within the population boundaries. However, some change has occurred in the mainstem John Day River which would affect the North Fork population.

> *Adult migration timing:* Low flows in the late summer and early fall in the John Day River likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable, but a negligible proportion of the population is likely subject to these effects. Thus, the impact of habitat changes on this trait is **low.**
>
> *Juvenile migration timing:* Late spring and early summer temperatures are elevated relative to historical conditions. There has likely been some effect on juvenile migration timing as temperatures can reach stressful levels in the John Day River mainstem in late spring and early summer in some years. Selection intensity is considered negligible and the heritability of this trait is moderate to low. The rating for this trait is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

Juvenile migration timing: Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

There is only one trait that has a moderate rating for one selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The combined integrated spatial structure/diversity rating is **Low Risk** for the North Fork John Day River population (Table 4). The rating for Goal A (allowing natural rates and level of spatially mediated processes) was **very low risk**. The current spawner distribution mimics the intrinsic distribution. The population is distributed broadly across the landscape in numerous MaSAs and MiSAs. Good continuity exists between spawning areas and current gaps between spawning areas are similar to historic gaps.

The rating for Goal B (maintaining natural levels of variation) was **low risk**. However, there remains considerable uncertainty about the ratings for genetic variation and out-of-DPS hatchery strays in the natural spawners. Additional genetic analyses and interpretation is needed to determine the degree of genetic variation and differentiation, as well as to examine evidence for degree of stray hatchery fish introgression. We rated the metric for out-of-DPS hatchery strays as very high. The data used for this rating are a composite from four John Day River populations. Additional population-specific spawner composition data are needed to improve the certainty of the out-of-DPS stray hatchery risk rating. If there is significant hatchery introgression that is affecting the genetic variation through time then the risk rating for "genetic variation" will increase and the overall risk rating for Goal B and spatial structure/diversity will also increase.

Overall Viability Rating

The North Fork John Day River summer steelhead population currently meets ICTRT viability criteria and is rated **HIGHLY VIABLE** (Figure 7). Overall abundance and productivity is rated at **Very Low Risk.** The 10-year geometric mean abundance of natural-origin spawners is 1,740, which exceeds the minimum abundance threshold of 1,500. The 20-year geometric mean productivity (2.41 R/S; Table 6) is well above the 1.26 R/S required at the minimum abundance threshold. Overall spatial structure and diversity is rated at **Low Risk.** The ratings for genetic variation and out-of-DPS hatchery-origin spawner composition were the most influential on the overall spatial structure/diversity assessment. There is considerable uncertainty regarding the genetic effect of out-of-DPS strays, as well as the actual proportion of natural spawners that are hatchery strays. There are limited population-specific data to estimate the spawner composition in the North Fork population. Enhanced monitoring efforts should be undertaken to develop better estimates of the composition of North Fork John Day River spawners.

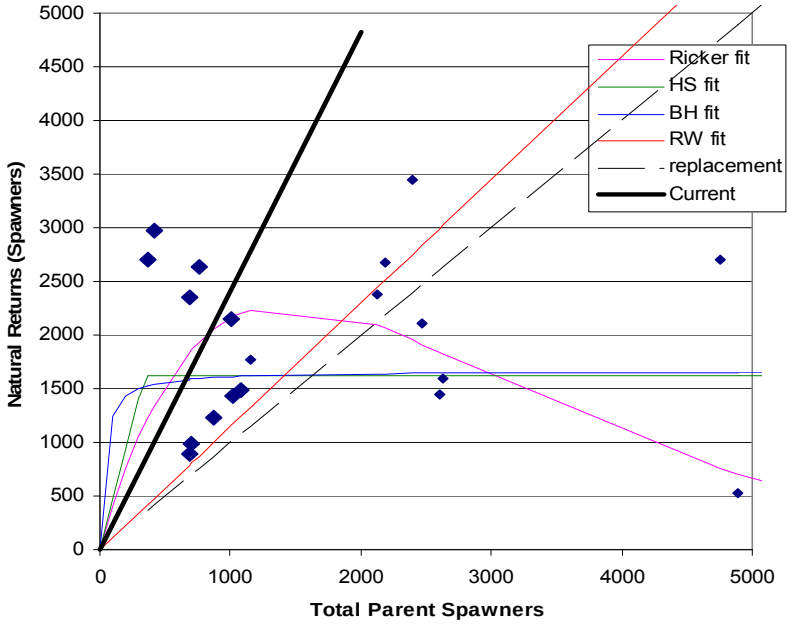

Figure 9. North Fork John Day River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Middle Fork John Day River Summer Steelhead Population

The Middle Fork John Day River summer steelhead population (Figure 1) is one of five populations in the John Day River MPG within the Mid-Columbia steelhead DPS. All five populations in this MPG are summer run.

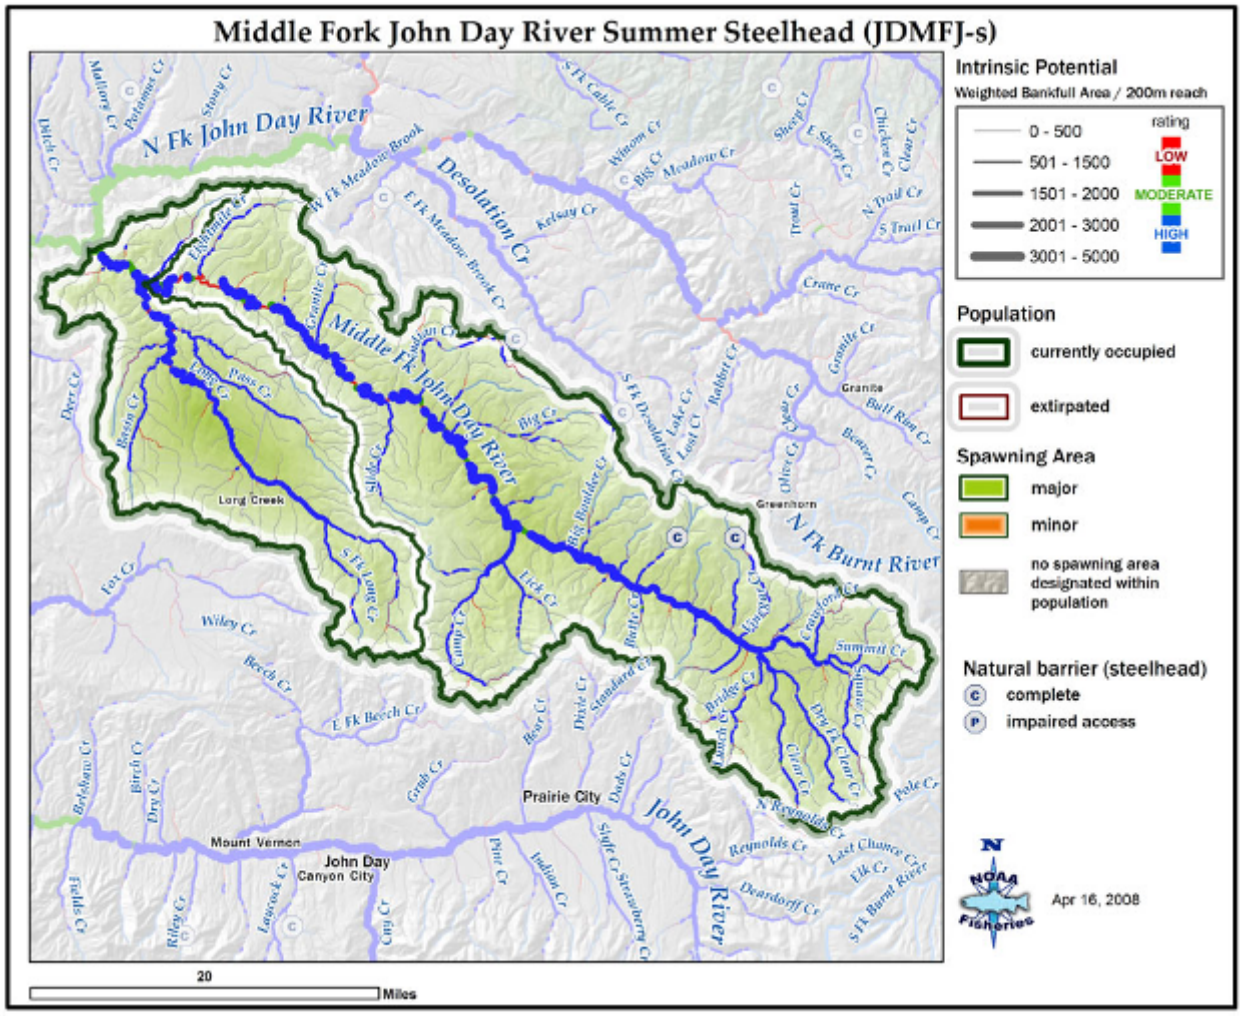

Figure 1. Middle Fork John Day River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Middle Fork population as "intermediate" in size and complexity (Table 1) based on historical habitat potential (ICTRT 2007). A steelhead population classified as intermediate has a mean minimum abundance threshold of 1,000 natural-origin spawners with a sufficient intrinsic productivity (≥ 1.35 recruits per spawner at the minimum abundance threshold) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the Middle Fork population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.64 recruits per spawner at the minimum abundance threshold.

Table 1. Middle Fork John Day River summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	2,052
Stream lengths km (total) [a]	704
Stream lengths km (below natural barriers) [a]	690
Branched stream area weighted by intrinsic potential (km^2)	2.592
Branched stream area km^2 (weighted and temp. limited) [b]	2.592
Total stream area weighted by intrinsic potential (km^2)	2.963
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	2.963
Size / Complexity category	Intermediate / "B" (dendritic structure)
Number of major spawning areas (MaSAs)	2
Number of minor spawning areas (MiSAs)	0

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

Current (1966-2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 337 in 2005 to 3,538 in 1979 (Figure 2). Abundance estimates are based on expanded redd counts. Index surveys of steelhead redds from the Oregon Department of Fish and Wildlife (ODFW), John Day District, were used for the historical dataset. We used index surveys that showed relatively consistent visitation through years (Beaver, Camp, Deep, and Lick creeks). The current spawning distribution was used for the miles of available habitat within each population's range. The index redd densities were then multiplied by a correction factor based on the ratio of index densities to EMAP (Environmental Monitoring and Assessment Program) densities for 2004-2005; the ratio was consistent for these years (0.36, 0.35). The estimated redd density for the entire spawning area (0.355 x index density) was multiplied by the total miles of currently utilized spawning habitat. Total annual redds were converted to fish by multiplying the total annual number of redds by the number of fish per redd. Fish/redd ratios were developed from four years of data of complete and repeated surveys (censuses) on Deer Creek in the Grande Ronde River basin of redds above a weir where we have a complete count. The average fish per redd estimate from Deer Creek was 2.1.

The hatchery-origin/natural-origin composition of spawners were computed separately for the Lower Mainstem John Day River population, and combined for all other populations in the MPG. Data used to represent the Middle Fork population included observations of positively identified adipose fin-clipped spawners (1992-present) from spawning survey observations in the four populations above the Lower Mainstem population, and observations from rotary screw trap and seine collections of adults (2000-present). There is evidence from the Deschutes River that hatchery straying was substantially lower before 1992, and because the source of strays in the John Day River subbasin is the same as the Deschutes River, we are assuming a similar trend. No other data are available for earlier years so the hatchery fraction was set at zero. Age composition was derived from scale readings of creel sampled unmarked fish collected during the 1980s from locations above Tumwater Falls.

Recent year natural spawners include returns originating from naturally spawning parents, and a small fraction of strays from the Snake and Columbia River hatchery programs. Since documentation of hatchery strays began in 1992, spawners originating from naturally spawning parents have comprised an average of 93%, ranging from 87%-99%.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 756 (Table 2). During the period 1969-1998, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Middle Fork John Day River ranged from 0.17 in 1992 to 3.84 in 1997. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 20-year (1979-1998) geometric mean productivity was 2.45 R/S, adjusted for SAR and delimited at 75% (563 spawners) of the abundance threshold (Table 2).

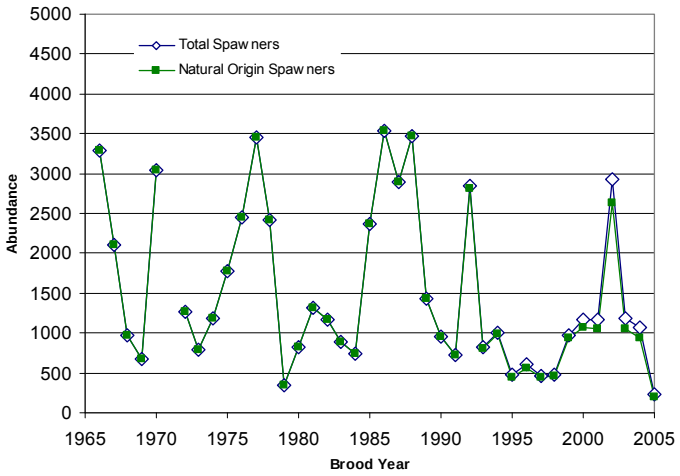

Figure 2. Middle Fork John Day River summer steelhead spawner abundance estimates (1966-2005).

Table 2. Middle Fork John Day River summer steelhead population abundance and productivity.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	756	(195-3538)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.93	(0.87-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (20-year R/S, SAR adjusted & delimited) [a]	2.45	(1.81-3.32)	0.16
Productivity (20-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	0.97	(0.93-1.06)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	1.00	(0.79-1.26)	0.50
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.01	(0.80-1.27)	0.53

a. Delimited productivity excludes any recruit/spawner pair where the spawner number >75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Middle Fork John Day River population is at **Moderate Risk** based on current abundance and productivity. The point estimate is between the 5% and 25% risk curves (Figure 3).

The abundance of natural-origin spawners in the Middle Fork population has fluctuated substantially over the recent 20-year period. The average trend in natural-origin spawner abundance has been 0.97; the population growth rate metric (calculated with relative hatchery effectiveness set to 1.0) was 1.00 for the same period (Table 2). The pattern in returns from 1991 through 2005 is similar

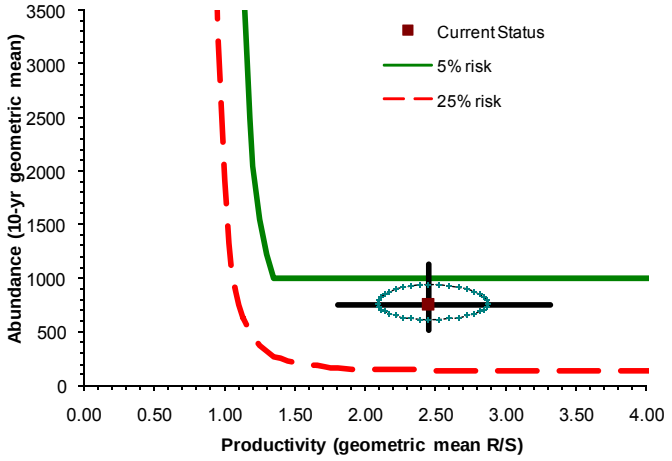

Figure 3. Middle Fork John Day River summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

to the pattern for several other Mid-Columbia DPS steelhead populations, including the Deschutes River Eastside—an increasing trend beginning in 1996 followed by an abrupt decrease to levels observed in the early 1990s. The estimated proportion of spawners of hatchery-origin has averaged approximately 7% for the period. The relative effectiveness of hatchery-origin spawners in contributing to natural production in this population is not known. Setting the value to 0.0, the opposite extreme from 1.0, results in an estimated annual growth rate of 1.01 (0.53 probability of exceeding 1.0).

Spatial Structure and Diversity

The ICTRT has identified two major spawning areas (MaSAs) and no minor spawning areas (MiSAs) within the Middle Fork John Day River summer steelhead population (Figure 4). Spawning is distributed broadly throughout the population boundaries including mainstem areas in the lower and upper Middle Fork John Day River and Long Creek. There are numerous tributary spawning streams distributed from the lower end of the population boundary to the uppermost reaches. Spawners within the Middle Fork John Day River are primarily natural-origin fish; however, outside-DPS hatchery fish, primarily from Snake River stocks, are present in the Middle Fork population.

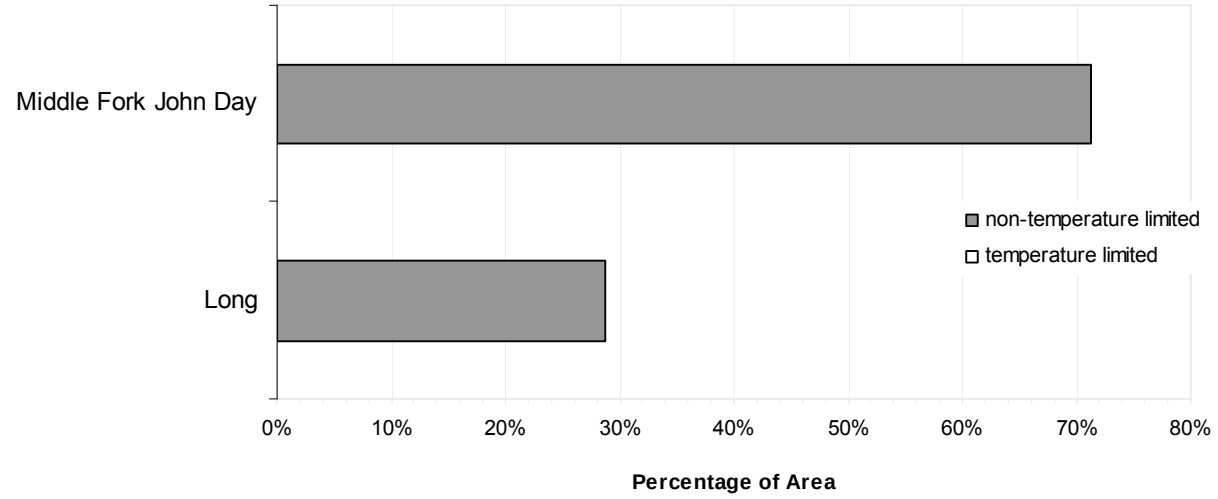

Figure 4. Middle Fork John Day River summer steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs).

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Middle Fork population has two MaSAs (no MiSAs) which are distributed in a dendritic pattern. Based on the ODFW spawner distribution database all of the major and minor spawning areas are occupied and a total of 546 km are currently used for spawning (Figure 5). The Middle Fork population rates at **low risk** because it has two MaSAs occupied in a non-linear configuration.

A.l.b. Spatial extent or range of population

The current spawner distribution mirrors the historical distribution as represented by the intrinsic potential analyses. All MaSAs are currently occupied (Figure 5). The current spatial extent and range criteria are rated as **very low risk** for the Middle Fork population. There are four index spawning survey reaches in the Middle Fork population. Recent spawning ground surveys results will be analyzed for future viability assessments.

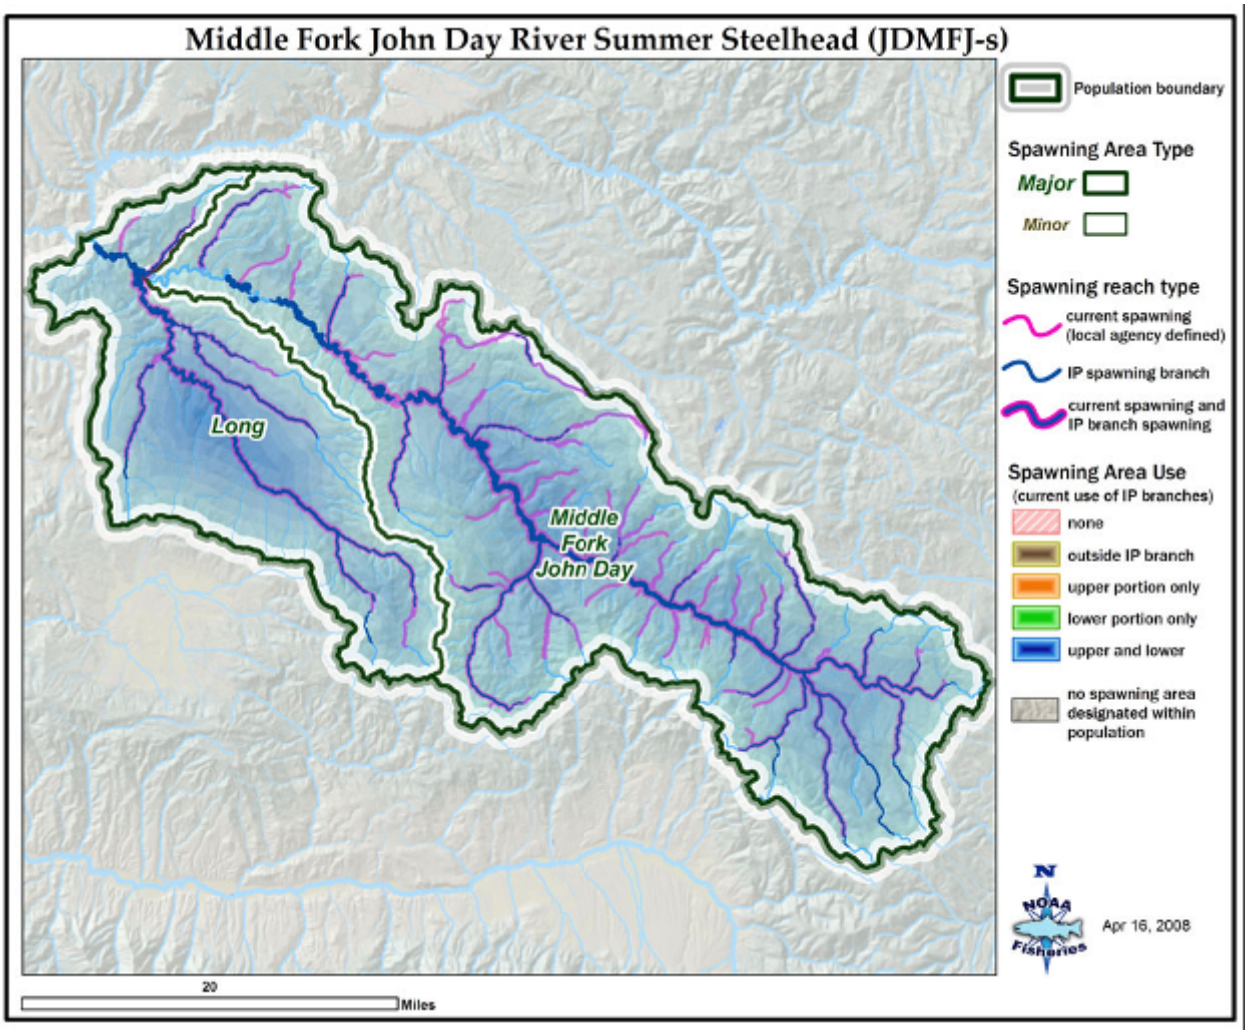

Figure 5. Middle Fork John Day River summer steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There has been little or no increase in gaps or loss in continuity between spawning areas within the Middle Fork population. Thus, the Middle Fork population rates as **low risk** for gaps and continuity.

B.1.a. Major life history strategies

There are no direct observations to assess loss in major life history strategies for the Middle Fork John Day River steelhead population; therefore we infer loss of life history diversity based on habitat changes. Although habitat conditions, particularly temperature, have been altered through time, there remains the theoretical opportunity to express diverse life history strategies similar to intrinsic potential. Juvenile steelhead exhibit diverse patterns of movement throughout their life cycle and rear in a variety of habitat types. Middle Fork John Day River steelhead are A-Run steelhead and appear to exhibit typical A-Run age at out-migration and ocean residence duration. The rating for loss of life history strategies is **low risk** for this metric.

B.1.b. Phenotypic variation

Current habitat conditions are not such that selective pressures would have significantly changed or eliminated any phenotypic traits. Mainstem Columbia River migrating corridor temperature changes and temperature changes in the John Day River have likely altered juvenile migration timing, thus reducing trait variability. We hypothesize that conditions have not altered the mean or variability of traits to the point that the risk level rises to moderate. Current habitat conditions and absence of other significant phenotypic selective pressure indicate that the Middle Fork population is at **low risk** for this metric.

B.1.c. Genetic variation

There are limited genetics data for John Day River steelhead populations and only one sample from the Middle Fork population. The samples from populations within the John Day River MPG are not well differentiated from one another. However, these samples were taken from a relatively small geographic area over a short time frame. There is no biological basis for the low level of differentiation. Samples were collected in the mid-1980s before any significant potential effects of hatchery strays. There have been no bottlenecks or other demographic factors that would have resulted in genetic variation impairment. There are out-of-DPS strays in the Middle Fork population; however the degree of introgression is unknown. We have assigned a rating of **low risk** for this metric. This rating is driven by balance between apparent similarity within and between populations and the relative degree of differentiation within and between the John Day River populations. Samples from multiple locations were collected in 2005 and will be analyzed to better inform the risk rating for this metric in the future.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners*: Inadequate data exist to estimate the out-of-DPS hatchery fraction specifically for the Middle Fork population. Estimates we used in this assessment were based on data from a composite of the four populations (South Fork, Middle Fork, Upper John Day, and North Fork) in the John Day River MPG that are above the Lower Mainstem population. These estimates are based on observations from spawning surveys and kelt collections seined from the mainstem. Since 1992, the estimated hatchery fraction ranged from 0.01-0.13. The mean hatchery fraction was 0.067. Based on recovery of hatchery fish with coded wire tags (CWTs), primarily from angler caught fish, the majority of stray hatchery fish originate from Snake River

hatcheries. Given that the hatchery fraction of out-of-DPS strays is estimated to be greater than 0.05 for two or more generations, the rating is **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS*: There have been four steelhead with CWTs recovered in the John Day River MPG from out-of-MPG within-DPS origin. Three originated from the Umatilla Hatchery program and one from the Deschutes. It appears very few within-DPS hatchery fish stray into the John Day River, thus the rating is **low risk** for this metric.

(3) *Out-of-population spawners from within the MPG:* There are no steelhead hatchery programs operated within the John Day River basin, therefore this metric is rated as **very low risk**.

(4) *Within-population hatchery spawners:* There are no steelhead hatchery programs operated within the John Day River basin, therefore this metric is rated as **very low risk**.

The overall rating for the spawner composition metric is **high risk**, due to the high proportion of out-of-DPS strays that spawn naturally in this population**.**

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution of the Middle Fork population encompassed four ecoregions, with the John Day Clarno Highlands, John Day Clarno Uplands, and Melange being the dominant ecoregions (Figure 6). There has been little change in ecoregion distribution between intrinsic and current. All MaSAs in the intrinsic distribution are currently occupied in a similar distribution pattern (Table 3). The rating is **low risk** for this metric.

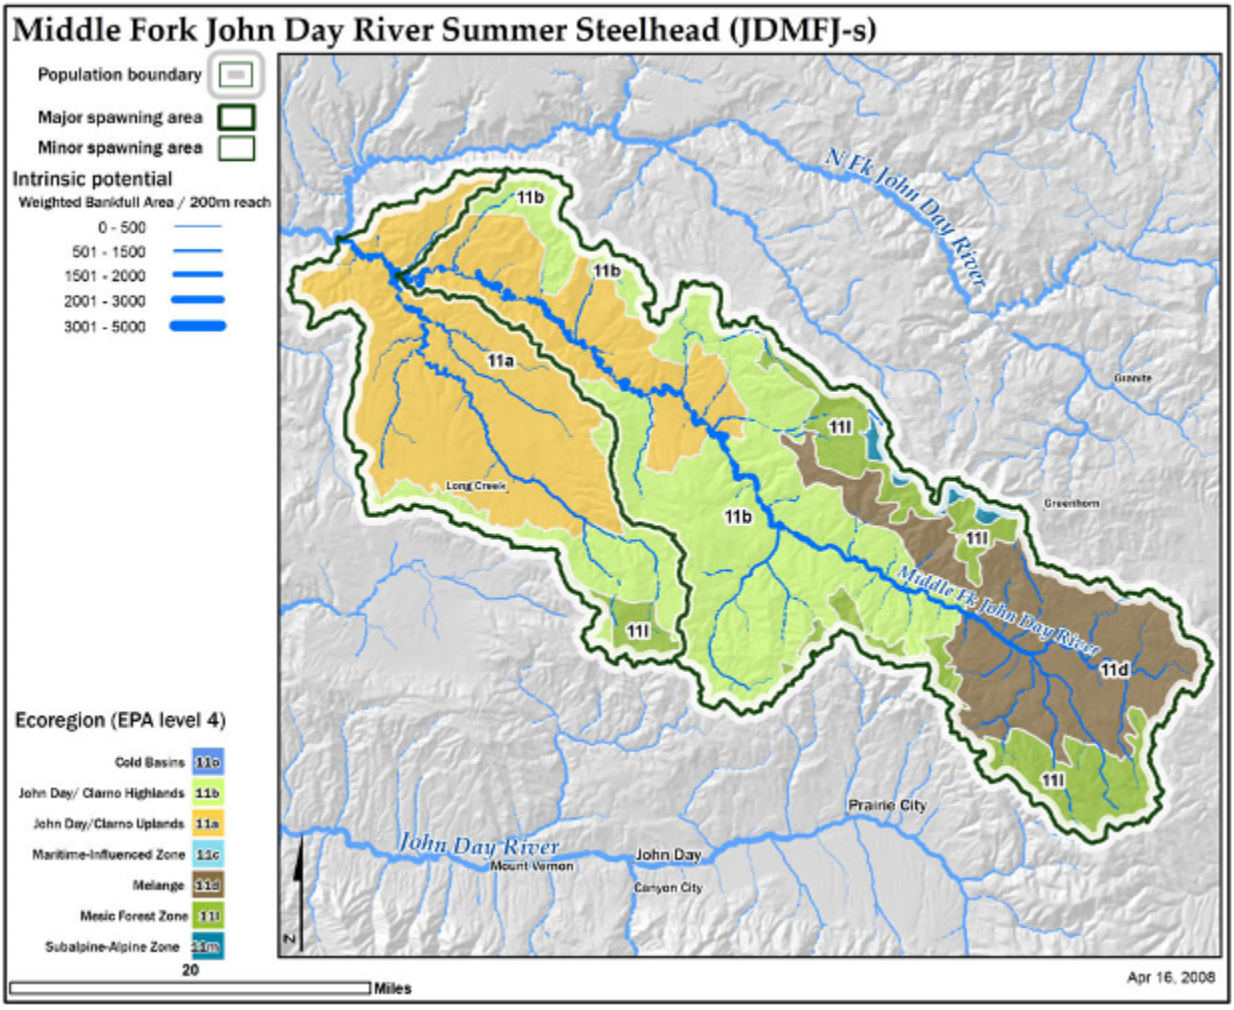

Figure 6. Middle Fork John Day River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Middle Fork John Day River summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
John Day Clarno Highlands	30.9	37.7
John Day Clarno Uplands	46.2	38.2
Melange	19.6	22.2
Mesic Forest Zone	3.3	2.0

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population crosses three dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Adult migration timing:* These dams establish a thermal barrier in the reservoirs that delays and potentially induces some mortality of migrating adults. This barrier is diminished later in the migration season. Because the timing of the barrier varies from year to year and does not develop in some years, and the degree of differential survival is likely low and not well-understood, we rate the selection intensity as low. Heritability of this trait is high, thus the hydropower rating for this trait is **moderate risk**.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is very limited tribal harvest of natural-origin fish within the John Day River subbasin; impacts from the recreational fishery are incidental to hatchery-origin fish harvest and are not selective. No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: There are no steelhead hatchery programs operated within the population; therefore, the hatchery rating is **very low risk** for all traits.

Habitat: Altered flow profiles and increased temperatures have been in place for many generations and are ongoing; there is likely some selection on juvenile and adult migration timing.

> *Adult migration timing:* Low flows in the late summer and early fall in the John Day River likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable, but a negligible proportion of the population is likely subject to these effects. Thus, the impact of habitat changes on this trait is **low risk.**
>
> *Juvenile migration timing:* Late spring and early summer temperatures are elevated relative to historical conditions. There has likely been some effect on juvenile migration timing as temperatures can reach stressful levels in the John Day River mainstem in late spring and early summer in some years. Selection intensity is considered negligible and the heritability of this trait is moderate to low. The rating for this trait is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective

predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

There is only one trait that has a moderate rating for one selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** for the Middle Fork John Day River summer steelhead population (Table 4). The rating for Goal A (allowing natural rates and levels of spatially mediated processes) was **low risk**. The current spawner distribution of the Middle Fork population mimics the intrinsic distribution. The population is distributed broadly across the landscape, in both MaSAs with adequate gaps and good continuity between spawning areas.

The rating for Goal B (maintaining natural levels of variation) was **moderate risk**. Additional genetics analyses are needed to better assess genetic variation and hatchery introgression. This population was rated high risk for proportion of out-of-DPS hatchery strays based on a limited time series of composite John Day River population data. Better population-specific spawner composition data are needed to better understand the out-of-DPS hatchery stray influence. If there is significant hatchery introgression that affects genetic variation through time, then the risk rating may increase.

Overall Viability Rating

The Middle Fork John Day River summer steelhead population does not currently meet the ICTRT criteria for viable status. However, the population does meet the criteria to be rated as **MAINTAINED** (Figure 7). Overall abundance and productivity is rated at **Moderate Risk.** The 10-year geometric mean abundance of natural-origin spawners is 756, which is 76% of the minimum abundance threshold of 1,000. The 20-year geometric mean productivity (2.45 R/S; Table 6) exceeds the minimum required productivity of 1.35 R/S at the abundance threshold. Overall spatial structure and diversity is rated at **Low Risk** and the lower end of the adjusted standard error met the low risk criteria. Increased annual abundance would allow this population to achieve an abundance/productivity risk rating of low and raise the overall viability rating to viable.

Abundance/ Productivity Risk	Spatial Structure/Diversity Risk: Very Low	Low	Moderate	High
Very Low (<1%)	**HV**	**HV**	**V**	**M**
Low (1-5%)	**V**	**V**	**V**	**M**
Moderate (6 – 25%)	**M**	**M**	**M** Middle Fork John Day River	**HR**
High (>25%)	**HR**	**HR**	**HR**	**HR**

Figure 7. Middle Fork John Day River summer steelhead population risk ratings integrated across the four viable salmonid population (VSP) metrics. ***Viability Key: HV – Highly Viable; V – Viable; M – Maintained; HR – High Risk; Shaded cells - does not meet viability criteria (darkest cells are at greatest risk).***

Data Summary – Middle Fork John Day River

Data type: Redd count expansion - Index area redd counts expanded to total population estimate by applying ratio of average redd densities (samples across all areas to samples from index reaches) from EMAP surveys. Assumed 2.1 fish per redd.

Smolt-to-Adult Return rate (SAR): Mid-Columbia composite series (see *Methods*).

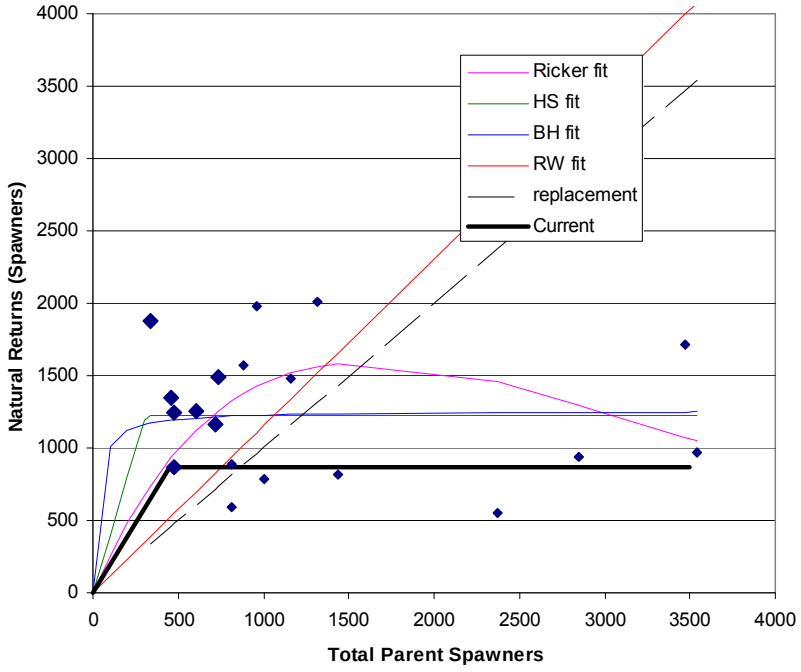

Figure 9. Middle Fork John Day River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

South Fork John Day River Summer Steelhead Population

The South Fork John Day River summer steelhead population (Figure 1) is one of five populations in the John Day River MPG within the Mid-Columbia River DPS. All five populations in this MPG are summer run.

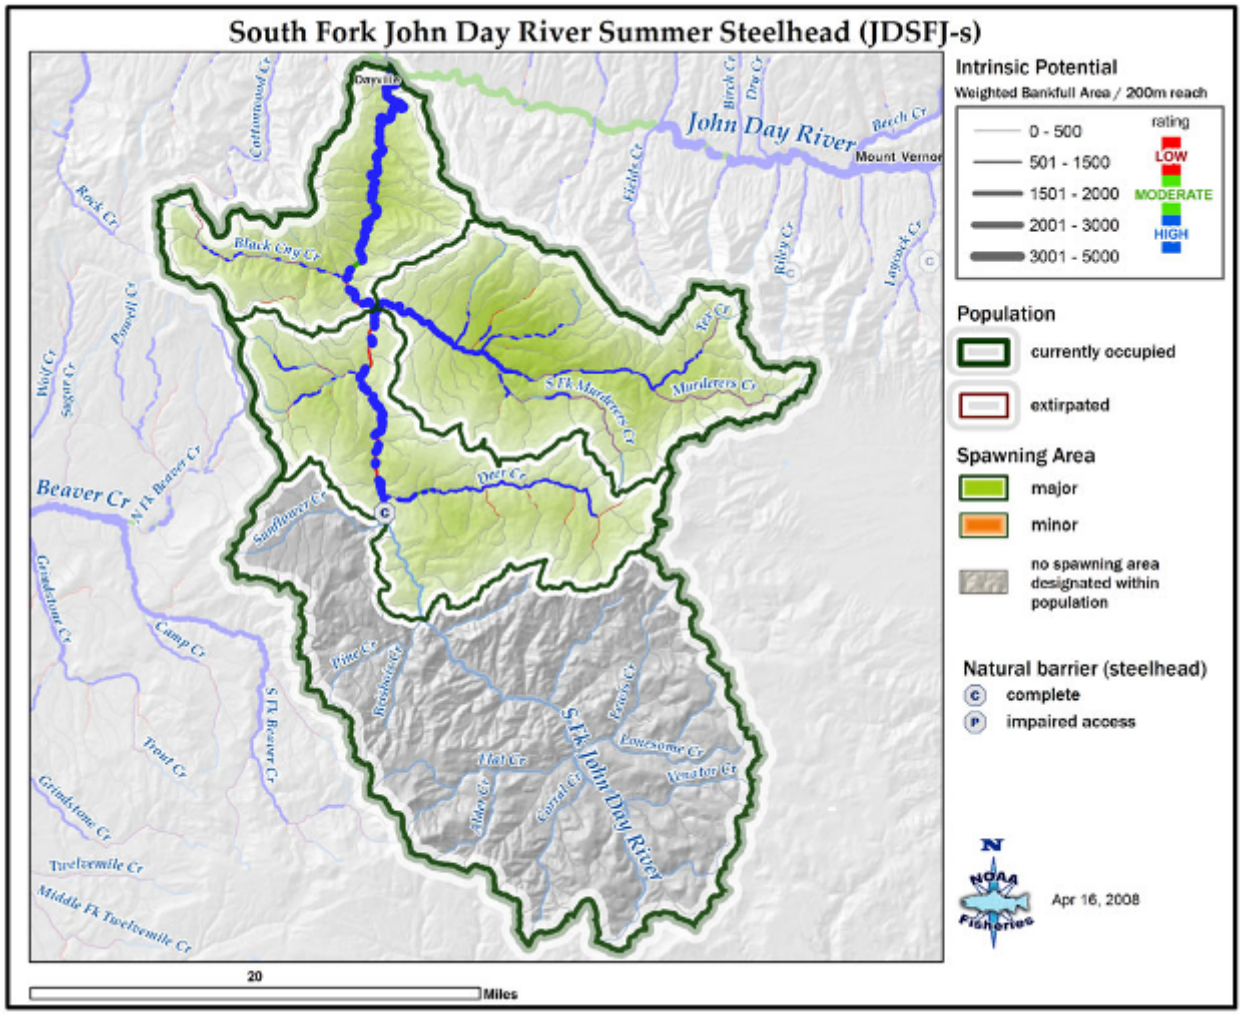

Figure 1. South Fork John Day River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the South Fork population as "basic" in size and complexity (Table 1) based on historical habitat potential (ICTRT 2007), which is the smallest population classification. A steelhead population classified as basic has a minimum abundance threshold criteria of 500 natural-origin spawners with sufficient intrinsic productivity (≥ 1.56 recruits per spawner at the minimum abundance threshold) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the South Fork population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 2.00 recruits per spawner at the minimum abundance threshold.

Table 1. South Fork John Day River summer steelhead basin statistics and intrinsic potential analysis.

Drainage area (km^2)	1,570
Stream lengths km (total) [a]	451
Stream lengths km (below natural barriers) [a]	226
Branched stream area weighted by intrinsic potential (km^2)	0.881
Branched stream area km^2 (weighted and temp. limited) [b]	0.881
Total stream area weighted by intrinsic potential (km^2)	1.030
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	1.030
Size / Complexity category	Basic / "B" (dendritic structure)
Number of major spawning areas (MaSAs)	3
Number of minor spawning areas (MiSAs)	0

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22°C.

Current Abundance and Productivity

Current (1960-2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 105 in 1999 to 2,454 in 1962 (Figure 2). Abundance estimates are based on expanded redd counts. Index surveys of steelhead redds from the Oregon Department of Fish and Wildlife (ODFW), John Day District, were used for the historical dataset. We used index surveys that showed relatively consistent visitation through the years. Survey data from Black Canyon, Deer, upper Murderer's, lower Murderer's, Tex, and Wind creeks were used in the analyses. The current spawning distribution was used for the miles of available habitat within each population's range. The index redd densities were then multiplied by a correction factor based on the ratio of index densities to EMAP (Environmental Monitoring and Assessment Program) densities for 2004-2005. The ratio was consistent for these years (0.36, 0.35). The estimated redd density for the entire spawning area (0.355 x index density) was multiplied by the total miles of currently utilized spawning habitat. Total annual redds were converted to fish by multiplying the total annual number of redds by the number of fish per redd. An average ratio of 2.1 fish per redd was developed from Deer Creek survey data in the Grande Ronde River basin. The ratio is an average from four years of data of complete and repeated surveys (censuses) of redds above a weir where we have a complete count.

The hatchery-origin/natural-origin composition of spawners were computed separately for the Lower Mainstem John Day River population, and combined for all other populations in the John Day River MPG. Data used to represent the South Fork population included observations of positively identified adipose fin-clipped spawners (1992-present) from spawning survey observations in the four populations above the Lower Mainstem, and observations from rotary screw trap and seine collections of adults (2000-present). There is evidence from the Deschutes River that hatchery straying was substantially lower before 1992, and since the source of strays in the John Day River subbasin is the same as in the Deschutes River, we assumed a similar trend. No other data are available for earlier years so the hatchery fraction was set at zero. Age composition was derived from scale readings of creel sampled unmarked fish collected during the 1980s from locations above Tumwater Falls.

Recent year natural spawners include recruits originating from naturally spawning parents and a small fraction of strays from the Snake and Columbia River hatchery programs. Since documentation of hatchery strays began in 1992, spawners originating from naturally spawning parents have comprised an average of 93%, ranging from 87% to 99%.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 259 (Table 2). During the period 1961-1998, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the South Fork John Day River ranged from 0.20 in 1987 to 13.54 in 1968. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 20-year (1979-1998) geometric mean productivity was 2.06 R/S, adjusted for SAR and delimited at 75% (375 spawners) of the abundance threshold.

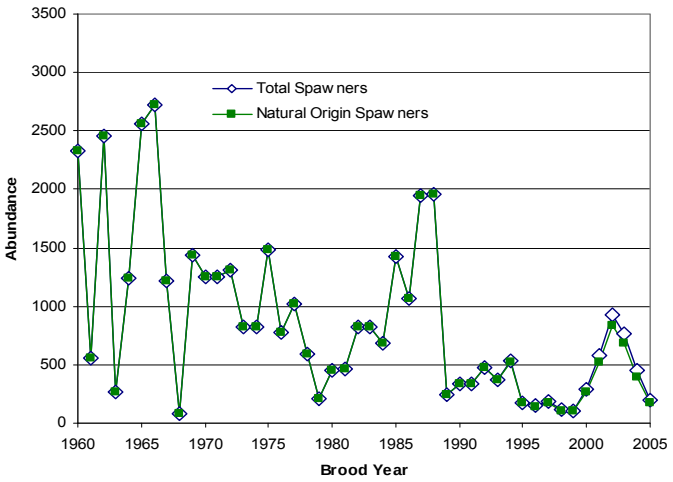

Figure 2. South Fork John Day River summer steelhead population spawner abundance (1960-2005).

Table 2. South Fork John Day River summer steelhead population abundance and productivity.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	259	(76-2729)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.93	(0.87-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (20-year R/S, SAR adjusted & delimited) [a]	2.06	(1.26-3.38)	0.27
Productivity (20-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	0.95	(0.91-1.09)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	0.98	(0.74-1.32)	0.44
Population growth rate (λ): Hatchery effectiveness = **0.0**	0.99	(0.74-1.33)	0.47

a. Delimited productivity excludes any recruit/spawner pair where the spawner number >75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The South Fork John Day River population is at **Moderate Risk** based on current abundance and productivity. The point estimate resides between the 5% and 25% viability curves (Figure 3). The lower bound of the adjusted standard error for both the productivity and abundance extend below the 25% risk level.

The average trend in abundance over the most recent 20 years has been below 1.0 based on both the trend in natural-origin spawner abundance and the population growth rate metrics (Table 2). The pattern in returns from 1980 through 2005 is similar to the pattern for several other Mid-

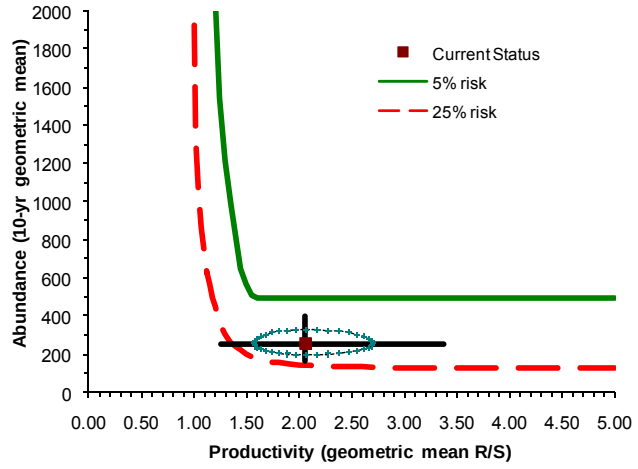

Figure 3. South Fork John Day River summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

Columbia DPS steelhead populations—generally high returns in the mid-1980s, increasing trend beginning in 2000, followed by an abrupt decline in the most recent years. The estimated proportion of hatchery-origin spawners for this population has been relatively low. Therefore the alternative estimate of population growth rate (assuming that hatchery spawners are not contributing as parents to natural production) is slightly higher than, but similar to, the standard estimate. The data series for South Fork John Day steelhead abundance extends back to 1960. Spawning levels in the 1970s were generally higher than levels observed from 1980 through 2005.

Spatial Structure and Diversity

The ICTRT has identified three major spawning areas (MaSAs) and no minor spawning areas (MiSAs) within the South Fork John Day River steelhead population (Figure 4). A natural barrier at Izee Falls limits distribution in the mainstem South Fork John Day River. Spawning is distributed broadly throughout the population boundaries including mainstem areas in the South Fork John Day River, Murderers Creek, and Canyon Creek, as well as many tributaries. Spawners within the South Fork population are primarily natural-origin fish; however, out-of-DPS hatchery fish, primarily from Snake River stocks, are present in the South Fork population.

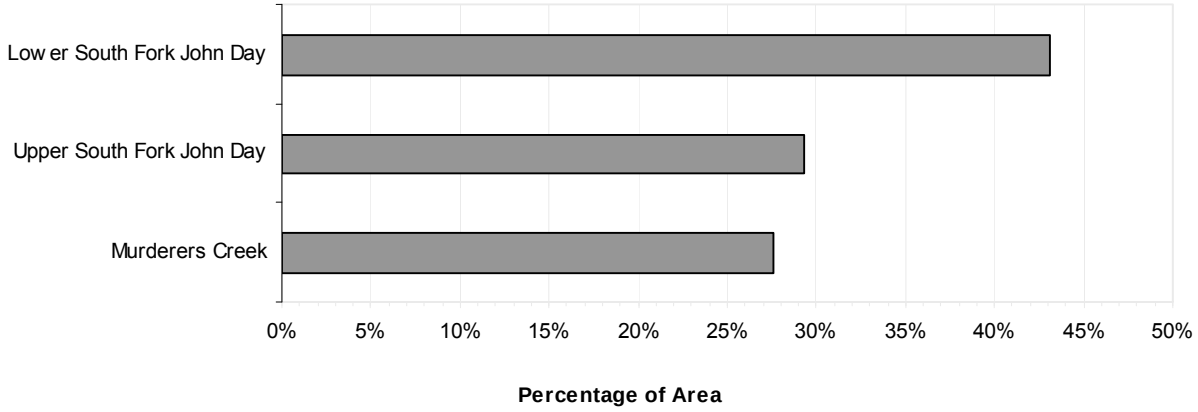

Figure 4. South Fork John Day River summer steelhead population distribution of intrinsic potential habitat across major spawning areas (MaSAs). No minor spawning areas present.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The South Fork John Day River has three MaSAs which are distributed in a dendritic pattern. Intrinsic potential is distributed relatively equally between the three MaSAs in the lower mainstem South Fork, Murderer's Creek, and the upper South Fork. Based on the ODFW spawner distribution database, all of the spawning reaches identified within the intrinsic potential distribution are currently occupied, and 247 km of habitat are presently used for spawning (Figure 5). The South Fork population rates at **low risk** for this metric because all three MaSAs are occupied.

A.l.b. Spatial extent or range of population

The current spawning distribution based on the ODFW distribution database mirrors the historical distribution represented by the intrinsic potential analyses. All MaSAs are currently occupied (Figure 5). The South Fork population is rated **very low risk** for spatial extent and range criteria. Index area spawning surveys are conducted in five creeks, including at least one reach in each MaSA. Recent spawning ground surveys results will be analyzed for future viability assessments.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There has been no increase or decrease in gaps between spawning areas. Spawning habitat connectivity appears to be unchanged within the South Fork population. The South Fork population rates at **very low risk** for gaps and connectivity.

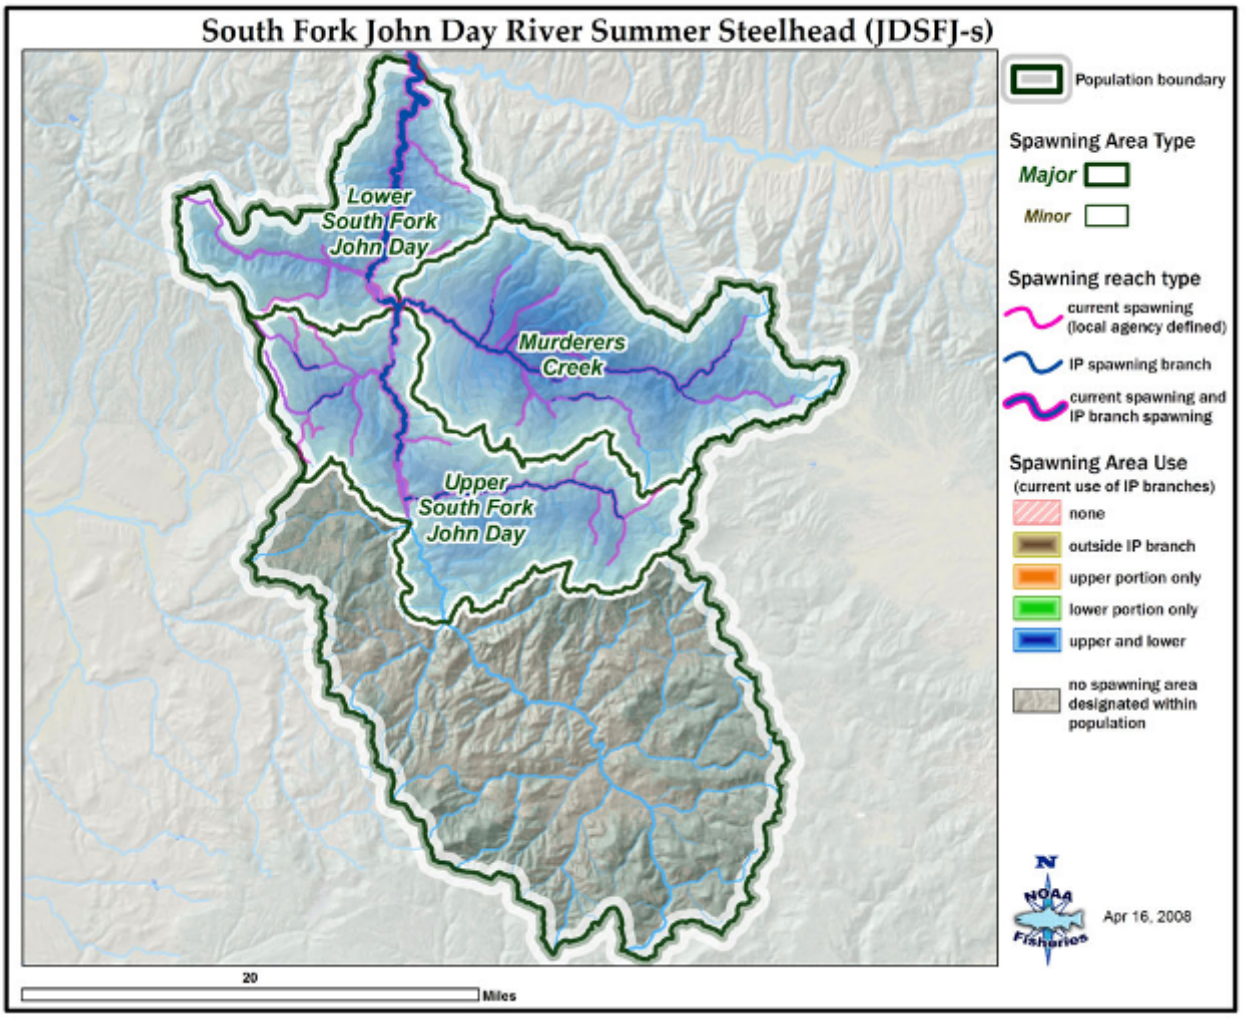

Figure 5. South Fork John Day River summer steelhead population current spawning distribution and spawning area occupancy designations.

There are no direct observations to evaluate current life history strategies relative to historic; therefore we infer loss of life history diversity based on habitat changes. Increased water

temperatures have likely reduced connectivity and quantity of habitats available during summer, but have not likely resulted in loss of any major life history strategies. Juvenile steelhead currently exhibit diverse patterns of movement to and from tributaries and mainstem reaches throughout the life cycle. These diverse movement patterns result in rearing in a diversity of habitat types. South Fork John Day River steelhead are A-run with predominant smolt age-at-migration of age 2 and age 3 and return primarily after one or two years in the ocean. These characteristics are typical for summer run steelhead in the Columbia River basin. Evidence does not indicate loss of any major life history strategies, thus the population rates at **low risk** for this metric**.**

B.1.b. Phenotypic variation

We have no data to assess if any phenotypic traits have been significantly changed or lost. Although habitat conditions are altered from historic conditions the types of alterations would not result in loss of significant phenotypic traits. Due to water temperature changes in the mainstem Columbia River and John Day River, there have likely been reductions in the variation of adult migration timing and some reduction in distribution of summer rearing. There are no other major selective pressures which would cause significant changes or loss of traits. The South Fork population rates at **low risk** for phenotypic variation.

B.1.c. Genetic variation

There are limited genetics data for John Day River steelhead populations and only one sample from the South Fork population. The South Fork population shows greater between-population divergence than the other John Day River samples. Overall, the John Day River samples were not well differentiated. Samples were taken from a relatively small geographic area over a short timeframe. There is no biological basis for the low level of differentiation. Past genetic samples were likely taken prior to potential significant hatchery influence. For the genetic variation metric, we have assigned a level of **low risk** to the South Fork population. This rating reflects a balance between apparent similarity between populations in the John Day River MPG and some degree of differentiation. Samples were collected from multiple locations in 2005 and will be analyzed in the near future to better inform the genetic variation risk assessment.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners:* There are inadequate data to estimate the out-of-DPS hatchery fraction specifically for the South Fork population. Estimates we used in this assessment were based on data from a composite of four John Day River populations (South Fork, Middle Fork, North Fork and Upper Mainstem). These estimates are based on observations from spawning surveys and kelt collections. Since 1992 the estimate hatchery fraction has ranged from 0.01-0.13 with a mean of 0.067. Based on coded wire tags (CWTs) recovered primarily from recreational fisheries, most of the strays are from Snake River hatcheries. Given the level and duration of strays, the population rated at **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS:* There have been a total of four fish with CWTs recovered in the John Day River from out-of-MPG within-DPS origin. Three originated from

the Umatilla Hatchery program and one from the Deschutes. It appears very few within-DPS hatchery fish stray into the John Day River MPG, thus the rating is **low risk**.

(3) *Out-of-population spawners from within the MPG:* There are no steelhead hatchery programs operated within the John Day River basin, and this metric is rated as **very low risk**.

(4) *Within-population hatchery spawners*. There are no steelhead hatchery programs operated within the John Day River basin, therefore this metric is rated as **very low risk**.

The overall rating for spawner composition is **high risk** due to the high proportion of out-of-DPS strays that spawn naturally in this population**.**

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution of the South Fork population encompassed five ecoregions, with the John Day Clarno Uplands being predominant. The current distribution is nearly identical to the intrinsic distribution (Figure 6 and Table 3), thus we have rated this population at **low risk** because only two of the ecoregions contain greater than 10% of the historic distribution.

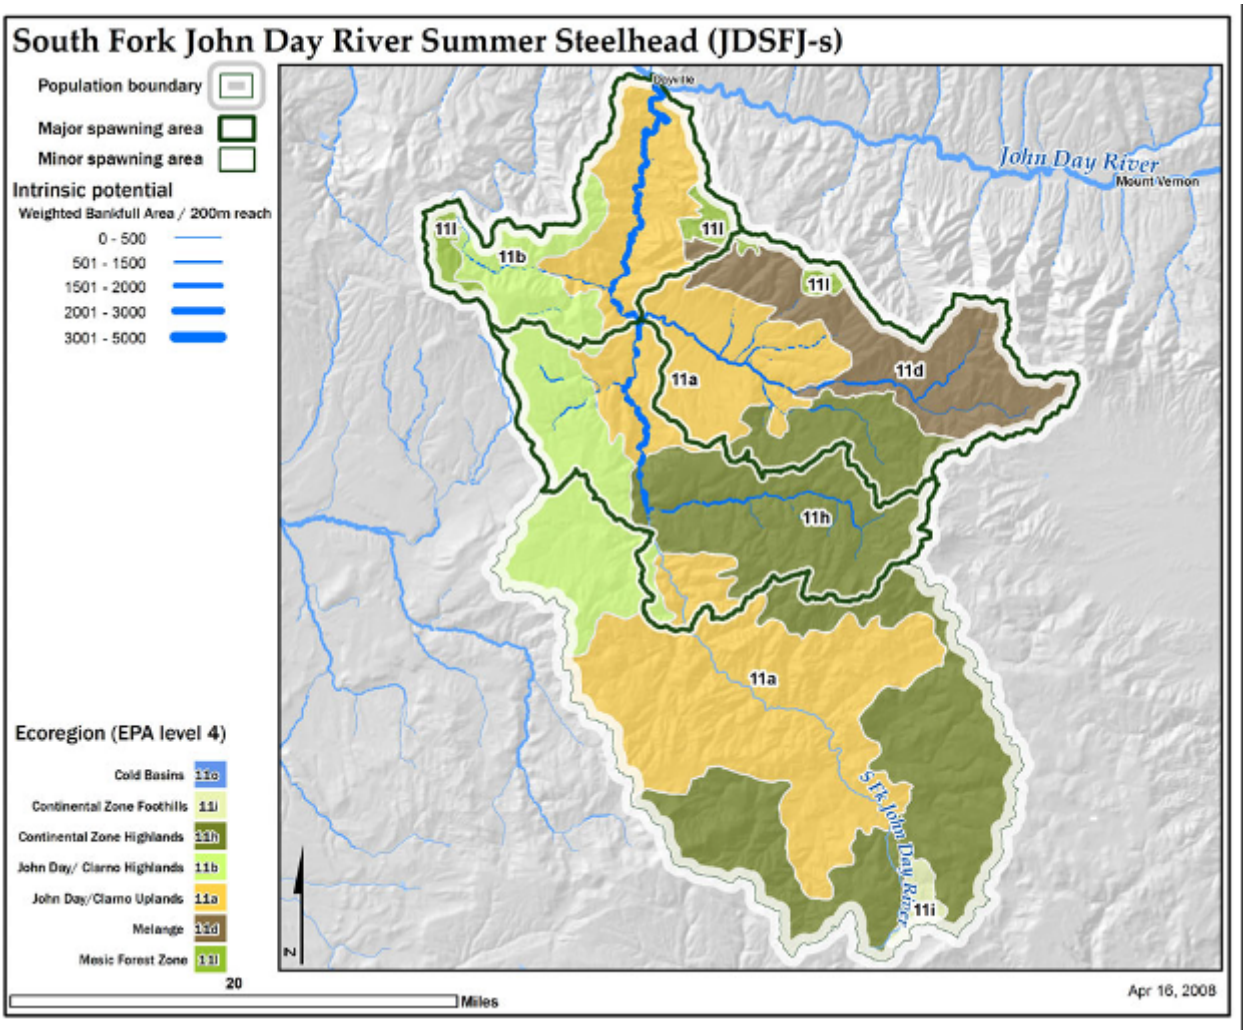

Figure 6. South Fork John Day River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. South Fork John Day River summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Continental Zone Highlands	16.7	16.4
John Day Clarno Highlands	3.4	3.4
John Day Clarno Uplands	69.9	70.2
Melange	9.9	9.9
Mesic Forest Zone	0.1	0.1

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes three dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Adult migration timing*: These dams establish a thermal barrier in the reservoirs that delays and potentially induces some mortality of migrating adults. This barrier is diminished later in the migration season. Because the timing of the barrier varies from year to year and does not develop in some years, and the degree of differential survival is likely low and not well-understood, we rate the selection intensity as low. Heritability of this trait is high, thus the hydropower rating for this trait is **moderate risk**.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is very limited tribal harvest of natural-origin fish within the John Day River subbasin; impacts from the recreational fishery are incidental to hatchery-origin fish harvest and are not selective. No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: There are no steelhead hatchery programs operated within the population; therefore, the hatchery rating is **very low risk** for all traits.

Habitat: Altered flow profiles and increased temperatures have been in place for many generations and are ongoing; there is likely some selection on juvenile and adult migration timing.

> *Adult migration timing:* Low flows in the late summer and early fall in the John Day River likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable, but a negligible proportion of the population is likely subject to these effects. Thus, the impact of habitat changes on this trait is **low risk.**
>
> *Juvenile migration timing:* Late spring and early summer temperatures are elevated relative to historical conditions. There has likely been some effect on juvenile migration timing as temperatures can reach stressful levels in the John Day River mainstem in late spring and early summer in some years. Selection intensity is considered negligible and the heritability of this trait is moderate to low. The rating for this trait is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective

predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

There is only one trait that has a moderate rating for one selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** (Table 4) for the South Fork John Day River population. The rating for Goal A (allowing natural rates and levels of spatially mediated processes) was **very low risk**. Although the current spawner distribution mimics the intrinsic distribution, only three MaSAs exist within the population. Good continuity exists between spawning areas and gaps between areas have remained relatively unchanged.

The rating for Goal B (maintaining natural levels of variation) is **moderate risk**. As is the case for all John Day River steelhead populations there is uncertainty in ratings of metrics "genetic variation" and "proportion of spawners that are out-of-DPS strays." We have limited genetics data for South Fork steelhead to determine if the current population variation is similar to historic conditions and to examine the degree of hatchery fish introgression. The metric for proportion of out-of-DPS strays rated as high risk. However, the analyses relied on composite data from four John Day River populations. Additional population-specific spawner composition data are needed to better inform the risk rating and to reduce the associated uncertainty.

Overall Viability Rating

The South Fork John Day River summer steelhead population does not currently meet the ICTRT criteria for viable status (Figure 7). However, the population does meet criteria to be rated as **MAINTAINED**. Overall abundance and productivity is rated at **Moderate Risk.** The 10-year geometric mean abundance of natural-origin spawners is 259, which is only 52% of the minimum abundance threshold of 500. The 20-year geometric mean productivity (2.06 R/S; Table 6) exceeds the minimum required productivity of 1.56 R/S at the abundance threshold. Overall spatial structure and diversity is rated at **Moderate Risk.** Improvement in abundance will allow this population to achieve viable status. There is considerable uncertainty regarding the spawner composition data. Enhanced monitoring of the hatchery-origin/natural-origin ratios on the South Fork John Day River spawning grounds should be conducted to improve the hatchery fraction estimate and reduce the degree of uncertainty.

		Spatial Structure/Diversity Risk

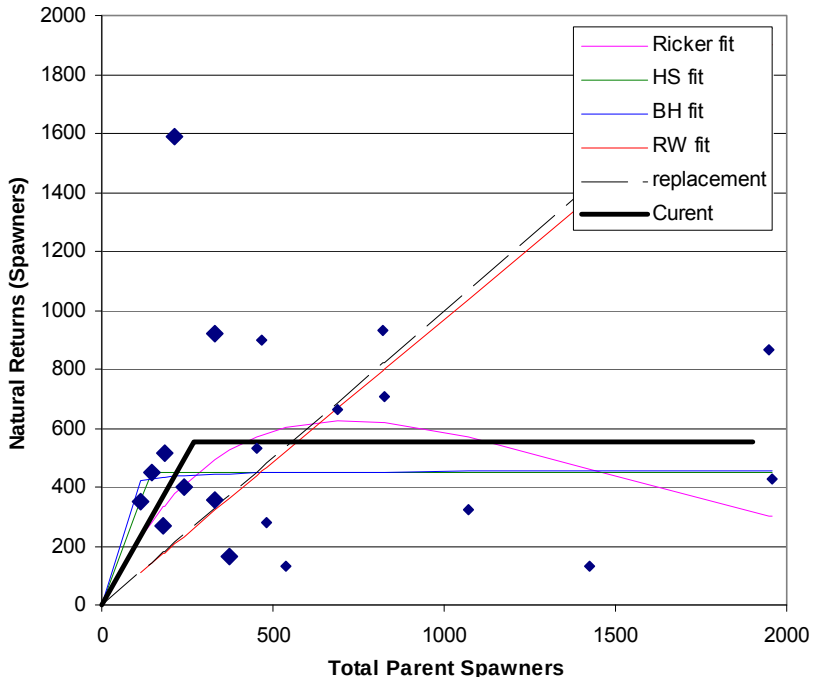

Figure 9. South Fork John Day River steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Upper Mainstem John Day River Summer Steelhead Population

The Upper Mainstem John Day River summer steelhead population (Figure 1) is one of five populations in the John Day River MPG within the Mid-Columbia River DPS. All five populations in this MPG are summer run.

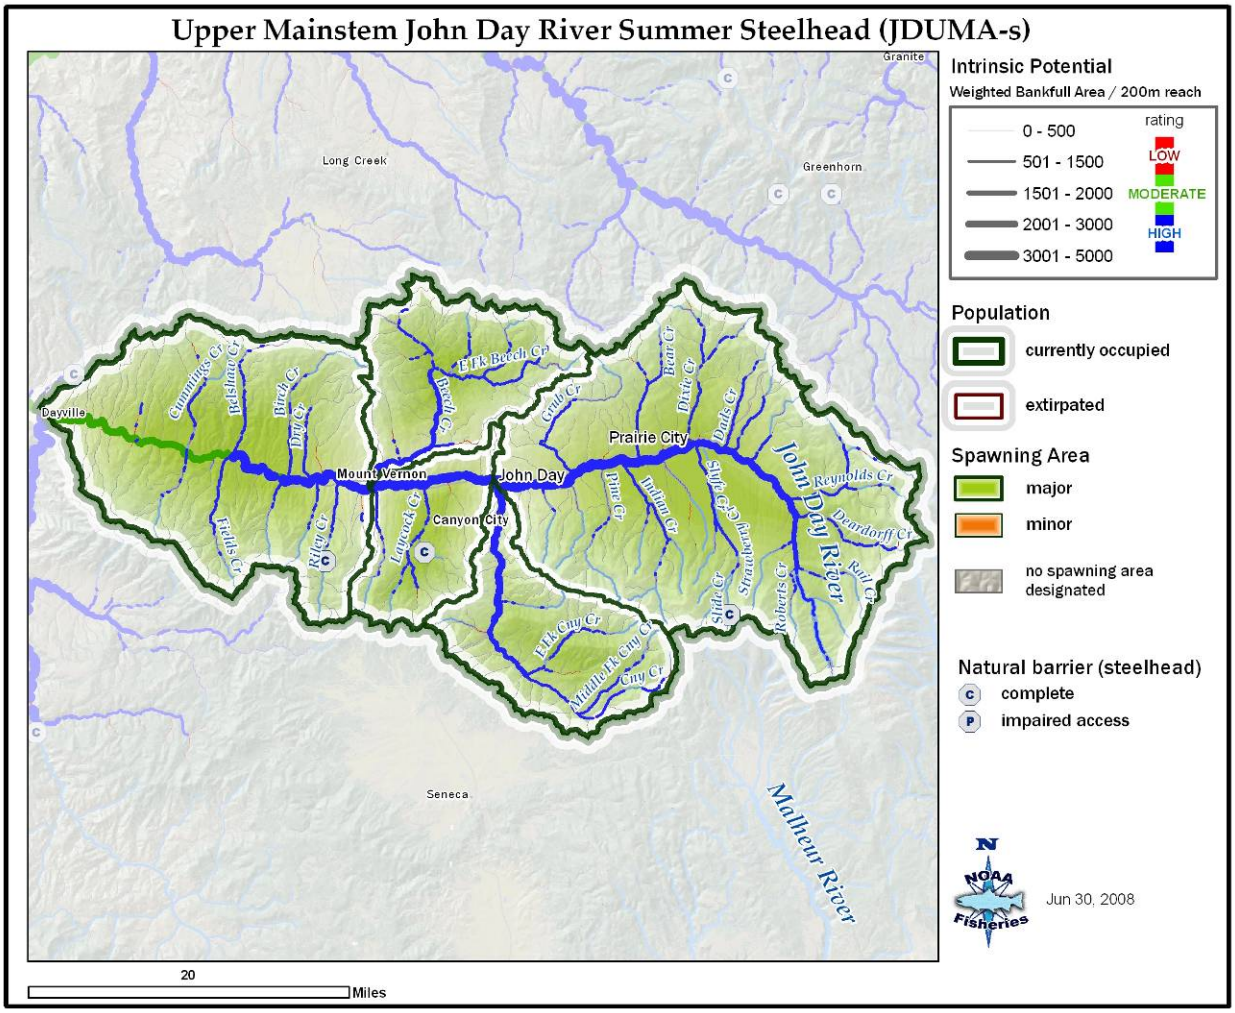

Figure 1. Upper Mainstem John Day River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Upper Mainstem John Day River population as "intermediate" in size and complexity (Table 1) based on historical habitat potential (ICTRT 2007). A steelhead population classified as intermediate has a minimum abundance threshold of 1,000 natural-origin spawners with sufficient intrinsic productivity (≥ 1.35 recruits per spawner at the minimum abundance threshold) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the Upper Mainstem population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.64 recruits per spawner at the minimum abundance threshold.

Table 1. Upper Mainstem John Day River summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	2,511
Stream lengths km (total) [a]	801
Stream lengths km (below natural barriers) [a]	767
Branched stream area weighted by intrinsic potential (km^2)	3.091
Branched stream area km^2 (weighted and temp. limited) [b]	3.091
Total stream area weighted by intrinsic potential (km^2)	3.346
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	3.346
Size / Complexity category	Intermediate / "B" (dendritic structure)
Number of major spawning areas (MaSAs)	5
Number of minor spawning areas (MiSAs)	0

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where the mean weekly modeled water temperature was > 22ºC.

Current Abundance and Productivity

Current (1965-2005) total spawner abundance (number of adult spawners in natural production areas) has ranged from 197 in 1995 to 4,235 in 1988 (Figure 2). Abundance estimates are based on expanded redd counts. Index surveys of steelhead redds from the Oregon Department of Fish and Wildlife (ODFW), John Day District, were used for the historical dataset. We used index surveys that showed relatively consistent visitation through years (Belshaw, Bear, Beech, East Fork Beech, Canyon, Middle Fork Canyon, McClellan, Riley, and Tinker creeks). The current spawning distribution was used for the miles of available habitat within each population's range. The index redd densities were then multiplied by a correction factor to estimate the annual redd densities for the entire spawning distribution, based on the ratio of index redd densities to EMAP (Environmental Monitoring and Assessment Program) redd densities for 2004-2005; the ratio was consistent for these years (0.36, 0.35). The estimated redd density for the entire spawning area (0.355 x index density) was multiplied by the total miles of spawning habitat currently utilized. Total annual redds were converted to fish by multiplying the total annual number of redds by the number of fish per redd. Fish per redd ratios were developed from four years of data of complete and repeated surveys (censuses) on Deer Creek in the Grande Ronde River basin of redds above a weir where there was a complete fish count; the calculated average fish per redd estimate was 2.1.

The hatchery-origin/natural-origin composition of spawners was computed separately for the Lower Mainstem John Day River population and combined for all other populations in the MPG. Data used to represent the Upper Mainstem population included observations of positively identified fin-clipped spawners (1992-present) from spawning survey observations in the four populations above the Lower Mainstem, and observations from rotary screw trap and seine collections of adults (2000-present). Evidence from the Deschutes River indicates that hatchery straying was substantially lower before 1992; because the source of strays in the John Day River subbasin is the same as in the Deschutes River we assumed a similar trend. No data are available for earlier years so the hatchery fraction was set at zero. Age composition was derived from scale readings of creel sampled unmarked fish collected during the 1980s above Tumwater Falls.

Recent year natural spawners include recruits from naturally spawning parents and a small fraction of strays from Snake and Columbia River hatchery programs. Spawners originating from naturally spawning parents have comprised an average of 93% since hatchery strays were documented in 1992. Since then, the percentage of natural spawners has ranged from 87%-99%.

Abundance in recent years has been moderately variable. The 10-year (1994-2003) geometric mean abundance of natural-origin spawners was 524 (572 total spawners). During the period 1969-1998, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Upper Mainstem John Day River ranged from 0.19 in 1992 to 5.43 in 1979. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 20-year (1979-1998) geometric mean productivity was 2.14 R/S, adjusted for SAR and delimited at 75% (750 spawners) of the abundance threshold.

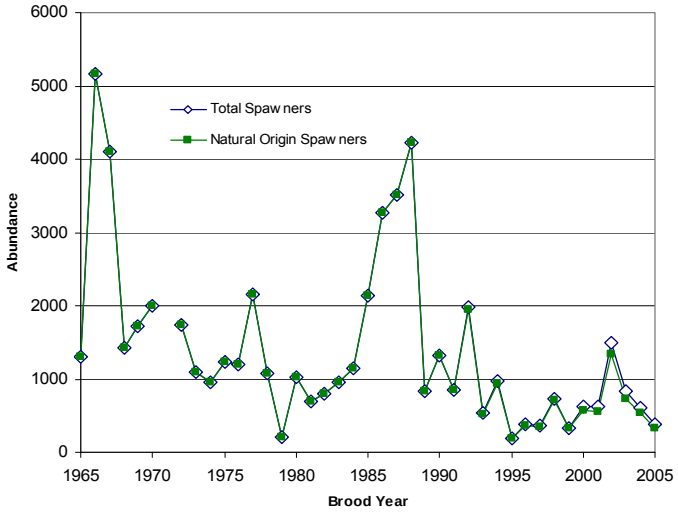

Figure 2. Upper Mainstem John Day River summer steelhead population spawner abundance (1960-2003).

Table 2. Upper Mainstem John Day River summer steelhead population abundance and productivity.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	524	(185-5169)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.93	(0.87-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (20-year R/S, SAR adjusted & delimited) [a]	2.14	(1.52-2.76)	0.33
Productivity (20-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	0.95	(0.92-1.03)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	0.99	(0.77-1.27)	0.44
Population growth rate (λ): Hatchery effectiveness = **0.0**	0.99	(0.77-1.28)	0.47

a. Delimited productivity excludes any recruit/spawner pair where the spawner number >75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Upper Mainstem John Day River population is at **Moderate Risk** based on current abundance and productivity. The point estimate for abundance and productivity resides between the 5% and 25% risk curves (Figure 3).

The average trend in abundance over the most recent 20 years has been below 1.0 based on both the trend in ln(natural-origin spawner abundance) and the population growth rate metric (λ) with no adjustment for relative hatchery-origin spawner effectiveness (Table 2). Like most Mid-Columbia DPS steelhead

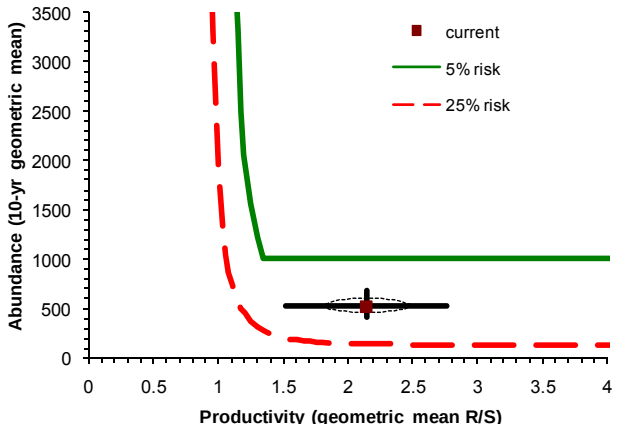

Figure 3. Figure 3. Upper Mainstem John Day River steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

populations, the estimated number of spawners in the Upper Mainstem John Day increased in the mid 1980s, and then dropped back down by the early 1990s. Annual returns since 1999 have generally been below the early 1980s levels, except for increased returns peaking in 2002. The estimated proportion of hatchery-origin spawners has been relatively constant over the period at 7% (Table 3.5.5–2). The relative effectiveness of hatchery-origin spawners in contributing to natural production in this population is not known. Setting the value to 0.0, the opposite extreme from 1.0, does not substantially alter the estimated population growth rate given the relatively low proportion of hatchery-origin spawners recorded for this population.

Spatial Structure and Diversity

The ICTRT has identified five major spawning areas (MaSAs) and no minor spawning areas (MiSAs) within the Upper Mainstem John Day River steelhead population (Figure 4). Most of the production area resides in the Upper John Day MaSA. Spawning is distributed broadly across the population including mainstem reaches in the Upper John Day River, Canyon Creek, and Beech Creek, as well as in numerous tributaries from the town of Dayville, OR, upstream to the headwaters. Spawners within the Upper John Day River are primarily natural-origin fish, although a small proportion of out-of-DPS hatchery fish, primarily from Snake River stocks, are present in the Upper Mainstem population.

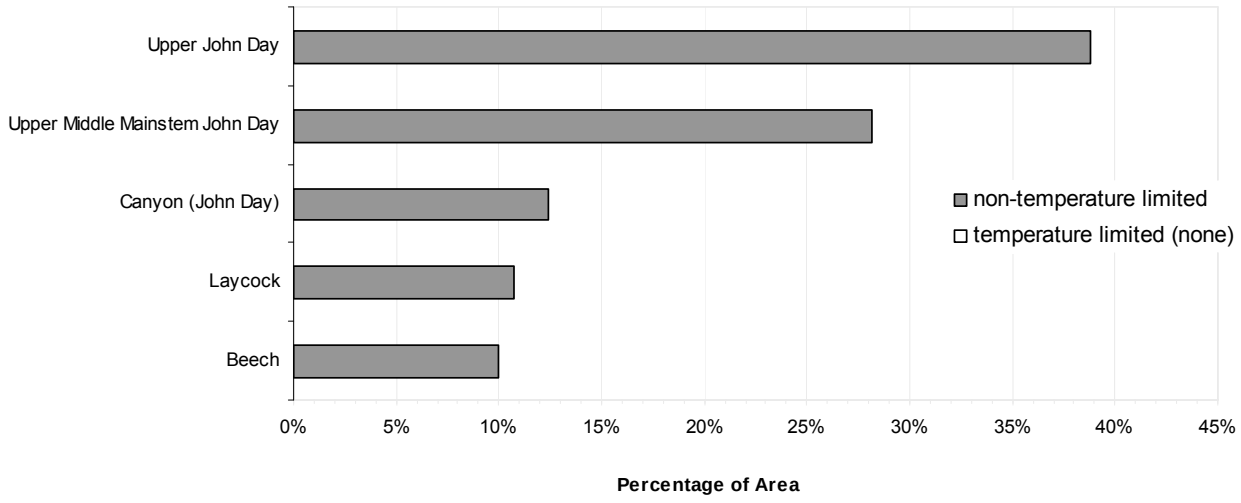

Figure 4. Upper Mainstem John Day River summer steelhead population distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs).

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Upper Mainstem John Day River population has five MaSAs (no MiSAs) which are distributed in a complex dendritic pattern. Based on the ODFW spawner distribution database all of the MaSAs are currently occupied and a total of 489 km are presently used for spawning (Figure 5). The Upper Mainstem John Day River population rates at **very low risk** because all five MaSAs are occupied in a dendritic configuration.

A.l.b. Spatial extent or range of population

All of the historical MaSAs are currently occupied (Figure 5). This population rates at **very low risk** for spatial extent and range, since greater than 90% of the historical MaSAs are occupied. There are nine spawning survey index sites in the Upper Mainstem John Day River population covering all five MaSAs. Recent survey results will be analyzed for future viability assessments.

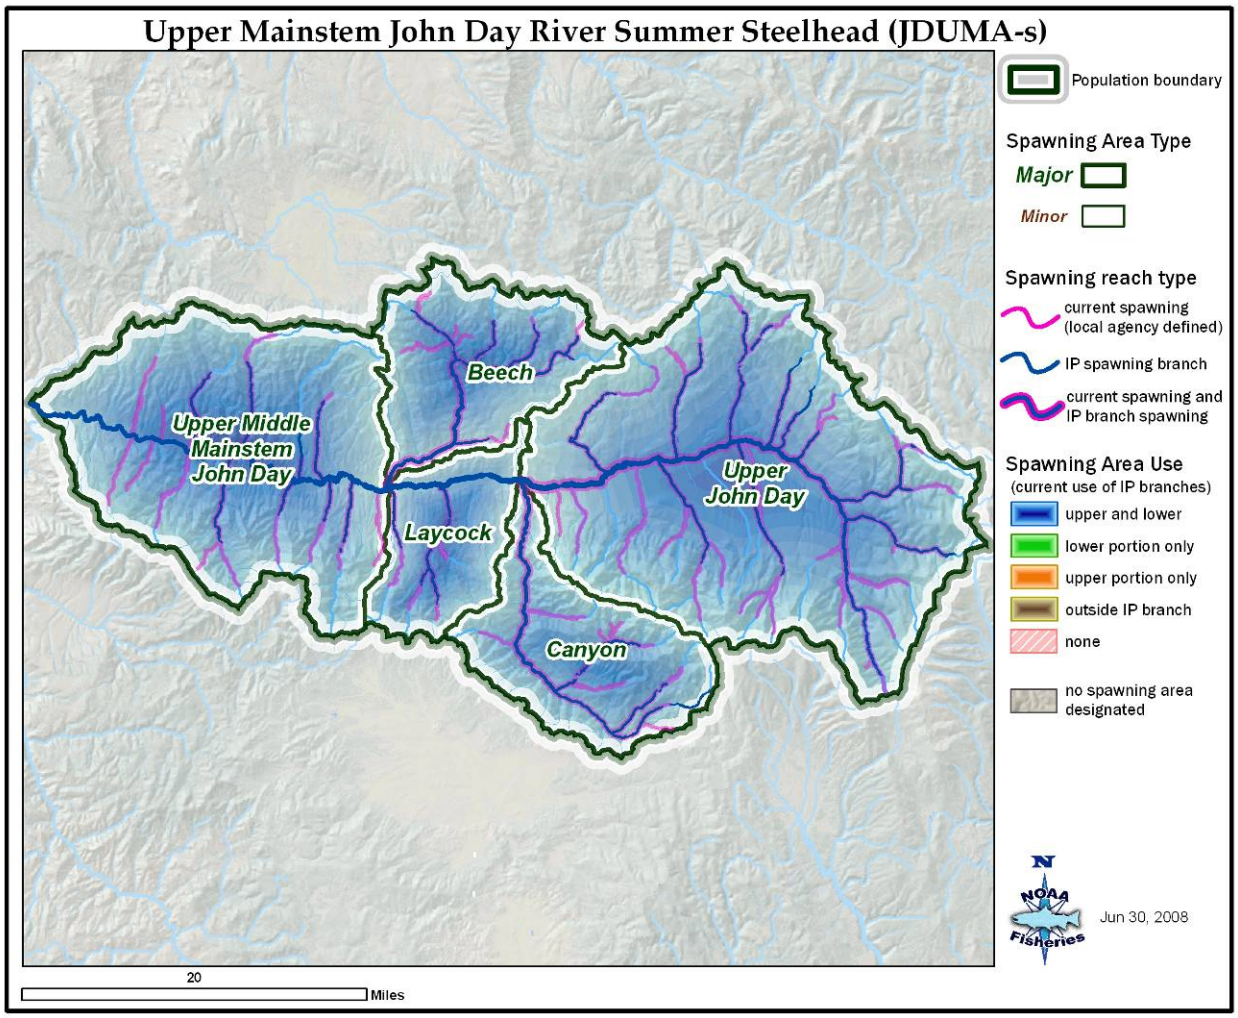

Figure 5. Upper Mainstem John Day River summer steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There have been no increases or decreases in gaps between spawning areas relative to historic distribution. Spawning connectivity appears to be unchanged, thus the population rates at **very low risk** for this metric.

B.1.a. Major life history strategies

There are no direct observations to assess loss in major life history strategies for the Upper Mainstem population; therefore we infer changes in life history from habitat information. Habitat conditions have been altered resulting in decreased flows and increased temperatures. The habitat changes limit juvenile movement patterns and rearing distribution during summer. The age-at-migration and ocean residence data are based on scale analyses from angler caught fish and represent a composite for John Day River populations. Smolt age-at-migration and ocean residence appear to be normal for A-run steelhead. There is no evidence for loss of major life history pathways. We have rated this metric as **moderate risk** because of the significant loss of summer rearing in the upper mainstem and tributaries.

B.1.b. Phenotypic variation

Mainstem Columbia River temperatures, as well as temperatures within the John Day River basin, have likely reduced the variation in both adult and juvenile migration. Warmer temperatures in the summer and autumn hinder or prevent adult movement upstream into the John Day River. Warmer temperatures in early summer have likely truncated the smolt migration timing so that fewer fish migrate at the tail end of the distribution. The reduction in these phenotypic traits results in a rating of **low risk** for the Upper Mainstem John Day River population.

B.1.c. Genetic variation

There are limited genetics data for the John Day River steelhead populations and only one sample from the Upper Mainstem population. We have no indications of past bottlenecks and the only major genetics concern is related to introgression from out-of-DPS hatchery fish. Overall the John Day River samples are not well differentiated. Samples were taken from a relatively small geographic area for only one year. We have rated the population as **low risk**. This rating is driven by balance between apparent similarity within and between populations and relative degree of differentiation. There is the need for better genetic assessment of this population to characterize genetic diversity and hatchery fish genetic introgression. Samples were collected in 2005 to provide better information for assessing genetic variation.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners*: Inadequate data exist to estimate the out-of-DPS hatchery fraction specifically for the Upper Mainstem population. Estimates we used in this assessment are based on data from a composite of the four populations (South Fork, Middle Fork, North Fork and Upper Mainstem) in the John Day River that are above the Lower Mainstem population. These estimates are based on observations from spawning surveys and kelt collections seined from the mainstem. Since 1992, the estimated hatchery fraction ranged from 0.01-0.13. The mean hatchery fraction was 0.067. Based on coded wire tags (CWTs) recovered primarily from angler caught fish, the majority of stray hatchery fish originate from Snake River hatcheries. Given that the hatchery fraction of out-of-DPS strays is estimated to be greater than 0.05 for two or more generations, the rating is **high risk** for this metric.

(2) *Out-of-MPG spawners from within the DPS*: There have been four fish with CWTs recovered in the John Day River from out-of-MPG within-DPS origin. Three originated from the Umatilla Hatchery program and one from the Deschutes. It appears very few within-DPS hatchery fish stray into the John Day River, thus the rating is **low risk** for this metric.

(3) *Out-of-population spawners from within the MPG*: There are no steelhead hatchery programs operated within the John Day River basin, and this metric is rated as **very low risk**.

(4) *Within-population hatchery spawners*: There are no steelhead hatchery programs operated within the John Day River basin, therefore this metric is rated as **very low risk**.

The overall spawner composition rating is **high risk** due to the high proportion of out-of-DPS strays that spawn naturally in this population**.**

B.3.a. Distribution of population across habitat types

The initial distribution of the Upper Mainstem population encompassed four ecoregions of which only two were greater than 10% of the distribution (Figure 6). The John Day Clarno Uplands is the dominant ecoregion. There has been very little change in ecoregion distribution as the current distribution mimics the intrinsic potential (Table 3). The risk level is **low risk** only because two ecoregions have proportions greater than 10%.

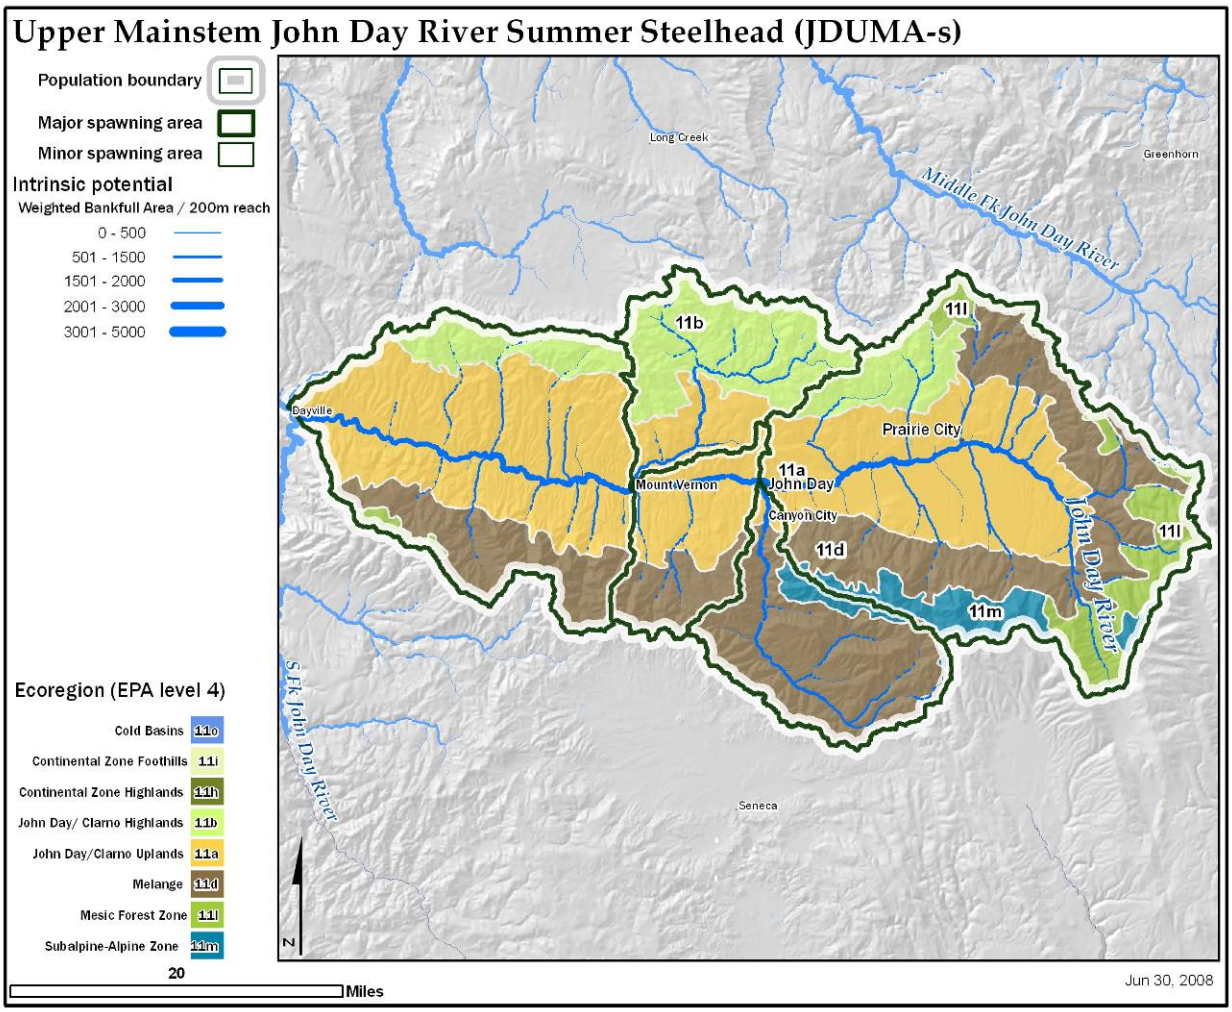

Figure 6. Upper Mainstem John Day River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Upper Mainstem John Day River summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
John Day Clarno Highlands	7.0	9.4
John Day Clarno Uplands	72.5	63.2
Melange	18.3	24.7
Mesic Forest Zone	2.2	2.7

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population crosses three dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Adult migration timing:* These dams establish a thermal barrier in the reservoirs that delays and potentially induces some mortality of migrating adults. This barrier is diminished later in the migration season. Because the timing of the barrier varies from year to year and does not develop in some years, and the degree of differential survival is likely low and not well-understood, we rate the selection intensity as low. Heritability of this trait is high, thus the hydropower rating for this trait is **moderate risk**.

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is very limited tribal harvest of natural-origin fish within the John Day River subbasin; impacts from the recreational fishery are incidental to hatchery-origin fish harvest and are not selective. No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: There are no steelhead hatchery programs operated within the population; therefore, the hatchery rating is **very low risk** for all traits.

Habitat: Altered flow profiles and increased temperatures have been in place for many generations and are ongoing; there is likely some selection on juvenile and adult migration timing.

> *Adult migration timing:* Low flows in the late summer and early fall in the John Day River likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable, but a negligible proportion of the population is likely subject to these effects. Thus, the impact of habitat changes on this trait is **low risk.**
>
> *Juvenile migration timing:* Late spring and early summer temperatures are elevated relative to historical conditions. There has likely been some effect on juvenile migration timing as temperatures can reach stressful levels in the John Day River mainstem in late spring and early summer in some years. Selection intensity is considered negligible and the heritability of this trait is moderate to low. The rating for this trait is **low risk**.

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing:* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later

out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

There is only one trait that has a moderate rating for one selective activity. Therefore, the overall selectivity rating for this population is **low risk.**

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** for the Upper Mainstem John Day River population (Table 4). The rating for Goal A (allowing natural rates and levels of spatially mediated processes) was **very low risk** since the current distribution is nearly identical to the historic distribution.

The rating for Goal B (maintaining natural levels of variation) was **moderate risk**. This risk rating was a result of a moderate rating for changes in major life history strategies. Additional genetics information needs to be assessed to determine current genetic variation and to examine for the degree of introgression of hatchery fish. The population was rated as high risk for out-of-DPS hatchery strays based on a limited time series of composite John Day River population hatchery fish observation data. Better population-specific spawner composition data are needed to better determine the out-of-DPS hatchery fraction. If there is significant hatchery introgression which affects the genetic variation of this population through time, then the risk rating for Goal B will increase, and the overall risk rating for spatial structure/diversity will increase.

Table 4. Upper Mainstem John Day River steelhead population spatial structure and diversity risk rating.

Overall Viability Rating

The Upper Mainstem John Day River summer steelhead population does not currently meet the ICTRT criteria for viable status (Figure 7). However, the population does meet criteria to be rated as **MAINTAINED**. Overall abundance and productivity is rated at **Moderate Risk.** The 10-year geometric mean abundance of natural-origin spawners is 524, which is only 52% of the minimum abundance threshold of 1,000. The 20-year geometric mean productivity (2.14 R/S; Table 6) exceeds the minimum required productivity of 1.35 R/S at the abundance threshold and the lower end of the adjusted standard error is above the 25% risk level. Overall spatial structure and diversity is also rated at **Moderate Risk** due to loss in life history diversity and high risk for spawner composition. In order for this population to achieve a viable rating, an increase in abundance is required so that abundance/productivity risk is reduced to low risk.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V**	**V**	**M**
	Moderate (6 – 25%)	**M**		**M** Upper Mainstem John Day River	**HR**
	High (>25%)	**HR**	**HR**	**HR**	**HR**

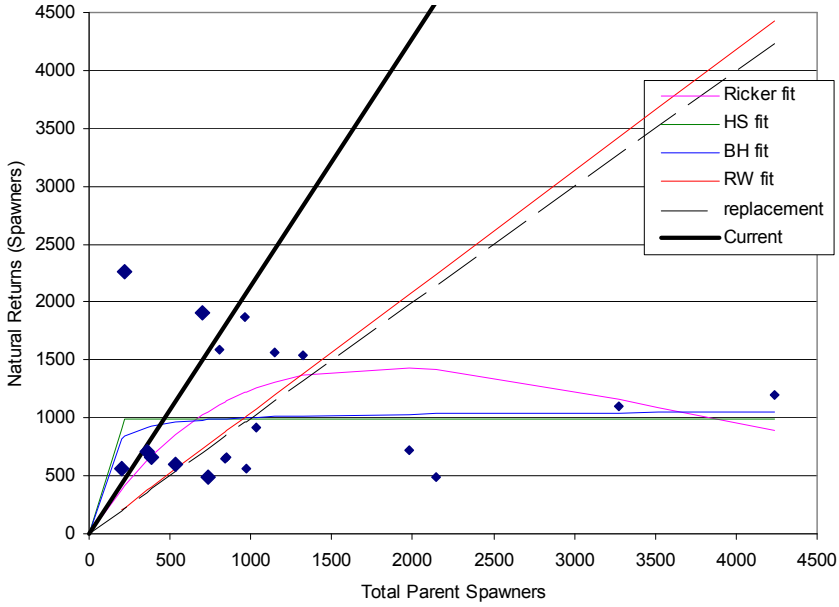

Figure 9. Upper Mainstem John Day River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Umatilla River Summer Steelhead Population

The Umatilla River summer steelhead population (Figures 1, 2) is one of three populations in the Umatilla/Walla Walla Rivers MPG within the Mid-Columbia River DPS. All three populations in this MPG are summer run.

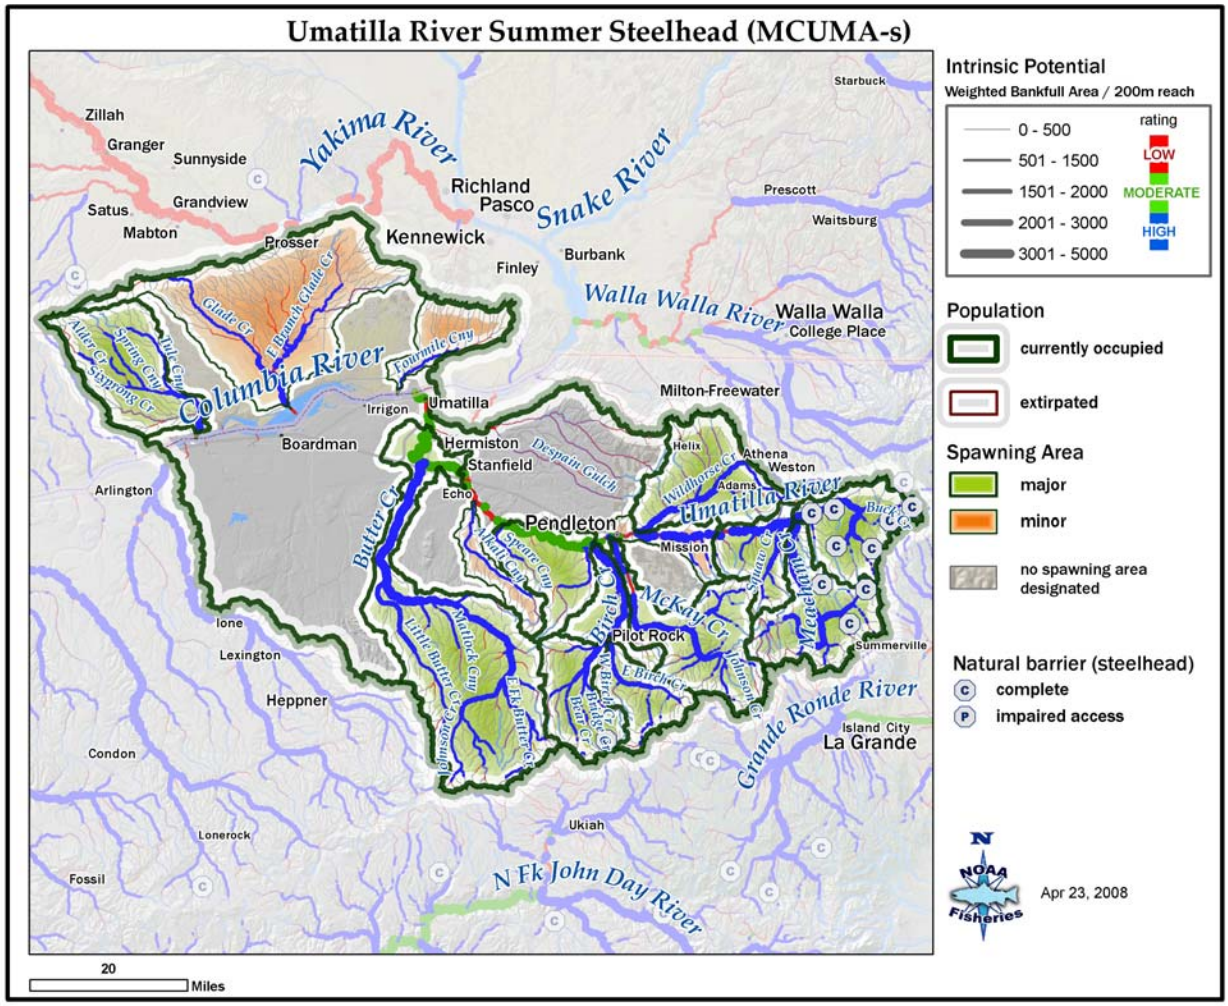

Figure 1. Umatilla River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

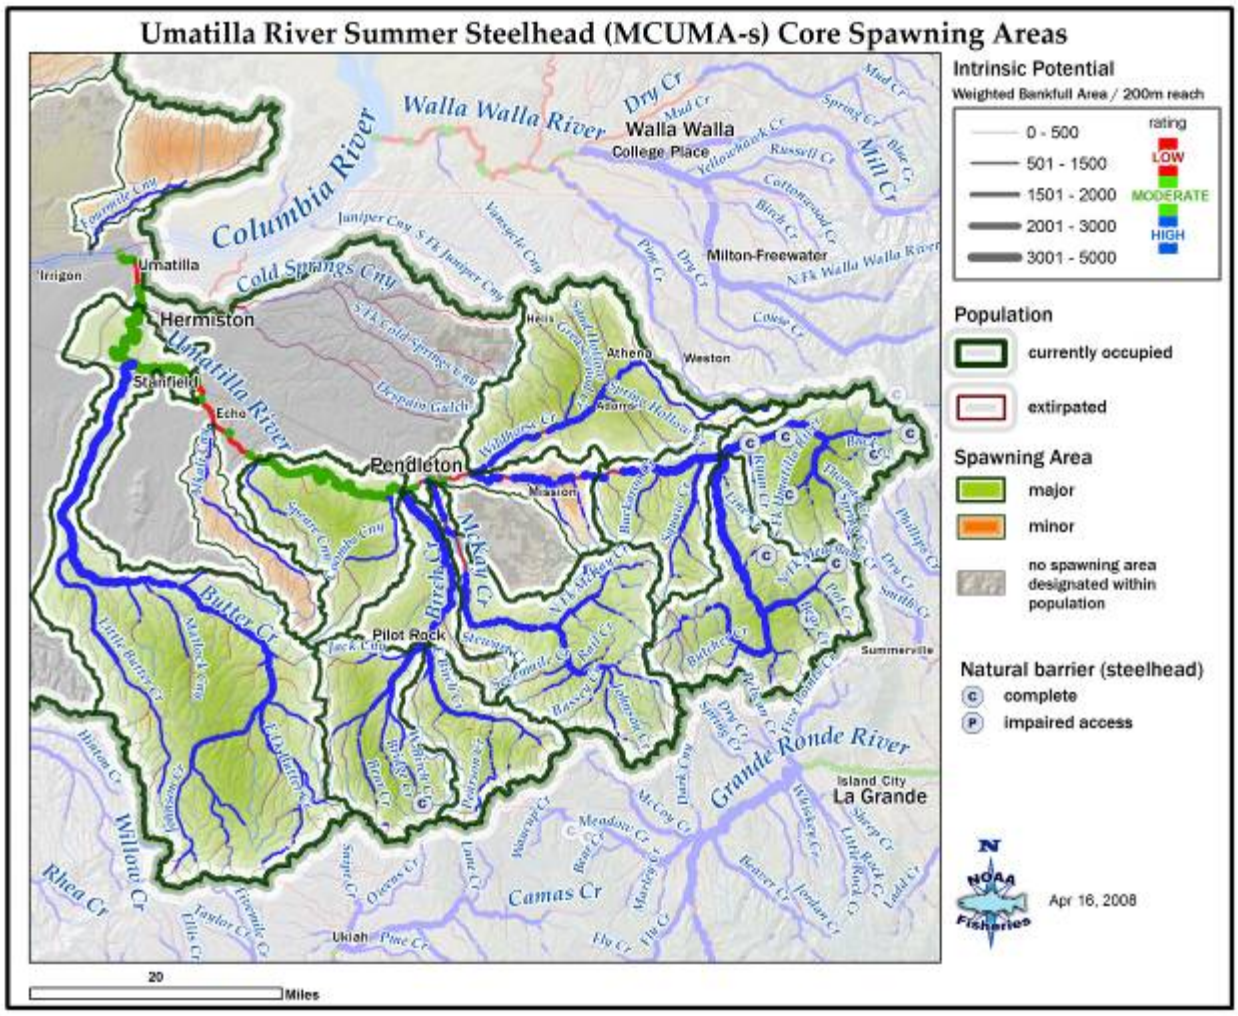

Figure 2. Umatilla River summer steelhead population boundary and core major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Umatilla River population as "large" in size and complexity (Table 1) based on historical habitat potential. A steelhead population classified as large has a mean minimum abundance threshold of 1,500 natural-origin spawners with sufficient intrinsic productivity (≥ 1.26 recruits per spawner at the minimum abundance threshold) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the Umatilla River population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.53 recruits per spawner at the minimum abundance threshold. The core production area for this population is the Umatilla River drainage (Figure 2). The population as defined by the ICTRT includes production from small, relatively isolated tributaries to the mainstem Columbia River entering downstream of the Umatilla River. Annual estimates of abundance for the downstream tributaries included as components of this population are not available. The Umatilla River drainage contains sufficient intrinsic potential habitat by itself to meet the definition of a large population. Given those considerations, the current abundance and

productivity metrics for the Umatilla River are used to characterize abundance and productivity of the population.

Table 1. Umatilla River summer steelhead basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	10,457
Stream lengths km (total) [a]	2,322
Stream lengths km (below natural barriers) [a]	2,278
Branched stream area weighted by intrinsic potential (km^2)	7.531
Branched stream area km^2 (weighted and temp. limited) [b]	7.456
Total stream area weighted by intrinsic potential (km^2)	9.070
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	3.415
Size / Complexity category	Large / "B" (dendritic structure)
Number of major spawning areas (MaSAs)	13
Number of minor spawning areas (MiSAs)	3

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where mean weekly modeled water temperature was > 22°C.

Current Abundance and Productivity

Current (1967 to 2004) total abundance (number of adult spawners in natural production areas) has ranged from 771 in 1998 to 5,172 in 2002 (Figure 3). Spawner abundance estimates for natural and hatchery summer steelhead in the entire Umatilla River Basin were determined from complete counts of adult returns to Three Mile Falls Dam (TMFD) at river mile 3.7. These counts did not include removals or mortality at and above the dam in all years except brood years (BY) 1984-1987. Fish were enumerated using electronic counters (BY 1967-1983), trapping (BY 1988-2000), and a combination of trapping and video monitoring (BY 2001-present). For BYs 1984-1987 abundance estimates were made with mark-recapture estimates. Missing abundance data for BY 1971, 1972, and 1979 were reconstructed using the known mean brood age structure from BY 1991-1998 and all available counts of brood returns in years before and after the missing counts. Counts in BY 1976 and 1978 were also incomplete but not reconstructed. In these years, electronic counters only operated from 24 December – 31 May and 13 December – 9 March, respectively. Age structure was determined by reading about 100-150 scales per year collected from adults returning in BY 1994-2004. Missing run year age structure data before BY 1994 were estimated as the BY 1994-2004 mean age structure.

Several sets of missing data for removals and mortalities at and above TMFD were estimated from the best available data. Missing harvest removals were estimated from creel survey data collected from the non-tribal fishery from BY 1993-2004 and the tribal fishery from BY 1993-2001. Harvest of hatchery fish from BY 1988-1992 was estimated as the mean percent harvest of the hatchery run passed above TMFD from the later time period (2.5% non-tribal and 6.4% tribal). All harvested fish were assumed to be natural-origin before BY 1988. For years when harvest of natural-origin fish was allowed in the non-tribal fishery (before BY 1993), harvest was estimated as mean percent catch of the natural-origin run passed above TMFD (6.8 %) (1993-2004) corrected by the mean percent of catch released (26%). Tribal harvest for BYs 1967-1987 of hatchery and natural-origin steelhead was estimated as their respective mean percent harvest of their runs passed above TMFD (6.7% of the combined natural and hatchery run passed above TMFD). Missing broodstock removals in BY 1981 and 1982 were estimated as one natural-origin fish collected for brood per 750 smolts produced based on the ratio of brood collected and smolts released in the early 1980s. All 95 hatchery fish collected for brood in BY 1991 were

assumed to have coded wire tags (CWTs) and were included in the total removal of 124 hatchery fish at TMFD for CWT recovery.

Recent year natural spawners include returns originating from naturally spawning parents, Umatilla River hatchery-origin fish and out-of-DPS spawners, primarily from the Snake River basin. Natural-origin fish have comprised an average of 73% of natural spawners since documentation of hatchery returns began in 1988. Since that time, the percentage of natural-origin spawners has ranged from 41% to 96%.

Abundance in recent years has been moderately variable. The 10-year (1995-2004) geometric mean abundance of natural-origin spawners was 1,472 (2,347 total spawners). During the period 1967-2000, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Umatilla River ranged from 0.3 in 1978 to 4.98 in 1998. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 20-year (1981-2000) geometric mean productivity was 1.50 R/S, adjusted for SAR and delimited at 75% (1,125 spawners) of the abundance threshold (Table 2).

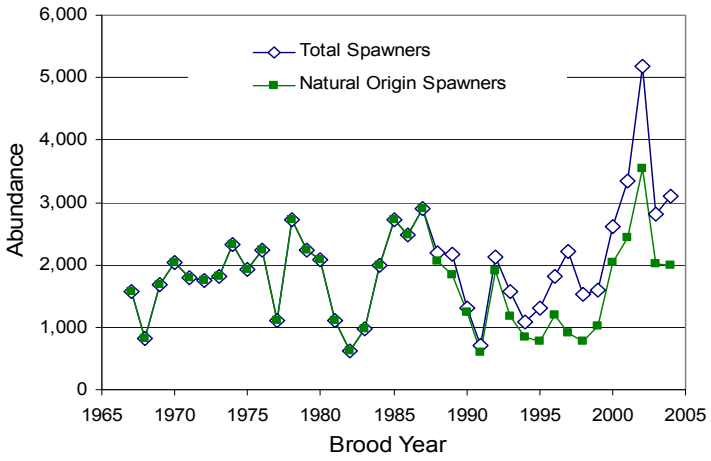

Figure 3. Umatilla River summer steelhead population spawner abundance estimates (1967-2004).

Table 2. Umatilla River summer steelhead population abundance and productivity.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	1472	(592-3542)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.73	(0.41-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (20-year R/S, SAR adjusted & delimited) [a]	1.50	(1.11-2.03)	0.15
Productivity (20-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2004)	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	1.01	(0.98-1.13)	
Population growth rate (λ): Hatchery effectiveness = **1.0**	0.99	(0.83-1.17)	0.41
Population growth rate (λ): Hatchery effectiveness = **0.0**	1.04	(0.86-1.25)	0.68

a. Delimited productivity excludes any recruit/spawner pair where the spawner number >75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.

The Umatilla River summer steelhead population is at **Moderate Risk** for abundance and productivity metrics. The productivity is at **low risk** because the point estimate is above the 5% risk level and the adjusted standard error is above the 25% risk level. Abundance is at **moderate risk** because the point estimate is slightly below the 5% risk level (Figure 4).

The trend in annual spawner abundance has been slightly positive since 1983; the population growth rate metric with no adjustment for relative hatchery effectiveness is 0.99. Annual variations in the estimated annual numbers of

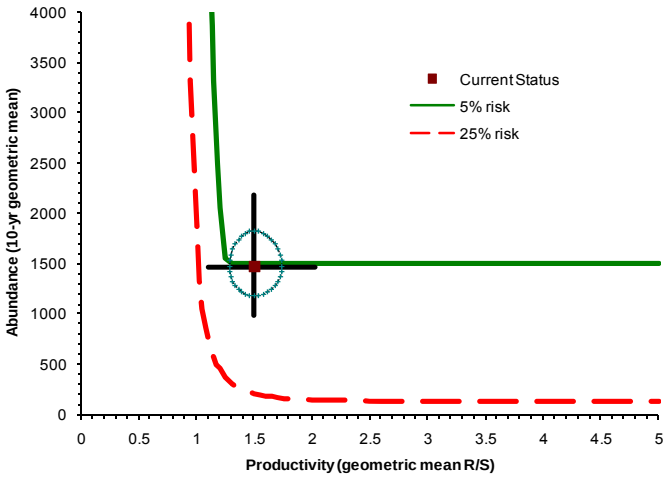

Figure 4. Umatilla River summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

steelhead spawners in the Umatilla River fluctuated considerably over the 1980-2005 period. The general timing of peaks and declines in annual spawning numbers is similar to many other Mid-Columbia DPS steelhead populations—peak in the mid-1980s, increasing returns beginning in 2000 followed by an abrupt decline to early 1980s levels. The relative effectiveness of hatchery-origin spawners in this basin is not known. Hatchery proportions on the spawning grounds have averaged 27% over the recent period. As a sensitivity analysis, we recalculated the recent average population growth rate after setting the assumed relative hatchery effectiveness value to 0.0. The average population growth rate generated from the sensitivity model run was 1.04.

Spatial Structure and Diversity

The ICTRT has identified 13 historic major spawning areas (MaSAs) and 3 minor spawning areas (MiSAs) within the Umatilla River summer steelhead population. In addition, two MaSAs (Alder Creek and Glade Creek) and one MiSA (Fourmile Canyon) are direct tributaries to the Columbia River on the Washington side and were included in the Umatilla River population. We do consider these areas in the assessment of spatial structure/diversity for the Umatilla River steelhead population (Figure 5). Current spawning distribution is somewhat limited relative to historic and is concentrated in Birch Creek, Iskulpa Creek, Meacham Creek, Upper Umatilla River, and the North and South Forks of the Umatilla River. There is documented recent year spawning in both Glade Creek and Alder Creek subbasins (Yakama Indian Nation Fisheries Program 2005); however, we are uncertain if the distribution of spawners and the frequency of use meet the occupancy criteria.

Spawners within the Umatilla River population include natural-origin returns, hatchery-origin returns of Umatilla River origin broodstock, and hatchery strays primarily originating from the Snake River basin. Hatchery-origin fish comprise a significant proportion of the naturally spawning fish in most recent years.

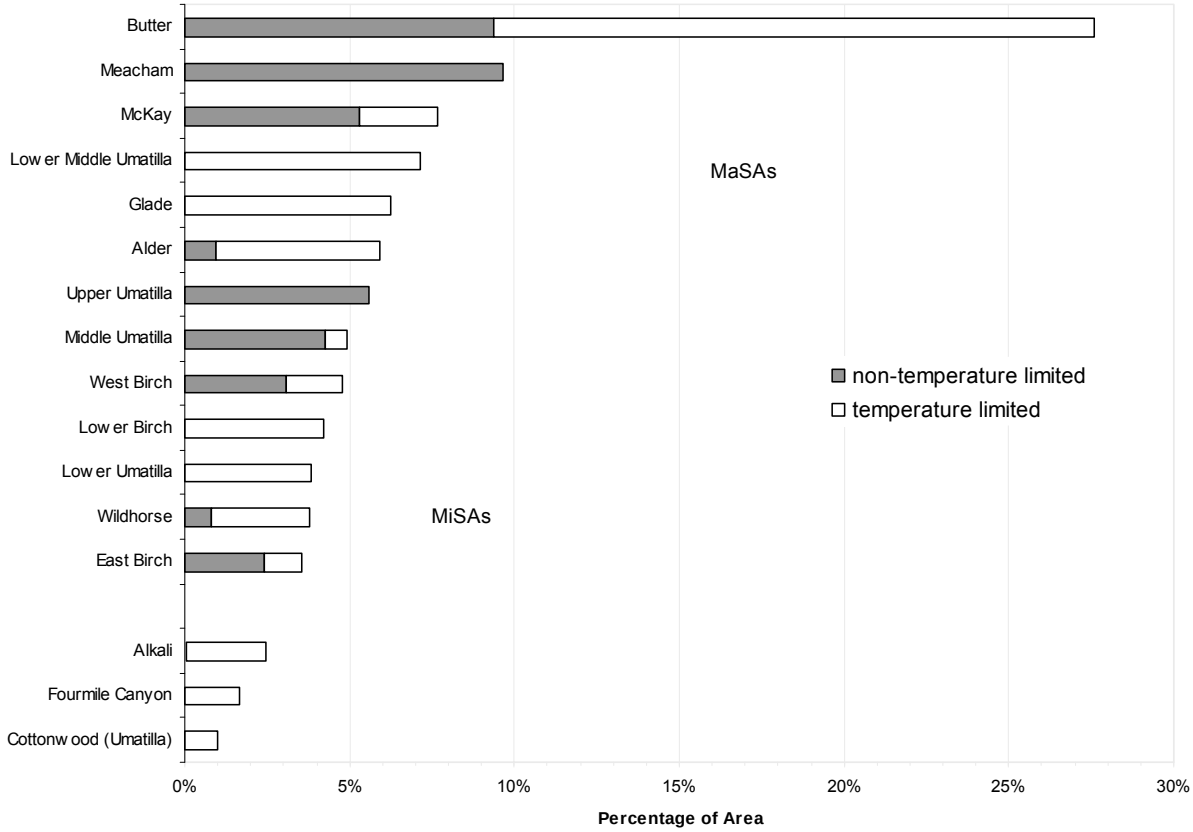

Figure 5. Umatilla River summer steelhead distribution of intrinsic potential habitat across major (MaSAs) and minor spawning areas (MiSAs). White bars represent current temperature limited areas that could potentially have had historical temperature limitations.

Factors and Metrics

A.1.a. Number and spatial arrangement of spawning areas

The Umatilla River population has 13 MaSAs and 3 MiSAs which are distributed in a complex dendritic pattern. Historically the major production areas included Butter Creek, Meacham Creek, McKay Creek, Iskulpa Creek, Birch Creek, and the middle and upper Umatilla River. Spawning distribution has been reduced significantly from the intrinsic historic distribution. Currently 8 of the 13 MaSAs are occupied. The Butter Creek, Lower Umatilla, Lower Middle Umatilla, and McKay MaSAs are unoccupied. One of the three MiSAs is currently occupied (Cottonwood Creek). Figure 6 shows both Alder and Glade MaSAs as unoccupied; however, recent information indicates that these MaSAs may be occupied. The map has not been updated because the actual spawner distribution has not been determined. Although there has been a significant reduction in spawner distribution, the Umatilla River population rates at **low risk** because it has more than four occupied MaSAs in a dendritic configuration. We have rated this metric as low risk instead of very low risk because of the uncertainty in occupancy of the Alder and Glade MaSAs.

A.l.b. Spatial extent or range of population

The current spawner distribution is reduced substantially from the intrinsic distribution. Based on the Oregon Department of Fish and Wildlife (ODFW) spawner database and the Washington Department of Fish and Wildlife (WDFW) information, 8 of 13 (61.5%) MaSAs are currently occupied and only 1 of 3 (33.3%) MiSAs is occupied (Figure 6). The spatial extent and range of spawning distribution has been reduced to an extent that this population rates as **moderate risk** for this metric. There are 12 index area spawning survey sites in the Umatilla River population. Recent survey results will be analyzed for use in future viability assessments.

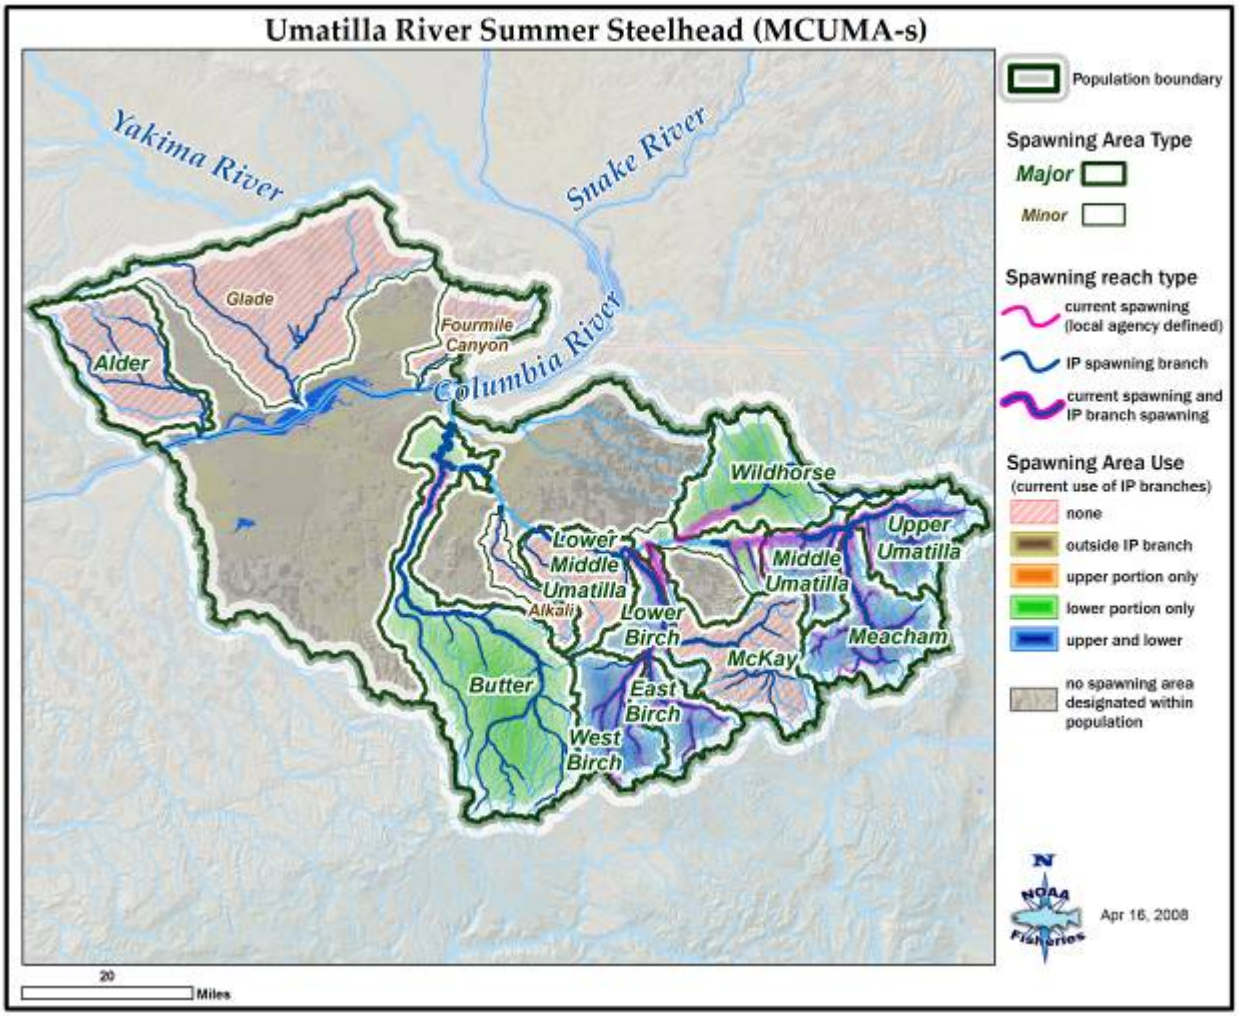

Figure 6. Umatilla River summer steelhead population current spawning distribution and spawning area occupancy designations.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There has been a change in gaps and continuity as a result of the loss of spawning in the McKay Creek and Lower Middle Umatilla River drainages as well as very limited production in the lower portion of the Butter Creek MaSA. Although some spawning occurs in lower Butter Creek, habitat conditions are such that no significant sustained production occurs. Due to the

low level of production in Butter Creek it does not serve any connectivity role within or between populations. In addition, less than 75% of the intrinsic MaSAs are currently occupied, thus the rating is **moderate risk** for this metric.

B.1.a. Major life history strategies

We have no observational data to allow any direct comparisons of historic and current life history strategies. Therefore, we have used EDT (Ecosystem Diagnosis and Treatment) analyses and habitat conditions to infer loss of life history strategies. Flow and temperature changes in the Umatilla River basin have limited movement patterns for both juvenile and adult steelhead. Juvenile steelhead cannot move into some mainstem rearing reaches above McKay Creek for over-summer rearing due to high temperatures. Adults are unable to enter the Umatilla River in early fall in many years because of the lack of flow as well as high water temperatures. Large areas, such as Butter and McKay Creek drainages, no longer support production. Flow enhancement projects have improved conditions for adult fall migration and summer rearing, particularly below McKay Creek. Past habitat changes have undoubtedly reduced diversity in life history pathways. However, it does not appear that any major pathways have been lost, and improved fall flows have provided conditions allowing adult migration throughout the fall season. The Umatilla River summer steelhead population still exhibits a diverse age structure, including multiple ages at smolt migration, multiple years of ocean residence, and repeat spawning. The population rated at **moderate risk** because all pathways exist but there has been significant reduction in variability and changes in distribution.

B.1.b. Phenotypic variation

We have no data to assess loss or substantial change is phenotypic traits, therefore we infer based on habitat changes. The changes in flow patterns and temperature profile within the Umatilla River and the mainstem Columbia River have likely resulted in reduced variation in adult and juvenile migration patterns. Juveniles have a much narrower window to successfully migrate out of the Umatilla River in the spring because water temperatures increase earlier than historically. Even though flow enhancement has improved conditions for adult fall migration, the run-timing distribution is likely truncated from historic. Adults cannot enter the river in early fall in some years because of flow and temperature limitations. We have rated the Umatilla River population at **moderate risk** because two or more phenotypic traits have changed.

B.1.c. Genetic variation

The genetics data for Umatilla River summer steelhead indicate that there is significant within-population variation between Umatilla River steelhead and other populations in the MPG (Touchet River and Walla Walla River). In addition, the within-population diversity shows no indication of impairment. The hatchery fish are similar to natural-origin fish as expected, since they are offspring of natural-origin fish. There are out-of-DPS spawners, primarily from Snake River stocks, spawning naturally in the Umatilla River basin. Given the degree of genetic variation, the Umatilla River population rated at **low risk** for this metric. Given that the genetics samples used in the analyses were collected in the mid-1980s prior to significant hatchery influence, the genetic analyses need to be updated with recent samples.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners*: A significant number of out-of-DPS spawners enter the Umatilla River. Estimates of out-of-DPS spawners are based on expanded CWT recoveries of hatchery fish at TMFD. From 1993-2004, out-of-DPS spawners have comprised from 1.8-9.7% (mean = 4.8%) of the fish that arrived at TMFD. These strays are not selectively removed because they are not distinguishable from Umatilla Hatchery supplementation steelhead. Given the length of time of influence and the hatchery fraction, we have rated the Umatilla River population at **moderate risk** for out-of-DPS spawners. This risk rating assumes that strays were present at a similar rate for the past three generations and that the proportion observed at TMFD represents proportions on the spawning grounds.

(2) *Out-of-MPG spawners from within the DPS:* There have been few, if any, out-of-MPG within-DPS spawners recovered in the Umatilla River basin, thus the rating is **very low risk** for this metric.

(3) *Out-of-population spawners from within the MPG:* There are two out-of-population within-MPG hatchery programs which could provide stray fish to the Umatilla River: Lyons Ferry Fish Hatchery releases in the Walla Walla River and Touchet River hatchery fish. No strays from these two programs have been observed. The rating is **very low risk** for this metric.

(4) *Within-population hatchery spawners:* The Umatilla River population is supplemented annually with hatchery fish produced from natural-origin broodstock collected at TMFD. The supplementation program has been ongoing since the late 1980s. Since 1993, Umatilla Hatchery fish have comprised an average of 29.4% of the naturally spawning fish. We characterize this program as using "best management practices" based on the following:

- Most of the broodstock collected annually are natural-origin fish.
- Mating protocols provide for a high number of family groups annually.
- There presently is no culling or grading of parr or smolts.
- Hatchery smolts are released in localized areas of the middle and upper mainstem.
- There does not appear to be any genetic differentiation between hatchery and natural-origin fish.

Given that best practices are used, the average hatchery fraction is 29%, and the program has been underway for three generations, the rating is **moderate risk** for within-population hatchery fish.

The spawner composition rating is **high risk** due to the moderate risk ratings for both the out-of-DPS spawners and the within-population hatchery proportions.

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution encompasses seven ecoregions, four of which account for at least 10% of the distribution (Figure 7, Table 3). There has been only one significant shift greater than 67% in the ecoregion distribution (Pleistocene Lake Basins). This population rates at **low risk**.

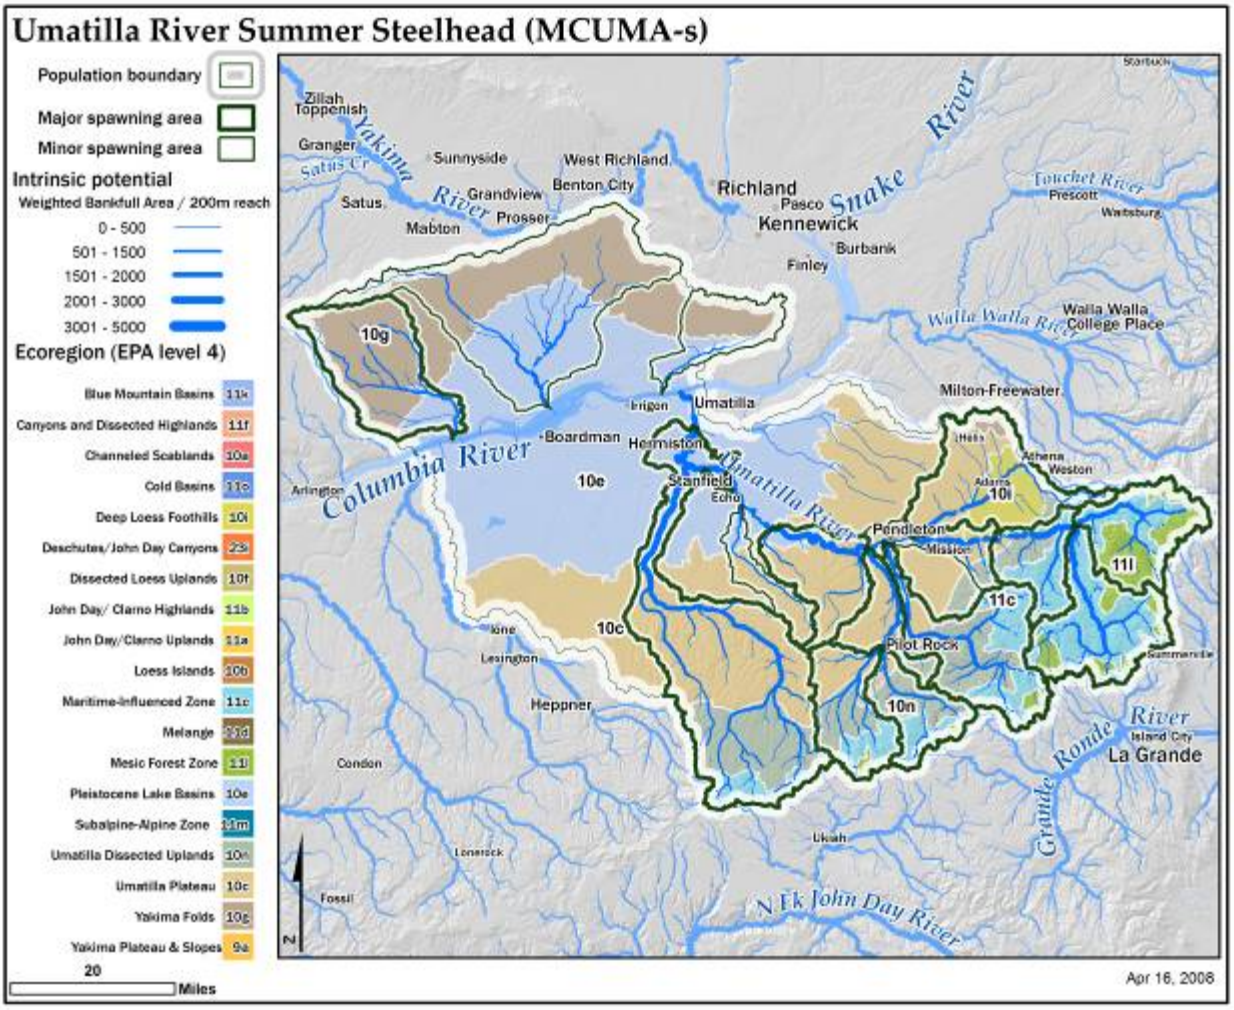

Figure 7. Umatilla River steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Umatilla River steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Umatilla Plateau	32.4	27.0
Pleistocene Lake Basins	25.0	6.2
Yakima Folds	5.3	0.0
Deep Loess Foothills	2.7	1.2
Umatilla Dissected Uplands	15.3	19.3
Maritime-influenced Zone	17.7	42.9
Mesic Forest Zone	1.7	3.4

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes three dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Juvenile migration timing:* Changes in flow and temperature patterns likely inhibit out-migration in late spring as temperatures rise and flow decreases, causing increased travel time, increased energy expenditure and greater physiological stresses. Given the number of dams that this population must cross, and likely increased mortality as the season progresses, overall selection intensity on the population is likely moderate. Heritability of this trait has not been assessed so we assume a moderate to low heritability. Therefore the impact of the hydrosystem on this trait is **moderate**.
>
> *Adult migration timing:* Umatilla River adult migrants are affected by thermal blocks that are larger in size and longer in duration relative to historic conditions in the Columbia River system. These result in delays, likely result in increased energy expenditure (due to increased temperatures) and may result in increased straying. Adult migration timing is highly heritable. The proportion of fish in the population affected is relatively unknown, although the effect likely results in low mortality. The effect is highly variable from year to year and in some years no thermal barriers develop. We rated the selection intensity as low. Thus, the impact of the hydrosystem on this trait is **moderate.**

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect only slightly more than 2% of the total population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the impacts are slight enough to be negligible. There is very limited tribal harvest of natural-origin fish within the Umatilla River subbasin and impacts from the recreational fishery are incidental to hatchery fish harvest. No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: Hatchery broodstock collection has the potential to disproportionately remove specific fish (e.g., of a certain size or timing) from the wild population. The Umatilla River summer steelhead hatchery program is operated to provide hatchery fish for harvest and to supplement natural production. Broodstock are collected at TMFD. Typically, 100 natural-origin and 20 hatchery-origin fish are collected for broodstock. Broodstock are collected representatively so that their run-timing, sex, and age of broodstock mimic that of the total run at TMFD. We are uncertain of the degree of substructure within the basin or if there are different characteristics between spawning aggregates in the basin. If life history characteristics differ between different aggregates, there is the possibility that collection of broodstock representing TMFD timing may be differentially impacting spawning aggregates. However, the broodstock removal does not appear to be selective at the population level and no phenotypic traits appear to be at risk as a result of this activity. The hatchery rating is **low risk** for all traits.

Habitat: Altered flow profiles and increased temperatures, which have been in place for many generations and are ongoing, likely impose some selection on juvenile and adult migration timing.

> *Juvenile migration timing:* Late spring and early summer temperatures are substantially elevated relative to historical conditions. There has likely been some impact on juvenile migration timing as temperatures reach stressful levels early in the summer, essentially truncating migration timing. Heritability of this trait is moderate to low and the selection intensity is assumed to be low, thus the habitat rating for this trait is **low**.
>
> *Adult migration timing:* Late summer and early fall flows are often low in the Umatilla River and likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable but a relatively low proportion of the population is likely subject to these effects, and we rated the selection intensity as moderate. Thus, the impact of habitat changes on this trait is **moderate.**

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

> *Juvenile migration timing.* Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

The adult migration timing trait has two moderate ratings and the juvenile migration timing trait has one moderate rating. Therefore, the overall selectivity rating for the Umatilla River steelhead population is **moderate risk**.

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating is **Moderate Risk** (Table 4) for the Umatilla River summer steelhead population. The rating for Goal A (allowing natural rates and levels of spatially mediated processes) was **moderate risk**. There has been significant reduction in spawner distribution relative to intrinsic potential distribution. This reduction has caused significant increases in gaps between spawning areas as well as disrupted continuity.

The rating for Goal B (maintaining natural levels of variation) was **moderate risk**. Habitat changes have been significant in the Umatilla River basin resulting in changes to flow profiles and elevated temperatures. These changes have resulted in impacts to life history diversity and phenotypic trait variation. The out-of-DPS spawners in combination with local origin hatchery fish spawning naturally put the population at high risk for spawner composition. Hydrosystem effects and within-basin habitat changes have likely resulted in selective mortality of the adult run timing phenotypic trait, resulting in a moderate risk rating for the selectivity metric.

Overall Viability Rating

The Umatilla River summer steelhead population does not meet viability criteria. However, the population does meet criteria to be rated as **MAINTAINED** (Figure 8). Overall abundance and productivity is rated at **Moderate Risk.** The 10-year geometric mean abundance of natural-origin spawners is 1,472, which is 98.1% of the minimum abundance threshold of 1,500. The 20-year geometric mean productivity is 1.50 R/S with the lower end of the adjusted standard error above the 25% risk level. This productivity exceeds the minimum intrinsic productivity criteria of 1.26 R/S, thus placing the productivity at low risk. Overall spatial structure and diversity is also rated at **Moderate Risk.** Improvement in many of the spatial structure/diversity metrics and a small increase in the average abundance will raise the population to viable status.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V**	**V**	**M**
	Moderate (6 – 25%)	**M**	**M**	**M** **Umatilla River**	**HR**
	High (>25%)	**HR**	**HR**	**HR**	**HR**

Data Summary – Umatilla River Summer Steelhead Population

Data type: Estimated number of annual spawners estimated based on annual counts at Three Mile Falls Dam in the lower Umatilla River. Natural-origin proportion estimated based on hatchery and natural-origin counts, adjusted for removals or mortalities above the dam.

SAR: Mid-Columbia SAR index (incorporates the Deschutes, Umatilla, Snake, and Upper Columbia River steelhead series).

Table 5. Umatilla River steelhead population abundance and productivity data used for curve fits and R/S analysis. Bold values were used in estimating the current productivity (Table 6).

Brood Year	Spawners	%Wild	Natural Run	Nat. Rtns	R/S	SAR Adj. Factor	Adj. Rtns	Adj. R/S

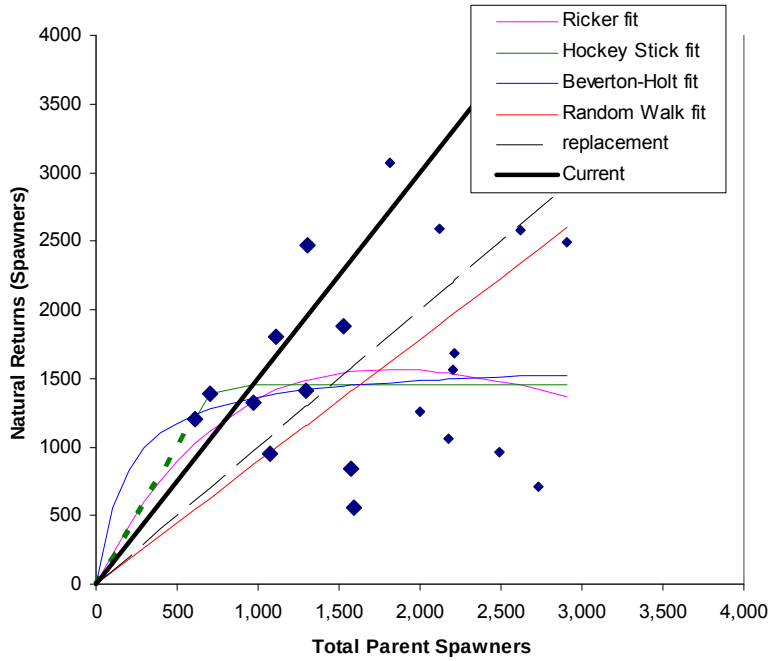

Figure 10. Umatilla River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "Current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

Walla Walla River Summer Steelhead Population

The Walla Walla River summer steelhead population (Figure 1) is one of three populations in the Umatilla/Walla Walla Rivers MPG within the Mid-Columbia River DPS. All three populations in this MPG are summer run.

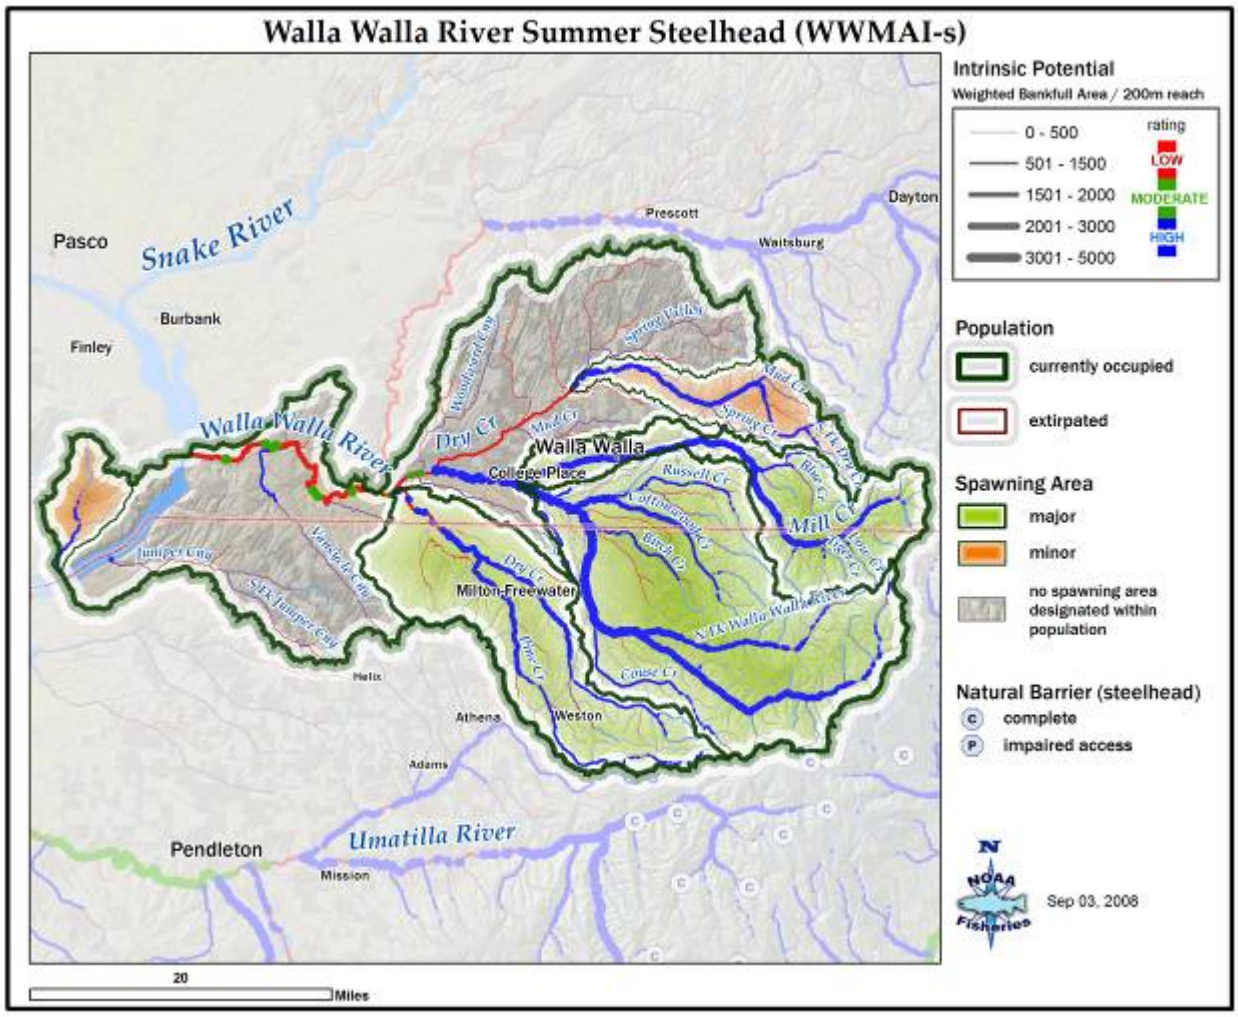

Figure 1. Walla Walla River summer steelhead population boundary and major (MaSA) and minor (MiSA) spawning areas.

The Interior Columbia Technical Recovery Team (ICTRT) classified the Walla Walla River population as "intermediate" in size and complexity based on historical habitat potential (Table 1). A steelhead population classified as intermediate has a mean minimum abundance threshold of 1,000 natural-origin spawners with sufficient intrinsic productivity (≥ 1.35 recruits per spawner at the minimum abundance threshold) to achieve a 5% or less risk ("low risk") of extinction over a 100-year timeframe. In order for the Walla Walla River population to achieve a 1% or less risk ("very low risk") of extinction over 100 years, productivity would need to be at or greater than 1.64 recruits per spawner at the minimum abundance threshold.

Table 1. Walla Walla River summer steelhead population basin statistics and intrinsic potential analysis summary.

Drainage area (km^2)	2,988
Stream lengths km (total) [a]	1,147
Stream lengths km (below natural barriers) [a]	1,111
Branched stream area weighted by intrinsic potential (km^2)	2.448
Branched stream area km^2 (weighted and temp. limited) [b]	0.774
Total stream area weighted by intrinsic potential (km^2)	3.711
Total stream area weighted by intrinsic potential (km^2) temp limited [b]	0.907
Size / Complexity category	Intermediate / "B" (dendritic)
Number of major spawning areas (MaSAs)	3
Number of minor spawning areas (MiSAs)	2

a. All stream segments ≥ 3.8m bankfull width were included.
b. Temperature limited areas were assessed by subtracting area where mean weekly modeled water temperature was > 22°C.

Current Abundance and Productivity

Current (1993 to 2003) total spawner abundance (number of adult spawners in natural production areas) has ranged from 421 in 1999 to 1,811 in 2002 (Figure 2). Abundance of natural-origin summer steelhead in the portion of the Walla Walla River basin above Nursery Bridge Dam (NBD; North Fork, South Fork, and Couse Creek) was determined from counts of adult returns to NBD at river mile 44. These counts did not include removals or mortality at and above the dam. Fish were enumerated using trap counts and mark-recapture methods from brood years (BY) 1993-2001, and video counts in BY 2002, 2003, and 2005. Mark-recapture methods were used to account for fish that jumped the dam. Mark-recapture methods were discontinued following dam modifications that are thought to prevent fish from jumping the dam (T. Bailey, Oregon Department of Fish & Wildlife, personal communication). Almost all hatchery fish trapped at NBD were removed during BY 1993-1999. The BY 2003 count (547) was incomplete as the west side ladder was opened from February 21 through March 11 due to passage problems with the east side ladder. Fish passing through the west bank ladder were not counted. The number of uncounted fish in BY 2003 was estimated as the mean percent of the run that passed NBD from February 21-March 11 during BY 1993-2001 (12.3%). The percent of the run passing NBD during that time period ranged from 5.4 % to 18.7% during BY 1993-2001. Counts were not available for BY 2004 because video equipment was inoperable during most of the migration season. Missing abundance data for BY 2004 were reconstructed using mean brood age structure estimated from BY 1991-1998 data and all available counts of brood returns in years before and after the 2004 missing count. Age structure was determined by scale analyses from adults returning in 1993-1995. Missing run year age structure data after 1995 were estimated as the 1993-1995 mean age structure. Origin (natural or hatchery) could not be determined from video monitoring (2002-2005) and was estimated as the 1993-2001 mean percent of natural (96.4%) and hatchery (3.6%) origin fish in the run to NBD. Spawner abundance for the entire Walla Walla River natural-origin summer steelhead population was estimated by expanding abundance of spawners above NBD by a factor of 1.503. The expansion estimate was developed from the ratio of current smolt capacity of the entire population divided by the current smolt capacity above NBD. The current smolt capacity estimates were developed based on Ecosystem-Diagnosis-Treatment (EDT) analyses of current conditions. Harvest removals were not factored into the estimate of spawning escapement above NBD. Tribal and non-tribal fishing pressure is thought to be minimal (T. Bailey, personal communication).

Recreational angling was prohibited from 1996-2002 and limited to retention of hatchery-origin fish after 2002.

Recent natural spawners include returns originating from naturally spawning adults and from outside-DPS spawners that originate from Lyons Ferry Hatchery releases in the lower Walla Walla River. Natural-origin fish have comprised an average of 98% over the 11 years of available data. Throughout the period, the percentage of natural-origin fish has ranged from 95.4% to 99.8%.

Abundance in recent years has been moderately variable. The 10-year (1996-2005) geometric mean abundance of natural-origin spawners was 650 (Table 3.3.2-2). During the period 1993-2000, recruits per spawner (R/S, in terms of spawner to spawner) for steelhead in the Walla Walla River ranged from 0.39 in 1993 to 2.65 in 1998. The annual R/S estimates were adjusted to reflect the average smolt-to-adult return rate (SAR). The 8-year (1993-2000) geometric mean productivity was 1.34 R/S, adjusted for SAR and delimited at 75% (750 spawners) of the abundance threshold (Table 2).

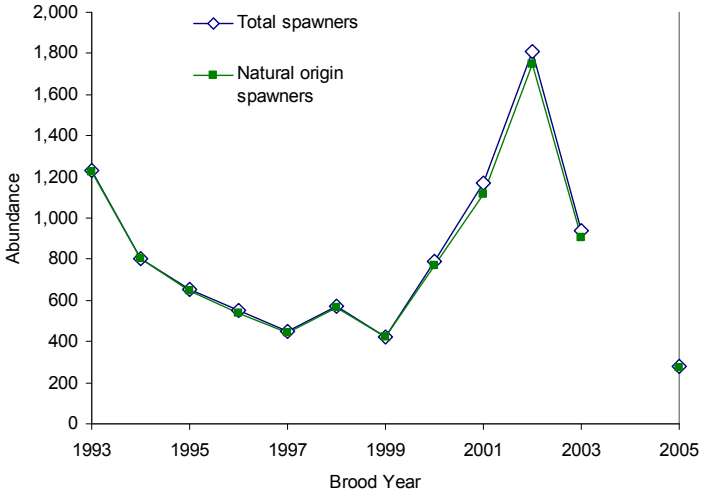

Figure 2. Walla Walla River summer steelhead population spawner abundance estimates (1993-2005).

Table 2. Walla Walla River summer steelhead population abundance and productivity estimates.

Abundance/Productivity Statistics	Estimate	(Range)	
Abundance: natural-origin spawners (10-year geometric mean, range)	650	(270-1746)	
Proportion: natural-origin spawners (10-year geometric mean, range)	0.98	(0.95-1.00)	
	Estimate	**(90% CI)[b]**	**SE**
Intrinsic productivity (8-year R/S, SAR adjusted & delimited) [a]	1.34	(1.05-1.71)	0.12
Productivity (8-year Beverton-Holt fit, SAR adjusted)	n/a		n/a
Trend Statistics (1980-2005) [c]	**Estimate**	**(95% CI)**	**P>1.0**
ln(natural-origin spawner abundance)	n/a		
Population growth rate (λ): Hatchery effectiveness = **1.0**	n/a		
Population growth rate (λ): Hatchery effectiveness = **0.0**	n/a		

a. Delimited productivity excludes any recruit/spawner pair where the spawner number >75% of the population's minimum abundance threshold. This approach attempts to remove density dependence effects that may influence the productivity estimate.
b. Lower end of the 90% CI on productivity is used in evaluating the impact of parameter uncertainty on risk.
c. Insufficient data series to calculate 1980- 2005 trend metrics.

The Walla Walla River summer steelhead population is at M**oderate Risk** based on current abundance and productivity. The point estimate falls between the 5% and 25% risk curves (Figure 3). The moderate risk rating should be viewed with caution given two considerations: 1) the time series is short, with only eight brood years, and there is considerable uncertainty if the data adequately represent the true value; and 2) there is considerable uncertainty associated with the amount of spawning and production that occurs within the

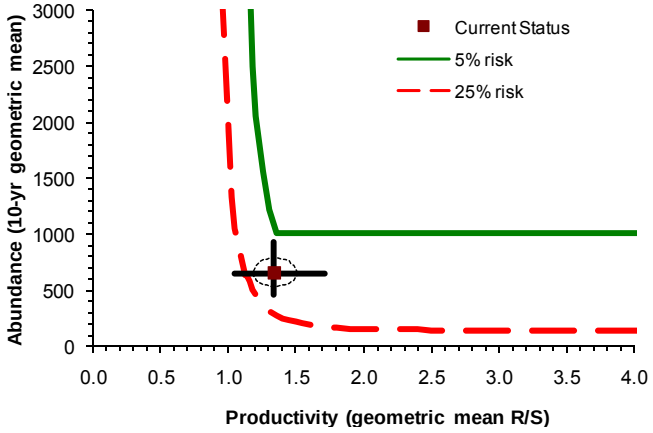

Figure 3. Walla Walla River summer steelhead population current abundance/productivity (A/P) compared to the DPS viability curve. Ellipse = 1 SE about the point estimate. Error bars = 90% CI for A/P.

population outside of the area above Nursery Bridge Dam, particularly in Mill Creek. Better information relating abundance above Nursery Bridge Dam to the remaining area in the population is needed to reduce this data uncertainty.

The natural-origin spawner abundance series for the Walla Walla steelhead population was initiated in 1993; therefore it was not possible to calculate the 1980-present trend metrics. The general pattern over the 1993 to 2005 period is similar to the patterns in returns over the same period for other Mid-Columbia DPS steelhead populations: declining annual abundance followed by a short increasing trend beginning in 1999 and then an abrupt decline after 2003.

Spatial Structure and Diversity

The ICTRT has identified three historic major spawning areas (MaSAs) and two minor spawning areas (MiSAs) within the Walla Walla River steelhead population (Figure 4). Two small watersheds, which are classified as MiSAs and which empty directly into the Columbia River below the Walla Walla River confluence, are included in the Walla Walla population boundaries (Juniper Canyon, OR and Switzler, WA). Current spawning distribution is substantially reduced relative to the historic intrinsic distribution. Current production is concentrated in the North and South Fork Walla Walla River, Couse Creek, Mill Creek and Dry Creek (WA). It should be noted that the map does not show Yellowhawk Creek, which runs between Mill Creek and Cottonwood Creek, and there is spawning in the lower reaches of Yellowhawk Creek. Spawners within the Walla Walla population are primarily natural-origin fish with a small proportion of hatchery strays which are Snake River-origin fish produced at Lyons Ferry Hatchery and released into the lower Walla Walla River. Hatchery fish were removed at NBD by trapping until 1999 when it was discontinued and replaced with video monitoring. Currently, hatchery fish pass above NBD to spawn naturally.

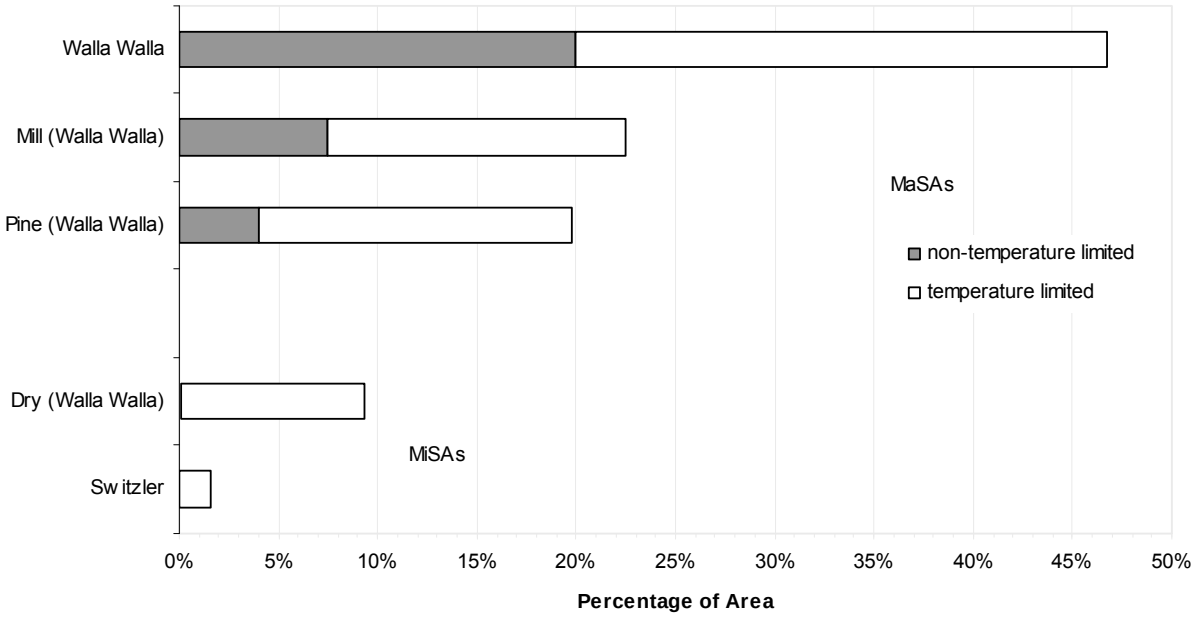

Figure 4. Walla Walla River summer steelhead population distribution of intrinsic potential habitat across major and minor spawning areas. White bars represent current temperature limited areas that could potentially have had historical temperature limitations.

Factors and Metrics

A.1.a Number and spatial arrangement of spawning areas

The Walla Walla River population has three MaSAs and two MiSAs distributed in a dendritic pattern. Historically, major production areas included Pine Creek, South Fork Walla Walla River, North Fork Walla Walla River, Mill Creek, Cottonwood Creek and Dry Creek (WA). Spawning distribution has been reduced significantly relative to historic distribution. Currently two of three of the MaSAs are occupied, including Walla Walla and Mill. Spawning and rearing do not occur in the Pine Creek MaSA. One of two MiSAs is occupied—Dry Creek. Even though there has been significant reduction in distribution, the population rated at **low risk** because it has two MaSAs occupied in a dendritic pattern.

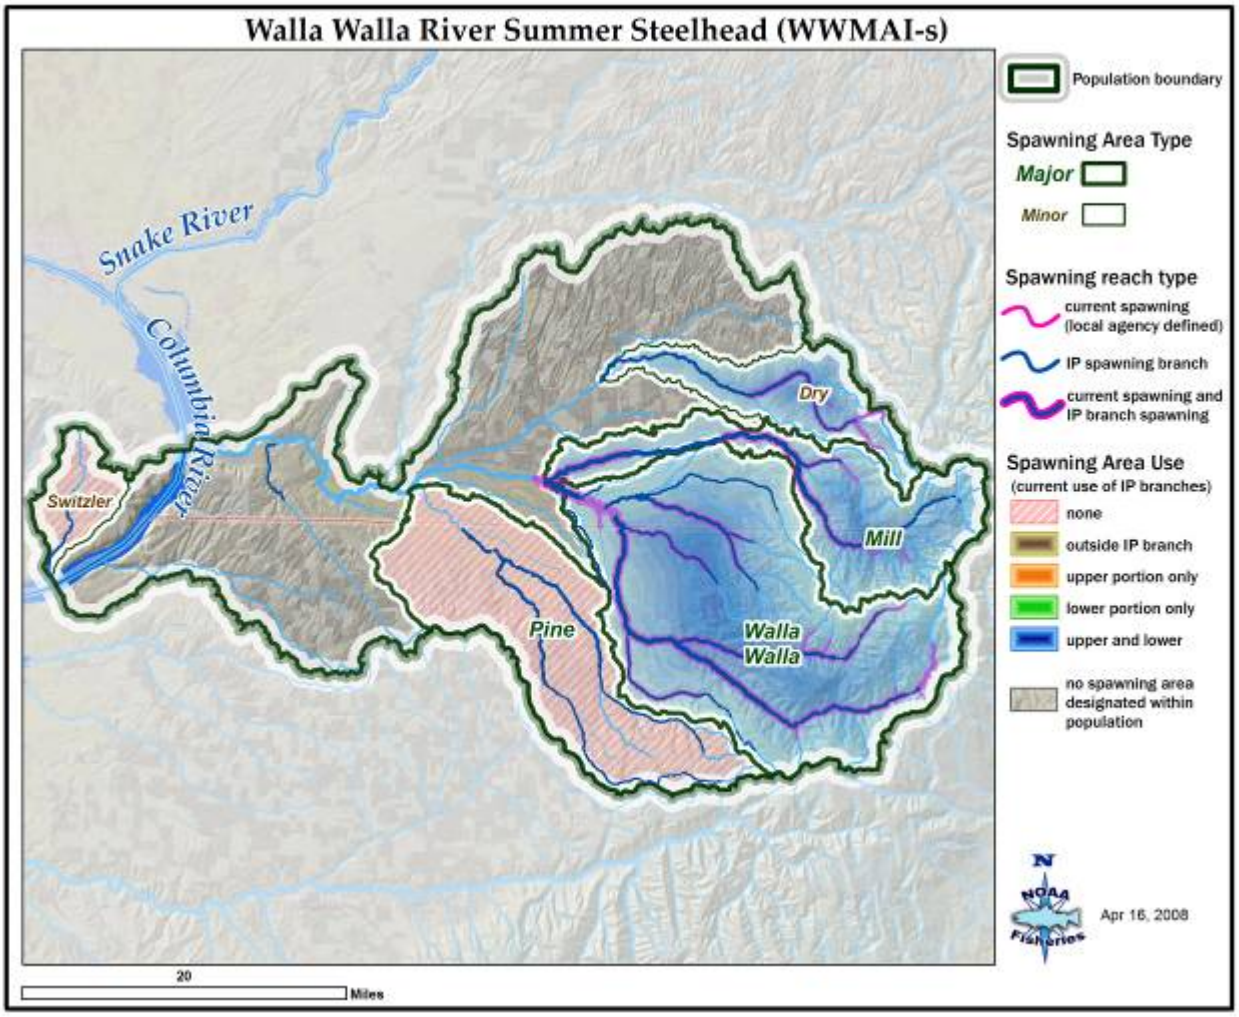

Figure 5. Walla Walla River summer steelhead population current spawning distribution and spawning area occupancy designations.

A.l.b. Spatial extent or range of population

Based on comparisons of the current spawner distribution databases from the Oregon Department of Fish and Wildlife (ODFW) and the Washington Department of Fish and Wildlife (WDFW) with the intrinsic distribution, there has been substantial reduction in the range. Currently two of three MaSAs (67%) and one of two MiSAs (50%) are occupied (Figure 5). Due to the significant reduction, the population is rated at **moderate risk** because less than 75% (but greater than 50%) of the historical MaSAs are currently occupied. . There are limited spawning survey data to evaluate occupancy for this population. Additional spawning survey data needs to be collected to improve future viability assessments.

A.1.c. Increase or decrease in gaps or continuities between spawning aggregates

There have been significant changes in gaps and continuity as a result of the loss of spawning in the Pine Creek MaSA and the Switzler MiSA. The loss of occupancy in these areas has increased the distance between the Walla Walla population and other Mid-Columbia DPS steelhead populations. Due to these considerations, and because less than 75% of the historical MaSAs are occupied, the population is rated at **moderate risk** for this metric.

B.1.a. Major life history strategies

We have no data to allow any direct comparisons between historic and current life history strategies. Flow and temperature changes and barriers in the Walla Walla River basin have limited movement patterns of juvenile and adult steelhead during recent decades. Juvenile steelhead are unable to use many of the mainstem areas during the summer months due to high temperatures and low flows. Adults are unable, in some years, to enter the Walla Walla River in early fall. These types of changes have likely resulted in reduced life history diversity. However, it does not appear that any major life history pathways have been lost. The age structure and run-timing of adults is within the range observed for other summer steelhead populations. The population exhibits multiple ages of smolt out-migration and ocean residence time, as well as repeat spawners. The habitat changes have likely resulted in significant reduction in variability as well as a change in distribution of life history pathways, thus we have rated the population at **moderate risk** for this metric.

B.1.b. Phenotypic variation

There are no data to assess loss or substantial change in phenotypic traits, therefore we infer from habitat changes. The changes in flow patterns and temperature profile within the Walla Walla River, as well as the effects of adult passage barriers, have likely resulted in reduced adult and juvenile phenotypic traits. Juveniles have narrower windows for successful out-migration through the Walla Walla River as well as through the Columbia River. Adults cannot enter and migrate through the Walla Walla River during late summer and early fall in some years due to temperature limitations. The Walla Walla population rated at **moderate risk** because of likely change in mean and variability of two or more phenotypic traits.

B.1.c. Genetic variation

The genetic information for the Walla Walla population demonstrates levels of within and between-population differentiation that are healthy and do not indicate any substantial change from likely historical condition. In addition, there is little signal of introgression of outside-DPS hatchery fish which are known to be present in spawning areas. The population rated at **low risk** for genetic variation.

B.2.a. Spawner composition

(1) *Out-of-DPS spawners*: There are out-of-DPS spawners present in the population that originate from Lyons Ferry hatchery releases into the mainstem Walla Walla River. Until 1999, wandering hatchery fish destined for the upper Walla Walla River basin were removed at Nursery Bridge Dam. Since that time, hatchery fish have passed upstream to spawn naturally. The removal of these out-of-basin hatchery-origin fish had reduced the hatchery proportion and the risk to the natural population. We estimated that about 2% of the natural spawners have been out-of-basin hatchery-origin fish for recent generations. With 2% out-of-DPS spawners for the past three generations the population is rated at **moderate risk**. It should be noted that two management actions may influence the future proportion of the out-of-DPS spawners. Annual smolt releases from Lyons Ferry Hatchery have been reduced substantially which will reduce the source of hatchery adults. On the other hand, hatchery fish are no longer removed at Nursery Bridge Dam which results in an increase in the proportion of hatchery spawners above this location. The overall effect of these two offsetting management changes is unknown.

(2) *Out-of-MPG spawners from within the DPS*: There are no documented out-of-MPG within-DPS strays in this population, so the rating is **very low risk** for this metric.

(3) *Out-of-population spawners within the MPG*: There are no documented out-of-population within-MPG strays, so the rating is **very low risk** for this metric. However, this risk rating may increase in the future due to potential within-population Touchet River hatchery strays.

(4) *Within-population hatchery spawners*: There is no within population hatchery program, so the population is rated at **very low risk** for this metric.

The overall spawner composition rating is **moderate risk** due to the moderate risk of out-of-DPS hatchery strays spawning naturally in this population.

B.3.a. Distribution of population across habitat types

The intrinsic potential distribution of the Walla Walla River population encompassed six ecoregions, of which four accounted for 10% or more of the ecoregion distribution (Figure 6, Table 3). Within these four ecoregions there have been no significant changes in the proportions from the historic intrinsic to the current distribution. The population is rated at **very low risk** because all historical ecoregions are occupied, there are more than four currently occupied, and there have been no substantial changes in ecoregion occupancy (Table 3).

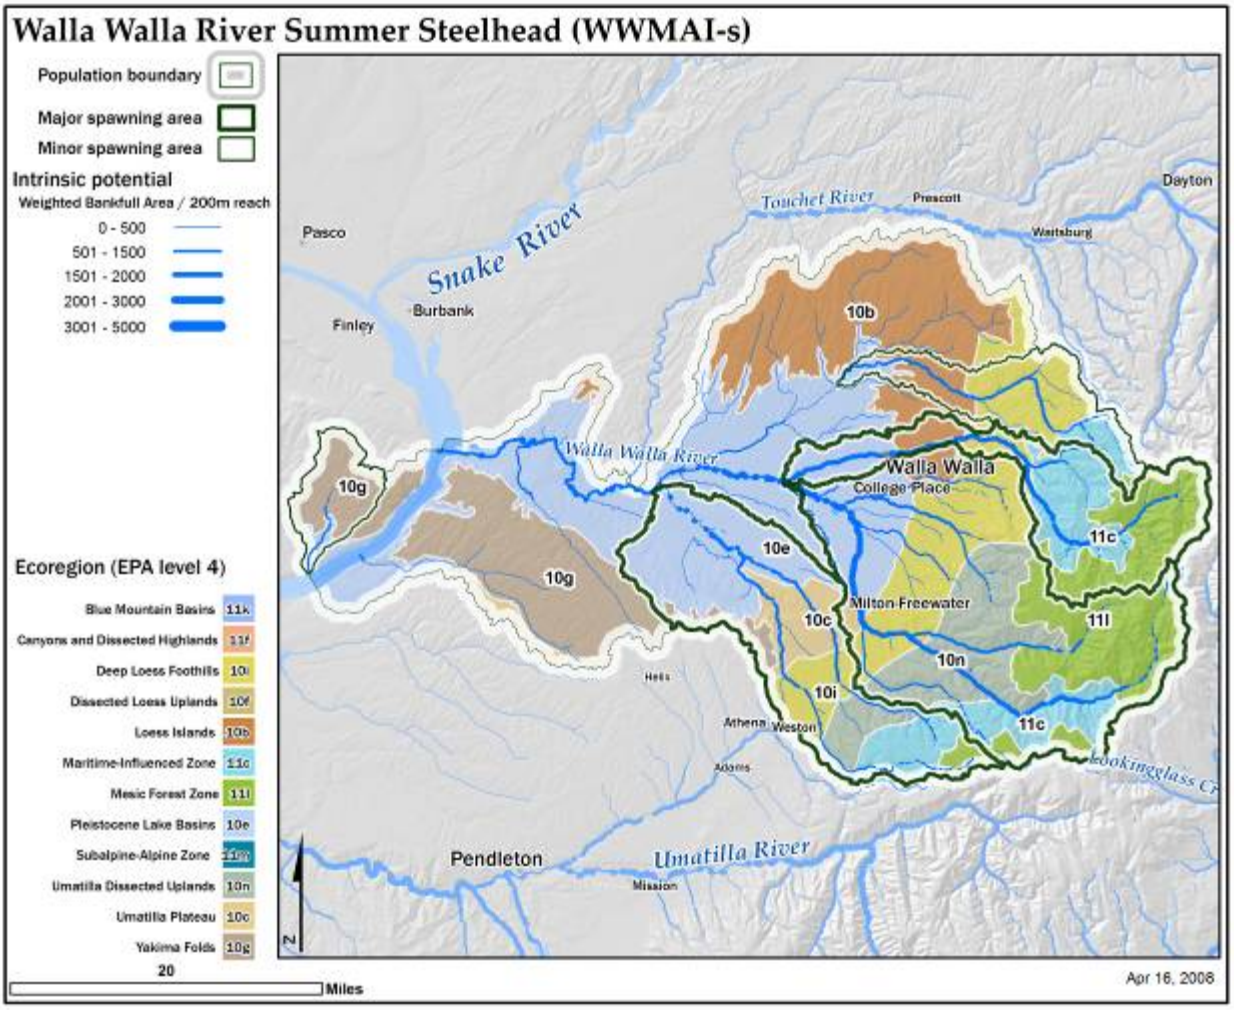

Figure 6. Walla Walla River summer steelhead population spawning distribution across EPA level IV ecoregions.

Table 3. Walla Walla River summer steelhead population proportion of current spawning areas across EPA level IV ecoregions.

Ecoregion	% of historical spawning area (non-temp. limited)	% of currently occupied spawning area (non-temp. limited)
Deep Loess Foothills	19.0	30.4
Loess Islands	8.0	0.9
Maritime-Influenced Zone	11.1	18.8
Mesic Forest Zone	4.6	6.6
Pleistocene Lake Basins	45.9	25.8
Umatilla Dissected Uplands	11.3	17.6

B.4.a. Selective change in natural processes or selective impacts

Hydropower system: This population passes four dams on the lower mainstem Columbia River in its seaward and spawning migrations. The hydropower system and associated reservoirs appear to impose some selection on smolt and adult migration timing. All hydropower effects have persisted for multiple generations and are ongoing.

> *Juvenile migration timing:* Changes in flow and temperature patterns likely inhibit out-migration in late spring as temperatures rise and flow decreases, causing increased travel time, energy expenditure and physiological stress. Given the number of dams that this population must cross, and likely increased mortality as the season progresses, overall selection intensity on the population is likely moderate. Heritability of this trait has not been assessed so we assume a moderate to low heritability. Therefore the impact of the hydrosystem on this trait is **moderate**.
>
> *Adult migration timing:* Adult migrants are affected by thermal blocks that are larger in size and longer in duration relative to historic conditions in the Columbia River system. These result in delays, likely result in increased energy expenditure (due to increased temperatures) and may result in increased straying. Adult migration timing is highly heritable. The proportion of fish in the population affected is relatively unknown, although the effect likely results in low mortality. The effect is highly variable from year to year and in some years no thermal barriers develop. We rated the selection intensity as low. Thus, the impact of the hydrosystem on this trait is **moderate.**

Harvest: Harvest has the potential to affect migration timing, maturation timing and size. However, recent harvest rates for A-run steelhead in the Columbia River mainstem are generally less than 10% annually. Although some harvest may be size-selective for larger fish, the selective mortality would affect slightly greater than 2% of the largest fish in the population. There may be a very slight advantage for earlier returning fish as a result of the timing of the Chinook salmon fishery, and while heritability of adult migration timing is high, the selection intensity is low enough to be negligible. There is very limited tribal harvest of natural-origin fish within the Walla Walla River subbasin and impacts from the recreational fishery are incidental to hatchery fish harvest No phenotypic traits appear to be at risk as a result of this activity. The harvest rating is **low risk** for all traits.

Hatcheries: No natural-origin adults are collected for broodstock within the population; therefore, the hatchery rating is **low risk** for all traits.

Habitat: Altered flow profiles and increased temperatures, which have been in place for many generations and are ongoing, likely impose some selection on juvenile and adult migration timing.

> *Juvenile migration timing:* Late spring and early summer temperatures are elevated relative to historical conditions. There has likely been some effect on juvenile migration timing as temperatures reach stressful levels early in the summer. Juvenile migration timing has likely been truncated; however we are uncertain of the degree of change. Heritability of this trait is moderate to low, and the selection intensity is assumed to be low, therefore the impact of habitat changes on this trait is **low.**

Adult migration timing: Late summer and early fall flows are often low in the Walla Walla River and likely expose adults that enter the river early to above normal mortality rates. Adult migration timing is highly heritable but a relatively low proportion of the population is likely subject to these effects, and we rated the selection intensity as moderate. Thus, the impact of habitat changes on this trait is **moderate.**

Other: A population of Caspian terns in the estuary has been artificially enhanced by a combination of increased habitat (created by dredge spoils) and artificially increased food availability (large-scale releases of hatchery smolts). These terns appear to exert a size-selective predation pressure that primarily impacts the large steelhead smolts. The rate of predation is highest during tern nesting season in May. This pressure may affect smolt migration timing.

Juvenile migration timing. Steelhead smolts pass through the estuary from April to June. The relatively high predation (10%) on smolts in May could select for earlier and later out-migrants. However, heritability of this trait has not been assessed, so we assume a moderate to low heritability. Because this predation occurs at the peak of migration, the impact of this selective factor is **low risk**.

The adult migration timing trait has two moderate ratings and the juvenile migration timing trait has one moderate rating. Therefore, the overall selectivity rating for the Walla Walla River steelhead population is **moderate risk**.

Spatial Structure and Diversity Summary

The integrated spatial structure/diversity rating for the Walla Walla River summer steelhead population is **Moderate Risk** (Table 4). The rating for Goal A (allowing natural rates and levels of spatially mediated processes) was **moderate risk**. There has been significant reduction in spawner distribution which has resulted in increased gaps and loss of continuity within the population and between the Walla Walla population and other Mid-Columbia DPS steelhead populations.

The rating for Goal B (maintaining natural levels of variation) was **moderate risk**. Water temperature and hydrograph changes as well as barriers have likely influenced life history diversity and phenotypic expression. Out-of-DPS spawners have put the population in the moderate risk category for the spawner composition metric. Hydrosystem effects and within-basin habitat changes have likely resulted in selective mortality of the adult run timing phenotypic trait, resulting in a moderate risk rating for the selectivity metric.

Overall Viability Rating

The Walla Walla River summer steelhead population does not meet viability criteria. However, the population does meet ICTRT criteria to be rated as **MAINTAINED** (Figure 7). Overall abundance and productivity is rated at **Moderate Risk.** The 10-year geometric mean abundance of natural-origin spawners is 650, which is 65% of the minimum abundance threshold of 1,000. The 8-year geometric mean productivity (1.34 R/S; Table 6) is nearly at the 1.35 R/S minimum required at the abundance threshold. However, there is considerable uncertainty due to the short time series. Analysis of additional brood years will be critical to demonstrating sustained recruits per spawner and abundance values above the low risk criteria level. Overall spatial structure and diversity is also rated at **Moderate Risk.** Significant improvements to spatial structure and diversity are needed to improve the risk level.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V**	**V**	**M**
	Moderate (6 – 25%)	**M**	**M**	**M Walla Walla River**	**HR**
	High (>25%)	**HR**	**HR**	**HR**	**HR**

Figure 7. Walla Walla River summer steelhead population risk ratings integrated across the four viable salmonid population (VSP) metrics. ***Viability Key: HV – Highly Viable; V – Viable; M – Maintained; HR – High Risk; Shaded cells – does not meet viability criteria (darkest cells are at greatest risk).***

Data Summary – Walla Walla River Summer Steelhead Population

Data type: Dataset reconstructed from dam counts
SAR: Averaged Deschutes, Umatilla, Snake, and Upper Columbia River steelhead series
Productivity: Only 8 recruit/spawner pairs for this population exist; therefore results must be interpreted carefully.

Table 5. Walla Walla River summer steelhead population abundance and productivity data used for curve fits and R/S analysis. Bold values were used in estimating the current productivity (Table 6).

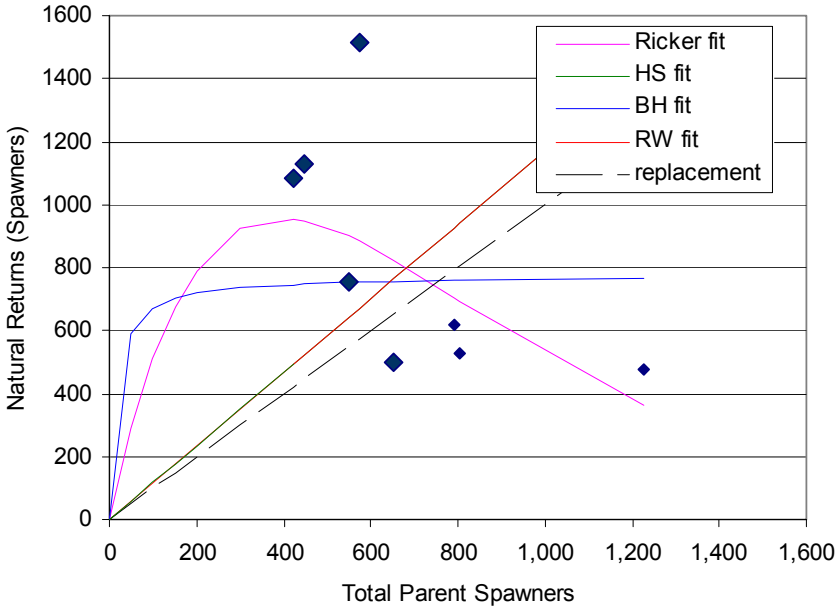

Figure 8. Walla Walla River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were not adjusted for marine survival.

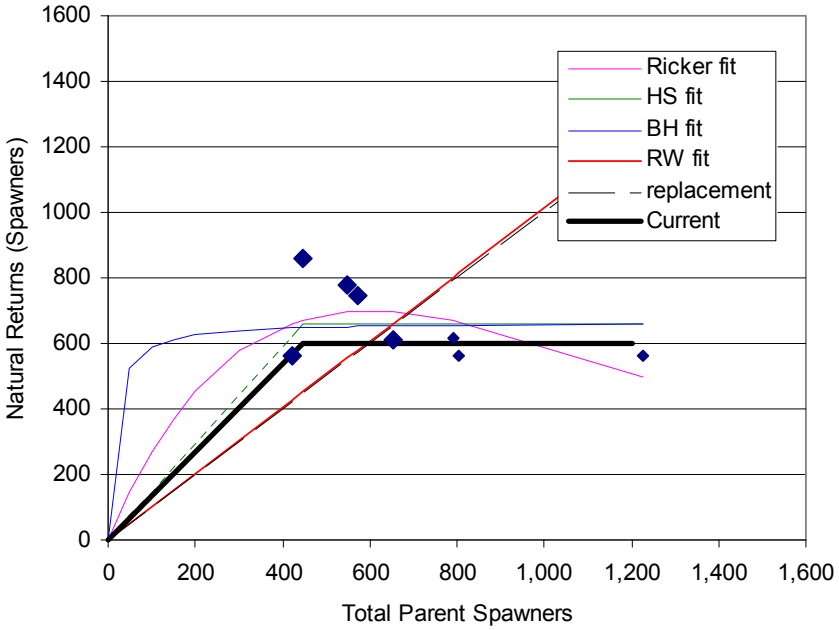

Figure 9. Walla Walla River summer steelhead population stock recruitment curves. Bold points were used in estimating the current productivity. Data were adjusted for marine survival. Function labeled "current" is a Hockey Stick function derived by fixing the slope of the ascending limb at the geometric mean productivity at low to moderate abundance (Table 2) and fitting a capacity estimate to the data series.

APPENDIX C

Summary of habitat projects completed within Oregon's Mid-Columbia River steelhead populations on private and public lands from 1995-2005

Data provided by OWEB, USFS, BLM and Watershed Councils

Summary of habitat projects completed within Oregon's Mid-Columbia River steelhead populations on private and public lands from 1995-2005 (data provided by OWEB and USFS).

Habitat Restoration Projects in Oregon Mid-Columbia steelhead population areas from 1995 through 2005 (OWEB 2006)						
OWEB Project Number	Stream Name	Project Description	Quantity	Year	Project Leader	Total Cost
Fifteenmile Creek Population						
20030865	Fifteenmile Cr	Instream habitat enhancement: anchored structures, bank stabilization	4 structures, 0.13 m	2003	Wasco SWCD	$112,355.00
20030866	Mosier, Chenowith	Upland	6,000 ac	2003	Wasco SWCD	$95,518.00
20030867		Upland	?	2003	Wasco County SWCD	$1,297.00
20030868		Upland	23 ac	2004	Wasco SWCD	$5,460.00
20030869	Lucky Canyon	Upland	4 ac	2003	Wasco County SWCD	$3,906.00
20020839	Fifteenmile Cr, trib of	Weather stations	?	2002	Wasco County SWCD	$46,194.00
20030871	Threemile Cr	Upland	6 ac	2003	Wasco County SWCD	$6,199.00
20030872	Brown's Cr	Upland	12 ac	2003	Wasco County SWCD	$1,263.00
20030873	Lucky Canyon	Upland erosion control, planted	1 ac	2003	Wasco County SWCD	$542.00
20030874	Brown's Cr	Upland erosion control	80 ac	2003	Wasco County SWCD	$6,522.00
20030875	Chenowith Cr	Upland	7 ac	2003	Wasco County SWCD	$1,969.00
20030876	Threemile Cr	Upland erosion control and planting	2 ac erosion, 8 ac planted	2003	Wasco County SWCD	$1,371.00
20030877	Fifteenmile Cr	Riparian fencing	0.59 miles	2001	ODFW	$10,795.00
20030878	Fifteenmile Cr	Riparian fencing	0.5 miles	2001	ODFW	$9,000.00
20030879	Fifteenmile Cr	Riparian fencing	0.5 miles	2003	ODFW	$11,000.00
20030880	Eightmile Cr	Riparian fencing	2.5 miles	2001	ODFW	$43,900.00
20030870	Douglas Hollow	Riparian fencing, upland off-channel watering	0.25 M, 2 off sites	2003	Wasco County SWCD	$9,776.00
20020838	Dry Cr	Off-channel livestock watering, upland erosion control	5 sites	2002	Wasco County SWCD	$12,729.00
990469	Fifteenmile Cr	Off-channel livestock watering	5 sites	1999	ODFW	$12,000.00
20030881	Fivemile Cr	Riparian fencing, off-channel site	0.63 M, 2 sites	2001	ODFW	$12,775.00
1281	Fifteenmile Cr	Instream habitat enhancement: deflectors, bank stabilization; riparian fencing; upland vegetation management	4.5 miles	1996	ODFW	$23,500.00
990734	Mosier Cr, trib of	Peak flow passage improvements, surface drainage improvements, road vacated; fish passage improvements: culvert removed and not replaced	1 structure, 5 ditches, 60 stations, 10 stations, 2 culverts	1999	Longview Fibre Co.	$28,429.00
20020842	Dry Cr & Mosier Cr	Irrigation systems for improved water conservation	30 ac	2001	Wasco County SWCD	$11,997.00
1282	Eightmile Cr	Instream large wood placement, deflectors, bank stabilization, boulder placement; riparian fencing; off-channel livestock watering	3.5 miles	1997	ODFW	$39,000.00

Habitat Restoration Projects in Oregon Mid-Columbia steelhead population areas from 1995 through 2005 (OWEB 2006)						
OWEB Project Number	Stream Name	Project Description	Quantity	Year	Project Leader	Total Cost
20020841	Rock Cr	Irrigation systems for improved water conservation	?	2002	Wasco County SWCD	$1,020.00
20020835	Mosier Cr	Irrigation systems for improved water conservation	20 ac	2002	Wasco County SWCD	$1,281.00
20001121	Rock Cr	Peak flow passage improvements	2 structures	2000	SDS Lumber Co.	$0.00
990467	Fifteenmile Cr	Off-channel livestock watering	?	1999	ODFW	$4,000.00
981112	Mosier Cr	Surface drainage improvements	75 stations	1998	Longview Fibre Co.	$15,072.00
981108	Mosier Cr	Surface drainage improvements	8 culverts, road	1998	Longview Fibre Co.	$16,229.00
991044	Fifteenmile Cr	Instream water rights transfers/leases		1998	Oregon Water Trust	$23,958.00
990472	West Fork Mosier Cr	Peak flow passage improvements, road vacated	1 structure removed	1999	Longview Fibre Co.	$26,942.00
20010913	West Fork Mosier Cr	Peak flow passage improvements, surface drainage improvements, road relocated, road reconstruction	1 structure, 2 cross-drain, 9 culverts	2001	Longview Fibre Co.	$46,114.00
20000725	West Fork Mosier Cr	Peak flow passage improvements, surface drainage improvements	140	2000	Longview Fibre Co.	$62,497.00
990468	Eightmile Cr	Off-channel livestock watering	1 off-channel site	1999	ODFW	$3,500.00
20030882	Fivemile Cr	Riparian fencing, off-channel	1.52 m fence, 2 sites	2002	ODFW	$45,582.00
20040791	Eightmile Cr	Riparian fencing	1.96 m	2004	ODFW	$11,289.00
20040790	Fivemile Cr	Riparian fencing	1.75 m	2004	ODFW	$9,715.00
20040789	Eightmile Cr	Riparian fencing	1 m	2004	ODFW	$8,226.00
20040788	Fifteenmile Cr	Riparian, off-channel	1.5 m, 1 site	2004	ODFW	$21,034.00
20040754	Fifteen Mile Cr	Upland no-till ag	3,501 ac	2005	Wasco SWCD	$284,928.00
20050680	Mill Cr	Upland irrigation improvements	9 ac	2005	Wasco SWCD	$14,351.00
20050678	Fifteenmile Cr	Guzzlers	2	2005	Wasco SWCD	$9,517.00
20050677	Mill Cr	Upland irrigation improvement	5 ac	2005	Wasco SWCD	$1,814.00
20030888	Dry Cr	Riparian fencing, off-channel watering site	0.56 m fence, 1 sites	2003	ODFW	$11,350.00
20030891	Fivemile Cr	Riparian fencing	0.25 m	2003	ODFW	$6,890.00
20030887	Fifteenmile Cr	Riparian fence, off-channel	1.38 m, 3 sites	2003	ODFW	$16,249.00
20030886	Dry Cr	Riparian fencing, off-channel	2.5 m, 8 sites	2002	ODFW	$72,400.00
20030885	Fivemile Cr	Riparian fencing	0.5 m	2001	ODFW	$8,000.00
20030884	Fivemile Cr	Riparian fencing	0.25 m	2001	ODFW	$4,400.00
20030883	Eighmile Cr Rail Hollow	Riparian fencing	1.26 m	2002	ODFW	$22,500.00
20030889	Fifteenmile Cr	Riparian fencing	1.4 m	2003	ODFW	$16,600.00
20030890	Eightmile Cr	Riparian fencing	1.5 m	2003	ODFW	$22,200.00
	Fifteenmile Cr	Underburn	585 ac	1995	USFS	$58,500.00
	Fifteenmile Cr	Instream and floodplain LWD placement	1 RM	1995	USFS	$27,000.00
	Eightmile Cr	Underburn	834 ac	1997	USFS	$83,400.00
	MF Fivemile Cr	Instream and floodplain LWD placement	0.5 RM	1997	USFS	$14,000.00
	Fifteenmile Cr	Floodplain LWD placement	10 ac	1998	USFS	$14,500.00
	MF Fivemile Cr	Replaced round culvert with bridge	1 site	1999	USFS	$150,000.00
	SF Fivemile Cr	Replaced round culvert with bottomless pipe arch	1 site	1999	USFS	$85,000.00

Habitat Restoration Projects in Oregon Mid-Columbia steelhead population areas from 1995 through 2005 (OWEB 2006)						
OWEB Project Number	Stream Name	Project Description	Quantity	Year	Project Leader	Total Cost
	Ramsey Cr	Instream and floodplain LWD placement	3 RM	2000-2002	USFS	$269,745.00
	Eightmile Cr	Round pipe culvert replacements with bottomless arch culverts	4	2002	USFS	$260,428.00
	Fifteenmile Cr	Instream and floodplain LWD placement	0.25 RM	2003	USFS	$21,000.00
	Ramsey Cr	Underburn	815 ac	2003	USFS	$95,000.00
	Ramsey Cr	Riparian and in-stream restoration	2 mi	2000	USFS Mt. Hood NF	$30,700
Deschutes River Eastside Population						
20050687		Upland irrigation improvement	?	2005	Jefferson SWCD	$5,668.00
990909	Fulton Canyon & Gordon Canyon	Erosion control: terraces & WASCOB systems	78 ac; 15 w/s basins	1999	Sherman SWCD	$21,283.00
20040725	Deschutes, trib of	WASCOB	600 ac	2004	Sherman SWCD	$3,242.00
20030849		Upland	1,080 ac	2003	Sherman SWCD	$6,656.00
20030926		Upland, invasive plants	?	2003	Sherman County Weed District	$14,756.00
990938	Warm Springs R & Skookum Cr	Riparian fencing	9.5 m	1999	Deschutes Resources Conservancy	$153,000.00
20020526		WASCOBs, Terraces	500 ac	2002	Sherman SWCD	$55,603.00
20040753	Fifteen Mile Cr	No-till; off-channel watering; WASCOB	4,173 ac; 5 off; 19 WACOBs	2004	Wasco SWCD	$292,855.00
20010914	Neal Cr & Mosier Cr	Peak flow passage improvements, surface drainage improvements, road relocated, road reconstruction	2 cross-drains, 18 culverts, 60 rocking, 3 relocation, 220 other	2001	Longview Fibre Co.	$47,790.00
20020577	East Fork Neal Cr & Mosier Cr	Surface drainage improvements, road reconstruction	?	2002	Longview Fibre Co.	$24,459.00
20020833		Beaver management	?	1999	Confederated Tribes of Warm Springs Reservation	$21,686.00
20050777	Rock Cr	Road, upland	8 cross-drains, 1 m road seeded, 3 structures	2003	Umatilla SWCD	$84,248.00
20050613	Pine Cr	Upland veg. management	11 ac	2004	Umatilla SWCD	$6,961.00
990910	Gerking Canyon	Erosion control: terraces & WASCOB systems	1,700 ac	1999	Sherman SWCD	$56,852.00
990466	Taylor Lake	Instream air diffuser	1	1999	ODFW	$31,500.00
20030923	Macks Canyon	WASCOB, off-channel watering,	468 ac, 2 off	2003	Sherman SWCD	$34,664.00
20020834	Bakeoven Cr	Off-channel livestock watering, other grazing management, upland erosion control	33 off, 15,527 ft cross fence, 1,048 ac, 77 ac plant, 804 ac no till,14 WASCOB,	2002	Wasco County SWCD	$307,816.00
20040726	Macks Canyon, Area of	Upland terrace, off-channel watering	2,120 ft, 1 site	2004	Sherman SWCD	$3,245.00
545	Willow Cr & Higgins Cr	Bank stabilization	?	1995	Ochoco Lumber Company	$3,500.00
20040724	Elder Cr, Area of	Upland fence	3,749 ft	2004	Sherman SWCD	$4,024.00
20030919	Mud Springs (Trout C. trib)	Up. Irrigation improvement	?	2003	Jefferson County SWCD	$13,165.00

Habitat Restoration Projects in Oregon Mid-Columbia steelhead population areas from 1995 through 2005 (OWEB 2006)						
OWEB Project Number	Stream Name	Project Description	Quantity	Year	Project Leader	Total Cost
20001189	Trout Cr	Boulder placement; grass seeding; fish passage improvements: 3 push-up dams removed and replaced with infiltration galleries	3 dams; unknown boulders, stabilization	1999	Jefferson County SWCD	$98,802.00
20050690	Deschutes R	Upland irrigation improvement	20 ac	2005	Jefferson SWCD	$26,933.00
20040687	Willow Cr	Up. WASCOB, planting	3 ac, 4.5 ac plant	2004	Jefferson SWCD	$13,416.00
20030922	Macks Canyon	WASCOB, off-channel	46 ac, 1 off site	2003	Sherman SWCD	$8,673.00
1201	Willow Cr	Instream habitat enhancement: weirs, bank stabilization; riparian tree planting, riparian fencing; peak flow passage improvements	6 weirs, 14.5 ac treated/planted, 1 mile fence, 20 trees anchored	1997	Central Oregon Small Woodlands Association	$25,700.00
20030924	Buck Hollow Cr	Upland erosion control	30 ac	2003	Sherman SWCD	$2,364.00
20030768	Foley Cr, (Trout C. trib)	Rip. fence, off channel watering site	5 m, 2 sites	2003	Jefferson County SWCD	$56,880.00
20030769	Willow Cr	Upland irrigation improvements	?	2003	Jefferson County SWCD	$25,079.00
20030770	Frog Springs	Upland irrigation improvements	?	2003	Jefferson County SWCD	$7,067.00
20050685	Willow Cr	Riparian planting	2.35 m	2005	Deschutes River Conservancy	$5,162.00
20030928	Buck Hollow Cr	Upland WASCOB, fenced, treated, erosion	300 ac fenced, 16 WASCOB, 565 ac treated, 245 ac erosion, 4 off-channel,	2003	Wasco SWCD	$251,285.00
997	Trout Cr	Instream habitat enhancement: weirs, deflectors, bank stabilization, boulder placement; riparian fencing	40 boulders, 20 deflectors, 5 weirs, 70 miles fence	1997	ODFW	$200,000.00
998	Trout Cr	Fish passage improvements: 1 gravel push-up dam replaced with concrete diversion and fish ladder	1 push-up dam, 1 ladder	1997	ODFW	$67,000.00
20050780	Bakeoven Cr, Buck Hollow Cr	Upland fencing	163,891 ft	2004	Wasco SWCD	$138,517.00
990905	Willow Cr	Riparian fencing	1.5 m	1999	Willow Creek Watershed Council, Jeff County SWCD	$19,150.00
20001129	Tenmile Cr (Trout C. trib)	Upland pasture fencing	989 ac treated, 1 off-channel site	2000	Trout Creek Watershed Council	$57,521.00
980495	Fulton Canyon & Gordon Canyon	Erosion control: terraces & WASCOB systems	13 WASCOB	1998	Sherman SWCD	$28,510.00
990906	Trout Cr	Instream habitat enhancement: anchored structures, bank stabilization	16 anchored structs, 0.066 M stabilized	1999	Trout Creek Watershed Council, Jeff County SWCD	$58,900.00
20020811	Trout Cr	Fish passage improvements: 6 push-up dams removed, replaced with infiltration galleries	6	2002	Jefferson County SWCD	$115,681.00
20010980	Trout Cr	Fish passage improvements: 3 push-up dams removed, replaced with infiltration galleries	3	1998	Jefferson County SWCD	$64,705.00
20010981	Trout Cr	Fish passage improvements: 1 push-up dam removed, replaced with infiltration gallery	1	2002	Jefferson County SWCD	$124,400.00
20040756	Ward Cr	Upland off-channel watering site	1	2004	Wasco SWCD	$3,482.00

Habitat Restoration Projects in Oregon Mid-Columbia steelhead population areas from 1995 through 2005 (OWEB 2006)						
OWEB Project Number	Stream Name	Project Description	Quantity	Year	Project Leader	Total Cost
20020784		Upland erosion control	65 acres	2002	Sherman SWCD	$3,100.00
20050683	Trout Cr	Upland fence, off-channel watering site, grazing management	76 ac fenced, 2 off-channel sites, 76 ac grazing	2005	Jefferson SWCD	$30,975.00
20040747	Newcomb Draw	Upland fence	5,998 ft	2004	Wasco SWCD	$2,925.00
	Auger Cr	Ingram Meadows structure repair, riparian planting and riparian fencing	6 mi	2000	USFS Ochoco NF	$55,425.00
	Trout Cr and tribs	Culvert replacement for flow and fish passage	13 sites	1996-2005	USFS Ochoco NF	$1 million
	Trout Cr watershed	Road closures in Trout watershed along streams and culverts pulled	50 mi	1996-2006	USFS Ochoco NF	$100,000.00
	Trout Cr watershed	Grazing changed from livestock to sheep, improve riparian vegetation to stabilize streambanks		1989	USFS Ochoco NF	
	Auger Creek	Ingram Meadows structure repair, riparian planting and riparian fencing	6 miles	2000	USFS Ochoco NF	$55,425.00
		Culvert replacement for flow & fish passage	13 sites	1996-2005	USFS Ochoco NF	$1 million
	Trout Cr watershed	50 miles of road closures in Trout Watershed along streams and culverts pulled	50 mi	1996-2006	USFS Ochoco NF	$100,000.00
	Trout Cr watershed	Grazing changed from livestock to sheep, improve riparian vegetation to stabilize streambanks		1989	USFS Ochoco NF	
	Deschutes River	Harpham Flat Riparian Exclosure	.5 mile	2000	BLM	$10,000.00
	Trout Cr	OHV area closure fence and rehab to protect riparian area	1 mile fence	2001	BLM	$10,000.00
	Trout Cr	Widen boat ramp, eliminate indiscriminate boat launching to protect riparian area	1 site	2001	BLM	$6,000.00
Deschutes River Westside Population						
20020837	Rock Creek Res. (White R)	Irrigation systems for improved water conservation	?	2002	Wasco County SWCD	$120,717.00
20020836	Boulder Cr	Irrigation systems for improved water conservation	?	2002	Wasco County SWCD	$104,912.00
990939	Deschutes R	Instream habitat enhancement: anchored structures	175 structures	1999	Deschutes Resources Conservancy	$73,141.00
20040748	Threemile Cr	Upland irrigation	4.4 ac	2004	Wasco SWCD	$13,483.00
990940	Deschutes R	Instream water right transfer		1999	Deschutes Resources Conservancy	$425,400.00
20030728	Deschutes R	Riparian treatment	2 M treated	2003	Deschutes SWCD	$11,123.00
20030930	Threemile Cr	Upland irrigation	200 ac	2003	Wasco County SWCD	$23,028.00
20030929	unnamed draw	Wetland creation	?	2003	Wasco County SWCD	$25,730.00
20030927	Deschutes R	Riparian fencing	0.8 miles	2003	Upper Deschutes Watershed Council	$14,110.00
20050781	Jordan Cr (White R)	Riparian fence/plant, upland erosion	1.5 m rip fence, 0.75 m planted, 2 crossings	2004	Wasco SWCD	$49,462.00
20050688	Threemile Cr	Upland irrigation improvements	375 ac	2005	Wasco SWCD	$13,518.00

Habitat Restoration Projects in Oregon Mid-Columbia steelhead population areas from 1995 through 2005 (OWEB 2006)						
OWEB Project Number	Stream Name	Project Description	Quantity	Year	Project Leader	Total Cost
20040755	Tygh Cr	Upland water storage	?	2004	Wasco SWCD	$6,546.00
20040805	Trout Cr	Wetland improvement	0.15 ac	2004	Upper Deschutes Watershed Council	$28,856.00
	Middle and Upper Whychus	Riparian/floodplain protection/road closure	15 mi	2006	USFS Deschutes NF	$29,000.00
	Middle Whychus	Riparian planting	1 mi	2006	USFS Deschutes NF	$2,000.00
	Middle Whychus	Riparian planting	1 mi	1995	USFS Deschutes NF	$1,000.00
	Middle Whychus	Riparian planting	1 mi	2007	USFS Deschutes NF	$1,000.00
	Deschutes River	Bully Point Fence. Construct .75 mile of fencing to improve livestock management in riparian area	.75 mile	2000	BLM	$6,000.00
	Oak Canyon Creek	Riparian fencing exclosure	1 mile	2002	BLM	$10,000.00
996	Whychus Cr	instream water transfers/leases	0.86 cfs	1998	Deschutes Watershed Council	$42,900
990941	Whychus Cr	instream water right transfer	1.81 cfs	1999	Deschutes River Conservancy	$78,950
990942	Whychus Cr	instream water right transfer	0.6 cfs	2000	Deschutes River Conservancy	$105,000
991045	Whychus Cr	instream water rights transfers/leases		1998	Oregon Water Trust	$54,343
991046	Whychus Cr	instream water rights transfers/leases	1.61 cfs	1999	Oregon Water Trust	$17,211
20010982	Whychus Cr	instream water right transfer/lease		2001	Deschutes River Conservancy	$581,698
20020571	Whychus Cr	instream water rights transfer; irrigation systems for improved water conservation	1.5 cfs, 377 acres	2002	Deschutes SWCD	$548,233
20040775	Whychus Cr	upland tree planting, upland vegetation planting	0.1 acre	2004	Deschutes Basin Land Trust	$20,914
20050067	Whychus Cr	instream habitat enhancement: anchored structures	0.75 mile	2001	ODFW	$6,262
20060760	Whychus Cr	instream water right transfers/leases	1.2 cfs	2006	Deschutes River Conservancy	$914,000
20020862	Tumalo Cr	irrigation systems for improved water conservation		2002	Tumalo Irrigation District	$1,350,000
20020863	Tumalo Cr	irrigation systems for improved water conservation		2002	Tumalo Irrigation District	$760,000
20050821	Tumalo Cr			2004	Tumalo Irrigation District	$1,180,695
20060534	Deschutes R		0.09	2006	Upper Deschutes Watershed Council	$9,686

APPENDIX D

Hydropower Configuration and Operational Improvements Implemented in Recent Years that Provide Survival Benefits to Oregon's Mid-C Steelhead Populations

and

Estuary Improvements Implemented in Recent Years that Provide Survival Benefits to Oregon's Mid-C Steelhead Populations

Hydropower Configuration and Operational Improvements Implemented in Recent Years that Provide Survival Benefits to Oregon's Mid-C Steelhead Populations:

- Bonneville Powerhouse I (PH1) minimum-gap turbine runner (MGR) installations
- Bonneville PH1 juvenile bypass system (JBS) screen removal
- Bonneville PH2 corner collector installation
- Bonneville PH2 fish guidance efficiency (FGE) improvements
- Bonneville PH2 operation as first priority
- Bonneville spill operation improvements including five additional flow deflectors
- The Dalles spill wall construction
- The Dalles spill pattern improvements
- The Dalles sluiceway operation improvements
- The Dalles adult collection channel improvements
- John Day spill operation improvements
- John Day South Fish Ladder improvements
- McNary spill operation improvements
- McNary end spillbay deflectors and hoists
- McNary full flow juvenile passive integrated transponder (PIT)-tag detections
- McNary juvenile transport facility bypass piping improvements
- McNary spare extended-length submerged base screen
- McNary improved juvenile bypass dewatering screens
- McNary adult PIT-tag detection in fish ladders
- McNary overhauling auxiliary water supply (AWS) pumps
- McNary upgrading of adult fish ladders tilting weir controls

Estuary Improvements Implemented in Recent Years that Provide Survival Benefits to Oregon's Mid-C Steelhead Populations:

- Replaced three culverts with full-spanning bridges
- Provided approximately 10 miles of improved tidal channel connectivity by installing a tide gate retrofit
- Acquired approximately 473 acres of off-channel and riparian habitats
- Restored and created 90 acres of marsh and tidal sloughs and approximately 100 acres of riparian forests
- Protected approximately 55 acres of high quality riparian and floodplain habitat
- Restored and preserved approximately 154 acres of off-channel habitat
- Protected 80 acres of high-value off-channel forested wetland habitat
- Restored approximately 96 acres of tidal wetlands habitat by replacing undersized culvert that limited fish access
- Conserved 155 acres of forested riparian and upland habitat
- Provided partial tidal channel reconnection by tide gate retrofit (acreage unknown at this time)
- Provided integrated pest management (purple loosestrife)
- Reconnected and restored 183 acres of historical floodplain by dike removal
- Restored 25 acres of historical floodplain by breaching a dike

APPENDIX E

U.S. Forest Service
Bureau of Land Management

Forest Service and Bureau of Land Management Programs in Support of Mid-Columbia Steelhead Recovery Sufficiency Assessment

Forest Service and Bureau of Land Management Programs in Support of Mid-Columbia Steelhead Recovery Sufficiency Assessment

May, 2007

Executive Summary

The Forest Service (FS) and Bureau of Land Management (BLM) have in place a *Management and Conservation Framework* that is comprised of programs that contribute to recovery of ESA-listed salmon and steelhead on federal lands, these include:

1. A diverse body of environmental laws and regulations
2. Agency policies
3. Land Management Plans with associated aquatic strategies, and
4. Guidance and procedures for project design, implementation, and monitoring

Collectively, this existing *Management and Conservation Framework* represents the "baseline" that governs land management, contributing to both short and long-term recovery goals for ESA-listed salmon and steelhead on federal lands. While elements of the framework may be revised or amended over time, the interwoven nature of statutes, regulations and policies, as well as interagency and public processes, maintains the integrity and overall effectiveness of the framework in providing meaningful contributions to salmon and steelhead recovery.

The foundation of the Management and Conservation Framework are two aquatic strategies known as (PACFISH and the Northwest Forest Plan – Aquatic Conservation Strategy (NWFP-ACS). PACFISH was incorporated into FS and BLM Land Management Plans in 1995 and the NWFP ACS amended Forest Service plans on the east slope of the Cascade mountain range in 1994. These aquatic strategies provide for the long-term protection and appropriate management of physical or biological features essential to recovery of ESA-listed salmon and steelhead on federal lands.

Forest Service and BLM Aquatic & Riparian Habitat Management and Conservation Framework

Introduction

The Forest Service (FS) and Bureau of Land Management (BLM) have in place a *Management and Conservation Framework* that is comprised of programs that contribute to recovery of ESA-listed steelhead on federal lands. These include:

1. A diverse body of environmental laws and regulations; for example, the Clean Water and Endangered Species Acts;
2. Agency policies
3. Land Management Plans with associated aquatic strategies, and
4. Guidance and procedures for project design, implementation, and monitoring

Collectively, this existing *Management and Conservation Framework* represents the "baseline" that governs land management, contributing to both short and long-term recovery goals for ESA-listed steelhead on federal lands. While elements of the framework may be revised or amended over time (e.g., Congress may pass new statutes, agencies may revise plans, etc.), the interwoven nature of statutes, regulations, and policies – as well as interagency and public processes – maintains the integrity and overall effectiveness of the framework in providing meaningful contributions to salmon and steelhead recovery.

The following describes the primary building blocks in the *Management and Conservation Framework* the Forest Service (FS) and Bureau of Land Management (BLM) apply to federally-managed lands within the Pacific Northwest (States of Idaho, Oregon, and Washington) that contribute to salmon and steelhead recovery goals and objectives, and guide recovery actions:

Land Management Plans

FS and BLM *Land Management Plans* contribute to recovery by providing assurances that public lands are managed in accordance with Federal Land Policy and Management Act of 1976 (43 U.S.C. 1701 *et seq.*)/(FLPMA), the National Forest Management Act/(NFMA) of 1986, and other applicable laws, regulations and policy. These legal and policy requirements ensure the federal land managing agencies make informed decisions and provide for the responsible management of public land resources, including ESA-listed species.

Both FS and BLM *Land Management Plans* describe broad, multiple-use guidance for managing public lands and mineral estates. Plan decisions are made at a broad scale and guide site-specific project design and approval. *Land Management Plans* highlight goals and objectives for resource management and establish management guidance needed to achieve them. Plans also identify what public and commercial uses are appropriate and where they should occur. Land *Management Plans* contain protective management direction, in some cases even stronger than PACFISH or the NWFP-ACS. Applicable to specific large blocks of land, these additional protections include; Congressionally designated Wilderness, Wild and Scenic Rivers and municipal watersheds. In addition, some types of management areas also receive strong watershed-scale protections based on land use decisions contained in land management plans. Examples include; allocations and management direction for non-motorized dispersed recreation areas, and Scenic Areas. All *Land Management Plans* are developed with public involvement,

and impacts of a plan are analyzed in an appropriate NEPA document. Plans also contain a monitoring component to provide continuous feedback on the efficacy of direction in meeting {plan} objectives.

Within the range of Columbia and Snake River basins, the FS and BLM rely on these two aquatic strategies, PACFISH and the NW Forest Plan – ACS, to ensure that actions on federal lands prevent further degradation and begin to restore high quality in-stream and riparian habitat conditions in support recovery of ESA-listed salmon and steelhead. Current FS and BLM *Land Management Plans* west of the Cascades in Oregon and Washington were amended by the NWFS EIS Record of Decision (ROD) in 1994, amended in 2003. East of the Cascades (eastern OR/WA, ID) were amended by a PACFISH Decision Notice in 1995

PACFISH and the NWFP-ACS are described individually in more detail below:

PACFISH

(Aquatic Strategy for Managing National Forest System and Bureau of Land Management Anadromous Fish Producing Watersheds in Eastern Oregon, Washington, Idaho, and portions of northern California)

In February, 1995, Forest Service (FS) and Bureau of Land Management (BLM) administrative units with anadromous fish, outside the range of the northern spotted owl covered by the Northwest Forest Plan – Aquatic Conservation Strategy (NWFP-ACS) in Oregon, modified their *Land Management Plans* through amendment by PACFISH. PACFISH was developed as an ecosystem-based, interim strategy designed to arrest the degradation of habitat and begin restoration of in-stream and riparian habitats on lands administered by the FS and BLM in eastern Oregon and Washington, Idaho, and portions of northern California. The intent of the strategy was to allow for 'passive' restoration of the ecological health and productivity of watersheds that contain present or potential anadromous fish habitat through the application of riparian standards and guidelines to both proposed and ongoing actions. PACFISH was to remain in place until longer term aquatic conservation strategies, similar to the NWFP-ACS were completed through *Land Management Plan* amendment or revisions (PACFISH Environmental Assessment, 1994). Those revisions have not yet occurred, and PACFISH still applies wherever NWFP-ACS does not already apply.

PACFISH contains the following components that are applied to FS and BLM management actions to maintain and restore ecological processes that support high quality habitat for salmon and steelhead:

- Riparian Goals – *establishes an expectation of the characteristics of healthy, functioning watershed, riparian areas, and associated fish habitats;*
- Riparian Management Objectives (RMOs)- quantitative *RMOs for stream channel, riparian and watershed conditions were developed to provide the criteria against which attainment or progress toward attainment of the riparian goals are measured. RMOs provide measurable targets toward which managers are aiming as they conduct resource management activities across the landscape. The objectives are time specific to reflect the ecological capabilities of specific ecosystems;*

- Delineation of streamside areas (Riparian Habitat Conservation Areas, aka "RHCA"s) that are important to maintenance of high quality aquatic habitat and where special management considerations are applied - *PACFISH requires that proposed actions within RHCAs do not prevent or retard attainment of RMOs. RHCAs include traditional riparian corridors, wetlands, intermittent streams, and other areas that help maintain the integrity of aquatic ecosystems by (1) influencing the delivery of coarse sediment, organic matter, and woody debris to streams, (2) providing root strength for channel stability, (3) shading the stream, and (4) protecting water quality;. RHCA widths vary depending upon the aquatic and riparian resources to be protected in each stream reach, based on stream and riparian characteristics.*
- Standards and/or guidelines *to ensure to the extent legally possible, that projects do not prevent or retard attainment of riparian goals and management objectives*;
- Designation of *Key* or *Priority* watersheds - *areas where additional management emphasis and/or watershed analysis is required to ensure that salmon and steelhead habitat is maintained or provided priority for restoration*;
- Watershed analyses - *to provide sufficient context for designing actions that support maintenance or restoration of aquatic habitats needed for recovery of ESA-listed salmon and steelhead* ;
- Watershed restoration efforts focused through watershed analysis;
- Monitoring program to evaluate project implementation (compliance) and effectiveness of PACFISH as a strategy for protecting and improving aquatic habitat conditions on federal lands. http://www.fs.fed.us/rm/boise/research/techtrans/projects/pacfish_home.shtml

PACFISH, combined with underlying Land Management Plans and *BLM* Rangeland Health Standards, and complemented by consultation programs conducted for compliance with the Endangered Species Act, provides the program guidance needed to protect and conserve steelhead and their habitat on federal lands. The protective guidance provided by these programs is applied on every FS and BLM project during project development and implementation. They have been determined to be sufficient in terms of their intended purpose of protecting habitat for ESA-listed salmon and steelhead to the extent permitted by law, thereby promoting recovery of the species and their habitats.

PACFISH provides a framework for minimizing adverse effects from land management activities on aquatic resources through the assessment of proposed or ongoing management actions, within RHCAs, with Riparian Goals and Riparian Management Objectives (RMOs). Standards and Guidelines are applied to actions within Riparian Habitat Conservation Areas (RHCAs) to ensure that they do not prevent or retard attainment of high quality aquatic habitat (RMOs). The use of Watershed Analysis and special considerations provided in *KEY* watersheds (priority populations) provide another level of management consideration that increases certainty of outcomes for protection and meeting of both short and long-term recovery goals.

Preliminary results from broad-scale aquatic habitat status and trend monitoring of FS and BLM lands within the interior Columbia River basin since 2001 indicates conditions have improved over the past 5 years, continuing the habitat recovery presumed to have begun in 1995 as a result of the protections PACFISH instituted. Implementation and Effectiveness Monitoring will both

continue to evaluate the overall long-term effectiveness of PACFISH policy and program directives at preventing further degradation of habitat for native anadromous and resident salmonids, and its effectiveness at restoring near-natural rates of habitat and species recovery on actively managed FS and BLM lands, particularly within streamside riparian areas on streams affected by ongoing livestock grazing.

Northwest Forest Plan's Aquatic Conservation Strategy and Protective Land Allocations In Oregon and Washington

The Northwest Forest Plan ACS (NWFP-ACS) was designed to incorporate all elements of an aquatic and riparian ecosystem necessary to maintain its natural disturbance regime. The NWFP-ACS applies to all FS and BLM lands within western WA, OR, and the east face of the Cascades in WA.

Aquatic ecosystem elements embedded in the NWFP-ACS include; maintenance of hydrologic function, high water quality, adequate amounts of coarse woody debris, complex stream channels that provide a diversity of aquatic habitat types, and riparian areas with suitable microclimate and vegetation. These elements directly or indirectly correspond to each of the physical and biological attributes of 'Primary Constituent Elements' identified as characterizing salmon and steelhead designated critical habitat: water quality and quantity; substrates; shade; large wood; cover; conditions suitable for forage production; channel form and connectivity with floodplains; and, unobstructed migration corridors. Since being amended to FS *Land Management Plans* in the eastern Cascades in 1994, the NWFP-ACS has created a connected system of aquatic and riparian habitats throughout the plan area that are assumed to be reversing the trend of aquatic and riparian habitat degradation and begun the long recovery process for these habitats over the past 12 years.

Most primary program components of the NWFP-ACS are similar to those found in PACFISH. NWFP-ACS components include:

- Aquatic Goals and Objectives - *each project must maintain or restore the physical and biological processes required by riparian dependent-resources at the watershed scale or broader to comply with the ACS*
- Riparian Reserves - *portions of watersheds where riparian-dependent resources receive primary emphasis. The extensive Riparian Reserves within the Northwest Forest Plan area protect the stream and adjacent riparian areas critical to maintaining a highly functioning aquatic ecosystem,*
- Standards and Guidelines – *Standards and Guidelines prohibit and regulate activities in Riparian Reserves that retard or prevent attainment of the ACS aquatic/riparian objectives. Use of these provides assurances that a project cannot have a negative impact in the long- term on riparian-dependent resources or ecological processes in the Riparian Reserves at the watershed scale.*
- Key Watershed network *-serves as refugia for anadromous salmonids,*
- Watershed analyses - *to provide sufficient context for designing actions that support maintenance or restoration of aquatic habitats needed for recovery of ESA-listed salmon and steelhead* ;

- Watershed Restoration Strategy-*a formal restoration strategy based on watershed analysis.*
- Monitoring-*a formal long-term broad-scale monitoring program*
- Adaptive Management-*ongoing adjustments in management based on monitoring and other new information as it becomes available.*

Riparian Reserves
The NWFP-ACS provides the foundation for the conservation and recovery of anadromous fish species on federally-managed lands through use of Riparian Reserves. Riparian Reserves are portions of watersheds where riparian-dependent resources receive primary emphasis. In conjunction with the Key Watershed network, these areas serve as refugia for ESA-listed and non-listed anadromous fish.

Land Allocations
The NWFP-ACS, with additional protective land allocations, collectively provides an extensive network of Riparian Reserves and watersheds contributing to the protection and restoration of aquatic ecosystems on federally-managed lands.

Large proportions of federal lands within the NWFP area in Oregon are in some form of *Reserve* or *Special Management* status. *Reserve* or *Special Management* status lands are those where land management actions are largely prohibited or significantly shaped by application of protective Standards and Guidelines (S&Gs) for land management activities. These specially-managed lands are located both within and outside Key Watersheds. Federal lands outside of Key Watersheds are also protected under other land allocations including; Riparian Reserves, Congressional Reserves such as Wild and Scenic River corridors, Wilderness and/or Municipal Watersheds; spotted owl Late-Successional Reserves (LSRs) and Areas Withdrawn from active management (Forest Service) through Forest Plans.

NWFP-ACS Standards and Guidelines are also required to be applied within LSRs, providing increased protection for all stream types. As LSRs have late-successional characteristics, and are overlain with Riparian Reserves, they serve as core areas of high quality stream habitat, fish refugia, and centers from which degraded aquatic systems can be recolonized once they are restored. Streams within these reserves may also be particularly important for endemic or locally distributed fish species and stocks. Collectively, these protective upland land allocations (non-Riparian Reserve; not located in Key Watersheds) comprise 1,331,636 acres or 17 percent of federally-managed lands within the area of designated critical habitat for anadromous fish in Oregon and Washington.

Watershed Analysis and Watershed Restoration
Watershed analysis, a requirement of the NWFP-ACS, provides an understanding of aquatic habitat conditions and processes. This informs land management decisions regarding the timing, location, and magnitude of activities on the landscape to protect and/or restore the physical and biological features essential to the conservation of anadromous fish. Watershed analysis also provides information on priorities for watershed restoration. The FS has made significant investments in watershed restoration in the NWFP area since its inception in 1994. Activities have emphasized; restoration of fish passage, reductions in the delivery of fine sediments to

stream channels, placement of large wood debris in stream channels, riparian plantings and thinning to accelerate large wood recruitment/increase shade/improve nutrient cycling, and have included control of noxious weeds, and obliteration or high-level maintenance of as risks to meeting aquatic habitat objectives

Monitoring
The NWFP-ACS also contains a long-term monitoring component to evaluate progress towards goals for protection and management of physical and biological features essential to long-term conservation of ESA-listed salmon and steelhead. In the NWFP ACS, monitoring is considered an essential component of management as the information it provides helps to evaluate the overall success of the applied strategies and allows for needed adjustments. Four types of monitoring are conducted by the FS:

- *Implementation monitoring* - to determine if activities (i.e., timber sales, silvicultural projects, watershed restoration, etc.) were implemented as planned and whether or not they meet NWFP-ACS Standards and Guidelines.
- *Effectiveness monitoring* - evaluate if NWFP-ACS Standards and Guidelines are meeting the strategy's goals and objectives. www.reo.gov/monitoring/watershed.
- *Validation monitoring* is primarily research-oriented and directed at testing underlying assumptions upon which management strategies are based. http://www.reo.gov/monitoring/10yr-report/documents/synthesis-reports/all.pdf., http://ocid.nacse.org/nbii/density/pubs.html, http://www.fs.fed.us/pnw/publications/index.shtml
- *Local* - In addition, many of the local FS and BLM administrative units conduct annual monitoring (implementation, effectiveness) to address local management issues.

Adaptive Management

Adaptive Management is described in the Northwest Forest Plan (USDA and USDI 1994a) as a continuing process of action-based planning, monitoring, researching, evaluating and adjusting with the objective of improving the implementation and achieving the goals of the standards and guidelines. Using this process, new information is evaluated and then serves as the basis for decisions on needed adjustments to management. Adjustments may also result in the refinement of standards and guidelines, land-use allocations, or amendments to FS and BLM Land Management Plans.

Collectively, these NWFP-ACS program components emphasize aquatic habitat management for protection and recovery ESA-listed anadromous salmonid ESUs on NFS and BLM lands.

Executive Summary

Natural resource agencies within the State of Oregon conducted an internal review of their habitat-based programs to assess sufficiency in addressing threats, and associated limiting factors, to the recovery of listed anadromous salmonids in Oregon. This assessment is a component of Oregon's recovery planning effort, specifically in guiding development of basin actions for specific populations. The process builds on the foundation of the Oregon Plan for Salmon and Watersheds wherein the collective and coordinated actions of natural resource agencies synergistically care for Oregon's watersheds and salmon.

Sufficiency of statewide programs was based on technical, institutional, budgetary, implementation, and documentation criteria, and categorized according to certainty, or lack thereof, of sufficiency in addressing limiting factors. Program jurisdiction on federal, state, and private forests, agricultural lands, and urban/rural residential lands was also identified. Factors limiting to salmonid viability were characterized as habitat access, food web dynamics, physical habitat quality and quantity, water quality, and water quantity and flow timing. Eight management strategies were identified for addressing limiting factors and threats related to freshwater habitat conditions.

(*Note: final sufficiency analysis is ongoing and incomplete*).

Key constraints to program effectiveness included inadequate outreach and education, monitoring, technical assistance, prioritization, and program oversight, all of which are a result of inadequate funding and staff resources. Monitoring of program actions on the ground was identified as being crucial to providing rigor and necessary documentation of program effectiveness and sufficiency.

Introduction

Oregon is in the process of developing recovery plans for salmon and steelhead populations in the state that are listed as threatened or endangered under the U.S. Endangered Species Act (ESA). One step in the development of these recovery plans is consideration of the ability of existing regulatory, management, or incentive-based programs to address the habitat factors that have historically limited, or are currently limiting, the salmon and steelhead populations in Oregon. This document provides information about limiting factors and critical "bottlenecks", and evaluates the likely influence the agency programs will have on addressing limiting factors and bottlenecks for improving habitat and population trends.

While completion of this document is not a federal ESA requirement, its contents will be included in recovery plans being developed across the state, and will serve as a resource for the planning teams tasked with developing specific action plans for each of the salmon and steelhead recovery planning domains in Oregon.

State regulatory and management mechanisms are important tools to preventing the continued decline of habitats and promoting their protection and restoration to create healthy watersheds for fish. Thus, in evaluating the various regulatory programs, the process considers the degree to which practices that were historically adverse have been stopped, the impact of the current standard to improve conditions over time, and the adequacy of companion non-regulatory programs to timely restore desired conditions. This process will also serve as a baseline from which improvement can be measured toward reducing threats that initially contributed to a listing decision. The listing (and delisting) decision includes as one criteria (among several) the "inadequacy of existing regulatory mechanisms" that threaten the continued existence of a species.

This process builds on the regulatory, incentive-based and management foundation established prior to and for the Oregon Plan for Salmon and Watersheds, wherein the collective and coordinated actions of natural resource agencies work to synergistically care for Oregon's watersheds and salmon. While agency programs in large part were not intended to achieve habitat conditions that foster recovery, they *were* intended to improve watershed conditions in general for salmon.

Conceptual Framework

Limiting factors are the physical, biological, or chemical conditions and associated ecological processes and interactions (e.g., population size, habitat connectivity, water quality, water quantity, streambank sloughing etc.) experienced by the fish that may influence viable salmonid population (VSP) parameters (i.e. abundance, productivity, spatial structure, and diversity). There are five broad categories of habitat limiting factors:

Water quantity/hydrograph –Magnitude and timing of flows.

Water quality – Water characteristics including temperature, dissolved oxygen, suspended sediment, pH, toxics, etc.

Food Web – The complex of interrelated food chains that ultimately feed salmon and steelhead.

Physical habitat quality/quantity – The amount and characteristics of physical habitat such as amount of large wood in the stream channel, occurrence of deep pools, and silt free spawning gravel.

Habitat access – Impaired access to spawning and/or rearing habitat.

As illustrated in Figure 1, many interrelations exist between the limiting factor categories. For example, a water quantity/hydrograph limitation can influence habitat access (dewatered stream channels), water quality (less dilution of pollutants), physical habitat quality (changing macro and micro habitat conditions), and food web (altering nutrient retention rates).

Threats are the human actions (e.g., fishing, operation of hatcheries, operation of the hydro system, road building, riparian habitat degradation, channel straightening, etc.) or natural occurrences (e.g., flood, drought, volcano, tsunami, etc.) that *cause or contribute-to* limiting factors and site-specific "bottlenecks".

Management strategies describe how recovery goals will be achieved by stating the general approaches that set the path from current conditions to the desired future state. Management strategies guide the creation of *management actions*, which are specific activities or behaviors intended to address the bottleneck to help achieve one or more recovery goals.

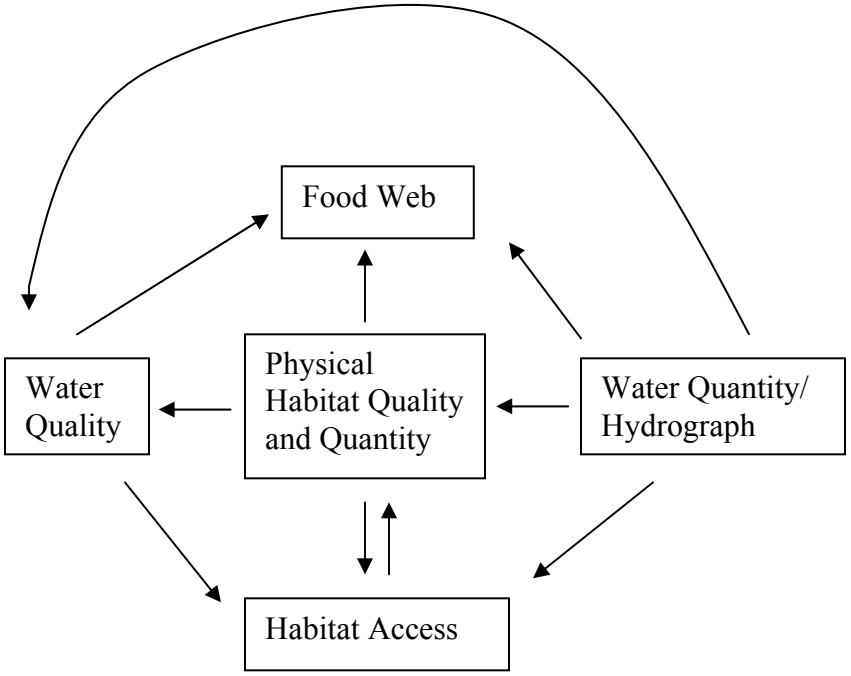

Figure 1. Interrelation between limiting factor categories.

Recovery planners have identified eight management strategies that are needed to address limiting factors (or bottlenecks) and threats related to freshwater habitat conditions. Table 1 shows these management strategies and the limiting factor categories they address as well as examples of threats that can lead to the limiting factor becoming a concern.

Although the management strategies provide a useful general approach and framework for recovery efforts, they do not necessarily provide the detail needed to assess if specific key limiting factors are adequately addressed by existing management programs. This review focuses on the adequacy of State of Oregon programs to impact the following specific key limiting factors common to all recovery planning domains in Oregon:

- Excessive fine sediment in spawning gravel
- Low habitat complexity
- High water temperature
- Impaired passage
- Inadequate stream flows or altered timing of flows
- Agricultural and forestry chemicals
- Animal waste
- Human, urban, or industrial waste

Table 1. Relationship between limiting factors, specific threats and management strategies addressed by statewide programs.

Management Strategies	Limiting Factors Addressed	Examples of Threats Addressed
1 - Protect and conserve ecological processes that support the viability of populations and their life history strategies throughout their life cycle.	All habitat limiting factors	See individual limiting factors.
2 – Restore and maintain floodplain connectivity and function	Habitat access, Food web, & Physical habitat quality	Stream straightening, channelization and diking, wetland draining and filling, dams that limit sediment movement
3 - Restore riparian condition and LWD recruitment, and maintain conditions adequate to support natural stream function and processes	Water Quality, Food web, & Physical habitat quality	Riparian habitat use and degradation, introduction of non-native plants that alter riparian function.
		Urban, residential or commercial development
		Stream cleaning and splash damming.
		Fine sediment from roads and other upland disturbances.
4 – Restore and maintain passage and connectivity to habitats blocked or impaired by artificial barriers	Habitat access	Dams, culberts, tidegates, road crossings, and hatchery weirs.
5 - Restore stream flows and natural hydrograph to provide sufficient flow during critical periods.	Water quantity/hydrograph & Habitat Access	Municipal and irrigation water withdrawals
		Urban, residential or commercial development
		Hydropower and flood control dams
		Riparian habitat use and degradation, introduction of non-native plants that alter riparian and upland functions.
6 - Restore and maintain channel structure and complexity.	Physical habitat quality & Food web	Riparian use and degradation, and introduction of non-native plants that alter riparian and upland functions.
		Stream cleaning, splash damming, straightening, channelization, and diking.
7 - Improve degraded water quality and maintain unimpaired water quality	Water quality	Municipal and irrigation water withdrawals
		Hydropower and flood control dams
		Agricultural, municipal, and industrial effluent and toxins.
		Fine sediment from roads, agricultural practices, development.
		Riparian habitat use and degradation, introduction of non-native plants that alter riparian and upland functions.
8 - Restore degraded upland processes to limit potential adverse impacts of uncharacteristic erosion and runoff, and maintain healthy upland processes.	Water & Physical habitat quality	Fine sediment from roads, agricultural practices, development.
		Urban, residential, or commercial development
		Riparian habitat use and degradation, introduction of non-native plants that alter upland functions.

Program Review Process

Program managers from each natural resource agency were asked to provide information on statewide programs currently implemented by their agencies that address the key limiting factors described earlier. Four categories of information regarding these programs were requested:

1) A general description of the program, including documentation of the program's guidance, jurisdiction, and implementation timeline. Appendix Table 1 lists this information for each program evaluated.
2) A list of the management strategies addressed by the program and the land use for which the program is intended. Appendix Table 2 lists this information for each program evaluated.
3) An evaluation of the program ("sufficiency") in the context of the key limiting factors (*ongoing)*, the rationale for the sufficiency characterization, recommendations for modification to the program to improve its sufficiency, and constraints on the program that may hamper its ability to fully address the key limiting factor. Varying levels of documentation is also provided that supports or addresses "sufficient" or "likely to be sufficient" assessments. Table 2 shows the criteria used to assess the programs. Appendices Tables 3-10 show this information by key limiting factor for each program.
4) A list of references that provide more detailed information about the program (see Appendix 11).

Table 2. Criteria used to determine sufficiency of programs to address key habitat limiting factors to the recovery of Oregon salmon and steelhead populations.

Sufficiency Designation	Criteria for Designation
Yes	Adequate technical, institutional, and budgetary capacity to implement the program, has a clear timeline for implementation, and documentation that the program can significantly reduce the limiting factor/threat within the program's jurisdictional area.
Likely	Adequate technical, institutional, and budgetary capacity to implement the program, has a clear timeline for implementation, and documentation that the program can significantly reduce the limiting factor/threat within the programs jurisdictional area, but it is a relatively new program with limited documentation on program effectiveness.
Uncertain	Adequate technical, institutional, and budgetary capacity to implement the program within its jurisdictional area, but the program lacks an adequate monitoring program, or has no clear timeline for implementation.
No	Inadequate technical, institutional, or budgetary capacity to implement the program within its jurisdictional area.

Program managers were asked to focus their efforts on "programs" that implement conservation, protection, or restoration actions. Programs whose sole function is monitoring the status and/or trend in natural resources are not included in this review.

Results

A total of 36 programs within nine natural resource agencies were evaluated (Table 3; Appendix Tables 1, 3-10). ODEQ had the most programs (7) addressing the most limiting factors (6), while ODLCD and ODOT had the fewest programs (1) addressing from 1-3 limiting factors.

Note: Sufficiency analysis is ongoing, therefore final results are not adequately complete for presentation in this report. Refer to Appendices for descriptive analysis of programs.

Agencies identified the need for adequate and dependable funding and increased staff resources to improve program sufficiency, especially those programs characterized as uncertain or insufficient. These limitations hamper or preclude sufficient outreach and education to landowners, effectiveness and compliance monitoring, technical assistance, program development, implementation, and oversight, and necessary inventories. Monitoring of program action effectiveness is crucial to understanding and acknowledging program sufficiency, and to adjusting program elements for improved adequacy. Trend monitoring is especially important to delineating progress or problems over time.

Jurisdictional limitations, overly broad statutory directives, increasing costs, and reliance on other state and local authorities for implementation constrain effectiveness of some programs. In addition, coordination and collaboration, both internally among state agencies and externally with federal land managers and private land owners, remains an important need to more fully address landscape issues. Some voluntary programs also conflict with landowner values and priorities, necessitating highly favorable incentives to overcome these social hurdles to effect positive change.

Conclusions and Recommendations

This review was conducted prior to specific benchmarks being established for recovery goals or an analysis of the predicted benefits of specific actions currently undertaken by each program, and programs combined. Nonetheless, using the detailed information provided in the Appendices on program objectives, jurisdiction, guidance, timelines, modifications and constraints should provide useful information for individual planning teams for each recovery domain as they formulate specific action plans for each ESA-listed salmon and steelhead population. This information will likely be helpful in the future as the state strives to improve its effectiveness in addressing habitat limiting factors.

Note: Sufficiency analysis of programs is incomplete.

Monitoring is especially critical to improving accountability, increasing knowledge of action effectiveness, and strengthening rigor in future assessments. An appropriate evaluation of a program's sufficiency requires field monitoring and documentation to assess whether program implementation on the ground is having the desired effect in addressing threats and limiting factors. For many programs, monitoring is absent or limited, tempering the ability to adequately evaluate its effectiveness. A number of program evaluations were based on the sufficiency and soundness of the infrastructure or process for implementing the program or an accounting of activities. To adequately assess action effectiveness and program sufficiency, actual monitoring and measurement of habitat conditions and trends must take place.

Continued emphasis on agency collaboration and coordination will strengthen the Oregon Plan foundation to better meet recovery needs now and into the future. The integrated workings and commitments of multitude agencies are needed to provide greater and more durable benefits to Oregon's salmon, watersheds, and citizens. Unfortunately, the relative contribution of these programs, in the context of overall importance to the landscape, was not assessed. Also not assessed was the cumulative and synergistic contribution of various programs to achieve overall habitat protection goals. This is an important consideration as no one program was intended to address any one limiting factor completely. *It is possible that individual programs by themselves are not adequate to address specific threats and limiting factors for meeting recovery goals, but the combined suite of available state agency programs in aggregate may create an adequate overall program for the state regarding a specific limiting factor.*

The collective efforts of state habitat programs has made comparative progress in improving trends over the past ten or more years, due in part to the Oregon Plan. The services these programs provide to the public and the regulatory oversight afforded are essential to maintaining a balance in protecting Oregon's natural resources within the context of resource use and development. However, improving landscape function to achieve recovery will require a concerted and conscious effort by many, including Oregon's natural resource agencies. Future funding packages to support and bolster programs to facilitate effectiveness would enhance this state's efforts toward recovery.

Appendix Table 1. Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODA	Agricultural Water Quality Management (SB 1010)	In 1993 the legislature established the Agricultural Water Quality Management Act. In 1995, the legislature supplemented the Act with ORS 561.191. This statute reinforces ODA's responsibility for and jurisdiction over agricultural practices and water pollution associated with activities on agricultural and rural lands. Administrative rules adopted to guide Program administration are found in OAR Chapter 603, Divisions 90 and 95. Regulatory actions address violations when they arise. Monitoring tools include DEQ ambient monitoring sites, local monitoring programs such as Rogue Valley Council of Government's Bear Creek monitoring and ODA Riparian Conditional Analysis for agricultural lands.	Ag Water Quality Mgmt Act	All agricultural practices and water pollution associated with activities on agricultural and rural lands, excluding federal or tribal trust lands.	Affected by rate of riparian vegetation development where needed. Development timeline will vary from 5 to 50 years depending on present site condition and site potential.
ODA	Confined Animal Feeding Operation (CAFO)	Confined Animal Feeding Operation (CAFO) program protects water quality by preventing animal wastes from discharging into waters of the state. ODA's CAFO program provides a means for the state to meet the requirements of the federal Clean Water Act. Operators know what is expected of them and are visited by ODA inspectors on an annual basis to insure compliance.	ORS 468B0.50 and 468B.0125	All permitted and non-permitted Confined Animal Feeding Operations.	In place, regulation ongoing
ODA	Pesticides	The ODA Pesticide Division regulates pesticide applicators, labeling, and regulates misuse.	Oregon State Pesticide Control Act, ORS 634, and the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)	All pesticide use throughout the state (commercial and private)	In place, regulation is ongoing
ODA	Soil and Water Conservation Districts	SWCDs identify and address natural resource concerns within their respective boundaries and work w/ local, state, federal and private interests to deliver conservation services.	Oregon's 45 SWCDs are organized under ORS Chapter 568 and are governed by an elected board of directors who serve without pay.	All lands within district boundaries	Program is in place, outreach and technical support is ongoing
ODA	Weed Control and Invasive Species	The Noxious Weed Control Program provides leadership and technical expertise for weed control programs throughout the state. ODA also tracks invasive exotic plants, insects and animals through a number of detection programs including reporting from citizens and other agencies.	The Oregon Invasive Species Council, which was created by the legislature, was initiated in 2002 with functions identified by ORS 561.685.	Non-regulatory program – weed control statewide (Federal, State, Public and Private lands)	Program is in place, outreach and implementation are ongoing
ODEQ	401 Dredge & Fill Certifications	Section 401 of the federal Clean Water Act requires that an applicant for a federal permit, to conduct an activity that may result in a discharge to waters of the State, must provide the permitting agency with a State water quality certification. A water quality certification is the mechanism by which the State evaluates whether an activity will meet water quality standards. Certifications may be denied, approved or approved with conditions, which if met, will ensure that water quality standards are met.	Federal Clean Water Act; ORS 468B.035 & .047; OAR 340-048	All waters of the State	In-place and on-going

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODEQ	401 Hydroelectric Recertification	Section 401 of the federal Clean Water Act requires that an applicant for a federal permit, to conduct an activity that may result in a discharge to waters of the State, must provide the permitting agency with a State water quality certification. A water quality certification is the mechanism by which the State evaluates whether an activity will meet water quality standards. Certifications may be denied, approved or approved with conditions, which if met, will ensure that water quality standards are met.	Federal Clean Water Act; ORS 468B.035 & 040 - .047; OAR 340-048	All waters of of the State	In-place and on-going
ODEQ	Environmental Clean Ups	DEQ's Environmental Cleanup Program protects human health and the environment by identifying, investigating, and remediating sites contaminated with hazardous substances. The Cleanup Programs objective is to guide all sites to No-Further-Action (NFA) determinations as quickly and inexpensively as possible. DEQ has issued over 1,000 NFAs since 1994, some of which include institutional or engineering controls to manage site risks.	Various Federal Laws; ORS465; OAR 340-122	All waters of of the State	In-place and on-going
ODEQ	Non-Point Source Program	DEQ requires Designated Management Agencies to develop Non Point Source Implementation Plan for sub basins that have TMDLs. Additionally, DEQ works in cooperation with other state, federal and local agencies to enhance their programs to address elements of non point source pollution and administers grants and loans to implement on-the-ground projects.	Federal Clean Water Act; ORS 468B.035	All waters of of the State	In-place and on-going
ODEQ	Point Source Permits	DEQ issues water quality permits to protect surface and ground waters of the state. These permits regulate sewage and industrial wastewater discharges from industrial and municipal sources.	Federal Clean Water Act; ORS 468B.035, 030 & 050; OAR 340-045.	All waters of of the State	In-place and on-going
ODEQ	Storm Water Permits	DEQ issues water quality permits to protect surface and ground waters of the state. Stormwater permits are required for and regulate storm water discharges to surface waters from: Construction activities (that disturb greater than 1 acre); industrial activities (subject to federal permitting requirements determined by SIC codes listed in the federal regulations); and municipalities (covered under Phase 1 (populations over 100,000) and Phase 2 (populations over 50,000) permitting requirements).	Federal Clean Water Act; ORS 468B.035, 030 & 050; OAR 340-045.	All waters of of the State	In-place and on-going

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.					
Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODEQ	Water Quality Standards	DEQ develops numeric and narrative water quality standards to protect for the most sensitive beneficial uses of the waters of the state – typically for protection of fish and other aquatic life and human health. As required under the Clean Water Act, these standards are to be reviewed every three years to insure that they are scientifically up-to-date.	Federal Clean Water Act; ORS 468B.035 & 048; OAR 340-041-0001 to 340-041-0350	All waters of of the State	In-place and on-going
ODF	Fire Program	The Fire Program of the Oregon Department of Forestry provides effective protection from fire for forest resources including water and watersheds, fisheries, wildlife, soil productivity and soil stability. National Fire Plan activities target fuel reduction and stand management that contribute to stands that are more fire resilient and benefit all forest resources. The Fire Program also educates forest landowners and forest homeowners about the value off fire hazard and risk reduction measures and takes positive action to minimize threats.	ORS Chapter 527, 526	Private forestlands, BLM land on Westside.	Program is active & ongoing.

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODF	Oregon Forest Practices Act	The FPA encourages economically efficient forest practices that ensure the continuous growing and harvesting of forest tree species and the maintenance of forestland for such purposes as the leading use on privately owned land consistent with sound management of soil, air, water, fish and wildlife resources. The FPA regulates road construction and road maintenance. Road construction must allow the migration of adult and juvenile fish upstream and downstream during conditions when fish movement in that stream normally occurs. For roads constructed after 1994, the forest practices act requires fish passage to be maintained. For all other roads the FPA encourages this standard. For roads constructed prior to 1994, other statutes apply that are outside the jurisdiction of the Department of Forestry. The water protection rules protect, maintain and, where appropriate, improve the functions and values of streams, lakes, wetlands, and riparian management areas. These functions and values include water quality, hydrologic functions, the growing and harvesting of trees, and fish and wildlife resources. Temperature is primarily addressed in the water protection rules that include general vegetation retention prescriptions for streams, lakes and wetlands. Requirements for vegetation along fish bearing streams varies by stream size and geographic region, however along all fish bearing streams, trees within 20 feet, vegetation within 10 feet, and trees leaning over the channel are required to be retained. Retention requirements beyond this vary. With regards to habitat complexity and off-channel habitat availability, the FPA regulates slash treatment, reforestation, chemical applications, road construction, harvesting, and hauling. Statutes and administrative rules vary for each practice, Each is designed to protect function and value of these resources. Requirements vary by stream size and geographic region, however along all fish bearing streams, trees within 20 feet, vegetation within 10 feet, and trees leaning over the channel are required to be retained. Retention requirements beyond this vary. These rules take a precautionary, passive approach by protecting the existing condition. They allow restoration activities only with site specific, written plans. With regards to fine sediment, the forest practices act regulates slash treatment, road construction, harvesting, and hauling. Rules vary for each practice. Each set of rules is designed to prevent or minimize sediment or debris delivery to waters of the state and to meet clean water standards. In addition to regulations for each specific practice, riparian buffers along fish bearing streams add an additional area of filtration between operation activities and waters of the state. A staff of field foresters works with landowners and operators to assist, educate, and enforce the rules. A statewide monitoring program assesses compliance with the rules and rule effectiveness at achieving objectives.	ORS Chapter 527, OAR Chapter 629	Operations on or pertaining to non-federal forestlands regardless of zoning or taxation, with the exception of where local governments (cities) have taken on responsibility of administering regulations within Urban Growth Boundaries that provide protection of forestland resources. Jurisdiction includes limited federal lands such as lands owned by Army Corp of Engineers, Bureau of Reclamation, and US Fish and Wildlife. USDA Forest Service and BLM lands are regulated through designation of those two agencies as the designated management agency under agreement with ODEQ. Operation means any commercial activity relating to the establishment, management or harvest of forest tree species. There are certain exceptions regarding Christmas trees, trees grown as intensive agriculture crops, trees grown to mitigate the effects of agricultural practices, and where approved land use conversions have commenced. See OAR 629-600-0100 (47).	Program is active & ongoing. Recent changes include wet weather hauling rules, road drainage, and measures around certain streams. Monitoring of small and medium fish bearing streams is under way. Board of Forestry work plan indicates evaluation of small non-fish bearing streams for temperature in 2008.

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODF	Private forestry component of the Oregon Plan for Salmon and Watersheds	Forest Landowners contribute to the Oregon Plan by complying with Oregon's Forest Practices Act and by accomplishing additional projects that contribute to Oregon Plan goals. Regarding fish passage, forest landowners close or rehabilitate legacy roads and update functioning roads to meet current standards, Oregon Plan measures on forestland are currently being updated to include recommendations from the work of the forest practices advisory committee and the DEQ sufficiency analysis. With regards to temperature, forest landowners manage riparian areas, leave additional conifers along streams, increase RMAs for non-fish bearing streams, and place leave trees to benefit Oregon Plan objectives. Oregon Plan measures on forestland are currently being updated to include recommendations from the work of the forest practices advisory committee and the DEQ sufficiency analysis. With regards to fine sediments, forest landowners voluntarily rehabilitate legacy roads to reduce the threat of fine sediment. This includes adding water bars, removing culverts, and pulling back perched soils on roads built prior to adoption of the FPA. Oregon Plan measures on private forestland are currently being updated to include recommendations from the work of the forest practices advisory committee and the DEQ sufficiency analysis. Regarding habitat complexity and off channel habitat availability, forest landowners place wood in streams, manage riparian areas, restore conifers in riparian management areas, and participate in habitat restoration activities. Oregon Plan measures on forestland are currently being updated to include recommendations from the work of the forest practices advisory committee and the DEQ sufficiency analysis.	ORS Chapter 521 and OAR 629-605-0103	Voluntary	Ongoing, updated voluntary measures planned for 2007.

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODF	State Forest Program	The State Forest Program implements actions related to roads to minimize effects upon fish passage. First, roads are built and maintained according to the standards of the Forest Roads Manual. Additionally, stream crossings are surveyed at the watershed scale to identify locations of potential effects to fish passage. (This is usually conducted through the watershed analysis process.) Based on these surveys, actions are taken to improve fish passage, where necessary. Finally, ODF conducts monitoring to ensure that actions are applied properly and to evaluate the effectiveness of these actions. The State Forest Program applies management standards for aquatic and riparian areas that include wide riparian buffers on fish bearing streams. These same standards apply to large and medium perennial streams without fish. Small perennial streams without fish also have tree retention requirements. ODF also applies additional risk-reduction strategies in Salmon Anchor Habitats (until 2011).. Finally, monitoring is conducted. ODF evaluates the effectiveness of its riparian strategies through its adaptive management program. The State Forest Program applies management standards for aquatic and riparian areas which are designed to increase the development of riparian large wood to restore aquatic habitats. These include a wider riparian management zone than specified under the FPA, with additional tree retention. Where appropriate, the FMP promotes the use of alternative vegetation treatments to accelerate the development of large wood. Active restoration is also applied to improve habitat complexity. Restoration projects include wood placement and re-routing of roads away from streams. Priority areas for restoration are generally identified through the watershed analysis process. Finally, monitoring is conducted. ODFW conducts monitoring to evaluate the effectiveness of restoration projects, while ODF evaluates the effectiveness of its riparian strategies through an adaptive management process. The State Forest Program implements actions related to roads and timber harvest to minimize the ability of sediment to reach streams. First, roads are built and maintained according to the standards of the Forest Roads Manual. Additionally, roads are surveyed at the watershed scale to identify locations of potential effects to streams. (This is usually conducted through the watershed analysis process.) Based on these surveys, actions are taken to reduce hydrologic connectivity, potential for road failure, and other potential sediment impacts. Timber harvest, likewise, is conducted to minimize sediment contributions to streams. The wide buffers specified by the Forest Management Plan prevent disturbance in the near stream area that might otherwise result in sediment delivery to streams. Finally, ODF conducts monitoring to ensure that actions are applied properly and to evaluate the effectiveness of these actions.	ORS Chapter 527, 521, OAR 629-640-0100 & -0200 through -0440, Northwest Oregon State Forests Management Plan, Forest Roads Manual, ODFW rules/statutes, OWEB guidance on fish passage	State Forest Land	

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODFW	Conservation Strategy for Oregon	Previously called the Comprehensive Wildlife Conservation Strategy, the Conservation Strategy for Oregon provides a non-regulatory, statewide approach to species and habitat conservation. It synthesizes existing plans, scientific data, and local knowledge into a broad vision and conceptual framework for long-term conservation of Oregon's native fish, wildlife and habitats. Conservation of instream and upland habitats will promote watershed health.	USFWS and Association of Fish and Wildlife Agencies guided the development and review process for the Strategy. For guidance on the implementation, see the Oregon Conservation Strategy document: http://www.dfw.state.or.us/conservationstrategy/	The Conservation Strategy for Oregon is meant to apply to all lands, rivers, streams, and estuaries in Oregon.	Internal review by January 2008; varying levels of external review to occur at 5 – and 10 – year intervals.
ODFW	Fish Passage Program	The owner or operator of an artificial obstruction located in waters in which native migratory fish are currently or were historically present must address fish passage requirements by gaining approval from ODFW prior to certain trigger events. Trigger events include installation, major replacement, a fundamental change in permit status (e.g., new water right, renewed hydroelectric license), or abandonment of the artificial obstruction. In addition, ODFW is working toward identification of the highest priority passage sites, at which passage can be addressed.	Laws regarding fish passage may be found in ORS 509.580 through 910 and in OAR 635, Division 412.	Artificial obstructions located in Oregon waters in which native migratory fish are currently or were historically present	ongoing
ODFW	Fish Screening and Passage Grant Program	Oregon water users may be eligible for an ODFW cost-share incentive program and state tax credit designed to promote the installation of ODFW approved fish screening or fish passage devices. Fish screens prevent fish from entering water diversions. Fishways provide fish passage to allow migration. ODFW works with owners who apply for funding, as well as actively seeks projects at which to provide fish screening and passage.	Laws regarding passage, screening, and cost share can be found in ORS 315.138, 496.085, 496.141, 496.303, 497.124, 498.301 through 346, 509.580 through 910, 537.141, 540.525, and in OAR 635, Division 412.	Oregon water users including independent agriculture users, private domestic users, municipal water suppliers, irrigation districts and commercial industries.	On-going

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODFW	Lands Resources Program	The Wildlife Division Land Resources Program helps guide land-use activities in Oregon that affect fish and wildlife habitats. The program offers tax incentives, grants and technical assistance to private and public landowners, businesses and governments to promote conservation of fish and wildlife habitats, and to ensure environmental protection standards are met. Programs goals promote healthy riparian and wetland corridors - decreasing bank erosion and filtering run-off.	OAR's for Landowner Incentive Program (LIP), Access and Habitat Program, Bird Stamp Program, and Riparian Lands Tax Incentive Program) can be found at http://arcweb.sos.state.or.us/rules/OARS_600/OAR_635/635_tofc.html	All owners of private and public land in Oregon interested in conserving fish and wildlife habitats.	Ongoing
ODFW	Restoration and Enhancement Program	ODFW oversees a comprehensive program to assist in enhancing natural fish production, improve hatchery programs, and provide additional public access to fishing waters. To achieve these goals, the R and E Program provides funding that directly benefits fish by addressing items such as fish passage, habitat restoration, public education, research and monitoring.	OAR's 635-009-0200 through -0240; Stat. Auth.: ORS 512	All streams, rivers, lakes, and estuaries in Oregon.	Ongoing.
ODFW	Salmon Trout Enhancement Program	The Salmon and Trout Enhancement Program (STEP) recognizes that volunteers play an important role in the restoration of salmon, steelhead and trout. STEP (1) educates the public about Oregon's salmon and trout resources and the habitats they depend on, (2) inventories and monitors fish populations and their habitat, (3) enhances, restores and protects habitat for native stocks of salmon, steelhead, and trout, and (4) produces fish to supplement natural fish production, augment fisheries, or, in the case of the classroom egg incubation program, provide educational opportunities. Habitat monitoring and enhancement function under STEP, could be used to address this limiting factor.	OAR's 635-009-0090 through -0150; Stat. Auth.: ORS 496	All Oregonians that are eager to contribute time, muscle, money, and perseverance to the restoration of salmon, steelhead and trout in Oregon.	Ongoing.
ODFW	Watershed Council Liaison	The ODFW Watershed Council Liaison position provides technical support to watershed councils involved in assessing watershed conditions and conducting restoration projects designed to address watershed needs. Among those projects are actions that specifically address fish passage barriers, iparian enhancement, habitat complexity, and fine sediments in streams.	Oregon Aquatic Habitat Restoration Guidelines.	All watershed councils in Oregon.	Not identified.
ODLCD	Statewide Comprehensive Land use Planning	Oregon's statewide comprehensive land use program requires cities and counties to plan for and manage land use in compliance with 19 statewide planning goals. Local land use plans and ordinances must identify and protect natural resources and identify and plan for hazard areas. The statewide land use program provides a framework for local governments to adopt land use plans and ordinances and approve development that are salmon-friendly.	(ORS 197,)RS 195, ORS 215, ORS 227)	City and county land use plans and ordinances.	Implementation is on-going. Plans and ordinances are updated according to local needs and as a result of legislation.

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
ODOT	Salmon-Fish Passage Program	Oregon Department of Transportation's (ODOT) Salmon-Fish Passage Program originated in 1997 through the Oregon Plan for Salmon and Watersheds (Oregon Plan). This program, initiated by Governor Kitzhaber and authorized by the Oregon Transportation Commission (OTC), defined ODOT's Oregon Plan contributions. The OTC invested $12 million Immediate Opportunity Funds prior to the 2000-2003 State Transportation Improvement Plan (STIP) to replace and retrofit high priority fish passage culverts owned and managed by ODOT. ODOT's Salmon-Fish Passage program funding levels continue to be approved by the OTC (FY 2008 through FY 2011 are $ 3.7, $ 3.9, $4.1, and $4.2 million respectively). ODOT's Salmon-Fish Passage Program has invested approximately $30 million into culvert improvements and provided access to nearly 370 miles of stream habitat once blocked to native migratory fish. These capital investment improvements, at culverts identified by Oregon Department of Fish and Wildlife (ODFW) as high priority fish passage locations, are critical elements of ODOT's Oregon Plan contributions. These projects promote the recovery and sustainability of threatened and endangered native migratory fish in Oregon. The goal of this program is to continue to support the Oregon Plan and to repair (replace or retrofit) priority fish passage culverts in the most aggressive, cost effective, and efficient means as practicable with limited program funds.	ORS 509-580 through 910, OAR Chapter 635-412-0010 through OAR 635-412-0040, Executive Order (EO) 99-01, and ODOT's Mission Statement	ODOT's Salmon-Fish Passage Program addresses fish passage needs at priority hydraulic facilities located within ODOT rights of way. These rights of way bisect multiple jurisdictions and land use.	ODOT's program is ongoing and presently funded through FY 2011. Funding requests through FY 2013 are complete and it is expected that the ODOT Salmon-Fish Passage Program will continue to be funded.
ODSL	Voluntary Restoration Initiative	Under DSL's new Voluntary Restoration Initiative, two Wetland Restoration Specialists are working with landowners and organizations interested in restoring wetlands. Primary objectives are to provide technical assistance on restoration site assessment, permitting and monitoring, facilitate restoration of historical wetland types (emphasis on rare and at-risk habitats), and accurately track/report quality/ quantity of projects	ORS Chapter 196.600-692; OAR 141-085-0240 -0257 and 0610-1660	Wetlands that meet the three wetland indicators described in the Corps of Engineers' 1987 Wetland Manual.	Initiative began in March 2006 and is scheduled as a 3-year program.
ODSL	Removal-Fill Program	Oregon's Removal-Fill Law requires people who plan to remove or fill material in waters of the state to obtain a permit from the Department of State Lands. Proposed permanent impacts to instream and off-channel habitat, as well as to wetlands, are required to be offset with compensatory mitigation actions such as riparian planting, large wood placement, or wetland restoration. All permits issued by DSL include conditions that require protection of fish habitat and water quality, including in-water timing restrictions, turbidity monitoring and sediment and erosion control requirements, and riparian vegetation removal restrictions and revegetation requirements. By offering streamlined General Authorizations for projects with minimal impacts (i.e. bioengineering methods and planting instead of riprap), the permit process encourages applicants to design projects with minimized impacts to water resources. The Department recently implemented a pilot program for an expedited permitting process for fish habitat enhancement activities including placement of large woody debris and boulders.	ORS Chapter 196.795 - 990 and ORS Chapter 390.835; OAR 141-085-0005 - 0165.	Waterways to the ordinary high water mark and wetlands that meet the three wetland indicators described in the Corps of Engineers' 1987 Wetlands Manual.	Program is ongoing

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
OWEB	CREP Program	OWEB is the state cost share partner for the Conservation Reserve Enhancement Program (CREP) that pays for riparian restoration and provides a 10-15 year conservation rental for maintenance of the plantings. The program has enrolled nearly 2,000 miles of stream since 1999.	ORS 541.351 - 541.420 and OAR 695-001-0000 through 695-050-0050	Agricultural lands	Ongoing
OWEB	Grant Program	OWEB's grant program supports voluntary efforts by Oregonians seeking to maintain and restore native fish and healthy watersheds. OWEB funds projects that restore, maintain, and enhance the state's watersheds, supports the capacity of local watershed-based citizen groups to carry out a variety of restoration projects, promotes citizen understanding of watershed needs and restoration ideas, provides technical skills to citizens working to restore urban and rural watersheds, and monitors the effectiveness of investments in watershed restoration. OWEB regular grants are awarded every 6 months for restoration and protection of ecological resources. Grant applications are reviewed by a regional multidisciplinary team to develop recommendations and prioritization of grant applications for OWEB consideration. The review teams evaluate whether the grant applications address limiting factors and the technical soundness of the proposals.	ORS 541.351 - 541.420 and OAR 695-001-0000 through 695-050-0050	All lands	Ongoing
OWRD	Administration of Water Rights	Surface waters in many areas of the state are fully allocated during critical flow periods for fish. However, there are several aspects of the review process for new water right applications that are protective of fish and fish habitat. All new groundwater permits are evaluated to determine the potential to cause substantial interference with surface flows. Surface water availability is modeled monthly and includes existing instream water rights. Applications to appropriate surface waters are evaluated at the 80% exceedance level. Permits are subject to public interest review standards that include interagency consultation on potential impacts of further appropriation to fish and fish habitat. All new water right applications are subject to review through an interagency review and consultation process. Permits, if approved, may be conditioned to address impacts on listed species identified through the consultation process.	OAR 690-009, 033, 051, 310	With few exceptions, all surface and ground waters of the state	Program is in place and ongoing
OWRD	Enclosed Livestock Water Delivery Systems	Livestock owners with legal access to use surface waters are exempt from the requirement to obtain a permit or certificate to divert water to a trough or tank through an enclosed water delivery system meeting minimum requirements. OWRD Watermasters provide technical support to interested landowners.	ORS 537.141	Water rights appurtenant to agricultural lands.	In place and ongoing

Appendix Table 1 (continued). Description of statewide programs currently implemented by the State of Oregon that support habitat management strategies in tributaries.

Agency	Program	Description	Guidance	Jurisdiction	Timeline
OWRD	Flow Restoration Programs	ODFW and OWRD have identified priority watersheds where flow restoration will produce the most benefit for listed species. OWRD staff work with water rights holders to restore streamflows through voluntary flow restoration measures. Voluntary measures include instream leases, instream transfers, allocations of water conserved through improved efficiencies, and changes to existing rights including consolidation or transfers of points of diversion. In certain circumstances, reclaimed water from certain municipal, industrial and confined animal feeding operations may provide an effective alternative to new diversions of surface water or ground water.	OAR 690-018, 077, 380	All interested water right holders	Program is in place, outreach, administration and technical assistance are ongoing
OWRD	Lease/Transfer Water Rights Associated with CREP Program	Perfected water rights appurtenant to lands enrolled under the CREP program are not subject to forfeiture for non-use during the enrollment period. OWRD encourages CREP participants to voluntarily lease or temporarily transfer associated water rights instream while enrolled in CREP. Associated water rights leased or transferred instream can be protected instream to benefit minimum flows and listed species.	ORS 537.348, 540.610 (Revised), OAR 690-077, 380	Water rights appurtenant to agricultural lands enrolled in CREP.	Program is in place, outreach, administration and technical assistance are ongoing
OWRD	Water Distribution and Regulation	Distribution and regulation of water use for the protection of senior water rights, including instream rights, is a priority for OWRD. Staff regularly monitor streamflow, particularly on those streams with established instream rights, and work to eliminate illegal use through compliance and enforcement of Oregon water law.	OAR 690-250, 077, ORS 540.045	With few exceptions, all surface and ground waters of the state	Program is in place. Distribution and regulation are ongoing.
OWRD	Water Supply and Conservation Planning	OWRD Staff work with water rights holders to address water supply through the development of water management and conservation plans. The development of these plans for new and extended municipal rights and through voluntary participation of irrigation districts must identify conservation measures that will be pursued. Municipal plans must also include five year benchmarks for implementation of conservation activities.	OAR 690-086 (Guidance is also available through the League of Oregon Cities)	Municipal and Agricultural water right holders interested in preparing, or required to prepare, water management and conservation plans.	In place and ongoing.
OWRD	Water Use Measurement Strategy	Federal and state agencies, cities, counties, schools, irrigation districts and other special districts are required to report water use on an annual basis. Since 1990, many new permits have required water meters to be installed and annual reports to be submitted to the state. In addition, the Water Resource Commission considered water use measurement in 2000 and adopted a strategy for improving water measurement statewide. The strategy includes a program to inventory and complete field assessments of significant points of diversion and to look for opportunities to increase measurement at those diversions by ensuring compliance and promoting voluntary measurement via cost-share programs. Significant diversions are characterized as those required to measure through a water right condition, or those diversions without a measurement condition that are greater than 5 cfs, or greater than 10% of the lowest monthly 50% exceedance flow as defined in the water availability model, and greater than 0.25 cfs.	OAR 690-085, ORS 537.099 and the Water Resource Commission's Strategy for Statewide Water Measurement	With few exceptions, all surface and ground waters of the state	Ongoing with partial implementation

Appendix 2. Strategies and land uses addressed by statewide management programs. A checked box indicates that the program addresses components of the management strategy or has jurisdiction over a land use. See Table 1 for a description of management strategy codes. Land use codes are: FF = Federal Forest; SF = State Forest; PF = Private Forest; Ag = Agriculture; UR = Urban/Rural residential;

		Management Strategy								Land use

Appendix Table 3. Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODA	Agricultural Water Quality Management (SB 1010)		Basin plans and rules are reviewed biennially to determine whether the plan is sufficient to meet and address water quality standards, and modified as necessary to meet deficiencies and new requirements or information. Reviews include review of compliance actions, outreach activities, projects, and monitoring results. ODA focuses efforts and resources on areas of highest priority and program is enforced. "Compliance" is based on inspections prompted by "notification" of inappropriate occurrences; increasing complaints and notifications reflect an increased public awareness and greater number of basin rules in place. Water quality monitoring is conducted by DEQ at permanent sites. Aerial photography at 4-5 yr intervals documents riparian condition trends.	Biennial reviews will determine if modifications are needed. Given more resources (funding) implementation of on-the-ground actions, including monitoring, would be accelerated. More monitoring would provide improved documentation of program adequacy. Resources are needed for site capability assessment through GIS.	Landowner cooperation, capacity for outreach, changing land ownerships and new landowners knowledge of agricultural issues, perception that this is only a complaint driven process, technical assistance, adequate monitoring at meaningful scales
ODA	Soil and Water Conservation Districts		Strong local infrastructure, provides strong local involvement and action. Districts focus efforts and resources on areas of highest priority. An accounting of outreach activities and conservation planning and practices reported by SWCDs on an annual basis is available from ODA.	None at this time. Given more resources (funding) implementation of on-the-ground actions would be accelerated.	Stable and adequate levels of resources (Funding)
ODA	Weed Control and Invasive Species		Weed and invasive species negatively affect desired riparian condition and function. ODA focuses efforts and resources on areas of highest priority. This is a voluntary program and not under regulatory control	None at this time. Given more resources (funding) implementation of on-the-ground actions would be accelerated.	Adequate technical support, capacity for outreach, perception that this is not doable because it is an ongoing challenge
ODEQ	401 Dredge & Fill Certifications		Limited monitoring for compliance and lack of cumulative impacts tracking.	A greater number of specific types of projects will be monitored for compliance in the future. This will help in evaluating adequacy of portions of the program but additional monitoring and evaluation is needed.	The state review is primarily fee based. Fees need to be periodically adjusted to cover the cost of the program.
ODEQ	Non-Point Source Program		The program relies on existing state and local authorities to address non point sources of pollution. Programs to address nonpoint sources, especially in urban and agricultural areas, are relatively recent and additional time and trend monitoring is needed to document results. Additionally, while a schedule for implementation is to be identified, timing of implementation is often dependent on adequate future funding which often is not guaranteed or certain.	Adequate monitoring program needed; see other programs listed in this document for modifications needed as it relies on other existing state and local authorities for implementation. See other programs listed in this document for Modifications Needed,	See other programs listed in this document for constraints as it relies on other existing state and local authorities for implementation.
ODEQ	Storm Water Permits		Stormwater permitting program is: - a relatively recent program where programs, practices and technology are evolving (e.g. phase 2 permits are being developed by 2007) and therefore there has been limited time to monitor the effectiveness of this program; - In the case of municipal storm water, permits require implementation of best management practices to the maximum extent practicable which may not restore upland processes or may not water quality standards in some areas.	Additional staff for technical assistance and program oversight. Additional Staffing.	Number of staff is always a limitation. Funding is a blend of federal, state and fee support. Additional funding has recently been provided based on a Blue Ribbon Committee Report which recommended changes to fee structures and additional general funds.

Appendix Table 3 (continued). Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODEQ	TMDLs		TMDLs target bringing waters back into compliance with water quality standards. Oregon entered into a Consent Decree and Memorandum of Agreement with USEPA in 2000 under which it committed to substantially complete TMDLs statewide by 2010 (based on number of waters listed on the 1998 303(d) list). Uncertainty is based on the fact that sedimentation is likely to underlisted and therefore only a few sedimentation TMDLs have been developed in Oregon. Additionally, DEQ has not had much experience in addressing sedimentation under the TMDL program.	The Department is currently working on updating the turbidity standard and has identified that the sedimentation standard needs to be addressed in future triennial standards reviews. The Department is also re-examining its 303(d) listing criteria based on the current narrative standard. Subsequent sedimentation TMDLs will address these concerns. Additional Staffing.	Staffing resources.
ODEQ	Water Quality Standards		A growing backlog of standards need to be updated. At current staffing levels, DEQ cannot update standards on a three year cycle nor undertake complex standard development that would be needed to adequately address complex issues such as sedimentation and turbidity. Without updates, DEQ would rely on current standards or those promulgated by the USEPA. In the case of addressing sedimentation, DEQ relies on use of its current narrative standard.	Additional staffing for this program (DEQ had a preliminary budget request in for the 2007 Legislature, but did receive the Governor's approval).	Number of staff

Appendix Table 3 (continued). Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Fire Program		Resources are needed to assist forest landowners to reduce fuels that place forested watersheds at risk. Infrastructure is also needed to support resource enhancement opportunities through biomass conversion projects.	More coordinated efforts by all of Oregon's agencies and landowners to work collaboratively with federal partners to increase the contribution for recovery from federal forests.	Federal and private forest 'checker-board' ownership can place private forestlands at risk for uncharacteristic wildfire when either forest is not managed. There is a need for both ODF and ODF&W, and all landowners to play a role in the management of federal forests located in Oregon. A collaborative relationship between state natural resource agencies and federal forest management agencies may restore the health, diversity, and resilience of federal forests by increasing the information shared and by providing a variety of perspectives on site-specific and landscape level determinations. Wildfire-prone areas are identified in a community wildfire protection plans identifying priority areas for hazardous fuel removal from federal lands.

Appendix Table 3 (continued). Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Oregon Forest Practices Act		Current practices under the Act have reduced sediment inputs and will sustain a trend of reducing fine sediment inputs over time. Past activities that have unnecessarily contributed fine sediments have been abandoned or modified. Modifications to practices have been designed to address the key mechanisms for delivery of fine sediment from forest operations. Legacy issues are addressed over time through the regulatory process when culverts are replaced or roads become part of an active operation. Legacy issues are also addressed in an expedited manner through voluntary measures. Documentation Links: Final Oregon Coastal Coho Assessment: http://nrimp.dfw.state.or.us/OregonPlan Sufficiency Analysis: A Statewide Evaluation of Forest Practices Act Effectiveness in Protecting Water Quality, ODF and DEQ 2002. Pages 6, 7 (Wet Weather road use rules subsequently adopted.) Pgs. 6-7, 32-35, 59-61, C3-8. http://egov.oregon.gov/ODF/PRIVATE_FORESTS/docs/fp/AllSAv1031.pdf ODF BMP Compliance study 2002 pages 19-25 http://egov.oregon.gov/ODF/PRIVATE_FORESTS/docs/fp/BMPfinalTR15.pdf Additional monitoring: o Road Hazard Inventory (pdf) o FPMP Technical Report #17 (pdf) - Wet Season Road Use Monitoring Project: Final Report, June 2003 o FPMP Technical Report #8 (pdf), Evaluation of the Effectiveness of Forest Road BMPs to Minimize Stream Sediment Impacts - Final FY 96 Report to the Oregon DEQ o FPMP Technical Report #9 (pdf), Forest Roads, Drainage, and Sediment Delivery in the Kilchis River Watershed, June 1997 o FPMP Technical Report #10 (pdf), Forest Road Sediment and Drainage Monitoring Project Report for Private and State Lands in Western Oregon, February 1998 o Storm Impacts & Landslides of 1996 : http://egov.oregon.gov/ODF/PRIVATE_FORESTS/landslides.shtml	Additional resources for monitoring and program implementation would increase the certainty that the current rules are efficient and effective at delivering desired outcomes. The Board of Forestry has adopted an indicator to address road related risks. The metrics for the indicator are: 1) Percent of road system disconnected from the stream network; 2) Percent of stream crossings on fish streams providing passage; 3) Land area in non-forest condition due to roads (road subgrade plus cutslope). The desired trend is an increasing proportion of sampled Oregon forest roads are determined to pose a low risk to soil and water resources. Additional resources and interagency coordination are needed to implement this indicator.	Resources and collaboration remain constraining. Current resource needs include the resources necessary to implement Forestry Program for Oregon indicator monitoring for roads and fish passage and the resources necessary to conduct more Private Forests Program compliance and effectiveness monitoring.

Appendix Table 3 (continued). Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Private forestry component of the Oregon Plan for Salmon and Watersheds		The trend for fine sediment regimes is clearly improving. Past practices that contributed fine sediments have been abandoned or modified. Existing rules regulate practices on current operations. Voluntary investments mitigate legacy sediment problems. The Oregon Plan is designed to address known sources of sediment not addressed as active operations under the Forest Practices Act. The contribution of sediment from these sources is unknown as is the total amount of work that would be needed to address these sources. Considering this uncertainty, adequacy of the program is deemed likely. Reporting and communication indicate that many landowners actively participate in the Oregon Plan and road work on roads built prior to the adoption of the Oregon forest practices act has become routine maintenance for many landowners. OWEB Watershed Restoration Inventory data indicates that landowners are actively participating in the Oregon Plan. Documentation Oregon Watershed Enhancement Board Watershed Restoration Inventory	More resources to inventory roads, especially on small, non-industrial private lands, would increase our understanding of legacy roads, fine sediment and the links to listed species	As always, more resources would increase project accomplishment, education, coordination, and monitoring.
ODF	State Forest Program		The program is built on a sound theoretical basis. Similar practices to those employed by ODF have been proven to reduce sediment production, transport, and delivery in other studies. While this gives reason to believe that the FMP standards are effective, the degree of effectiveness has not yet been established because monitoring is not yet complete. Documentation Because program standards meet or exceed those under the FPA, the documentation listed to support the sufficiency of the FPA will also support the sufficiency of the State Forests Program. Future monitoring reports produced by the State Forests Program will likely document any additional benefits produced by FMP strategies.	The need for modification to the current program is uncertain, pending the results of monitoring.	Staffing and funding are the major constraints to sediment reduction projects. While new roads are built according to current standards, and road maintenance is ongoing, improvements to existing roads are scheduled as time and funding allows.
ODFW	Conservation Strategy for Oregon		The Oregon Conservation Strategy is a new voluntary program. As such, monitoring and evaluation will be necessary to determine the effectiveness of the program.	None at this time. The role of this new program as it pertains specfically to listed salmon and steelhead is still being defined.	Voluntary measures – no assurance that it will be implemented
ODFW	Lands Resources Program		Uncertain of funding status or participation by public and private entities (i.e. Riparian Lands Tax Incentive Program).	Need further promotion of existing programs by I and E, Wildlife Division, and District staff.	Funding and staff time.

Appendix Table 3 (continued). Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODFW	Restoration and Enhancement Program		Funding for this program is through a surcharge imposed on all sport fishing licenses and commercial salmon fishing licenses and poundage fees. As such, funding is a subject to annual variations in fish abundance, harvest rates, and license sales.	None. The Program will evaluate their ability to shift resources to priorities that emerge from recovery planning. Further changes in program scope and focus would require legislative action.	Broad legal mandates of the program limit the ability of the program to focus solely on the needs of recovery planning, variable funding due to funding mechanism.
ODFW	Salmon Trout Enhancement Program		Current staffing and the broad scope of the program limits the capacity of the program to address any single program element.	Additional funding, additional FTE.	Funding.
ODFW	Watershed Council Liaison		Currently there are only two watershed council liaison positions in ODFW, both in the North Coast Watershed District. There are no positions for other regions of Oregon.	New positions.	Funding.
ODLCD	Statewide Comprehensive Land Use Planning		The land use actions taken by local governments can supplement and support other specific restoration activities but are not sufficient in themselves to achieve restoration. Local land use actions will likely not remediate legacy conditions or significantly alter current practices, but will affect future development.	None. The statewide land use program is not intended to be sufficient to recover salmon.	Technical and planning assistance to local governments would be highly beneficial in enlisting local planning efforts in salmon recovery.
ODSL	Removal-Fill Program		DSL's removal-fill permits include conditions designed to protect water quality, including turbidity monitoring and sediment and erosion control rquirements. Not enough projects are monitored for compliance.	A greater number of projects need to be monitored for compliance. Additional, permanent compliance staff are needed.	The half-time Compliance Monitoring Specialist position is funded for three years and is subject to reauthorization each year of the three year period. The status of the position is uncertain after that time.
OWEB	CREP Program		Limitation on recruiting private landowners for voluntary water quality restoration projects. Limitation to water quality restoration opportunities due to existing infrastructure. The limitation of CREP technical assistance has been demonstrated to be the single most important factor linked to enrollment.	Increased capital and non-capital funds	Funding
OWEB	Grant Program		There is a limitation on local capacity to provide the landowner outreach, project design and facilitate implementation to address agricultural management, forest management and urban runoff that affects sediment delivery to streams.	Increased funds available to support local conservation capacity in watershed councils and soil and water conservation districts. A direct conversation with the industrial forest landowners about identifying ways to further address forest road runoff.	Funding and focus for effort by land use category (forest, urban and agriculture).

Appendix Table 3 (continued). Program sufficiencies to address fine sediment impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
OWRD	Enclosed Livestock Water Delivery Systems		When combined with riparian fencing programs, opportunities to protect and restore riparian communities, including filtering of fine sediments, while providing livestock watering capabilities are increased. There is currently no monitoring program in place to evaluate program effectiveness.	No modifications to program design are proposed. The program would benefit from expanded outreach and education.	The program is reliant on landowner interest. Construction and subsequent maintenance of fencing and off-channel watering devices require adequate financial resources.

Appendix Table 4. Program sufficiencies to address habitat complexity impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODA	Soil and Water Conservation Districts		Strong local infrastructure, provides strong local involvement and action. Districts focus efforts and resources on areas of highest priority. However, addressing this limiting factor requires a reduction in productive land which is not a priority for landowners. There is no monitoring to demonstrate effectiveness.	None at this time. Given more resources (funding) implementation of on-the-ground actions would be accelerated. Incentives are needed to foster landowner buy-in.	Stable and adequate levels of resources (Funding). Conflict with landowner values and priorities.
ODF	Fire Program		Resources are needed to assist forest landowners to reduce fuels that place forested watersheds at risk. Infrastructure is also needed to support resource enhancement opportunities through biomass conversion projects.	More coordinated efforts by all of Oregon's agencies and landowners to work collaboratively with federal partners to increase the contribution for recovery from federal forests.	Federal and private forest 'checker-board' ownership can place private forestlands at risk for uncharacteristic wildfire when either forest is not managed. There is a need for both ODF and ODF&W, and all landowners to play a role in the management of federal forests located in Oregon. A collaborative relationship between state natural resource agencies and federal forest management agencies may restore the health, diversity, and resilience of federal forests by increasing the information shared and by providing a variety of perspectives on site-specific and landscape level determinations. Wildfire-prone areas are identified in a community wildfire protection plans identifying priority areas for hazardous fuel removal from federal lands.

Appendix Table 4. Program sufficiencies to address habitat complexity impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Oregon Forest Practices Act		The trend should be improving for in-stream habitat complexity and off channel availability. Vegetation retention along streams was not required until FPA rules were first established in 1972. Vegetation retention standards were revised in 1983, 1987, 1994, and 2006. Under the current Forest Practices Act, riparian areas are designed to provide the vegetation necessary for riparian functions including shade, large wood, and nutrients. A monitoring program is in place and an adaptive management process incorporates information. Rules are modified as necessary to meet the goals for riparian function and water quality. The existing vegetation in these riparian management areas will mature and provide these functions; however this will take many decades to occur. In the short term, landowners make voluntary contributions to habitat complexity through the Oregon Plan. Documentation Links Final Oregon Coastal Coho Assessment: http://nrimp.dfw.state.or.us/OregonPlan Sufficiency Analysis: A Statewide Evaluation of Forest Practices Act Effectiveness in Protecting Water Quality, ODF and DEQ 2002. http://egov.oregon.gov/ODF/PRIVATE_FORESTS/docs/fp/AllSAv1031.pdf Harvest Effects on Riparian Function & Structure o FPMP Technical Report #12 (pdf) - Harvest Effects on Riparian Function and Structure , July 2001 o Executive Summary (pdf)	Evaluation of the vegetation retention requirements along western Oregon small and medium fish-bearing streams is underway. If modifications are needed, methods to accomplish these modifications through regulatory and non-regulatory means will be considered.	Lack of production functions for fish populations and habitat conditions is a major constraint. Lack of incentives and technical assistance to provide forest landowners more site-specific options is also a major constraint.

Appendix Table 4 (continued). Program sufficiencies to address habitat complexity impacts

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Private forestry component of the Oregon Plan for Salmon and Watersheds		The protection and voluntary measures should result in improving trends for in-stream habitat complexity and off channel availability. Under the Forest Practices Act, riparian areas are designed to provide the vegetation necessary for riparian functions including shade, large wood, and nutrients.. A monitoring program is in place, and an adaptive management process incorporates information. Rules are modified as necessary to meet the goals for riparian function. The existing vegetation in these riparian management areas will mature and provide these functions; however this will take many decades to occur. In the short term, landowners make voluntary contributions to improve habitat complexity through the Oregon Plan. Through the voluntary measures, the temporal and spatial opportunities for improvements are greatly accelerated. Forest landowners are contributing directly to the habitat complexity and off-channel availability by actively placing large wood during the course of forest operations. While not yet fully systematic, the proportion of operations conducting restoration as part of the operation should increase over time. Prioritization concepts, such as high aquatic potential are being developed. Documentation Links Oregon Watershed Enhancement Board Watershed Restoration Inventory OAR 629-640-0105: Placing Large Wood Key Pieces in Type F Streams to Improve Fish Habitat: This rule streamlines the process for placing large wood when conducted during a forest operation under the FPA. It is anticipated that this new rule will facilitate increased voluntary placement of large wood. This assessment is based on more than just monitoring. Every “call” is based on monitoring, rules, policies, incentives, education, and guidance.	More information about the needs and priorities would assist landowners in efficiently spending limited resources. Monitoring of effectiveness could be improved	Sufficient incentives are necessary to increase the scope of non-regulatory measures to match the needs. More stewardship foresters and habitat biologists are necessary to support the commitment landowners have willingly made. This would strengthen the educational component and complement the technical assistance from ODF, ODF&W, and OSU Extension foresters.

Appendix Table 4 (continued). Program sufficiencies to address habitat complexity impacts

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	State Forest Program		The program is built on a sound theoretical basis. Similar practices to those employed by ODF have been proven to improve fish habitats and populations in other studies. While this gives reason to believe that the FMP standards are effective, the degree of effectiveness has not yet been established because monitoring is not yet complete. Documentation Because program standards meet or exceed those under the FPA, the documentation listed to support the sufficiency of the FPA will also support the sufficiency of the State Forests Program. Future monitoring reports produced by the State Forests Program will likely document any additional benefits produced by FMP strategies.	The need for modification to the current program is uncertain, pending the results of monitoring.	Staffing and funding are the major constraints to habitat restoration projects. Projects are generally conducted opportunistically in connection with timber sales. Additional projects could be conducted with increased staffing and funding.
ODFW	Conservation Strategy for Oregon		The Oregon Conservation Strategy is a new voluntary program. As such, monitoring and evaluation will be necessary to determine the effectiveness of the program.	None at this time. The role of this new program as it pertains specifically to listed salmon and steelhead is still being defined.	Voluntary measures – no assurance that it will be implemented
ODFW	Lands Resources Program		Uncertain of funding status or participation by public and private entities (i.e. Riparian Lands Tax Incentive Program).	Need further promotion of existing programs by I and E, Wildlife Division, and District staff.	Funding and staff time.
ODFW	Restoration and Enhancement Program		Funding for this program is through a surcharge imposed on all sport fishing licenses and commercial salmon fishing licenses and poundage fees. As such, funding is a subject to annual variations in fish abundance, harvest rates, and license sales.	None. The Program will evaluate their ability to shift resources to priorities that emerge from recovery planning. Further changes in program scope and focus would require legislative action.	Broad legal mandates of the program limit the ability of the program to focus solely on the needs of recovery planning, variable funding due to funding mechanism.
ODFW	Salmon Trout Enhancement Program		Current staffing and the broad scope of the program limits the capacity of the program to address any single program element.	Additional funding, additional FTE.	Funding.
ODFW	Watershed Council Liaison		Currently there are only two watershed council liaison positions in ODFW, both in the North Coast Watershed District. There are no positions for other regions of Oregon.	New positions.	Funding.
ODLCD	Statewide Comprehensive Land Use Planning		The land use actions taken by local governments can supplement and support other specific restoration activities but are not sufficient in themselves to achieve restoration. Local land use actions will likely not remediate legacy conditions or significantly alter current practices, but will affect future development.	None. The statewide land use program is not intended to be sufficient to recover salmon.	Technical and planning assistance to local governments would be highly beneficial in enlisting local planning efforts in salmon recovery.

Appendix Table 4 (continued). Program sufficiencies to address habitat complexity impacts

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODSL	Removal-Fill Program		DSL's removal-fill permitting process encourages protection and restoration of instream and off channel habitat and wetlands. At current staffing levels, DSL does not always have the resources to do the outreach necessary to encourage landowners to protect and restore water resources.	Additional funding would increase the effectiveness of the program.	The fact that DSL does not have jurisdiction over the removal of large wood hinders our ability to protect instream and off- channel habitat.
ODSL	Voluntary Restoration Initiative		The Initiative provides direct technical assistance to landowners and organizations involved in restoring wetlands that provide off channel habitat. Because the Initiative is only funded for three years, its impact will be too limited to significantly address the threat of off channel habitat loss. The Initiative is too new to document program effectiveness.	Converting this three-year program to a permanent program would increase effectiveness. The Initiative is too new to determine what program modifications might be needed.	The Initiative is funded for three years and is subject to reauthorization each year of the three-year period. The status of the program is uncertain after that time.
OWEB	CREP Program		Limitation on recruiting private landowners for voluntary water quality restoration projects. Limitation to water quality restoration opportunities due to existing infrastructure. The limitation of CREP technical assistance has been demonstrated to be the single most important factor linked to enrollment.	Increased capital and non-capital funds	Funding
OWEB	Grant Program		Limitation on technical assistance to design floodplain restoration and stream complexity projects that can provide benefits through the range of natural flow conditions. Limitation on recruiting private landowners for voluntary floodplain restoration project implementation and protection and restoration of side-channel habitat. Limitation to floodplain and side-channel restoration and protection opportunities due to existing infrastructure.	Increased funding for technical assistance for project design and outreach to engage landowners. Effectiveness monitoring of large wood placement projects to answer questions about the stability and movement of large wood through Oregon streams.	Funding

Appendix Table 5. Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODA	Agricultural Water Quality Management (SB 1010)		Basin plans and rules are reviewed biennially to determine whether the plan is sufficient to meet and address water quality standards, and modified as necessary to meet deficiencies and new requirements or information. Reviews include review of compliance actions, outreach activities, projects, and monitoring results. ODA focuses efforts and resources on areas of highest priority and program is enforced. "Compliance" is based on inspections prompted by "notification" of inappropriate occurrences; increasing complaints and notifications reflect an increased public awareness and greater number of basin rules in place. Water quality monitoring is conducted by DEQ at permanent sites. Aerial photography at 4-5 yr intervals documents riparian condition trends.	Biennial reviews will determine if modifications are needed. Given more resources (funding) implementation of on-the-ground actions, including monitoring, would be accelerated. More monitoring would provide improved documentation of program adequacy.	Landowner cooperation, capacity for outreach, changing land ownerships and new landowners knowledge of agricultural issues, perception that this is only a complaint driven process, technical assistance, adequate monitoring at meaningful scales
ODA	Soil and Water Conservation Districts		Strong local infrastructure, provides strong local involvement and action. Districts focus efforts and resources on areas of highest priority. An accounting of outreach activities and conservation planning and practices reported by SWCDs on an annual basis is available from ODA.	None at this time. Given more resources (funding) implementation of on-the-ground actions would be accelerated. Additional measurement of program effectiveness is needed through documentation of habitat improvement.	Stable and adequate levels of resources (Funding)
ODEQ	401 Hydroelectric Recertification		Certifications are based on review that the proposed project will meet water quality standards. Given that most major hydroelectric projects are going through relicensing and that some actions will be based on further monitoring and adaptive management strategies (monitoring and adaptive management needs are specified for each project), additional data will be collected in the future to document program effectiveness. Documentation will be developed as part of the TMDL implementation process.	Additional Funding and Staff	the state review is primarily fee based. Fees need to be periodically adjusted to cover the cost of the program
ODEQ	Non-Point Source Program		The program relies on existing state and local authorities to address non point sources of pollution. Programs to address nonpoint sources, especially in urban and agricultural areas, are relatively recent and additional time and trend monitoring is needed to document results. Additionally, while a schedule for implementation is to be identified, timing of implementation is often dependent on adequate future funding which often is not guaranteed or certain.	Adequate monitoring program needed; see other programs listed in this document for modifications needed as it relies on other existing state and local authorities for implementation. See other programs listed in this document for Modifications Needed.	See other programs listed in this document for constraints as it relies on other existing state and local authorities for implementation.

Appendix Table 5. Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODEQ	Point Source Permits		Permits are written to meet water quality standards, sources not in compliance have to come into compliance within the permit cycle (typically, 5 years). Compliance monitoring is required. Permits are reviewed and updated on at least 5-year basis or as needed, based on new requirements. Additionally, the TMDL program can require additional treatment to meet water quality based conditions. The CWA has a citizen lawsuit provision which is an effective oversight provision for permitting. Studies are required as part of the permit process, including mixing zones surveys. Additional data and reports are available through ODEQ.	None	Number of staff is always a limitation. Funding is a blend of federal, state and fee support. Additional funding has recently been provided based on a Blue Ribbon Committee Report which recommended changes to fee structures and additional general funds.

Appendix Table 5. (continued). Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODEQ	TMDLs		TMDLs target bringing waters back into compliance with water quality standards. Oregon entered into a Consent Decree and Memorandum of Agreement with USEPA in 2000 under which it committed to substantially complete TMDLs statewide by 2010 (based on number of waters listed on the 1998 303(d) list). Most of the subbasins in Oregon are listed for temperature with TMDLs developed to address temperature issues for the entire subbasin. Therefore, most of the state should have TMDLs for temperature in the coming years. Implementation follows the TMDLs although there are many programs already in place in much of Oregon. Given that this program is fairly new and it will take years to decades to address degraded riparian conditions, there is limited documentation on the effectiveness of TMDL-related programs to address temperature. TMDL processes will be a condition of 401 hydroelectric certifications	Additional Staffing.	Staffing resources.
ODEQ	Water Quality Standards		Temperature Standards were recently updated (December 2003) and approved by the U.S. Environmental Protection Agency (March 2004). The numeric and narrative criteria, when achieved, should protect fish and other aquatic life in all life stages. Given that the criteria were adopted recently, programs that target achieving these criteria have been recently modified or developed, therefore field documentation of the effectiveness of the standard to protect fish is limited. Documentation will be developed as part of the TMDL process.	Additional staffing for this program (DEQ had a preliminary budget request in for the 2007 Legislature, but did receive the Governor's approval).	Number of staff

Appendix Table 5. (continued). Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Fire Program		Resources are needed to assist forest landowners to reduce fuels that place forested watersheds at risk. Infrastructure is also needed to support resource enhancement opportunities through biomass conversion projects.	More coordinated efforts by all of Oregon's agencies and landowners to work collaboratively with federal partners to increase the contribution for recovery from federal forests.	Federal and private forest 'checker-board' ownership can place private forestlands at risk for uncharacteristic wildfire when either forest is not managed. There is a need for both ODF and ODF&W, and all landowners to play a role in the management of federal forests located in Oregon. A collaborative relationship between state natural resource agencies and federal forest management agencies may restore the health, diversity, and resilience of federal forests by increasing the information shared and by providing a variety of perspectives on site-specific and landscape level determinations. Wildfire-prone areas are identified in a community wildfire protection plans identifying priority areas for hazardous fuel removal from federal lands.

Appendix Table 5. (continued). Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Oregon Forest Practices Act		Shade levels for streams on forestlands are consistently measured at high levels. A sufficiency analysis established that on a landscape level and for most streams the water quality standards are being met by the current rules. Areas of concern that were identified were limited and increments of temperature change that might result from the areas of concern are not of the magnitude to result in adverse stress or mortality. The relationships among temperature, sunlight, and fish productivity in some streams is being evaluated in several large research projects including an ODF riparian function study, the Hinkle Creek watershed study, and the Trask River watershed study. An adaptive management process will incorporate monitoring and research results into the Forest Practices Act. Documentation Links Final Oregon Coastal Coho Assessment: http://nrimp.dfw.state.or.us/OregonPlan Sufficiency Analysis: A Statewide Evaluation of Forest Practices Act Effectiveness in Protecting Water Quality, ODF and DEQ 2002. http://egov.oregon.gov/ODF/PRIVATE_FORESTS/docs/fp/AllSAv1031.pdf Stream Temperature Monitoring o FPMP Technical Report #2 (pdf), Cooperative Stream Temperature Monitoring: Project Completion Report For 1994 - 1995 (Small Type N Streams), Sept. 1999 o FPMP Technical Report #3 (pdf), Effectiveness of Riparian Management Areas and Hardwood Conversions in Maintaining Stream Temperature, March 1997 Shade Quality Study o FPMP Technical Report #13 (pdf) - Shade Conditions Over Forested Streams in the Blue Mtn and Coast Range Georegions of Oregon, August 2001 o Executive Summary (pdf)	Research and monitoring is currently under way to determine the linkages am	Funding for existing and planned research and monitoring projects is critical to understanding water temperature, riparian conditions, and stress and mortality of salmon and steelhead. These studies span multiple years of data collection and take a long-term commitment of funding and resources to provide feedback to inform policy decisions.

Appendix Table 5. (continued). Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Private forestry component of the Oregon Plan for Salmon and Watersheds		The trend for water temperature is improving. Oregon Plan measures contribute to developing healthy riparian stand conditions that are presumed necessary for salmonids and water temperature, The Oregon Plan is designed to decrease the time to get to healthy conditions through active management. Where landowners choose not to participate in the Oregon Plan, standard Oregon Forest Practices RMA protections apply that develop healthy riparian conditions through passive management. Documentation Oregon Watershed Enhancement Board Watershed Restoration Inventory	Modifications should keep pace with best available science.	Funding for existing and planned monitoring projects is critical to understanding water temperature, riparian conditions, and stress and mortality of salmon and steelhead. These studies span multiple years of data collection and take a long term commitment of funding and resources to provide feedback to inform policy decisions. More resources would increase project accomplishment, education, and coordination.
ODF	State Forest Program		The program is built on a sound theoretical basis: The FMP provides for shade along fish-bearing streams. While this gives reason to believe that the FMP standards are effective, the degree of effectiveness has not yet been established because monitoring is not yet complete. Documentation Because program standards meet or exceed those under the FPA, the documentation listed to support the sufficiency of the FPA will also support the sufficiency of the State Forests Program. Future monitoring reports produced by the State Forests Program will likely document any additional benefits produced by FMP strategies.	The need for modification to the current program is uncertain, pending the results of monitoring.	None identified.
ODFW	Conservation Strategy for Oregon		The Oregon Conservation Strategy is a new voluntary program. As such, monitoring and evaluation will be necessary to determine the effectiveness of the program.	None at this time. The role of this new program as it pertains specfically to listed salmon and steelhead is still being defined.	Voluntary measures – no assurance that it will be implemented.
ODFW	Lands Resources Program		Uncertain of funding status or participation by public and private entities (i.e. Riparian Lands Tax Incentive Program).	Need further promotion of existing programs by I and E, Wildlife Division, and District staff.	Funding and staff time.
ODFW	Restoration and Enhancement Program		Funding for this program is through a surcharge imposed on all sport fishing licenses and commercial salmon fishing licenses and poundage fees. As such, funding is a subject to annual variations in fish abundance, harvest rates, and license sales.	None. The Program will evaluate their ability to shift resources to priorities that emerge from recovery planning. Further changes in program scope and focus would require legislative action.	Broad legal mandates of the program limit the ability of the program to focus solely on the needs of recovery planning, variable funding due to funding mechanism.
ODFW	Salmon Trout Enhancement Program		Current staffing and the broad scope of the program limits the capacity of the program to address any single program element.	Additional funding, additional FTE.	Funding.

Appendix Table 5. (continued). Program sufficiencies to address water temperature impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODFW	Watershed Council Liaison		Currently there are only two watershed council liaison positions in ODFW, both in the North Coast Watershed District. There are no positions for other regions of Oregon.	New positions.	Funding.
ODSL	Removal-Fill Program		DSL's removal-fill permits include conditions designed to protect water quality, including riparian vegetation removal restrictions and revegetation requirements. Not enough projects are monitored for compliance.	Modifications Needed: A greater number of projects need to be monitored for compliance. Additional, permanent compliance staff are needed.	The half-time Compliance Monitoring Specialist position is funded for three years and is subject to reauthorization each year of the three-year period. The status of the position is uncertain after that time.
OWEB	CREP Program		Limitation on recruiting private landowners for voluntary water quality restoration projects. Limitation to water quality restoration opportunities due to existing infrastructure. The limitation of CREP technical assistance has been demonstrated to be the single most important factor linked to enrollment.	Increased capital and non-capital funds	Funding
OWEB	Grant Program		Limitation on recruiting private landowners for voluntary water quality restoration projects. Limitation to water quality restoration opportunities due to existing infrastructure.	Increased capital and non-capital funds	Funding
OWRD	Enclosed Livestock Water Delivery Systems		When combined with riparian fencing programs, opportunities to protect and restore riparian communities, including filtering of fine sediments, while providing livestock watering capabilities are increased. There is currently no monitoring program in place to evaluate program effectiveness.	No modifications to program design are proposed. The program would benefit from expanded outreach and education.	The program is reliant on landowner interest. Construction and subsequent maintenance of fencing and off-channel watering devices require adequate financial resources.

Appendix 6. Program sufficiencies to address fish passage impacts.					
Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	Oregon Forest Practices Act		An improving trend for fish passage is clear. Past practices that constrained fish passage have been abandoned and passage will be systematically restored through the regulatory program at the time of normal structure replacement. Fish passage rules under the jurisdiction of the Department of Forestry were first established in 1973 and last modified in 1994. Prior to 1994, the design standard was for passage of adult fish upstream, without a clear requirement to maintain passage. Current rules require that all roads built since 1994 provide and maintain fish passage (adult and juvenile fish) and as culverts and other crossing structure on roads built prior to 1994 are replaced they will then be required to meet the current standards for fish passage. Landowners voluntarily increase the rate of restoring passage on roads built prior to 1994 as part of the Oregon plan. FPA monitoring shows high levels of fish passage are attained on new and replacement structures. Documentation Links Sufficiency Analysis: A Statewide Evaluation of Forest Practices Act Effectiveness in Protecting Water Quality, ODF and DEQ 2002. http://egov.oregon.gov/ODF/PRIVATE_FORESTS/docs/fp/AllSAv1031.pdf **FPMP Technical Report #14** (pdf) - Compliance With Fish Passage and Peak Flow Requirements at Stream Crossings - Final Study Results **FPMP Technical Report #6** (pdf) - 1998 Pilot Study Results Executive Summary - 1998 Pilot Study Results (pdf), March 2000 - brief overview of the Pilot Study Results	No modifications are currently needed.	Resources and collaboration remain constraining. Current resource needs include the resources necessary to implement Forestry Program for Oregon indicator monitoring for roads and fish passage and the resources necessary to conduct more Private Forests Program compliance and effectiveness monitoring.
ODF	Private forestry component of the Oregon Plan for Salmon and Watersheds		The trend for fish passage at road crossings is clearly improving. Landowners voluntarily increase the rate of restoring passage on roads built prior to 1994 as part of the Oregon plan. FPA monitoring shows high levels of fish passage are attained on new and replacement structures. OWEB reporting indicates high levels of work on forestlands. Reporting indicates many stream crossing structures built prior to 1994, while still functioning as crossing structure, are being replaced on forestland ahead of the normal replacement schedule. This is done to restore fish passage. The number and potential impacts of existing fish barriers and blocked habitat remain unknown, however, most landowners have inventoried and prioritized barriers based upon some type of restoration schedule. Documentation Oregon Watershed Enhancement Board Watershed Restoration Inventory	Oregon Plan Measures for Private Forestlands are in the process of being updated. Changes reflect that many landowners have shifted emphasis from a 'voluntary' approach and now include legacy road work in routine road & stream crossing maintenance plans.	More resources would increase project accomplishment, education, coordination, and monitoring. For some landowners, the OWEB grant cycle is a disincentive when road work is done on an opportunistic basis. While high levels of investment in this program exist, there has been little monitoring of effectivenss.

Appendix 6. Program sufficiencies to address fish passage impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODF	State Forest Program		FPA monitoring shows high levels of fish passage are attained on new and replacement structures. Monitoring results and on-the-ground consultation with ODF stewardship foresters and ODFW habitat biologists results in a high level of success. Additionally, the state forests program provides monitoring to ensure that fish passage meets the program's performance measures. Documentation Because program standards meet or exceed those under the FPA, the documentation listed to support the sufficiency of the FPA will also support the sufficiency of the State Forests Program. Future monitoring reports produced by the State Forests Program will likely document any additional benefits produced by FMP strategies	No modifications are currently needed.	New road construction and reconstruction projects are completed to current fish passage standards. Limited funding exists for passage improvement projects not associated with timber harvest. Highest priority projects are completed first, with lower priority projects being completed as funds become available. Some districts work closely with watershed councils to attain funding for non-timber related passage improvement projects.

Appendix Table 6. (continued). Program sufficiencies to address fish passage impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODFW	Conservation Strategy for Oregon		The Oregon Conservation Strategy is a new voluntary program. As such, monitoring and evaluation will be necessary to determine the effectiveness of the program.	None at this time. The role of this new program as it pertains specifically to listed salmon and steelhead is still being defined.	Voluntary measures – no assurance that it will be implemented
ODFW	Fish Passage Program		Compliance by owners or operators is obligatory, but approval is distributed, reporting mechanisms are not in place, and compliance rates are unknown; availability of funds to implement program.	Funding for staff to perform regulatory and outreach role.	None identified.

Appendix Table 6. (continued). Program sufficiencies to address fish passage impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODFW	Fish Screening and Passage Grant Program		Actions dependent on voluntary participation in the program; availability of funds to implement projects.	Funding for outreach.	None identified.
ODFW	Lands Resources Program		Uncertain of funding status or participation by public and private entities (i.e. Riparian Lands Tax Incentive Program).	Need further promotion of existing programs by I and E, Wildlife Division, and District staff.	Funding and staff time.
ODFW	Restoration and Enhancement Program		Funding for this program is through a surcharge imposed on all sport fishing licenses and commercial salmon fishing licenses and poundage fees. As such, funding is a subject to annual variations in fish abundance, harvest rates, and license sales.	None. The Program will evaluate their ability to shift resources to priorities that emerge from recovery planning. Further changes in program scope and focus would require legislative action.	Broad legal mandates of the program limit the ability of the program to focus solely on the needs of recovery planning, variable funding due to funding mechanism.
ODFW	Salmon Trout Enhancement Program		Current staffing and the broad scope of the program limits the capacity of the program to address any single program element.	Additional funding, additional FTE.	Funding.
ODFW	Watershed Council Liaison		Currently there are only two watershed council liaison positions in ODFW, both in the North Coast Watershed District. There are no positions for other regions of Oregon.	New positions.	Funding.
ODLCD	Statewide Comprehensive Land Use Planning		The land use actions taken by local governments can supplement and support other specific restoration activities but are not sufficient in themselves to achieve restoration. Local land use actions will likely not remediate legacy conditions or significantly alter current practices, but will affect future development.	None. The statewide land use program is not intended to be sufficient to recover salmon.	Technical and planning assistance to local governments would be highly beneficial in enlisting local planning efforts in salmon recovery.

Appendix Table 6. (continued). Program sufficiencies to address fish passage impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODOT	Salmon-Fish Passage Program		ODOT's Salmon-Fish Passage Program provides adequate technical and institutional capacity to implement the program within its jurisdictional area. The program selects, designs, constructs, monitors, and documents fish passage improvement projects. The program is held in high regards and is effective for improving fish passage at known fish passage impediments; however, it lacks budgetary capacity and a clear timeline for full implementation. Currently, the ODFW statewide artificial obstruction inventory (Inventory) identifies a total of 770 priority structures owned and managed by ODOT that do not provide adequate fish passage (255 or 33%=High Priority, 167 or 22%= Medium Priority, 348 45%=Low Priority for repair). From 1997 to 2006 the ODOT program repaired 109 high priority fish passage culverts (35 high priority culverts with replacements and 74 high priority culverts with retrofits) or 42% of the ODOT managed statewide high priority culvert inventory total. ODOT high priority culvert repairs have made 370 miles of stream habitat accessible to native migratory fish. Post construction effectiveness monitoring and documentation to satisfy federal and state regulatory agencies are complete for these projects. To date, 146 high priority culverts owned and managed by ODOT continue to need repairs. We anticipate the list will grow as more culverts are inventoried. At the current rate of ~4 culvert projects repaired each year it will take approximately 36 years to repair or replace the remaining balance of high priority culverts. Similarly, there are an additional 515 (67% of the statewide total) medium and low priority culverts that will need repairs once the high priority culvert list is complete. Using the projected rate of numbers of projects completed annually (n=4) it will take significantly longer to repair the medium and low priority culverts. At the current funding and repair rate, it will take decades (over 100 years) to make the appropriate repairs to all ODOT owned and managed culverts (n=661) that currently do not provide adequate fish passage.	ODOT is working to repair as many high priority fish passage culverts as program funds will allow. Additional funding for project development and construction is necessary to decrease the timeframe this program can repair the remaining high priority culverts owned and managed by ODOT. Another key program management tool that continues to be lacking is an updated and prioritized comprehensive artificial obstruction inventory. The current Inventory is not adequate for managers to make informed planning decisions for future investments of limited fish passage funds. The Inventory aggregates artificial obstructions into three priority categories: (high, medium, and low) and some culverts known to impede fish passage are not included in the Inventory. There is no systematic standardized method or protocol for the aggregation of these culverts into the three priority categories. It would be beneficial if high priority culverts were re-evaluated and re-ranked numerically either statewide and/or basin-wide. A numeric ordering of the high priority culverts will allow ODOT and other owners and operators of substandard culvert facilities to make more informed project selection decisions based on statewide or basin-wide priorities. A comprehensive artificial obstruction inventory and robust prioritization of know fish passage impediments will provide ODOT and other owners the management tools necessary to make informed planning decisions that are consistent with salmon recovery goals.	In addition to the limitations associated with this program's budget, project development and construction costs continue to escalate. During FY 2006, construction costs increased approximately 10% due to increased costs associated with engineering design, construction materials, fuel, contractor supervision and management, etc. These increased costs continue to burden the program and result in fewer fish passage projects constructed in a given year.

Appendix Table 6. (continued). Program sufficiencies to address fish passage impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODSL	Removal-Fill Program		DSL's removal-fill permitting process requires that permitted projects maintain or restore fish passage, and encourages removal or replacement of road crossings and other passage impediments. At current staffing levels, DSL does not always have the resources to do the outreach necessary to encourage landowners to remove or replace fish passage impediments. In addition, very few projects are monitored for compliance.	Additional funding would increase the effectiveness of the program. A greater number of projects need to be monitored for compliance. Additional, permanent compliance staff are needed.	The half-time Compliance Monitoring Specialist position is funded for three years and is subject to reauthorization each year of the three -year period. The status of the position is uncertain after that time.
OWEB	Grant Program		The primary limitation to effectively addressing fish passage barriers has been lack of complete information on the nature and location of barriers in relation to productive fish habitat. OWEB has funded data gathering on a watershed scale and used information to prioritize barriers for removal. Where this information is available grants have been available to remedy high priority barriers.	Increased capital and non-capital funds	Funding

Appendix Table 7. Program sufficiencies to address instream flow impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODEQ	Non-Point Source Program		The program relies on existing state and local authorities to address non point sources of pollution. Programs to address nonpoint sources, especially in urban and agricultural areas, are relatively recent and additional time and trend monitoring is needed to document results. Additionally, while a schedule for implementation is to be identified, timing of implementation is often dependent on adequate future funding which often is not guaranteed or certain.	Adequate monitoring program needed; see other programs listed in this document for modifications needed as it relies on other existing state and local authorities for implementation. See other programs listed in this document for Modifications Needed.	See other programs listed in this document for constraints as it relies on other existing state and local authorities for implementation.
OWEB	Grant Program		Limitation on willing participation and effective grant process for purchase of water rights	Increased capital and non-capital funds	Funding

Appendix Table 7. Program sufficiencies to address instream flow impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
OWRD	Administration of Water Rights		Program design for the review of new permits is sufficient to consider needs of listed fish species. OAR Chapter 690 Division 33 lays out public interest standards for new appropriations including surface waters and hydraulically connected groundwater with the potential for substantial interference (OAR 690-009-040). Included in Division 33 are interagency consultations to determine consistency of proposed applications with the Columbia River Basin Fish and Wildlife Program. Consultation occurs with NPPC, ODFW, USFWS, NMFS, Indian tribes and appropriate local governments. Permits that cannot be conditioned to achieve consistence are presumed to impair or be detrimental to the public interest. Ongoing implementation of these OARs includes completion of documentation for each new applicant. Surface water availability is modeled for each month and evaluated at the 80% exceedance level. This information is available through the OWRD on line interactive mapping program: http://map.wrd.state.or.us/apps/wr_mapping/.	Provide flow data to support the evaluation of flows and their sufficiency during critical periods, and the adaptive management process to help assure the review and consultation process for new permits remains sufficiently protective.	Funding to support monitoring capabilities has been unstable and declining. Funding for the 2007-2009 biennium will improve statewide monitoring capabilities.
OWRD	Flow Restoration Programs		These programs are voluntary in nature. Instream leases are limited to a five year period, but leases may be renewed indefinitely. Transfers may be temporary or permanent. Allocations of conserved water are permanent. Participation in Voluntary Flow Restoration programs continues to grow. Based on the best available data, over 287 cfs have been permanently restored and 580 cfs temporarily restored instream as of 12/31/2006. Benefits realized will vary by participation levels, season, stream reach, region, and by the duration of the lease or transfer. Although the benefits of incremental improvements to flow at various times and on various life stages of listed species may not be certain, OWRD encourages incremental improvements to flow through these voluntary programs. Voluntary flow restoration programs include temporary instream leases, permanent allocations of conserved water and temporary or permanent transfers. Performance is currently available through measures tracked annually (KPM#1). Performance measures are posted online through: http://www.wrd.state.or.us/OWRD/LAW/performance.shtml Performance is tied to flows restored in key watersheds. Key watersheds, or priority water availability basin, can be found through the online interactive mapper. The performance measure is tracked by Oregon fiscal year. Graphical representation of restored flows for 2006 is available through: http://www.wrd.state.or.us/OWRD/mgmt_flow_restoration.shtml. This representation shows a positive trend in participation as outreach continues and awareness of the program grows. Accessibility of these data via the OWRD website provides documentation of program success, tools to assist willing water right holders identify needs as they relate to key watersheds and flow restoration, and will provide data important to monitoring and adaptive management.	These programs would benefit from increased education and outreach to increase participation levels, and from coordinated follow-up to encourage re-enrollment where possible. Provide available flow restoration data to support the evaluation of flows and their sufficiency during critical periods and the adaptive management process. In September 2006, funding was awarded through the National Fish and Wildlife's Columbia Transactions Program to migrate instream leasing, transfer and allocations of conserved water data to OWRD's online Water Rights Information System (WRIS). Access through this OWRD website will provide critical data for evaluating current flow restoration activities and supporting adaptive management.	Programs are constrained by limited funding and resources for outreach and education, lease/transfer follow-up and re-enrollment, and accessibility of lease/transfer data to support monitoring and evaluation of flow restoration efforts and their impacts on listed species.

Appendix Table 7 (continued). Program sufficiencies to address instream flow impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
OWRD	Lease/Transfer Water Rights Associated with CREP Program		This program works in conjunction with CREP to benefit both the restoration of riparian function and minimum flows as lands are enrolled and associated water rights are returned instream. Participation in the CREP program and instream leasing or transfer of associated water rights are voluntary. Water rights that are not leased or transferred instream may be used consistent within the terms and conditions of the water right, which may, depending on the nature of the water right, reduce potential benefits to minimum flows and riparian function.	Outreach and education programs could be improved through increased resources and greater coordination. Provide available flow restoration data to support monitoring, evaluation and the adaptive management process.	The program is dependent upon private landowner awareness of the program and voluntary participation levels. Outreach and education are constrained by available resources.
OWRD	Water Distribution and Regulation		Instream water rights do not guarantee minimum flows. Rather, they establish a quantity of water for instream beneficial use, regulated by priority date. Many instream water rights have priority dates that are junior to other water rights, reducing opportunities to regulate on their behalf. The resulting impacts to instream flows may vary by stream reach, season and priority date of the instream right. Voluntary compliance with water rights and regulations was approximately 96% statewide in 2005. However, there are over 80,000 surface water rights in Oregon. Efforts to monitor streamflow and protect instream water rights are limited by staff resources and monitoring capabilities.	Increased monitoring capabilities will support water distribution and regulation activities on behalf of water rights, including instream water rights. These additional data may also support evaluation of incremental changes to flow and the sufficiency of those flows during critical periods	Funding for staff and monitoring capabilities has been unstable and declining. The 2007-2009 budget provides funding to add monitoring and distribution capacity. The junior status of some instream water rights may limit their flow benefit in some areas. In these instances, voluntary restoration measures are key to achieving recovery goals as they relate to flow.

Appendix Table 7 (continued). Program sufficiencies to address instream flow impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
OWRD	Water Supply and Conservation Planning		Water Management and Conservation Plans are not designed to directly address flow needs for listed fish species. However, stream flows may benefit from implementation of these plans and identified conservation measures. Plan implementation may delay the need for increased municipal diversions. Stream flows may improve through implementation of agricultural plans. OWRD encourages instream protection for all or a portion of increases to stream flow brought by implementation of agricultural plans. Voluntary enrollment in the Allocation of Conserved Water Program includes incentives for agricultural water suppliers and opportunities to restore instream flows and regulate on their behalf. Potential improvements to flow are dependent upon participation and full implementation of plans. There is currently no OWRD monitoring program in place to evaluate the effectiveness of these programs. While stream flows may benefit, for the recovery of listed species, this and other plans are best considered in aggregate. Considered in aggregate, the sufficiency of some programs may change.	The Agricultural Water Management and Conservation Plan program would benefit from expanded outreach and education. OWRD is currently developing a guidebook to assist agricultural water suppliers to prepare plans that meet Oregon and Federal requirements. This guidebook will help agricultural water suppliers describe their water systems and needs, identify their sources of water, and identify ways to manage and conserve those supplies to meet present and future needs. OWRD has also received funding for the majority of requested elements of a statewide Water Supply and Conservation Initiative. This initiative will strive to address statewide water supply needs through a statewide water needs assessment, inventory of potential above and below ground water storage sites, analyses of water conservation opportunities, investigation of basin yield estimates, and match funding for community-based and regional water supply planning.	Water supply and conservation planning is constrained by limited funding and resources for outreach, education, and program development. The 2007-2009 agency budget includes the majority of funding requested for the Water Supply and Conservation Initiative.
OWRD	Water Use Measurement Strategy		Measurement of water use does not directly protect flows, but may support the evaluation of needed flows. On a statewide scale, the Water Use Measurement and Reporting position was eliminated during the last biennium and has been restored for the 2007-2009 biennium. This position is responsible for database maintenance, maintenance of on-line reporting processes and helping to assure compliance with permit reporting conditions. Efforts to promote voluntary actions may be deterred by the cost associated with installation and maintenance of measuring equipment. A cost-share program to promote voluntary water use measurement and reporting is in place, but not currently funded. Ongoing implementation of the significant diversion program is constrained by staffing levels.	No modifications to the design of this program are suggested. Restoration of the Water Use Measurement and Reporting position and funding for the existing cost-share program for voluntary water use measurement and reporting will improve ongoing implementation of the water use measurement strategy. Restoration of county-based Assistant Watermasters would further aid this strategy.	Ongoing implementation of the water use measurement strategy is constrained by available resources and staff.

Appendix Table 8. Program sufficiencies to address agriculture and forestry chemical impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODA	Agricultural Water Quality Management (SB 1010)		Basin plans and rules are reviewed biennially to determine whether the plan is sufficient to meet and address water quality standards, and modified as necessary to meet deficiencies and new requirements or information. Reviews include review of compliance actions, outreach activities, projects, and monitoring results. ODA focuses efforts and resources on areas of highest priority and program is enforced. "Compliance" is based on inspections prompted by "notification" of inappropriate occurrences; increasing complaints and notifications reflect an increased public awareness and greater number of basin rules in place. Water quality monitoring is conducted by DEQ at permanent sites. Aerial photography at 4-5 yr intervals documents riparian condition trends.	Biennial reviews will determine if modifications are needed. Given more resources (funding) implementation of on-the-ground actions, including monitoring, would be accelerated. More monitoring would provide improved documentation of program adequacy.	Landowner cooperation, capacity for outreach, changing land ownerships and new landowners knowledge of agricultural issues, perception that this is only a complaint driven process, technical assistance, adequate monitoring at meaningful scales
ODA	Pesticides		ODA is the EPA designated agency to enforce FIFRA in Oregon. This program operates under an MOA with EPA and is consistent with FIFRA requirements. There are several layers of controls to maintain responsible use of pesticides by the agricultural industry.	None, meets federal requirements	capacity for outreach
ODEQ	TMDLs		TMDLs set targets to bring waters back into compliance with water quality standards. TMDLs can address those pesticides which have numeric standards established and can address excess nutrients which can cause other water quality standard exceedences (e.g. pH, dissolved oxygen). However, very few agricultural chemicals (such as pesticides that are currently in use) have numeric water quality standards established for them and would be addressed under this program only if they exceeded a narrative standard (e.g. introducing substances in levels that are harmful to aquatic life or bioaccumulate to levels that adversely affect public health or wildlife). Additionally, the cost for monitoring many of these chemicals is high so they are not routinely monitored, unless a problem is suspected. Given the limitation in monitoring for these chemicals and in having standards established to determine impact on beneficial uses, it is uncertain if the TMDL is adequate to address the universe of Agricultural Chemicals which could cause water quality problems. That is why, since 1999, ODEQ has been using a voluntary, collaborative approach called Pesticide Stewardship Partnerships (PSPs) to identify problems and improve water quality associated with pesticide use at the local level. The PSP approach uses local expertise in combination with water quality sampling and toxicology expertise of ODEQ to encourage and support voluntary changes that cause measurable environmental improvements.	Additional staffing for this program or for an alternative program, such as the Pesticide Stewardship Partnership, to address this issue (DEQ has a budget request in for the 2007 Legislature to develop a toxics monitoring program).	Sufficient resources for monitoring to identify chemicals of concern (see Water Quality Monitoring) and for developing water quality standards to identify levels that affect beneficial uses.

Appendix Table 8. (continued). Program sufficiencies to address agriculture and forestry chemical impacts

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODEQ	TMDLs		TMDLs set targets to bring waters back into compliance with water quality standards. TMDLs can address those pesticides which have numeric standards established and can address excess nutrients which can cause other water quality standard exceedences (e.g. pH, dissolved oxygen). However, very few agricultural chemicals (such as pesticides that are currently in use) have numeric water quality standards established for them and would be addressed under this program only if they exceeded a narrative standard (e.g. introducing substances in levels that are harmful to aquatic life or bioaccumulate to levels that adversely affect public health or wildlife). Additionally, the cost for monitoring many of these chemicals is high so they are not routinely monitored, unless a problem is suspected. Given the limitation in monitoring for these chemicals and in having standards established to determine impact on beneficial uses, it is uncertain if the TMDL is adequate to address the universe of Agricultural Chemicals which could cause water quality problems. That is why, since 1999, ODEQ has been using a voluntary, collaborative approach called Pesticide Stewardship Partnerships (PSPs) to identify problems and improve water quality associated with pesticide use at the local level. The PSP approach uses local expertise in combination with water quality sampling and toxicology expertise of ODEQ to encourage and support voluntary changes that cause measurable environmental improvements.	Additional staffing for this program or for an alternative program, such as the Pesticide Stewardship Partnership, to address this issue (DEQ has a budget request in for the 2007 Legislature to develop a toxics monitoring program).	Sufficient resources for monitoring to identify chemicals of concern (see Water Quality Monitoring) and for developing water quality standards to identify levels that affect beneficial uses.
ODF	Oregon Forest Practices Act		The rules include specific best management practices (BMPs) in addition to label requirements. Spill risks are addressed and reporting of spills is required. ODF Monitoring has shown that the BMPs protect water quality from drift impacts and otherwise protect riparian vegetation. Documented adverse impacts to salmonids from forestland chemical use are not known. Documentation Links Sufficiency Analysis: A Statewide Evaluation of Forest Practices Act Effectiveness in Protecting Water Quality, ODF and DEQ 2002. http://egov.oregon.gov/ODF/PRIVATE_FORESTS/docs/fp/AllSAv1031.pdf Chemicals/Pesticides **FPMP Technical Report #7** (pdf) - Aerial Pesticide Application Monitoring Final Report, March 2000 • Executive Summary (pdf) - shortened version of the Final Report • Eugene Water and Electric Board, Karl Morgenstern. May 2007. Case Study: Hydrologic Impacts of Forest Management on Municipal Water Supplies	None identified.	Lack of monitoring data related to post application runoff. Lack of funding and cooperation for monitoring across land uses.

Appendix 9. Program sufficiencies to address animal waste impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODA	Confined Animal Feeding Operation (CAFO)		This program limits/controls nutrient impacts on water quality for both surface and ground water. It is consistent with the federal Clean Water Act requirements for CAFOs. An Application to Register is a new requirement to meet the new federal and state requirements for permitting and concentrated animal feeding operations. A continued goal of the CAFO program is to inspect each permitted CAFO once per year. ODA also reviews, approves or rejects, Animal Waste Management Plans and specifications for animal waste control facilities to verify they have been prepared in accordance with OAR 340-051 design criteria, and USDA-NRCS conservation practice standard guidance 590 for Oregon. As a result of this increased effort, ODA has seen overall improvement in compliance on permitted operations.	None exceeds federal requirements.	Economic conditions impede the ability of operators to be more proactive in addressing fish habitat needs
ODEQ	TMDLs		TMDLs set targets to bring waters back into compliance with water quality standards, most typically targets for bacteria and nutrients that would address concerns from animal wastes. These targets include load allocations for sectors such as agriculture, forestry and urban land uses with animal wastes typically being of concern in agricultural and urban land uses. The agricultural sector has programs that address a portion of animal wastes from Confined Animal Feeding Operations (CAFO) and smaller live stock facilities through the CAFO and Agricultural Water Quality Management Plans respectively. However, programs in urban areas to address pet wastes or other sources of animal wastes (birds, etc) that get into streams via storm water runoff are relatively new, in development in many areas (especially the larger cities) or do not exist (especially in smaller cities). There is limited monitoring of the effectiveness of these programs, therefore it is uncertain if TMDLs will be adequate to address animal wastes.	None at this time.	Sufficient resources for monitoring and time to determine if programs to address storm water and agricultural water quality management are sufficient.

Appendix 10. Program sufficiencies to address human, urban, or industrial waste impacts.

Agency	Program	Sufficiency	Rationale	Modifications Needed	Constraints
ODEQ	Environmental Clean Ups		Clean up/remediation of sites addressed under this program occurs until DEQ determines that they pose no significant threat to human health or the environment and therefore require no further action. Monitoring is required to document the effectiveness of the Clean Up activity. Cleanups require documentation to assess "no further action" needed.	None	Need for a sustainable programs that matches revenues and expenses.
ODEQ	Point Source Permits		Permits are written to meet water quality standards, sources not in compliance have to come into compliance within the permit cycle (typically, 5 years). Compliance monitoring is required. Permits are reviewed and updated on at least 5-year basis or as needed, based on new requirements. Additionally, the TMDL program can require additional treatment to meet water quality based conditions. The Clean Water Act provides for citizen lawsuit as an oversight provision.	None	Number of staff is always a limitation. Funding is a blend of federal, state and fee support. Additional funding has recently been provided based on a Blue Ribbon Committee Report which recommended changes to fee structures and additional general funds.
ODEQ	TMDLs		TMDLs set targets to bring waters back into compliance with water quality standards. These targets include waste load allocations for industrial and municipal point sources and load allocation for sector specific (forestry, agricultural and urban) non-point sources of pollution. Typically municipal and industrial waste sources that discharge to waters are regulated under a permit program. Additional requirements can be established based on the TMDLs. The TMDL program is relatively new (TMDLs in Oregon have been established since the late 1980's but work is underway to develop them statewide) and has focused on a limited number of parameters (temperature, bacteria, nutrients, solids and selected toxics). It is likely that TMDLs are effective at addressing these waste sources but further documentation of the program effectiveness is needed. Also, as additional toxic pollutants are monitored and problems are identified, TMDLs or other similar types of programs will need be developed. Documentation is developed as part of the TMDL process which is often a part of the 401 certification.	None at this time	Sufficient resources for monitoring and developing TMDLs and time to determine if programs is being made.

Appendix G

Culverts which Need to be Improved or Replaced Within Oregon Mid-C Steelhead Populations

Number and location of culverts which need to be improved or replaced within steelhead populations in Fifteenmile Creek and the Deschutes River Basin. This is an incomplete list as comprehensive culvert inventories have not been conducted.

Fifteenmile Creek Total Culverts = 6				
5th Field HUC	Stream	Ownership	Number of Culverts	Priority
	Ramsey Cr (FS 4450 Rd)	USFS	1	H
	Fifteenmile Cr (FS 44 Rd)	USFS	1	H
	Threemile (Hwys I-84 & 197)	ODOT	2	M
	Chenowith Cr (Bridge at Hwy 30)	ODOT	1	M
	NF Mill Cr (RM 6.0)	Wasco Co	1	U
Deschutes River Eastside Total Culverts = 2				
5th Field HUC	Stream	Ownership	Number of Culverts	Priority
	Mud Springs Cr (RR culvert in Sec. 15 above Gateway)	Jefferson City	1	H
	Hay Cr (new channel near mouth)	Private	1	H
Deschutes River Westside Total Culverts = TBD				
5th Field HUC	Stream	Ownership	Number of Culverts	Priority
	Warm Springs River		TBD	H
	Beaver Cr		TBD	H
	Shitike Cr		TBD	H
	Oak Cr		TBD	
	Metolius River		TBD	

Number and location of culverts which need to be improved or replaced within steelhead populations in the John Day Basin.

APPENDIX H

Management Actions Effectiveness and Model Data and Assumptions

Management Actions Effectiveness and Model Data and Assumptions

This appendix is presented in two parts. Part 1 provides action effectiveness assumptions and related factor scalars used in analyzing actions. Part 2 provides a series of graphic reports that give additional information about the predicted outcomes of the subbasin habitat scenarios analyzed in Section 10. These graphic reports are extracted from output produced by EDT.

Part 1: Action Effectiveness Assumptions

Part 1 consists of fifteen tables that describe action effectiveness assumptions and related factor scalars used in analyzing the subbasin habitat actions, as well as, the life stage specific survival rate assumptions applied to the component life stages from smolt leaving the subbasin to adult return to the subbasin. See Section 10 of the report for a full description of how the assumptions and scalars are applied. The tables are:

H-1. List of habitat actions analyzed within the subbasins.
H-2. Subbasins where habitat actions were designated to be applied.
H-3. Action effectiveness assumptions and levels applied in analysis.
H-4. Action implementation intensity assumptions and levels applied in analysis.
H-5. Action effectiveness lag scalars applied to habitat actions.
H-6. Action implementation schedule scalars at 25 years applied to habitat actions.
H-7. Action implementation schedule scalars at 100 years applied to habitat actions.
H-8. Attribute scalars applied to habitat actions.
H-9. Definitions of freshwater habitat attributes shown in Table H-8.
H-10. Out-of-basin survival rates in AHA modeling for baseline (B), current (C) and prospective future action scenarios for Fifteenmile Creek winter steelhead.
H-11. Out-of-basin survival rates in AHA modeling for baseline (B), current (C) and prospective future action scenarios for Deschutes River Eastside and Westside summer steelhead.
H-12. Out-of-basin survival rates in AHA modeling for baseline (B), current (C) and prospective future action scenarios for John Day River summer steelhead populations.
H-13. Out-of-basin survival rates in AHA modeling for baseline (B), current (C) and prospective future action scenarios for Umatilla River summer steelhead.
H-14. Out-of-basin survival rates in AHA modeling for baseline (B), current (C) and prospective future action scenarios for Walla Walla River summer steelhead.

Tributary Habitat Action Effectiveness Assumptions
Tributary habitat actions, locations, intensity, time scalars, and effectiveness scalars are presented in tables H-1 – H-9.

Table H-1. Habitat actions analyzed within Oregon subbasins for their effects on population performance of Mid-Columbia steelhead. See Section 9 for further descriptive details of actions.

(Table H-1. List of actions.)

Strategy	Action	Description
1. Protect/conserve ecological processes		
	Acquisition/conservation	Protect the highest quality habitats through acquisition or conservation measures.
	Protect rare functioning habitats	Protect and conserve rare and unique functioning habitats.
	BMPs to conserve eco processes	Consistently apply Best Management Practices (BMPs) and existing laws to protect and conserve natural ecological processes.
	Cooperative Agreements	Adopt and manage Cooperative Agreements.
	Special mgmt designations	Special management designations on public lands.
	Increase wild-scenic status	Designate additional wilderness and wild and scenic status.
	Protect access to key habitats	Protect access to key habitats.
	Outreach to users and managers	Conduct outreach to resource users and managers (resulting in improved management practices).
	Public lands protection	Continue existing protections and/or increase protection of Federal lands; implement Forest Practices Act and PACFISH/INFISH.
	Waterway setbacks	Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function.
	Enforce floodplain regs	Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues.
	Natural Area Overlay Zone	Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance.
	Legislate priority areas	Explore opportunities to incorporate priority areas into state legislation (resulting in improved management practices).
2. Restore fish passage blocked/impaired by barriers		
	Barrier removal	Replace barriers blocking passage including dams, road culverts and irrigation structures.
	Add irrigation screening	Provide screening at 100% of irrigation diversions.
	Pelton Round Butte passage	Restore passage at Pelton Round Butte Complex in the Deschutes river system.
	Upgrade irrigation screening	Replace screens that do not meet criteria.
	Reduce push up dams	Remove or minimize use of push up dams.
	Fish ladder construction	Construct ladders over existing permanent concrete or earth fill dams, or remove the barrier.
	Maintain passage facilities	Operate and maintain fish passage facilities to meet criteria.
3. Restore floodplain connectivity and function		
	Reconnect floodplain	Reconnect floodplains to channels.
	Reconnect side channels	Reconnect side channels and off-channel habitats to stream channels.

(Table H-1. List of actions.)

Strategy	Action	Description
	Reintroduce beaver	Reintroduce beaver in suitable habitat.
	Restore wet meadows	Restore wet meadows.
	Dike removal	Remove dikes and levies.
	Manage beavers	Manage beaver population and educate public.
4. Restore degraded channel structure/complexity		
	Restore natural channel form	Restore natural channel form.
	Large wood enhancement	Increase role and abundance of wood and large organic debris in streambeds.
	Add structure	Increase instream habitat through manual placement of structures.
	Stabilize streambanks	Stabilize streambanks.
	Build pool weirs	Construct rock and log weirs to create pool habitats or elevate incised channels.
	BMP bridge maintenance	Implement bridge maintenance BMPs.
	LWD education	Educate landowners on importance of large woody debris (LWD)(resulting in improved LWD management practices).
5. Restore riparian condition and LWD recruitment		
	Restore riparian communities	Restore natural riparian communities.
	Improve grazing practices	Develop grazing strategies that promote riparian recovery (and implement).
	Eradicate invasive plants	Eradicate invasive plant species from riparian areas.
	Fencing	Install fencing to exclude livestock from riparian areas.
	Off-stream livestock watering	Install off-stream livestock watering.
	Riparian plantings	Plant riparian vegetation where appropriate.
	Increase riparian shading	Plant riparian vegetation where appropriate.
	No cultivation buffer zones	Develop no-cultivation riparian buffer on agricultural lands and establish riparian setbacks for structures in areas where activities could upset riparian function.
	Maintain RHCAs on USFS lands	Maintain existing widths of riparian habitat conservation areas (RHCAs) on USFS lands.
	Remove riparian roads	Close, remove, and restore riparian road prisms.
	Riparian protection	Protect high quality riparian habitats and unstable areas.
6. Restore natural hydrograph components		
	Ag water conservation	Implement agricultural water conservation measures.
	Improve irrigation conveyance	Improve irrigation conveyance and efficiency.
	Orchard Ridge/Wolf Run	Finish piping Orchard Ridge and Wolf Run diversions.
	Urban conservation	Implement urban conservation measures.
	Convert water rights	Lease or purchase water rights and convert to instream.
	Regulate water withdrawals	Monitor/regulate water withdrawals.
	Water retention structures	Water retention structures.

(Table H-1. List of actions.)

Strategy	Action	Description
	Increase pool habitat (beav ponds)	Increase pool habitat (beaver ponds).
	Floodplain aquifer recharge	Floodplain aquifer recharge.
	H2O rights transfer downstream	Downstream water rights transfers.
	Water storage investigate	Investigate feasibility of water storage or exchange to improve instream flows for steelhead (assumed to improve water conservation/management).
	No new H2O appropriation	Close areas to appropriation of new water uses.
	Criteria for new H2O appropriation	Set criteria to protect flows for fish habitat from new appropriations.
	Enhance hyporheic flows	Enhance hyporheic flows and spring inputs.
	Recharge shallow aquifers	Implement shallow aquifer recharge.
	Aquifer storage & recovery	Aquifer storage and recovery.
	Umatilla Basin Project Phase I and II	Implement Umatilla Basin Project Phase I and II. The Umatilla Basin Project Act, passed by Congress in 1988, allows irrigators to exchange Umatilla River water for Columbia River water. Two phases of the Act have been completed and a third phase has been proposed. This action that addresses Phases 1 and II would continue the operation of the project under these phases.
	Umatilla Basin Project Phase III	Implement Umatilla Basin Project Phase III. This action would provide a substantial increase of Umatilla River water to remain instream compared to the action associated with just Phases I and II.
	ISWRs	File for additional instream water rights (ISWRs) (assumed to be successful). While instream water rights have been established on many of the important spawning and rearing stream in the Umatilla and Walla Walla subbasins, some have not. Where important spawning and rearing streams have not been protected by instream water rights, instream flow studies would be conducted and instream water rights applied for (it is assumed that some would be granted).
7. Improve degraded water quality		
	Manage irrigation return flow	Manage irrigation return flow to reduce extreme stream temperatures.
	Measures to improve DO	Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels.
	Reduce chemical pollution	Reduce chemical pollution inputs.
	Implement Ag WQP	Implement an Agricultural Water Quality Plan. (Oregon's agricultural water quality plans created by Senate Bill 1010 are locally-driven area-wide plans addressing agricultural water quality problems while providing a regulatory backstop. They provide landowner flexibility in solving local water quality issues. Enforcement is not a primary method for assuring success, although compliance is a component. The premise is that when landowners are given opportunities to address issues, and offered technical assistance, success will generally follow. This approach has proven successful in some subbasins (see http://www.oregon.gov/ODA/news/0407aq.shtml)

(Table H-1. List of actions.)

Strategy	Action	Description
	TMDL monitoring	Continue TMDL monitoring. A TMDL is the calculated pollutant amount that a waterbody can receive and still meet Oregon water quality standards. The process for building a plan to improve water quality starts when a waterbody appears on DEQ's 303(d) list, which lists waterbodies that do not meet water quality standards. Federal law requires that streams, rivers, lakes and estuaries that appear on the 303(d) list be managed to meet state water quality standards. Plans to restore streams and rivers to water quality standards are developed by governmental agencies in cooperation with landowners. Agriculture issues are addressed by the Oregon Department of Agriculture working with landowners (under Senate Bill 1010 -- see Ag Water Quality plan above). Private and state forest issues are addressed the Oregon Department of Forestry (through the Forest Practices Act). Federal agencies (such the U.S. Forest Service or the Bureau of Land Management) have responsibility for federal lands. Urban and rural areas not covered by other state or federal agencies are addressed by cities and counties, working with local watershed councils.
	Reduce mine discharge toxicants	Address contamination from mine related discharge.
	Animal feeding BMPs	Apply BMPs to animal feeding operations.
	Point source pollution controls	Address point sources of water pollution.
	H2O quality mgmt plans	Implement water quality management plans (it is not specified that these are Agricultural Water Quality Plans but it is presumed; this is kept separate from the Agricultural Water Quality Plan due to uncertainty in the type of plan and in implementation).
	Pest mgmt plans for fruit growers	Implement pest management plans for fruit growers. Note: it is assumed that this action would entail an integrated pest management program comparable to the action below specified as "Implement IFPnet plans" to be implemented in Fifteenmile subbasin.
	Municipal stormwater mgmt	Improve municipal stormwater management and treatment.
	Waterway alteration permitting	Permit waterway alteration activities and enforce rules. "Waterway alteration" means any action that will result in excavation, dredging, filling, rechannelization, construction, or any other type of modification of an aquatic habitat area occupied by ESA-listed species that will affect the conservation value of that habitat. This action is only relevant for analysis if other actions are to be analyzed that consist of waterway alternations, in which case, the action would serve as a measure of protection. Permitting can require compensation or mitigation but would be assumed to only offset any take.
	Permitting for H2O quality activities	Permit and enforce actions that could affect water quality. This action is aimed at improving permitting/enforcement of land/water use activities that could impact water quality. This action is only relevant in the present analysis if other actions (such as build-out) are to be analyzed that would degrade water quality, in which case the action would serve protect.

(Table H-1. List of actions.)

Strategy	Action	Description
8. Restore upland processes to reduce erosion		
	Convert till farming	Provide incentives to farmers to convert to no till farming; target achieving 95% conversion to no till farming in specified areas.
	Convert to perennial crops	Convert to perennial crops/vegetation.
	Implement IFPnet plans	The project encourages growers in Wasco County (Fifteenmile Creek subbasin) to reduce the use of broad-spectrum OP pesticides and replace them with new generation, less toxic pesticides. It utilizes methods referred to as integrated fruit management. Using a web-based interface, IFP project participants use the degree-day models and data to make better decisions and precise timed application of new generation, less toxic pesticides. Note: action should more correctly be placed under Strategy 7.
	Improve/remove forest roads	Upgrade or remove problem forest roads.
	Reforest/fuels management	Promote fuel management.
	Upland demo projects	Initiate demonstration projects (assumed to be instrumental in improving upland lands management).
	BMPS to reduce soil erosion	Employ BMPs to minimize unnatural rates of erosion.
	Remove junipers	Remove junipers.
	Restore native upland plants	Restore native upland plants.
	Invasive plant mgmt & junipers	Manage vegetation, including juniper removal.
	BMPs on land uses	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices.
	CREP & CCRP buffers	Implement Continuous Conservation Reserve Program and Conservation Reserve Enhancement Program (CREP and CCRP) buffers; voluntary, non-competitive, programs for agricultural landowners providing financial incentives.
	Outreach to upland users	Conduct outreach to resource users and managers (assumed to lead to improvements in uplands lands management).

Table H-2. Subbasins where habitat actions were designated to be applied. See Section 9 for further descriptive details of actions.

Table H-3A and B. Action effectiveness assumptions and levels applied in analysis (A) and corresponding effectiveness values assigned to each action with rationale/comments (B). See Section 10 for how effectiveness values were applied.

Table H-3A. Action effectiveness levels.

Effectiveness level	Definition	Effectiveness
1	Very high	0.80
2	Moderately high	0.56
3	Moderate	0.32
4	Low	0.08
5	Negligible	0.01
6	No effect	0.00

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
1. Protect/conserve ecological processes			
	Acquisition/conservation	0.80	Land set-asides can be expected to return to their natural condition over time, passively restoring adjacent aquatic habitats. Maximum effectiveness should be very high unless constraints have been imposed by previous land uses. Such an effectiveness level assumes a sufficient scale of implementation to affect an entire stream reach. The action would also have very high effectiveness for protection purposes.
	Protect rare functioning habitats	0.08	It is assumed that rare functioning habitats are very limited in size and distribution. Therefore, actions to restore such habitats would likely be limited by being able to fully address the suite of conditions that create such habitats, providing only low effectiveness. Protection of such habitats against further degradation would be more effective than in restoring them (protection against further degradation would be analyzed if build-out actions were to be addressed).
	BMPs to conserve eco processes	0.32	Best management practices to conserve ecological processes within watersheds are generally known and further improvements in understanding can be expected in the near future as there are on-going studies to address this issue. These practices would be aimed at root causes of how ecological processes have been altered by land use (Beechie and Bolton 1999). Bolton et al. (2005) suggest that such practices will be beneficial in first conserving, then restoring natural processes, especially in watersheds where urbanization is not increasing. A moderate effectiveness is reasonable to expect.
	Cooperative Agreements	0.08	Cooperative Agreements involving voluntary agreements between private land owners and governments can address a variety of issues. Lack of specificity here is assumed to provide a generally low potential for effectiveness that addressing wide scale issues.
	Special mgmt designations	0.32	Special management designations can specify types of management that can occur on lands, here taken to mean federal lands (no actions in the Oregon plan call for special designations on state lands). Such designations can specify areas of critical environmental concern or other types of designations, and limit types of management practices allowed. Moderate effectiveness is assumed because the type of special management designation has not been specified.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Increase wild-scenic status	0.32	Wild and scenic status limits types of management practices allowed but not all activities. This status would provide for passive restoration within the areas specified. A moderate level of effectiveness is assumed given that various types of management practices can still occur.
	Protect access to key habitats	--	Issue is covered completely by other actions as this action was described; not given an effectiveness value here.
	Outreach to users and managers	0.08	Modest results as a separate action are expected from this because education can be expected to accompany other line item actions. Low effectiveness assumed.
	Public lands protection	0.32	This action continues previously enacted protection policies/practices on public lands. The action can be expected to have high value to protect against further degradation. For restoration purposes, the action would be passive, which would continue to maintain or improve conditions on certain public lands; moderate effectiveness assumed.
	Waterway setbacks	0.56	This action would establish setbacks (like buffers) along selected waterways to minimize active land uses such as agriculture and forest harvest. When enforced, setbacks can be particularly effective at protecting and restoring riparian and floodplain processes. Moderately high effectiveness is assumed.
	Enforce floodplain regs	0.32	Action calls for making floodplain regulations more effective than they are currently and providing for enforcement. Action is assumed to be only moderately effective because of the on-going need that will occur to maintain some level of protection against flooding and stream channel instability in areas where roads, bridges, and private lands exist.
	Natural Area Overlay Zone	0.08	This provision of the Umatilla County Development Ordinance was developed to protect and preserve ecologically and scientifically significant natural areas; it was developed as an add on, being added to other provisions that addressed protection of riparian zones and stream setbacks. It was assigned a low effectiveness value because it is an add on to other provisions that already address similar issues. It would be given greater values for protection benefits, but here would serve mainly as a passive restoration action.
	Legislate priority areas	0.01	This action would be mainly investigative, considering new legislation to identify and protect priority habitat issues. As such it is considered here to have a negligible effect because of uncertainty it what it would address; many other avenues are considered to be in place or proposed for action to address such issues.
2. Restore fish passage blocked/impaired by barriers			
	Barrier removal	>0.80	Where barriers are identified in the actions to be fixed or removed, it is assumed that passage will be provided in full.
	Add irrigation screening	0.80	Adding irrigation screening where absent will almost always correct any screening related mortalities at the immediate site. Very high effectiveness is assumed.
	Pelton Round Butte passage	0.75-0.99	Don Ratliff of PGE provided passage values to be applied: 75% for downstream juvenile passage and 99% for upstream adult passage.
	Upgrade irrigation screening	0.80	Where need for upgrading irrigation screening exists, it is assumed these screens would be outdated. It is assumed that such upgrading would be highly effective.
	Reduce push up dams	0.56	Concerted efforts to reduce or eliminate push up dams can be assumed to be moderately high if measures are so enacted. Even with such measures, their effectiveness would be limited because of likely difficulties in fully enforcing or requiring their elimination.
	Fish ladder construction	--	This measure is addressed as part of barrier removal in the analysis.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Maintain passage facilities	0.00	Maintenance of fish passage facilities is assumed to occur in the analysis. A separate action that specifies maintenance is not considered to add to effectiveness.
3. Restore floodplain connectivity and function			
	Reconnect floodplain	0.32	Measures to reconnect floodplain channels can be limited by how channels and floodplains have been altered by past land use practices. Channel incision, for example, can be difficult to reverse. A moderate level of effectiveness is assumed.
	Reconnect side channels	0.32	Measures to reconnect side channels can be limited by how channels and floodplains have been altered by past land use practices. Channel incision, for example, can be difficult to reverse. A moderate level of effectiveness is assumed.
	Reintroduce beaver	0.56	Beavers historically were a significant factor in the creation and maintenance of channel structure and off-channel habitats in some types of streams (Naiman et al. 1988). When reintroduced, and managed, they can be an effective way of restoring some types of habitats and natural channel form. Moderately high effectiveness is assumed.
	Restore wet meadows	0.32	Wet meadows are a key element in some streams for helping to maintain flows and in providing some aspects of off-channel habitats in some seasons. A moderate level of effectiveness is assumed where such sites can be targeted for restoration, where land use practices can be effectively controlled. Effectiveness is not regarded as high because of constraining factors in the drainage that would tend to limit the degree that completely restored channel function could occur where impacts have been high in the past.
	Dike removal	0.56	This action would have a comparable effectiveness to waterway setbacks. When implemented, dike removal can be particularly effective at restoring riparian and floodplain processes. Moderately high effectiveness is assumed. Limitations would exist in watersheds where development has occurred.
	Manage beavers	0.56	Beavers historically were a significant factor in the creation and maintenance of channel structure and off-channel habitats in some types of streams (Naiman et al. 1988). When reintroduced, and managed, they can be an effective way of restoring some types of habitats and natural channel form. Moderately high effectiveness is assumed.
4. Restore degraded channel structure/complexity			
	Restore natural channel form	0.32	Measures to natural channel form can be limited by how channels and floodplains have been altered by past land use practices. Channel incision, for example, can be difficult to reverse. A moderate level of effectiveness is assumed.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Large wood enhancement	0.32	Enhancement of large wood can have a significant effect on channel form and function, in both small and large streams. The ability of large wood to so function depends in part on its abundance, size, and type of wood, and on the size and geomorphology of the stream system (Maser and Sedell 1994; Collins et al. 2003; Fox 2001; Fox 2003). When wood can be completely restored to its pre-development level, it can very effectively restore channel conditions, though not necessarily to pre-development conditions due to other operating factors (such as change in hydrograph, sediment loading, floodplain development, etc.). However, wood enhancement is often limited by availability, size classes available, ability to locate properly, and other logistical difficulties. Additionally, wood enhancement is usually not maintained, hence it can be naturally depleted without future recruitment. A moderate level of effectiveness is assumed.
	Add structure	0.32	Similar limitations exist in adding structure of various kinds to streams as for large wood enhancement. A moderate level of effectiveness is assumed.
	Stabilize streambanks	0.32	Stream bank stabilization is affected by various factors besides just what can be affected at specific sites at the time of implementation. Success is often determined by factors occurring at the landscape level. Well designed stabilization projects can be quite effective, however. Overall, a moderate level of effectiveness is assumed.
	Build pool weirs	0.08	Success of actions that construct pool weirs are often strongly affected by factors outside the control of managers, such as those occurring at the landscape scale (Beechie and Bolton 1999). Such structures often fail. Well designed structures do sometimes persist and can promote creation of long-term habitats that are desired. Overall, a low level of effectiveness would be more normal; a low level is assumed here.
	BMP bridge maintenance	0.01	BMPs to maintain bridges, their footings, and adjacent stream banks are needed to reduce effects of bridges on surrounding aquatic habitats. Overall, a negligible effectiveness is assumed, however, due the limited scope of their effect on stream habitat.
	LWD education	0.32	Maintenance and protection of large wood recruited to streams is often highly dependent on the level of scavenging that occurs for wood from active flood channels by local residents. In some areas, wood recruited to streams is very rapidly removed by local residents. Reasons for removal are use for firewood and a belief that wood removal will promote stream stability. Well designed, concerted efforts to educate local residents about the importance of maintaining in-stream wood is assumed to be moderately effective--such effectiveness could only be achieved by a long-term commitment to address the issue.\
5. Restore riparian condition and LWD recruitment			
	Restore riparian communities	0.80	It is assumed here that restoring riparian communities over a substantially long reach can be very effective when various conditions can be controlled (such as controlling grazing----Platts 1991) and where natural watershed processes are largely intact (such as having a normative or natural hydrograph--Naiman et al. 2005). Intensive efforts to restore riparian conditions can produce significant progress towards predevelopment conditions in relatively few years in some ecoregions (Opperman and Merenlender 2004). This level of effectiveness is assumed to be applicable to an eastside ecoregion. With an intensive application to restore conditions, and in conjunction with activities that simultaneously restore the natural hydrograph, effectiveness is assumed to be very high.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Improve grazing practices	0.32	Grazing practices can be managed to reduce impacts on sediment loading, temperature, stream bank and channel stability, and other aspects of stream habitat (Elmore 1992). A moderate level of effectiveness is assumed for a comprehensive program of improving grazing practices.
	Eradicate invasive plants	0.08	Invasive plants are widespread in all Northwest watersheds. Some species are changing the structure of stream channels due to their prolific growth. An intensive effort to control invasives would have very limited success due to their extensive distributions and productivity. A low level of effectiveness is assumed.
	Fencing	0.80	Enclosures, such as by fencing, can have significant success in restoring riparian areas within eastside streams (Opperman and Merenlender 2004). A similar level of effectiveness is assumed here as described for "Restore riparian communities", i.e., very high effectiveness.
	Off-stream livestock watering	0.32	Off-stream livestock watering can significantly aid in reducing grazing pressure immediately adjacent to streams. A moderate level of effectiveness is assumed with a concerted effort to achieve the objective.
	Riparian plantings	0.32	Riparian plantings can accelerate and promote restoration of riparian areas. However, they would have limited success without on-going efforts to control grazing. A moderate level of effectiveness is assumed.
	Increase riparian shading	0.32	This action is like that of "Riparian plantings." A moderate level of effectiveness is assumed.
	No cultivation buffer zones	0.56	In areas where farming occurs, no cultivation buffer zones will be effective at re-establishing riparian communities. A moderately high level of effectiveness is assumed where such restrictions are maintained; some level of impact could remain present due to other activities besides cultivation.
	Maintain RHCAs on USFS lands	0.32	The action would maintain existing widths on USFW riparian habitat conservation areas, which provide some level of protection while allowing for grazing and other management activities. The level of effectiveness for this action is considered moderate, as certain types of impacts would persist, but conditions in the riparian area would be improved over existing conditions.
	Remove riparian roads	0.56	This action would remove riparian riparian roads, which are highly intrusive to riparian corridors, adding sediment, intercepting and diverting groundwater seeps, and impeding other floodplain functions. Effectiveness at restoring certain conditions within the floodplain corridor of this action is deemed moderately high.
	Riparian protection	0.32	This action would afford protection to some types of riparian areas and any unstable areas associated with them. The action would also provide passive restoration, which would help recover any degraded aspects of the riparian area. It is considered to be moderately effective as it is unclear what types of activities might continue to be allowed.
6. Restore natural hydrograph components			
	Ag water conservation	0.32	This action would implement certain conservation measures on agricultural uses of water to the extent that opportunities exist. In areas where such opportunities do exist, a moderate level of effectiveness is assumed. Actual realized effectiveness would be limited by opportunities.
	Improve irrigation conveyance	0.56	This action would target irrigation conveyance systems to improve their efficiency and reduce water wastage.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Orchard Ridge/Wolf Run	0.32	Within the Fifteenmile subbasin, Orchard Ridge Ditch and Wolf Run Ditch have a combined total of about 12 miles of unpiped ditches with significant water loss. Piping both of these ditches would save approximately 1.5 cfs each, which, according to the Oregon State "Allocation of Conserved Water Statute", could be allocated partially to instream flow and partially to the water rights holders (Fifteenmile subbasin plan). Because of this sharing between providing for instream use, together with providing an allocation to users, a moderate level of effectiveness was assigned.
	Urban conservation	0.08	Urban water users are considered a relatively small water use in the subbasins of concern, except in some specific areas. Also, continued growth in these areas will limit effectiveness of conservation measures. A low effectiveness is assigned.
	Convert water rights	0.32	Under an aggressive program to lease or purchase rights and convert the water to flow downstream, a moderate level of effectiveness is assumed. Realized effectiveness would be a function of opportunity (seen in action intensity).
	Regulate water withdrawals	0.32	This action would implement a more accountable form of monitoring and regulation to better ensure compliance on water withdrawals. A moderate level of effectiveness is assumed.
	Water retention structures	0.08	This action is only applicable to some areas in the Deschutes subbasin. It would place water retention structures in key tributaries to augment flow during low flow periods. The type of structures and their operation remain uncertain and undefined. A low effectiveness is assumed.
	Increase pool habitat (beaver ponds)	0.32	This action would seek to increase pool area habitat (thereby augmenting flow during low flow periods) by facilitating creation of beaver ponds. In areas suitable for such habitat creation, the action should be quite effective. A moderate level of effectiveness is assumed where opportunities exist (specified by the intensity assumption). This action would only be implemented in some areas of the John Day system.
	Floodplain aquifer recharge	0.32	This action would seek to recharge the floodplain aquifer at specific sites and thereby increase flows downstream during periods of low flow. Plan specifics, though not described, suggest a high level of certainty. The level of effectiveness was assumed to be moderate, but realized effectiveness would be limited to opportunities and willingness of land owners.
	H2O rights transfer downstream	0.32	This action would seek to transfer water rights downstream, presumably creating more instream flow within reaches affected by those existing rights. Realized benefits downstream would depend on issues existing in those areas. A moderate level of effectiveness is assumed, but realized benefits would depend on opportunities and arrangements of water rights along the stream corridor.
	Water storage investigate	0.01	This action would be mainly investigative, considering ways of learning new ways of storing water and improving overall efficiency of use in the subbasin. Due to uncertainties, a negligible effectiveness is assumed.
	No new H2O appropriation	0.00	This action would close areas to new water appropriation. While it would protect against increases in water use, it would have no effect on current use.
	Criteria for new H2O appropriation	0.32	This action would set updated criteria to protect flows for fish habitat from new appropriations and it is assumed that it could have a carryover effect to save more water for instream uses than currently allowed. Where opportunities exist, it is assumed to have a moderate effectiveness (though a low intensity of likely opportunities for water savings would make realized effectiveness very small).

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Enhance hyporheic flows	0.08	This action would seek to enhance hyporheic flows and flows in springs. Uncertainty in action details result in this action being assigned a low effectiveness. These types of projects are highly experimental in nature with uncertain expected results.
	Recharge shallow aquifers	0.08	This action would seek to recharge shallow aquifers. Uncertainty in action details result in this action being assigned a low effectiveness. Plan specifics state that certainty of outcome is undetermined. These types of projects are highly experimental in nature with uncertain expected results.
	Aquifer storage & recovery	0.08	This action would seek to improve aquifer storage and recharge. Plan specifics state that the effectiveness of the action is "unknown." A low effectiveness is assumed.
	Umatilla Basin Project Phase I and II	0.32	Phase I and II of the Umatilla Basin Project are currently meeting certain critical flow needs in the mainstem of the Umatilla River. The program would be continued under this action. Target flows for the Umatilla River mainstem were established as part of the Basin Project to meet essential life history needs of Chinook and coho salmon and steelhead. The Basin Project as currently implemented does not provide adequate water to meet the target flows throughout all of the times needed by these species, and fails to provide any flow mitigation for a significant length of the river in July and August. It is assumed that project effectiveness under this action is moderate (see additional details spelled out in the Umatilla subbasin plan).
	Umatilla Basin Project Phase III	0.32	Phase I and II of the Umatilla Basin Project are currently meeting certain critical flow needs in the mainstem of the Umatilla River. Target flows for the Umatilla River mainstem were established as part of the Basin Project to meet essential life history needs of Chinook and coho salmon and steelhead. Phases 1 and II do not provide adequate water to meet the target flows throughout all of the times needed by these species, and fails to provide any flow mitigation for a significant length of the river in July and August. Phase III would keep a substantial amount of Umatilla River water instream. This action is assigned a moderate level of effectiveness (combined with Phase I and II action, it would result in an overall effectiveness of moderately high).
	ISWRs	0.32	While instream water rights (ISWRs) have been established on many of the important spawning and rearing stream in the Umatilla and Walla Walla subbasins, some have not. Where important spawning and rearing streams have not been protected by instream water rights, appropriate instream flow studies would be conducted and instream water rights applied for. It is assumed that a moderate level of effectiveness for this action would result.
7. Improve degraded water quality			
	Manage irrigation return flow	0.08	This action would consist of measures to reduce irrigation return flow to streams--or improve its quality--to reduce extreme water temperatures. This action is assigned a low effectiveness due to strong influence of other factors affecting high water temperatures in the subbasins of interest. Types of measures to minimize return flows are listed as use of cover crops, straw mulch, and grass filter strips (Middle Deschutes Local Advisory Committee 2006).
	Measures to improve DO	0.08	This action would consist of measures to reduce unnatural factors that affect dissolved oxygen levels in the streams of interest. This action is assigned a low effectiveness due to strong influence of other factors affecting nutrient loading, flow levels, water temperatures and related oxygen levels in the subbasins of interest.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Reduce chemical pollution	0.32	This action addresses chemical (e.g., pesticides) pollution related to agricultural practices in the Fifteenmile, Deschutes, and John Day subbasins. Actions specified in the plan state that levels reaching streams are generally unknown and need to be determined. The plan also states that certainty of outcome of treatment is moderate to high (depending on subbasin). Action effectiveness assigned here is moderate. Realized effectiveness would be determined by the intensity of application of the action (but given uncertainties in where and when the problem is occurring, a low intensity is applied.
	Implement Ag WQP	0.32	This action calls for implementation of an agricultural water quality plan in the Fifteenmile and Deschutes subbasins. The plans are locally-driven area-wide plans that address agricultural water quality problems while providing a regulatory backstop. The plans provide landowner flexibility in solving local water quality issues. Enforcement is not a primary method for assuring success, although compliance is a component. The planning teams responsible for Section 9 (this plan) expect certainty of outcome to be high in both basins and suggest a significant degree of success. A moderate level of effectiveness is assumed here in both subbasins (with a high level of intensity of application).
	TMDL monitoring	0.08	This action utilizes TMDL monitoring to help trigger the formulation of management plans to address specific water quality issues. All of the issues that might trigger a TMDL response management plan are addressed through other actions in this suite of actions. Therefore, an effectiveness of low is assigned to this action as an add-on effect, presuming that TMDL monitoring will aid in making other actions more effective.
	Reduce mine discharge toxicants	0.32	This action addresses past mining in the John Day subbasin. The action is described by the planning team as having a high certainty of outcome, although it would be contingent upon adequate maintenance of needed components. The action would require long term implementation. An effectiveness of moderate is assumed given uncertainties associated with long-term maintenance.
	Animal feeding BMPs	0.56	This action is aimed at a small number of feedlots in the John Day subbasin, which operate in conjunction with use of riverside meadows for winter feeding operations. The plan (Section 9) states that certainty of outcome, once a treatment has been agreed upon, is high. A moderately high effectiveness level is assigned to the action.
	Point source pollution controls	0.56	This action addresses point source pollutants in the Umatilla and Walla Walla subbasins. It primarily targets chemical pollutants. The planning team (Section 9) identified a high certainty of outcome. Because point sources are easier to control than non-point sources, and means have been identified for assessing load levels in streams of concern, a high effectiveness is assigned here.
	H2O quality mgmt plans	0.32	This action that addresses water quality issues is specified to be applied in the Umatilla and Walla Walla subbasins. It is not specifically stated to be an Agricultural Water Quality Plan (implemented through provisions of Senate Bill 1010) but presumably it could be. See related rationale for effectiveness under "Implement Ag WQP" above. The planning teams that outlined this action (Section 9) identified the degree of implementation for this action to be uncertain in both subbasins but suggested a moderate level of success. The level of effectiveness assumed here is moderate (realized effectiveness will be a function of implementation intensity, which here is also assumed to be moderate).

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Pest mgmt plans for fruit growers	0.32	This action addresses fruit pests in the Walla Walla subbasin. It is assumed here that it encompasses all aspects described below for "Implement IFPnet plans." A moderate level of effectiveness is assumed.
	Municipal stormwater mgmt	0.32	This action addresses municipal stormwater management in the Walla Walla basin. Technology for managing stormwater runoff in municipalities is developed in general and can be applied. The level of effectiveness is related to some degree by how aggressive a program is designed to be. The planning team (Section 9) stated that the outcome of implementation is uncertain. Part of this uncertainty may be related to the human population growth in the targeted areas. A moderate level of effectiveness is assumed here because of the relatively small areal extent of urbanization in the targeted subbasins relative to the extent in other areas of the Pacific Northwest. Effectiveness is likely to be related to the extent of urbanization and remains essentially experimental (Konrad 2003).
	Waterway alteration permitting	0.00	This action would require permitting of waterway alteration activities, presumably that are expected in the mainstem Walla Walla River. “Waterway alteration” means any action that will result in excavation, dredging, filling, rechannelization, construction, or any other type of modification of an aquatic habitat areas occupied by ESA-listed species that will affect the conservation value of that habitat. Under Section 9 of this document, it states "While permit processes implemented by the US Army Corps of Engineers are thorough and actions authorized are protective of aquatic resources, the program lacks personnel resources to insure that terms and conditions of permitted actions are followed. In addition, this agency lacks resources to adequately monitor waterways for non-permitted actions or act upon non-permitted situations reported by other agencies or private parties." This action is meant to provide protection against presumed future waterway alterations in the Walla Walla River. As such, an effectiveness of "no effect" is assigned here that would benefit habitat values.
	Permitting for H2O quality activities	0.00	This action would provide for improved permitting and enforcement of activities that might degrade water quality in the Walla Walla subbasin. The action is only relevant in the present analysis if other actions (such as build-out) are to be analyzed that would degrade water quality, in which case the action would serve protect. As such, an effectiveness of "no effect" is assigned here that would benefit habitat values.
8. Restore upland processes to reduce erosion			
	Convert till farming	0.32	Conversion to no till farming would reduce sediment loading to streams. Replacement of conventional tillage systems for dryland wheat production with new methods, such as direct seed/no till systems, is known to reduce sediment delivery to streams from these typically highly erodible soils. This action would seek to achieve a 95% conversion in targeted areas. A moderate level of effectiveness is assumed though available information is not readily available on effectiveness; realized effectiveness will be strongly driven by the overall scope and distribution of targeted areas.
	Convert to perennial crops	0.32	This action would entail shifting from annual grains to perennial crops in order to reduce erosion. The scope of the action is uncertain but it potentially could produce a significant reduction in sediment delivery to streams. A moderate level of effectiveness was assumed; realized effectiveness will be strongly driven by the overall scope and distribution of targeted areas.
	Implement IFPnet plans	0.32	This action is aimed at promoting use of less toxic pesticides in the concentrated fruit orchards of the Fifteenmile subbasin. The program is described in Cockrum and Omeg (2003). A moderate level of effectiveness is assumed on reported results. Note: action should more correctly be placed under Strategy 7.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Improve/remove forest roads	0.32	Roads are a major source of sediment in managed watersheds. Road closures, obliteration, and improvements known to be effective at reducing sediment loading to streams. A moderate level of effectiveness is assumed; realized effectiveness will be strongly driven by the amount of roads closed or improved (defined by the intensity factor).
	Reforest/fuels management	0.32	This action calls for improvements in fuels management and should overtime reduce potential erosion of soils and sediment delivery to streams. Intensive application should provide a moderate level of effectiveness.
	Upland demo projects	0.32	This action calls for demonstration projects to show the benefits of new concepts in land management, thus their scale of implementation is necessarily small. In areas where implemented, it can be assumed that they should demonstrate benefits, hence a moderate level of effectiveness is assumed.
	BMPS to reduce soil erosion	0.32	Best management practices to promote improved land use practices are generally known and further improvements in understanding can be expected in the near future as there are on-going studies to address this issue. A moderate effectiveness is reasonable to expect as a result of continued progress in how lands are being managed. It is expected that land owners will over time improve their practices in the uplands. (This action is essentially the same as "BMPs on land uses" - the two actions are called for in different subbasins.)
	Remove junipers	0.32	Western juniper has increased in abundance in eastern Oregon due to changes in land use management practices, principally reduction in fire. Juniper removal is one management technique to reduce the density of junipers. Because of the water use of junipers, groundwater levels have been affected (even significantly) where junipers are in high abundance. Removal of junipers has been shown to have a significant effect on water yield where removal is extensive. This can also change vegetation patterns and species, promoting grasses and reducing erosion. It is assumed that effectiveness is moderate when removal occurs on a large enough scale. See for example http://egov.oregon.gov/ODF/AGENCY_AFFAIRS/Juniper_Story.shtml and http://www.oregon.gov/OPSW/stories/lakes_basin.shtml
	Restore native upland plants	0.32	This action would seek to restore natural assemblages of plant species in upland communities, promoting more natural hydrographs and improved erosion control. When intensively conducted, a moderate effectiveness is assumed.
	Invasive plant mgmt & junipers	0.32	This action would combine activities in the two actions above, affording improved erosion control and more natural water yield patterns. When intensively conducted, a moderate effectiveness is assumed.
	BMPs on land uses	0.32	Best management practices to promote improved land use practices are generally known and further improvements in understanding can be expected in the near future as there are on-going studies to address this issue. A moderate effectiveness is reasonable to expect as a result of continued progress in how lands are being managed. It is expected that land owners will over time improve their practices in the uplands.
	CREP & CCRP buffers	0.32	This action would implement a Continuous Conservation Reserve Program and a Conservation Reserve Enhancement Program for streamside buffers, affording voluntary, non-competitive, programs for agricultural landowners built on financial incentives. Voluntary participation by local landowners is sought through a cost share program designed to restore and enhance habitat and increase bank stability along waterways on private lands with a cropping history. It is implemented in areas with highly erodible soils. When implemented fully, it should be quite effective, here it was assumed to have a moderate effectiveness (vs. a higher effectiveness) due to uncertainties in reported results that were reviewed.

Table H-3B. Action effectiveness values.

Strategy	Action	Effect.	Rationale/comment
	Outreach to upland users	0.32	Education and on-going interactions with upland land owners is deemed critical to restore vegetation and reduce erosion. Where intensively implemented, an add-on benefit is assumed, producing a greater effectiveness to targeted practices for reducing erosion. A moderate level of effectiveness is assumed.

Table H-4A and B. Action implementation intensity assumptions and levels applied in analysis (A) and corresponding intensity scalars assigned to each action with rationale/comments (B). See Section 10 for how intensity scalars were applied.

Table H-4A. Action implementation intensity levels.

Intensity level	Definition	Scalar
1	Very high	0.85
2	High	0.40
3	Moderate	0.15
4	Low	0.05
5	Negligible	0.02
6	None	0.00

Table H-4B. Action implementation intensity scalars.

Strategy	Action	Scalar	Rationale/comment
1. Protect/conserve ecological processes			
	Acquisition/conservation	0.05	Areas to be acquired or conserved for habitat values will likely be low relative to the sheer size of areas designated to encompass set-asides.
	Protect rare functioning habitats	0.15	Reasonable attempts would be made to fully protect rare functioning habitats where opportunities exist; assume moderate intensity.
	BMPs to conserve eco processes	0.15	Moderate intensity overall would be reasonable to expect for realizing BMPs in conserving ecological processes.
	Cooperative Agreements	0.40	A high intensity of implementation would be prudent in initiating new cooperative agreements.
	Special mgmt designations	0.05	New Special Management Designations are not expected to exceed a low intensity of implementation.
	Increase wild-scenic status	0.15	New Wild and Scenic Status could likely not be expected to exceed a moderate intensity of implementation.
	Protect access to key habitats	0.00	Issue is covered completely by other actions as this action was described; not given an intensity value here.
	Outreach to users and managers	0.05	Low intensity of implementation is expected for this action because education can be expected to accompany other line item actions.
	Public lands protection	0.05	Protection of public lands are integral part of various other actions within the action list; a low intensity of additional implementation is afforded this action as an add-on to the other actions.
	Waterway setbacks	0.15	Moderate intensity overall would be reasonable to expect for initiating new waterway setbacks in targeted stream segments.
	Enforce floodplain regs	0.15	Moderate intensity overall would be reasonable to expect for implementing new activities designed to enforce floodplain regulations.
	Natural Area Overlay Zone	0.15	Moderate intensity overall would be reasonable to expect for realizing BMPs in conserving ecological processes.
	Legislate priority areas	0.02	A very low (negligible) level of intensity is envisioned in legislating new priority measures. This measure is largely investigative. Many other avenues are considered to be in place or proposed for action to address such issues.
2. Restore fish passage blocked/impaired by barriers			
	Barrier removal	--	All barriers identified in Section 9 to be addressed would be targeted for action.
	Add irrigation screening	0.85	A very high level of intensity of implementation is assumed to add irrigation screening where it is currently lacking.

Table H-4B. Action implementation intensity scalars.

Strategy	Action	Scalar	Rationale/comment
	Pelton Round Butte passage	--	Passage will be implemented at the Pelton Round Butte complex; it is also assumed that passage will be implemented at diversion barriers in Whychus Creek.
	Upgrade irrigation screening	0.40	A high level of implementation intensity overall would be prudent to expect for upgrading screens as they are determined to be under performing.
	Reduce push up dams	0.40	A high level of implementation intensity overall would be prudent to address push up dams in selected stream segments.
	Fish ladder construction	--	This matter is addressed under Barrier removal above.
	Maintain passage facilities	--	It is expected that efforts will be sufficiently implemented to maintain passage facilities in good working condition.
3. Restore floodplain connectivity and function			
	Reconnect floodplain	0.15	A moderate level of implementation intensity overall is reasonable to expect for reconnecting floodplain habitats in selected stream segments.
	Reconnect side channels	0.15	A moderate level of implementation intensity overall is reasonable to expect for reconnecting side channels in selected stream segments.
	Reintroduce beaver	0.15	A moderate level of implementation intensity overall is reasonable to expect for restoring beaver populations as watershed functions are gradually restored, and more normative stream channel and floodplain conditions are restored.
	Restore wet meadows	0.15	A moderate level of implementation intensity overall is reasonable to expect for restoring wet meadows in selected stream segments as related watershed functions are gradually restored.
	Dike removal	0.15	A moderate level of implementation intensity overall is reasonable to expect for dike removal in selected stream segments as watershed function gradually restored.
	Manage beavers	0.05	A low level of implementation intensity is assumed to be needed for beaver management. Uncertainty about issues related to effects of beavers on private properties in the targeted areas exist, however.
4. Restore degraded channel structure/complexity			
	Restore natural channel form	0.15	A moderate level of implementation intensity overall is reasonable to expect for restoring channel form in selected stream segments as related watershed functions are gradually restored.
	Large wood enhancement	0.15	A moderate level of implementation intensity overall is reasonable to expect for actively enhancing large wood quantities in the active channel in selected stream segments (in conjunction with related actions such as LWD education).
	Add structure	0.15	A moderate level of implementation intensity overall is reasonable to expect for adding a diversity of structure to selected stream reach segments.
	Stabilize streambanks	0.15	A moderate level of implementation intensity overall is reasonable to expect for stabilizing streambanks in selected stream segments.
	Build pool weirs	0.02	Because this action frequently is ineffective, only a very low (negligible) level of implementation intensity overall is expected in selected stream segments.
	BMP bridge maintenance	0.02	A low level of implementation is assigned to this action (note: the author of the analysis subsequently concluded that a high level of intensity would be prudent for this action - though this would have an inconsequential effect on the overall analysis due to the very low effectiveness assigned to this action).
	LWD education	0.15	A moderate level of implementation intensity overall is reasonable to expect for providing LWD education in areas targeted for restoration.

Table H-4B. Action implementation intensity scalars.

Strategy	Action	Scalar	Rationale/comment
5. Restore riparian condition and LWD recruitment			
	Restore riparian communities	0.40	A high level of implementation intensity overall should be pursued for this action, as riparian integrity is deemed so important for the overall health of the stream and its populations. Riparian restoration has a very high effectiveness.
	Improve grazing practices	0.15	A moderate level of implementation intensity overall is prudent to expect for improving grazing practices in areas targeted for restoration work.
	Eradicate invasive plants	0.15	A moderate level of implementation intensity overall is reasonable to expect for eradicating invasive plants in areas targeted for restoration work.
	Fencing	0.40	A high level of implementation intensity overall should be pursued for this action in stream segments with opportunities for restoration. Fencing is an effective tool for restoring riparian zones. Riparian restoration has a very high effectiveness.
	Off-stream livestock watering	0.15	A moderate level of implementation intensity overall is prudent to expect for achieving off-stream livestock watering.
	Riparian plantings	0.15	A moderate level of implementation intensity overall is reasonable to expect for using riparian plantings in selected stream segments.
	Increase riparian shading	0.15	A moderate level of implementation intensity overall is reasonable to expect using various means to increase riparian shading in selected stream segments.
	No cultivation buffer zones	0.05	A low level of implementation is assigned to this action due to uncertainties about opportunities for establishing no cultivation buffers.
	Maintain RHCAs on USFS lands	0.85	A high level of implementation intensity overall should be pursued for this action in stream segments targeted with USFW lands.
	Remove riparian roads	0.15	A moderate level of implementation intensity overall is prudent to expect for removal of riparian roads in the stream segments targeted.
	Riparian protection	0.15	A moderate level of implementation intensity overall is prudent to expect protecting riparian areas associated with new riparian measures.
6. Restore natural hydrograph components			
	Ag water conservation	0.15	A moderate level of implementation intensity overall is prudent to expect for initiating new water conservation measures on agricultural lands. This action includes application and not conveyance systems.
	Improve irrigation conveyance	0.40	A high level of implementation intensity overall is warranted for improving irrigation conveyance as an effective way of reducing leakage/loss of water in arid areas selected for restoration work.
	Orchard Ridge/Wolf Run	0.85	A very high level of implementation intensity overall is assumed for completion of these two irrigation systems in Fifteenmile subbasin.
	Urban conservation	0.15	A moderate level of implementation intensity overall is assumed for urban water conservation measures.
	Convert water rights	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities.
	Regulate water withdrawals	0.40	A high level of implementation intensity overall is warranted for monitoring and regulating water withdrawals consistent with laws, regulations, and agreements.
	Water retention structures	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities.
	Increase pool habitat (beaver ponds)	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities that would likely have the desired result for augmenting stream flow.

Table H-4B. Action implementation intensity scalars.

Strategy	Action	Scalar	Rationale/comment
	Floodplain aquifer recharge	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities that would likely have the desired result for augmenting stream flow. The action is seen as being highly experimental.
	H2O rights transfer downstream	0.15	A moderate level of implementation intensity overall is prudent to expect for transfer of water rights downstream, if opportunities avail themselves to implementation.
	Water storage investigate	0.02	This action would be mainly investigative, considering ways of learning new ways of storing water and improving overall efficiency of use in the subbasin. Due to uncertainties, a negligible intensity of implementation is assumed here. Other actions would serve the same purpose and are included with higher intensities.
	No new H2O appropriation	0.00	This action would close areas to new water appropriation. While it would protect against increases in water use, it would have no effect on current use. A zero intensity of implementation would occur that could help restore flow to the stream.
	Criteria for new H2O appropriation	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about real opportunities for new water appropriations.
	Enhance hyporheic flows	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities that would likely have the desired result for augmenting stream flow. The action is seen as being highly experimental.
	Recharge shallow aquifers	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities that would likely have the desired result for augmenting stream flow. The action is seen as being highly experimental.
	Aquifer storage & recovery	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities that would likely have the desired result for augmenting stream flow. The action is seen as being highly experimental.
	Umatilla Basin Project Phase I and II	0.85	A very high level of implementation intensity is assumed in maintaining Phases I and II of the project.
	Umatilla Basin Project Phase III	0.85	A very high level of implementation intensity is assumed in implementing Phase III of the project.
	ISWRs	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about opportunities.
7. Improve degraded water quality			
	Manage irrigation return flow	0.40	A high level of implementation intensity overall is warranted so that irrigators are performing as effectively as they can reasonably do in reducing effects of return flow.
	Measures to improve DO	0.15	A moderate level of implementation intensity overall is prudent to expect for reducing unnatural factors that affect dissolved oxygen in targeted stream segments.
	Reduce chemical pollution	0.05	A low level of implementation intensity is assigned to this action given uncertainties in where and when the problem is occurring.
	Implement Ag WQP	0.40	A high level of implementation intensity overall is expected in the Fifteenmile and Deschutes subbasins in implementing Agricultural Water Quality Plans.
	TMDL monitoring	0.15	A moderate level of implementation intensity is expected for TMDL monitoring in the targeted subbasins.
	Reduce mine discharge toxicants	0.40	A high level of implementation intensity overall is expected to be targeted on known areas of mining pollution in the John Day subbasin.

Table H-4B. Action implementation intensity scalars.

Strategy	Action	Scalar	Rationale/comment
	Animal feeding BMPs	0.15	A moderate level of implementation intensity overall is expected to be targeted on areas used as animal feedlots, as there are only a few sites of concern.
	Point source pollution controls	0.40	A high level of implementation intensity overall should be pursued for this action in targeted stream segments. Point source pollution is readily identifiable and can be addressed through monitoring and attentive solutions.
	H2O quality mgmt plans	0.15	A moderate level of implementation intensity overall is expected in the Umatilla and Walla subbasins in implementing new water quality plans due to uncertainties about participation (as described in Section 9 for this action).
	Pest mgmt plans for fruit growers	0.40	A high level of implementation intensity overall is prudent to expect in targeted stream segments using the IFPnet model developed on in Fifteenmile Creek, based on. The IFP project has grown out of the public's concern over pesticide residues on food, exposure to farm workers, and contamination in the environment (Cockrum and Omeg 2004).
	Municipal stormwater mgmt	0.15	A moderate level of implementation intensity overall is prudent to expect for addressing stormwater runoff in municipal areas given the level of concern that accompanies this in watersheds of the Pacific Northwest as it relates to effects on salmonids (Konrad 2004). Uncertainties exist, however, about effectiveness and approaches are still largely experimental.
	Waterway alteration permitting	--	This action is by intent for protection purposes only -- it provides no restoration purpose. The effectiveness assumption was set to zero, therefore intensity of implementation has no scaling effect in this case.
	Permitting for H2O quality activities	--	This action is by intent for protection purposes only -- it provides no restoration purpose. The effectiveness assumption was set to zero, therefore intensity of implementation has no scaling effect in this case.
8. Restore upland processes to reduce erosion			
	Convert till farming	0.15	A moderate level of implementation intensity overall is prudent to expect for reducing erosion through this action given levels of concern about soil loss and sedimentation of streams in the targeted subbasins.
	Convert to perennial crops	0.15	A moderate level of implementation intensity overall is prudent to expect for reducing erosion through this action given levels of concern about soil loss and sedimentation of streams in the targeted subbasins.
	Implement IFPnet plans	0.40	A high level of implementation intensity overall is prudent to expect in targeted stream segments using the IFPnet model developed on in Fifteenmile Creek, based on. The IFP project has grown out of the public's concern over pesticide residues on food, exposure to farm workers, and contamination in the environment (Cockrum and Omeg 2004).
	Improve/remove forest roads	0.40	A high level of implementation intensity overall is expected for this action in targeted areas of the subbasins. Forest roads are frequently major sources of sediment in streams of the Pacific Northwest, including those in central and northeast Oregon.
	Reforest/fuels management	0.40	A high level of implementation intensity overall is expected for this action in targeted areas of the subbasins. Significant concerns about forest health and fire management exist in the forested portions of watersheds in central and northeast Oregon.
	Upland demo projects	0.02	An overall very low (negligible) implementation intensity is expected for this action given uncertainties about benefits relative to other actions with known benefits.

Table H-4B. Action implementation intensity scalars.

Strategy	Action	Scalar	Rationale/comment
	BMPS to reduce soil erosion	0.40	A high level of implementation intensity is prudent to achieve BMPs on land practices that result in elevated sediment delivery to targeted segments of streams in the designated subbasins (Fifteenmile and Deschutes). The planning teams that described actions in Section 9 identified certainty of outcome for this action as high, indicating a high degree of participation by stakeholders.
	Remove junipers	0.15	A moderate level of implementation intensity is expected to reduce juniper abundance in targeted areas in the Deschutes subbasin. Benefits accrue to water conservation, fire management, and juniper harvesters. See planninhttp://egov.oregon.gov/ODF/AGENCY_AFFAIRS/Juniper_Story.shtml
	Restore native upland plants	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about participation suggested in description of action in Section 9 in the designated subbasins.
	Invasive plant mgmt & junipers	0.05	A low level of implementation intensity is assigned to this action due to uncertainties about participation suggested in description of action in Section 9 in the designated subbasins.
	BMPs on land uses	0.15	A moderate level of implementation intensity is expected to achieve BMPs on land practices associated with a variety of factors afffecting targeted segments of streams in the designated subbasins (John Day, Umatilla, and Walla Walla). The planning teams that described actions in Section 9 identified certainty of outcome for this action as moderate based on uncertainties about extent of voluntary participation by stakeholders.
	CREP & CCRP buffers	0.15	A moderate level of implementation intensity is expected for participation in the CREP and CCRP programs in the Walla Walla subbasin. Walla Walla County has roughly 25% of the CREP for the entire state of Washington, though state funding is currently uncertain.
	Outreach to upland users	0.02	Very low (negligible) intensity of implementation is projected for this action because education can be expected to accompany other line item actions.

Table H-5. Action effectiveness lag scalars applied to habitat actions. Lag scalars are assumed values, representing the expected amount of the potential effectiveness that would be realized 25 years after implementation. A lag scalar value reflects the expected rate that an action's effectiveness will mature with time (e.g., due to tree growth, change in sediment load, reshaping of hydrograph) . All lag scalars were assumed to attain values of 1.0 after 100 years. See Section 10 for how lag scalars were applied.

Table H-5. Action effectiveness lag scalars at 25 years.

Strategy	Action	Scalar
1. Protect/conserve ecological processes		
	Acquisition/conservation	0.50
	Protect rare functioning habitats	0.80
	BMPs to conserve eco processes	0.80
	Cooperative Agreements	0.70
	Special mgmt designations	0.70
	Increase wild-scenic status	0.70
	Protect access to key habitats	0.70
	Outreach to users and managers	0.70
	Public lands protection	0.50
	Waterway setbacks	0.80
	Enforce floodplain regs	0.80
	Natural Area Overlay Zone	1.00
	Legislate priority areas	0.80
2. Restore fish passage blocked/impaired by barriers		
	Barrier removal	1.00
	Add irrigation screening	1.00
	Pelton Round Butte passage	1.00
	Upgrade irrigation screening	1.00
	Reduce push up dams	1.00
	Fish ladder construction	1.00
	Maintain passage facilities	1.00
3. Restore floodplain connectivity and function		
	Reconnect floodplain	0.80
	Reconnect side channels	0.80
	Reintroduce beaver	0.80
	Restore wet meadows	0.70
	Dike removal	0.90
	Manage beavers	0.90
4. Restore degraded channel structure/complexity		
	Restore natural channel form	0.80
	Large wood enhancement	1.00
	Add structure	0.90
	Stabilize streambanks	0.90
	Build pool weirs	1.00
	BMP bridge maintenance	1.00
	LWD education	1.00

Table H-5. Action effectiveness lag scalars at 25 years.

Strategy	Action	Scalar
5. Restore riparian condition and LWD recruitment		
	Restore riparian communities	0.70
	Improve grazing practices	0.80
	Eradicate invasive plants	0.90
	Fencing	0.80
	Off-stream livestock watering	1.00
	Riparian plantings	0.80
	Increase riparian shading	0.80

Table H-6. Action implementation schedule scalars at 25 years applied to habitat actions. Implementation schedule scalars define how the schedule for implementing an action—relative to what might be considered year 0 of a recovery program—would affect realized effectiveness in either year 25 or year 100 of the program. Use of this scalar in the analysis recognizes that the recovery programs will be long-term in implementation due to their very extensive scope. The planning teams who described actions (Section 9) specified implementation schedules. See Section 10 for how lag scalars were applied.

Table H-6. Action implementation schedule scalars at 25 years.

Strategy	Action	Fifteenmile	Deschutes	John Day	Umatilla	Walla Walla
1. Protect/conserve ecological processes						
	Acquisition/conservation	0.80	0.96	0.80	0.80	0.80

	Restore native upland plants		0.90	0.90	0.90	0.90
	Invasive plant mgmt & junipers			0.90		
	BMPs on land uses			0.90	0.90	0.90
	CREP & CCRP buffers					0.95
	Outreach to upland users					0.90

Table H-8. Attribute scalars applied to habitat actions. Attribute scalars define whether the potential effectiveness of an action will be the full amount (scalar = 1) or reduced due to an attribute effect. Some actions have no effect on some attributes (scalar = 0). For each action, attributes were identified as being affected or not affected. A scalar of 1 was assigned to any attribute that would be affected, except for those that characterize some aspect of sediment, flow, and temperature. Scalars for these were set to 0.75, recognizing that these attributes are broadly affected by watershed conditions and can be more difficult to influence than attributes driven mainly by site-specific conditions. See Section 10 for how scalars were applied. See Table H-9 for definitions of attributes.

Table H-8. Attribute scalars.

Table H-9. Definitions of freshwater habitat attributes shown in Table H-8 (shown as attribute codes there). The attributes are applied in EDT analysis.

Attribute code	Attribute name	Definition
BdScour	Bed scour	Average depth and frequency of bed scour of small-cobble/gravel substrates of pool-tail outs, glides, and riffles during high flow events.
BenComRch	Benthos diversity and production	Measure of the diversity and production of the benthos community.
ConfineHydro	Confinement - Hydromodifications	The extent that man-made structures within or adjacent to the stream channel constrict flow (as at bridges) or restrict flow access to the stream's floodplain (due to streamside roads, revetments, diking or levees) or the extent that the channel has been ditched or channelized.
DisOxy	Dissolved oxygen	Average dissolved oxygen within the water column for the specified time interval.
Emb	Embeddedness	The extent that larger cobbles or gravel are surrounded by or covered by fine sediment.
FlwDielVar	Flow - Intra daily (diel) variation	Variability in flow level during a daily period. This attribute is informative mainly for regulated rivers or when flow patterns are influenced by storm water runoff.
FlwHigh	Flow - change in interannual variability in high flows	A measure of between year variation in magnitude of high flow levels and/or the extent of change in overall high flow level during a month relative to an undisturbed watershed of comparable size, geology, and geography.
FlwIntraAnn	Flow - intra-annual flow pattern	The average extent of intra-annual flow variation during a month -- a measure of a stream's "flashiness" during a season.
FlwLow	Flow - changes in interannual variability in low flows	A measure of between year variation in the severity of low flow discharge during a month. Variation in low flows as applied here is relative to an undisturbed watershed of comparable size, geology, and geography.
FnSedi	Fine sediment	Percentage of fine sediment within pool-tailouts and riffles.
HbOfChFctr	Habitat type - off-channel habitat factor	A multiplier used to estimate the amount of off-channel habitat based on the wetted surface area of the all combined in-channel habitat.
HbPls	Habitat type - primary pools	Percentage of the wetted channel surface area comprising pools.
Icing	Icing	Extent (magnitude and frequency) of icing events.
MscToxWat	Miscellaneous toxic pollutants - water column	The extent of miscellaneous toxic pollantants within the water column.
NutEnrch	Nutrient enrichment	The amount of nutrient enrichment consisting of such items as ammonia, nitrogen, phosphorous.
Obstr	Obstructions to fish migration	Obstructions to fish passage by physical barriers (not dewatered channels or hinderances to migration caused by pollutants or lack of oxygen).
RipFunc	Riparian function	A measure of riparian function that has been altered within the reach.

Attribute code	Attribute name	Definition
TmpMonMn	Temperature - daily minimum (by month)	Minimum water temperatures within the stream reach reach during a month.
TmpMonMx	Temperature - daily maximum (by month)	Maximum water temperatures within the stream reach reach during a month.
TmpSptVar	Temperature - spatial variation	The extent of water temperature variation within the reach as influenced by inputs of groundwater.
Turb	Turbidity	The relative extent of turbidity episodes within the stream reach.
WdDeb	Wood	The amount of wood within the reach. Note definition of "large wood" under terms/clarification.
Wdrwl	Water withdrawals	The number and relative size of water withdrawals in the stream reach.
WidthMn	Channel month Minimum width (ft)	Average width of the wetted channel. If the stream is braided or contains multiple channels, then the width would represent the sum of the wetted widths along a transect that extends across all channels.
WidthMx	Channel month Maximum width (ft)	Average width of the wetted channel during peak flow month (average monthly conditions). If the stream is braided or contains multiple channels, then the width would represent the sum of the wetted widths along a transect that extends across all channels.

Out-of-Basin Survival Rates Assumptions

Out-of-subbasin survival rates incorporated into the AHA modeling are listed in Tables H-10 to H-14; their derivation is described below. Each table lists survivals by life stage segment for baseline, current, and prospective future conditions. Prospective future conditions are the scenarios formulated in a stepwise fashion by adding in actions sequentially, each effect being added to the previous scenario (see Table 10-1). Survivals are listed for three life stage segments, followed by the combined survival across the three segments. The survival for each of the three life stage segments encompasses the following:

1. Smolt to smolt (smt-smt) – survival of migrant smolts from the time of departing the subbasin (i.e., entry into the mainstem Columbia River) to the point of immediately downstream of Bonneville Dam;
2. Estuary and ocean (est-ocn) – the smolt to adult survival rate (SAR) covering the entirety of the time spent in the Columbia River estuary (i.e., beginning immediately below Bonneville Dam) and ocean as smolts, sub-adults, and adults; and
3. Adult to adult (adt-adt) – survival of returning adults from the time of departing the Columbia River estuary (i.e., beginning with passage at Bonneville Dam) to the point of entry into the natal subbasin.

Baseline survival rates were formulated from several sources. The baseline smolt to smolt rates were provided for each population by NOAA Fisheries (correspondence between Ritchie Graves and Tracy Hillman dated August 9, 2007). The combined estuary and ocean survival rate was based on an average default value applied in EDT analysis, here rounded to an average of 7.5%. This average rate was applied to each of the populations modeled in AHA. The adult to adult rate

was derived by using the survival rate applied in EDT (extracted by analyzing life history trajectories used in EDT modeling) and the average mainstem harvest rate for the baseline period (converted to a survival rate).[1]

The current years survival rates for each life stage segment k ($Csurv_k$) then are derived as

$$Csurv_k = Bsurv_k \times \prod m_{i,j}$$

where $Bsurv_k$ is baseline survival rate in life stage segment k

$m_{i,j}$ is the survival multiplier for survival factor i and scenario j (here the scenario is the current condition)

The prospective future years (i.e., including future scenario actions) survival rates for each life stage segment k ($Psurv_k$) are then derived as

$$Psurv_k = Csurv_k \times \prod m_{i,j}$$

[1] / The average harvest rate (0.1267) for years 1991-2003 was used for the baseline period, as given in Appendix G of the Comprehensive Analysis dated August 2007.

Table H-10. Out-of-subbasin survival rates applied in AHA modeling for baseline (B), current (C), and prospective future action scenarios for Fifteenmile Creek winter steelhead. Future action scenarios were modeled sequentially, where hydro (Hyd) actions were added to current conditions, predation (Pred) actions were added to hydro, estuarine (Est) actions were added to predation, and harvest (Harv) actions were added to estuarine. Decreased (MarLow) and increased (MarHigh) marine survival rate scenarios were then added to the combined prospective future action scenarios.

Part 2: Summaries of Diagnostic Reports

A series of graphic reports are presented here giving additional information about the predicted outcomes of the subbasin habitat scenarios analyzed in Section 10. These reports are extracted from output produced by EDT.

Summaries from three different EDT reports are provided for each steelhead population. The first report—the Baseline Diagnostic Report—summarizes basic diagnostic information for each population under baseline habitat conditions within the relevant subbasin. It is based on a comparison of habitat conditions within the baseline period to the pre-development state (see Lichatowich et al. 1995). Some of this information served as the basis of parts of the diagnostic summaries described in Section 8 of this report. The baseline diagnostic report serves here to help illustrate—in conjunction the other reports described below—the extent that subbasin habitat factors responsible for changes in population performance are expected to be affected by the proposed habitat scenarios. It shows the relative extent that population performance has been affected by habitat changes (due to land and water uses) within each individual stream reach or geographic area within the subbasin.[2] One aspect of the report displays the potential benefits of full restoration or full protection (i.e., avoiding future habitat degradation) for each stream reach or geographic area. This report (together with a more detailed presentation in the full EDT output) summarizes the limiting factors analysis produced by the EDT model.

The second report—the Scenario Profile Report—summarizes the extent of changes to the habitat factors expected to result from a habitat action scenario once implemented within a subbasin. It identifies the relative gain (or loss in some cases) in population performance that would occur as a result of the scenario's effect within the subbasin. The extent of changes to population performance are shown for the scenario's effects within each stream reach or geographic area.

The third report—the Scenario Diagnostic Report—is like the baseline diagnostic report, only instead of comparing the baseline to the pre-development state, it compares the habitat scenario to the pre-development condition. It identifies the geographic areas and habitat factors that would be expected to still be inhibiting population performance after action implementation relative to the pre-development habitat condition. The report is essentially a limiting factors analysis of the habitat as it is predicted to exist following implementation and maturation of effects of the habitat scenario. As such, it helps identify areas/factors where additional habitat actions might be considered. Hence, it can serve to further refine proposed actions as a part of future planning efforts.

Each report consists of two figures. The first one is a "tornado chart" displaying the potential benefits from restoration or protection actions—or in the case of the Scenario Profile Report the

[2] / The spatial scale used in this report was defined by the individuals who did the original EDT analysis for subbasin planning. In some cases, individuals grouped stream reaches into geographic areas for the sake of simplifying the diagnosis. In some subbasins, reaches were not grouped in such a manner. The graphic reports presented in this appendix employ whatever scale was used in subbasin planning. For definitions of stream reaches or geographic areas, see the appropriate subbasin report.

relative gain/loss of the habitat scenario. Geographic areas near the top of the chart offer the highest potential for gain in performance (or that would result in the highest gain in the Scenario Profile Report). The charts show an assigned level of benefit, listed as A through E, where A areas are those the greatest amount of benefit and D and E provide essentially no benefit. The charts also show the expectation of amount of benefit/loss in population performance as the percentage of increase or decrease in a particular performance measure. (See Section 10 for definitions of performance measures.)

Each tornado chart is followed by a second figure giving a summary of the diagnostics for the various habitat factors affecting survival within each stream reach or geographic area. This chart summarizes where and what factors are most responsible for the loss in population performance. For the Scenario Profile Report, it shows the relative extent that each factor is expected to be affected by the scenario as pertaining to population performance. The chart is meant only to be a summary snapshot of the effects of each factor (or the effects on each factor for the Scenario Profile Report).

Results for the habitat scenario consisting of all subbasin actions (both Priority 1 and 2) at 100 years are presented. For the Deschutes westside population, results are shown passage provided at the Pelton-Round Butte Complex.

APPENDIX I

Oregon Mid-Columbia Steelhead
Cost Estimates for Recovery Actions

Cost Estimates for Recovery Actions
Draft – 9 October 2007

Introduction

The ESA section 4(f)(1) requires that recovery plans include "estimates of the time required and the cost to carry out those measures needed to achieve the Plan's goal and to achieve intermediate steps toward that goal" (16 U.S.C. 1531-1544, as amended). This draft appendix is intended to meet this ESA requirement and will be used by NMFS to estimate the total recovery costs for the Mid-Columbia steelhead DPS in its draft Mid-Columbia Steelhead DPS Plan.

The Oregon Department of Fish and Wildlife (ODFW), together with its Recovery Planning Team, Management Action Teams, and the Oregon Mid-Columbia River Sounding Board have developed an extensive list of projects needed to recover the Oregon populations in the Mid-Columbia steelhead DPS. These projects are intended to address the recovery of ESA-listed Mid-Columbia River steelhead. The project list was developed using the most up-to-date assessment of Mid-Columbia steelhead recovery needs, without consideration of cost or potential funding. This draft appendix provides cost estimates for each project where available information was sufficient to do so.

Methods and Data

The basic approach taken to estimate the cost of each project was to combine estimates of the scale of the project and the cost per scalar unit for that type of project. This method is known as the unit cost method, and it is appropriate when approximate estimates are sufficient. The estimation took the following steps:

1. Actions listed in Section 9 of the draft Mid-Columbia Steelhead DPS Plan were grouped into a set of project types (*e.g.*, bank stabilization and exclusion fencing). In some cases, the actions listed in Section 9 differed only in minor variations in wording; in other cases, actions had more significant descriptive variations but could still be linked to a standard project type.
2. The scale for each action listed in Section 9 was determined using information in that section or supplemental information provided by ODFW. Scale was measured in two basic ways:

    a. Stream miles of treatment, taken from the EDT analysis used in the recovery plan; or
    b. Number of structures, taken from Section 9 of the recovery plan or provided by ODFW.

    In a few cases, the scale of an action was not used in the cost estimation, as the action was unique to a particular location (*e.g.*, Phase III of the Umatilla Basin Project). For

some actions, no scale estimate is available at this time, in which case no cost estimate is provided in this draft appendix.

3. The unit cost of a project type was estimated using cost data from existing habitat restoration projects and professional judgment. These costs reflected the materials and labor needed to implement a project (see step #4 for additional costs). Three sets of data were used to support the estimation of unit costs:

    a. Habitat restoration project costs in the Oregon portion of the NMFS Interior Columbia recovery domain and in adjacent Washington subbasins. The cost data were drawn from three funding sources: the Oregon Watershed Enhancement Board (OWEB) grant program, the Grande Ronde Model Watershed Program (GRMWP), and the Washington State Salmon Recovery Funding Board (SRFB) grant program. This data set included approximately 1400 individual habitat restoration projects. Projects that included only one type of activity were then analyzed to estimate the unit cost of that activity.
    b. GRMWP unit cost estimates. For a limited number of project types, the GRMWP estimated unit costs of their projects (personal communication, Cecilia Noyes, GRMWP).
    c. SRFB unit costs. As part of the SRFB grant process, applicants provide the SRFB with estimates of the unit costs for various project types. Unit cost estimates were drawn from SRFB projects in the Washington portion of the NMFS Interior Columbia recovery domain for this dataset.

    The three data sources provided different amounts of coverage for the full set of project types constructed in the first step and in a few cases (*e.g.*, land acquisition and water rights transfers), they did not have sufficient data to support the estimation of unit costs. Where the data were judged to be sufficient in quantity and quality, professional judgment was used to develop a unit cost estimate, favoring the mid-point of a range across data sources and projects (where a valid range existed) and rounding appropriately to avoid a false sense of precision.

4. Finally, the resulting total cost estimate was multiplied by 1.6 to reflect the additional costs of project planning, coordination, engineering, permits, and so forth. The multiplier was estimated after consulting with ODFW and other parties experienced in habitat restoration project implementation.

Cost Estimates for Recovery Actions

Table I-1 provides cost estimates for all recovery actions by population, strategy, and category of action. The action categories are the following:

- Baseline: These are the actions categorized as part of an ongoing, existing program. No cost estimate is provided for these actions.
- Cost estimate exists: These are actions for which a estimate and scale are available.

- TBD: These are actions that do not have cost estimates at this time and that are listed as To Be Determined (TBD). The reason for the TBD status is indicated in the following way:
    - TBD (1): In these cases, costs need to be developed for specific sites and projects.
    - TBD (2): These are actions for which a unit cost estimate exists but for which no scale (stream miles or project inventory) is available.
    - TBD (3): These are actions for which a unit cost estimate needs to be developed. These actions may also need a scale estimate.

The Action name is taken from Section 9 of the draft Mid-Columbia Steelhead DPS Plan. The Total Cost Estimate columns are the following:

- P1 miles: Cost estimate for the Priority 1 stream miles used in the EDT analysis.
- P1-2 miles: Cost estimate for the Priority 1 and Priority 2 stream miles used in the EDT analysis.
- Projects: Cost estimate for the number of structures (screens, culverts, etc.) identified for that action and population.

If an action is categorized as Baseline, the cost estimate is listed as N/A (Not Applicable). The cost estimates for P1 miles and P1-2 miles are cumulative (P1 cost estimate < P1-2 cost estimate) and should not be added together. The Projects cost estimate can be added to either the P1 miles estimate or the P1-2 estimate.

Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Table I-2 provides information on current expenditures and expected five year budget amounts for habitat projects by a wide range of local, state, and federal agencies and NGOs. This table provides context for the estimated costs of recovery actions and provides a basis for estimating possible levels of funding for recovery plan implementation over a given period of time.

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
Deschutes River Eastside				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Develop new and manage existing habitat Cooperative Agreements	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect and conserve rare and unique functioning habitats	TBD (3)		
	Protect the highest quality habitats through acquisition or conservation easements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Baseline	Maintain irrigation diversions and screens	N/A		
Cost estimate exists	Culverts: Replace or remove barriers blocking passage including dams, road culverts, irrigation structures, infiltration galleries	$0	$0	$160,000
	Provide screening at 100% of irrigation diversions	$0	$0	$0
TBD	Dams: Replace or remove barriers blocking passage including dams, road culverts, irrigation structures, infiltration galleries	TBD (2)		
	Irrigation Structures: Replace or remove barriers blocking passage including dams, road culverts, irrigation structures, infiltration galleries	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$4,893,840	$8,897,760	$0
	Reconnect side channels and off-channel habitats to stream channels	$4,893,840	$8,897,760	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Increase role and abundance of wood and large organic debris in streambeds	$743,821	$743,821	$0
	Restore natural channel form, includes berm and levee removal	$4,893,840	$8,897,760	$0
	Stabilize streambanks with passive restoration processes	$4,893,840	$8,897,760	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Install off-stream livestock watering	$0	$0	$0
	Install/maintain fencing to exclude livestock from riparian areas	$724,320	$2,516,734	$0
	Restore natural riparian communities	$1,957,536	$4,530,120	$0
TBD	Eradicate invasive plant species from riparian areas	TBD (2)		
	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Monitor/regulate water withdrawals	N/A		
Cost estimate exists	Water retention structures	$316,324	$197,702	$0
TBD	Lease or purchase water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Continue TMDL monitoring	N/A		
	Implement Agricultural Water Quality Management Plan	N/A		
	Manage irrigation return flow to reduce extreme stream temperatures	N/A		
	Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	N/A		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Convert to perennial crops/vegetation (CRP)	N/A		
	Employ BMPs to minimize unnatural rates of erosion	N/A		
	Promote reforestation and fuels management	N/A		
TBD	Achieve 95% conversion to no till farming	TBD (2)		
	Remove junipers	TBD (2)		
	Restore native upland plants and remove noxious weeds	TBD (2)		
	Upgrade or remove problem forest roads	TBD (2)		
Deschutes River Westside				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Adopt and manage Cooperative Agreements	N/A		
	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Special management designations on public lands	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect and conserve rare and unique functioning habitats	TBD (3)		
	Protect the highest quality habitats through acquisition or conservation easements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Baseline	Restore passage at Pelton-Round Butte Complex	N/A		
Cost estimate exists	Culverts: Replace barriers blocking passage including dams, road culverts and irrigation structures	$0	$0	$0
	Provide screening at 100% of irrigation diversions	$0	$0	$0
	Replace screens that do not meet criteria	$0	$0	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Dams: Replace barriers blocking passage including dams, road culverts and irrigation structures	TBD (2)		
	Irrigation Structures: Replace barriers blocking passage including dams, road culverts and irrigation structures	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$5,407,200	$25,249,680	$0
	Reconnect side channels and off-channel habitats to stream channels	$5,407,200	$25,249,680	$0
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Increase role and abundance of wood and large organic debris in streambeds	$875,197	$2,308,992	$0
	Restore natural channel form	$5,407,200	$25,249,680	$0
	Stabilize streambanks	$5,407,200	$25,249,680	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Install fencing to exclude livestock from riparian areas	$0	$153,920	$0
	Install off-stream livestock watering	$0	$0	$0
	Plant riparian vegetation where appropriate	$1,120,933	$1,120,933	$0
	Restore natural riparian communities	$372,384	$9,351,936	$0
TBD	Eradicate invasive plant species from riparian areas	TBD (2)		
	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Lease or purchase water rights and convert to instream	TBD (3)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Continue TMDL monitoring	N/A		
	Implement Agricultural Water Quality Management Plan	N/A		
	Manage irrigation return flow to reduce extreme stream temperatures	N/A		
	Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	N/A		
TBD	Reduce chemical pollution inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to minimize unnatural rates of erosion	N/A		
	Utilize appropriate fire suppression techniques	N/A		
TBD	Achieve 95% conversion to no till farming	TBD (2)		
	Restore native upland plants	TBD (2)		
	Upgrade or remove problem forest roads	TBD (2)		
Fifteenmile				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect and conserve rare and unique functioning habitats	TBD (3)		
	Protect the highest quality habitats through acquisition or conservation easements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Cost estimate exists	Culverts: Replace barriers blocking passage including dams, road culverts and irrigation structures	$0	$0	$480,000
	Provide screening at 100% of irrigation diversions	$0	$0	$0
	Replace screens that do not meet criteria	$0	$0	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Dams: Replace barriers blocking passage including dams, road culverts and irrigation structures	TBD (2)		
	Irrigation Structures: Replace barriers blocking passage including dams, road culverts and irrigation structures	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$779,528	$912,978	$0
	Reconnect side channels and off-channel habitats to stream channels	$5,846,464	$6,847,336	$0
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Increase role and abundance of wood and large organic debris in streambeds	$622,397	$622,397	$0
	Restore natural channel form	$5,846,464	$6,847,336	$0
	Stabilize streambanks	$9,620,850	$9,620,850	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Install fencing to exclude livestock from riparian areas	$638,230	$825,006	$0
	Install off-stream livestock watering	$438,365	$541,992	$0
	Plant riparian vegetation where appropriate	$0	$0	$0
	Restore natural riparian communities	$1,148,814	$1,485,011	$0
TBD	Eradicate invasive plant species from riparian areas	TBD (2)		
	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Implement urban conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Finish piping Orchard Ridge and Wolf Run diversions	TBD (1)		
	Lease or purchase water rights and convert to instream	TBD (3)

Baseline	Continue TMDL monitoring	N/A		
	Implement Agricultural Water Quality Management Plan	N/A		
	Manage irrigation return flow to reduce extreme stream temperatures	N/A		
	Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	N/A		
TBD	Reduce chemical pollution inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Convert to perennial crops/vegetation	N/A		
	Develop Integrated Fruit Production (IFPnet) plans	N/A		
	Employ BMPs to minimize unnatural rates of erosion	N/A		
	Promote fuel management	N/A		
TBD	Initiate demonstration projects	TBD (1)		
	Achieve 95% conversion to no till farming	TBD (2)		
	Upgrade or remove problem forest roads	TBD (2)		
Lower John Day				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Adopt and manage Cooperative Agreements	N/A		
	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Designate additional wilderness and wild and scenic status	N/A		
	Protect access to key habitats	N/A		
	Special management designations in forest and BLM plans	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect high quality habitats through acquisition or conservation easements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
Cost estimate exists	Culverts: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	$0	$0	$6,560,000
	Provide screening at 100% of irrigation diversions	$0	$0	$640,000
	Replace screens that do not meet criteria	$0	$0	$400,000
TBD	Dams: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Irrigation Structures: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Remove or minimize use of push up dams	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$15,839,274	$21,082,046	$0
	Reconnect side channels and off-channel habitats to stream channels	$9,583,718	$21,082,046	$0
TBD	Restore wet meadows	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Place stable wood and other large organic debris in streambeds	$1,102,763	$2,459,573	$0
	Restore natural channel form	$7,165,397	$21,082,046	$0
	Stabilize streambanks	$11,271,989	$21,082,046	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Restore natural riparian vegetative communities	$6,148,883	$17,121,854	$0
TBD	Develop grazing strategies that promote riparian recovery	TBD (3)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**

6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Lease or acquire water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Apply BMPs to animal feeding operations	N/A		
	Continue TMDL monitoring	N/A		
Cost estimate exists	Increase riparian shading	$2,273,984	$4,507,195	$0
TBD	Reduce chemical pollution inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
TBD	Initiate demonstration projects	TBD (1)		
	Continue to promote no-till farming or other seeding techniques that reduce erosion where site conditions and technology are suitable	TBD (2)		
	Manage vegetation, including juniper removal	TBD (2)		
	Restore native upland plant communities	TBD (2)		
	Upgrade or remove problem forest roads	TBD (2)

TBD	Restore wet meadows	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Place stable wood and other large organic debris in streambeds and in floodplains	$316,626	$704,531	$0
	Restore natural channel form	$4,889,888	$5,665,810	$0
	Stabilize streambanks	$2,340,901	$5,477,170	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Restore natural riparian vegetative communities	$2,542,437	$5,262,030	$0
TBD	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Increase pool habitat (beaver ponds)	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Lease or acquire water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Apply BMPs to animal feeding operations	N/A		
	Continue TMDL monitoring	N/A		
	Manage return flow to reduce extreme stream temperatures	N/A		
Cost estimate exists	Increase riparian shading	$891,400	$1,489,614	$0
TBD	Reduce chemical pollution and nutrient inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
Cost estimate exists	Upgrade or remove problem forest roads	$1,060,800	$1,060,800	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Initiate demonstration projects	TBD (1)		
	Manage vegetation, including juniper removal	TBD (2)		
	Restore native upland plant communities	TBD (2)		
North Fork John Day				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Adopt and manage Cooperative Agreements	N/A		
	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Designate additional wilderness and wild and scenic status	N/A		
	Protect access to key habitats	N/A		
	Special management designations in forest and BLM plans	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect high quality habitats through acquisition or conservation easements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Cost estimate exists	Culverts: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	$0	$0	$16,000,000
	Provide screening at 100% of irrigation diversions	$0	$0	$120,000
TBD	Construct ladders over existing permanent concrete or earth fill dams, or remove the barrier	TBD (2)		
	Dams: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Irrigation Structures: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Remove or minimize use of push up dams	TBD (2)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$2,104,989	$3,364,150	$0
	Reconnect side channels and off-channel habitats to stream channels and reconnect surface flow/restore fish passage in tributaries.	$2,237,203	$3,364,150	$0
TBD	Restore wet meadows	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Place stable wood and other large organic debris in streambeds and in floodplains	$504,664	$1,157,562	$0
	Restore natural channel form	$2,082,064	$3,364,150	$0
	Stabilize streambanks	$775,710	$1,766,690	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Restore natural riparian vegetative communities	$2,108,218	$3,116,517	$0
TBD	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Increase pool habitat (beaver ponds)	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Lease or acquire water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Apply BMPs to animal feeding operations	N/A		
	Continue TMDL monitoring	N/A		
	Manage return flow to reduce extreme stream temperatures	N/A		
Cost estimate exists	Increase riparian shading	$679,021	$1,704,357	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Address contamination from mine related discharge	TBD (1)		
	Reduce chemical pollution inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
Cost estimate exists	Upgrade or remove problem forest roads	$707,200	$707,200	$0
TBD	Initiate demonstration projects	TBD (1)		
	Manage vegetation, including juniper removal	TBD (2)		
	Restore native upland plant communities	TBD (2)		
South Fork John Day				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Adopt and manage Cooperative Agreements	N/A		
	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Designate additional wilderness and wild and scenic status	N/A		
	Protect access to key habitats	N/A		
	Special management designations in forest and BLM plans	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect high quality habitats through acquisition or conservation easements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Cost estimate exists	Culverts: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	$0	$0	$5,520,000
	Provide screening at 100% of irrigation diversions	$0	$0	$0
	Replace screens that do not meet criteria	$0	$0	$160,000

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Construct ladders over existing permanent concrete or earth fill dams	TBD (2)		
	Dams: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Irrigation Structures: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Remove or minimize use of push up dams	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$0	$275,830	$0
	Reconnect side channels and off-channel habitats to stream channels	$0	$275,830	$0
TBD	Restore wet meadows	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Place stable wood and other large organic debris in streambeds and in floodplains	$205,523	$205,523	$0
	Restore natural channel form	$0	$275,830	$0
	Stabilize streambanks	$0	$0	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Restore natural riparian vegetative communities	$926,317	$1,234,920	$0
TBD	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Increase pool habitat (beaver ponds)	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Lease or acquire water rights and convert to instream	TBD (3)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Apply BMPs to animal feeding operations	N/A		
	Continue TMDL monitoring	N/A		
	Manage return flow to reduce extreme stream temperatures	N/A		
Cost estimate exists	Increase riparian shading	$94,026	$532,170	$0
TBD	Reduce chemical pollution and nutrient inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
TBD	Initiate demonstration projects	TBD (1)		
	Manage vegetation, including juniper removal	TBD (2)		
	Restore native upland plant communities	TBD (2)		
	Upgrade or remove problem forest roads	TBD (2)		
Umatilla				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Continue existing protections and/or increase protection of Federal lands; implement Forest Practices Act and PACFISH/INFISH	N/A		
	Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function	N/A		
	Explore opportunities to incorporate priority areas into state legislation.	N/A		
	Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance	N/A		
	Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues.	N/A		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect high quality habitats through acquisition, conservation easements and cooperative agreements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Baseline	Operate and Maintain fish passage facilities to meet criteria	N/A		
Cost estimate exists	Construct ladders over existing permanent concrete or earth fill dams	$0	$0	$1,600,000
	Culverts: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	$0	$0	$800,000
	Irrigation Structures: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	$0	$0	$2,880,000
	Provide screening at 100% of irrigation diversions	$0	$0	$0
	Replace screens that do not meet criteria	$0	$0	$0
TBD	Dams: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Cost estimate exists	Reconnect floodplains to channels	$5,595,674	$5,595,674	$0
	Reconnect side channels and off-channel habitats to stream channels	$5,595,674	$5,595,674	$0
TBD	Remove dikes and levies	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Place stable wood and other large organic debris in streambeds	$1,067,592	$1,067,592	$0
	Restore natural channel form	$4,966,422	$6,089,248	$0
	Stabilize and protect streambanks	$5,019,445	$5,019,445	$0
TBD	Construct rock and log weirs to create pool habitats or elevate incised channels	TBD (2)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Baseline	Maintain existing widths of RHCAs on USFS lands.	N/A		
Cost estimate exists	Develop no-cultivation riparian buffer on agricultural lands and establish riparian setbacks for structures in areas where activities could upset riparian function	$263,339	$263,339	$0
	Restore natural riparian vegetative communities	$3,701,598	$3,701,598	$0
	Riparian exclosure fencing	$1,890,197	$1,890,197	$0
TBD	Close, remove, and restore riparian road prisms	TBD (2)		
	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Implement Umatilla Basin Project Phase I and II	TBD (1)		
	Implement Umatilla Basin Project Phase III	TBD (3)		
	Downstream water rights transfers	TBD (3)		
	File for additional ISWRs	TBD (3)		
	Lease or acquire water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Implement water quality management plans	N/A		
TBD	Address point sources of water pollution	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
TBD	Restore native upland plant communities	TBD (2)		
	Initiate demonstration projects	TBD (1)		
	Upgrade or remove problem forest roads	TBD (2)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
Upper John Day				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Adopt and manage Cooperative Agreements	N/A		
	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Designate additional wilderness and wild and scenic status	N/A		
	Protect access to key habitats	N/A		
	Special management designations in forest and BLM plans	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect high quality habitats through acquisition or conservation easements	TBD (3		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Cost estimate exists	Culverts: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	$0	$0	$8,800,000
	Provide screening at 100% of irrigation diversions	$0	$0	$1,560,000
	Replace screens that do not meet criteria	$0	$0	$1,880,000
TBD	Construct ladders over existing permanent concrete or earth fill dams	TBD (2)		
	Dams: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Irrigation Structures: Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	TBD (2)		
	Remove or minimize use of push up dams	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$4,459,760	$4,459,760	$0
	Reconnect side channels and off-channel habitats to stream channels	$6,132,419	$7,431,558	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Restore wet meadows	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Cost estimate exists	Place stable wood and other large organic debris in streambeds	$357,072	$1,082,350	$0
	Restore natural channel form	$7,520,379	$9,277,286	$0
	Stabilize streambanks	$4,459,760	$5,496,088	$0
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Restore natural riparian vegetative communities	$2,337,970	$5,731,272	$0
TBD	Develop grazing strategies that promote riparian recovery	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Implement agricultural water conservation measures	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Increase pool habitat (beaver ponds)	N/A		
	Monitor/regulate water withdrawals	N/A		
TBD	Lease or acquire water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Apply BMPs to animal feeding operations	N/A		
	Continue TMDL monitoring	N/A		
	Manage return flow to reduce extreme stream temperatures	N/A		
Cost estimate exists	Increase riparian shading	$1,787,741	$2,324,475	$0
TBD	Reduce chemical pollution and nutrient inputs	TBD (1)		
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Employ BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
Cost estimate exists	Upgrade or remove problem forest roads	$104,000	$104,000	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Initiate demonstration projects	TBD (1)		
	Manage vegetation, including juniper removal	TBD (2)		
	Restore native upland plant communities	TBD (2)		
Walla Walla				
1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Baseline	Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	N/A		
	Continue existing protections and/or increase protection of Federal lands; implement Forest Practices Act and PACFISH/INFISH	N/A		
	Establish setbacks to protect waterways from forest management, agricultural activities, and other land use practices that would disrupt ecosystem function	N/A		
	Explore opportunities to incorporate priority areas into state legislation.	N/A		
	Incorporate priority habitat areas into the Natural Area Overlay Zone provision of the Umatilla County Development Ordinance	N/A		
	Review, modify and enforce existing land use planning documents and ordinances pertaining to riparian and floodplain management to better address habitat and water quality issues.	N/A		
Cost estimate exists	Conduct outreach to resource users and managers	$0	$0	$176,000
TBD	Protect and conserve rare and unique functioning habitats	TBD (3)		
	Protect high quality habitats through acquisition, conservation easements and cooperative agreements	TBD (3)		
2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain unimpaired passage and connectivity.				
Baseline	Operate and Maintain fish passage facilities	N/A		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
Cost estimate exists	Construct ladders over existing permanent irrigation diversions	$0	$0	$1,760,000
	Culverts: Remove or replace barriers blocking passage such as dams, bridges, road culverts and irrigation structures	$0	$0	$1,760,000
	Irrigation Structures: Remove or replace barriers blocking passage such as dams, bridges, road culverts and irrigation structures	$0	$0	$0
	Provide screening at 100% of irrigation diversions	$0	$0	$0
	Replace screens that do not meet criteria	$0	$0	$0
TBD	Dams: Remove or replace barriers blocking passage such as dams, bridges, road culverts and irrigation structures	TBD (2)		
3. Restore floodplain connectivity and function and maintain unimpaired connectivity and function.				
Baseline	Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	N/A		
Cost estimate exists	Reconnect floodplains to channels	$1,969,200	$2,589,120	$0
	Reconnect side channels and off-channel habitats to stream channels	$1,969,200	$7,197,120	$0
TBD	Remove dikes and levies	TBD (2)		
4. Restore degraded channel structure and complexity and maintain unimpaired structure and complexity.				
Baseline	Implement bridge maintenance BMPs	N/A		
Cost estimate exists	Place stable wood and other large organic debris in streambeds	$302,064	$302,064	$0
	Restore natural channel form	$2,589,120	$7,197,120	$0
	Stabilize and protect streambanks	$2,589,120	$7,197,120	$0
TBD	Construct rock and log weirs to create pool habitats or elevate incised channels	TBD (2)		
5. Restore riparian condition and LWD recruitment and maintain unimpaired conditions.				
Cost estimate exists	Develop no-cultivation riparian buffer on agricultural lands and establish riparian setbacks for structures in areas where activities could upset riparian function	$129,456	$359,856	$0
	Restore natural riparian vegetative communities	$1,035,648	$2,878,848	$0
	Riparian exclosure fencing	$575,360	$1,599,360	$0

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
TBD	Close, remove, and restore riparian road prisms	TBD (2)		
	Develop grazing strategies that promote riparian recovery	TBD (3)		
	Protect high quality riparian habitats and unstable areas	TBD (3)		
6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Baseline	Close areas to appropriation of new water uses	N/A		
	Improve irrigation conveyance and efficiency	N/A		
	Investigate feasibility of water storage or exchange to improve instream flows for steelhead	N/A		
	Monitor/regulate water withdrawals	N/A		
	Set criteria to protect flows for fish habitat from new appropriations	N/A		
TBD	Aquifer storage and recovery	TBD (1)		
	Enhance hyporheic flows and spring inputs	TBD (1)		
	Implement shallow aquifer recharge	TBD (1)		
	Downstream water rights transfers	TBD (3)		
	File for additional ISWRs	TBD (3)		
	Lease or acquire water rights and convert to instream	TBD (3)		
7. Improve degraded water quality and maintain unimpaired water quality.				
Baseline	Implement pest management plans for fruit growers	N/A		
	Implement water quality management plans	N/A		
	Improve municipal stormwater management and treatment	N/A		
	Permit and enforce actions that could affect water quality	N/A		
	Permit waterway alteration activities and enforce rules	N/A		
TBD	Address point sources of water pollution	TBD (1)		

Table I-1: All Actions by Population, Strategy, and Category				
Population, Strategy, Category	**Action name**	**Total Cost Estimate**		
		P1 miles	**P1-2 miles**	**Projects**
8. Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes.				
Baseline	Apply BMPs to forest practices, livestock grazing, road management and agricultural practices	N/A		
TBD	Implement CREP and CCRP buffers	TBD (3)		
	Initiate demonstration projects	TBD (1)		
	Restore native upland plant communities	TBD (2)		
	Upgrade or remove problem forest roads	TBD (2)		

Table I-2
Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Agency or Organization	Program	Recent average annual expenditures or budget	Expected next five year expenditures	Comments
Fifteenmile Creek Population				
CTWSRO	CREP	$10,000/yr	$50,000	
	Fifteenmile habitat program		100,000	Coordinate LWD, riparian exclosures, riparian plantings
Wasco Co. SWCD	Riparian buffers	$103,000/yr	$500,000	Funds are for technical work. USDA Farm Services Agency and OWEB leveraging technical dollars under CREP program.
	No-till conversion	$40,000/yr	$100,000	Nearing saturation/completion
	Irrigation efficiency	$30,000/yr	150,000	
	Fish habitat	$125,000/yr	$250,000	eliminate passage barriers, add rootwads, jhooks, eliminate fords
USFS	Fish habitat – Fifteenmile Cr	$25,000/yr		Partner in project
ODFW	Fish Habitat- Fifteenmile Cr	$322,662/yr	$1,600,000	Riparian exclosures, off channel water, instream habitat, M&E
	Fish Screening	$200,000/yr	$800,000	New construction and O&M
Totals - **Fifteenmile Creek Population**		$855,662/yr	$3,550,000	
Eastside Deschutes River Population				
USFS	Fish habitat - Trout Cr	$30,000/yr	$150,000	Partner in project
	Culvert Replacements	$75,000/yr	$500,000	
	Trout Creek (2)			
	Dick Creek			
Sherman County SWCD	CREP	$300,000/yr	$1,250,000	Depends on program availability, Includes rental payments, installed practices, maintenance, etc.
	Habitat	$20,000/yr	$100,000	Passive restoration projects, i.e. off-stream water, tree planting
	Upland	$155,000/yr	$775,000	Erosion control structures, pasture fencing, brush control, range reseeding, etc.

Table I-2
Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Agency or Organization	Program	Recent average annual expenditures or budget	Expected next five year expenditures	Comments
Jefferson SWCD	Trout Creek Watershed Improvement and CREP – Fish Habitat	$395,000/yr		Phase 3 Trout Creek Channel Habitat Improvement Project – Channel Reconstruction Project
	Trout Creek Watershed Improvement & CREP– Fish Habitat		$650,000	Antelope Creek Channel Habitat Improvement Project & CREP – 2 miles
	IWM		$500,000	Irrigation Improvement Projects
Deschutes River Conservancy	Instream habitat restoration	$15,000/yr	$75,000	
PGE	Fish habitat – Trout Cr Ranch	$75,000/yr	$950,000	PGE-managed project
	Fish habitat – Trout Cr	$300,000 in 2006	$600,000	Funding of projects. PGE spent $300,000 funding 3 projects in 2006.
Wasco Co. SWCD	Riparian buffers	$40,000/yr	$200,000	Funds are for technical work. USDA Farm Services Agency and OWEB are leveraging the technical dollars under the CREP program.
	Upland conservation	$120,000/yr	$400,000	
ODFW	Fish habitat – Trout Creek	$335,000/yr	$1,750,000	Riparian exclosures, off channel water developments, berm removal/channel reconstruction work.
	Fish screening and passage- Trout Creek	$100,000/yr	$500,000	New construction and O&M
BLM	Upland and riparian weed treatment	$36,000/yr	$180,000	
	Stream and riparian restoration	$29,000/yr	$150,000	Includes maintenance work on existing projects
Totals - **Eastside Deschutes River Population**		$2,025,000/yr	$8,730,000	
Westside Deschutes River Population				
USFS	Fish habitat - Whychus Cr	$30,000/yr	$150,000	Partner in project
	Fish habitat – Metolius R	$25,000/yr	$150,000	Partner in project

Table I-2
Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Agency or Organization	Program	Recent average annual expenditures or budget	Expected next five year expenditures	Comments
	Culvert Replacements in Metolius River Watershed	$100,000/yr	$150,000	Lake Creek, Roaring Creek and Bear Valley Creek
CTWSRO	Reservation Watershed maintenance (Shitike, Warm Springs rivers)	$46,000/yr	$750,000	Implementing and maintaining riparian exclosures, solar jacks, off channel water sources.
	Fish habitat (Beaver Creek, Whychus, Mill, Shitike, Coyote, Quartz, Metolius, lower Deschutes river)	$32,000/yr	$250,000	Large channel reconstruction, lwd, gabion and berm removals, riparian plantings
	Passage improvements road decommissioning	$120,000/yr	$600,000	Replacing or removing culverts for improved passage and capacity
Deschutes River Conservancy	Instream Leasing	$30,000/yr	$150,000	Whychus Creek
	Water Rights Acquisitions	$200,000/yr	$1,000,000	Whychus Creek
	Water Conservation	$900,000/yr	$4,500,000	Whychus Creek
Upper Deschutes Watershed Council	Fish habitat / stream restoration / riparian restoration (private land)	$275,000/yr	$3,250,000	Major projects scheduled on Whychus Creek (4 miles), Lake Creek, and Metolius River
	Screening / passage at diversions	$0/yr	$875,000	Major diversion retrofit projects scheduled.
	Culvert upgrades	$0/yr	$125,000	Several small improvement projects scheduled.

Table I-2
Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Agency or Organization	Program	Recent average annual expenditures or budget	Expected next five year expenditures	Comments
PGE	Fish habitat – Whychus Cr	$18,000 – 2006		
	Fish habitat – Metolius R			
	Fish habitat – Lower Deschutes	$120,000 – 2006		
Wasco So. SWCD	Riparian buffers	$15,000/yr	$75,000	Funds are for technical work. USDA Farm Services Agency and OWEB are leveraging the technical dollars under the CREP program.
	Upland conservation (includes irrig. efficiency)	$50,000/yr	$250,000	
ODFW	Fish habitat – planning, coordination, M&E	$15,000/yr	$75,000	Whychus Creek and Metolius River
BLM	Upland and riparian weed treatment	$9,000/yr	$45,000	
	Stream and riparian restoration	$29,000/yr	$150,000	Includes maintenance work on existing projects
Totals - **Westside Deschutes River Population**		$2,014,000/yr	$12,545,000	
Crooked River Population (reintroduction area)				
PGE	Fish habitat – Crooked R	$150,000 in 2006		Funding of projects, including McKay Cr
Deschutes River Conservancy	Instream leasing	$40,000/yr	$200,000	
	Water rights acquisitions	$400,000/yr	$2,000,000	
	Water conservation	$1,000,000/yr	$5,000,000	
Crooked River Watershed Council	Passage and screening		$2,700,000	Lower Crooked River and McKay Creek
	Fish habitat – Crooked River & McKay Creek		$1,400,000	Habitat enhancement – Prineville Valley and Private Lands (McKay Cr)
USFS	Fish habitat – McKay Creek drainage	$50,000/yr	$120,000	McKay and Little McKay fish habitat improvements

Table I-2
Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Agency or Organization	Program	Recent average annual expenditures or budget	Expected next five year expenditures	Comments
	Culvert Replacements	$100,000/yr	$375,000	Improvements in passage in the Little McKay and McKay Creeks and tribs.
ODFW	Fish screening and Passage	$200,000/yr	$1,000,000	New construction and O&M
	Fish habitat – planning, coordination, M&E	$15,000/yr	$75,000	
BLM	Upland and riparian weed treatment	$27,000/yr	$110,000	
	Stream and riparian restoration	$22,000/yr	$110,000	Includes maintenance work on existing projects
	Fish Passage		$155,500	Stearns Dam Removal
Totals - **Crooked River Population (reintroduction area)**		$2,004,000/yr	$13,245,500	
Lower John Day River Population (below Dayville)				
Gillian County SWCD	habitat	$33,000/yr	$165,000	OWEB
	Rock Creek project	$28,000/yr		One year
	Weed control	$30,000/yr	$120,000	From Oregon Weed Board
ODFW	Fish Habitat - Lower	$100,000/yr	$500,000	(BPA funded @ $540,000 in 2007 and $440,000 for 2008-2009). The budget is spread out depending on projects within the John Day Subbasin.
	Fish screening and Passage	$450,000/yr	$2,250,000	New construction and O&M – John Day screen shop
Sherman County SWCD	CREP	$400,000/yr	$2,000,000	Depends on program availability, Includes rental payments, installed practices, maintenance, etc.
	Habitat	$30,000/yr	$150,000	Passive restoration projects, i.e. off-stream water, tree planting, and 1 possible channel project
	Upland	$185,000/yr	$925,000	Erosion control structures, pasture fencing, brush control, range reseeding, etc.
CTWSRO	Pine Creek Conservation area	$210,000/yr	$1,750,000	Invasive weed control, CREP implementation, prescribed fire, juniper control
	John Day watershed restoration program	$42,000/yr	$325,000	Riparian plantings, juniper control, off channel water developments.

Table I-2
Current Average Expenditures on Habitat Projects for Mid-Columbia River Steelhead

Agency or Organization	Program	Recent average annual expenditures or budget	Expected next five year expenditures	Comments
	John Day watershed restoration program	$294,532/yr	$1,500,000	Pushup dam removals, Point of diversion consolidation, return flow coolers,
USFS	Fish Habitat – Rock Creek	$30,000/yr		
	Various projects		$100,000	Ochoco NF
	Culvert Replacements – Various tribs		$375,000	Ochoco NF
Wasco Co. SWCD	Riparian buffers	$15,000/yr	$75,000	Funds are for technical work. USDA Farm Services Agency and OWEB are leveraging the technical dollars under the CREP program.
Wheeler County SWCD	Passage – diversion projects, culverts, bridge	$485,000/yr	$2,425,000	Replacement of push-up dams and other barriers, culvert replacement, fish ladder, screen, Service Creek bridge
	Irrigation efficiency	$390,000/yr	$1,450,000	Converting open ditch to pipelines
	uplands	$99,300/yr	$500,000	Upland development, juniper removal and abatement, spring development
BLM	Upland and riparian weed treatment	$54,000/yr	270,000	
	Stream and riparian restoration	$43,000/yr	$215,000	Includes maintenance work on existing projects
Totals - **Lower John Day River Population (below Dayville)**		$2,918,832/yr	$15,095,000	
North Fork John Day Population				
CTUIR	Fish habitat	$321,000/yr	$1,600,000	(BPA - $249,000; NRCS - $50,000; PCSRF - $22,000)
ODFW	Fish habitat – North Fork drainage	$200,000/yr	$500,000	(BPA funded @ $540,000 in 2007 and $440,000 for 2008-2009). The budget is spread out depending on projects within the John Day Subbasin.
	Fish screening and Passage	$300,000/yr	$1,500,000	New construction and O&M – John Day screen shop
CTWSRO	John Day watershed restoration program	$136000/yr	0	Pushup dam removals/ replacements
Grant SWCD	Fish Habitat – mine tailings, shaping for	$192,000/yr	$960,000	OWEB, Umatilla NF, CTUIT, USFW Service Partners and Acid Spill

ODFW John Day screen shop	Fish screening and Passage	$100,000/yr	$500,000	New construction and O&M
Totals - **Walla Walla River Population**		$1,772,142/yr	$9,160,000	

APPENDIX J

U.S. Forest Service Briefing Paper

Fuels Treatment as an Action Contributing to Recovery of ESA-listed Anadromous Salmonids

Forest Service Briefing Paper

Subject Fuels treatment as an action contributing to recovery of ESA-listed anadromous salmonids

Key Messages

- Science-based assessments of the Columbia and Snake River basins have documented that both forest and aquatic ecosystems have undergone important changes from historical conditions.
    - Forests structure, composition, and patterns have been significantly altered, resulting in a higher risk of stand replacement fires.
    - Watersheds have been degraded, threatening the stability and persistence of native fishes -- including ESA-listed salmon and steelhead stocks.
- Growing public recognition of degraded forest and aquatic ecosystem condition has resulted in policy and scientific debate over whether fuels treatments provide benefits to ESA-listed salmonid populations, or conversely, represent a risk of further degradation in watershed conditions on which they depend.
- Context matters – any evaluation of trade-offs (benefits and risks) to ESA-listed salmonids from fuels treatments will be dependent on local conditions and successful integration of objectives.
- Three primary elements must be integrated to meet both forest and aquatic system restoration objectives:
    - Conservation of key remnant aquatic and forested habitats with their associated native fish and wildlife populations, to serve as 'building blocks' for the future;
    - Restoration of degraded watersheds (both forest and aquatic conditions); and
    - Restoration of more natural patterns of forest habitat, including patterns of dead and down trees to reduce the landscape risk of large and damaging wildfires.
- A multi-scale analysis –assessments at both the recovery domain and watershed scales--- is clearly an important process to evaluate tradeoffs between the benefits and risks of fuels treatment activities and assess their value in support of recovery of ESA-listed salmonids. Such analyses provide a framework and necessary geographic context and specificity to evaluate fuels treatments based on each recovery domain and watershed's unique bio-physical characteristics.

Reiman et al. (2000) provide a critical "first step" or "coarse filter" analytical framework to assist managers, policy-makers, and technicians in evaluating these trade-offs (benefits/risks). Based on their integrated analysis of terrestrial and aquatic ecosystems in the Interior Columbia River Basin, each subbasin was assigned a general 'theme' and specific management recommendations are outlined regarding opportunities for fuels treatment actions and other restorative actions to maintain and restore the integrity of watershed and aquatic systems (Figure 1). Additional, finer-scale watershed analyses will often be necessary to refine this approach in order to: 1) recognize commonality in management goals, opportunities, and conflicts; and 2)

identify specific, integrated actions needed to support ESA-listed fishes. An example of such an analysis is displayed in Figures 2 and 3.

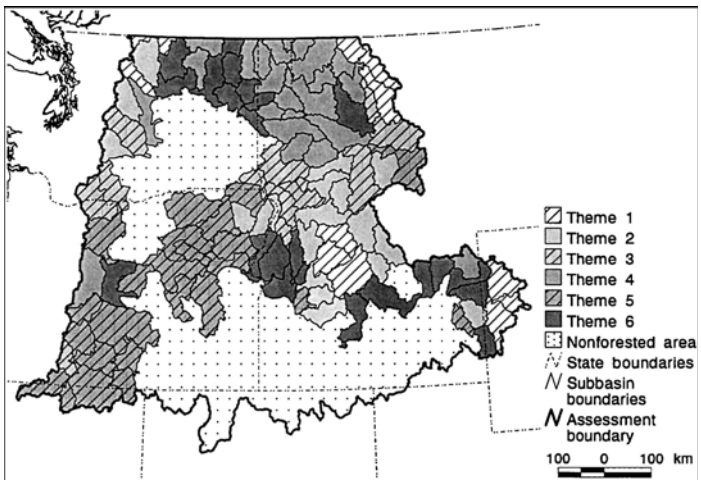

Figure 1 (from Rieman et al. 2000)

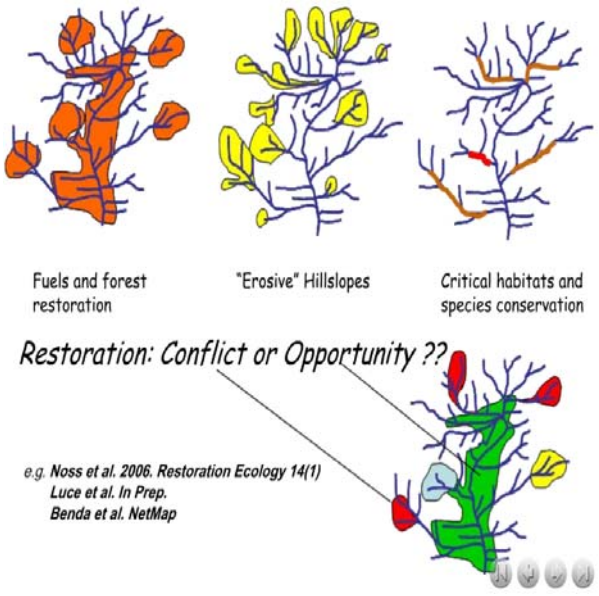

Figure 2 (from Rieman et al. 2007)

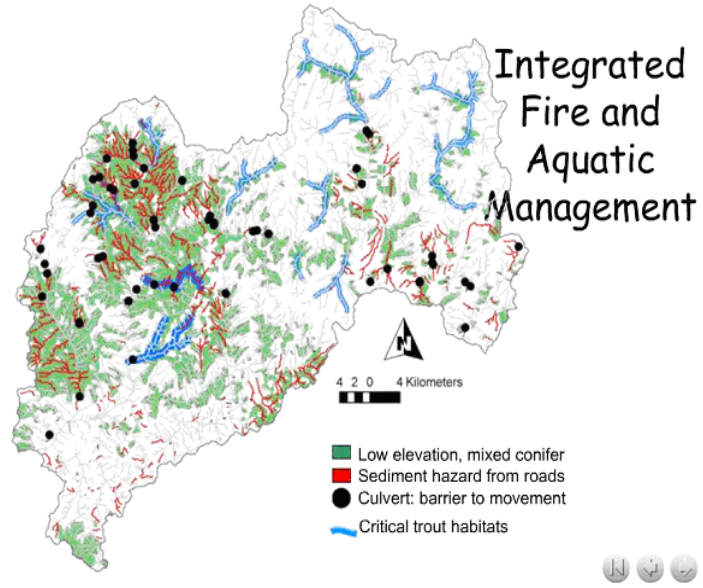

Figure 3 (from Rieman et al. 2007)

Where management objectives and conditions in forested and aquatic systems are in conflict, significant care and investment in analysis and management activities may be required. Placing subbasins into the appropriate theme, as described above, should be considered as an important first step in the prioritization of management resources expended in recovery. By focusing intensive restoration initially in areas of greatest potential ecological benefit and least risk, the skills and opportunity to move into more sensitive areas will likely emerge.

This paper was summarized and sections excerpted from the Rieman et al. (2000) publication by L. Ulmer, B. Staab, D. Shively, and S. Woltering; USDA, Forest Service, Portland, Oregon.

Reiman, B, C. Luce, J. Dunham, A. Rosenberger, J. Buffington, M. Dare, H. Neville, P. Hessburg, A. Black, and C. Miller. 2007. Wildfire and Fish: Implications for Management. Presentation. USFS Watershed Seminar Series.

Attachment A: Themes from Rieman (2000)

Theme 1: Wild and Minimally Roaded, Cold and Moist Forests – exhibit the least departure from historical conditions in either forest or aquatic ecosystems (roadless, wilderness) and provide the best opportunity to conserve elements of ecosystems most resembling natural or historical conditions

Management Implications

- Due to low departure from historical conditions (forested & aquatic), active restoration is a low priority relative to subbasins under other 'themes'
- Primary management opportunity is to conserve existing conditions
- Both managed and natural ignitions can play an important role in restoring forests

Theme 2: Semi-Wild and Moderately-Roaded Areas – represent forest and aquatic conditions varying from fair to relatively healthy (blocks of wilderness, roadless)

Management Implications

- Conserve existing integrity of high-elevation and headwater areas
- Actively restore more productive and lower risk conditions in middle and lower montane settings

Theme 3: Mixed and Opposing Conditions – conditions in forest and aquatic ecosystems are not consistent. Forests within these subbasins have the highest departure in mean fire frequency and severity. Although aquatic systems are rated as favorable, in contrast to forested areas, strong salmonid populations are found in only an average number of subbasins but most fish communities are still dominated by native species.

Management Implications

- Maintaining and improving the productivity of aquatic ecosystems and restoring forests will likely require active management.
- Although there may be opportunities to restore aquatic and forest conditions simultaneously, it may necessitate trade-offs. Aquatic systems within this theme are generally in good condition but overlap with poor forest conditions. Emphasis of forest treatments may pose unacceptable risks to watershed objectives
- Potential conflict between management objectives support the need for more
- detailed risk analysis (watershed scale)

Theme 4: Mixed Conditions, Moist Forests – subbasins in this class exhibit moderate to high levels of departure from historical conditions in both forest and aquatic systems due to extensive land management and high road densities. The need for restoration in both systems, and the productive nature of the forests, implies both risks and opportunities for management.

Management Implications

- There is a need to restore both.
- As there are productive forests, and areas of both productive aquatic habitat and intact fish communities, these subbasins may be priorities for investments in restoration.
- Due to the extensive and, potentially surplus road networks, opportunities for active forest restoration is high. Removal of roads after forest restoration work is completed could lead to improved watershed conditions where sediment and fragmentation is limiting recovery.
- The presence of large areas of moist forest types within this theme expands management opportunities. Historically, mixed and lethal fire regimes were dominant suggesting large and intense disturbance events with long recovery periods
- Recommend focused and intense restoration actions over short time periods (5-10 years) with longer time periods for recovery (30-50 years). This restoration strategy may minimize the need for extensive and permanent road networks and enable large-scale restoration with less funding.

Theme 5: Mixed Condition, Dry Forest – both forest and aquatic systems are similar to subbasins under Theme 4 (departure from historical conditions, high road densities, extensive land management) but dry forest types are dominant. Theme 5 differs from Theme 4 in that forests are less productive, historical fire regimes were primary non-lethal and mixed and had frequent fire return intervals.

Management Implications

- Restoration needs similar to those recommended under Theme 4 but active restoration will require more frequent entry and a higher level of maintenance for a more extensive road network.
- Economic benefits from logging (dry forest types) are lower than under Theme 4 and probably will not support low-impact operations (e.g., helicopter logging) as often as in more productive moist forest types. This will in turn require that existing road networks remain in place, long-term to derive any economic benefit.
- Although the same opportunities for aquatic habitat restoration are found as under Theme 4 (removal of unnecessary roads), forest restoration should make use of existing roads, rather than construct new ones, and attempt to eliminate roads limiting watershed integrity.

Theme 6: Poor Conditions – both forest and aquatic systems are in poor condition. For aquatic systems, they are in a degraded condition with remaining populations of native fishes often isolated and fragmented. Fragmentation of habitat is most common in lower elevation lands adjoining forested areas. For forest systems, the composition and degree of departure from historical conditions is similar to Theme 5. In contrast, subbasins under Theme 6 comprise a more diverse mix of dry and moist forest conditions with fire frequency changes also not as pronounced. Road densities are also lower than under Theme 4 or 5.

Management Implications

- Limited opportunity for restoration of functional aquatic networks
- Conserve remnant habitats of native fishes and maintain high water quality
- Forest restoration activities would present low risk to remaining critical habitat providing these are sited appropriately

Recovery Plan
for the Klickitat River Population of the Middle Columbia River Steelhead Distinct Population Segment

September 2009

Prepared by
National Marine Fisheries Service
Northwest Region

DISCLAIMER

Endangered Species Act (ESA) recovery plans delineate reasonable actions which the best available information indicates are necessary for the conservation and survival of listed species. Plans are published by the National Marine Fisheries Service (NMFS), usually with the assistance of recovery teams, state agencies, local governments, salmon recovery boards, non-governmental organizations, interested citizens of the affected area, contractors, and others. ESA recovery plans do not necessarily represent the views, official positions, or approval of any individuals or agencies involved in the plan formulation, other than NMFS. They represent the official position of NMFS only after they have been signed by the Northwest Regional Administrator. ESA recovery plans are guidance and planning documents only; identification of an action to be implemented by any public or private party does not create a legal obligation beyond existing legal requirements. Nothing in this plan should be construed as a commitment or requirement that any Federal agency obligate or pay funds in any one fiscal year in excess of appropriations made by Congress for that fiscal year in contravention of the Anti-Deficiency Act, 31 U.S.C. 1341, or any other law or regulation. Approved recovery plans are subject to modification as dictated by new information, changes in species status, and the completion of recovery actions.

With respect to the Middle Columbia Steelhead Recovery Plan, where areas of disagreement arose between a management unit plan and the species level, distinct population segment (DPS) plan, NMFS worked with the relevant parties to resolve the differences and in a few cases, identified in the DPS plan, decided not to incorporate the disputed material into the DPS plan.

ESA recovery plans provide important context for NMFS's determinations pursuant to section 7(a)(2) of the Endangered Species Act. However, recovery plans do not place any additional legal burden on NMFS or the action agency when determining whether an action would jeopardize the continued existence of a listed species or adversely modify critical habitat. The procedures for the section 7 consultation process are described in 50 CFR 402 and are applicable regardless of whether or not the actions are described in a recovery plan.

Recovery Planning Glossary

abundance: In the context of salmon recovery, unless otherwise qualified, abundance refers to the number of adult fish returning to spawn.

adaptive management: Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. A plan for monitoring, evaluation, and feedback is incorporated into an overall implementation plan so that the results of actions can become feedback on design and implementation of future actions.

anadromous fish: Species that are hatched in freshwater, migrate to and mature in salt water, and return to freshwater to spawn.

baseline monitoring: In the context of recovery planning, baseline monitoring is done before implementation, in order to establish historical and/or current conditions against which progress (or lack of progress) can be measured.

biogeographical region: an area defined in terms of physical and habitat features, including topography and ecological variations, where groups of organisms (in this case, salmonids) have evolved in common.

broad-sense recovery goals: Goals defined in the recovery planning process, generally by local recovery planning groups, that go beyond the requirements for delisting, to address, for example, other legislative mandates or social, economic, and ecological values.

compliance monitoring: Monitoring to determine whether a specific performance standard, environmental standard, regulation, or law is met.

delisting criteria: Criteria incorporated into ESA recovery plans that define both biological viability (biological criteria) and alleviation of the causes for decline (threats criteria based on the five listing factors in ESA section 4[a][1]), and that, when met, would result in a determination that a species is no longer threatened or endangered and can be proposed for removal from the Federal list of threatened and endangered species. These criteria are a NMFS determination and may include both technical and policy considerations.

distinct population segment (DPS): A listable entity under the ESA that meets tests of discreteness and significance according to USFWS and NMFS policy. A population is considered distinct (and hence a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics, it occupies an unusual or unique ecological setting, or its loss would represent a significant gap in the species' range.

diversity: All the genetic and phenotypic (life history, behavioral, and morphological) variation within a population. Variations could include anadromy vs. lifelong residence in

freshwater, fecundity, run timing, spawn timing, juvenile behavior, age at smolting, age at maturity, egg size, developmental rate, ocean distribution patterns, male and female spawning behavior, physiology, molecular genetic characteristics, etc.

endangered species: A species in danger of extinction throughout all or a significant portion of its range.

effectiveness monitoring: Monitoring set up to test cause-and-effect hypotheses about recovery actions: Did the management actions achieve their direct effect or goal? For example, did fencing a riparian area to exclude livestock result in recovery of riparian vegetation?

ESA recovery plan: A plan to recover a species listed as threatened or endangered under the U.S. Endangered Species Act (ESA). The ESA requires that recovery plans, to the extent practicable, incorporate (1) objective, measurable criteria that, when met, would result in a determination that the species is no longer threatened or endangered; (2) site-specific management actions that may be necessary to achieve the plan's goals; and (3) estimates of the time required and costs to implement recovery actions.

evolutionarily significant unit (ESU): A group of Pacific salmon or steelhead trout that is (1) substantially reproductively isolated from other conspecific units and (2) represents an important component of the evolutionary legacy of the species.

extinct: No longer in existence. No individuals of this species can be found.

extirpated: Locally extinct. Other populations of this species exist elsewhere. The ICTRT considers extirpated steelhead populations to be those that are entirely cut off from anadromy, such as the Crooked River population. Functionally extirpated populations are those of which there are so few remaining numbers that there are not enough fish or habitat in suitable condition to support a fully functional population.

factors for decline: Five general categories of causes for decline of a species, listed in the Endangered Species Act section 4(a)(1)(b): (A) the present or threatened destruction, modification, or curtailment of its habitat or range; (B) overutilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; or (E) other natural or manmade factors affecting its continued existence.

functionally extirpated: Describes a species that has been extirpated from an area; although a few individuals may occasionally be found, there are not enough fish or habitat in suitable condition to support a fully functional population.

hyporheic zone: Area of saturated gravel and other sediment beneath and beside streams and rivers where groundwater and surface water mix.

implementation monitoring: Monitoring to determine whether an activity was performed and/or completed as planned.

independent population: Any collection of one or more local breeding units whose population dynamics or extinction risk over a 100-year time period is not substantially altered by exchanges of individuals with other populations.

indicator: A variable used to forecast the value or change in the value of another variable.

interim regional recovery plan: A recovery plan that is intended to lead to an ESA recovery plan but that is not yet complete. These plans might address only a portion of an ESU or lack other key components of an ESA recovery plan.

intrinsic potential: The estimated relative suitability of a habitat for spawning and rearing of anadromous salmonid species under historical conditions inferred from stream characteristics including channel size, gradient, and valley width.

intrinsic productivity: The expected ratio of natural-origin offspring to parent spawners at levels of abundance below carrying capacity.

iteroparous: Capable of reproducing more than once in a lifetime.

kelts: Steelhead that are returning to the ocean after spawning and have the potential to spawn again in subsequent years (unlike most salmon, steelhead do not necessarily die shortly after spawning).

large woody debris (LWD): A general term for wood naturally occurring or artificially placed in streams, including branches, stumps, logs, and logjams. Streams with adequate LWD tend to have greater habitat diversity, a natural meandering shape, and greater resistance to flooding.

legacy effects: Impacts from past activities that continue to affect a stream or watershed in the present day.

limiting factor: Physical, biological, or chemical features (e.g., inadequate spawning habitat, high water temperature, insufficient prey resources) experienced by the fish that result in reductions in viable salmonid population (VSP) parameters (abundance, productivity, spatial structure, and diversity). Key limiting factors are those with the greatest impacts on a population's ability to reach a desired status.

locally developed recovery plan: A plan developed by state, tribal, regional, or local planning entities to address recovery of a species. These plans are being developed by a number of entities throughout the region to address ESA as well as state, tribal, and local mandates and recovery needs.

maintained status: Population status in which the population does not meet the criteria for a viable population but does support ecological functions and preserve options for ESU/DPS recovery.

major population group (MPG): A group of salmonid populations that are geographically and genetically cohesive. The MPG is a level of organization between demographically independent populations and the ESU or DPS.

major spawning area (MaSA): A system of one or more branches that contain sufficient spawning and rearing habitat to support more than 500 spawners. For Interior Columbia salmonid populations: defined using results from intrinsic potential analysis.

management unit: A geographic area defined for recovery planning purposes on the basis of state, tribal or local jurisdictional boundaries that encompass all or a portion of the range of a listed species, ESU, or DPS.

metrics: A metric is something that quantifies a characteristic of a situation or process; for example, the number of natural-origin salmon returning to spawn to a specific location is a metric for population abundance.

minor spawning area (MiSA): A system of one or more branches that contain sufficient spawning and rearing habitat to support 50-500 spawners. For Interior Columbia salmonid populations: defined using results from intrinsic potential analysis.

morphology: The form and structure of an organism, with special emphasis on external features.

natural-origin fish: Fish that were spawned and reared in the wild, regardless of parental origin.

parr: The stage in anadromous salmonid development between absorption of the yolk sac and transformation to smolt before migration seaward.

phenotype: Any observable characteristic of an organism, such as its external appearance, development, biochemical or physiological properties, or behavior.

piscivorous: (Adj.) Describes fish that eat other fish.

productivity: The average number of surviving offspring per parent. Productivity is used as an indicator of a population's ability to sustain itself or its ability to rebound from low numbers. The terms "population growth rate" and "population productivity" are interchangeable when referring to measures of population production over an entire life cycle. Can be expressed as the number of recruits (adults) per spawner or the number of smolts per spawner.

recovery domain: An administrative unit for recovery planning defined by NMFS based on ESU boundaries, ecosystem boundaries, and existing local planning processes. Recovery domains may contain one or more listed ESUs.

recovery goals: Goals incorporated into a locally developed recovery plan, which may include delisting (i.e. no longer considered endangered or threatened), reclassification

(e.g., from endangered to threatened), and/or other goals. Broad-sense goals are a subset of recovery goals (see glossary entry above).

recovery plan supplement: A NMFS supplement to a locally developed recovery plan that describes how the plan addresses ESA requirements for recovery plans. The supplement also proposes ESA delisting criteria for the ESUs addressed by the plan, since a determination of these criteria is a NMFS decision.

recovery scenarios: Scenarios that describe a target status for each population within an ESU, generally consistent with TRT recommendations for ESU viability.

redd: A nest constructed by female salmonids in streambed gravels where eggs are fertilized and deposited.
recovery strategy: Statements that identify the assumptions and logic – the rationale – for the species' recovery program.

riparian area: Area with distinctive soils and vegetation between a stream or other body of water and the adjacent upland.

salmonid: Fish of the family *Salmonidae*, including salmon, trout, chars, grayling, and whitefish. In general usage, the term usually refers to salmon, trout, and chars.

smolt: A juvenile salmonid that is undergoing physiological and behavioral changes to adapt from freshwater to saltwater as it migrates toward the ocean.

spatial structure: Characteristics of a fish population's geographic distribution. Current spatial structure depends upon the presence of fish, not merely the potential for fish to occupy an area.

stakeholders: Agencies, groups, or private citizens with an interest in recovery planning, or who will be affected by recovery planning and actions.

Technical Recovery Team (TRT): Teams convened by NMFS to develop technical products related to recovery planning. TRTs are complemented by planning forums unique to specific states, tribes, or regions, which use TRT and other technical products to identify recovery actions.

threatened species: A species likely to become endangered within the foreseeable future throughout all or a significant portion of its range.

threats: Human activities or natural events (e.g., road building, floodplain development, fish harvest, hatchery influences, volcanoes) that cause or contribute to limiting factors. Threats may exist in the present or be likely to occur in the future.

viability criteria: Criteria defined by NMFS-appointed Technical Recovery Teams to describe a viable salmonid population, based on the biological parameters of abundance, productivity, spatial structure, and diversity. These criteria are used as technical input

into the recovery planning process and provide a technical foundation for development of biological delisting criteria.

viability curve: A curve describing combinations of abundance and productivity that yield a particular risk of extinction at a given level of variation over a specified time frame.

viable salmonid population (VSP): an independent population of Pacific salmon or steelhead trout that has a negligible risk of extinction over a 100-year time frame.

VSP parameters: Abundance, productivity, spatial structure, and diversity. These describe characteristics of salmonid populations that are useful in evaluating population viability. See NOAA Technical Memorandum NMFS-NWFSC-42, *Viable salmonid populations and the recovery of evolutionarily significant units* (McElhany et al. 2000).

Executive Summary

The Endangered Species Act of 1973 (ESA) requires NOAA's National Marine Fisheries Service (NMFS) to develop recovery plans for species listed under the Act. The purpose of recovery plans is to identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA.

This plan focuses on the conservation and survival of Middle Columbia River steelhead (*Oncorhynchus mykiss*) in the Klickitat River subbasin (Figure ES-1).[1] It is one of several recovery plans developed for independent populations of the Middle Columbia River steelhead distinct population segment (DPS), which was listed as threatened under the ESA on March 25, 1999 and reconfirmed on January 5, 2006 (NMFS 2006a, 71 FR 834). Similar plans have been prepared for Middle Columbia steelhead populations in the White Salmon River, Rock Creek, and Yakima River, as well as in areas of southeast Washington and the State of Oregon. These separate plans are part of a DPS-level plan that integrates recovery actions across the DPS.

The Klickitat River population is of particular interest because it contains both summer and winter runs, and it potentially could make a significant contribution to recovery of the Middle Columbia steelhead DPS. The Klickitat River is one of the largest salmon producing watersheds in the Columbia basin. Recent passage improvements at Castile Falls in the upper Klickitat have opened an additional 56 miles of high quality steelhead habitat. Passage improvements in the lower Klickitat (Lyle Falls at RM 2.2) are also expected to benefit immigrating adults. In addition, a hatchery master plan under development by the Yakama Nation in consultation with NMFS is expected to improve hatchery management to support conservation of the naturally spawning steelhead (Sharp et al. 2008). Moving existing *U.S. v. Oregon* production of fall Chinook and coho from the Klickitat hatchery to the new Wahkiacus Acclimation Facility 26 miles downstream will minimize the impacts of large-scale hatchery releases on wild spring Chinook and steelhead rearing between the two facilities.

Purpose of Plan

The plan provides a roadmap for restoring the Klickitat steelhead population and its habitats to a level that supports recovery of the Middle Columbia River steelhead DPS and allows the population to become a viable component of its ecosystem. A recovery plan is a guidance document, not regulatory.

The plan describes the current status of the Klickitat population, identifies the factors and threats affecting the population, and proposes strategies and actions designed to aid in the population's recovery and build on past and current recovery efforts. Finally, the plan

[1] A description of the Major Creek watershed is included as Appendix I of this plan. Major Creek flows into the Columbia River immediately downstream of the Klickitat River and is believed to contain Middle Columbia steelhead. The Interior Columbia Technical Recovery Team has not evaluated the data for Major Creek, but because of its proximity to the Klickitat River, its steelhead may have genetic characteristics similar to the Klickitat steelhead population.

provides an implementation schedule and adaptive management framework for making needed future adjustments on the road to recovery.

Context of Plan Development

The plan is the product of a process initiated by NMFS; it incorporates information from the Yakama Nation (YN), Washington Department of Fish and Wildlife (WDFW), Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal agencies, state agencies, local governments, and the public.

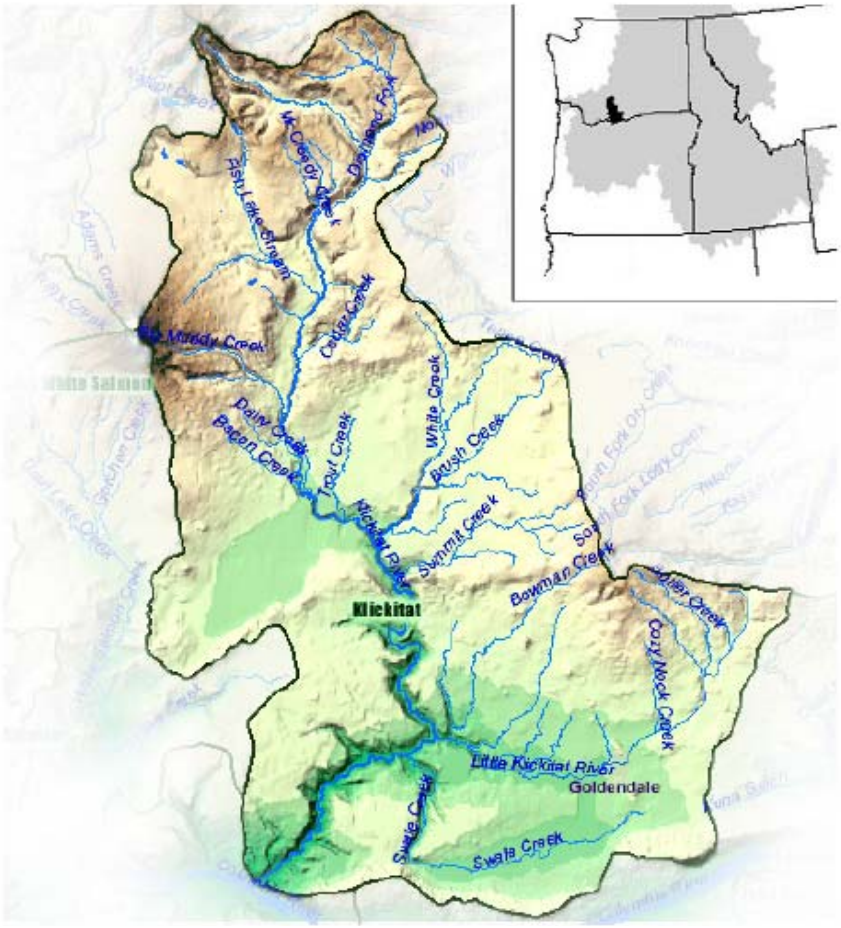

Figure ES-1. Klickitat Subbasin.

The Klickitat Plan reflects direction for Klickitat steelhead adopted into the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program subbasin plan (NPCC 2004). The subbasin plan was produced through a collaborative process involving the Yakama Nation, Washington Department of Fish and Wildlife, and NPCC.

In addition, the plan reflects technical data drawn from:

- Watershed Resource Inventory Area (WRIA) 30 watershed assessment (WPN and Aspect 2005a) and watershed management plan (WPN and Aspect 2005b)
- The Interior Columbia Technical Recovery Team (ICTRT) viability criteria for the Middle Columbia River steelhead DPS (ICTRT 2007)

Biological Background

The Klickitat River drains approximately 1,350 square miles in south central Washington before joining the Columbia River at Lyle, Washington (RM 180.4), 34 miles upstream of Bonneville Dam. The Klickitat is one of the longest undammed rivers in the Northwest.

Reasons for listing the Middle Columbia River steelhead DPS as threatened under the ESA included low returns to the Yakima River, poor abundance estimates for Klickitat River and Fifteenmile Creek steelhead, uncertainty regarding the influence of hatchery releases on the natural steelhead population, and an overall decline of naturally producing "stocks" within the DPS (64 FR 14517). The Klickitat River population is of particular interest because of containing both summer and winter runs.

The ICTRT identified 17 extant and 3 extirpated independent steelhead populations in the Middle Columbia River steelhead DPS (McClure et al. 2003). These populations are shown in Figure ES-2. The ICTRT delineated the populations based on genetic information, geography, life history traits, morphological traits, and population dynamics.

The ICTRT grouped these independent populations into four major population groups (MPGs) within the DPS: the Cascades Eastern Slope Tributaries MPG, Yakima subbasin MPG, John Day River MPG, and Umatilla/Walla Walla MPG. The Klickitat River population is one of the five extant populations (Klickitat River, Fifteenmile Creek, Rock Creek, Deschutes Eastside, and Deschutes Westside) and two extirpated populations (White Salmon River and Deschutes Crooked River) comprising the Cascades Eastern Slope Tributaries MPG (Figure ES-3). Populations in the group are united primarily by proximity and occupy diverse habitats, generally those draining the eastern slopes of the Cascades and the Columbia Plateau.

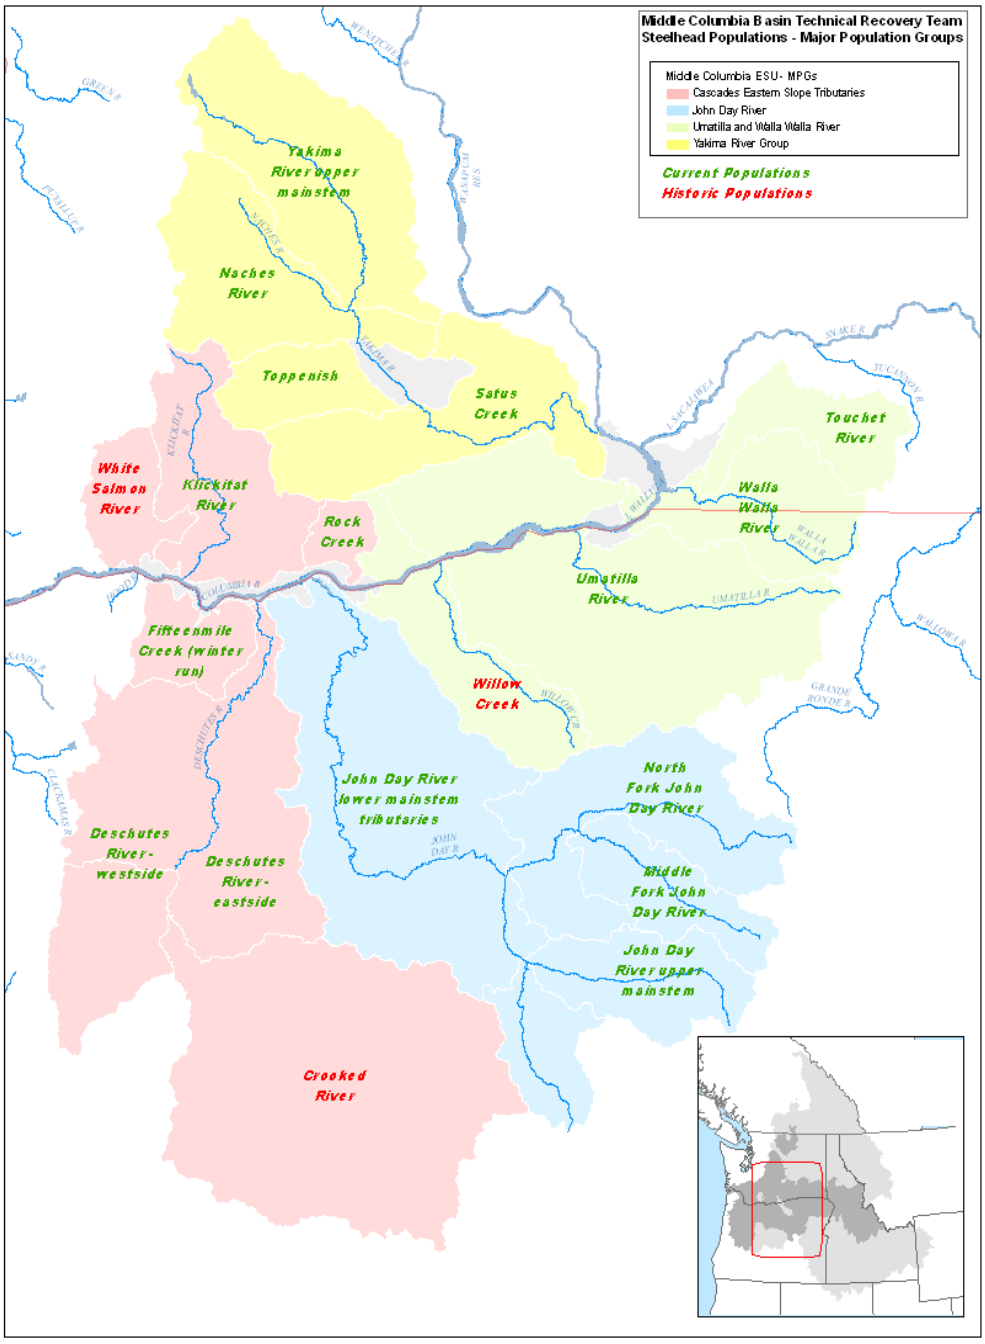

Figure ES-2. Independent Populations in the Middle Columbia River Steelhead DPS.

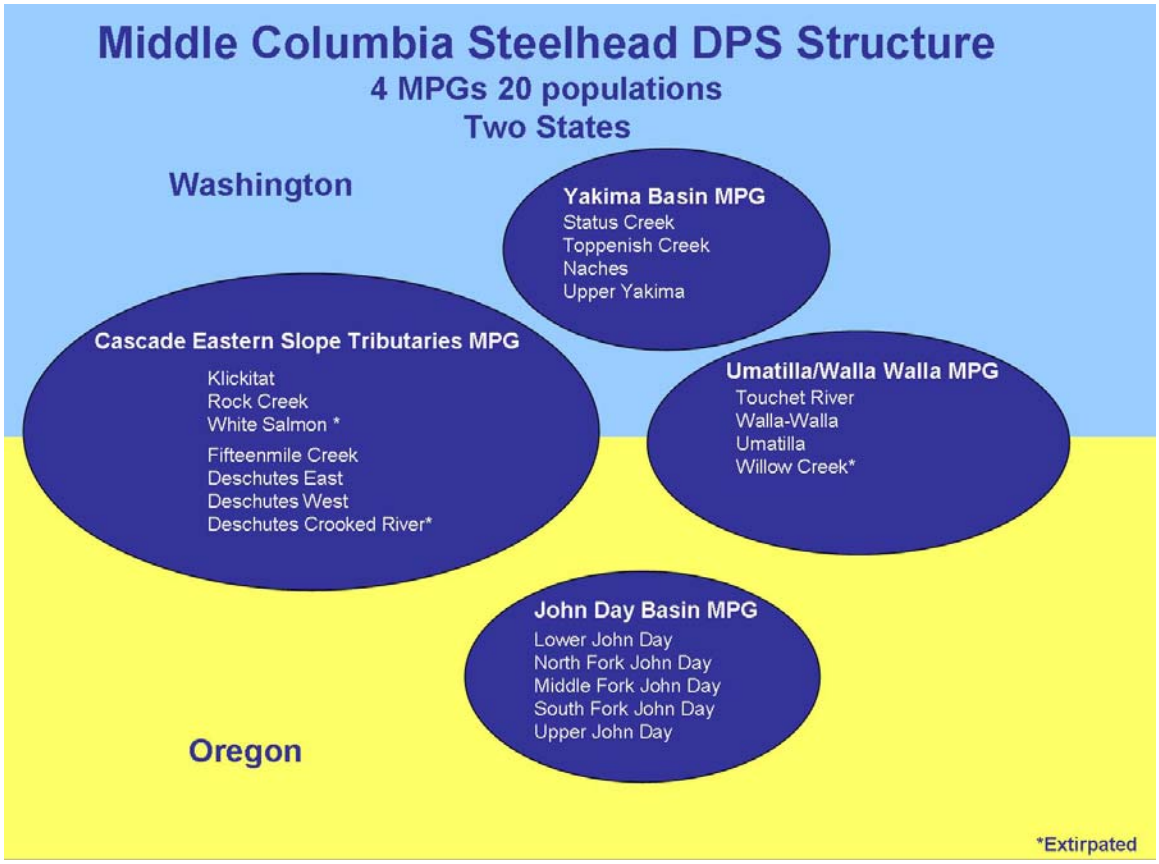

Figure ES-3. Major Population Groups and Populations of Middle Columbia Steelhead.

Historically, the presence of several natural migration barriers in the Klickitat watershed may have limited anadromous fish production, particularly during low water years. The Klickitat River flows through a deep, steep-walled canyon with several historically impassable or marginally passable falls and cascades where the river flows over resistant bedrock. In addition, access to many of the tributaries is restricted because of impassably high gradients or waterfalls close to the tributary mouths. Such historical barriers were important in maintaining separate life history strategies of *O. mykiss*, including summer steelhead, winter steelhead, and resident rainbow trout.

Approximately 102,000 summer-run steelhead from Skamania and Vancouver hatcheries are currently released directly into the Klickitat River annually. Release sites are Leidl Bridge (RM 32), the mouth of the Little Klickitat River (RM 20.2), Wahkiacus Bridge (RM 17), and Pitt Bridge (RM 10.4). The Skamania Hatchery broodstock is maintained by using adult steelhead returning to the Skamania Hatchery on the North Fork of the Washougal River. The original broodstock for the program was established with wild fish taken from both the Washougal and Klickitat River systems. In addition to the hatchery releases of steelhead, an average of 4,349,710 fall Chinook, 595,318 spring Chinook, and 3,714,083 coho are released from the hatcheries into the Klickitat River each year (Sharp et al. 2008). Coho and fall Chinook are not native to the basin upstream of Lyle Falls.

Recovery Goals and Criteria

The primary goal of ESA recovery plans is for the species to reach the point that it no longer needs the protection of the Act – i.e. to be delisted. Recovery plans may also contain "broad-sense" goals, defined in the recovery planning process, that go beyond the requirements for delisting to address, for example, other legislative mandates or social, economic, and ecological values.

Delisting criteria are applied at the DPS level, and are based on determinations of the viability of the independent populations that make up the DPS. Criteria for delisting the Middle Columbia steelhead DPS are described in the *Middle Columbia River Steelhead ESA Recovery Plan*, to which this plan is an appendix. This chapter provides recovery goals for the Klickitat steelhead population, describes the criteria to be used to assess progress toward those goals, and describes the role of the Klickitat steelhead population in overall DPS viability.

There are two kinds of criteria that enter into a delisting decision: population or demographic parameters (the biological viability criteria) and "threats" criteria related to the five listing factors detailed in the ESA (see Section 1.1). The threats criteria define the conditions under which the listing factors, or threats, can be considered to be addressed or mitigated. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B). Both kinds of criteria are discussed in this chapter.

The primary goal of this plan is for the Klickitat steelhead population to be restored to viable status and thus to support recovery of the Mid-Columbia steelhead DPS. A viable salmonid population is defined as an independent population that has negligible risk of extinction over a 100-year timeframe (McElhany et al. 2000).

If a local, collaborative Washington Gorge Recovery Board is formed, it may choose to define additional, broad-sense goals for the Klickitat steelhead population and other steelhead populations within the Washington Gorge Management Unit. The board's broad-sense goals for the area would likely build upon direction already adopted by various stakeholders in the area. These goals would then guide the board as it defines and implements future recovery actions for the Klickitat subbasin.

In the meantime, the Yakama Nation has proposed, as a broad-sense goal for the Klickitat steelhead population, the achievement of "highly viable" status, which corresponds to a one percent risk of extinction over a 100-year period. Achieving highly viable status for the population would provide for long-term, sustainable harvest and other social, cultural, and ceremonial needs, although it would likely exceed the minimum necessary to support delisting the DPS.

The ICTRT developed biologically based viability criteria for ESA-listed salmon and steelhead in the Interior Columbia domain. The ICTRT based its approach to recovery on guidance from the NMFS Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). This

memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels.

The ICTRT criterion for a viable ESU/DPS is that all extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS should be at low risk. The ICTRT provided additional criteria for determining MPG viability (Section 3.2.1). Applying the ICTRT's viability criteria to the Cascades Eastern Slope Tributaries MPG results in the conclusion that the Klickitat steelhead population should reach viable status in order to support overall DPS viability, because of its historical abundance and the presence of both summer and winter runs.

The ICTRT classified the Klickitat steelhead population as an "Intermediate" sized population, based on historical habitat potential (ICTRT 2007) and provided viability criteria for an Intermediate population, as follows (ICTRT 2007):

Abundance

For an Intermediate population, viable status, i.e. a 5 percent or less risk of extinction over a 100-year timeframe, would require a mean minimum abundance threshold of 1,000 naturally produced spawners.

Productivity

Productivity rates at relatively low numbers of spawners should, on average, be sufficiently greater than 1.0 to allow the population to rapidly return to abundance target levels.

Spatial Structure and Diversity

In general, the ICTRT defined two goals, or biological or ecological objectives, that spatial structure and diversity criteria should achieve (ICTRT 2007, p. 47):

- Natural rates and levels of spatially mediated processes should be maintained.
- Natural patterns of variation should be maintained.

Threats Criteria and Approach

Section 3.2.2 of the Plan describes the listing factors and listing factor/threats criteria that must be addressed to delist the DPS. The listing factors are the features that were evaluated under ESA section 4(a)(1) when the initial determination was made to list the species for protection.

At the time of a delisting decision, NMFS will use the listing factors/threats criteria to review the status of the section 4(a)(1) listing factors and determine whether the affected DPS is recovered to the point that it no longer requires protections of the ESA. NMFS expects that if the proposed actions described in this and other Middle Columbia River steelhead recovery plans are implemented, the fish will make substantial progress toward meeting the listing factor/threats criteria. These criteria are identified in Section 3.3 and address the five listing factors that were evaluated under section 4(a)(1): 1) the present or threatened destruction, modification, or curtailment of the species' habitat or range; 2) over-utilization for commercial, recreational, scientific or educational purposes; 3)

disease or predation; 4) the inadequacy of existing regulatory mechanisms; and 5) other natural or human-made factors affecting its continued existence.

Current Status Assessment

There are currently neither solid historical data nor accurate metrics for assessing current status of the Klickitat steelhead population. Yakama Nation biologists have provided substantial data, summarized in Chapter 4, which is, however, of a relatively short generational span and limited by significant uncertainties. The first priority for recovery for this population is to reduce these uncertainties with a targeted monitoring program (see Chapter 6, Recovery Strategy and Actions).

The ICTRT reviewed existing data, previous assessment findings, and GIS analysis for its 2005 viability assessment of this population, which is available on the Northwest Fisheries Science Center website, http://www.nwfsc.noaa.gov/trt/trt columbia.cfm.

In this recovery plan the ICTRT viability assessment is presented first, followed by currently available status information from the Yakama Nation. Discussion is also provided of findings from the ICTRT, Yakama Nation, and Klickitat County regarding identification of major and minor spawning areas.

The ICTRT found that the data for steelhead spawning in the Klickitat drainage were insufficient to estimate current abundance. It also found that the productivity of Klickitat steelhead is currently uncertain because both naturally produced and hatchery-origin steelhead return to the Klickitat River. Returns to the Klickitat River include hatchery-origin adults from annual outplants of Skamania summer steelhead stock (approximately 100,000 smolts per year) into the middle sections of the mainstem Klickitat. The spawning success of these hatchery fish is unknown. While redd surveys of steelhead spawning in the Klickitat drainage have been conducted in recent years, there is insufficient coverage to estimate the annual contribution of hatchery vs. natural steelhead in the natural production areas.

Because of insufficient data and the uncertainties regarding naturally occurring production, the ICTRT provisionally assigned the Klickitat River population **Moderate risk** for abundance and productivity (ICTRT 2007).

The ICTRT rated the Klickitat River steelhead population at **Moderate risk** for spatial structure and diversity because of the potential impact on wild steelhead from outside-stock hatchery fish. It determined that reducing the spatial structure/diversity risk to a low rating would require reducing the impacts of the outside-stock hatchery program on natural spawning areas, or determining that the natural population is actually experiencing very little impact from the Skamania stock origin returns.

Limiting Factors and Threats

1. Hatchery influences

Currently there is insufficient information to determine the effects of hatchery releases on the natural steelhead population. While it is likely that hatchery hybridization of Skamania stock with wild steelhead has occurred in the Klickitat subbasin (NPCC 2004),

the level of impact on the natural population remains uncertain. However, based on hatchery release levels and sport catch estimates, the ICTRT found that it is very likely that the hatchery contribution rate to natural steelhead spawning in the Klickitat subbasin has exceeded 5 percent for more than four generations (ICTRT 2007). Straying of out-of-subbasin hatchery-produced steelhead, primarily from the Snake River and Upper Columbia, into the Klickitat subbasin may also affect the viability of the Klickitat steelhead population.

Coho and fall Chinook are not native, but have naturalized in the basin as a result of hatchery releases and are known to spawn in relatively large numbers (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009). The effects of these hatchery releases and/or the subsequently naturalized species on the Klickitat River steelhead population are unknown.

2. Habitat

Habitat factors that likely limit steelhead production in the Klickitat watershed are affected by past and/or current land use practices that stress naturally occurring conditions. For example, while low summer flows and high summer water temperatures occur naturally in some parts of the watershed because of bedrock terrain and steep slopes, anthropogenic changes in the subbasin may have increased the intensity of such factors. The habitat factors that potentially limit steelhead abundance, productivity, spatial structure, and diversity within the Klickitat watershed are the following: lack of key habitat quantity and habitat diversity, loss of floodplain function, altered hydrology, degraded channel structure, obstructed fish passage, increased fine sediment delivery, high water temperature, and altered food web. Chapter 5 and Appendix II provide more detail on these factors, as well as their potential effects on steelhead viability.

3. Harvest

Tributary recreational steelhead fisheries in the Klickitat River are selective for marked hatchery steelhead; the release of unmarked wild steelhead is required. In the Klickitat River, the recreational fisheries impact on wild summer-run steelhead is estimated to be 6 percent and for winter-run steelhead 3 percent (WDFW 2003). Treaty Native American fisheries also occur in the mainstem Klickitat River. The treaty Native American catch of all types of steelhead (summer and winter, wild and hatchery combined) in the Klickitat River is estimated at an average of 1,146 steelhead per year since 1986 (Sharp et al. 2008). Estimated tribal harvest of wild steelhead in the Klickitat averages 178 fish per year (Table 2-1) (Sharp et al. 2008).

4. Out-of-Subbasin Factors

Out-of-subbasin limiting factors and threats are discussed briefly in Section 5.4. The 2008 Biological Opinion on the operation of the FCRPS, and particularly the Supplemental Comprehensive Analysis (NMFS 2008a). http://www.nwr.noaa.gov/Salmon-Hydropower/Columbia-Snake-Basin/Final-BOs.cfm, details the influences from the Columbia River hydrosystem. The Columbia River Estuary Module http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery -

Plans/upload/Estuary-Module.pdf discusses factors that may limit the viability of Klickitat steelhead in the Columbia River estuary.

Recovery Strategy and Actions

The rationale linking what is known about the population's current conditions and the actions that should be taken to achieve recovery is called the recovery strategy.

Lack of information about the Klickitat River steelhead population is a major problem for recovery planning for the Middle Columbia River steelhead DPS. Using the ICTRT criteria for DPS viability, this population (among others) needs to be viable for the DPS to be viable. The Klickitat population's moderate risk rating was assigned primarily on the basis of uncertainty and lack of data, particularly with respect to the influence of hatchery fish on the wild steelhead population. Therefore, the first importance for a recovery strategy is to reduce the uncertainties by obtaining more information.

A targeted monitoring program is needed for the following purposes:

- To determine abundance and productivity of natural spawners
- To determine the proportion of hatchery and wild spawners in the Klickitat subbasin.
- To determine the adverse effects of Skamania broodstock on the Klickitat population, if any.
- Continue study and further refine understanding of habitat limiting factors.

The Yakama Nation is working with NMFS, WDFW, tribal fish and wildlife leaders, and others to develop a master plan for an integrated hatchery program for the Lower Klickitat River. The program will minimize adverse impacts on the natural steelhead spawning population. One option being explored by hatchery program managers is to replace the current program, which releases out-of-basin Skamania hatchery-origin smolts in the Klickitat River system, with a hatchery program that relies entirely on the use of natural-origin summer steelhead from the Klickitat River for broodstock. The new program would continue to provide harvest opportunities for treaty and non-treaty fisheries. A feasibility study would likely be conducted as part of the program to investigate broodstock collection and juvenile rearing strategies, expected smolt-to-adult survival rates, and the risks associated with current steelhead hatchery practices.

The Yakama Nation also is working with NMFS, WDFW, tribal leaders, and others to examine whether a conservation hatchery program could be used to accelerate recolonization of the Upper Klickitat watershed. The program could also be used to provide harvest opportunities. The need for, and use of, artificial production to accelerate recolonization would be contingent upon the rate and extent that natural recolonization occurs in the upper watershed now that passage has been restored at Castile Falls. The decision to implement an artificial propagation program in the upper Klickitat watershed would likely imply that natural recolonization has been minimal and/or is occurring at an extremely slow rate. The draft Klickitat River Anadromous Fisheries Master Plan, which describes in detail these hatchery actions, was submitted for review to fulfill the requirements for step one of the NPPC's three-step process for major projects (WDFW and Sharp et al. 2008).

Habitat conditions (e.g. high water temperatures in some tributaries) and the various natural and constructed migration barriers are considered to be limiting factors for the Klickitat steelhead population. Protecting the existing good quality habitat, restoring habitat where appropriate, and improving access to spawning areas would likely improve abundance, productivity, spatial structure, and diversity for this population. Further identification of the factors limiting the Klickitat population is a priority action.

Managing harvest to maintain current low impacts from both mainstem and tributary fisheries, and to reduce any adverse impacts that may be occurring, also is an important contribution to the population's viability.

The actions recommended to support recovery are described in more detail in the following sections. Table ES-1 organizes priority actions in terms of larger categories, called strategies. Out-of-basin recovery strategies and actions are addressed in two NMFS documents, The Columbia River Estuary Module, available at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Other-Documents.cfm, and the 2008 FCRPS Biological Opinion (NMFS 2008c).

Table ES-1. Recovery Strategies and Actions for the Klickitat River Steelhead Population.

Strategy	Key Types of Actions
Hatchery	
Determine impact of hatchery steelhead releases on viability of Klickitat steelhead population.	• Conduct annual spawner surveys to track adult steelhead occupancy of MaSAs. • Sample carcasses on spawning grounds to estimate natural/hatchery adult spawner ratios. • Increase juvenile and adult genetic sampling and analysis at spawning grounds and at various trap locations to assess level of domestication and interbreeding between hatchery and natural steelhead. • Conduct radio-tagging study to determine spatial and temporal distribution of natural population and Skamania Hatchery steelhead, and overlap between summer and winter runs.
Minimize adverse impacts of hatchery releases on natural steelhead spawning population.	• Develop and implement Klickitat steelhead integrated hatchery program. • Conduct feasibility study to gain needed information on broodstock collection, rearing strategies and expected smolt-to-adult survival rates, and to assess risks associated with current and proposed hatchery practices.
Improve steelhead passage at Lyle Falls Fishway.	• Reconstruct Lyle Falls Fishway to Federal design criteria to ease passage of steelhead and to possibly function as the broodstock collection facility.
Assess steelhead natural recolonization of upper Klickitat watershed and the potential use of artificial propagation to accelerate recolonization.	• Monitor annual natural escapement of steelhead into the upper subbasin. • Use Castile Fishway trap to collect biological data on *O. mykiss* migrating into the upper watershed, and to monitor trends in the genetic composition and diversity of the upper basin population. • Explore need for a conservation hatchery program to accelerate recolonization of upper Klickitat watershed.
Minimize adverse impacts of large-scale hatchery releases of *U.S. v. Oregon* production stocks (coho and fall Chinook) on Klickitat steelhead.	• Develop the satellite Wahkiacus Hatchery/Acclimation Facility at RM 17.0. • Transfer existing *U.S. v. Oregon* production of fall Chinook and coho from Klickitat Hatchery to new Wahkiacus facility.
Determine and minimize impacts of hatchery trout releases in the subbasin.	• Investigate impacts of WDFW hatchery trout plants into the Klickitat subbasin.
Determine the effects of hatchery releases of coho and fall Chinook and subsequent naturalization of the species on Klickitat River steelhead	• Conduct annual spawner surveys to document adult coho and fall Chinook occupancy. • Sample carcasses on spawning grounds to estimate natural/hatchery adult spawner ratios. • Develop population estimates of naturally spawning coho and fall Chinook and evaluate productivity of those species. • Conduct studies as needed to determine the effect of coho and fall Chinook on steelhead population.
Tributary Habitat	
Protect stream corridor structure and function	• Protect highest quality habitats through land acquisition, conservation easements or land trusts with willing landowners. • Adopt and manage Cooperative Agreements where beneficial. • Conserve rare and unique functioning habitats. • Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.
Restore passage and connectivity between habitat areas.	• Monitor effectiveness of passage improvements at Castile Falls. • Remove or replace barriers blocking or impairing passage including dikes, road culverts and irrigation structures. • Monitor and continue restoration efforts in Snyder Creek mill reach. • Ensure that pump intakes are adequately screened.
Restore riparian condition	• Restore natural riparian vegetative communities. • Develop grazing strategies that promote riparian recovery. • Monitor and continue restoration efforts in Snyder Creek mill reach.

Strategy	Key Types of Actions
Restore altered hydrographs to enhance instream flows during critical periods	• Implement agricultural water conservation measures. • Improve irrigation conveyance and efficiency. • Employ BMPs to forest, agriculture and grazing practices and to road management. • Assess effects of groundwater development on tributary flow. • Protect and/or rehabilitate springs • Increase pool habitat.
Restore water quality, including water temperatures.	• Increase riparian shading where stream temperatures are high • Assess nutrient and dissolved oxygen levels in the Little Klickitat River, particularly downstream of Goldendale. • Employ BMPs for forest, agriculture and grazing practices and for road management. • Upgrade or remove problem forest roads.
Harvest	
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	Maintain current management regulations for low impact fisheries and adjust tributary harvest regulations in areas where harvest significantly impacts steelhead viability.
Study and limit adverse impacts of harvest practices in Klickitat subbasin on ESA-listed species.	Eliminate illegal harvest by enforcing tribal and sport regulations in Klickitat subbasin.
Monitoring	
Monitor to determine abundance and productivity of natural spawners, proportion of hatchery and wild spawners in the Klickitat subbasin, and adverse effects, if any, of Skamania broodstock on Klickitat steelhead population.	• Continue to enumerate upstream adult migrants and downstream migrating smolts at the fish traps • Develop estimates of the efficiencies of the traps • Annually estimate the abundance of the adult and smolt populations • Develop annual estimates of productivity of natural spawners Develop improved methods for estimating abundance and productivity of natural spawners.

Cost Estimates

The highest priority strategies for the Klickitat basin address data gaps (see Section 6-1). As such, these priority strategies fall into the category of research, monitoring, and evaluation. The costs associated with these efforts are detailed in Chapter 8. Table 8-1 estimates the cost of ongoing and expanded RM&E activities to be up to $4,484,402 for years 1 through 3, and up to $15,142,783 for years 4 through 10. Information gained through filling the priority data gaps will help to refine the actions needed to reach recovery.

Costs for actions to address hatchery-related effects are distributed among research, monitoring and evaluation, detailed in Chapter 8, and capital costs and operations and maintenance costs that have been included in programs proposed under the NPCC Fish and Wildlife Program or are ongoing under that program or the Mitchell Act administered by NMFS. Capital costs for hatchery and fish passage improvements are estimated at $41.6 million; these are proposed as part of the Klickitat River Anadromous Fisheries Master Plan, submitted to the NPCC in 2008 (Sharp et al. 2008). Ongoing operations and maintenance costs are not included in the total cost of recovery calculated for the plan, per NOAA guidance for cost estimating (Plummer 2006).

The total estimated cost for completing all of the habitat projects identified in Chapter 6 is estimated to be up to $129,451,630 ($25,890,326.00 for years 1-10, and

$103,561,304.00 for years 11-50). Estimates are expressed in 2007 dollars. Estimated costs are general range summaries arranged to align with the Klickitat River Anadromous Fisheries Master Plan (Sharp et al. 2008) and Yakima/Klickitat Fisheries Project.

Implementation

NMFS has worked independently with the Yakama Nation, Washington Department of Fish and Wildlife, and local entities to develop the recovery plan for the Klickitat steelhead population. NMFS encourages the formation of a planning forum for the Washington Gorge Management Unit, a forum or entity that would take responsibility for coordinating implementation of the plan. The creation of a Washington Gorge Area Regional Board (subject to concurrence by state, tribal and local governments, including the Yakama Nation) would provide a *collaborative process* for further prioritizing recovery actions and for implementation of the Washington Gorge Management Unit plans.

Implementation of the Klickitat Subbasin Recovery plan involves addressing data gaps through research, monitoring, and evaluation; establishing schedules and priorities for recovery actions; engaging stakeholders and landowners; identifying responsibilities; and securing funding. Implementation of this plan depends on the voluntary actions and cooperation of local entities and citizen groups. An important part of implementation will be working cooperatively to develop a detailed research, monitoring, and evaluation plan addressing the additional information needs described in Chapter 8.

Funding sources for salmon and steelhead recovery actions in the Columbia Basin are varied. They include:

- Pacific Coastal Salmon Recovery Fund (PCSRF) (States and tribes)
- Salmon Recovery Funding Board (SRFB) (a combination of PCSRF and Washington State funds)
- Columbia Basin Fish Accords
- Congressional appropriations (Federal agencies)
- State appropriations (state agencies)
- Northwest Power and Conservation Council Fish and Wildlife Program (states and tribes)
- Federal / state grants
- Non-profit organization programs and grants

The 2008 Columbia River Fish Accords Memorandum of Agreement between the Three Treaty Tribes and FCRPS Action Agencies identifies funds for hatchery planning and operations and maintenance covering some of the existing and expanded activities in the Klickitat River basin. The Accords identify hatchery capital funds for the design and construction of the hatchery and passage facilities in the Klickitat River basin except the Wahkiacus Hatchery facility, and include language that states that the Action Agencies will work toward finding funding for this facility.

Research, Monitoring, and Adaptive Management

As part of implementing the Klickitat recovery plan, a detailed monitoring and evaluation program will be designed and incorporated into an adaptive management framework based on the principles and concepts laid out in the NMFS guidance document, *Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance.*

The Klickitat monitoring and evaluation program will build on existing programs designed for monitoring tributary habitat in the subbasin, hydropower actions in the Mid-Columbia, Mid-Columbia hatchery programs, and other actions outside of the Mid-Columbia tributary subbasins (e.g., Columbia mainstem hydropower, estuary and ocean conditions, mainstem and ocean harvest). The monitoring and evaluation program will provide (1) a clear statement of the metrics and indicators by which progress toward achieving goals can be assessed, (2) a plan for tracking such metrics and indicators, and (3) a decision framework through which new information from monitoring and evaluation can be used to adjust strategies or actions aimed at achieving the plan's goals.

1. Introduction

The Endangered Species Act of 1973 (ESA) requires NOAA's National Marine Fisheries Service (NMFS) to develop recovery plans for species listed under the Act. The purpose of recovery plans is to identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA.

This recovery plan focuses on the conservation and survival of Middle Columbia River steelhead (*Oncorhynchus mykiss*) in the Klickitat subbasin (Figure 1-1). The Klickitat River drains approximately 1,350 square miles in south central Washington before joining the Columbia River at Lyle, Washington (RM 180.4), 34 miles upstream of Bonneville Dam. The Klickitat is one of the longest undammed rivers in the Northwest. The subbasin supports both summer and winter runs of steelhead.

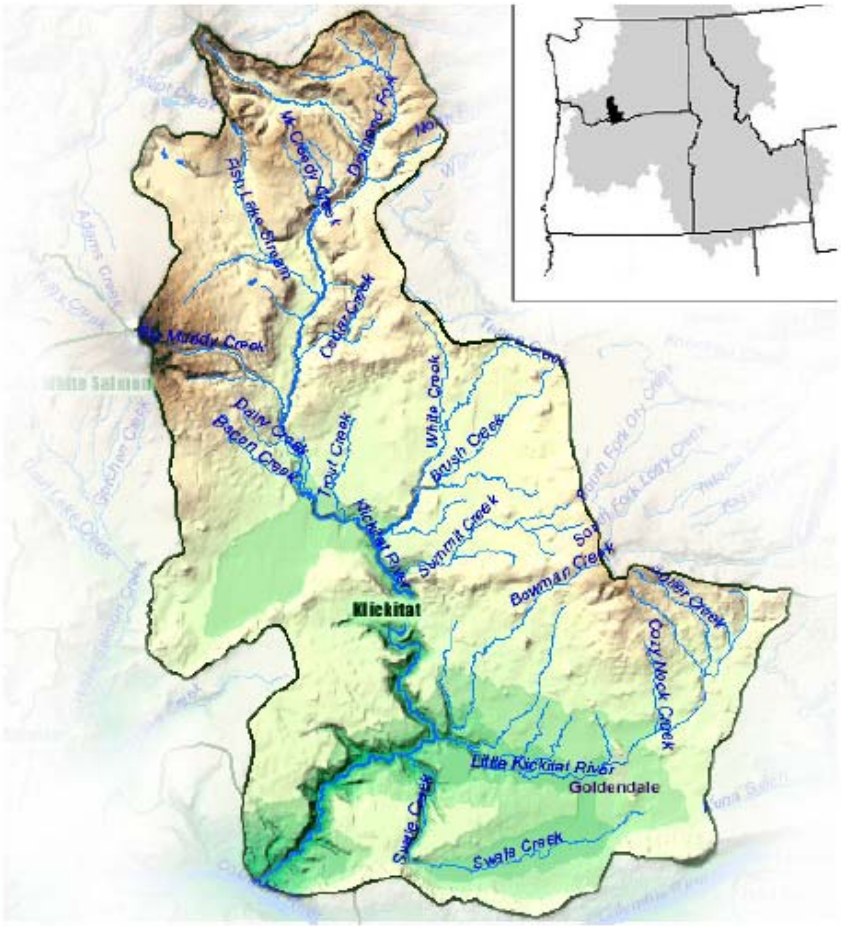

Figure 1-1. Klickitat Subbasin.

"Steelhead" is the name commonly applied to the anadromous form of the biological species *Oncorhynchus mykiss*. The species also has a non-anadromous, or resident, form

that is commonly called rainbow trout. NMFS originally listed the species as threatened on March 25, 1999 (NMFS 1999), calling it an "evolutionarily significant unit" (ESU) of salmonids, which included both forms. Recently, NMFS revised its species determinations for West Coast steelhead under the ESA, delineating anadromous, steelhead-only "distinct population segments" (DPS). NMFS listed the Middle Columbia River steelhead DPS as threatened on January 5, 2006 (NMFS 2006a, 71 FR 834). The DPS is made up of steelhead populations in Oregon and Washington tributaries of the Columbia River upstream of the Hood and Wind River systems, up to and including the Yakima River. Reasons for listing the Middle Columbia River steelhead DPS included low returns to the Yakima River, poor abundance estimates for Klickitat River and Fifteenmile Creek winter steelhead, and an overall decline of naturally producing "stocks" within the DPS.

The Klickitat River population is of particular interest because of containing both summer and winter runs, and it potentially could make a significant contribution to recovery of the Middle Columbia steelhead. The Klickitat River is one of the largest salmon producing watersheds in the Columbia basin. It is located above only one dam (Bonneville), contains headwaters in the well-managed forests of the Yakama Reservation, and has had relatively little development, with relatively low human population growth expected in the near future. Recent passage improvements at Castile Falls in the upper Klickitat have opened an additional 56 miles of high quality steelhead habitat. Passage improvements in the lower Klickitat (Lyle Falls at RM 2.2) are also expected to benefit immigrating adults. In addition, a hatchery master plan under development by the Yakama Nation in consultation with NMFS is expected to improve hatchery management to support conservation of the naturally spawning steelhead.

NMFS developed this recovery plan with involvement and input from the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal agencies, state agencies, local governments, and the public. While NMFS is the agency responsible for recovery planning for salmon and steelhead under the ESA, NMFS believes it is critically important to base ESA recovery plans for salmon on the many state, regional, tribal, local, and private conservation efforts already underway throughout the region. Local support of recovery plans by those whose activities directly affect the listed species, and whose actions will be most affected by recovery efforts, is essential. NMFS therefore supports and participates in locally led collaborative efforts to develop recovery plans, involving local communities, state, tribal, and Federal entities, and other stakeholders.

1.1 Purpose of Plan

The Plan provides a roadmap for restoring the Klickitat steelhead population and its habitats to a level that supports recovery of the Middle Columbia River steelhead DPS and allows the population to become a viable component of its ecosystem.

The Plan is a guidance document. It describes the current status of the Klickitat population and its habitat in the Klickitat drainage, and summarizes the results of a technical assessment examining the population's viability. The Plan also identifies the

factors and threats potentially limiting the population and proposes strategies and actions designed to aid in the population's recovery by building on past and current efforts. Finally, the Plan provides an implementation and adaptive management framework for making needed future adjustments on the road to recovery.

1.1.1 ESA Requirements

Section 4(f) of the ESA requires that a recovery plan be developed and implemented for species listed as endangered or threatened under the statute.

ESA section 4(a)(1) lists factors for re-classification or delisting that are to be addressed in recovery plans:

A. The present or threatened destruction, modification, or curtailment of [the species'] habitat or range
B. Over-utilization for commercial, recreational, scientific or educational purposes
C. Disease or predation
D. The inadequacy of existing regulatory mechanisms
E. Other natural or human-made factors affecting its continued existence

ESA section 4(f)(1)(B) directs that recovery plans, to the extent practicable, incorporate:

1. a description of such site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species;
2. objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this chapter, that the species be removed from the list; and;
3. estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal.

In addition, it is important for recovery plans to provide the public and decision makers with a clear understanding of the goals and scientifically supported strategies needed to recover a listed species (NMFS 2006b).

Once a species is deemed recovered and therefore removed from a listed status, section 4(g) of the ESA requires the monitoring of the species for a period of not less than five years to ensure that it retains its recovered status.

1.1.2 Coordination with Others

The Plan aims to provide consistency among related recovery planning and management efforts, including NOAA's Federal treaty and trust responsibilities and the many state and local entities involved in salmon recovery.

Federal Treaty and Trust Responsibilities

Northwest Native American tribes have legally enforceable treaty rights reserving to them a share of the harvestable salmon and steelhead. Achieving the basic purposes of the ESA such that the species no longer needs the protection of the Act may not by itself

fully meet these rights and expectations, although it will lead to major improvements in the current situation. Ensuring a sufficient abundance of salmon to sustain harvest can be an important element in fulfilling trust and treaty rights as well as garnering public support for these plans.

It is NMFS policy that recovery of salmonid populations must achieve two goals: (1) the recovery and delisting of salmonids listed under the provisions of the ESA, and (2) the restoration of the meaningful exercise of tribal fishing rights. "It is the agency's view that there is no conflict between the statutory goals of the ESA and Federal trust responsibility to Indian tribes" (Letter from Terry Garcia, Assistant Secretary for Oceans and Atmosphere, to Ted Strong, Executive Director, Columbia Inter-Tribal Fish Commission, July 21, 1998). Additionally, NMFS "will continue to join with states and tribes to develop a comprehensive approach to the restoration of fish and wildlife resources in a manner that fulfills all obligations under Federal law, including trust obligations to Indian tribes" (ibid.).

Thus, it is appropriate for recovery plans to take these considerations into account and plan for a recovery strategy that includes harvest. In some cases, the desired abundances for harvest may come about through increases in the naturally spawning population. In others, the recovery strategy may include appropriate use of hatcheries to support a portion of the harvest. So long as the overall plan is likely to achieve the biological recovery of the listed ESU, it will be acceptable as a recovery plan.

Treaty Native American fishing rights in the Columbia basin are under the continuing jurisdiction of the U.S. District Court for the District of Oregon in the case of *United States v. Oregon*, No. 68-513 (filed in 1968). The parties to *U.S. v. Oregon* are the United States acting through the Department of Interior (USFWS and Bureau of Indian Affairs) and Department of Commerce (NMFS), the Warm Springs, Umatilla, Nez Perce, Yakama, and Shoshone-Bannock Tribes, and the states of Oregon, Washington, and Idaho. In *U.S. v. Oregon*, the Court affirmed that the treaties reserved for the tribes 50 percent of the harvestable surplus of fish destined to pass through their usual and accustomed fishing areas.

The Klickitat watershed is part of the Yakama Nation's ceded area. Yakama Nation staff developed much of the data on the Klickitat population. The Yakama Nation is voluntarily participating in recovery planning and implementation in the Yakima subbasin and throughout its ceded area as a sovereign with treaty-reserved rights on and off the reservation, and as a fish and wildlife co-manager. In so doing, the Yakama Nation does not waive or in any way alter its treaty-reserved rights.

Other Federal, State and Local Responsibilities

To ensure consistency in goals, strategies, and actions and to eliminate needless duplication of effort, the process aims to provide consistency between planning for ESA recovery, the Northwest Power and Conservation Council (NPCC) Fish and Wildlife Program, the State of Washington Watershed Management and Salmon Recovery Programs, and local planning and regulatory efforts.

This recovery plan follows ESA guidelines and builds upon direction in the Klickitat Subbasin Plan (NPCC 2004). The 2004 Klickitat Subbasin Plan was developed for the NPCC by the Yakama Nation, Washington Department of Fish and Wildlife, and other Federal, state, and local entities. It contains an assessment and inventory of fish and wildlife resources in the subbasin, as well as a management plan establishing locally informed fish and wildlife protection and restoration priorities. The NPCC adopted the Klickitat Subbasin Plan into its Fish and Wildlife Program in 2004. The NPCC and Bonneville Power Administration use the Klickitat Subbasin Plan to direct funding for projects that protect, mitigate, and enhance fish and wildlife that have been adversely impacted by the development and operation of the Columbia River hydropower system, pursuant to their obligations for implementing the Northwest Power Act of 1980.

Information and direction was also drawn from the Watershed Management Plan for Watershed Resource Inventory Area (WRIA) 30, the Klickitat drainage. The Watershed Management Plan was developed and approved in accordance with Chapter 90.82 Revised Code of Washington (Chapter 90.82 RCW). The "initiating governments" for the planning effort were Klickitat County, City of Goldendale, and Public Utility District No. 1 of Klickitat County (KPUD). The Watershed Management Plan provides for 5 years of funding for watershed plan implementation via the WRIA planning organization.

1.2 Context of Plan Development

This plan for the Klickitat steelhead population is one part of a larger effort to recover species listed throughout the Pacific Northwest. Not only is it one of several recovery plans for steelhead populations in the Middle Columbia River steelhead DPS, it is also one of many recovery plans within NMFS' larger framework of recovery planning efforts for listed salmon and steelhead populations across the Pacific Northwest.

Currently 13 ESUs and 6 DPSs of Pacific salmon and steelhead in the Pacific Northwest are listed under the ESA. NMFS has designated five geographically based recovery domains for preparing recovery plans for the listed species. The Middle Columbia River steelhead DPS falls within the Interior Columbia recovery domain (which is divided into three sub-domains: the Snake River, Mid-Columbia, and Upper Columbia). The other recovery domains are the Willamette/Lower Columbia, Puget Sound and Washington Coast, Oregon Coast, and the Southern Oregon/Northern California Coast. (http://www.nwr.noaa.gov/Salmon-Recovery-Planning/Recovery-Domains/Middle-Upper-Columbia/Index.cfm). Similar opportunities for technical and stakeholder involvement exist in each domain.

1.2.1 Technical Recovery Teams

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each Technical Recovery Team (TRT) was to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population viability criteria – criteria to be used, along with criteria based on mitigation of the factors for decline, to determine whether a species has recovered sufficiently to be downlisted or delisted. These principles are described in a NMFS technical memorandum, *Viable Salmon Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). Viable salmonid populations (VSP) are defined in terms of four parameters: abundance, population productivity or growth rate, population spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework, based on data availability, the unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective experience and expertise. Although NMFS has encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs are working from a common scientific foundation.

The Interior Columbia Technical Recovery Team (ICTRT) provided technical support for the Mid-Columbia River steelhead DPS recovery planning effort. The ICTRT included biologists from NMFS, state and tribal entities, and academic institutions.

1.2.2 Planning Forums

In each domain, NMFS has worked with state, tribal, local and other Federal entities to develop planning forums that build to the extent possible on ongoing, locally led recovery efforts. NMFS defined "management units" based on jurisdictional boundaries as well as areas where citizen planning efforts were underway. The Mid-Columbia management units are (1) Oregon; (2) Washington Gorge, which, in turn, is subdivided into three planning areas, White Salmon, Klickitat, and Rock Creek; (3) Yakima subbasin; and (4) Southeast Washington. These management units have active planning and implementation forums, with the exception of the Washington Gorge Management. In the Washington Gorge Management Unit, NMFS has worked independently with the Yakama Nation, Washington Department of Fish and Wildlife (WDFW), Klickitat County, and local entities to develop the recovery plan for the Klickitat steelhead population. NMFS encourages the formation of a planning forum for the Washington Gorge Management Unit (Figure 1-2).

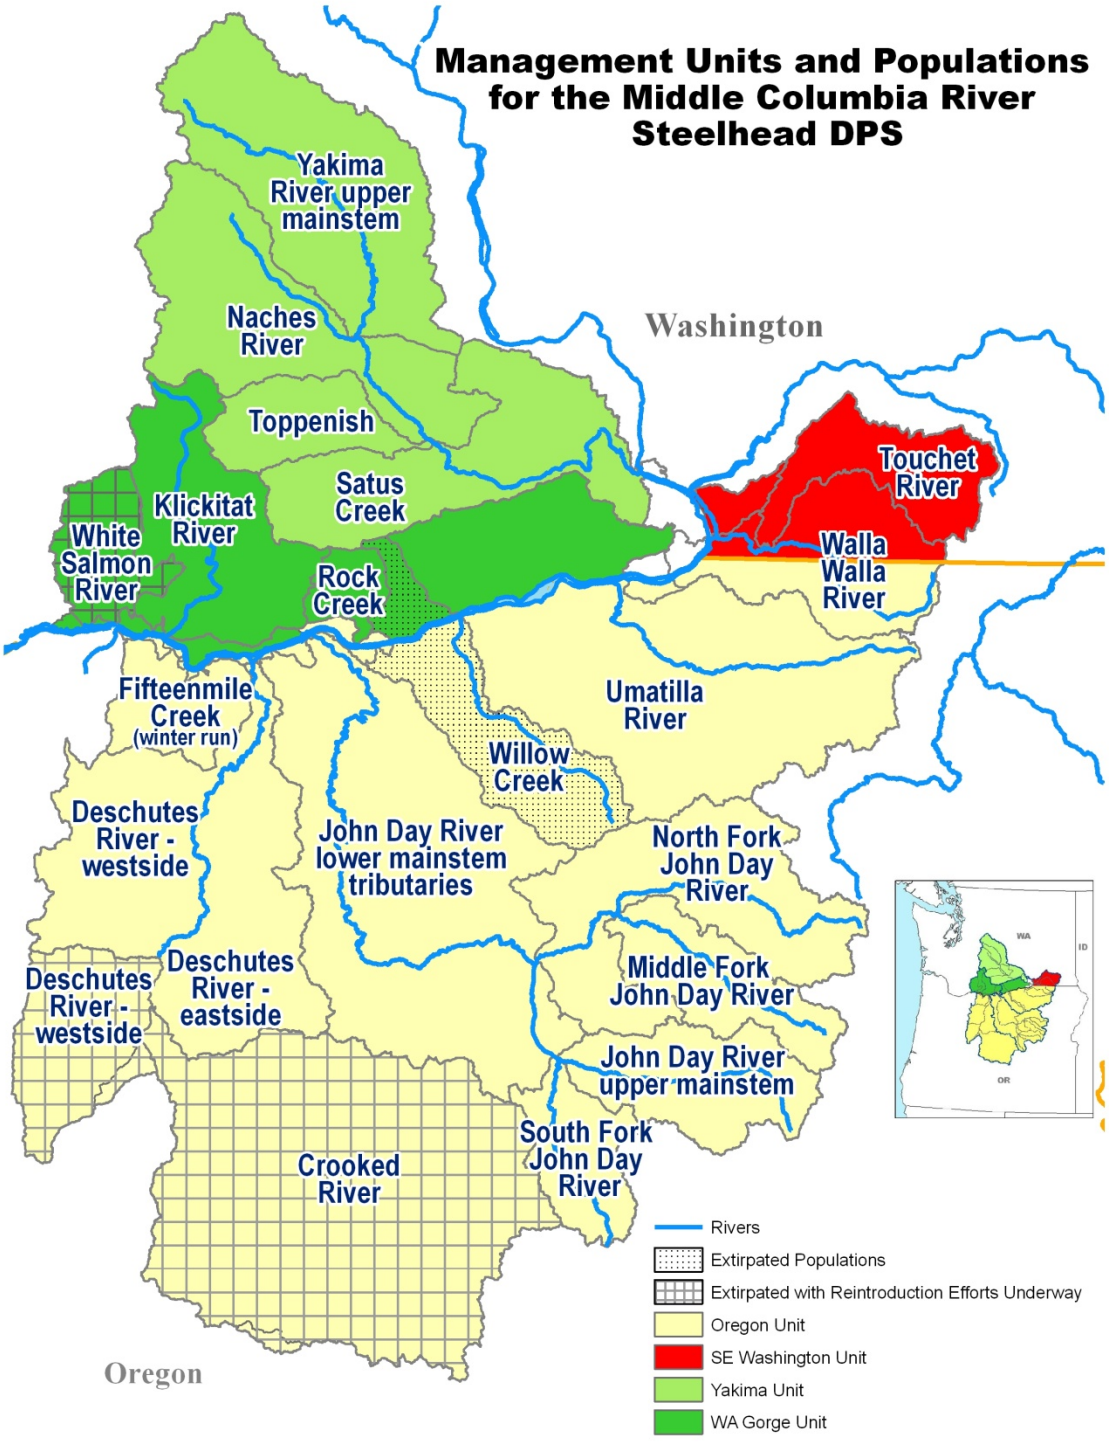

Figure 1-2. Management Units for Middle Columbia River Steelhead DPS.

1.3 How NMFS Intends to Use the Plan

Although recovery plans are not regulatory and their implementation is voluntary, they are important tools that help to do the following:

- Provide context for regulatory decisions.
- Guide decision making by Federal, state, tribal, and local jurisdictions.
- Provide criteria for status reporting and delisting decisions.
- Organize, prioritize, and sequence recovery actions.
- Organize research, monitoring, and evaluation efforts.

NMFS will encourage Federal agencies and non-Federal jurisdictions to take recovery plans under serious consideration as they make the following sorts of decisions and allocate their resources:

- Actions carried out to meet Federal ESA section 7(a)(1) obligations
- Actions that are subject to ESA sections 4d, 7(a)(2), or 10
- Hatchery and Genetic Management Plans and permit requests
- Harvest plans and permits
- Selection and prioritization of subbasin planning actions
- Development of research, monitoring, and evaluation programs
- Revision of land use and resource management plans
- Other natural resource decisions at the state, tribal, and local levels

NMFS will emphasize recovery plans in ESA section 7 (a)(2) consultations, section 10 permits, and application of the section 4(d) rule by considering:

- Delisting criteria that address both viability and threats
- Description of limiting factors and threats (factors for decline)
- Description of a recovery program (site-specific management actions necessary to achieve recovery of the species)
- Estimates of the time and cost to carry out measures to achieve the plans' goals

In implementing these programs, recovery plans will be used as a reference and a source of context, expectations, and goals. NMFS staff will encourage the Federal "Action Agencies" to describe in their biological assessments how their proposed actions will affect specific populations and limiting factors identified in the recovery plans, and to describe any mitigating measures and voluntary recovery activities in the action area.

2. Biological Background

This chapter describes population and habitat characteristics for Middle Columbia River steelhead in the Klickitat subbasin. The chapter also discusses hatchery production and releases and harvest management in the Klickitat subbasin.

2.1 Populations and Major Population Groups

The ICTRT identified 17 extant and 3 extirpated independent steelhead populations in the Middle Columbia River steelhead DPS (McClure et al. 2003). These populations are shown in Figure 2-1. The ICTRT delineated the populations based on genetic information, geography, life history traits, morphological traits, and population dynamics.

The ICTRT grouped these independent populations into four major population groups (MPGs) within the DPS: the Cascades Eastern Slope Tributaries MPG, Yakima subbasin MPG, John Day River MPG, and Umatilla/Walla Walla MPG. The Klickitat River population is one of five extant populations (Klickitat River, Fifteenmile Creek, Rock Creek, Deschutes Eastside, and Deschutes Westside) and two extirpated populations (White Salmon River and Deschutes Crooked River) comprising the Cascades Eastern Slope Tributaries MPG (Figure 2-2). Populations in the group are united primarily by proximity and occupy diverse habitats, generally those draining the eastern slopes of the Cascades and the Columbia Plateau.

2.2 Physical Setting

The Klickitat River drains an area of approximately 1,350 square miles in south central Washington. It begins in the Cascades Mountains below Cispus Pass near 5,000 feet elevation and flows just over 95 miles to join the Columbia River at Lyle, Washington (RM 180.4), 34 miles upstream of Bonneville Dam (elevation 74 feet). It is one of the longest undammed rivers in the Northwest. The Klickitat drainage stretches west to the Cascade Mountain crest, north and east to the basalt ridges and plateaus of the Yakama Reservation, and south to the Columbia River Gorge. Major tributaries to the Klickitat River include Swale Creek (RM 17.2), Little Klickitat River (RM 19.8), Outlet Creek (RM 39.7), Big Muddy Creek (RM 53.8), West Fork Klickitat River (RM 63.1), and Diamond Fork (RM 76.8) (NPCC 2004). Major Creek is a small tributary to the Columbia River that lies just downstream of the Klickitat River drainage and is believed to support Middle Columbia steelhead. Appendix I provides an overview of the Major Creek watershed and current knowledge concerning steelhead use.

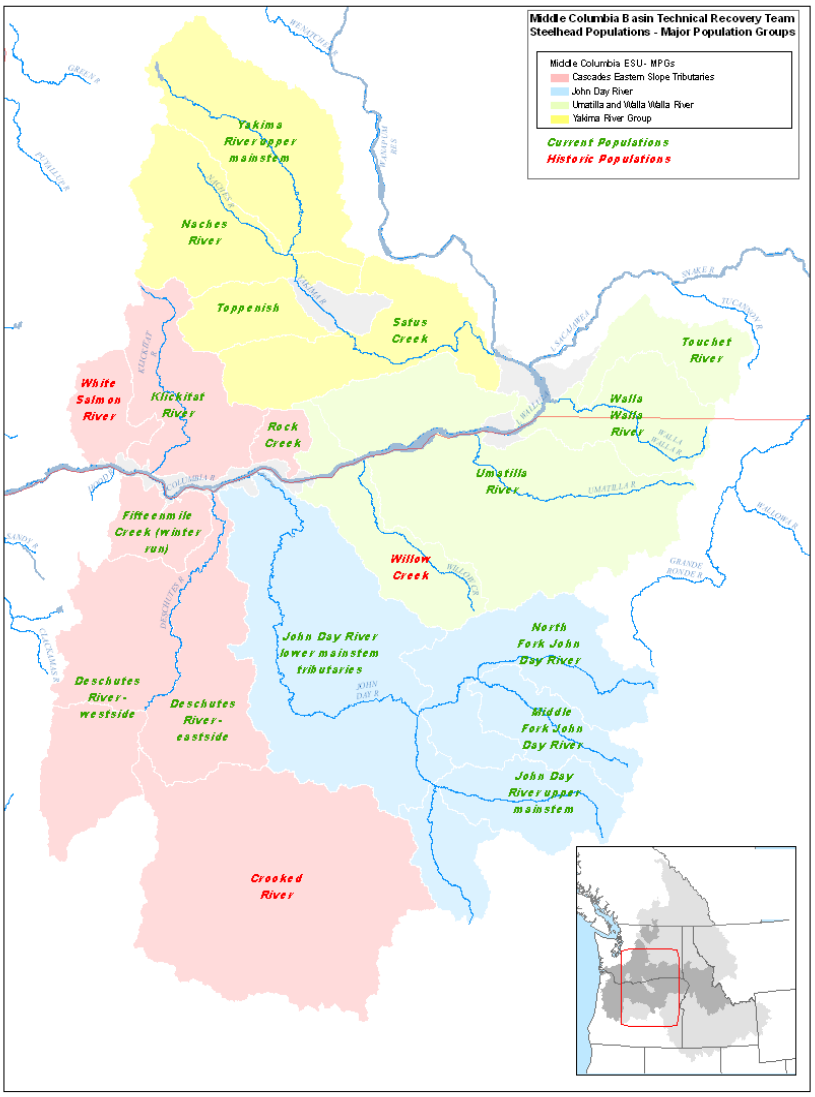

Figure 2-1. Independent Populations in the Middle Columbia River Steelhead DPS.

Forests cover three-quarters of the watershed: the Yakama Nation is the primary timberland landowner. These lands are managed according to the Yakama Nation Forest Management Plan, which designates the Klickitat watershed a "Reserve Area," where no timber harvest is planned. The State of Washington and numerous private parties own the remaining forested land, which is managed pursuant to the State Forest Practices Rules and an approved Habitat Conservation Plan (HCP). The rest of the watershed is used primarily for pasture, orchards, dry-land farming and livestock grazing. Agricultural use is concentrated in the Glenwood/Camas Prairie area in the western part of the watershed and on the southeastern plateau. Portions of the southernmost part of the Klickitat subbasin are within the Columbia River Gorge National Scenic Area (extending roughly 3 miles upstream from the mouth) (http://www.fs.fed.us/r6/columbia/maps/map.htm). The lower 10 miles of the Klickitat River are designated as a Recreational River under the National Wild and Scenic Rivers Act (http://www.rivers.gov/wsr-klickitat.html). The

Klickitat Wildlife Area, owned and managed by WDFW, covers 14,700 acres, encompasses a significant portion of the Klickitat River between the confluence with the Little Klickitat River and White Creek, as well as smaller segments of land along the lower river, downstream of the Little Klickitat River http://www.ecy.wa.gov/services/gis/maps/wria/mpl/mpl30.pdf. Columbia Land Trust recently acquired for conservation the west bank of the Klickitat River extending from just below the confluence with the Little Klickitat River north approximately 15 miles.

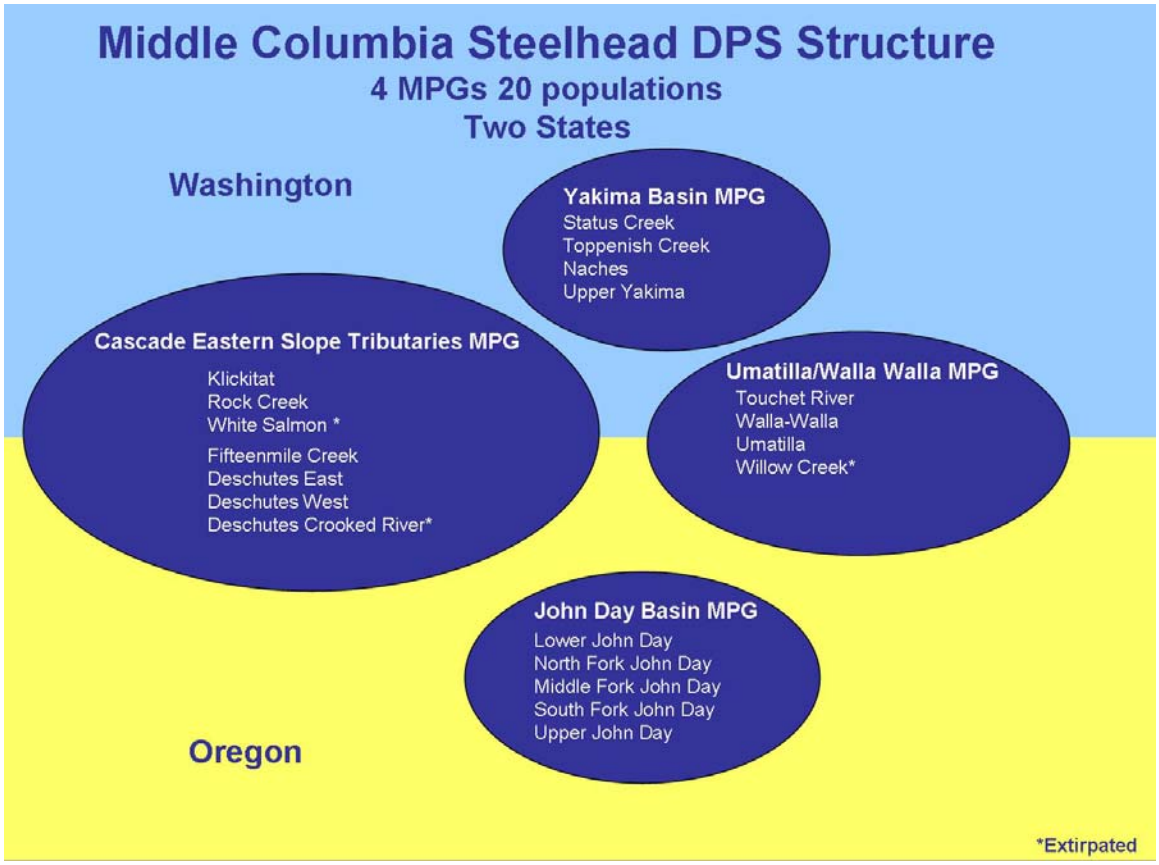

Figure 2-2. Major Population Groups and Populations of Middle Columbia Steelhead.

Several entities share responsibility for land and water management in the Klickitat subbasin (Figure 2-3). The subbasin is almost equally divided between Klickitat and Yakima counties. The City of Goldendale is the Klickitat County seat. The City of Yakima is the Yakima County seat. The subbasin supports a total population of approximately 11,000 people. As of the 2000 census, the City of Goldendale had a population of 3,760 (www.census.gov). The towns of Klickitat, Lyle, and Glenwood are unincorporated. The Yakama Nation is also a caretaker of subbasin resources. The Yakama Reservation comprises 1,573 square miles in Klickitat and Yakima counties. About a third of the Klickitat watershed, including the headwaters of the Klickitat River, lies within the reservation. The Yakama Nation ceded the rest of the Klickitat area in the June 9, 1855 treaty with the United States, reserving fishing, hunting and gathering rights, among other rights and responsibilities. The Klickitat watershed contains a "usual and accustomed fishing area" of historical, traditional, and modern cultural significance

at Lyle Falls. In addition, the subbasin falls within Washington's Middle Columbia River Salmon Recovery Region ─ one of several Salmon Recovery Regions designated within Washington State ─ which includes salmon-bearing streams in Benton, Kittitas, Yakima, and parts of Chelan and Klickitat counties. It is also designated as the state's Water Resource Inventory Area (WRIA) 30.

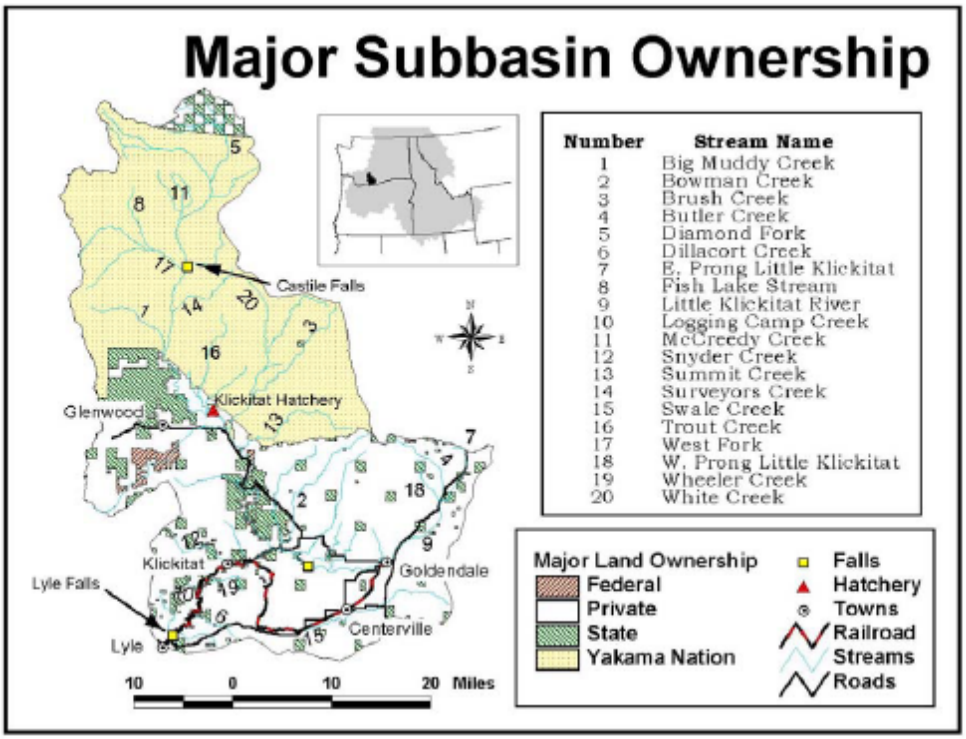

Figure 2-3. Klickitat Subbasin Land Ownership, Towns and Stream Locations (NPCC 2004).

2.3 Ecosystem Conditions

The Klickitat subbasin consists primarily of a basalt plateau with a total thickness of several thousand feet (Cline 1976), which is dissected by deep, steep-walled canyons carved by the watershed's network of streams and rivers. The Klickitat River, for example, flows through a deep canyon (700 to 1500 feet deep), and most of its tributaries are similarly incised. The erosion-resistant nature of some of the basalt strata has caused the formation of numerous waterfalls that restrict fish movement, including three notable waterfalls: Lyle Falls (RM 2.2 on the mainstem Klickitat River), Castile Falls (RM 64.0 to 64.5 on the mainstem Klickitat River), and Little Klickitat Falls (RM 6.1 on the Little Klickitat River).

2.3.1 Hydrology

Most streams in the Klickitat subbasin have natural runoff patterns, since there is no flow regulation within the watershed. Flow in the Klickitat River is primarily fed by snowmelt in spring and early summer, and by glacial melt in late spring and summer. Peak flows in the upper subbasin (upstream of Cedar Valley tributaries and some of the smaller tributaries to the north of Glenwood, e.g. Dairy and Bacon creeks) are predominantly

snowmelt-driven, although the largest events (e.g., 1996) involve rain at high elevations and rapid melting throughout the entire Klickitat subbasin (Figure 2-4). Peak flows in the middle and lower Klickitat subbasin often occur during the winter and are driven by rain-on-snow events.

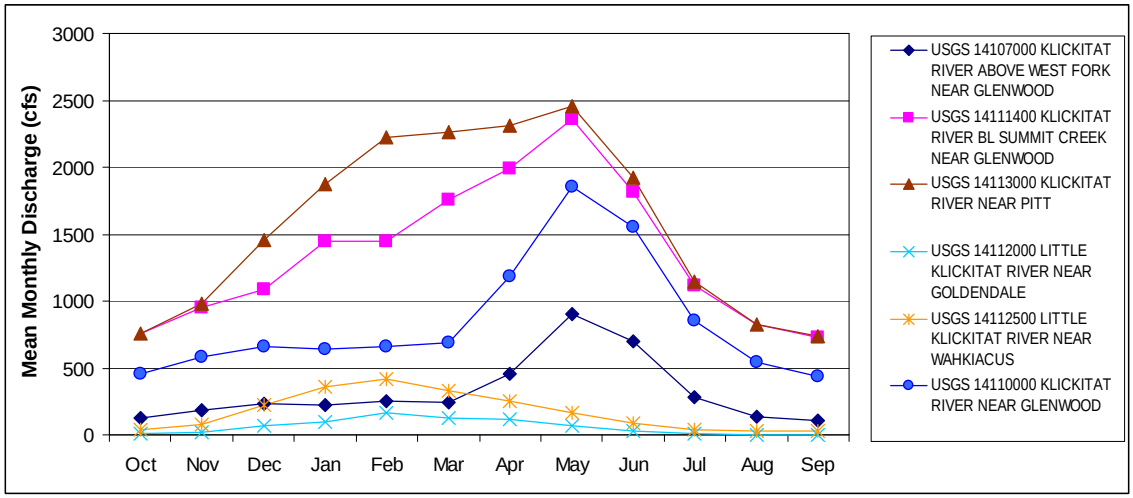

Figure 2-4. Mean Monthly Stream Flow for Six USGS-Operated Gauges on the Little Klickitat and Mainstem Klickitat rivers. (data source: USGS 2009).

The Little Klickitat River flows from the Simcoe Mountains and is largely fed by snowmelt supplemented by base flow from groundwater sources. Snow melts out of the Simcoe Mountains earlier than in the Cascade Mountains and snow pack tends to be substantially smaller. Peak flows in the Little Klickitat occur through the winter because the elevation of the watershed is within the rain-on-snow zone. The Little Klickitat River has continuous flow over nearly all of its length (Ecology 2008).

In some areas, groundwater discharge adds substantial flow to local streams. The volcanic rocks on the Mt. Adams side of the Klickitat River contain permeable volcanic debris and lava tubes. The Columbia River Basalt that underlies most of the Klickitat River Basin represents the largest source for groundwater supply within the subbasin. Cline (1976) estimates that about 60 percent of the average annual stream flow leaving the Yakama Reservation in the Klickitat River is groundwater discharge, with individual springs discharging up to 40 cubic feet/second (cfs). Springs are common in the Camas Prairie (Glenwood) area, reflecting the abundance of shallow ground water in the area (WPN and Aspect 2005a).

The middle and upper subbasin provide the vast majority of surface and ground water that contribute to mainstem baseflow. As shown in Figure 2-4, flow that supports the lower Klickitat River from July through November originates from the upper and middle Klickitat subbasin (measured at Summit Creek).

Low flow may limit steelhead production in many streams in the lower and middle Klickitat watersheds. In the lower subbasin, Swale Creek, Knight Canyon, Dillacort, Wheeler, upper Canyon, Beeks Canyon, and Dead Canyon creeks, and portions of White

Creek, dry up partially or completely in most years (WPN and Aspect 2005a). The only lower subbasin tributaries that maintain continuous or nearly continuous surface flow are the Little Klickitat River, Logging Camp Canyon and Snyder Canyon creeks, though perennial flows become restricted to middle and upper portions of Logging Camp Canyon and Snyder Creek after mid- to late-June (J. Spencer, personal communication 2006).

2.3.2 Water Quality

Water quality in the Klickitat River is influenced by natural and human factors. Glaciers on Mt. Adams, a 12,000-foot dormant volcano with an extensive glacier system, are prone to occasional outburst floods that deliver torrents of water, volcanic debris, and fine sediment via snowmelt to Big Muddy and Little Muddy creeks and the West Fork Klickitat. This results in high mainstem suspended sediment during summer months that colors the Klickitat River from the West Fork to the Columbia River, 63 miles downstream. Fine sediments associated with forestry, roads, agricultural practices, and construction may also be delivered to streams. The quantities of sediment delivered through land use practices and the effects of anthropogenic inputs have not been evaluated.

One segment of Swale Creek has been included on the Washington Department of Ecology's (WDOE's) 2008 list of impaired water bodies (303d list) because of temperature impairment (http://www.ecy.wa.gov/programs/wq/303d/2008/index.html). A water quality study was completed between June and December 2003 to assess the water temperature situation in Swale Creek and to estimate the potential and natural temperature situation in the lower portion of the creek which runs through a canyon (WPN and Aspect 2005a). The temperature criterion of 18ºC was exceeded at all stations monitored in 2003. Under current conditions, the upper two reaches of the canyon (covering roughly nine miles) are largely dry, with isolated bedrock dominated pools. In this area, shade tends to be very sparse around the pools (<25 percent). The lower three miles of Swale Creek (excluding the mouth) maintain a continuous flow during summer months with negligible volume (estimated at 0.25 to 0.5 cfs during the 2003 study; WPN and Aspect 2005a). Shade in the lower three miles approaches 100 percent effective shade in some areas. The *Klickitat River Watershed Management Plan*, developed pursuant to section 90.82 RCW, calls for an analysis to determine whether Swale Creek is appropriately categorized with respect to Washington State's surface water temperature standards, and it calls for the development and implementation of a plan to improve stream temperatures (WPN and Aspect 2005b). According to a 2002 assessment, Swale Creek has the potential to provide viable habitat for anadromous salmonids if the channel is restored and perennial water enhanced (Inter-Fluve 2002).

Several reaches in the Little Klickitat River were previously on WDOE's water quality assessment (also known as the 303(d) list) as Category 5 (i.e., impaired) for water temperature, but were reclassified to "Category 4A" (water bodies that have an approved TMDL) once the TMDL was completed for that subbasin (Brock and Stohr 2002, Anderson 2004, Ecology 2008). The TMDL and its detailed implementation plan outline actions to be taken to increase shade levels and stream flow in the Little Klickitat River

subbasin. Many of these actions are being implemented. The City of Goldendale previously relied on springs to meet water demand. Use of most of the spring facilities has been discontinued in favor of deep groundwater sources (personal communication, Dave Griffin, City of Goldendale). The Central Klickitat Conservation District (CKCD), in cooperation with area landowners, has completed tree planting along the stream in many areas (personal communication, Jim Hill CKCD). In 2006 the CKCD was awarded a grant for stream flow and temperature monitoring, riparian planting, and other actions to implement the TMDL Detailed Implementation Plan. A study completed in 2009 comparing riparian condition current canopy closure condition with historical photos found that riparian cover along the stream has been increasing over the past 30 to 40 years (Aspect and WPN 2009). The study results will serve as a baseline for future monitoring. Other actions to address the temperature issue in the stream are in progress.

2.3.3 Riparian Function and Condition

Riparian areas in most of the subbasin remain more or less intact; however, in some areas past and current timber harvest practices, roads, cattle access to riparian areas, and other localized actions have resulted in riparian corridor degradation.

In the plateau reaches, agricultural and urban land uses likely had a significant impact on the ecological functions of the riparian forest. The McCormick Meadow area of the upper Klickitat River in the tribally designated Primitive Area was heavily grazed for approximately 60 years, leaving a legacy of related problems (e.g., bank erosion, poor riparian cover, etc.). Heavy grazing in the area was terminated about 15 years ago and more recent grazing has been lighter. Riparian vegetation along Swale Creek and the Little Klickitat River has been increasing over the past 30 to 40 years (Aspect and WPN 2009). There has been no assessment of trends in riparian vegetation along the lower Klickitat River.

Reductions in beaver populations in the subbasin may have contributed to the drying and loss of some wetland and riparian habitats. Outlet Creek has been mechanically drained through the construction of ditches, but there is a natural barrier to steelhead near the mouth of the creek. It is possible that loss of wetlands in tributary headwaters in conjunction with water withdrawals may have diminished storage capacity and recharge capability. However, studies by USGS in other basins indicate that surface irrigation can increase recharge over predevelopment conditions, depending on the scale of the irrigation and other variables (Bauer and Vaccaro 1990, Vaccaro and Olsen 2007). A detailed examination of the hydrology of the Klickitat subbasin currently underway as part of implementing the WRIA 30 watershed plan will be useful for recovery planning.

2.3.4 Migration Barriers

The presence of several natural migration barriers in the Klickitat watershed may have historically limited anadromous fish production, particularly during low water years. The Klickitat River flows through a deep, steep-walled canyon with several historically impassable or marginally passable falls and cascades where the river flows over resistant bedrock. In addition, access to many of the tributaries is restricted because of impassably high gradients close to the tributary mouths. Such historical barriers were important in

maintaining separate life history strategies of *O. mykiss*, including summer steelhead, winter steelhead and resident rainbow trout.

The most significant natural barriers are the following:

- Lyle Falls (RM 2.2), a series of 5 falls from 4 to 12 feet high that historically were considered impassable during lowest water conditions in the summer and early fall (WSCC 2000). Historical data on steelhead distribution in the Klickitat subbasin are scarce; however, it is assumed that summer steelhead, like spring Chinook, were able to negotiate Lyle Falls (Bryant 1949). In 1952, Washington Department of Fisheries removed rock and constructed two fishways at the falls. Currently, Lyle Falls is not a barrier to salmon and steelhead, but passage at the natural falls is considered difficult under certain flow conditions (WSCC 2000). Planned repairs, modifications, and retrofits to the Lyle Falls Fishway will increase passage into the Klickitat subbasin.

- Castile Falls (RM 64), a series of 11 falls with an elevation drop of 80 feet over one-half mile. The falls historically presented an impediment to upstream passage of adult fish, but a 1960s attempt to improve fish passage at the falls inadvertently obstructed nearly all migration to habitat above the fishway. Recent improvements, including development of the Castile Falls Fishway, were completed in 2005 and provide steelhead and Chinook passage to the headwaters of the Klickitat. The fishway allows access to approximately 56 miles of spawning and rearing habitat in the upper mainstem and tributaries (NPCC 2004).

- Little Klickitat River Falls (RM 6.1), a 15 to 16-foot falls, restricts steelhead access to habitat areas in the upper Little Klickitat drainage. Fish passage is possible in rare cases, but these tend to be very high flow events (floods) in winter (D. Rawding, personal communication 2006). Steelhead redds above the falls were documented in 1996 and 1997, but these were years of high stream flow (WPN and Aspect 2005a). Further research is needed to obtain accurate estimates of passage frequency above the falls and steelhead spawning in the upper Little Klickitat (NPCC 2004).

- Two sets of falls on the West Fork Klickitat River — a 15 to 20-foot falls at RM 0.3 and another 15 to 20-foot falls just below the confluence of Little Muddy Creek and Fish Lake Stream at RM 4.8 — currently hinder upstream anadromous fish passage, and probably limited historical passage to upstream habitat (Thiesfeld 2001).

- A steep set of falls near the mouth of Surveyor's Creek. "The stream is impassible to salmon from the mouth upstream for about 0.8 mile. This area drops 400 feet in a series of cascades and impassable falls formed by huge slabs of rock" (LeMeir and Smith 1952).

- A 60 foot falls on Outlet Creek (RM 1.1) presents a complete barrier to all salmonids both presently and historically.

2.4 Life History Characteristics

Oncorhynchus mykiss, of which steelhead and rainbow trout are members, have a wide variety of life history strategies (Busby et al. 1996). Anadromy is not obligatory in *O. mykiss*, and the heritability of anadromy is much debated (Rounsefell 1958; Mullan et al. 1992). Progeny of anadromous steelhead can spend their entire lives in freshwater (residualize), while progeny of rainbow trout can migrate seaward. Although anadromous steelhead are the focus of interest within the Klickitat, both anadromous and resident forms are well documented in the Klickitat watershed. Resident rainbow trout are more widespread in the upper mainstem and perennial tributaries without barriers than in the lower subbasin tributaries. Anecdotal evidence, however, suggests historically wider distribution and greater population of resident *O. mykiss* in the Klickitat subbasin (B. Sharp, personal communication with YN Tribal Elders 2007).

Steelhead can be divided into two basic run types based on their level of sexual maturity at the time they enter fresh water and the duration of the spawning migration. The stream-maturing type, or summer steelhead, enters fresh water in a sexually immature condition and requires several months in fresh water to mature and spawn. The ocean-maturing type, or winter steelhead, enters fresh water with well-developed gonads and spawns relatively shortly after river entry (Bambrick et al. 2004).

The Klickitat River subbasin supports runs of winter and summer steelhead. Both are native to the system. Ocean-maturing or winter-run fish typically ascend streams between November and April, while summer-run, stream-maturing fish typically enter rivers between May and October. Genetic analysis shows some degree of differentiation between tributaries to the Klickitat River; genetic samples from the upper Klickitat, White Creek and Trout Creek seem to diverge most widely from the Skamania Hatchery stock (Phelps et al. 2000). Six or seven genetically distinct subpopulations have been identified within the Klickitat subbasin in recent genetic analysis (Narum et al. 2006). Analysis of genetic structure of Klickitat *O. mykiss* is ongoing. Further genetic sampling of adult native summer and winter steelhead will help identify genetic structure and enable a parentage analysis.

All winter populations in the Middle Columbia River steelhead DPS are small and unmonitored. Oregon estimates that during the early 2000s there were approximately 500 winter steelhead distributed across several small basins centered near Fifteenmile Creek. Washington populations are centered near the Klickitat. More accurate abundance estimates and productivity information are not available for winter steelhead populations in this DPS (WDFW and ODFW 2006). Little is known for certain about the small winter-run in the Klickitat (of perhaps <100 spawners), though winter steelhead appear to ascend into the river from November to April, peaking in March. Howell et al. (1985) hypothesized that winter-run fish spawned in the mainstem Klickitat from just above the confluence with the Columbia to the Little Klickitat confluence from March

through June. Recent years of observations show that mainstem steelhead spawning is concentrated between the Little Klickitat (RM 20.44) and Leidl Bridge (RM 32). It is difficult to differentiate between the spawning distributions of the two stocks.

Steelhead spawn in clear, cool streams with suitable gravel size, depth and flow velocity. Productive steelhead habitat is characterized by complexity, primarily in the form of large and small wood. Depending on water temperature, steelhead eggs may incubate for 1.5 to four months before hatching. Summer rearing takes place primarily in the faster parts of pools, although young-of-the-year are abundant in glides and riffles. Winter rearing occurs more uniformly at lower densities across a wide range of fast and slow habitat types (Bambrick et al. 2004).

Young steelhead typically rear in streams for some time before migrating to the ocean as smolts, which usually peaks in April and May in the Klickitat (Howell et al. 1985). Steelhead smolts migrate at ages ranging from 1-5 years throughout the Columbia Basin: Klickitat steelhead age composition consists of 13 percent 1-year, 83 percent 2-year and 4 percent 3-year outmigrants (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009). Some older juveniles may move downstream to rear in larger tributaries and mainstem rivers. Steelhead grow rapidly after reaching the ocean, where they forage in coastal and offshore waters of the North Pacific. Most steelhead spend two years in the ocean (range 1-4) before migrating back to their natal stream (Shapovalov and Taft 1954; Narver 1969; Ward and Slaney 1988). Once in the river, steelhead rarely eat and grow little, if at all (Maher and Larkin 1954). These combined behaviors produce fish that range between 3 and 7 years of age at the time of spawning.

Some steelhead are *iteroparous* (do not die after spawning). A small proportion of repeat spawners (known as kelts) may return to the ocean for a short period and repeat the spawning migration, a life history adaptation that may be fundamental to ensuring population stability. Respawning rates may be affected by environmental conditions, location of the natal stream, sex, size at maturity, and differences in the energy investment of spawning among different stocks and species (Fleming 1998). Winter-run fish tend to have higher respawning rates, and enter fresh water in a sexually mature state, while summer fish tend to mature sexually in fresh water (Withler 1966). Reduced genetic contributions from populations formerly supplemented by repeat spawners may contribute to the decline of steelhead stocks in the Columbia River Basin (NMFS 2000).

Iteroparity rates for Klickitat River steelhead were reported at 3.2 percent from combined sampling periods 1979 to 1981 (Howell et al. 1985) and 2005 (Yakama Nation and WDFW unpublished adult trapping data 2005). Sampling of adults at Lyle Falls Fishway in 2004 and 2005 has indicated repeat spawning rates of 2.9 percent for summer steelhead and 8.8 percent for winters. Most repeat spawners are females. Acquiring better estimates of kelt presence in the subbasin remains a priority for the Yakama Nation.

Existing data on steelhead sex ratio, age structure and frequency of re-spawning in the Klickitat subbasin is based on a sport catch sample from 1979-1981, and preliminary results from the Lyle Falls adult trap sampling and scale analysis conducted from July 2004 to October 2005 (Yakama Nation and WDFW unpublished adult trapping data 2005). Trapping efficiency and steelhead passage frequency through the ladder at Lyle Falls are still not certain, but it is likely that the sample represents only a small percentage of the total run.

During adult trap sampling and scale analysis, researchers identified adult fish as winter or summer steelhead based on a combination of observed morphological traits, in-migration timing, copepods, and scale analysis. Scales from both hatchery and wild fish were sampled and a determination of age made; however, only those fish for which there was a high level of certainty as to their run affiliation (winter or summer) were included in the demographic analysis (C. Frederiksen, personal communication 2006). Wild are identified as non-clipped adult returns into the Lyle adult trap. Skamania Hatchery summer steelhead (100 percent marked) are released as smolts into the lower Klickitat River. There are no hatchery winter steelhead releases.

Combined results from the two sampling periods show that ocean ages at return of adult summer steelhead averaged 16.7 percent 1-ocean, 72.8 percent 2-ocean, 7.3 percent 3-ocean and 3.2 percent consisting of repeat spawners (Figure 2-5). Females constituted 57.5 percent of the sample; males 42.5 percent. Figure 2-6 illustrates the length frequency distribution at ocean age of Klickitat summer-run steelhead. Trap data also suggest that hatchery steelhead have an earlier peak in migration timing than wild fish (Yakama Nation and WDFW unpublished adult trapping data 2005).

Among those fish identified as winter steelhead during the adult trapping period of 2004-2005, 1-ocean fish were predominant 47.1 percent, 2-ocean fish made up 41.2 percent of the sample, and 8.8 percent were 3-ocean fish and 8.8 percent were repeat spawners (Figure 2-7). The proportion of female to male winter steelhead was 64.5 to 35.5 percent. Due to the sampling period representing one returning brood year, ocean age structures depicted here for winter-run steelhead may not be representative of average ocean age composition (Yakama Nation and WDFW unpublished adult trapping data 2005). Figure 2-8 illustrates the length frequency distribution at ocean age of Klickitat winter-run steelhead.

Genetic analysis currently being conducted may contribute to data distinguishing the two steelhead runs in the subbasin. Sampling will continue in the future. Results of ongoing analysis will help to better differentiate the run timing between summer and winter steelhead, and provide additional data on the age structure, sex ratio and length frequency of fishing passing through the adult trap.

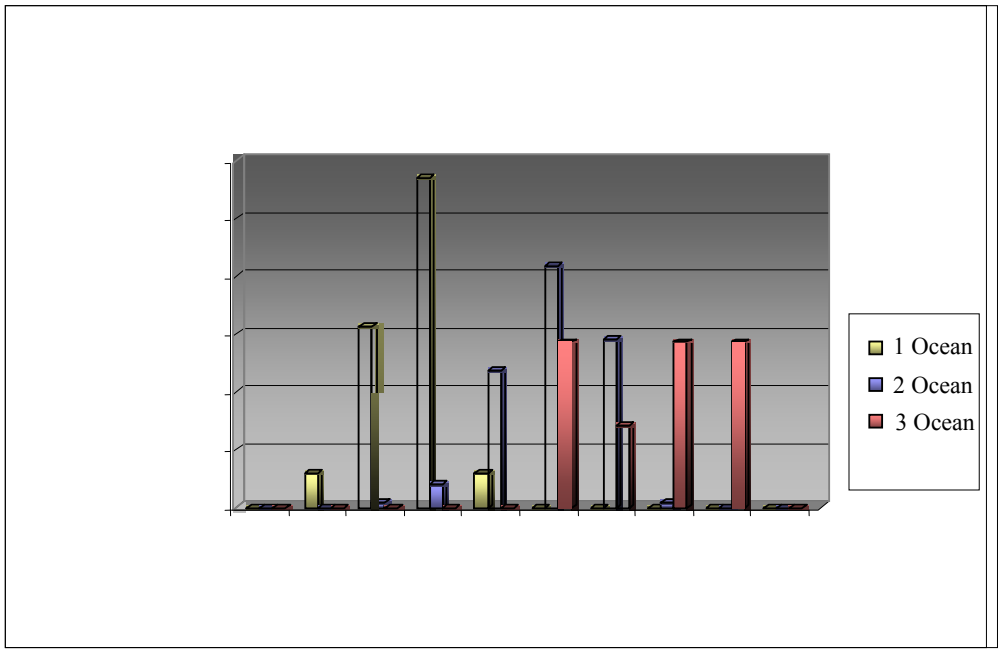

Figure 2-6. Frequency Distribution of Fork Length[2] at Ocean Age of Wild Summer Steelhead in the Klickitat River, 2004-2005 (Yakama Nation and WDFW unpublished adult trapping data 2005).

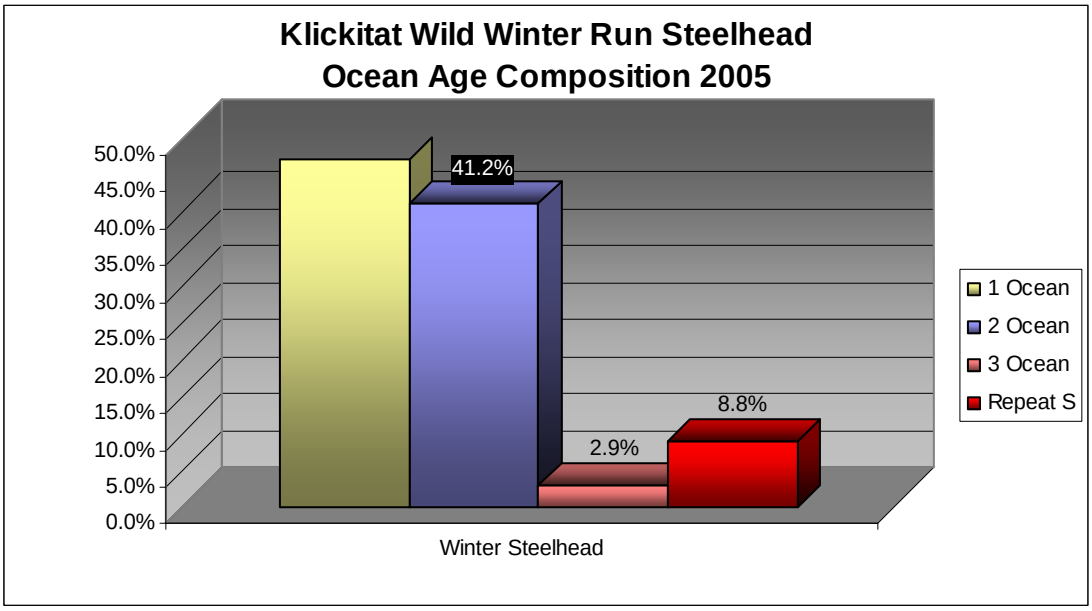
[2] Length of fish from tip of nose to fork of tail.



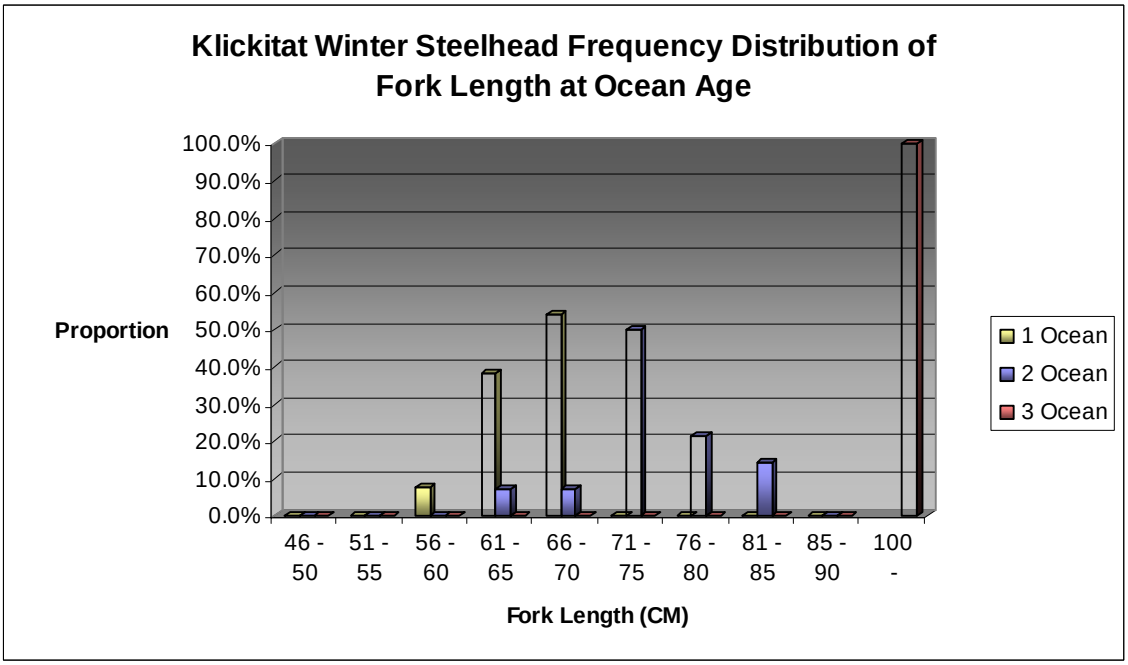


Figure 2-7. Average Ocean Age Composition of Klickitat Wild Winter-run Steelhead (Yakama Nation and WDFW unpublished adult trapping data 2005).

Figure 2-8. Frequency Distribution of Fork Length at Ocean Age of Wild Winter Steelhead in the Klickitat River, 2004-2005 (Yakama Nation and WDFW unpublished adult trapping data 2005).

***Only 1, 3-ocean wild winter steelhead was sampled, hence the abnormally high apparent proportion of fish assigned to large fork lengths.**

3. Recovery Goals and Viability Criteria

The primary goal of ESA recovery plans is for the species to reach the point that it no longer needs the protection of the Act – i.e. to be delisted. Recovery plans may also contain "broad-sense goals," defined in the recovery planning process, that go beyond the requirements for delisting to address, for example, other legislative mandates or social, economic, and ecological values.

Delisting criteria are applied at the DPS level, and are based on determinations of the viability of the independent populations that make up the DPS. Criteria for delisting the Middle Columbia steelhead DPS are described in the *Middle Columbia Steelhead ESA Recovery Plan*, to which this plan is an appendix. This chapter provides recovery goals for the Klickitat steelhead population, describes the criteria to be used to assess progress toward those goals, and describes the role of the Klickitat steelhead population in overall DPS viability.

There are two kinds of criteria that enter into a delisting decision: population, or demographic parameters (the biological recovery criteria) and "threats" criteria related to the five listing factors detailed in the ESA. The threats criteria define the conditions under which the listing factors, or threats, can be considered to be addressed or mitigated. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B) of the ESA. Both kinds of criteria are discussed in this chapter.

3.1 Recovery Goals

The primary goal of this plan is for the Klickitat steelhead population to be restored to viable status and thus to support recovery of the Mid-Columbia steelhead DPS. A viable salmonid population is defined as an independent population that has negligible risk of extinction over a 100-year timeframe (McElhany et al. 2000).

If a local, collaborative Washington Gorge Recovery Board is formed, it may choose to define additional, broad-sense goals for the Klickitat subbasin and other areas within the Washington Gorge Management Unit. The Board's broad-sense goals for the area would likely build on direction, and respond to the interests identified by various stakeholders in the area. These goals would then guide the Board as it defines and implements future recovery actions for the Klickitat subbasin.

In the meantime, the Yakama Nation has proposed, as a broad-sense goal for the Klickitat steelhead population, the achievement of "highly viable" status, which corresponds to a one percent risk of extinction in a 100-year period. Achieving highly viable status for the population would provide for long-term, sustainable harvest and other social, cultural, and ceremonial needs, although it would likely exceed the minimum necessary to support delisting the DPS.

3.2 Biological Viability Criteria

The ICTRT developed biologically based viability criteria for ESA-listed salmon and steelhead in the Interior Columbia domain. The ICTRT based its approach to recovery on guidance from the NMFS Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). This memorandum provides general direction for setting viability objectives at the ESU/DPS and component population levels.

Viability criteria at the population level address four VSP parameters (McElhany et al. 2000):

- *Abundance* – the average number of spawners in a population over a generation or more,
- *Productivity* – the performance of a population over time in terms of recruits produced per spawner,
- *Spatial Structure* – a population's geographic distribution and the processes that affect that distribution, and
- *Diversity* – the distribution of genetic, life history and phenotypic variation within and among populations.

The ICTRT grouped specific population level criteria into two categories to assess viability at the independent population level: measures addressing abundance and productivity, and measures addressing spatial structure and diversity. The viability of an independent population is determined by integrating risks across the four parameters.

3.2.1 DPS and MPG Viability Criteria

Since MPGs are geographically and genetically cohesive groups of populations, they are critical components of ESU/DPS spatial structure and diversity. Having all MPGs within an ESU/DPS at low risk provides the greatest probability of persistence for the ESU/DPS. Thus, the ICTRT criterion for a viable ESU/DPS is that all extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS should be at low risk.

Further, the following five criteria should be met for an MPG to be regarded as low risk (viable) (ICTRT 2007):

1. At least one-half of the populations historically within the MPG (with a minimum of two populations) should meet viability standards.

2. At least one population should be classified as "Highly Viable."

3. Viable populations within an MPG should include some populations classified (based on historical intrinsic potential) as "Very Large," "Large," or "Intermediate," generally reflecting the proportions historically present within the MPG. In particular, Very Large and Large populations should be at or above their composite historical fraction within each MPG.

4. All major life history strategies (e.g. spring and summer run timing) that were present historically within the MPG should be represented in populations meeting viability requirements.

5. Remaining MPG populations should be maintained with sufficient abundance, productivity, spatial structure, and diversity to provide for ecological functions and to preserve options for ESU/DPS recovery.

3.2.2 Application of Biological Viability Criteria to Klickitat Population

The ICTRT classified the Klickitat steelhead population as an "Intermediate" sized population based on historical habitat potential (ICTRT 2007).

Applying the ICTRT's viability criteria to the Cascades Eastern Slope Tributaries MPG results in the conclusion that the Klickitat steelhead population should reach viable status in order to support overall DPS viability, because of the population's historical abundance and the presence of both summer and winter runs.

Abundance
For an Intermediate population, viable status, i.e. a 5 percent or less risk of extinction over a 100-year timeframe, would require a mean minimum abundance threshold of 1,000 naturally produced spawners.

Productivity
Viable populations demonstrate sufficient productivity to support a net replacement rate of 1:1 or higher at abundance levels established as long-term targets. Productivity rates at relatively low numbers of spawners should, on average, be sufficiently greater than 1.0 to allow the population to rapidly return to abundance target levels.

Spatial Structure and Diversity
The ICTRT identified six major spawning areas (MaSAs) and four minor spawning areas (MiSAs) within the Klickitat population boundaries based on its historical intrinsic potential analysis. The analysis indicated that the upper mainstem Klickitat watershed was once a highly productive steelhead spawning area.

In general, the ICTRT defined two goals, or biological or ecological objectives, that spatial structure and diversity criteria should achieve:

- Maintaining natural rates and levels of spatially mediated processes. This goal serves (1) to minimize the likelihood that populations will be lost due to local catastrophe, (2) to maintain natural rates of recolonization within the population and between populations, and (3) to maintain other population functions that depend on the spatial arrangement of the population.

- Maintaining natural patterns of variation. This goal serves to ensure that populations can withstand environmental variation in the short and long terms. (ICTRT 2007, p. 47).

Data on Klickitat steelhead are limited. The primary factors contributing the moderate risk designation in the ICTRT (2009) viability assessment were related to lack of information on: a) the population's abundance and productivity, and, b) the effects of hatchery operations on the population. One of the primary goals of the Klickitat recovery plan is to attain the information needed to address these uncertainties.

3.3 Threats Criteria

Listing factors are those features that were evaluated under section 4(a)(1) when the initial determination was made to list the species for protection under the ESA. These may or may not still be limiting recovery when in the future NMFS reevaluates the status of the species to determine whether the protections of the ESA are no longer warranted and the species could be delisted.

At the time of a delisting decision, NMFS will examine whether the section 4(a)(1) listing factors have been addressed. To assist in this examination, NMFS will use the listing factors (or threats) criteria described below in addition to evaluation of biological recovery criteria and other relevant data and policy considerations.

To determine that the affected DPS is recovered to the point that it no longer requires the protections of the ESA, NMFS will review the status of the listing factors according to the specific criteria identified for each of them. The threats need to have been addressed to the point that delisting is not likely to result in their re-emergence. It is possible that current perceived threats will become insignificant in the future because of changes in the natural environment or changes in the way threats affect the entire life cycle of salmon. Consequently, NMFS expects that the ranking of threats will change over time and that new threats may be identified. During the status reviews, NMFS will evaluate and review the listing factor criteria under conditions at the time.

The specific criteria listed below for each of the relevant listing/delisting factors helps to ensure that underlying causes of decline have been addressed and mitigated prior to considering a species for delisting. NMFS anticipates that if the proposed actions described in the Plan are implemented, they will make substantial progress toward meeting the following listing factor (threats) criteria:

Factor A: The present or threatened destruction, modification, or curtailment of its habitat or range

To determine that the DPS is recovered, threats to habitat should be addressed to a degree sufficient to support a viable Middle Columbia River steelhead DPS as outlined below:

1. Impaired fish passage (e.g., dams and culverts) is addressed, either through removal or modification of obstructions, to improve survival and restore access to historically accessible habitat where necessary to support recovery goals.
2. Flow conditions that support sufficient steelhead rearing, spawning, and migration of a viable DPS are achieved, where possible, through management of mainstem and

tributary irrigation and hydropower operations, and through the improvement of other water user efficiencies and conservation, including for municipal supply and other consumptive purposes.

3. Forest management practices that protect watershed and stream functions are implemented on Federal, state, tribal, and private lands.
4. Agricultural practices, including grazing, are implemented to protect and restore riparian areas, floodplains, and stream channels, and to protect water quality from sediment, pesticide, herbicide, and fertilizer runoff.
5. Urban and rural development, including land use conversion from agriculture and forestland to residential uses, avoids impairment of water quality or impair natural stream conditions.
6. The effects of toxic contaminants on salmonid fitness and survival in the mainstem and tributaries are sufficiently limited so as not to affect recovery.
7. Channel function, including vegetated riparian areas, canopy cover, stream-bank stability, off-channel and side-channel habitats, natural substrate and sediment processes, and channel complexity is restored to provide adequate rearing and spawning habitat.
8. Floodplain function and the availability of floodplain habitats for salmon are restored to a degree sufficient to support a viable DPS. This restoration should include connectivity between river and floodplain and the restoration of altered sediment routing.
9. Water operations management in the mainstem and tributaries maximize survival of juvenile rearing, emigrating smolts, and immigrating and spawning adults.

Factor B: Over-utilization for commercial, recreational, scientific or educational purposes

To determine that the DPS is recovered, any utilization for commercial, recreational, scientific, or educational purposes should be managed as outlined below:

1. Fishery management plans for steelhead are in place that (a) accurately account for total fishery mortality (i.e., both landed catch and non-landed mortalities) and constrain mortality rates to levels that are consistent with achieving population viability (i.e., provide for adequate spawning escapement given their productivity); and (b) are implemented in such a way as to avoid deleterious genetic effects on populations or negatively affect the distribution of populations.
2. Federal, state and tribal fishing rules and regulations are effectively enforced.
3. Technical tools accurately assess the effects of the harvest regimes so that harvest objectives are met but not exceeded.
4. Scientific handling of fish from adult and juvenile trapping operations is minimized to reduce indirect mortalities associated with education or scientific programs, while

recognizing that monitoring, research, and education are key actions for conservation of the species.

5. To the degree sufficient to support a viable DPS, routine instream construction and maintenance practices are implemented in a manner to reduce or eliminate mortality of listed species.

Factor C: Disease or predation

To determine that the DPS is recovered, any disease or predation that threatens its continued existence should be addressed as outlined below:

1. Hatchery operations do not subject steelhead populations to deleterious diseases and parasites and do not result in increased predation rates of wild steelhead.
2. Predation by avian predators is managed in a way that promotes recovery of salmon and steelhead populations.
3. The northern pikeminnow are managed to reduce predation on steelhead to a degree sufficient to meet recovery goals.
4. Populations of introduced smallmouth bass, walleye, and catfish are managed such that competition or predation does not impede steelhead recovery.
5. Predation by marine mammals on steelhead runs below Bonneville Dam is managed within the framework of applicable statutes and to the degree necessary to protect upstream migration of steelhead.

Physiological stress and physical injury that may cause disease or increase susceptibility to pathogens during rearing or migration should be reduced during critical low flow periods (e.g. low water years) or poor passage conditions (e.g. at diversion dams or bypasses).

Factor D: The inadequacy of existing regulatory mechanisms

To determine that the DPS is recovered, any inadequacy of existing regulatory mechanisms that threatens its continued existence should be addressed to the degree necessary to support a viable DPS, as outlined below:

1. Sufficient resources, priorities, regulatory frameworks, and coordination mechanisms are established and/or maintained for effective enforcement of land and water use regulations that protect and restore habitats and for the effective management of fisheries.
2. Habitat conditions and watershed functions are protected through land-use planning that guides human population growth and development.
3. Habitat conditions and watershed function are protected through regulations that govern resource extraction such as timber harvest and gravel mining.

4. Habitat conditions and watershed functions are protected through land protection agreements as appropriate, where existing policy or regulations do not provide adequate protection.

5. Regulatory, control, and education measures to prevent additional exotic plant and animal species invasions are in place.

Factor E: Other natural or human-made factors affecting its continued existence

To determine that the DPS is recovered, other natural and human-made threats to its continued existence should be addressed as outlined below:

1. Steelhead hatchery programs are being operated in a manner that is consistent with individual watershed and region-wide recovery approaches; appropriate criteria should be used for the integration of hatchery steelhead populations and extant natural populations inhabiting watersheds where the hatchery fish return.

2. Hatcheries operate using appropriate ecological, genetic, and demographic risk containment measures for (1) hatchery-origin adults returning to natural spawning areas, (2) release of hatchery juveniles, (3) handling of natural-origin adults at hatchery facilities, (4) withdrawal of water for hatchery use, (5) discharge of hatchery effluent, and (6) maintenance of fish health during their propagation in the hatchery.

3. Mechanisms are in place to effectively continue monitoring the proportion of hatchery and wild spawners in the subbasin.

4. Mechanisms are in place to reduce the incidence of, and impacts from, introduced, invasive, or exotic plant and animal species.

5. Nutrient enrichment programs should be evaluated to determine where additional nutrient inputs can provide significant benefits.

4. Current Status Assessment

There are currently neither solid historical data nor accurate metrics for assessing current status of the Klickitat steelhead population. The first priority for recovery planning for this population is to reduce the uncertainties with a targeted monitoring program (see Chapter 6, Recovery Strategy and Actions, and Chapter 8, Monitoring, Research, and Adaptive Management).

The ICTRT reviewed existing data, previous assessment findings and GIS analysis for its 2005 viability assessment of the Klickitat population. This work has been updated by the ICTRT (2009). The Yakama Nation staff biologists provided substantial additional data, summarized in this chapter, which is, however, of a relatively short generational span and limited by significant uncertainties.

The ICTRT viability assessment is presented first, followed by currently available status information from the Yakama Nation. Discussion is also provided of ICTRT, Yakama Nation, and Klickitat County findings regarding identification of major and minor spawning areas.

4.1 ICTRT Status Assessment

4.1.1 Major and Minor Spawning Areas

The ICTRT identified major and minor spawning areas in the Klickitat system using model results that estimated the historical amount of potentially accessible spawning and rearing habitat available to the specific population based on stream width, gradient, and valley width from GIS-based analysis of tributary habitat associated with each population (ICTRT 2007). This historical intrinsic potential analysis conducted by the ICTRT identified six major spawning areas (MaSAs) and four minor spawning areas (MiSAs) within the Klickitat population boundaries (Figure 4-1). The ICTRT defines a major spawning area as a system of one or more branches that contains sufficient historical intrinsic habitat potential to support at least 500 spawners. This structure is typical of intermediate or large drainages. The ICTRT defines minor spawning areas as contiguous production areas capable of supporting between 50 and 500 spawners. The ICTRT does not consider any population fewer than 500 spawners to be viable, regardless of its intrinsic productivity (ICTRT 2007).

Major spawning areas identified by the ICTRT in the Klickitat drainage are the Upper Mainstem Klickitat, White River, Upper Little Klickitat, Lower Mainstem Klickitat, Middle Mainstem Klickitat and West Fork Klickitat MaSAs. Minor spawning areas are the Swale Creek, Lower Little Klickitat, Trout Creek and Surveyors Creek MiSAs. Middle Columbia steelhead occupy all major spawning areas in the Klickitat drainage with the exception of the West Fork Klickitat MaSA.

There is a high degree of correlation between the assessment areas used in the Klickitat River subbasin plan (NPCC 2004) and the areas identified using the ICTRT intrinsic potential analysis. In addition, the ICTRT analysis was modified based on input from regional biologists to identify reaches in the Little Klickitat drainage and MaSAs that are inaccessible under some annual flow conditions.

Yakama Nation Fisheries staff noted that several tributaries identified by the ICTRT as having high intrinsic habitat potential differ in various aspects from Yakama Nation resource specialists' understanding of the areas (see Figure 4-2). For example, there are discrepancies between a few headwater tributaries such as Sheep and Blue creeks. Sections of Swale, Big Muddy, and Hellroaring creeks, upper Knight and Wide Sky canyons and other creeks are included by the ICTRT as having segments of high intrinsic historical potential for steelhead spawning habitat, although Yakama Nation staff consider it highly improbable that the segments were even historically conducive to spawning, because of geomorphological and biotic factors. Yakama Nation staff also contend that historical spawning distribution of steelhead in Trout Creek and the Little Klickitat River was unlikely to have extended as far upstream as the ICTRT's GIS model indicates. The Yakama Nation Fisheries staff delineated 11 spawning areas in the Klickitat watershed, based on EDT analysis, that they believe better reflect spawning habitat areas for the steelhead population. Appendix III discusses these areas and compares them to the areas identified by the ICTRT.

Klickitat County staff agree that the distribution of steelhead in the Little Klickitat is unlikely to extend as far upstream as the ICTRT's GIS model indicates. They believe that fish distribution in the Little Klickitat stops at the falls at RM 6.1, except in rare years when some minor passage may occur under certain unusual flow conditions. They note that the ICTRT's estimate of fish distribution in Swale Creek is also over-represented, and that during summer and fall steelhead are found only in the lower three miles where there is water (WPN and Aspect 2005a).

Despite these differences between GIS data and hardcopy maps, the basic patterns of predicted and observed occupancy of the subbasin are similar. Because the intrinsic potential model incorporates broad scale landscape and hydrological variables, subbasin specific characteristics often cause local differences between observations, professional knowledge, and modeled predictions of pre-development habitat conditions. However, using the ICTRT's habitat branching and MaSA/MiSA accumulation methods, these disparities are generally insignificant at the MaSA/MiSA scale. Many of the tributaries mentioned above contain well below one percent of the total intrinsic habitat modeled within the Klickitat population.

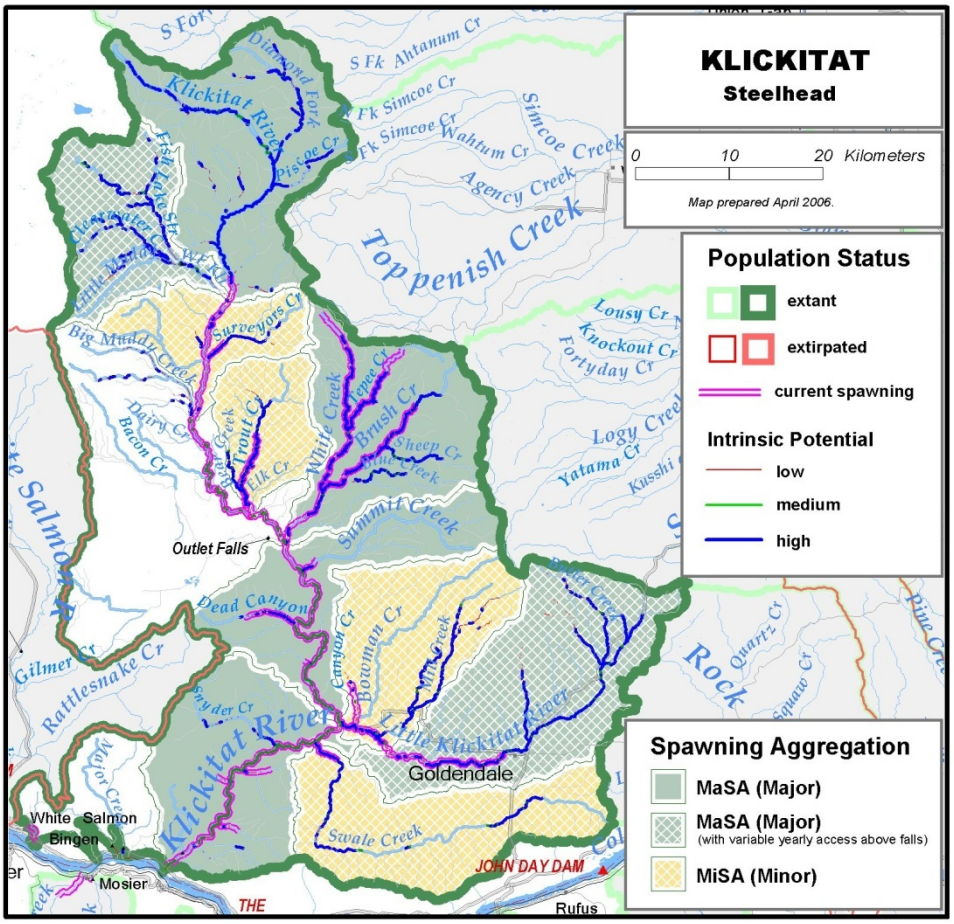

Figure 4-1. Klickitat River Steelhead population boundary and historical major and minor spawning areas (ICTRT 2007).

4.1.2 Abundance and Productivity

The ICTRT (2009) found that annual estimates of the total number of steelhead spawning in the Klickitat River drainage prior to the 2005-2006 return year have not been generated. Redd surveys of steelhead spawning in the Klickitat River drainage have been conducted in recent years, but there is insufficient coverage to allow for directly estimating annual abundance from those samples.

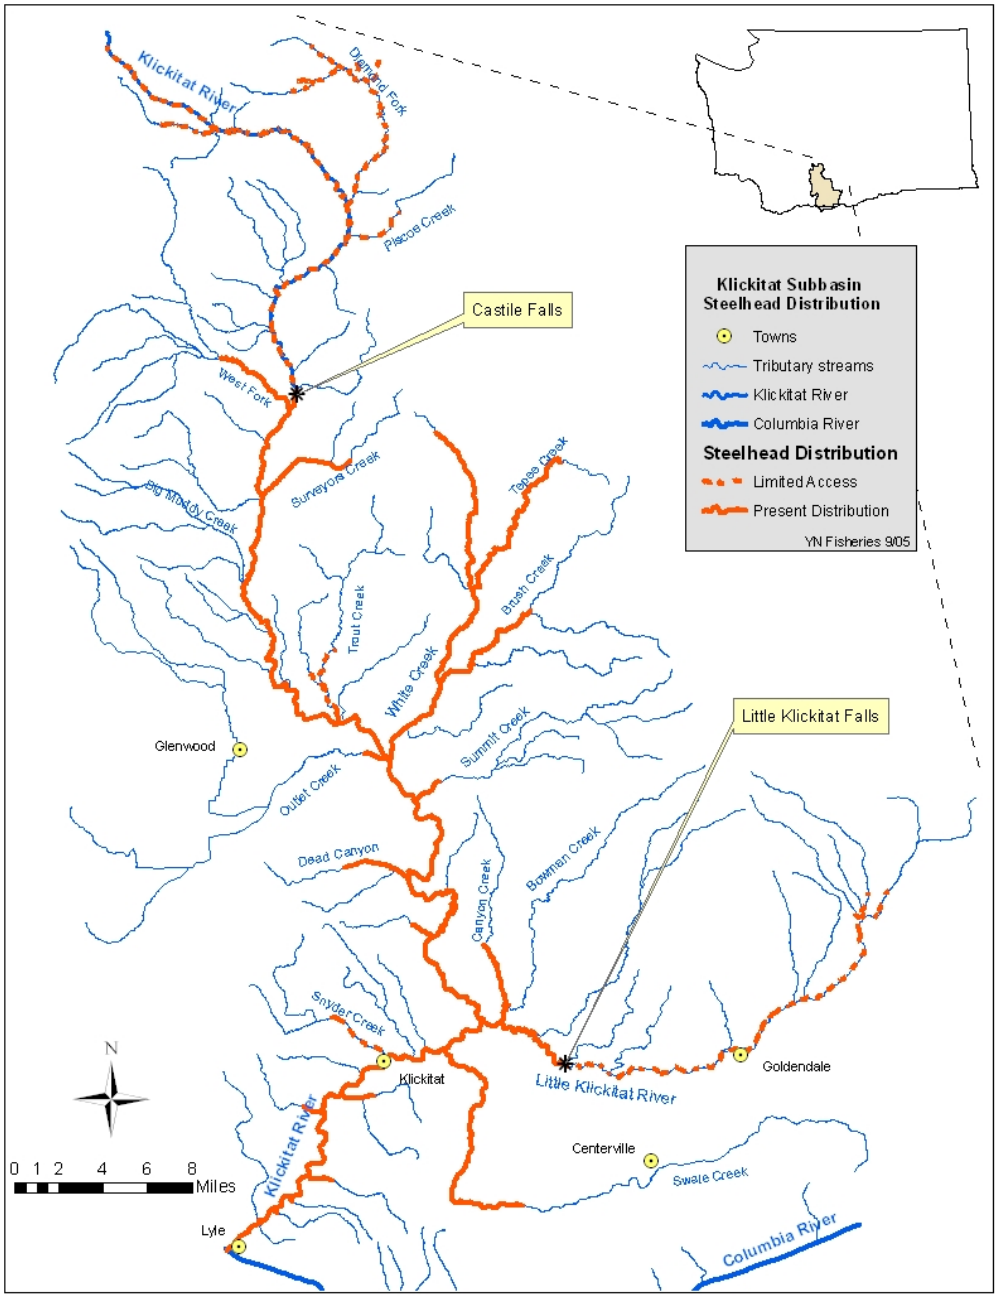
Separate estimates of the escapement of hatchery-origin and natural-origin steelhead past Lyle Falls have been generated for the 2005-2006 return year using mark-recapture methods (Gray 2007). An estimated 1,577 natural-origin and 1,833 hatchery-origin adult steelhead were estimated to have passed above Lyle Falls and the associated tribal fishery in that return year. Returns to the Klickitat River include hatchery-origin adults from annual out-plants of Skamania Hatchery summer steelhead from North Fork Washougal River broodstock (approximately 100,000 smolts per year) into the middle sections of the mainstem Klickitat River. A hatchery-directed sport fishery has harvested an estimated 1,400 to 3,700 fish per year between 2000 and 2004 (http://wdfw.wa.gov/fish/papers/steelhead/m_col_esu.pdf). The estimated returns above Lyle Falls would be reduced by hatchery sport harvest (direct catch of hatchery,

incidental mortalities of natural-origin fish), potential fall back and any pre-spawning mortalities.

Assuming that annual estimates of the number of steelhead passing Lyle Falls continue to be generated, after a sufficient number of estimates are accumulated, it may be possible to use a derived relationship between index area redd counts and total abundance to extend annual estimates back using the recent historical redd counts.

Determining the relative distribution of hatchery and natural-origin spawners on the spawning grounds would reduce uncertainty with generating productivity estimates from the return series. Estimated abundance and harvest data provided by the Yakama Nation are included as Appendix IV.

The ICTRT was able to assign a size category to the Klickitat steelhead population based on historical intrinsic potential analysis. Size categories reflect drainage complexity and the distribution of current and historical spawning habitat. Upstream limits on the potential use of tributary habitat for spawning and rearing were defined in terms of physical barriers, stream gradient, width, and water temperature, on the basis of multiple sources, including GIS data, published accounts, field personnel, and local expert review. The ICTRT considers the Klickitat River population to be an "intermediate" sized population. To be considered viable, i.e. having a 5 percent or less risk of extinction over a 100-year timeframe, an intermediate-sized population should have a mean minimum abundance of 1,000 naturally produced spawners.



Because of insufficient data and the uncertainties regarding naturally occurring production, the ICTRT provisionally assigned the Klickitat River population **Moderate risk** for abundance and productivity (ICTRT 2007).

4.1.3 Spatial Structure and Diversity

Current steelhead spawning in the Klickitat mainstem is concentrated between RM 5 and RM 50, with occasional spawning above Castile Falls (RM 64). Figure 4-2 shows current steelhead distribution in the Klickitat subbasin, with areas of "limited access," as inferred based on restrictions in passage conditions, represented by dashed lines. Tributary spawning currently occurs in the White Creek watershed (including Tepee and Brush creeks), Dead Canyon, Swale Canyon, Wheeler, Summit, and lower Bowman creeks, the lower (and occasionally upper) Little Klickitat River, and other smaller tributaries.

Winter steelhead are believed to spawn between the confluence of the Klickitat with the Columbia River and the confluence of the Little Klickitat with the mainstem (Howell et al. 1985). Further research on spawning distribution of winter steelhead in the Klickitat subbasin is needed. Steelhead distribution, however, is expected to extend into the upper watershed in the near future because passage for anadromous fish at Castile Falls has recently been restored and the upper subbasin is now re-connected.

Figure 4-2. Summer and Winter Steelhead Distribution in the Klickitat Subbasin (NPCC 2004).

Based on its historical intrinsic potential analysis, the ICTRT identified six major spawning areas (MaSAs) (systems of one or more branches capable of supporting 500 spawners), and four minor spawning areas (MiSAs) (able to support between 50 and 500 spawners) within the Klickitat population boundaries (ICTRT 2007) (Table 4-1 and Figure 4-3). The analysis assumed that the upper mainstem Klickitat watershed was once a highly productive steelhead spawning area.

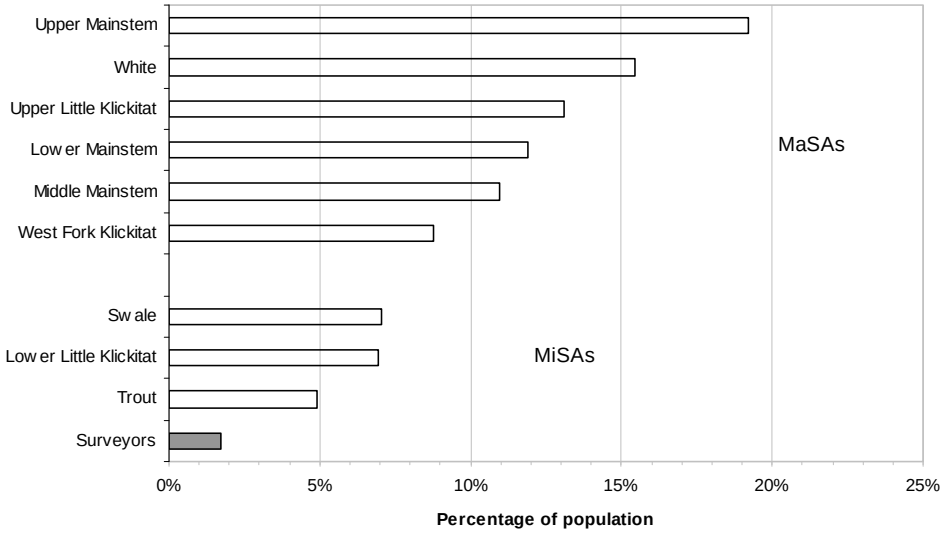


Table 4-1. Klickitat Summer/Winter Steelhead population basin statistics and intrinsic potential analysis summary (ICTRT 2009).

Drainage Area (km^2)	**3,632**
Stream lengths km[a] (total)	**2,590**
Stream lengths km[a] (below natural barriers)	**1,701**
Branched stream area weighted by intrinsic potential (km2)	**2.978**
Branched stream area km2 (weighted and temp. limited)[b]	**2.978**
Total stream area weighted by intrinsic potential (km2)	**3.990**
Total stream area weighted by intrinsic potential (km2) temp limited[b]	**3.990**
Size and Complexity category	**Intermediate / B (dendritic)**
Number of MaSAs	**6**
Number of MiSAs	**4**

[a]All stream segments greater than or equal to 3.8m bankfull width were included

[b]Temperature limited areas were assessed by subtracting area with mean weekly modeled water temperature greater than 22ºC

Figure 4-3. Percentage of Historical Spawning Habitat by Major/Minor Spawning Area. (ICTRT 2009).

Genetic samples from different areas within the Klickitat River system cluster together but appear to be relatively homogeneous. Compared to other populations, the Klickitat subpopulation samples cluster together. The closest association is with the Skamania Hatchery stock; the level of differentiation suggests a common origin. The ICTRT rated the Klickitat steelhead population as at **Moderate risk** for this metric (ICTRT 2009).

The ICTRT rated the Klickitat River steelhead population at **Moderate risk** for spatial structure and diversity based on an assessment of the cumulative scores across the individual spatial structure/diversity factors and metrics (Table 4-2). It determined that reducing the spatial structure/diversity risk to a low rating would require reducing the impacts of the outside stock hatchery program on natural spawning areas, or determining that the natural population is actually experiencing very little impact from the Skamania stock origin returns.

Table 4-2 summarizes ICTRT viability assessment results for Klickitat steelhead population spatial structure and diversity factors and metrics. Table 4-3 shows the ICTRT's spatial structure and diversity scoring table for the population.

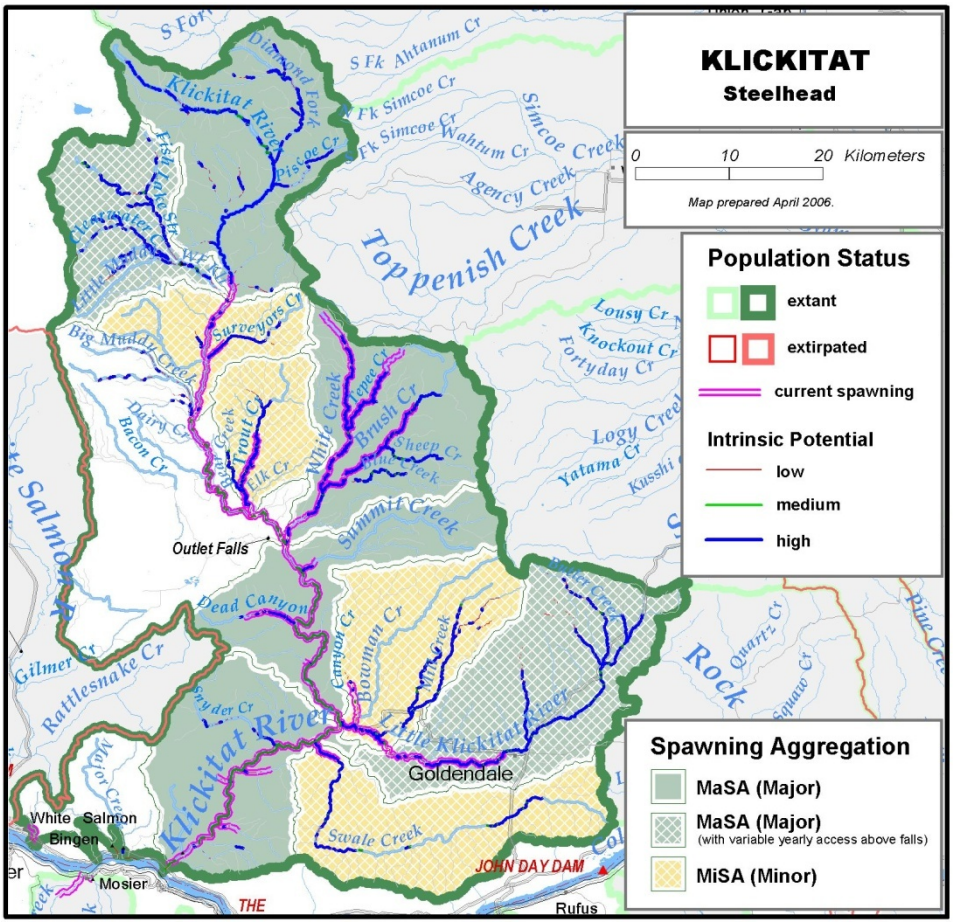
Table 4-2. ICTRT viability assessment results for Klickitat steelhead population spatial structure and diversity factors and metrics (ICTRT 2009).

Factors and Metrics	Risk Rating	ICTRT Comments
A.1.a. Number and spatial arrangement of spawning areas.	Low	All six of MaSAs inferred as occupied based on the WDFW and YN data. More data needed to confirm current distribution information.
A.l.b. Spatial extent or range of population.	Low	Intrinsic potential approach assumes that steelhead had access to the upper Klickitat (mainstem and tributaries above Castile Falls) and the upper sections of the Little Klickitat River. Historical access to the upper Klickitat may have been limited by Castile Falls. WDFW and YN data indicate that all MaSAs and MiSAs are currently occupied. Distributions should be confirmed through systematic ground surveys.
A.1.c. Increase or decrease in gaps or continuities between spawning areas	Low	The WDFW current distributions and the YN redd survey data sets indicate that the lower most MaSAs are at least partially occupied and there is a presence of steelhead spawners in the MiSAs below the Little Klickitat River. There are no intervening gaps among the occupied MaSAs in the Klickitat.
B.1.a. Major life history strategies	Low	There is no evidence of loss of a major juvenile life history pattern.
B.1.b. Phenotypic variation.	Moderate	It is possible that continual inputs of outside hatchery-origin spawners (Skamania stock) have altered spawning timing and other phenotypic characteristics of the native run. Rating is precautionary given absence of more specific information on the relative contributions of hatchery spawners to natural spawners.
B.1.c. Genetic variation.	Moderate	Genetic samples from different areas within the Klickitat River system cluster together but appear to be relatively homogeneous. Compared to other populations, the Klickitat subpopulation samples cluster together. The closest association is with the Skamania Hatchery stock; the level of differentiation suggests a common origin.
B.2.a. Spawner composition.	High	No systematic sampling studies have been done to determine the relative contribution of returns from the hatchery releases in the Klickitat to natural spawning areas. The only reported information on relative hatchery wild composition for the Klickitat are results of sport catch sampling efforts in the late 1980s, indicating that up to 2/3 of the catch were hatchery-origin. It is possible that those estimates reflect the contribution rates in the lower Klickitat and are not directly representative of hatchery contribution rates to spawning in the majority of natural production areas. Based on release levels and sport catch estimates, it is very likely that the hatchery contribution rate to natural spawning has exceeded 5 percent for more than 4 generations. Rating reflects the absence of direct information confirming differential spawning distribution of hatchery and natural fish and/or information on relative contribution rates to natural spawning areas.
B.3.a. Distribution of population across habitat types	Low	Current spawning distribution (WDFW GIS layer and YN fisheries redd survey results) indicates occupied MaSAs cover three of the four historical regions. Current and historical ecoregion ratios need to be checked (specifically the relative contribution of the Grand Fir Mixed Forest).
B.4.a. Selective change in natural processes or selective impacts.	Low	Low risk estimates given across the four sectors: hydropower system, harvest, hatcheries, habitat.

Table 4-3. Spatial Structure and Diversity Scoring Table: Klickitat Steelhead Population (ICTRT 2009).

Metric	Risk Assessment Scores				
	Metric	Factor	Mechanism	Goal	Population
A.1.a	L (1)	L (1)	Mean = 1.25 Low Risk	Low Risk	**Moderate Risk**
A.1.b	L (1)	L (1)			
A.1.c	L (1)	L (1)			
B.1.a	L (1)	L (1)	Moderate Risk	Moderate Risk	
B.1.b	M (0)	M (0)			
B.1.c	M (0)	M (0)			
B.2.a(1)	H (-1)	High Risk (-1)	High Risk (-1)		
B.2.a(2)	NA				
B.2.a(3)	NA				
B.2.a(4)	NA				
B.3.a	L (1)	L (1)	L (1)		
B.4.a	L (1)	L (1)	L (1)		

4.1.4 Overall Risk Rating



The ICTRT rated the Klickitat River steelhead population at **Moderate risk** of extinction in one hundred years for both abundance/productivity and spatial structure/diversity. Thus, the population does not meet the criteria for a viable population as defined by the ICTRT (ICTRT 2007). Figure 4-4 is a matrix that illustrates the combinations of risk levels for all four VSP parameters that define low, moderate, and high risk ratings for a population or DPS. "Viable" status is defined as having no more than a 5 percent likelihood of extinction within 100 years. Moderate risk corresponds to "maintained" status, which designates a population that can contribute to overall DPS viability by providing ecological functions and preserving options for recovery. Maintained populations can serve as buffers against catastrophic losses to other, more viable populations and/or uncertainty in the ICTRT population and MPG criteria. Ensuring that the less than viable populations meet maintained standards reduces the risk for the MPG. However, as previously noted, the Klickitat population has characteristics that are sufficiently important to the DPS to make it an appropriate candidate for viable status.

The ICTRT noted that developing a method for generating annual estimates of natural contributions to spawning in the Klickitat would allow for a more accurate assessment of both abundance and productivity. With respect to spatial structure and diversity, the population would benefit from actions that promote or confirm a high level of separation between hatchery-origin spawners and natural production. More detailed evaluations of

genetic patterns within the population, and of the range of life history variations present in the population, could also contribute to improving the status level assigned through application of the ICTRT criteria.

		Spatial Structure/Diversity Risk			
		Very Low	**Low**	**Moderate**	**High**
Abundance/ Productivity Risk	**Very Low** (<1%)	**HV**	**HV**	**V**	**M**
	Low (1-5%)	**V**	**V**	**V**	**M**
	Moderate (6 – 25%)	**M**	**M**	**M Klickitat River***	**HR**
	High (>25%)	**HR**	**HR**	**HR**	**HR**

Figure 4-4. Viable Salmonid Population Parameter Risk Ratings for the Klickitat River Steelhead Salmon Population (ICTRT 2009). ***Viability Key: HV – Highly Viable; V – Viable; M – Maintained; HR – High Risk; * = Candidate for Maintained; Shaded cells – does not meet viability criteria (darkest cells are at greatest risk).***

5. Limiting Factors and Threats

The reasons for a species' decline are generally described in terms of limiting factors and threats. Analysis of limiting factors and threats across the entire species' life cycle forms the basis for designing recovery strategies and actions. NMFS defines limiting factors as the biological and physical conditions limiting DPS and population status (e.g. elevated water temperature), and defines threats as those human activities or naturally induced actions that cause the limiting factors (e.g. removal of riparian vegetation for agricultural or residential purposes, which causes loss of shade and, consequently, elevated water temperature).

While the term "threats" carries a negative connotation, it does not mean that activities identified as threats are inherently undesirable. They are often legitimate human activities that may at times have unintended negative consequences on fish populations—and that can usually be managed in a manner that minimizes or eliminates the negative impacts.

For steelhead and other salmonids, survival to reproduce depends on a complex, interacting system of environmental conditions, with different conditions needed for each life stage. Optimal water temperature, for example, varies (within limits) for adult migration vs. egg incubation or juvenile rearing. In addition, the particular factors limiting production may vary across different sections of the tributary drainage used by a particular population. Data on a full range of potential limiting factors is rarely available at the reach level. As a result, the identification of limiting factors for salmonids often includes elements based on inference and expert opinion.

The list of potential limiting factors for the Klickitat steelhead population, as for the other populations that make up the DPS, is based on a substantial body of research on salmonids, local field data and field observations, and the considered opinions of regional experts. These are implicitly hypothetical statements, made with the expectation that by taking action in the face of some degree of scientific uncertainty, monitoring the results, continuing to conduct research as a high priority, and adapting our management actions in response, the state of our knowledge will improve and so will the survival of these fish, although not necessarily in a directly parallel process. In that spirit, this chapter describes the factors, based on the best available science, considered to be limiting Middle Columbia River steelhead production in the Klickitat subbasin.

5.1 Hatchery Effects

Uncertainty regarding the effects of hatchery releases on the naturally spawning population is one of the two primary reasons the ICTRT rated the Klickitat steelhead population as at moderate risk (the other factor is the lack of information regarding abundance) (ICTRT 2009). Hatchery releases and interactions between hatchery and wild fish are likely to have a significant impact on the viability and productivity of the naturally spawning population.

Hatchery-bred smolts from the Skamania and Vancouver hatcheries have been released into the Klickitat River for nearly 40 years. Releases were also made from the Beaver Creek and Naches hatcheries. Releases have averaged approximately 102,000 smolts annually since 1982, ranging from 16,000 smolts in 1995 to 118,500 smolts in 2000. The current hatchery steelhead production goal for the Klickitat subbasin is an annual release of 120,000 summer-run steelhead from Skamania and Vancouver hatcheries directly into the Klickitat River. Both hatcheries use Skamania Hatchery broodstock, which is maintained using steelhead returning to the Skamania Hatchery on the Washougal River. The broodstock for the program was originally established with wild fish taken from both the Washougal and Klickitat River systems. To limit adverse interactions with naturally produced juvenile steelhead, hatchery summer steelhead are released at times and sizes that result in rapid emigration from the subbasin. The releases occur in the mainstem Klickitat River below the primary upstream spawning and rearing areas.

Skamania summer steelhead releases in the Klickitat River mainly provide for sport fisheries in the river (Bosch et al. 2004). Hatchery-reared winter steelhead have never been released in the Klickitat subbasin (Sharp 2000).

Currently there is insufficient information to determine the effects of hatchery releases on the natural steelhead population. While it is likely that hatchery hybridization of Skamania stock with wild steelhead has occurred in the Klickitat subbasin (NPCC 2004), the level of impact on the natural population remains uncertain. In its recent viability assessment for the population, the ICTRT (2007) found that the only reported information on relative hatchery/wild composition for the Klickitat was from sport catch sampling in the late 1980s, indicating that up to two-thirds of the catch were hatchery-origin. The ICTRT noted that it is possible that those estimates reflect the contribution rates in the lower Klickitat and are not directly representative of hatchery contribution rates to spawning in the majority of natural production areas. However, based on release levels and sport catch estimates, the ICTRT found that it is very likely that the hatchery contribution rate to natural steelhead spawning in the Klickitat subbasin has exceeded 5 percent for more than four generations (ICTRT 2007). Updated information from Gray (2005) indicates that 47.6 percent of the returning fish were hatchery-origin, based on the number of fish passing through the Lyle fish trap between July 2004 and February 2005. The percentage of hatchery-origin steelhead that passed through the fish trap in 2007, 2008, and 2009 ranged from 55.4 to 67.0 (http://www.ykfp.org/klickitat/).

Narum et al. (2006) argued that only 4 percent of the naturally produced steelhead could be attributed to the hatchery stock, and that genetic integrity and variation of native Klickitat River steelhead have been maintained despite repeated hatchery introductions. Berejikian and Ford (2004) estimated that the non-local Skamania Hatchery summer steelhead are less than 30 percent as effective as the naturally produced steelhead in producing returning adults.

Hatchery releases of coho and spring and fall Chinook into the mainstem Klickitat River may also affect natural steelhead production. In addition to the steelhead hatchery

releases, an average of 4,349,710 fall Chinook, 595,318 spring Chinook, and 3,714,083 coho are released into the Klickitat River each year (Sharp et al. 2008). These species are not native, but have naturalized in the basin and are known to spawn in relatively large numbers (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009).

A synthesis of many studies in other basins by Weber and Fausch (2003) indicates that competition from hatchery outplants has the potential to decrease the productivity of the rearing life stages and increase predation on wild juvenile steelhead; however, the effects of the introduction of coho and fall Chinook on steelhead production in the Klickitat River have not been evaluated. It is believed that the current release of 3.7 million coho from the hatchery downstream into the middle mainstem Klickitat River may be competing with, and preying on listed steelhead juveniles (Sharp et al. 2008). The Klickitat Master Plan (Sharp et al. 2008) proposes to reduce the annual coho releases to 1.0 million and move all releases downstream to the proposed Wahkiacus Hatchery and Acclimation Facility. Hatchery releases of juvenile fall Chinook are not expected to compete with listed steelhead because of different habitat preferences; however, they may compete with naturally produced spring Chinook (Sharp et al. 2008).

Table 5-1. Results of redd surveys completed by Yakama Nation Fisheries in the Klickitat basin, 2002 through 2007 (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009).

Year	Species	Miles Surveyed	# Redds[1]	Redds/Mile	# Live Spawners	# Morts
2002	Spring Chinook	58.1	389	6.7	248	158
	Fall Chinook	48.6	1225	25.2	1655	1133
	Coho	67.2	480	7.1	1781	384
	Steelhead	127.6	261	2.0	150	17
2003	Spring Chinook	58.1	332	5.7	213	50
	Fall Chinook	40.6	474	11.7	1423	1258
	Coho	53.8	112	2.1	424	149

	Fall Chinook	48.7	777	16.0	1404	776
	Coho	53.9	57	1.1	404	19
	Steelhead	142.8	220	1.5	141	6
2005	Spring Chinook	68.2	50	0.7	98	0

Year	Species	Miles Surveyed	# Redds[1]	Redds/Mile	# Live Spawners	# Morts
	Fall Chinook	48.7	505	10.4	1466	243
	Coho	40.5	0	0.0	114	21
	Steelhead	146.3	157	1.1	288	2
2006	Spring Chinook	68.2	82	1.2	68	11
	Fall Chinook	36.9	119	3.2	684	286
	Coho	40.5	1	0.0	218	45
	Steelhead	123.8	10	0.1	23	3
2007	Spring Chinook	61.2	104	1.7	70	18
	Fall Chinook	48.8	253	5.2	557	62
	Coho	56	190	3.4	1499	133
	Steelhead	135.3	67	0.5	50	8

1 The number of redds is not directly comparable between species since differences in flows affect the efficiency of the surveys.

Straying of out-of-subbasin hatchery-produced steelhead, primarily from the Snake River and Upper Columbia River, into the Klickitat subbasin may also affect the viability of the Klickitat steelhead population. These strays are believed to enter the Klickitat to flee higher temperatures in the mainstem Columbia for cooler water refuges (Keefer et al. 2002). Juvenile transportation, artificial rearing, early run timing, and multiple fallbacks/ re-ascensions at dams also seem to be related to increased incidence of straying behavior (Keefer et al. 2005). Permanent strays, as opposed to "dip-ins" in the non-natal tributary, compete with endangered native fish. Out-of-subbasin spawning by hatchery fish can directly harm local wild populations (Waples et al. 1991; Chilcote 2003). Intra-basin stray rates for hatchery steelhead into Columbia River tributaries may be as high as 6.8 percent (Keefer et al. 2005).

5.2. Freshwater Habitat

The following discussion summarizes what is known and hypothesized regarding potential limiting factors based on best available information for each major and minor spawning area (MaSA and MiSA) identified by the ICTRT. Information used to identify these factors and the potentially associated threats came from available data reports and analyses for the basin, the Northwest Power and Conservation Council's 2004 subbasin planning process, the Klickitat Lead Entity process performed under the Washington State Salmon Recovery Planning process, SB2496, a Yakama Nation 2006 EDT model run incorporating major spawning areas (unpublished), and the watershed planning process, chapter 90.82 RCW.

As described in more detail in Section 2.3, Ecosystem Conditions, and Appendix II, the Klickitat watershed offers areas of good quality habitat for steelhead as well as areas of degraded riparian condition, decreased floodplain function, altered hydrology, degraded channel structure and complexity, fish migration barriers, increased sediment loads, and degraded water quality, particularly with respect to high summer temperatures.

5.2.1 Major Spawning Areas

The ICTRT identified the following six major spawning areas in the Klickitat drainage, all of which are occupied by Middle Columbia steelhead except the West Fork Klickitat MaSA.

Upper Mainstem Major Spawning Area

As identified by the ICTRT, the Upper Mainstem MaSA contains the Klickitat River mainstem from the confluence with the West Fork Klickitat to the headwaters, including McCreedy, Chaparral, Piscoe, Diamond Fork, Butte Meadows, Coyote creeks and Huckleberry Creek below the falls. All but a small section of the Upper Mainstem Klickitat MaSA is above Castile Falls.

Potential limiting factors: *Impaired fish passage, altered sediment routing, degraded water quality (temperature), degraded channel structure and complexity, habitat quality and quantity, altered hydrology, competition, harassment/poaching.*

Steelhead recently regained access to historical habitat above Castile Falls after the fishway was modified to allow fish passage over a wider range of river flow conditions. There is historical evidence (from Yakama Nation Tribal Elders) of steelhead above Castile Falls. Historically, the difficult passage over the falls probably limited the number of fish using upstream habitat. Based on fish surveys and interviews with Tribal fishermen, LeMeir et al. (1957) identified only resident trout upstream of Castile Falls. While it is believed that the falls has always impeded upstream passage of adult fish, a 1960s attempt to improve fish passage at the falls inadvertently obstructed nearly all migration to habitat above the fishway. The recently completed fishway modifications resolved this problem. In addition to the falls, at least three culverts in Piscoe Creek have been identified as barriers to upstream juvenile and resident fish passage, according to WDFW protocols (Yakama Nation Fisheries Program 2003).

The Yakama Nation has monitored sediment levels at 20 sites in the Klickitat basin (http://www.ykfp.org/klickitat/Data_SedRpts.htm; Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009). Reported fine sediment (<0.85 mm) levels in the creek are less than 20 percent (a widely used indicator of spawning gravel condition: gravels that contain fewer than 20 percent fines are considered to be reasonably healthy for salmonids) in all mainstem sample locations in the Upper Mainstem Klickitat MaSA (Table 5-2).

Stream temperatures in the Upper Mainstem Klickitat MaSA frequently exceed 16^{o} C in summer but rarely reach lethal temperatures (Table 5-3). (http://www.ykfp.org/klickitat/Data_SedRpts.htm; Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009). Temperatures above 22^{o} C (72^{o} F) are highly stressful for steelhead but not necessarily lethal. According to Washington State Water

Quality Standards, Class A waters should not exceed 22° C, and Class AA water summer temperatures should not exceed 62.3° F.

Table 5-2. Fine sediment concentrations in gravels in the major and minor spawning areas in the Klickitat basin (data source: Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 21005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009.

MaSA/MiSA	Location	Years Sampled	Average % fine sediment (<0.85mm) in spawning gravel	Average % fine sediment (<6.73mm) in spawning gravel
West Fork Klickitat	West Fork Klickitat near the 255 road	1999	14.3	33.8
Upper Mainstem Klickitat	Klickitat near Signal Park Bridge	1999, 2001-2002	11.4	26.1
	Klickitat near Parrot's Crossing	1999-2000, 2002-2007	13.9	32.0
	Klickitat near Hatchery	1999	49.3	60.8

Swale Creek	At Harms Rd	1997-2003	32.3	78.1	27.4
	Near Mouth	1997-2004	31.9	45.4	29.1

Threats in the Upper Mainstem MaSA are primarily the continued use and construction of roads, continued timber harvest in riparian areas, off-road vehicle use, and grazing. Timber harvest in this area on state and privately owned timberlands is subject to the Washington State Forest Practices rules, while harvest on the Yakama Reservation lands is governed by the Yakama Nation Forest Management Plan for 2005-2014. Future development in the upper portion of the Diamond Fork may affect habitat, depending on the use in that area, locations of development, and construction methods employed.

White Creek Major Spawning Area

The White Creek MaSA includes White Creek, Brush Creek, Tepee Creek, West Fork White Creek, and unnamed NW (White), E, NE and SE (Tepee) tributaries.

Potential limiting factors: *flow, habitat quality and quantity, impaired fish passage, altered sediment routing, degraded water quality (temperature), competition, degraded channel structure and complexity.*

The White Creek watershed (138 sq. miles), including Teepee Creek, supports a substantial portion of total observed steelhead spawning within the surveyed areas of the Klickitat subbasin (Evenson et al. 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009).

Fine sediment (<0.85 mm) levels in the White Creek exceed 20 percent in some areas (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009) (Table 5-2).

Stream temperatures in the White Creek basin frequently exceed 16°C in summer. Lethal or near-lethal temperatures occur rarely at the upper temperature monitoring sites, but exceed 22°C an average 11.1 days per year at the mouth (Table 5-3) (http://www.ykfp.org/klickitat/Data_SedRpts.htm; Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009).

Current habitat conditions in the White Creek watershed reflect past land use, particularly overgrazing, riparian timber harvest and road construction throughout the watershed. Instream large woody debris levels are low in many reaches and base flows are very low to non-existent in many reaches. Due to inhospitable flow and truncated flow duration in the vicinity of many spawning areas, post-emergence movement by steelhead fry and migration by juveniles is critical to their survival. Extensive reaches of both White and Tepee creeks have become incised and flow is now intermittent in many places where anecdotal evidence suggests it was once perennial.

Changes in channel morphology are related to livestock grazing, road interactions, and in some locations, historical removal of LWD. Impacts from grazing (in the form of altered riparian vegetation, bank erosion, and channel incision) are ongoing and evident in several meadow reaches within the watershed. At least seven culverts within the MaSA block upstream migration to spawning and rearing habitat ─ primarily for juveniles and residents, but also for some adults at some flows.

Much of Tepee Creek and portions of White and Brush creeks are highly incised with high, sparsely vegetated, eroding banks. The incision restricts floodplain access and has resulted in a higher-energy stream environment in which bed and bank erosion are common and habitat conditions are poor. Road inventory and analysis of watershed hydrology in the upper Tepee and White Creek watersheds indicated a marked increase in peak discharge (Northwest Hydraulic Consultants 2003).

LWD and pool frequency are very low (Conley 2005). Known historical failures of road crossings likely contributed to debris torrents which exacerbated downcutting of the channel bed, loss of LWD, reduced in-channel complexity and connectivity, and accelerated the export of spawning gravel. Spawning gravel and areas of velocity refugia are also limited.

Middle Mainstem Major Spawning Area

The Middle Mainstem MaSA contains the Klickitat River mainstem from the Little Klickitat River to the confluence with White Creek and includes Summit Creek, Beeks Canyon, and Dead Canyon.

Potential limiting factors: *altered sediment routing, habitat quality and quantity, degraded water quality (temperature), harassment/poaching, flow, predation, competition with hatchery fish, degraded channel structure and complexity, impaired fish passage.*

The middle mainstem Klickitat River MaSA supports over half of the observed mainstem steelhead spawning (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009), and has some of the greatest channel complexity. It also serves as the migration and rearing corridor for steelhead accessing upper reaches in the subbasin.

Large numbers of hatchery produced spring Chinook salmon, fall Chinook salmon, coho salmon and summer steelhead are released from the Klickitat Hatchery directly into the river within this MaSA (Sharp et al. 2008). These hatchery releases likely compete for food and rearing space with naturally produced steelhead. This area is also used extensively by the naturally spawning introduced fall Chinook and coho (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009), which also compete for food and rearing space.

Much of the middle mainstem Klickitat River is located in or adjacent to the Klickitat Wildlife Area. The right of way for the haul road paralleling the Klickitat River's west bank has been acquired by Columbia Land Trust. There is very little development and few roads in the unit. Some grazing occurs in the area. Logging occurs in the headwaters. As indicated in Section 2.3.2 of this Plan, the Big Muddy and Little Muddy creeks and West Fork Klickitat transport substantial quantities of sediment from a natural source to the Klickitat River above this MaSA. Logging-related impacts upstream of the MaSA might also be a source of sediment in the middle mainstem Klickitat River. However, available data suggest that fine sediment (<0.85 mm) levels in the spawning gravels in the mainstem Klickitat portion of the MaSA are reasonably low, below 20 percent fine sediment (Table 5-2) (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009). No data on stream flow, water temperatures, or levels of sediment in spawning gravels are available for Summit Creek, Beeks Canyon, or Dead Canyon.

Lower Mainstem Major Spawning Area

The Lower Mainstem MaSA extends from the mouth of the Klickitat River to the Little Klickitat River (RM 20.2) and includes Snyder Canyon, Dillacort, Wheeler and Logging Camp creeks. Lyle Falls (RM 2.19) restricts upstream passage to a degree.

Potential limiting factors: *habitat quality and quantity, competition, degraded water quality (temperature), altered sediment routing, predation, hatchery-related adverse effects, impaired fish passage, degraded channel structure and complexity, withdrawals, altered hydrology, harassment/poaching.*

The Lower Mainstem MaSA provides a migration and/or rearing corridor for 100 percent of steelhead, spring and fall Chinook, and coho in the Klickitat subbasin. The town of Klickitat is located near the upper end of the Lower Mainstem MaSA. A railroad and Highway 142 parallel the river along much of its length within the MaSA. The lower portion of the MaSA passes through a steep-sided bedrock canyon. Lyle Falls is located

near the lower end of the MaSA. The falls historically impeded passage for spring Chinook and steelhead, but prevented passage for fall Chinook and coho. Lyle Falls was first modified in 1954 to improve passage, and a major remodel of the fishway at Lyle Falls is scheduled to begin in 2010 (Sharp et al. 2008).

Data suggest that fine (<0.85 mm) sediment levels in the gravels are typically low (below 20 percent) in the mainstem Klickitat River portion of the MaSA (Table 5-2), but sediment data are not available for the tributaries within the MaSA. Data suggest that water temperatures in the mainstem Klickitat rarely reach potentially lethal temperatures (Table 5-3). Water temperatures in Snyder Creek, Logging Camp Creeks, and Dillacort Canyon frequently exceed state standards and also exceed lethal temperatures in some years (Table 5-4).

Large numbers of hatchery produced spring Chinook salmon, fall Chinook salmon, and coho salmon are released directly into the river above this MaSA, and hatchery summer steelhead are released within this MaSA (Sharp et al. 2008). These hatchery releases may compete for food and rearing space with naturally produced steelhead. Development impacts in the town of Klickitat likely have some local effect on habitat. There are stretches where the road prevents establishment of riparian vegetation. The road and railroad also impinge on the river in some locations.

Table 5-4. Summary of water temperature data collected in the tributaries included in the Lower Mainstem Major Spawning Area (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 21005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009).

Location	*Dates*	*Average Annual No. Days >16°C*	*Percent of days >18°C*	*Percent of days >22°C*
Snyder Creek at Mill	1997-2007	24.7	12.5	**0**
Snyder Creek at Mouth	1997-2007	65.5	40.6	11.2
Logging Camp Creek	2002-early 2007	59.4	43.2	10.8 (all in 2003 – 54 days total that year)
Dillacort Canyon	1997-early 2997	59.9	31.7	12.5

Upper Little Klickitat Major Spawning Area

The upper Little Klickitat MaSA encompasses the Little Klickitat River from Little Klickitat Falls to the headwaters and includes Spring, Cozy Nook, and Bloodgood creeks, West Prong and East Prong Little Klickitat, Idlewild Canyon, Dry and Butler creeks.

Potential limiting factors: *Upstream passage over a natural barrier. Other potential limiting factors include: habitat quality and quantity, flow, altered sediment routing, degraded water quality (temperature), disease, predation, competition, hatchery-related effects, and degraded channel structure and complexity.*

The upper Little Klickitat MaSA contains a mix of forested uplands managed for timber, with agricultural and grazing land in the lower region. As of the 2000 census, the City of

Goldendale, which has a population of approximately 3760 people (www.census.gov), is the only urban development in the Little Klickitat watershed. The two main thoroughfares of the Klickitat subbasin, SR 142 and US 97, converge at and pass through Goldendale. Hatchery rainbow trout are released into this MaSA to support recreational fisheries.

Little Klickitat Falls, located at river mile 6.1, is 15 to 16 feet high (WPN and Aspect 2005a). Fish passage is possible in rare cases, but these tend to be very high flow events (floods) in winter (D. Rawding, personal communication 2006). In some years when a very high flow event coincides with the time steelhead are moving upstream, a few fish may pass the falls and enter the MaSA. The presence of the barrier functionally excludes steelhead from the upper Little Klickitat MaSA in most years.

Water temperature in the Little Klickitat River frequently exceeds the state standard and can exceed the likely lethal temperature in some areas (Table 3, Broack and Stohr 2002). The East Prong, West Prong, and mainstem Little Klickitat River; and Butler Creek, a major tributary to the Little Klickitat River, were listed on the 1998 303(d) list for temperature. Subsequently, a TMDL assessment and implementation plan were developed and adopted for the Little Klickitat River subbasin (Brock and Stohr 2002; Anderson 2004). Currently, the Little Klickitat River is listed as a Category 4b stream, meaning that the stream has an approved TMDL in place that is actively being implemented (Ecology 2008).

Since steelhead rarely pass the falls, water temperatures in the Upper Little Klickitat MaSA likely do not affect overall steelhead production, except for the influence on water temperature downstream of the falls. A recent analysis of the trends in riparian vegetation within the Little Klickitat basin indicated that riparian vegetation has generally been increasing over the past 30 to 40 years (Aspect and WPN 2009).

Sediment inputs into the Little Klickitat River MaSA could potentially affect spawning areas in the lower Little Klickitat MiSA. A Watershed Analysis was completed for the headwaters of the Little Klickitat basin in 1999 (Raines et al. 1999). That analysis indicated that forest roads were contributing significant sediment to the headwater streams. Since the analysis was completed, the new Washington Forest Practices Rules were adopted; this area is now covered under a Habitat Conservation Plan (http://www.dnr.wa.gov/BusinessPermits/Topics/ForestPracticesHCP/Pages/fp_hcp.aspx). The rules mandate the treatment of roads to minimize sediment inputs.

West Fork Klickitat Major Spawning Area

The West Fork MaSA includes the West Fork Klickitat River from top of falls #1 to headwaters, including Clearwater, Trappers and Fish Lake creeks.

Potential limiting factors: Natural passage barriers and possibly altered sediment routing.

A falls that totals 15 feet at RM 0.3 on the West Fork Klickitat currently hinders upstream anadromous fish passage, and probably limited historical passage to upstream habitat (LeMeir and Smith 1952). Another falls, 15 to 20 feet high, lies approximately four miles upstream and likely poses a similar challenge to upstream migration. LeMeir and Smith (1952) considered these falls to be passage barriers. Although some potential spawning areas exist in the watershed, factors such as gradient and natural confinement contribute to the assumption that this watershed would not be heavily used by spawning anadromous fish (though it is a stronghold for bull trout).

This watershed ranked low in EDT model outputs for restoration potential, since existing data suggest that the West Fork environment has not been significantly altered from historical conditions. Currently, the biggest threat in the watershed is road failures upstream of fish-bearing reaches, which generate torrents and contribute fine sediment. Determining the extent and frequency of steelhead passage and spawning in this system is considered a research need.

5.2.2 Minor Spawning Areas

Swale Creek Minor Spawning Area

The Swale Creek MiSA includes Swale Creek from the mouth to the south tributary below Harms Rd (RM 12.22).

Potential limiting factors: *It is likely that high stream temperature and low stream flow are limiting factors in this MiSA. Degraded habitat quality and quantity, altered sediment routing, disease, competition, predation, and degraded channel structure and complexity are also potential limiting factors.*

Stream flow in Swale Creek is intermittent near the mouth and upstream of river mile 3.1 (WPN and Aspect, 2005a). Stream flow in the lower 3 miles of the creek has been estimated at less than 0.25 cfs during summer (WPN and Aspect 2005a, Aspect 2007).

Stream flow in Swale Creek is influenced by a unique geological situation. The Warwick Fault, running northwest-southeast through Warwick (at roughly RM 12), is an important structural control on groundwater flow in the basin (WPN and Aspect, 2005a; Aspect 2007). The fault forms a structural closure to the Swale Creek valley and creates an impoundment of groundwater to the east of the fault. The presence of the fault impedes westerly groundwater flow (WPN and Aspect 2005a; Aspect 2007). The upper and lower portions of Swale Creek are hydrologically connected in winter and spring when the alluvium upstream of the fault is saturated, resulting in surface flow. The groundwater subsequently drops after the spring rains. The upper and lower basins become hydrologically isolated once the groundwater level drops below the top of the fault. This normally occurs in April or May. Water present in Swale Creek in summer and fall downstream of Warwick is an expression of local seeps and springs located below the fault (WPN and Aspect, 2005a; Aspect 2007).

The cadastral survey notes of the 1800s generally indicate that the flow situation in the 1860s was similar to what is seen today (WPN and Aspect, 2005a). Studies of the local

geology and groundwater flow in the area also indicate that it is unlikely that land use has affected the quantity of water entering this segment (WPN and Aspect, 2005a).

Swale Creek has been listed as Category 5 (impaired, requires a water quality improvement plan) on the State of Washington's 303(d) list for exceedances of state temperature criteria (Ecology 2008). Water temperature at all monitoring stations exceed 22°C (potentially lethal) in all years (WPN and Aspect, 2005a). Since the creek is isolated from the Klickitat River in summer and movement of juvenile fish into the Klickitat is prevented, juveniles rearing in Swale Creek are likely subject to significant mortality when water temperatures rise above potentially lethal temperatures.

Riparian vegetation along the lower 3 miles of the creek, which are perennially wet, is generally dense (WPN and Aspect, 2005a). A review of aerial photographs taken since 1954 indicated that vegetation over the last 60 years has been influenced by a number of large flooding events that removed mature vegetation (WPN and Aspect, 2005a). An analysis of the trends in vegetation over time found that vegetation has generally been increasing along Swale Creek over the past 30 to 40 years (Aspect and WPN 2009).

Limited information is available regarding other habitat conditions in the MiSA. An abandoned railroad bed confines the creek upstream of the perennial wetted area.

Surveyor's Creek Minor Spawning Area

The Surveyor's Creek MiSA contains branched habitat from Surveyor's Creek. The MiSA, as shown in Figure 4-4, contains mainstem Klickitat habitat, but this is only due to the methodology of using existing Hydrologic Unit Code (HUC) GIS data where possible. In this case, because the relevant HUC for Surveyor's Creek was selected, the MiSA encompassed other reaches that did not meet branched habitat criteria but were within the HUC boundary.

Potential limiting factors: *Upstream passage is the primary limiting factor. Other potential limiting factors are altered sediment routing, water temperature, and competition.*

The stream is impassable to salmon and steelhead. Between the mouth of the creek and a location approximately 0.8 miles upstream, the creek drops about 400 feet in a series of cascades and impassable falls (LeMeir 1952). Water temperatures frequently exceed 16°C, and occasionally reach potentially lethal temperatures (Table 5-3).

Lower Little Klickitat Minor Spawning Area

The Lower Little Klickitat MiSA covers the Little Klickitat River from the mouth to Little Klickitat Falls (RM 6.2), including lower Canyon and Bowman creeks.

Potential limiting factors: *Temperature is likely the primary limiting factor in the Lower Little Klickitat MiSA. The following are also potential limiting factors: disease,*

altered sediment routing, competition, habitat quality and quantity, predation, flow, and hatchery-related effects.

The lower 6.1 miles of the Little Klickitat River provide rearing and limited spawning habitat for steelhead. Much of the MiSA runs through a deep canyon. There is little development along the canyon reach. Lower in the reach, some grazing and minor jeep trails are present. The mainstem Little Klickitat River and its tributaries Mill Creek and Bowman Creek are listed as a Category 4a for temperature on Ecology's 303(d) list (Ecology 2008). Water temperatures regularly exceed the state standard in summer and occasionally exceed potentially lethal temperatures (Table 5-3). Riparian vegetation has generally increased since 1969 within the MiSA (Aspect and WPN 2009). The Little Klickitat TMDL (Anderson 2004, Brock and Stohr 2002) includes the Lower Little Klickitat River MiSA. The WRIA 30 Management Plan (WPN and Aspect 2005b) and the TMDL outline actions that should be taken to address temperature in the MiSA. Little to no data are available to address any other factors in this MiSA.

Trout Creek Minor Spawning Area

The Trout Creek MiSA extends up Trout Creek from the top of the falls to the headwaters and includes Bear Creek.

Potential limiting factors: *Natural passage barrier. The following are also potential limiting factors: altered sediment routing, competition, degraded water quality (temperature), habitat quality and quantity, and flow.*

Lower Trout Creek has a relatively steep gradient (20-25 percent over almost 0.25 miles). It is composed primarily of a boulder substrate, which does not, however, exceed the WDFW criteria for anadromous fish-bearing waters (20 percent gradient for 160 meters - continuous, or waterfall over 12 feet in height). No steelhead have been observed to date above the high gradient reach (Evenson and Zendt 2004; Yakama Nation Fisheries Program 2003; Zendt and Evenson 2005; Zendt and Babcock 2007; Zendt 2006; Zendt and Babcock 2009).

5.3 Tributary Harvest

In the Klickitat River, there is both a recreational harvest and a Native American treaty harvest. Recreational fisheries for winter and summer steelhead occur in the Klickitat River from June 1 through November 30. Most steelhead are caught from June through September. A dip net fishery exclusive to enrolled Yakama tribal members is located at Lyle Falls (RM 2). Fishing seasons are set annually by the Yakama tribal council and are subject to in-year closures depending on run strength. The tribal steelhead dip net fishery generally occurs from April 1 through December 31. Harvest is monitored by Yakama Nation fisheries program personnel.

Recreational steelhead fisheries in the Klickitat River are restricted to adipose fin-clipped hatchery steelhead only. Current regulations prohibit sport fishing for steelhead in the Klickitat River from December through May, and the treaty fishery is closed from January through March to protect the winter run (Bosch et al. 2004). Release of all

unmarked wild steelhead is required. Tribal harvest regulations do not require the release of unmarked fish; however, many tribal fishers are returning wild fish to the river (J. Kiona, personal communication 2005). The Klickitat River Anadromous Fisheries Master Plan proposes to use an education outreach program to encourage more tribal fishers to adopt this practice while still respecting tribal culture and tradition (Sharp et al. 2008).

The overall mortality rate for catch-and-release fisheries depends on the encounter rate of naturally produced fish (percentage of run actually caught and released) in the fisheries, and the mortality rate associated with being caught and released (hook-and-release mortality). In winter steelhead fisheries, WDFW (2008) estimates that catch-and-release mortality is less than 5 percent, while mortality in summer steelhead fisheries in the Klickitat River is estimated to be less than 10 percent of the wild fish handled. The catch and release mortality only affects that proportion of the wild run that is encountered in the fishery. WDFW (2008) estimates that in the Klickitat River tributary fisheries that 63 percent of the summer-run steelhead and 34 percent of the winter-run steelhead are handled. Multiplying the catch and release mortality rates by the encounter rates provides the estimate of tributary fisheries impacts of 6 percent for summer-run and 2 percent for winter-run wild steelhead (WDFW 2008).

ODFW performed a number of Population Viability Assessment model runs for 27 steelhead populations to assess the impact of fisheries mortality on the status and recovery of steelhead in Oregon (Chilcote 2001). As mortality rates became greater than 40 percent the probability of extinction increased dramatically. To address this concern, steelhead fisheries are managed not to exceed a maximum mortality limit of 20 percent. This conservative approach is used to provide a buffer for errors, even though the model results suggest that management under a 40 percent limit is unlikely to cause extinction.

Treaty Native American fisheries also occur in the mainstem Klickitat River. The treaty Native American catch of all types of steelhead (summer and winter, wild and hatchery combined) in the Klickitat River is estimated at an average of 1,146 steelhead per year since 1986 (Sharp et al. 2008). Estimated tribal harvest of wild steelhead in the Klickitat averages 178 fish per year (Table 2-1) (Sharp et al. 2008).

Steelhead harvest (sport and tribal combined) in the Klickitat River has averaged about 2,500 fish annually from 1987 to 2004, with Skamania strain steelhead comprising an average 98.1 percent of the sport catch from 1986-2003 (Table 5-5). By contrast, a sport harvest-only table covering the years 1962-1966 averaged an annual catch of 3,312 steelhead (summer only), peaking in 1966 at 8,093 fish (Washington Department of Game and Oregon State Game Commission 1968).

Table 5-5. Estimated Harvest for Klickitat River Steelhead, 1986-2007 (Sharp et al. 2008).

Year	Sport			Tribal		
	Hatchery	Wild	Total	Hatchery[1]	Wild[1]	Total
1986-87	1,426	54	1,480	5,107	901	6,008

Avg:	1,378	20	1,398	968	178	1,146

Note: Data for this table are from YN and WDFW databases and US v. Oregon TAC reports

[1]Hatchery and wild proportions of tribal harvest are estimated as follows: For 1999-00 through 2005-06 percentages estimated from sampling of ceremonial and subsistence harvest were applied to total tribal harvest.
For 1986-87 through 1998-99 the average percentages from the 1999-2005 sampling were applied to total tribal harvest.
[2]Sport Harvest numbers include data from May 1 - April 30 except for 2003-04, which does not include April data

In the most recent ten years between 1997-98 and 2006-07, tribal harvest of wild steelhead in the Klickitat has ranged from 0 to 363 with an average of 107 fish annually (Table 5-5 above). Estimated harvest rates derived for years prior to 2005-06 are likely biased in favor of high returns, as a result of underestimated spawner escapement and total run size to the mouth of the Klickitat. For the return years of 2005-06 and 2006-07, estimated tribal harvest rates on wild steelhead were 5.8 percent and 3.5 percent, respectively (based on wild run abundance and tribal harvest below Lyle Falls as described in Appendix IV). Expansion of the spawner escapement estimates for harvest prior to these two years would suggest a much higher rate upward around 15 percent for the period of record of 1986-2007. Considering the recent two year average of 4.7 percent expanded from the mark recapture abundance estimates, actual harvest over the

recent ten year period of record has probably ranged from 3.5 percent - 10 percent of the wild run to the mouth of the Klickitat.

Steelhead occupy many waters that are also occupied by resident trout species. It is not possible to visually separate juvenile steelhead from similarly sized stream-resident rainbow trout. Because juvenile steelhead and resident rainbow trout are the same species, are similar in size, and have the same food habits and habitat preferences, it is reasonable to assume that catch-and-release mortality studies on stream-resident trout also apply to juvenile steelhead. WDFW has implemented a number of regulation changes to limit impacts on juvenile steelhead in the Klickitat River. These include increasing the minimum size limit for rainbow trout fisheries from 6 inches to the current size limit of 12 inches. The daily bag limit was also reduced from 6 fish to 2 fish. Trout angling is only open from June 1 to November 30. These changes have reduced impacts on naturally produced juvenile steelhead/trout to less than 1 percent of the population, a substantial reduction from historical impacts of tributary fisheries, which were estimated to be over 50 percent (WDFW 2008). The continued release of rainbow trout in tributaries to the Little Klickitat River and the associated fisheries that do not follow the same regulations may adversely affect those naturally produced steelhead that are able to pass above the falls in the lower Little Klickitat River. Fisheries that target non-resident warm water species can affect juvenile steelhead but these fisheries are not present in the Klickitat River (WDFW 2008). WDFW has submitted to NMFS a Fisheries Management and Evaluation Plan (FMEP) for tributary fisheries in the Middle Columbia steelhead DPS to cover impacts from these fisheries under the 4(d) rule limit 4 of the ESA (WDFW 2008).

Harvest of salmon and steelhead in the Klickitat River may include “dip-in” fish, which are destined for tributaries farther up the Columbia and Snake river systems, but temporarily stray to the Klickitat’s cool water refuges in the river’s lower reaches for short periods before continuing their upstream migrations. The contribution of dip-in hatchery steelhead in the Klickitat River harvest is believed to be small. Most hatchery steelhead are taken from river sections upstream of where dip-in fish are found, and the proportion of the harvest is primarily 2- and 3-salt fish typical of the Klickitat River steelhead (D. Rawding, personal communication 2006).

5.4 Out-of-Subbasin Limiting Factors and Threats

The Middle Columbia River Steelhead DPS Recovery Plan uses information from two “modules” developed by NMFS to address conditions in the Columbia River mainstem and estuary that affect all Middle Columbia steelhead: the Hydro Module, based on the NMFS 2008 Biological Opinion on the Federal Columbia River Power System, and the Estuary Module (NMFS 2007). In addition to proposed actions in the management unit plans, the DPS Plan relies upon Hatchery and Genetic Management Plans and Artificial Production for Pacific Salmon (Appendix C of the Supplemental Comprehensive Analysis, NMFS 2008 Biological Opinion) to address hatchery effects. For harvest effects, the Plan refers to fishery management planning through the 2008 U.S. v. Oregon agreement for mainstem fisheries, and Fisheries Management Evaluation Plans for

tributary fisheries. The reader is referred to the DPS plan for this information. The following is a summary of the information most relevant to the Klickitat Plan.

5.4.1 Harvest

Steelhead destined for the Klickitat drainage can be caught in three types of fisheries as they migrate through the Columbia River and Pacific Ocean: ocean fisheries or mainstem Columbia River tribal or nontribal fisheries.

Ocean Fisheries

Steelhead are rarely caught in ocean fisheries; therefore, these fisheries are not considered a significant source of mortality to Middle Columbia River steelhead (NMFS 2000). Ocean fishing mortality on Middle Columbia River steelhead is assumed to be zero.

Columbia River Mainstem Non-Tribal Fisheries

There has been no direct freshwater non-tribal harvest on wild steelhead from the Mid-Columbia DPS since 1992, when the last wild fish catch-and-release regulations on these populations became effective. Therefore, all current non-tribal harvest impacts on Mid-Columbia DPS steelhead are due to incidental bycatch in commercial or recreational fisheries that target hatchery steelhead or other species, and monitoring these impacts is complex. Released fish experience a mortality rate, possibly delayed and difficult to measure, that is highly variable and depends on what gear is used, how the fish is caught by the gear, how the fish are handled during capture and release, and environmental conditions. Release mortality is estimated to be very low (below 1 percent of encounters), with an unknown range of error. Recreational fisheries are monitored by creel surveys (fisheries technicians interview anglers about their catch, gear, and wild steelhead releases); the total recreational impact on winter and summer steelhead as they move through the mainstem to the tributaries is estimated to be less than 2.5 percent (ODFW 2009, Oregon Recovery Plan).

There are three stocks of summer steelhead used for management of treaty and non-treaty mainstem fisheries, including the lower Columbia River Skamania stock, upriver A-run stock, and upriver B-run stock. All MCR steelhead populations are designated A-run, with two populations being winter run. In NOAA's Biological Opinion for the 2008-2017 *U.S. v. Oregon* Fisheries Agreement the wild MCR steelhead DPS in the non-treaty winter, spring, and summer mainstem fisheries are subject to a 2 percent harvest rate limit (NMFS 2008b). Non-treaty fall fisheries are also limited to a 2 percent harvest rate limit for A-run summer steelhead. The total annual harvest rate limit for A-run steelhead in non-treaty fisheries is 4 percent and 2 percent for the summer-run and winter-run of the MCR steelhead DPS, respectively. The expected harvest impacts from non-treaty fisheries are less than the limits proposed in the *U.S. v. Oregon* fisheries Agreement. The yearly incidental catch of A-run steelhead in non-treaty fisheries has averaged 1.6 percent since 1999, and is not expected to change over the course of the Agreement (NMFS 2008b).

Treaty Native American Fisheries

Tribal fishers in Zone 6 of the Columbia mainstem (between Bonneville Dam and McNary Dam) continue to retain wild steelhead for commercial sale or for personal use. The *U.S. v. Oregon* Fisheries Agreement does not establish specific harvest rate limits for treaty-Native American fisheries on steelhead during the spring or summer seasons which extend through July 31. Reported steelhead catch in Zone 6 winter and spring fisheries for 2003 to 2005 ranged from 0.7 percent to 7.9 percent of the winter steelhead run over Bonneville Dam. In 2004, reported and estimated non-reported steelhead catch together amounted to 4.8 percent of the run at Bonneville, with an unknown error around these numbers (ODFW 2009, Oregon Recovery Plan).

Impacts on MCR steelhead from treaty-Native American fall fisheries are limited by harvest rate limits for B-run steelhead and Upper Columbia River bright fall Chinook (NMFS 2008b). The harvest rate on MCR summer-run steelhead in spring, summer, and fall Zone 6 treaty-Native American fisheries combined averaged 11.7 percent since 1985 and 6.64 percent since 1998 (NMFS 2008b, Table 8.8.5.5-1). The impacts resulting from the treaty- Native American fisheries are expected to be similar to the 1998-2006 average of 6.64 percent. The harvest rate is less for populations that pass fewer dams in Zone 6 and are therefore subject to fewer non- Native American and treaty Native American fisheries (e.g., Klickitat steelhead pass only one dam and would experience a harvest rate less than 6.64 percent).

5.4.2 Columbia River Hydro Operations

Hydropower system construction and operation (flow regulation) in the Columbia River basin has been a major cause of changes in the Columbia River and estuary from historical conditions.

Within the Klickitat subbasin, steelhead and salmon were affected by creation of the Bonneville Dam pool on the mainstem Columbia River, which effectively inundated the lower 1.19 miles of the Klickitat River. This resulted in the loss of riparian, spawning, and rearing habitat and increased predation by native and non-native fish in the lower river. A lack of historical data inhibits quantitative evaluation of the impacts of Bonneville pool inundation on native fish, plant and wildlife species.

In the mainstem Columbia River, changes in river flow, circulation, water quality, contaminants, channel alterations, and predation have negative impacts on adult and juvenile fish. Hydro operations have changed flow conditions in the Columbia River and through the estuary. Before the development of the hydrosystem, Columbia River flows were characterized by high spring runoff from snowmelt and regular winter and spring floods. Dam construction and operation have altered Columbia River flow patterns substantially throughout its basin. Historical flow records at The Dalles, Bonneville Dam, and Beaver, Oregon, demonstrate that annual peak flows have been reduced by about 50 percent, as water is stored for power generation and irrigation, and winter flows have increased about 30 percent.

The Columbia River Estuary Module, at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery -Plans/upload/Estuary-Module.pdf provides more information on factors that limit viability of Klickitat steelhead in the Columbia River Estuary.

5.4.3 Ocean Conditions

The effects of ocean conditions on abundance of Pacific salmon and steelhead vary among species and populations within species. Migration patterns in the ocean may differ dramatically and expose different stocks to different conditions in different parts of the ocean. Some species have broad, offshore migration patterns that may extend as far as the Gulf of Alaska (steelhead, chum, some Chinook). Others have migration patterns along the Washington, British Columbia, Oregon and California coasts (Chinook, coho, cutthroat). Thus, ocean conditions do not have coincident effects on survival across species or populations.

Ocean survival of steelhead has been dramatically affected by widespread changes in ocean conditions. Cooper and Johnson (1992) showed that variation in steelhead run sizes and smolt-to-adult survival was highly correlated between runs up and down the West Coast. Smolt-to-adult survival rates generally varied 10-fold between good and bad years. Ocean survival rates for three West Coast steelhead populations where good annual index data were available showed high variability and a generally declining trend since the late 1970s.

5.4.4 Climate Change

Climate change represents a potentially significant threat to recovery of Mid-Columbia steelhead populations. The Independent Scientific Advisory Board (ISAB) for the Northwest Power and Conservation Council, Columbia River Basin Indian Tribes, and NMFS reviewed the potential effects of climate change on salmonids in the Columbia River basin (ISAB 2007). The ISAB report shows that changes in climate may adversely affect steelhead in freshwater habitats across the DPS by exacerbating existing problems with water quantity (lower summer stream flows) and water quality (higher summer water temperatures). Consistently identified types of impacts on snow pack, stream flow, and water quality in the Columbia Basin are the following (ISAB 2007 p. 15-17):

- Warmer temperatures will result in more precipitation falling as rain rather than snow.
- Snow pack will diminish, and the timing of stream flow will be altered.
- Peak river flows will likely increase.
- Water temperatures will continue to rise.

These changes may affect steelhead more than other salmonids because of their long rearing period in freshwater.

Changing conditions could also affect salmonid health and survival in the ocean through a variety of mechanisms, including increased ocean temperatures, increased stratification of some waters, changes in the upwelling season, shifts in the distribution of salmonids,

long-term variability in winds and ocean temperatures, increased acidity, and increased atmospheric and oceanic variability (NMFS 2007, 2008a; ISAB 2007).

All other threats and conditions remaining equal, future deterioration of water quality, water quantity, and/or physical habitat can be expected to cause a reduction in the number of naturally produced adult steelhead returning to these populations across the DPS. This possibility further reinforces the importance of achieving survival improvements throughout the entire steelhead life cycle. Recent research also indicates that neighboring populations with differences in habitat may show different responses to climate changes (Crozier and Zabel 2006; Crozier et al. 2008). This research reinforces the importance of maintaining habitat diversity. Ongoing efforts to develop models of future climate effects should be considered in adaptive management.

5.4.5 Other Large-Scale Threats

Projected continued population growth will increase pressures for conversion of forestry and agricultural land uses to residential uses, with potential impacts on habitat and water conditions.

- Increase in exotic invasive species that potentially compete with native flora and fauna, and provide food and/or cover to species that potentially compete with, prey on or carry diseases which could affect native species.
- New disease and/or pathogen introductions (e.g. from marine aquaculture operations on steelhead ocean migration routes, illegal stocking of out-of-subbasin species).
- Natural catastrophic events (e.g. earthquake, volcanic eruption and related effects).

6. Recovery Strategy and Actions

The preceding chapters summarize recovery goals, biological criteria and threats criteria, current status assessment, and the major limiting factors and threats identified for the Klickitat River steelhead population. How will we reach recovery?

In this chapter, a recovery strategy is laid out to address the significant data gaps and uncertainties regarding the status of the Klickitat steelhead population and to address the potential limiting factors based on the existing, best available science; i.e. hatchery-related effects and degraded habitat, including natural barriers to fish passage. The strategy includes maintaining low harvest impacts and improving monitoring to verify those impacts. Fish passage and survival issues in the mainstem Columbia River and estuary are addressed in more detail in the Middle Columbia River Steelhead DPS ESA Recovery Plan; in Section 6.5, these are summarized as most directly related to the Klickitat population.

Lack of information about the Klickitat River steelhead population is a major problem for recovery planning for the Middle Columbia River steelhead DPS. The Klickitat population's moderate risk rating was assigned primarily on the basis of uncertainty and lack of data, particularly with respect to the influence of hatchery fish on the wild steelhead population. Therefore, the first importance for a recovery strategy is to reduce the uncertainties by obtaining more information through monitoring and research. Monitoring and research needs are summarized here and described in greater detail in Chapter 8.

Improvements in hatchery management and the construction of a new facility 26 river miles downstream of the major spawning area in the middle mainstem are designed to address the potential limiting factor of competition with hatchery fish.

To address habitat degradation in the Klickitat watershed, the plan proposes to protect and improve ecosystem functions and restore ecological processes, first, by protecting and maintaining existing high quality and/or unimpaired habitats and ecosystem functions; and, second, by restoring degraded habitat where appropriate, through passive and active measures.

Managing harvest for low impacts from both mainstem and tributary fisheries, and to reduce any adverse impacts that may be occurring, also is an important contribution to the population's viability.

For a species to achieve both ESA and broad-sense recovery, it would need to get on a definitive trajectory of improvement. The recovery strategies and actions are designed to work synergistically to improve survival throughout the steelhead life cycle, from egg to smolt to returning adult. Monitoring results will inform us of the progress the species has made toward recovery goals.

6.1 Strategies and Actions to Address Data Gaps

A research, monitoring, and evaluation plan should be designed collaboratively in the implementation phase of this plan to address the additional information needs that stakeholders and scientists have identified, as follows:

- Determine abundance and productivity of natural steelhead spawners
- Determine the impacts of Skamania hatchery steelhead releases on viability of the Klickitat population, if any.
- Determine the effects of non-native coho and fall Chinook released from the hatcheries and naturalized in the river, if any.
- Continue study and further refine understanding of habitat limiting factors.

Strategy 1. Determine abundance and productivity of natural steelhead spawners

Actions

- *Fin clipping of hatchery fish* – Continue fin clipping 100 percent of the hatchery released fish to facilitate the development of population estimates.

- *Adult counts at Lyle Falls Fishway adult trap* – Continue to monitor the number of steelhead passing through the Lyle Falls adult trap.

- *Estimates of trap efficiency* – Continue to monitor adult trap efficiencies with floy tags recovered in sport fisheries or during spawner/carcass surveys. Testing trap efficiency may be improved by releasing floy tagged fish downstream of the trap and identifying the percentage that re-enter the trap as they move upstream. Develop and publish annual estimates of trap efficiency.

- *Abundance estimates* – Based on the number of fish caught in the Lyle Falls Fishway adult trap and the estimates of trap efficiency, develop and publish annual estimates of the number of natural spawners.

- *Juvenile counts at the smolt trap locations* – Continue to monitor and report the number of fish caught in the three rotary screw trap locations currently operated by Yakama Nation Fisheries in cooperation with WDFW.

- *Productivity estimates* – Based on the number of fish caught at the rotary screw trap locations and the estimates of trap efficiency, develop and publish annual estimates of the number of naturally spawned steelhead smolts migrating out of the Klickitat basin.

Strategy 2. Determine impacts of Skamania Hatchery steelhead releases on viability of Klickitat steelhead population.

Actions

- *Spawner Surveys* -Continue to conduct and report annual spawner surveys to track adult steelhead distribution in the MaSAs and MiSAs.

- *Portion of Natural Spawners of Hatchery-Origin* - Estimate natural/hatchery adult spawner ratios by sampling carcasses on spawning grounds, or through other appropriate methods.

- *Estimates of Genetic Introgression* - Based on the estimated proportion of hatchery-origin steelhead spawning naturally each year, develop estimates of the amount of genetic introgression that has likely occurred over the 40 years of hatchery operations.

- *Genetic Sampling* - Increase juvenile and adult genetic sampling and analysis at spawning grounds and at various trap locations to help assess the level of domestication and interbreeding between hatchery and natural steelhead.

- *Stock Distribution* - Focus radio-tagging studies to determine spatial and temporal distribution of natural Klickitat steelhead population and Skamania Hatchery steelhead, and the overlap between summer and winter-run steelhead in the Klickitat River.

Strategy 3. Determine impacts of non-native coho and fall Chinook releases on viability of Klickitat steelhead population.

Actions

- *Fin clipping of hatchery fish* **–** Continue fin clipping 100 percent of the hatchery released coho and fall Chinook to identify the number of hatchery released fish that spawn naturally in the Klickitat River.

- *Adult counts at Lyle Falls Fishway adult trap* – Continue to monitor the number of coho and Chinook passing through the Lyle Falls adult trap.

- *Estimates of trap efficiency* **–** Estimate the efficiency of the trap in intercepting coho, fall Chinook, and spring Chinook. Publish annual estimates.

- *Abundance estimates* – Based on the number of fish caught in the Lyle Falls Fishway adult trap and the estimates of trap efficiency, make annual estimates of the number of adult coho, fall Chinook, and spring Chinook entering the Klickitat basin.

- *Juvenile counts at the smolt trap locations* – Continue to monitor and report the number of coho and Chinook caught in the three rotary screw trap locations currently operated by the Yakama Nation Fisheries in cooperation with WDFW.

- *Productivity estimates* - Based on the number of coho and Chinook caught at the rotary screw trap locations and the estimates of trap efficiency, develop and publish annual estimates of the number of coho and Chinook smolts migrating out of the Klickitat basin.

- *Spawner surveys* - Continue to conduct annual spawner surveys to track adult coho and fall Chinook distribution in the MaSAs and MiSAs, but expand the program to cover the entire area in which steelhead are known to spawn.

- *Estimate number of naturally spawning fish of hatchery-origin* - Sample carcasses on spawning grounds to estimate natural/hatchery adult spawner ratios.

- *Overlap in distribution of spawning habitats* - Assess the amount of overlap in the habitat occupied by steelhead and the introduced species.

- *Productivity of introduced species* - Determine the productivity of the naturally spawned coho and fall Chinook, using the same methods used to determine the productivity of steelhead.

- *Competition between species* – Evaluate the effects of competition with introduced species on rearing juveniles (differences in growth and survival with and without introduced species present) in a properly controlled experiment.

- *Estimate displacement of steelhead* - Determine the area of steelhead spawning and rearing habitat displaced by coho and fall Chinook.

- *Effects of introduced species on productivity* - Estimate the effect of introduced species on the productivity of steelhead in the basin.

Strategy 4. Continue study and further refine understanding of habitat limiting factors.

Actions

- Continue habitat study and incorporate new data into EDT, AHA, and/or other appropriate models.

- Continue biological studies and incorporate new data into models.

- Use adaptive management to adjust actions according to new information.

6.2 Hatchery-Related Strategies and Actions

The following strategies and actions address potential limiting factors and threats to Klickitat steelhead viability from hatchery-related effects.

Strategy 1. Minimize adverse impacts of large-scale hatchery releases of *U.S. v. Oregon* production stocks (coho and fall Chinook) on Klickitat steelhead population.

A satellite Wahkiacus Hatchery/Acclimation Facility (WHAF) at RM 17.0 on the Klickitat River is under development. Existing *U.S. v. Oregon* production of fall Chinook and coho will be transferred from the Klickitat Hatchery to the new facility. The 26 miles of river between Klickitat Hatchery (RM 42.6) and WHAF (RM 17) contain EDT reaches in the upper end of the Lower Klickitat, Middle Klickitat, and Upper Middle Klickitat MaSAs (See Appendix II, Table II-1 for correlation between ICTRT and YN MaSAs and MiSAs). Physical habitat surveys and resulting EDT output identify these reaches as having the highest potential for restoration and preservation. Annual steelhead spawner surveys indicate that 60 percent of the mainstem spawning occurs in these reaches.

The program is identified in the Klickitat Anadromous Fishery Master Plan (Sharp et al. 2008). Transferring *U.S. v. Oregon* production stocks (coho and fall Chinook) to the WHAF accomplishes two primary objectives. First, it frees up critical water and space at the Klickitat Hatchery, ensuring that optimal rearing densities and protocols (YKFP and HSRG guidelines) are met for the two endemic stocks (Klickitat spring Chinook and Klickitat summer steelhead). Second, transferring coho and fall Chinook production 26 miles downriver minimizes the impacts of large-scale hatchery releases on wild spring Chinook and steelhead rearing between the two facilities. Additionally, release of well-acclimated coho and fall Chinook from WHAF imprinted to the local groundwater signature will concentrate natural production in the immediate vicinity of the facility.

Actions

- Develop satellite Wahkiacus Hatchery/Acclimation Facility at RM 17.0.
- Transfer existing *U.S. v. Oregon* production of fall Chinook and coho from the Klickitat Hatchery to Wahkiacus facility.

Strategy 2. Minimize adverse impacts from hatchery program on the Klickitat steelhead population.

The Yakama Nation has been working with, the HSRG, NMFS, WDFW, Tribal fish and wildlife leaders, BPA, and others to develop a master plan for an integrated hatchery program for the Klickitat River (Sharp et al. 2008). The program will minimize adverse impacts on the natural steelhead spawning population. One option being explored by hatchery program managers is to replace the current program, which releases out-of-basin Skamania hatchery-origin smolts in the Klickitat River system, with a hatchery program that relies entirely on the use of natural-origin, summer steelhead from the Klickitat River for broodstock (Sharp et al. 2008). The new program would continue to provide harvest opportunities for treaty and non-treaty fisheries. A feasibility study will be conducted as

part of the program to investigate broodstock collection and juvenile rearing strategies, expected smolt-to-adult survival rates, and the risks associated with current steelhead hatchery practices.

Actions

- Develop and implement Klickitat steelhead integrated hatchery program (Sharp et al. 2008).
- Conduct feasibility study to gain needed information on broodstock collection, rearing strategies and expected smolt-to-adult survival rates, and to assess risks associated with current and proposed hatchery practices.
- Evaluate out-of-basin steelhead strays.

Strategy 3. Improve steelhead passage at Lyle Falls Fishway.

Passage for summer and winter steelhead at Lyle Falls (RM 2.2 on the Klickitat River) can become difficult during low flow conditions. At low flows, minimal water passes through the fishway, whose exit channel is often shallow with exposed bedload, resulting in fish reluctant to enter and exit the fishway. New fish passage technology provides solutions to remedy problems with the fishway and facilitate increased passage through a wider range of flows, particularly during low flow conditions. Increased passage through a properly functioning fishway will not only facilitate the monitoring of returns and enable the collection of steelhead broodstock for the integrated hatchery program but will also ease steelhead migration.

Actions

- Reconstruct Lyle Falls fishway to Federal design criteria to ease steelhead migration, facilitate the monitoring of returns, and function as a site for broodstock collection for the integrated hatchery program.

Strategy 4. Assess steelhead natural recolonization of upper Klickitat watershed and the potential use of artificial propagation to accelerate recolonization.

In 2005, full anadromous fish passage was restored into the Upper Klickitat watershed as a result of improvements to the Castile Falls Fishway. Analysis conducted by the Yakama Nation and ICTRT indicates that the current habitat potential above Castile Falls could substantially increase the abundance of Klickitat River steelhead once fully seeded. Efforts need to be implemented to adequately assess the natural recolonization of steelhead in the upper watershed and to explore the potential use of artificial propagation as a means to accelerate recolonization.

The Yakama Nation is working with the HSRG, NMFS, WDFW, tribal leaders, BPA, and others to examine whether a conservation hatchery program could be used to accelerate recolonization of the Upper Klickitat watershed (Sharp et al. 2008). The program may also be used to provide harvest opportunities. The need for, and use of, artificial production to accelerate recolonization would be contingent upon the rate and extent that natural recolonization occurs in the upper watershed now that passage has been restored

at Castile Falls. The decision to implement an artificial propagation program would likely imply that natural recolonization has been minimal and/or is occurring at an extremely slow rate.

Actions

- Monitor annual natural escapement of steelhead into the upper subbasin.
- Use Castile Fishway trap to collect biological data on *O. mykiss* migrating into the upper watershed, and to monitor trends in the genetic composition and diversity of the upper basin population.
- Explore need for a conservation hatchery program to accelerate recolonization of upper Klickitat watershed.

Strategy 5. Determine and minimize impacts of hatchery trout releases in the Klickitat subbasin.

The continued release of Goldendale Hatchery trout in the Little Klickitat River should be evaluated by WDFW, because of the potential for adverse interactions with naturally spawning steelhead that are known to escape above the falls. WDFW planting records for 2006 show 5,214 hatchery rainbow trout were released into the upper Little Klickitat River and 844 hatchery rainbow trout were released into Bird Creek, a tributary to Outlet Creek in the Glenwood Valley. Goldendale Hatchery rainbow trout have been cultured to be "fall spawners" to minimize genetic impacts. However competition, predation, disease, and harvest impacts should be evaluated.

Potential evaluations include investigating the use of triploid trout (sterile) releases into streams where steelhead directly reside, or where outplants can colonize downstream. Because of potential for negative interaction, the Yakama Nation releases only triploid hatchery trout in lakes for recreational fisheries within the reservation boundaries. At a minimum, mark all hatchery trout and require release of unmarked juveniles.

Actions

- Investigate impacts of WDFW hatchery trout plants into the Klickitat subbasin.
