Middle Columbia River Steelhead Distinct Population Segment ESA Recovery Plan

November 30, 2009

Prepared by
National Marine Fisheries Service
Northwest Region

DISCLAIMER

Endangered Species Act (ESA) recovery plans delineate reasonable actions which the best available information indicates are necessary for the conservation and survival of listed species. Plans are published by the National Marine Fisheries Service (NMFS), usually with the assistance of recovery teams, state agencies, local governments, salmon recovery boards, non-governmental organizations, interested citizens of the affected area, contractors, and others. ESA recovery plans do not necessarily represent the views, official positions, or approval of any individuals or agencies involved in the plan formulation, other than NMFS. They represent the official position of NMFS only after they have been signed by the Northwest Regional Administrator. ESA recovery plans are guidance and planning documents only; identification of an action to be implemented by any public or private party does not create a legal obligation beyond existing legal requirements. Nothing in this plan should be construed as a commitment or requirement that any Federal agency obligate or pay funds in any one fiscal year in excess of appropriations made by Congress for that fiscal year in contravention of the Anti-Deficiency Act, 31 U.S.C. 1341, or any other law or regulation. Approved recovery plans are subject to modification as dictated by new information, changes in species status, and the completion of recovery actions.

With respect to the Middle Columbia Steelhead Recovery Plan, where areas of disagreement arose between a management unit plan and the species level, distinct population segment (DPS) plan, NMFS worked with the relevant parties to resolve the differences and in a few cases, identified in the DPS plan, decided not to incorporate the disputed material into the DPS plan.

ESA recovery plans provide important context for NMFS determinations pursuant to section 7(a)(2) of the Endangered Species Act. However, recovery plans do not place any additional legal burden on NMFS or the action agency when determining whether an action would jeopardize the continued existence of a listed species or adversely modify critical habitat. The procedures for the section 7 consultation process are described in 50 CFR 402 and are applicable regardless of whether or not the actions are described in a recovery plan.

Acknowledgements

The Middle Columbia River Steelhead Distinct Population Segment ESA Recovery Plan represents the dedicated effort of numerous individuals, organizations, recovery boards, and interested citizens over many years in the Mid-Columbia River basin. In particular, we would like to thank NMFS consultant Margaret Hollenbach, who served as recovery plan writer and editor throughout the multi-year process of producing this plan. We would also like to thank the Middle Columbia Recovery Forum Steering Committee members, Management Unit organization members, and Middle Columbia Recovery Forum meeting participants for their input, support, and guidance throughout this recovery planning process. These individuals also provided valuable comments on draft versions of the recovery plan. In addition, the Interior Columbia Technical Recovery Team was instrumental in providing a comprehensive science basis for the plan, as well as reviewing and commenting on earlier drafts. NMFS reviewers of the plan were: Elizabeth Holmes Gaar, Rob Walton, Laurie Beale, Susan Pultz and Larissa Plants.

Recovery Planning Glossary

abundance: In the context of salmon recovery, unless otherwise qualified, abundance refers to the number of adult fish returning to spawn, measured over a time series.

adaptive management: Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. A plan for monitoring, evaluation, and feedback is incorporated into an overall implementation plan so that the results of actions can become feedback on design and implementation of future actions.

anadromous fish: Species that are hatched in freshwater, migrate to and mature in salt water, and return to freshwater to spawn.

baseline monitoring: In the context of recovery planning, baseline monitoring is done before implementation, in order to establish historical and/or current conditions against which progress (or lack of progress) can be measured.

biogeographical region: an area defined in terms of physical and habitat features, including topography and ecological variations, where groups of organisms (in this case, salmonids) have evolved in common.

broad sense recovery goals: Goals defined in the recovery planning process, generally by local recovery planning groups, that go beyond the requirements for delisting, to address, for example, other legislative mandates or social, economic, and ecological values.

compliance monitoring: Monitoring to determine whether a specific performance standard, environmental standard, regulation, or law is met.

delisting criteria: Criteria incorporated into ESA recovery plans that define both biological viability (biological criteria) and alleviation of the causes for decline (threats criteria based on the five listing factors in ESA section 4[a][1]), and that, when met, would result in a determination that a species is no longer threatened or endangered and can be proposed for removal from the Federal list of threatened and endangered species. These criteria are a NMFS determination and may include both technical and policy considerations.

distinct population segment (DPS): A listable entity under the ESA that meets tests of discreteness and significance according to USFWS and NMFS policy. A population is considered distinct (and hence a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics, it occupies an unusual or unique ecological setting, or its loss would represent a significant gap in the species' range.

diversity: All the genetic and phenotypic (life history, behavioral, and morphological) variation within a population. Variations could include anadromy vs. lifelong residence in freshwater, fecundity, run timing, spawn timing, juvenile behavior, age at smolting, age at maturity, egg size,

developmental rate, ocean distribution patterns, male and female spawning behavior, physiology, molecular genetic characteristics, etc.

endangered species: A species in danger of extinction throughout all or a significant portion of its range.

effectiveness monitoring: Monitoring set up to test cause-and-effect hypotheses about recovery actions: Did the management actions achieve their direct effect or goal? For example, did fencing a riparian area to exclude livestock result in recovery of riparian vegetation?

ESA recovery plan: A plan to recover a species listed as threatened or endangered under the U.S. Endangered Species Act (ESA). The ESA requires that recovery plans, to the extent practicable, incorporate (1) objective, measurable criteria that, when met, would result in a determination that the species is no longer threatened or endangered; (2) site-specific management actions that may be necessary to achieve the plan's goals; and (3) estimates of the time required and costs to implement recovery actions.

evolutionarily significant unit (ESU): A group of Pacific salmon or steelhead trout that is (1) substantially reproductively isolated from other conspecific units and (2) represents an important component of the evolutionary legacy of the species.

extinct: No longer in existence. No individuals of this species can be found.

extirpated: Locally extinct. Other populations of this species exist elsewhere. Functionally extirpated populations are those of which there are so few remaining numbers that there are not enough fish or habitat in suitable condition to support a fully functional population.

factors for decline: Five general categories of causes for decline of a species, listed in the Endangered Species Act section 4(a)(1)(b): (A) the present or threatened destruction, modification, or curtailment of its habitat or range; (B) overutilization for commercial, recreational, scientific, or educational purposes; (C) disease or predation; (D) the inadequacy of existing regulatory mechanisms; or (E) other natural or human-made factors affecting its continued existence.

functionally extirpated: Describes a species that has been extirpated from an area; although a few individuals may occasionally be found, there are not enough fish or habitat in suitable condition to support a fully functional population.

hyporheic zone: Area of saturated gravel and other sediment beneath and beside streams and rivers where groundwater and surface water mix.

implementation monitoring: Monitoring to determine whether an activity was performed and/or completed as planned.

independent population: Any collection of one or more local breeding units whose population dynamics or extinction risk over a 100-year time period is not substantially altered by exchanges of individuals with other populations.

indicator: A variable used to forecast the value or change in the value of another variable.

interim regional recovery plan: A recovery plan that is intended to lead to an ESA recovery plan but that is not yet complete. These plans might address only a portion of an ESU or lack other key components of an ESA recovery plan.

intrinsic potential: The estimated relative suitability of a habitat for spawning and rearing of anadromous salmonid species under historical conditions inferred from stream characteristics including channel size, gradient, and valley width.

intrinsic productivity: The expected ratio of natural-origin offspring to parent spawners at levels of abundance below carrying capacity.

kelts: Steelhead that are returning to the ocean after spawning and have the potential to spawn again in subsequent years (unlike most salmon, steelhead do not necessarily die shortly after spawning).

large woody debris (LWD): A general term for wood naturally occurring or artificially placed in streams, including branches, stumps, logs, and logjams. Streams with adequate LWD tend to have greater habitat diversity, a natural meandering shape, and greater resistance to flooding.

legacy effects: Impacts from past activities that continue to affect a stream or watershed in the present day.

limiting factor: Physical, biological, or chemical features (e.g., inadequate spawning habitat, high water temperature, insufficient prey resources) experienced by the fish that result in reductions in viable salmonid population (VSP) parameters (abundance, productivity, spatial structure, and diversity). Key limiting factors are those with the greatest impacts on a population's ability to reach a desired status.

locally developed recovery plan: A plan developed by state, tribal, regional, or local planning entities to address recovery of a species. These plans are being developed by a number of entities throughout the region to address ESA as well as state, tribal, and local mandates and recovery needs.

maintained status: Population status in which the population does not meet the criteria for a viable population but does support ecological functions and preserve options for ESU/DPS recovery.

major population group (MPG): A group of salmonid populations that are geographically and genetically cohesive. The MPG is a level of organization between demographically independent populations and the ESU or DPS.

major spawning area (MaSA) A system of one or more branches that contain sufficient spawning and rearing habitat to support more than 500 spawners. For Interior Columbia salmonid populations, defined using results from intrinsic potential analysis.

management unit: A geographic area defined for recovery planning purposes on the basis of state, tribal or local jurisdictional boundaries that encompass all or a portion of the range of a listed species, ESU, or DPS.

metrics: A metric is something that quantifies a characteristic of a situation or process; for example, the number of natural-origin salmon returning to spawn to a specific location is a metric for population abundance.

minor spawning area (MiSA) A system of one or more branches that contains sufficient spawning and rearing habitat to support 50 – 500 spawners (defined using intrinsic potential analysis).

morphology: The form and structure of an organism, with special emphasis on external features.

natural-origin fish: Fish that were spawned and reared in the wild, regardless of parental origin.

parr: The stage in anadromous salmonid development between absorption of the yolk sac and transformation to smolt before migration seaward.

phenotype: Any observable characteristic of an organism, such as its external appearance, development, biochemical or physiological properties, or behavior.

piscivorous: (Adj.) Describes fish that eat other fish.

productivity: The average number of surviving offspring per parent. Productivity is used as an indicator of a population's ability to sustain itself or its ability to rebound from low numbers. The terms "population growth rate" and "population productivity" are interchangeable when referring to measures of population production over an entire life cycle. Can be expressed as the number of recruits (adults) per spawner or the number of smolts per spawner.

recovery domain: An administrative unit for recovery planning defined by NMFS based on ESU boundaries, ecosystem boundaries, and existing local planning processes. Recovery domains may contain one or more listed ESUs.

recovery goals: Goals incorporated into a locally developed recovery plan, which may include delisting (i.e. no longer considered endangered or threatened), reclassification (e.g., from endangered to threatened), and/or other goals. Broad sense goals are a subset of recovery goals (see glossary entry above).

recovery plan supplement: A NMFS supplement to a locally developed recovery plan that describes how the plan addresses ESA requirements for recovery plans. The supplement also

proposes ESA delisting criteria for the ESUs addressed by the plan, since a determination of these criteria is a NMFS decision.

recovery scenarios: Scenarios that describe a target status for each population within an ESU, generally consistent with TRT recommendations for ESU viability.

redd: A nest constructed by female salmonids in streambed gravels where eggs are fertilized and deposited.

recovery strategy: Statements that identify the assumptions and logic – the rationale – for the species' recovery program.

riparian area: Area with distinctive soils and vegetation between a stream or other body of water and the adjacent upland.

salmonid: Fish of the family *Salmonidae*, including salmon, trout, chars, grayling, and whitefish. In general usage, the term usually refers to salmon, trout, and chars.

smolt: A juvenile salmonid that is undergoing physiological and behavioral changes to adapt from freshwater to saltwater as it migrates toward the ocean.

spatial structure: Characteristics of a fish population's geographic distribution. Current spatial structure depends upon the presence of fish, not merely the potential for fish to occupy an area.

stakeholders: Agencies, groups, or private citizens with an interest in recovery planning, or those who will be affected by recovery planning and actions.

Technical Recovery Team (TRT): Teams convened by NMFS to develop technical products related to recovery planning. Planning forums unique to specific states, tribes, or regions may use TRT and other technical products to identify recovery actions.

threatened species: A species likely to become endangered within the foreseeable future throughout all or a significant portion of its range.

threats: Human activities or natural events (e.g., road building, floodplain development, fish harvest, hatchery influences, volcanoes) that cause or contribute to limiting factors. Threats may exist in the present or be likely to occur in the future.

viability criteria: Criteria defined by NMFS-appointed Technical Recovery Teams to describe a viable salmonid population, based on the biological parameters of abundance, productivity, spatial structure, and diversity. These criteria are used as technical input into the recovery planning process and provide a technical foundation for development of biological delisting criteria.

viability curve: A curve describing combinations of abundance and productivity that yield a particular risk of extinction at a given level of variation over a specified time frame.

viable salmonid population (VSP): an independent population of Pacific salmon or steelhead trout that has a negligible risk of extinction over a 100-year time frame.

VSP parameters: Abundance, productivity, spatial structure, and diversity. These describe characteristics of salmonid populations that are useful in evaluating population viability. See NOAA Technical Memorandum NMFS-NWFSC-42, *Viable salmonid populations and the recovery of evolutionarily significant units* (McElhany et al. 2000).

EXECUTIVE SUMMARY

Introduction

This is a recovery plan (Plan) for the protection and restoration of Middle Columbia River steelhead (*Oncorhynchus mykiss*), which spawn and rear in tributaries to the Columbia River in central and eastern Washington and Oregon (Figure ES-1). The Middle Columbia River steelhead distinct population segment (DPS) was listed as threatened under the Endangered Species Act of 1973 (ESA) on January 5, 2006 (71 FR 834).

Section 4(f) of the ESA requires NOAA's National Marine Fisheries Service (NMFS) to develop recovery plans for marine species listed under the Act. Recovery plans identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA. Although recovery plans are guidance, not regulatory documents, the ESA clearly envisions recovery plans as the central organizing tool for guiding each species' recovery process. Recovery planning is an opportunity to search for common ground among affected parties, to organize protection and restoration of salmonid habitat, and to secure the economic and cultural benefits that accrue to human communities from healthy watersheds and rivers. While Federal, state, and tribal entities can make major contributions to the recovery of Middle Columbia steelhead, the actions of individuals on their land, as well as city and county codes and ordinances promoting conservation, are also essential.

Nineteen of the 33 salmon and steelhead species in the Northwest region are listed as threatened or endangered. The Middle Columbia steelhead is among those with the best prospects of recovery, although it will require considerable political will and investment of long-term effort and funding. Modeling of the potential effects of the actions that are proposed in this plan (see Chapter 9) predicts that the DPS can achieve a low risk of extinction within a reasonable time frame – e.g. 25 to 50 years – if the actions are taken and if they have the predicted effects on steelhead habitat and survival. Cautious though this statement may be, it is a beacon of hope in the complex realm of salmon and steelhead recovery in the Northwest. The following sections tell the story.

ESA Requirements

ESA section 4(a)(1) lists factors for re-classification or delisting that are to be addressed in recovery plans:

A. The present or threatened destruction, modification, or curtailment of [the species'] habitat or range
B. Over-utilization for commercial, recreational, scientific or educational purposes
C. Disease or predation
D. The inadequacy of existing regulatory mechanisms
E. Other natural or human-made factors affecting its continued existence

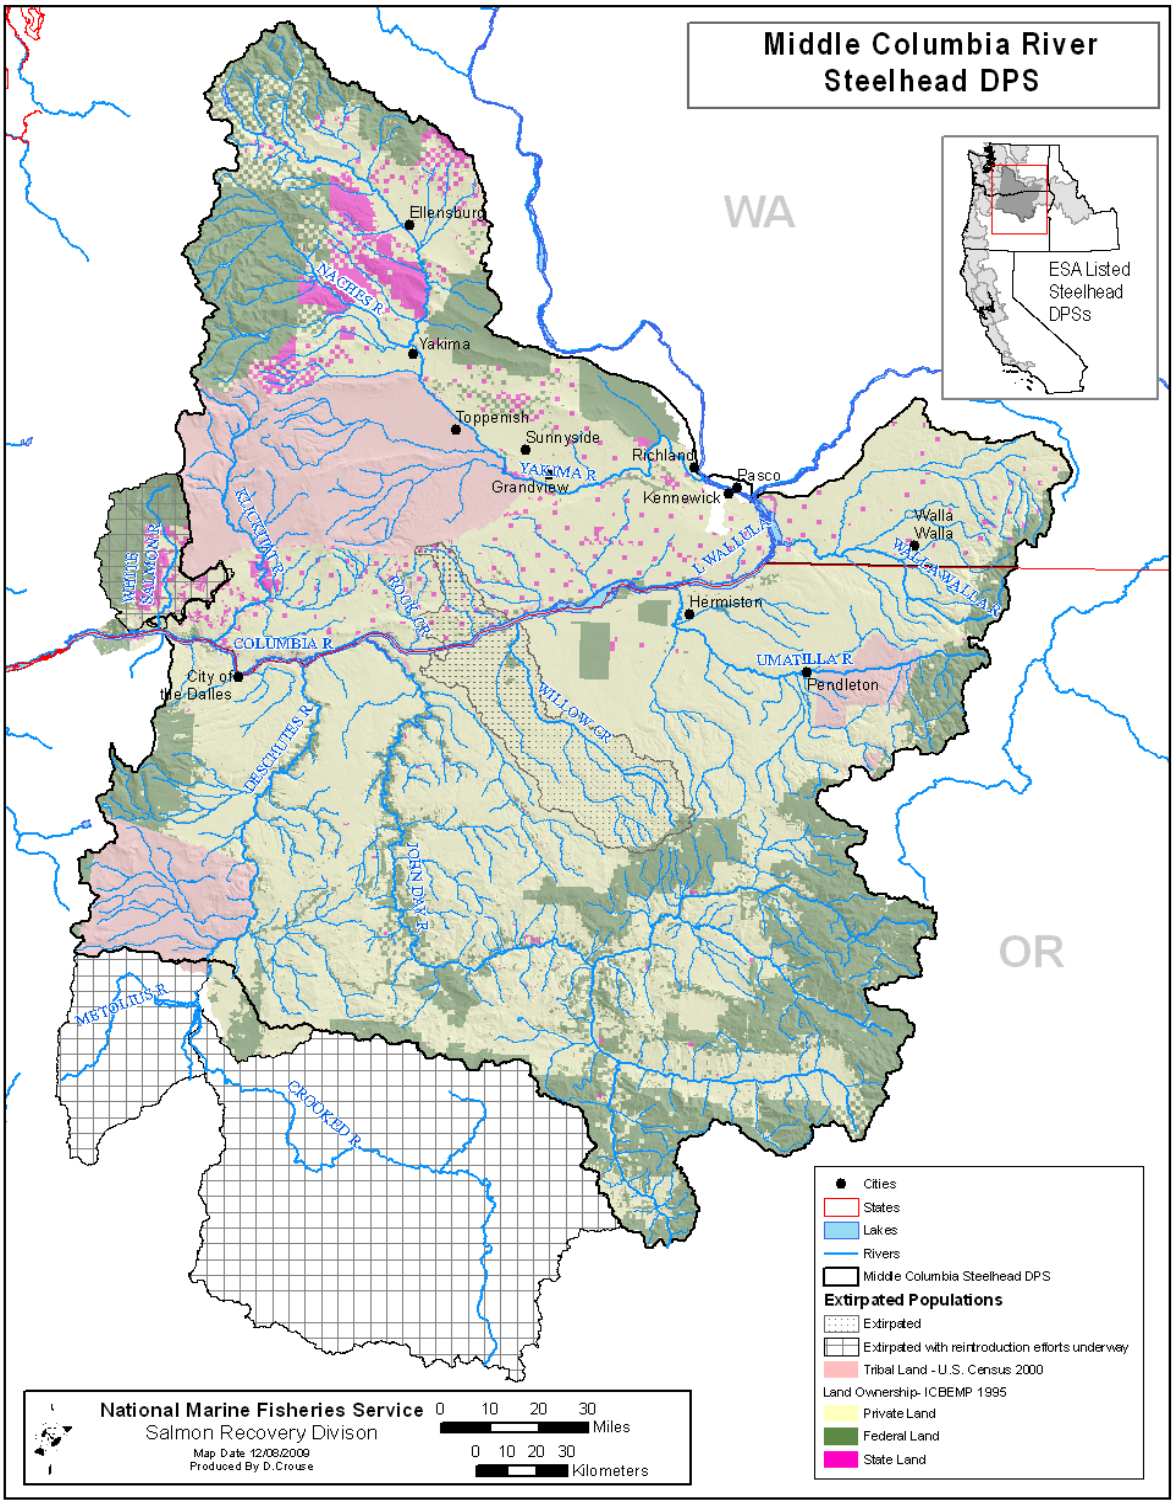

Figure ES-1. Geographic Boundaries of the Middle Columbia River Steelhead DPS, showing land ownership.

ESA section 4(f)(1)(B) directs that recovery plans, to the extent practicable, incorporate:

1. a description of such site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species;
2. objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this chapter, that the species be removed from the list, and;
3. estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal.

In addition, it is important for recovery plans to provide the public and decision makers with a clear understanding of the goals and strategies needed to recover a listed species and the science underlying these conclusions (NMFS 2006).

Once a species is deemed recovered and therefore removed from listed status, section 4(g) of the ESA requires the monitoring of the species for a period of not less than 5 years to ensure that it retains its recovered status.

Steelhead Distribution and Life History

The spawning range of the Middle Columbia River steelhead DPS extends over an area of approximately 35,000 square miles in the Columbia plateau of eastern Washington and eastern Oregon. The DPS includes all naturally spawned populations of steelhead in drainages upstream of the Wind River, Washington, and the Hood River, Oregon (exclusive), up to, and including, the Yakima River, Washington, excluding steelhead from the Snake River Basin (64 FR 14517; 71 FR 849). Major drainages in this DPS are the Deschutes, John Day, Umatilla, Walla Walla, Yakima, and Klickitat river systems. The Cascade Mountains form the western border of the plateau in both Oregon and Washington, while the Blue Mountains form the eastern edge. The southern border is marked by the divides that separate the upper Deschutes and John Day basins from the Oregon High Desert and drainages to the south. The Wenatchee Mountains and Palouse areas of eastern Washington border the Middle Columbia on the north.

Most of the region is privately owned (64 percent), with the remaining area under Federal (23 percent), tribal (10 percent) and state (3 percent) ownership (Figure ES-1). Most of the landscape consists of rangeland and timberland, with significant concentrations of dryland agriculture in parts of the range. Irrigated agriculture and urban development are generally concentrated in valley bottoms. Human populations in these regions are growing.

Steelhead produced in four artificial propagation programs are considered part of the DPS: the Touchet River Endemic Summer Steelhead Program, the Yakima River Kelt Reconditioning Program, and the Umatilla River and Deschutes River steelhead hatchery programs.

The species *Oncorhynchus mykiss* exhibits perhaps the most complex suite of life history traits of any species of Pacific salmonid. These fish can be anadromous (migratory) or freshwater residents (and under some circumstances, apparently yield offspring of the opposite form). Steelhead can spawn more than once (iteroparous), whereas all other *Oncorhynchus* except cutthroat trout (*O. clarki*) spawn once and then die (semelparous).

Within the range of West Coast steelhead, spawning migrations occur throughout the year, with seasonal peaks of activity. The "runs" are usually named for the season in which the peak occurs. Most steelhead can be categorized as one of two run types, based on their sexual maturity when they re-enter freshwater and how far they go to spawn. In the Pacific Northwest, summer steelhead enter freshwater between May and October and require several months to mature before spawning; winter steelhead enter freshwater between November and April with well-developed gonads and spawn shortly thereafter. Summer steelhead usually spawn farther upstream than winter steelhead (Withler 1966; Roelofs 1983; Behnke 1992).

The Middle Columbia River steelhead DPS includes populations of inland winter steelhead in the Klickitat River, White Salmon River, Fifteenmile Creek, and possibly Rock Creek.

Relationship of Steelhead DPS to Resident *O. mykiss*

"Steelhead" is the name commonly applied to the anadromous (migratory) form of the biological species *Oncorhynchus mykiss*. The common names of the non-anadromous, or resident, form are rainbow trout and redband trout. When NMFS originally listed the Middle Columbia River steelhead as threatened on March 25, 1999 (64 FR 14517), it was classified as an "evolutionarily significant unit" (ESU) of salmonids that included both the anadromous and resident forms. Recently, NMFS revised its species determinations for West Coast steelhead under the ESA, delineating anadromous, steelhead-only "distinct population segments" (DPS). NMFS listed the Middle Columbia River steelhead DPS as threatened on January 5, 2006 (71 FR 834). Rainbow trout and redband trout are under the jurisdiction of the states unless they are listed, when they come under the jurisdiction of the U.S. Fish and Wildlife Service (USFWS). This recovery plan addresses steelhead and not rainbow trout, as is consistent with the 2006 ESA listing decision.

Context of Plan Development

While NMFS is directly responsible for ESA recovery planning for salmon and steelhead, NMFS believes that ESA recovery plans for salmon and steelhead should be based on the many state, regional, tribal, local, and private conservation efforts already underway throughout the region. Local support of recovery plans by those whose activities directly affect the listed species, and whose actions will be most affected by recovery efforts, is essential. NMFS therefore supports and participates in locally led collaborative efforts to develop recovery plans that involve local communities, state, tribal, and Federal entities, and other stakeholders.

This Plan is the product of a collaborative process initiated by NMFS with assistance from the Middle Columbia Recovery Forum (Mid-C Forum), a group convened by NMFS to provide input on the development of the DPS recovery plan. NMFS developed this Plan by drawing upon the best available scientific information provided by the four regional recovery plans included as appendices to this Plan (i.e. the management unit plans, described below and in Section 1.6.), and by a regional team of scientists (the Interior Columbia Technical Recovery Team, described below). The Draft Plan went through repeated reviews and revisions in response to comments from both the scientific team and the Mid-C Forum. Participants in the Mid-C Forum include the Oregon Department of Fish and Wildlife (ODFW), Washington Department of Fish and Wildlife (WDFW), the Yakama Nation, Confederated Tribes of the Warm Springs Indian Reservation, Confederated Tribes of the Umatilla Indian Reservation, Washington Governor's Salmon Recovery Office, Oregon Governor's Natural Resources Office, Snake River Salmon Recovery

Board, Yakima Basin Fish and Wildlife Recovery Board, US Bureau of Reclamation (BOR), US Fish and Wildlife Service (USFWS), US Forest Service (USFS), US Army Corps of Engineers (COE), Klickitat County, and NMFS Northwest Region. The Draft Recovery Plan, including the four management unit plans and two scientific reports (McClure et al. 2003; ICTRT 2007a) that provide the scientific basis for the Plan, was made available for public review as a Proposed Recovery Plan. NMFS revised the Proposed Plan in response to public comments, including comments from the ICTRT as peer reviewers. The responses to public comments are available on the NMFS website, at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/Recovery-Domains/Interior-Columbia/Mid-Columbia/Mid-Col-Plan.cfm.

Tribal Trust and Treaty Responsibilities

Northwest Indian Tribes have legally enforceable rights reserving to them a share of the salmon harvest. A complex history of treaties, executive orders, legislation, and court decisions have culminated in the recognition of tribes as co-managers who share management responsibilities and rights for fisheries in the Columbia Basin.

Ensuring a sufficient abundance of salmon and steelhead to sustain harvest is an important element in fulfilling trust responsibilities and treaty rights as well as garnering public support for recovery plans. ESA and tribal trust responsibilities complement one another. Both depend on a steady upward trend toward ESA recovery and delisting in the near term, while making aquatic habitat, harvest, and land management improvements for the long term.

Recovery Domains and Technical Recovery Teams

Currently, there are 19 ESA-listed ESUs/DPSs of Pacific salmon and steelhead in the Pacific Northwest. For the purpose of recovery planning for these species, NMFS Northwest Region designated five geographically based "recovery domains" (Figure ES-2). The range of the Middle Columbia River steelhead DPS is located in the Middle Columbia sub-domain of the Interior Columbia domain.

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each Technical Recovery Team (TRT) was to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. The Interior Columbia TRT (ICTRT) includes biologists from NMFS, states, tribes, and academic institutions.

Viable Salmonid Populations

All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population viability criteria – criteria that may be used, along with criteria based on mitigation of the factors for decline, in determining whether a species has recovered sufficiently to be downlisted or delisted. These principles are described in a NMFS technical memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000).

Viable salmonid populations (VSP) are defined in terms of four parameters: abundance, productivity (growth rate), spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework, based on data availability, the unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective

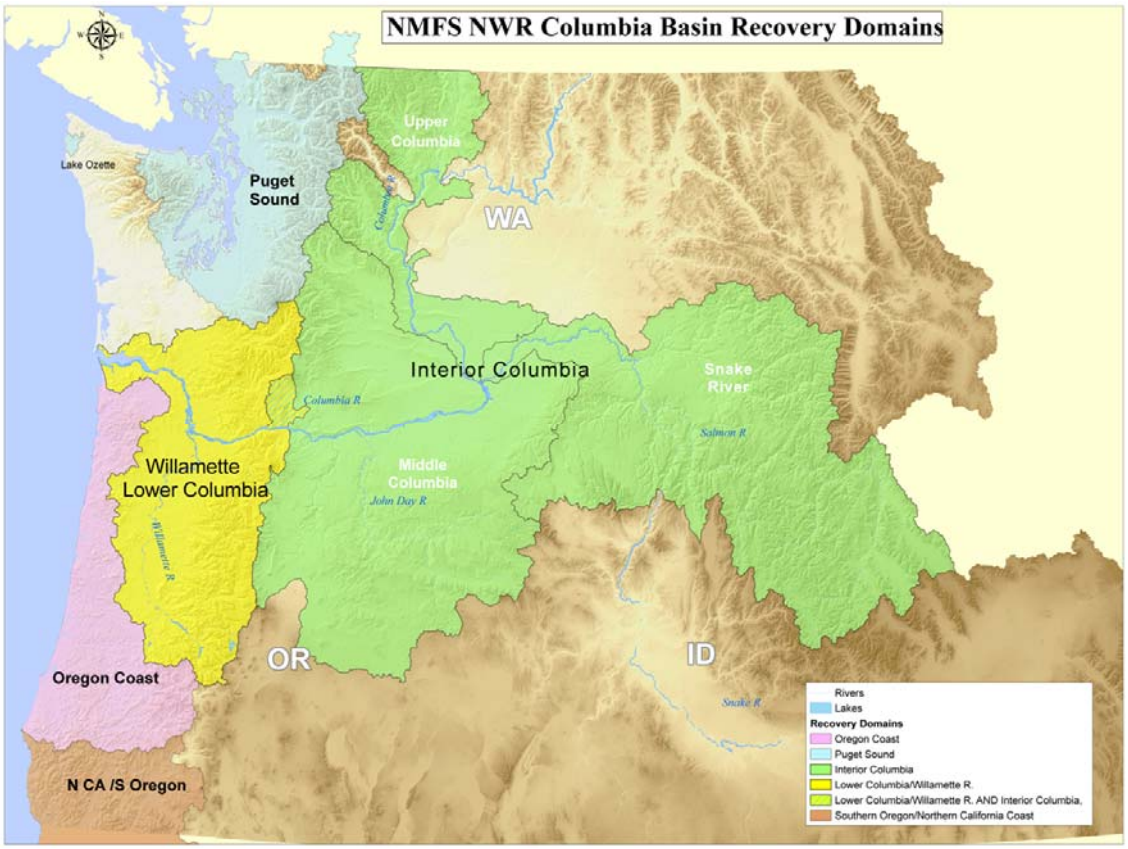

Figure ES-2. Columbia Basin Recovery Domains for NMFS Northwest Region.

experience and expertise. Although NMFS has encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs are working from a common scientific foundation. Viability criteria are an important part of recovery goals, as described later in this summary.

Management Units

In each domain, NMFS worked with state, tribal, local, and other Federal entities to develop planning forums that build to the extent possible on ongoing, locally led recovery efforts. NMFS defined "management units" based on jurisdictional boundaries as well as areas where local planning efforts were underway (Figure ES-3). It can be seen from the figure that the management units do not necessarily correspond to biological units, such as steelhead populations, but are defined for planning and administrative purposes. The Middle Columbia management units are (1) Oregon; (2) Washington Gorge, which, in turn, is subdivided into three planning areas, White Salmon, Klickitat, and Rock Creek; (3) Yakima subbasin; and (4) Southeast Washington.

Management Unit Recovery Plans and the Modules

Although NMFS has prepared this plan for the entire DPS, the management unit plans (Appendices A-E) are the work of local groups and county, state, Federal, and tribal entities within the Middle Columbia River region on both sides of the river. The management unit plans built on existing recovery plans, in particular, the Northwest Power and Conservation Council's subbasin plans, and targeted the specific ESA recovery needs of Middle Columbia steelhead. In addition, to deal with system effects that transcend the individual subbasins, domains, and management units, NMFS prepared two recovery planning modules: the Hydro Module (Appendix F), which summarizes the 2008 Federal Columbia River Power System Biological Opinion, and the Estuary Module (Appendix G), prepared by NMFS in collaboration with the Lower Columbia River Estuary Partnership.

- **Oregon Management Unit:** ***Conservation and Recovery Plan for Oregon Steelhead Populations in the Middle Columbia River Steelhead Distinct Population Segment (Oregon Steelhead Recovery Plan) (Appendix A)***

The Oregon Department of Fish and Wildlife (ODFW) is the lead for the Oregon Steelhead Recovery Plan. ODFW drew together three groups to help with the plan: the Middle Columbia Recovery Planning Team, made up of ODFW staff biologists and representatives from eight state natural resource agencies; a planning forum, the Middle Columbia Sounding Board, made up of representatives of local communities, agricultural water users, Federal and non-Federal land managers, governing bodies, tribes, and industry and environmental interests; and an Expert Panel of 12 biologists to examine limiting factors and threats for the 10 independent steelhead populations in Oregon.

- **Washington Gorge Management Unit:** ***Recovery Plans for the Klickitat River (Appendix B) and Rock Creek (Appendix C) subbasin populations of Middle Columbia River steelhead (the Klickitat Plan and the Rock Creek Plan)***

Since there is not presently a Washington State sponsored salmon recovery planning board for this area, NMFS staff drafted the Klickitat and Rock Creek plans in collaboration with the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal agencies, state agencies, local governments, and the public. The White Salmon River subbasin, which historically supported a population of Middle Columbia River steelhead, is also part of this management unit, but the recovery plan for that population will be finalized as part of the Lower Columbia ESA Recovery Plan. Single populations of three listed ESUs of salmon (Lower Columbia River Chinook, Lower Columbia River Coho, and Columbia River Chum) spawn in the White Salmon River subbasin in addition to steelhead. The need for an ecosystem approach warrants addressing in one single plan all the listed salmonids that spawn in the White Salmon subbasin. However, the delisting criteria, actions, and costs for the White Salmon steelhead are included in this DPS plan in order to have all the information on the Middle Columbia steelhead DPS in one place.

- **Southeast Washington Management Unit:** ***Snake River Salmon Recovery Plan for Southeast Washington (Southeast Washington Plan) (Appendix D)***

The Snake River Salmon Recovery Board developed the recovery plan for the Southeast Washington management unit, which is called the Southeast Washington Plan here in order to differentiate it from the forthcoming recovery plan for the five species of listed salmon and steelhead in the Snake River region (which includes parts of Washington, Oregon, and Idaho). The Snake River Salmon Recovery Board consists of representatives of the Confederated Tribes of the Umatilla Indian Reservation; a county commissioner and citizen representative from Asotin, Columbia, Garfield, Walla Walla and Whitman counties; a land owner representative from Asotin, Columbia and Garfield counties; and the Walla Walla county irrigation district. The Board appointed a Regional Technical Team for technical and scientific assistance.

- **Yakima Management Unit:** ***Yakima Steelhead Recovery Plan (Appendix D)***

The Yakima Basin Fish and Wildlife Recovery Board (YBFWRB), which includes representatives from the Yakama Nation, Benton, Kittitas, and Yakima counties, and 18 of the 24 municipalities in the Yakima Basin, developed the Yakima Steelhead Recovery Plan (available at www.ybfwrb.org).

- **Hydro Module (Appendix F)**

The Hydro Module summarizes the general effects of Columbia River mainstem hydropower projects on all 13 ESA-listed salmonids in the Columbia basin, including the limiting factors and threats and expected actions (including site-specific management actions), or strategy options, to address those threats. This module supports recovery plans for the Snake River, Upper Columbia, Middle Columbia, Lower Columbia, and Upper Willamette River species. It is a synthesis of information that has undergone public processes for review, including, but not limited to, the Federal Columbia River Power System (FCRPS) 2008 Biological Opinion, Federal Energy Regulatory Commission (FERC) licensing proceedings, and Habitat Conservation Plans (HCPs). This module may be updated as additional information becomes available.

- **Estuary Module (Appendix G)**

The Estuary Module focuses on habitat in the lower Columbia River below Bonneville Dam and how that habitat affects the survival of ESA-listed chum, steelhead, Chinook, and coho from throughout the Columbia River basin. It identifies and prioritizes limiting factors and threats in the estuary, then identifies 23 broad actions whose implementation would reduce the threats and thus increase survival of salmon and steelhead during their time in the estuary. The module also estimates the cost of implementing each action over a 25-year period. A description of monitoring, research, and evaluation needs that are appropriate to the management actions is included as an appendix to the module.

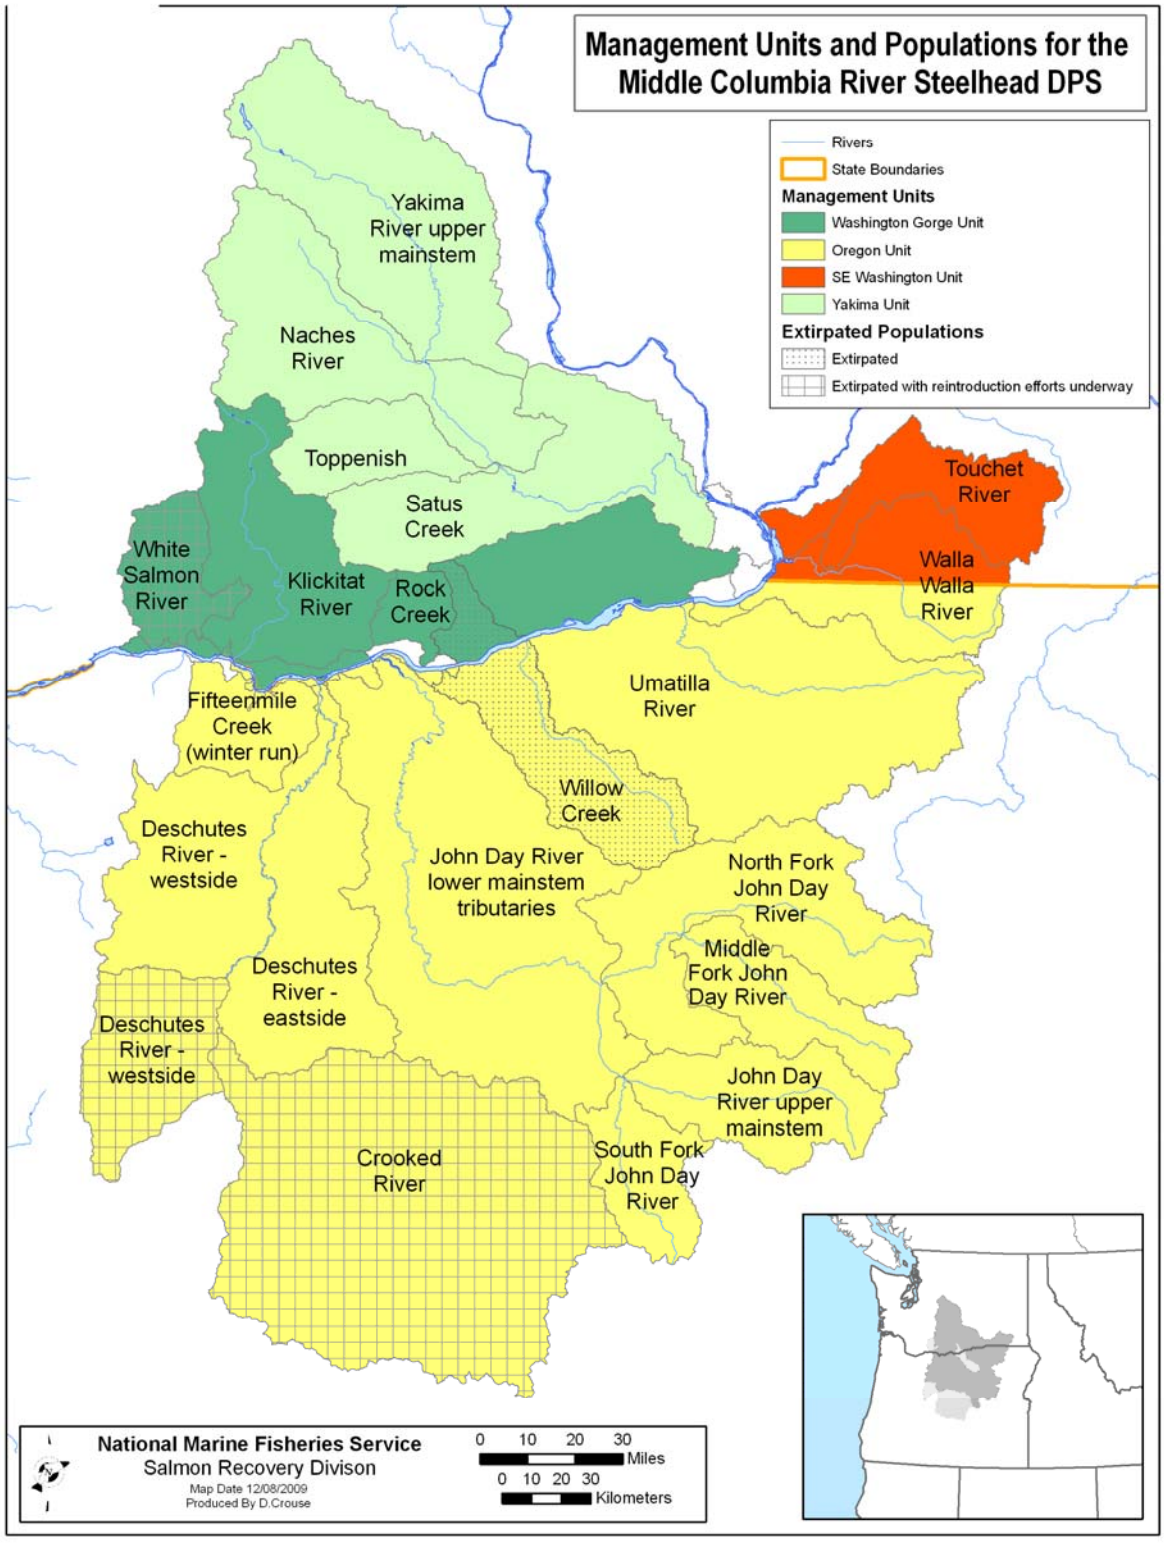

Figure ES-3. Management Units and Populations for the Middle Columbia River Steelhead DPS.

Important Concepts in Steelhead (and Salmon) Biology

Salmonid species' homing propensity (their tendency to return to the locations where they originated) creates unique patterns of genetic variation and connectivity that mirror the distribution of their spawning areas across the landscape. Diverse genetic, life history, and morphological characteristics have evolved over generations, creating runs highly adapted to diverse environments. It is this variation that gives the species as a whole the resilience to persist over time.

Historically, a salmon ESU or steelhead DPS typically contained multiple populations connected by some small degree of genetic exchange that resulted from some spawners "straying" into neighboring streams. Thus, the overall biological structure of the ESU/DPS is hierarchical; spawners in the same area of the same stream will share more characteristics than those in the next stream over. Fish whose natal streams are separated by hundreds of miles will have less genetic similarity.

Definition of Evolutionarily Significant Units/Distinct Population Segments

An ESU is defined as a group of Pacific salmon that is "substantially reproductively isolated from other conspecific units and represents an important component of the evolutionary legacy of the species" (Waples et al. 1991). A "population segment" is considered distinct (a DPS and hence a "species" for purposes of conservation under the ESA) if it is discrete from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics; or if it occupies an unusual or unique ecological setting; or if its loss would represent a significant gap in the species' range (71 FR 834).

ESUs/DPSs may contain multiple populations that are connected by some degree of genetic exchange through straying, and hence may have a broad geographic range across watersheds and river basins.

Major Population Groups

Within an ESU/DPS, independent populations can be grouped into larger populations that share similar genetic, geographic, and/or habitat characteristics (McClure et al. 2003). These "major groupings" of populations (MPGs) are isolated from one another over a longer time scale than that defining the individual populations, but retain some degree of connectivity greater than that between ESUs/DPSs.

Independent Populations

McElhany et al. (2000) defined an independent population as follows:

> *"…a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season."*

Abundance and Productivity

Abundance refers to naturally produced spawners (adults on the spawning ground), measured over a time series, i.e. some number of years. The ICTRT often uses a recent 10- or 12-year geometric mean of natural spawners as a measure of current abundance.

The productivity of a population (the average number of surviving offspring per parent) is a measure of the population's ability to sustain itself. Productivity can be measured as spawner:spawner ratios (returns per spawner or recruits per spawner) (or adult progeny to parent), annual population growth rate, or trends in abundance. Population-specific estimates of abundance and productivity are derived from time series of annual estimates, typically subject to a high degree of annual variability and sampling-induced uncertainties.

Abundance and productivity are linked, as populations with low productivity can still persist if they are sufficiently large, and small populations can persist if they are sufficiently productive. A viable population needs sufficient abundance to maintain genetic health and to respond to normal environmental variation, and sufficient productivity to enable the population to quickly rebound from periods of poor ocean conditions or freshwater perturbations.

Spatial Structure and Diversity

Spatial structure and diversity considerations are combined in the evaluation of a salmonid population's status because they often overlap. A population's spatial structure is made up of both the geographic distribution of individuals in the population and the processes that generate that distribution (McElhany et al. 2000, p. 18). Diversity refers to the distribution of traits within and among populations. Some traits are completely genetically based, while others, including nearly all morphological, behavioral, and life history traits, vary as a result of a combination of genetic and environmental factors (ibid. p. 19).

Populations with restricted distribution and few spawning areas are at a higher risk of extinction as a result of catastrophic environmental events, such as a landslide, than are populations with more widespread and complex spatial structures. Population-level diversity is similarly important for long-term persistence. Populations exhibiting greater diversity are generally more resilient to short-term and long-term environmental changes.

Middle Columbia Steelhead Populations and Major Population Groups

The ICTRT (McClure et al. 2003) identified 20 historical populations of Middle Columbia steelhead, shown in Figure ES-4. This identification was based on genetic information, geography, life history traits, morphological traits, and population dynamics. Seventeen of these populations are extant, and three extirpated (White Salmon River, Deschutes Crooked River above Pelton Dam, and Willow Creek).

The ICTRT stratified the Middle Columbia River steelhead populations into MPGs based on ecoregion characteristics, life history types, and other geographic and genetic considerations. It identified four MPGs: Cascades Eastern Slope Tributaries, Yakima Basin, John Day Basin, and Umatilla/Walla Walla. The John Day River MPG is wholly within Oregon and the Yakima Basin MPG is wholly within Washington. The other two include populations on both sides of the Oregon/Washington boundary.

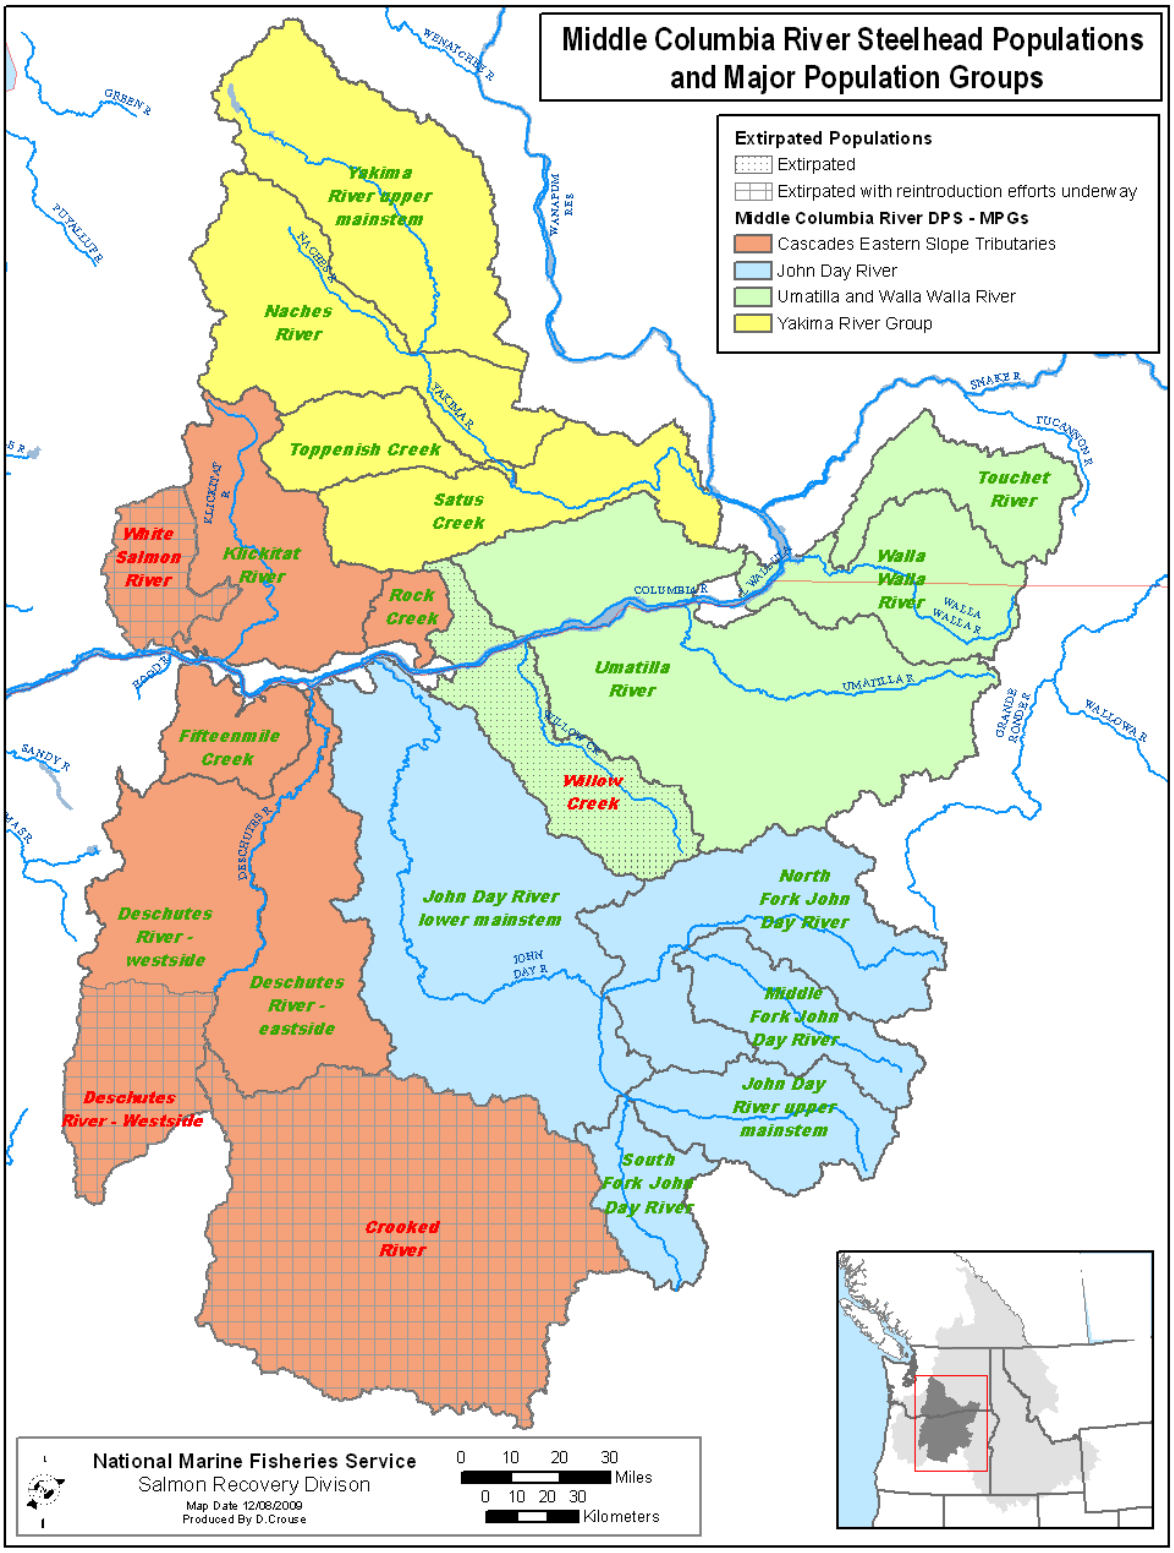

Figure ES-4. Middle Columbia River Steelhead Populations and Major Population Groups.

Recovery Goals and Delisting Criteria

The recovery goals that are incorporated into a locally developed recovery plan may include delisting and/or other "broad sense" goals that may go beyond the requirements for delisting to address, for example, other legislative mandates or social, economic, or ecological values. NMFS' delisting criteria may include both technical and policy considerations, and must meet the ESA requirements. A third term used in this recovery plan is recovery "scenarios" (Section 3.1.4). Recovery scenarios are combinations of viability status for individual populations within the DPS that will meet the ICTRT criteria for overall DPS viability.

Recovery criteria are of two kinds: the biological viability criteria, which deal with the VSP parameters at the population, MPG, and DPS levels, and the "threats" criteria, which relate to the five listing factors detailed in the ESA (see Sections 1.1 and 3.3 of this Plan). The threats criteria define the conditions under which the listing factors, or threats, can be considered to be addressed or mitigated. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B) for the delisting decision.

The delisting criteria are based on the best available scientific information and incorporate the most current understanding of the DPS and the threats it faces. As this recovery plan is implemented, additional information will become available that can increase certainty about whether the threats have been abated, whether improvements in population and DPS status have occurred, and whether linkages between threats and changes in salmon status are understood. These criteria will be assessed through an adaptive management program under development for the Plan, and NMFS may review the criteria if appropriate during its 5-year reviews of the DPS.

Biological Viability Criteria

In 2007, the ICTRT completed its Technical Review Draft of *Viability Criteria for Application to Interior Columbia Basin Salmonid ESUs* (ICTRT 2007a). Biological viability criteria describe DPS characteristics associated with a low risk of extinction for the foreseeable future. These criteria are expressed in terms of the VSP parameters of abundance, productivity, spatial structure, and diversity, according to guidelines developed by NOAA's Northwest Fisheries Science Center and published as a NOAA Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000; ICTRT 2007a). The ICTRT calculated varying levels of risk of extinction and related the risk levels to their criteria.

DPS Viability Criterion

Since MPGs are geographically and genetically cohesive groups of populations, they are critical components of ESU or DPS spatial structure and diversity. Having all MPGs within a DPS at low risk provides the greatest probability of persistence for the DPS.

DPS Viability Criterion (ICTRT 2007a)
All extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS[1] should be at low risk.

[1] The Middle Columbia steelhead DPS has four extant and no extirpated MPGs. The three extirpated populations are addressed as part of the MPG-level criteria.

MPG Viability Criteria

MPG viability depends on the number, spatial arrangement, and diversity associated with its component populations.

MPG-Level Viability Criteria (ICTRT 2007a)

The following five criteria should be met for an MPG to be regarded as at low risk (viable):

1. At least one-half of the populations historically within the MPG (with a minimum of two populations) should meet viability standards.
2. At least one population should be classified as "Highly Viable."
3. Viable populations within an MPG should include some populations classified (based on historical intrinsic potential) as "Very Large," "Large," or "Intermediate," generally reflecting the proportions historically present within the MPG. In particular, Very Large and Large populations should be at or above their composite historical fraction within each MPG.
4. All major life history strategies (e.g. spring and summer-run timing) that were present historically within the MPG should be represented in populations meeting viability requirements.
5. Remaining MPG populations should be maintained with sufficient abundance, productivity, spatial structure, and diversity to provide for ecological functions and to preserve options for ESU/DPS recovery.

The DPS criterion requiring viable populations in each of the extant MPGs would result in sustainable production across a substantial range of environmental conditions. The presence of viable populations across MPGs would preserve a high level of diversity within the DPS, thereby promoting long-term evolutionary potential for adaptation to changing conditions. The presence of multiple, relatively nearby, viable and maintained populations acts as protection against long-term impacts of localized catastrophic loss by serving as a source of re-colonization (ICTRT 2007a).

Population Viability Criteria

To be determined to be viable, populations should meet criteria for all four VSP parameters (abundance, productivity, spatial structure, and diversity). The abundance and productivity criteria are related to population size.

Population Size

The ICTRT developed criteria for characterizing the relative size and complexity of Interior Columbia Basin steelhead populations based on their analysis of the intrinsic or historical potential habitat available to the population (ICTRT 2005). Middle Columbia steelhead spawn in a wide range of tributary drainage areas, from small creeks, e.g. Fifteenmile Creek or Rock Creek, to very large rivers, such as the Lower John Day. The ICTRT categorized historical

population sizes as Basic, Intermediate, Large, and Very Large, and set minimum abundance thresholds for viable steelhead populations of each type. As explained in Section 2.4.1, abundance and productivity are linked, within limits; above a certain threshold, higher productivity can compensate for lower abundance and vice versa. Table ES-1 shows the minimum abundance and productivity thresholds for the Middle Columbia steelhead populations to have a 95 percent probability of persistence for the next 100 years.

Table ES-1. Middle Columbia Steelhead size categories (ICTRT 2007a).

Major Population Grouping	Population	Population Size	Abundance Threshold	Productivity Threshold
Cascades Eastern Slope Tributaries	White Salmon (functionally extirp.)	Basic	500	1.56
	Klickitat R.	Intermediate	1000	1.35
	Fifteenmile Cr.	Basic	500	1.56
	Deschutes R. East	Intermediate	1000	1.35
	Deschutes R. West	Large[2]	1500	1.26
	Rock Cr.	Basic	500	1.56
	Crooked River (Extirp.)	Very Large	2250	1.19
John Day River	Lower Mainstem JD	Very Large	2250	1.19
	North Fork John Day	Large	1500	1.26
	Middle Fork John Day	Intermediate	1000	1.35
	South Fork John Day	Basic	500	1.56
	Upper Mainstem JD	Intermediate	1000	1.35
Umatilla / Walla Walla Rivers	Umatilla R.	Large	1500	1.26
	Walla Walla R.	Intermediate	1000	1.35
	Touchet R.	Intermediate	1000	1.35
	Willow Crk. (Extirp.)	Intermediate	1000	1.35
Yakima River Group	Satus Cr.	Intermediate[3]	1000	1.35
	Toppenish Cr.	Basic	500	1.56
	Naches R.	Large	1500	1.26
	Upper Yakima	Large	1500	1.26

Abundance and productivity

The ICTRT defined abundance and productivity criteria for Middle Columbia steelhead populations (ICTRT 2005 and 2007a) based on analyses of the intrinsic potential of the historically available habitat, the locations and sizes of major and minor spawning areas, and, within these areas, the abundance and productivity relationships that would result in a probability of low risk of extinction within 100 years (see Table ES-1 above). The abundance "thresholds" shown in the table represent the number of spawners needed for a population of the given size category to achieve the 5 percent (low) risk level at a given productivity.

[2] This population is treated as Intermediate in size with respect to abundance and productivity criteria because of constraints on currently accessible habitat (i.e. Pelton Dam).

[3] For the historical population analysis, the ICTRT included the mainstem Yakima habitat below the confluence of Satus Creek in the Satus Creek population, making it Intermediate in size. However, if the mainstem component is lumped instead with mainstem Yakima River habitat upstream of Satus, the Satus Creek population would drop to Basic size. The Yakima Steelhead Recovery Plan discusses this question in more detail.

Spatial structure and diversity

The spatial structure and diversity criteria are specific to each population, and are based on historical spatial distribution and diversity, to the extent these can be known or inferred. The ICTRT cautions that there is a good deal of uncertainty in assessing the status of spatial structure and diversity in a population (ICTRT 2007a; McElhany et al. 2000).

Recovery Scenarios

The risk levels of the populations within the DPS collectively determine MPG viability and, in turn, the likely persistence of the DPS. The ICTRT recommended that all MPGs in a DPS should be viable; however, it may not be necessary for all of the populations to attain the lowest risk level. There may be more than one way for a DPS to meet the viability criteria.

The ICTRT, in a January 8, 2007 technical memorandum (ICTRT 2007a), offered a detailed discussion of possible recovery scenarios for each MPG. They cautioned against closing off the options for any population prematurely, however, because of the many uncertainties in predicting the biological response to recovery actions. The ICTRT concluded that "a low risk strategy will target more populations than the minimum for viability" (ICTRT 2007a).

The management unit plans include locally determined recovery goals as well as viability criteria for the individual steelhead populations and MPGs in each management unit. Most of the plans also provide targets or objectives to measure progress within specified time frames, e.g. 10 to 50 years.

Threats Criteria

At the time of a delisting decision for the Middle Columbia steelhead, NMFS will examine whether the section 4(a)(1) listing factors have been addressed. To assist in this examination, NMFS will use the listing factors (or threats) criteria described in Section 3.3 of this plan, in addition to evaluation of biological recovery criteria and other relevant data and policy considerations. It is possible that currently perceived threats will become insignificant in the future because of changes in the natural environment or changes in the way threats affect the entire life cycle of salmon. Consequently, NMFS expects that the relative priority of threats will change over time and that new threats may be identified. During the status reviews, NMFS will evaluate and review the listing factor criteria as they apply at that time. NMFS expects that if the proposed actions described in the Plan are implemented, they will make substantial progress toward meeting the listing factor (threats) criteria for the Middle Columbia steelhead.

Current Status Assessment

The status of a salmonid ESU or DPS is expressed in terms of likelihood of persistence over 100 years, or in terms of risk of extinction within 100 years. The ICTRT defines viability at two levels: less than 5 percent risk of extinction within 100 years (viable) and less than 1 percent risk of extinction within 100 years (highly viable). A third category, "maintained," represents a less than 25 percent risk. The risk level of the DPS is built up from the aggregate risk levels of the populations and MPGs. All four VSP parameters must be taken into account to determine the risk level.

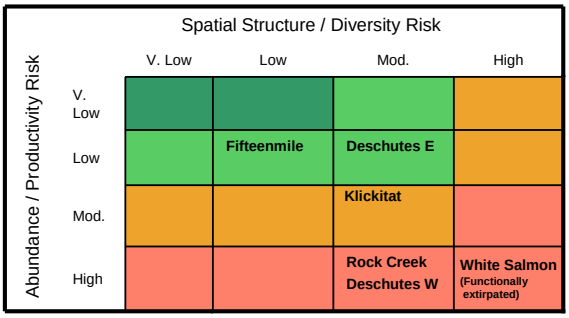
Table ES-2 summarizes current status of the Middle Columbia steelhead populations, showing 10-year geometric mean abundance by population, estimated productivity, and the minimum abundance threshold needed for long-term viability. The table also includes the 10-year geometric mean proportion of hatchery spawners for the populations where data are available, and the risk ratings of high, moderate, low, and very low, for abundance and productivity combined, and spatial structure and diversity combined. Figure ES-5 is a matrix combining all four parameters to illustrate the overall current risk rating of each population.

Current Population Status

According to the ICTRT viability criteria, the majority of naturally spawning Middle Columbia steelhead populations are rated at moderate risk for all four VSP parameters – abundance, productivity, spatial structure, and diversity (Table ES-2 and Figure ES-5). This DPS includes one highly viable population (North Fork John Day), two viable (Fifteenmile Creek and Deschutes River Eastside), and three at high risk of extinction within 100 years (Deschutes Westside, Upper Yakima Mainstem, and Naches River).

MPG Status

The viability ratings of the component populations of each Middle Columbia steelhead MPG are shown in Figure ES-5. None of the MPGs as a whole reaches low risk status according to the ICTRT's MPG-level criteria.



DPS Status

The ICTRT's DPS-level viability criterion is that all extant MPGs and any extirpated MPGs critical for proper functioning of the DPS should be at low risk (ICTRT 2007a). Thus, the Middle Columbia steelhead DPS does not currently meet viability criteria based on the determination that the four component MPGs are not at low risk.

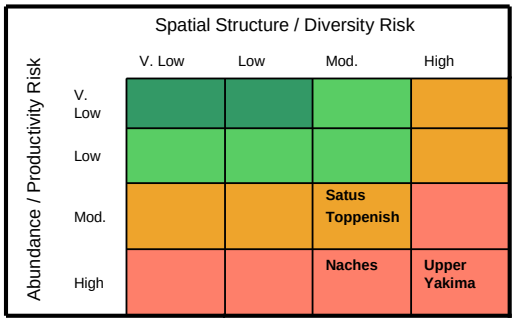


Table ES-2. Middle Columbia River steelhead DPS populations: summary of abundance, productivity, risk ratings, and minimum abundance thresholds (Source: ICTRT 2007a and 2008). (Numbers subject to periodic updates as additional information becomes available.)

Gap Analysis

The ICTRT assessed the difference between a listed species' or population's current status for abundance and productivity and the viability criteria. This difference is called the "gap." The gap, as used in this plan, is a measure, although it is inevitably imprecise, of the improvement in survival needed to meet viability criteria. As such, it is also an indicator of the level of effort needed to achieve recovery.

The ICTRT calculated the gap for each extant Middle Columbia steelhead population based on current abundance and productivity for the listed salmon and steelhead in the Interior Columbia Basin (ICTRT 2007b). They estimated the minimal survival rate changes needed for Middle Columbia steelhead populations to meet the abundance and productivity viability criteria for a 5 percent risk of extinction in a 100-year time frame.

In addition, the ICTRT (2007b) estimated gaps under three different early-ocean survival scenarios; historical ocean conditions (ocean conditions that fish experienced over the past 60 years), pessimistic ocean conditions (ocean conditions experienced by the 1975-1997 brood years), and recent ocean conditions (ocean conditions experienced by fish during the 20-year assessment period). The ICTRT also estimated gaps assuming three different hydropower scenarios. However, only the base hydro condition, which assumed that survival rates from the most recent 20 years would continue into the future, is reported here. (See NMFS 2008a for details on survival through the FCRPS under proposed improvements.)

A positive number, e.g. 21 percent gap for Cascades Eastern Slope MPG, means the population's overall survival needs to increase 21 percent over current conditions to achieve viability criteria. A zero or negative number would mean there is no gap – the population currently meets viability criteria.

The analysis showed that none of the MPGs would be able to achieve a 5 percent or less risk of extinction over 100 years without recovery actions (Table ES-3). The Yakima Basin MPG shows the largest gap (77 percent) and also contains two historically large populations now at high risk of extinction, the Upper Yakima River and Naches River populations.

Table ES-3. Median survival gap for the major population groups of the Middle Columbia Steelhead DPS (assuming recent ocean and base hydrosystem conditions and 5 percent risk).

Cascades Eastern Slope MPG	21 percent
John Day MPG	9 percent
Umatilla/Walla Walla MPG Sufficient data for only two of the three populations: Umatilla Walla Walla	 9 percent 34 percent
Yakima MPG	77 percent

It is important to include measures to address spatial structure and diversity (SS/D) risks in recovery planning. As described in Section 4.3 of this Plan, the ICTRT analyzed a population's spatial structure and diversity in terms of two goals: maintaining natural rates and levels of spatially mediated processes, and maintaining natural patterns of variation. The team developed a scoring system to derive a composite spatial structure and diversity rating for each population (ICTRT 2008). Using this method, the ICTRT rated only the Fifteenmile Creek and North Fork John Day populations at low risk of extinction with regard to spatial structure and diversity. The Upper Yakima River is at high SS/D risk, and the 15 other populations are rated at moderate risk. The Middle Columbia River steelhead DPS cannot reach viable status without closing these gaps as well as those identified in terms of abundance and productivity.

Limiting Factors and Threats

The reasons for a species' decline are generally described in terms of limiting factors and threats. NMFS defines limiting factors as the biological and physical conditions that limit a species' viability – e.g., high water temperature – and defines threats as those human activities or natural processes that cause the limiting factors. For example, removing the vegetation along the banks of a stream can cause higher water temperatures, because the stream is no longer shaded. The threats contributing to the limiting factors and causes for a species' decline are often described in terms of the "four Hs" – habitat (usually relating to the effects of land use and tributary water use), hydropower, harvest, and hatcheries. While the term "threats" carries a negative connotation, it does not mean that activities identified as threats are inherently undesirable. They are typically legitimate and necessary human activities that may at times have unintended negative consequences on

fish populations—and that can also be managed in a manner that minimizes or eliminates the negative impacts.

Designing effective recovery strategies and actions requires understanding limiting factors and threats across the species' entire life cycle and across the four Hs. This plan describes limiting factors and threats for the Middle Columbia steelhead DPS as a whole at a general level, and notes the most salient specific conditions that affect individual populations and limit the viability of specific MPGs. More detail is available in the individual management unit plans (Appendices A through E).

Limiting Factors and Threats for the DPS

At a general level, based on information from the ICTRT and the four management unit plans, the major factors limiting the viability of Middle Columbia steelhead populations are *degraded tributary habitat*, *impaired fish passage in the mainstem Columbia River and tributaries, hatchery-related effects, and predation/competition/disease.* Two other factors, degradation of estuarine and nearshore marine habitat and harvest-related effects, pose some risk to steelhead viability for the entire DPS, but less than the other factors. Climate change represents a potentially significant threat to recovery of Middle Columbia steelhead populations (see ISAB 2007). In Section 6.3 of this Plan, the limiting factors and threats are described in more detail, addressing all the Hs and all life stages. Sources for this information include the management unit plans (Appendices A through E); the Biological Opinion for the Federal Columbia River Power System (FCRPS BiOp) (NMFS 2008a), particularly the BiOp's Supplemental Comprehensive Analysis and its appendices; the Hydro Module (NMFS 2008c) (Appendix F of this Plan), and the Estuary Module (NMFS 2007) (Appendix G of this Plan).

Degraded tributary habitat. Tributary habitat degradation from past and/or present land use remains a key concern for all of the populations. Today, nearly all historical habitat lies in areas modified by human settlement and activities. In many areas, the contemporary watershed conditions created by past and current land use practices are so different from those under which native fish species evolved that they now pose a significant impediment to achieving recovery. The management unit plans contain detailed descriptions of tributary habitat threats and limiting factors.

Impaired fish passage. Impaired fish passage is identified as a key or secondary limiting factor for all populations of Middle Columbia steelhead. Dams, culverts, seasonal pushup dams, and unscreened diversions can directly prevent migration; seasonal areas of high water temperature, low flow, or dewatering can also function as barriers. There are various kinds of dams and other barriers in tributaries throughout the basin, and all populations of Middle Columbia steelhead use the mainstem Columbia River to migrate to and from the ocean. All are affected by the mainstem Federal dams. Development and operation of the mainstem Columbia River hydropower system significantly alters travel conditions in the mainstem Columbia River, resulting in direct mortality of both upstream migrating adults and downstream migrating steelhead kelts, and direct and indirect mortality for downstream migrants (juveniles). The hydro system also changes the hydrograph, depleting historically available nutrients, changing water temperatures, and degrading rearing and food resources for both presmolts and smolts in the Columbia.

Changes in the hydrograph leave steelhead more vulnerable to bird and fish predation in the Columbia River estuary and mainstem. In addition, broad deltas have been created at the mouths of tributaries where fine sediment has been deposited. These conditions have resulted in increased non-native piscivorous and avian predation on juveniles. All these impacts increase somewhat for each population in direct relation to the number of dams that fish must pass during their migration to and from the Pacific Ocean. Middle Columbia River steelhead populations pass from one to four Federal dams. Survival is estimated at 90, 73, 54, and 48 percent, respectively, for juvenile steelhead passage through one to four dams (see Table 6-2). Adult steelhead survival is relatively high through the lower Columbia River dams and reservoirs – estimated at 98.5 to 95 percent for one to four dams (Table 6-3) – as a result of dam operations and effective fish ladders.

Hatchery effects. Hatchery fish that stray into Middle Columbia tributaries and spawn naturally may represent a serious threat to steelhead recovery. More than 100 hatchery programs operate in the Columbia Basin above Bonneville Dam, mostly for the purpose of providing fish for harvest to mitigate losses caused by the FCRPS. Some hatchery programs may provide conservation benefits; however, hatchery programs also pose threats to natural-origin steelhead in some Middle Columbia watersheds. Hatchery-induced genetic change can reduce the fitness of both hatchery and natural-origin fish in the wild, and hatchery-induced ecological effects (competition for food and space) can reduce population productivity and abundance. In particular, hatchery programs designed to return summer steelhead to upstream Columbia River tributaries result in substantial numbers of stray hatchery steelhead spawning naturally among several Middle Columbia populations. Concern exists regarding the continuing detrimental impact of these stray out-of-DPS hatchery fish in natural spawning areas on the genetic diversity and productivity of naturally produced Middle Columbia River steelhead populations.

Predation, competition, disease. Anthropogenic changes in the Columbia River have altered the relationships between salmonids and other fish, bird, and pinniped species, resulting in changed opportunities for predation by non-native piscivorous fish, avian species such as terns and cormorants, and California sea lions below Bonneville Dam. Hatchery releases of juvenile steelhead may result in competition with natural-origin steelhead for food and other resources. Steelhead can be infected by a variety of bacterial, viral, fungal, and microparasitic pathogens. Numerous diseases may result from pathogens that occur naturally in the wild or that may be transmitted to wild fish via infected hatchery fish. However, studies have shown that naturally spawned fish tend to be less susceptible to pathogens than hatchery-reared fish (Buchanon et al. 1983; Sanders et al. 1992). Habitat conditions such as low water flows and high temperatures can exacerbate susceptibility to infectious diseases. Fish weakened by disease are more sensitive to other environmental stresses, and may become more vulnerable to predation or less able to compete with other species.

Climate change. Climate change may adversely affect steelhead in freshwater habitats across the DPS by exacerbating existing problems with water quantity (lower summer stream flows) and water quality (higher summer water temperatures). These changes may affect steelhead more than other salmonids because of their long rearing period in

freshwater. More detailed information on specific effects that climate change may have on Mid-Columbia steelhead at all their life stages is available in Section 8.8 of the Oregon Steelhead Recovery Plan (ODFW 2009).

Limiting Factors and Threats for the MPGs

The MPG-level summaries of limiting factors are based on population-level summaries compiled from the relevant management unit plans.

Cascades Eastern Slope Tributaries MPG

The following are major limiting factors for the Cascades Eastern Slope Tributaries MPG (see also the Oregon Steelhead Recovery Plan [Appendix A] and the Klickitat Recovery Plan [Appendix B]):

Tributary habitat. Degraded tributary habitat is a limiting factor to a greater or lesser degree throughout the area, including degraded riparian areas, reduced recruitment of large woody debris (LWD), altered sediment routing, low or altered stream flows, degraded water quality (especially high water temperatures), impaired floodplain connectivity/function, altered channel structure/complexity, and impaired fish passage.

Mainstem passage. Mainstem Columbia River hydro system effects are least for the Fifteenmile Creek and Klickitat River populations, which pass only one mainstem dam. The Deschutes River populations pass two mainstem dams, and the Rock Creek population passes three. Effects, to varying degrees, include direct mortality of pre-smolts and smolts at the dams; delayed upstream migration of returning adults; and cumulative impact of hydropower system on mainstem and estuary habitat.

Hatchery related effects. Influence from hatchery fish could be a significant factor for this MPG because of out-of-subbasin hatchery fish straying onto natural spawning grounds in the Deschutes River and also because of potential effects of hatchery releases on naturally produced steelhead in the Klickitat River. The Oregon Mid-C Expert Panel considered out-of-subbasin (and out-of-DPS) hatchery strays a primary threat to genetic traits and productivity of naturally produced Deschutes river steelhead populations. Out-of-DPS hatchery strays comprised an estimated average of 29 percent of the Eastside population and 15.2 percent of the Westside population since 1990 (ICTRT 2008). This high fraction resulted in moderate risk ratings for spawner composition for both populations.

Blocked migration to historically accessible habitat. Historically, summer steelhead had free access to most of the Deschutes watershed. Currently the Pelton-Round Butte Hydroelectric Project (Project), constructed at river mile (RM) 100 on the mainstem Deschutes River, creates the primary barrier to anadromous fish attempting to reach spawning and rearing areas in the upper basin. Plans are underway to reinitiate fish passage facilities at the Pelton-Round Butte complex (details in Section 9.4.2 of the Oregon Steelhead Recovery Plan) and reintroduce steelhead to the upper basin, including the Crooked River.

Predation/competition/disease. Anthropogenic changes in the Columbia River have altered the relationships between salmonids and other fish, bird, and pinniped species. Predation, competition, and disease issues in mainstem and estuary affect all of the Middle Columbia steelhead populations (see Section 6.3.5 of this plan). In addition, the Oregon Steelhead Recovery Plan hypothesizes that the abundance of the Deschutes River Westside population may be limited by competition with a large resident population of rainbow trout.

John Day River MPG

The following are major limiting factors for the John Day River MPG (see also the Oregon Steelhead Recovery Plan [Appendix A]):

Mainstem passage. These populations must pass three dams; thus, limiting factors include direct mortality of pre-smolts and smolts at John Day, The Dalles, and Bonneville dams; delayed upstream migration of returning adults; false attraction of returning adults over McNary Dam; and cumulative impact of hydropower system on mainstem and estuary habitat.

Hatchery related effects. Hatchery fish straying into natural spawning areas pose risks to genetic traits and productivity of naturally produced steelhead. Concern over competition for resources with wild fish and potential hybridization with natural-origin fish resulted in termination of all hatchery stocking of *O. mykiss* in the John Day River basin in 1997. Most hatchery stray recoveries occur in the lower mainstem John Day River below the North Fork; however, strays have been observed in all populations.

Tributary habitat. For all five John Day populations, degraded floodplain and degraded channel structure, altered sediment routing, degraded water quality (temperature), and altered hydrology are limiting factors. For the Lower and Upper Mainstem and South Fork populations, passage obstructions in some of the smaller tributaries are also significant.

Predation/competition/disease. Predation, competition, and disease issues in mainstem and estuary affect all of the Middle Columbia steelhead populations.

Umatilla/Walla Walla MPG

The following are the major limiting factors for the Umatilla/Walla Walla MPG (see also the Oregon Steelhead Recovery Plan [Appendix A] and the Southeast Washington Plan [Appendix D]):

Mainstem passage. The Walla Walla and Touchet populations must pass four major dams; the Umatilla population must pass three. Thus, limiting factors include direct mortality of pre-smolts and smolts at John Day, The Dalles, and Bonneville dams; delayed upstream migration of returning adults; false attraction of returning adults over McNary Dam; and cumulative impact of hydropower system on mainstem and estuary habitat.

Tributary habitat. For all three populations, degraded water quality (temperature), altered sediment routing, blocked and impaired fish passage, degraded floodplain and channel structure and hydrologic alterations are limiting factors.

Hatchery related effects. The hatchery program on the Umatilla River uses endemic (native) stock and is not currently considered a threat to wild steelhead; however, out-of-DPS strays pose a risk to spawner composition. Non-endemic hatchery fish are considered a potential threat to the Walla Walla wild steelhead population. Currently, data are insufficient to determine whether hatchery effects are a problem for the Touchet River population. An endemic stock program is under development for the Walla Walla and Touchet.

Predation/competition/disease. Predation, competition, and disease issues in mainstem and estuary affect all of the Middle Columbia steelhead populations.

Yakima Basin MPG

The following are primary limiting factors for the Yakima MPG (see also the Yakima Steelhead Recovery Plan [Appendix E]):

Mainstem passage. As the farthest upstream populations in the DPS, the Yakima populations must pass four dams and undergo higher exposure to altered habitat and avian and piscine predators in the mainstem Columbia. Limiting factors include direct mortality of pre-smolts and smolts at John Day, The Dalles, and Bonneville dams; delayed upstream migration of returning adults; false attraction of returning adults over McNary Dam; and cumulative impact of hydropower system on mainstem and estuary habitat.

Tributary habitat. Fish habitat in the Yakima subbasin is substantially influenced by the development of irrigation systems. Limiting factors include altered hydrology (low summer flow because of withdrawals in tributaries and the lower Yakima, scouring peak flows because of degraded watershed conditions, high summer delivery flows in mainstem Yakima and Naches rivers, reduced winter and spring flows due to irrigation storage, delivery, and withdrawals); degraded riparian area and LWD recruitment; blocked and impaired fish passage (primarily due to storage and diversion dams, as well as entrainment in unscreened diversions); altered sediment routing; degraded water quality; loss of historical habitat because of blocked or impaired fish passage; degraded floodplain connectivity and function (loss of off-channel habitat, side channels and connected hyporheic zone); degraded channel structure and complexity; reduced outmigrant survival in the mainstem Yakima.

Hatchery related effects. The Yakima populations have the lowest rates of hatchery strays in the DPS, and hatchery effects are not considered a significant limiting factor.

Predation/competition/disease. Of the Middle Columbia steelhead populations, the Yakima basin populations have the longest migration through the mainstem Columbia

River. They may therefore be more vulnerable to some factors such as avian and piscivorous fish predation. For example, Yakima steelhead, but not the others, are consumed by Caspian tern and double-crested cormorants nesting on islands at the mouth of the Snake River.

DPS Recovery Strategy

NMFS' overall goal for DPS viability, as formulated by the ICTRT and described in Chapter 3 of this plan, is to have all four extant MPGs at viable (low risk) status, with representation of all the major life history strategies present historically, and with the abundance, productivity, spatial structure and diversity attributes required for long-term persistence.

The ICTRT's current status assessment for the Middle Columbia steelhead DPS and the gaps analysis show that for this DPS, the outlook is optimistic. One population, North Fork John Day, is currently at very low risk or "highly viable." Two populations are currently viable (Deschutes Eastside, Fifteenmile); eleven are at moderate risk, with good prospects for improving. However, the three large populations at high risk (Deschutes Westside, Naches, and Upper Yakima), are important to DPS viability; as a minimum, Deschutes Westside and one of the two large Yakima populations should also reach viable status, with the other large Yakima population at least reaching "maintained" status. These present significant, though not insuperable, challenges.

If, as we believe, the decline of the Middle Columbia River steelhead DPS is caused by widespread habitat degradation, impaired mainstem and tributary passage, hatchery effects, and predation/ competition/ disease, then actions taken to improve, change, mitigate, reduce those factors will result in reduced risks and increased survival. Because of the steelhead's complex life cycle and the many changes that have taken place in its environment, the factors limiting its survival must be addressed in concert, and in an integrated way. The work needs to occur at a regional level, in terms of commitment to actions and funding, and at the local level, population by population and site by site. Significant investments of research, planning, regional coordination, actions, and political will are already underway. The intent for the DPS plan is to build upon, help to coordinate, and add to the ongoing efforts.

NMFS' 2006 listing decision called upon Federal, state, and tribal entities to do their best to manage land, hydropower, hatchery, and harvest activities in a manner that would support steelhead recovery. This plan reaffirms those recommendations and adds to them the contributions of updated science, basinwide programs, and consensus building among stakeholders.

The recovery strategy for the Middle Columbia steelhead DPS addresses both the basin-wide issues that affect all populations, such as conditions in the migratory corridor, and the subbasin and site-specific issues that are the focus of the management unit plans. The DPS Plan describes the overall strategy, summarizes the MPG-level strategies, and refers to Appendices A-G for more site-specific, population level actions.

The DPS-level recovery strategy for the Middle Columbia steelhead is made up of the following elements:

- Affirm and address the 2006 listing decision recommendations to address the limiting factors for the DPS and populations.
- Protect and restore tributary habitat and Columbia River mainstem habitat, through strategies and actions at both the Basin/programmatic level and at the local level as detailed in the management unit plans.
- Address impaired fish passage through strategies and actions in the mainstem Columbia River, as detailed in the 2008 FCRPS Biological Opinion (as summarized in the Hydro Module) and in the tributaries as detailed in the management unit plans
- Implement hatchery reforms at the population and site specific level through Hatchery and Genetic Management Plans (HGMPs) as required by the 2008 FCRPS Biological Opinion and as described in Appendix C of the Supplemental Comprehensive Analysis, (NMFS 2008a).
- Address ecosystem imbalances in predation, competition, and disease through the strategies and actions in the management unit plans, estuary module and FCRPS Biop.
- Maintain current low harvest levels, through fishery management planning for mainstem fisheries through the *U.S. v. Ore*gon 10-year agreement, updated Fisheries Management Evaluation Plans and Tribal Resource Management Plans for tributary fisheries, and Pacific Salmon Treaty and Pacific Fishery Management Council processes.
- Protect and restore the estuary and Columbia River plume as detailed in the Columbia River Estuary module.
- Respond to climate change threats with a strategy based on the principle of preserving biodiversity.
- Implement the Plan through effective coordination and governance.
- Research critical uncertainties, monitor and evaluate implementation and effectiveness and adjust course, as appropriate through adaptive management.

NMFS believes that if this strategy is implemented and the biological response is as expected, the Middle Columbia steelhead DPS is likely to achieve viable status within 25 to 50 years.

Degraded tributary and mainstem Columbia River habitat
Measures to improve tributary habitat are contained in the management unit plans and are summarized above by MPG. Relatively little information is available concerning Middle Columbia River steelhead use of mainstem Columbia River habitat above Bonneville, aside from passage through the dams. NMFS believes it is important to assess nearshore habitat and cold water refugia in the mainstem and to explore opportunities for, and potential benefits from, restoration and protection of these areas.

Impaired fish passage in the mainstem Columbia River

Passage for juvenile steelhead migrating to the ocean and adult steelhead returning to their natal streams is limited primarily by the four Federal dams on the Lower Columbia River mainstem – Bonneville, John Day, The Dalles, and McNary dams – which are part of the Federal Columbia River Power System (FCRPS). NMFS recently issued a new biological opinion on the effects of FCRPS operations on salmonids, including Middle Columbia River steelhead, and on the predicted results of current and planned improvements to the system that are intended to improve fish survival (NMFS 2008a). These improvements are expected to increase the in-river survival of Middle Columbia River juvenile steelhead by 0.3 percent, 5.1 percent, 8.2 percent, and 10.2 percent, depending on the number of dams they must pass. The survival of steelhead adults through the four dams is thought to be relatively high at the present time (about 98.5 percent per project from Bonneville to McNary), and is expected to be maintained or improved.

The plan for current mainstem hydro operations, as summarized in the Hydro Module (NMFS 2008c), and any further improvements for fish survival that may result from the ongoing FCRPS collaborative process, represent the hydropower recovery strategy for all listed salmonids that migrate through the mainstem Columbia River, including the Middle Columbia steelhead populations.

The Reasonable and Prudent Alternative (RPA) for the FCRPS takes a comprehensive approach to ESA protection that includes hydro, habitat, hatchery, harvest and predation measures to address the biological needs of salmon and steelhead in every life stage. The RPA is the product of the collaboration between NMFS and the action agencies ordered by the court. It is based on a comprehensive analysis of the salmon life cycle conducted down to the level of the populations that make up the listed species. Section 8.8 and the "Reasonable and Prudent Alternative Table" in the 2008 FCRPS Biological Opinion describe actions that should positively affect Middle Columbia River steelhead.

The current plan for operation of the FCRPS through 2018 (NMFS 2008a) contains the following actions intended to address the needs for survival and recovery of ESA-listed salmon and steelhead:

- Continue adult fish passage operations that have resulted in improved survival.
- Improve juvenile fish passage: install removable spillway weirs or similar surface bypass devices at John Day and McNary dams, an extended tailrace spill wall at The Dalles Dam, and various modifications at Bonneville Dam. Passage for steelhead smolts at each of the four Lower Columbia River mainstem projects must reach 96 percent survival.
- Continue and enhance spill for juvenile fish passage.
- Continue reservoir operations and river flows to benefit spring migrating juveniles.
- Develop dry water year operations to better protect migrating juveniles.
- Develop and implement a kelt management plan.

Dissenting View of State of Oregon Regarding Mainstem Operations

At the time the proposed recovery plan was finalized, August 2008, it was the position of the State of Oregon that additional or alternative actions should be taken in mainstem operations of the FCRPS for ESA-listed salmon and steelhead. Some additional or alternative actions recommended by Oregon, while considered, were not included in NOAA's FCRPS Biological Opinion. At this time, Oregon is a plaintiff in litigation against various federal agencies, including NOAA, challenging the adequacy of the measures contained in the current FCRPS Biological Opinion. NOAA is not in agreement with Oregon regarding the need for or efficacy of Oregon's additional or alternative actions. The actions sought by Oregon include:

- Draft storage reservoirs to help meet weekly and seasonal flow and velocity equivalent objectives for the lower Columbia and Snake rivers.
- Operate reservoirs at rule curves and seek additional flow augmentation volumes from Snake River and Canadian reservoirs for spring and summer flow and velocity objectives.
- Operate John Day reservoir at minimum operating pool (MOP) during spring and summer as long as barge transport and irrigation needs are met.
- Provide spill to total dissolved gas limits of water quality waivers or biological constraints at all dams, except maximize transportation at Snake River collector projects during lowest (10^{th} percentile) flow years.
- Maintain approximately 50/50 in-river and transportation proportions for spring and summer migrants in the Snake River by optimizing spill and surface-oriented routes of dam passage and transporting fish collected in the turbine screen bypass systems. Continue to provide spill and bypass all fish at McNary Dam at all flows during the spring migration period.
- Test removable spillway weirs and temporary spillway weirs to ensure they provide equal or better benefits of full spill before reducing spill.
- Establish more rigorous research, monitoring and evaluation to assure that fish survival is increasing and to inform adaptive management.
- Identify and prepare contingency actions for implementation if necessary to meet fish performance standards linked to the survival and recovery requirements of listed fish.

Impaired fish passage in the tributaries

Actions to address fish passage in tributaries include:

- Implement locally developed management unit plans to improve fish passage in tributaries.
- Implement recovery plan recommendations regarding improved passage and flow management by the U.S. Bureau of Reclamation below all its facilities in the Yakima River and the Umatilla River subbasins, provision of fish passage into significant tributaries, and provision of passage over at least two of its storage dams in the Yakima Basin.[9]
- Implement recovery plan recommendations regarding improvement of fish passage, screening, and flow management in the Walla Walla River subbasin by

[9] The conservation measures in NOAA's 2006 listing decision specifically identify the need for passage at two or more of the storage dams in the Yakima Basin. The Yakima Steelhead Recovery Plan strongly recommends the provision of passage at the storage dams, but notes that the geographic distribution criteria detailed in the plan do provide for combinations of spawning areas that would meet de-listing and short-term recovery thresholds without provision of access above the storage dams (See Appendix E, Section 4.3.7).

the U.S. Army Corps of Engineers, and alteration of the flood operating rule for Mill Creek, or alternatively screening the diversion into Bennington Lake.
- Provide passage into the upper Deschutes River above Round Butte/Pelton complex and into the White Salmon River above Condit Dam.

Hatchery Reform

The hatchery programs in the Middle Columbia are managed under the Mitchell Act and the *U.S. v. Oregon* process, involving the fisheries co-managers and regulated by NMFS. NMFS is working with the funding agencies and hatchery operators to update and complete Hatchery and Genetic Management Plans (HGMPs) for every hatchery program in the Middle Columbia region as a means of organizing hatchery review and reform. The HGMPs are the basis for NMFS' biological opinions on hatchery programs under ESA sections 7 and 10 and the 4(d) rule, which relate to incidental and direct take of listed species. The HGMPs describe each hatchery's operations and the actions taken to support recovery and minimize ecological or genetic impacts, such as straying and other forms of competition with naturally produced fish.

Evaluating the factors that influence interactions between hatchery fish and naturally produced fish under varying freshwater conditions and ocean conditions is an important area of future research as well as ESA consultations and NEPA review. This is dealt with in more detail in Appendix C of the 2008 FCRPS Biological Opinion (NMFS 2008a) and in the final report of the HSRG.

The management unit plans propose various actions to reduce deleterious effects of hatcheries on natural production. For example, The Oregon Steelhead Recovery Plan proposes increased marking of Columbia Basin hatchery steelhead with coded-wire tags, and requiring mass marking of all hatchery steelhead releases with, at a minimum, an adipose fin-clip. Regional consensus has not been reached on these strategies, and the Mid-Columbia Forum will continue to pursue agreement on appropriate site-specific strategies. The Klickitat subbasin plan recommends a targeted monitoring program to determine abundance and productivity of natural spawners, determine the proportion of hatchery and wild spawners in the Klickitat subbasin, and determine the adverse effects of Skamania broodstock on the Klickitat population, if any. Further details are available in each management unit plan.

Predation, Competition and Disease

Predation, competition and disease are grouped together as a category of concern because ultimately these factors relate to balance and imbalance in the ecosystem. Improving habitat for salmonids throughout the life cycle is the best strategy for addressing these potential limiting factors (ISAB 2007). Specific measures can also be taken; these are summarized in Section 7.1.5.

The Plan addresses major avian, marine mammal and piscivorous fish predation issues in the mainstem Columbia River and tributaries and recommends immediate actions as well as research and monitoring to track trends in predator populations, understand their impacts on steelhead, and develop appropriate management techniques to reduce

predation. Competition of hatchery fish with naturally produced fish, for food, spawning areas, or other habitat resources, can be an issue at any life stage. The Plan recommends actions, research and monitoring in areas where competition may be a problem, particularly in the Klickitat, John Day, and Deschutes populations. Disease in salmonids is caused by multiple factors and probably cannot be directly addressed by recovery actions except in specific instances of known causal factors. It is more likely that nearly all of the recommended recovery actions that improve spawning, rearing, and passage conditions for steelhead and increase the survival, abundance, and productivity of naturally produced fish will result in decreasing incidence of disease.

Harvest
Although in general harvest is not considered a major threat for the Middle Columbia steelhead DPS, it is important to ensure that impacts from fisheries do not impede recovery, and to perform monitoring and evaluation to verify impacts and reduce existing uncertainties.

Columbia River Estuary and Plume
Because juvenile steelhead spend less residence time in the shallow parts of the estuary than other salmonids, the characteristics of the Columbia River plume and the deeper channels of the estuary are more important to their survival. NMFS' Estuary Module (NMFS 2007) identifies 23 types of management actions that would improve conditions in estuary and plume for all salmonids.

Climate Change
A strategy for addressing the effects of climate change on Middle Columbia River steelhead needs to be based, broadly, on the principle of preserving biodiversity. Diversity in terms of both location and biological characteristics gives any species resilience in the face of environmental change. This principle underlies the viability criteria presented in Chapter 3 of this plan, as well as the strategies described in this chapter to address the factors limiting steelhead viability, as these are currently understood. NMFS supports the ISAB's recommendations for mitigating the effects of climate change (ISAB 2007), most of which are encompassed in Chapter 7 of this Plan.

The ISAB notes that "As climate and streams warm, tributary habitats will become increasingly important because they usually provide the cool waters for salmonids and other cool-water species in a watershed" (ISAB 2007). It follows that water temperature and stream flow are factors that will remain important throughout steelhead freshwater habitat. All strategies and actions that help to lower water temperature or prevent further increase will help to mitigate climate change. Protecting and/or restoring riparian areas to increase shade, as recommended in Chapter 7 and the management unit plans, is an important strategy for minimizing water temperature increases. Additional actions include purchasing water rights to leave more water in streams and restoration actions to improve channel complexity and establish side-channel rearing (FCRPS BiOp, NMFS 2008a).

Recovery Strategies for the Four Major Population Groups

These summaries of recovery strategies for the four major population groups are drawn from the management unit plans and the ICTRT's status assessment (ICTRT 2008).

Cascades Eastern Slope Tributaries MPG

Population	Current Risk Status
Fifteenmile Creek (Oregon)	Viable
Deschutes Eastside (Oregon)	Viable
Klickitat (Washington)	(provisional) Moderate risk – insufficient data, hatchery influence
Rock Creek (Washington)	(provisional) High risk – insufficient data
Deschutes Westside (Oregon)	High risk
White Salmon (Washington)	Functionally extirpated
Crooked River (Oregon)	Extirpated

Primary limiting factors and threats (Section 6.4.1):

- Degraded tributary habitat
- Mainstem passage
- Hatchery related effects
- Blocked migration to historically accessible habitat
- Predation, competition, disease – in mainstem and estuary; possibly also in Deschutes Westside as competition with resident rainbow trout.

Recovery Scenario: For the Cascades Eastern Slope Tributaries MPG to be considered viable based on the currently extant populations, the Klickitat, Fifteenmile, and both the Deschutes Eastside and Westside populations should reach viable status, with one highly viable. The Rock Creek population should reach "maintained" status (25 percent or less risk level). MPG viability could be further bolstered if reintroduction of steelhead into the Crooked River succeeds and if the White Salmon population is successfully reintroduced to its historical habitat.

Gap: The median survival gap (assuming recent ocean and base hydrosystem conditions and 5 percent risk) for the Cascades Eastern Slope MPG is 0.21 (meaning that a 21 percent increase in average life-cycle survival is required to achieve 5 percent risk in a 100-year time period). The gap ranges from –0.34 (Deschutes Eastside) (no gap) to 0.78 (Deschutes Westside) (needs 78 percent improvement). There was not enough information to estimate gaps for the Klickitat or Rock Creek populations.

Key actions proposed (Section 7.2.1):

- Protect, improve, and increase freshwater habitat for steelhead production. Improvements to freshwater habitat should be targeted to address specific limiting factors in specific areas as described in the Oregon Steelhead Recovery Plan and the Washington Gorge plans.

- Reduce straying of out-of-DPS hatchery fish onto natural spawning grounds within the Deschutes subbasin.
- Restore historical passage to the upper Deschutes subbasin including the Westside tributaries and Crooked River above Pelton Round Butte dam complex and the White Salmon River above Condit Dam.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007 and Appendix G of this Plan) and FCRPS Biological Opinion (NMFS 2008a) (as summarized in the Hydro Module (NMFS 2008c and Appendix F of this Plan).
- Improve hatchery management to minimize impacts from hatchery releases on naturally produced steelhead within the Deschutes West and East and Klickitat subbasins.
- Fill data gaps for better assessment of Klickitat and Rock Creek steelhead populations.
- Coordinate between scientists, planners, and implementers of recovery actions on both sides of the Columbia River for sequencing of recovery actions and monitoring for adaptive management.

John Day River MPG

Population	**Current Risk Status**
North Fork John Day	Highly viable
Upper Mainstem John Day	Moderate risk
Lower Mainstem John Day	Moderate risk
Middle Fork John Day	Moderate risk
South Fork John Day	Moderate risk

Main limiting factors and threats (Section 6.4.2):

- Degraded tributary habitat
- Mainstem passage
- Hatchery related effects
- Predation/competition/disease in mainstem and estuary

Recovery Scenario: For the John Day River MPG to reach viable status, the Lower Mainstem John Day River, North Fork John Day River, and either the Middle Fork John Day River or Upper Mainstem John Day River populations should achieve viable status, with one highly viable.

Gap: The median survival gap for the John Day MPG is 0.09, ranging from –0.49 (North Fork) (no gap) to 0.34 (South Fork) (needs 34 percent improvement in average survival over the life cycle).

Key Actions proposed (7.3.2):

- Protect and improve freshwater habitat conditions and connectivity for steelhead production. Improvements to freshwater habitat should be targeted to address specific factors in specific areas as described in the Oregon Steelhead Recovery Plan.

- Improve hatchery management to reduce straying from out-of-DPS hatchery fish onto natural spawning grounds within the John Day subbasin.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007 and Appendix G of this Plan) and FCRPS Biological Opinion (NMFS 2008a)

Umatilla/Walla Walla MPG

Population	Current Risk Status
Umatilla River	Moderate Risk
Walla Walla River	Moderate Risk
Touchet River	High Risk (provisional because of insufficient data)

Main limiting factors and threats (Section 6.4.3):

- Mainstem passage (Touchet and Walla Walla populations pass four major dams: the Umatilla population must pass three.)
- Tributary habitat
- Hatchery related effects
- Predation/competition/disease

Recovery Scenario: For the Umatilla/Walla Walla MPG to be viable, two populations should meet viability criteria, and one should be highly viable. The Umatilla River population is the only large population, and therefore should be viable. Either the Walla Walla River or Touchet River population also should be viable.

Gap: There was sufficient information available to estimate gaps for only two of the three populations within the Umatilla/Walla Walla MPG. Assuming base hydrosystem and recent ocean conditions, the survival gaps for the Umatilla and Walla Walla populations are 0.09 and 0.34, respectively.

Key actions proposed (Section 7.2.3):

- Coordinate between planners, scientists and those implementing recovery actions in Washington and Oregon for sequencing, monitoring, and adaptive management.
- Protect and improve freshwater habitat conditions and access for steelhead production. Improvements to freshwater habitat should be targeted to address specific factors in specific areas as described in the Southeast Washington Plan and the Oregon Steelhead Recovery Plan.
- Improve hatchery management to reduce straying by out-of-DPS hatchery fish onto natural spawning grounds within the Umatilla/Walla Walla subbasins.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007 and Appendix G of this Plan) and FCRPS Biological Opinion (NMFS 2008a) (as summarized in the Hydro Module, NMFS 2008c and Appendix F of this Plan).

Yakima River MPG

Population	Current Risk Status
Upper Yakima River	High Risk
Naches River	High Risk
Satus Creek	Moderate Risk
Toppenish Creek	Moderate Risk

Main limiting factors and threats (Section 6.4.4):

- Tributary habitat: Influence of major irrigation system development. Altered hydrology; degraded habitat; loss of habitat; impaired fish passage; reduced outmigrant survival in Yakima mainstem.
- Mainstem passage (four dams).

Status: The Yakima MPG is currently rated at High Risk. The two largest populations in the drainage (Naches and Upper Yakima) are rated at High Risk; the Satus Creek and Toppenish Creek populations are rated as Maintained.

Recovery Scenario: For the Yakima River MPG to achieve viable status, two populations should be rated as viable, including at least one of the two classified as Large – either the Naches River or the Upper Yakima River. The remaining two populations should, at a minimum, meet the Maintained criteria.

Gap: The median survival gap (assuming recent ocean and base hydrosystem conditions) for the Yakima MPG is 0.77 (needs 77 percent improvement in average survival over the life cycle), ranging from 0.22 (Satus—tributary only) to 1.15 (Upper Yakima). This is the highest median survival gap of the four MPGs in the Middle Columbia steelhead DPS.

Key actions proposed (Section 7.2.4):

- Protect and enhance habitat in key tributary watersheds in the Yakima Basin.
- Restore passage to blocked areas in the Naches and Upper Yakima population areas.
- Alter irrigation delivery and storage operations in the Yakima Basin to improve flow conditions for Middle Columbia steelhead and use managed high flows to maintain floodplain habitat.
- Improve channel and floodplain function and reduce predation through the mainstem Yakima and Naches Rivers.
    - Improve survival in the mainstem Columbia and its estuary through actions detailed in NMFS Estuary Module (NMFS 2007 and Appendix G of this Plan) and FCRPS Biological Opinion (NMFS 2008a) (as summarized in the Hydro Module, NMFS 2008c and Appendix F of this Plan).

Time Required and Cost Estimates

Estimating time and cost for salmon and steelhead recovery, given the complex relationship of these fish to the environment and to human activities on land, poses unique challenges. NMFS estimates that recovery of the Middle Columbia steelhead DPS could take 25 to 50 years. The management unit plans (Appendices A through E) contain extensive lists of actions to recover the Middle Columbia steelhead DPS populations. These projects were developed using the most up-to-date assessment of Middle Columbia steelhead recovery needs. The management unit plans focus, for the most part, on actions ranging from 5 to 15 years. There are many uncertainties involved in predicting the course of recovery and in estimating total costs. Such uncertainties include biological and ecosystem responses to recovery actions as well as long-term and future funding.

Cost Estimates

Cost estimates for recovery projects were provided by the management unit entities where available information was sufficient to do so, using the methods described in each management unit plan. No cost estimates are provided for (1) baseline actions (programs that are already in existence), which are listed as Not Applicable (N/A); or (2) actions for which costs, unit costs, or project-scale estimates are yet to be developed. These are listed as To Be Determined. Cost figures will be updated as improved information becomes available.

The total estimated cost of restoring habitat for the Middle Columbia steelhead DPS is approximately $235 million over the initial 5-year period, and approximately $996 million over 20 to 50 years for all DPS-wide recovery actions for which sufficient information exists upon which to base an estimate (Table ES-4). However, they do not include costs associated with implementing actions within the lower Columbia River, estuary or Federal Columbia River Power System (FCRPS).

This estimate includes expenditures by local, tribal, state, and Federal governments, private business, and individuals, in implementing both capital projects and non-capital work. Administrative costs are embedded in the total management unit cost estimates in Table ES-4. Preliminary research, monitoring and evaluation costs have, in some cases, been estimated at the management unit level; however, these costs are not included at this time pending completion of research and monitoring plans and further development of each project.

Table ES-4 Summary of Cost Estimates for Habitat Projects for Middle Columbia Steelhead DPS.

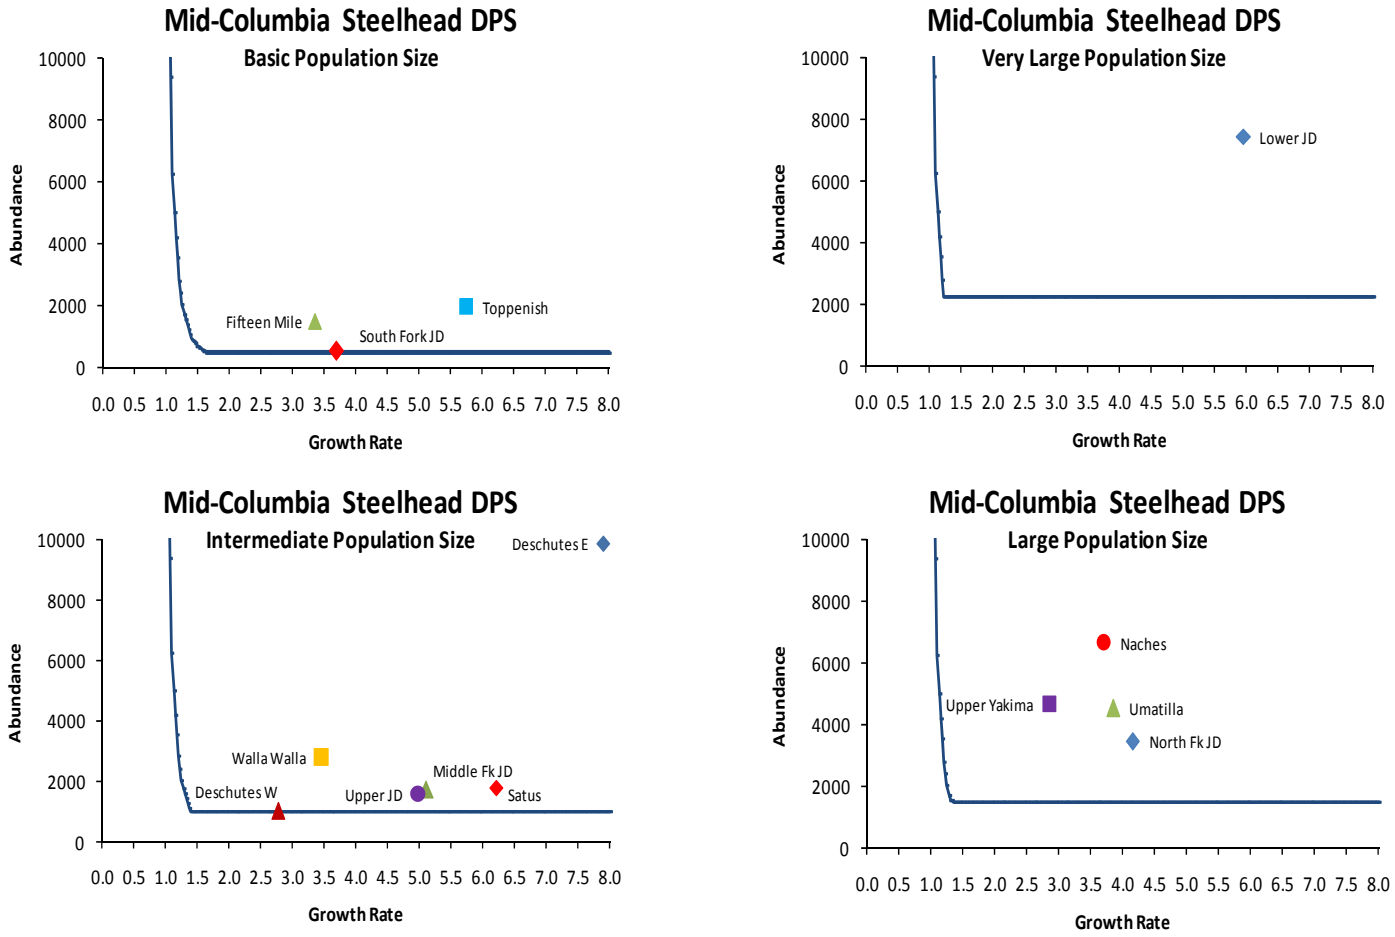
Recovery Plan	First 5 Years ($M)	Project/Program Total ($M)
Oregon	$ 103.5	$ 512.8
Yakima Steelhead[10]	$ 91.9	$ 269.3
SE Washington[11]	$ 25.5	$ 76.4
Klickitat[12],[13]	$ 12.9	$ 129.4
Rock Creek[14]	$ 0.9	$ 1.8
White Salmon Steelhead	N/A	$ 6.5
DPS Totals	**$ 234.7**	**$ 996.2**

These cost estimates do not include expenses associated with implementing actions within the lower Columbia River, estuary, or Federal Columbia River Power System (FCRPS), first, because of the basin-wide scope and applicability of these actions to all 13 Columbia Basin salmonid species listed as threatened or endangered, and second, because they are considered "baseline actions" that are required through other processes such as section 7 consultations, FERC licensing agreements, and Habitat Conservation Plans. Cost estimates for estuary actions are included in a module that is incorporated into the Plan as Appendix G, and is available on the NMFS website: www.nwr.noaa.gov/Salmon Recovery Planning/ESA Recovery Plans/Other Documents.cfm. The estuary recovery costs could be further refined following public comment on the module and on the ESA recovery plan for the three listed lower Columbia River ESUs and one listed lower Columbia River steelhead DPS in 2009. Costs for hatchery actions required through other processes such as consultations, permits, and 4(d) Rule implementation are not part of recovery costs reported here because the programs are already in existence or are undergoing required modifications. There are few estimated costs for recovery actions associated with harvest to report at this time. This is because no actions are currently proposed that go beyond those already being implemented through *U.S. v. Oregon* and other harvest management forums. In the event that additional harvest actions are implemented through these forums, those costs will be

[10] The Yakima steelhead plan estimates costs for the first 6 years, and includes preliminary RME cost estimate of $300K/year. The 5-year estimate is extrapolated from the 6-year cost data .
[11] The SE Washington plan estimates annual steelhead implementation costs at about $5 million per year. The 5-year estimate is extrapolated by multiplying the annual amount by five.
[12] The Klickitat plan estimates costs for the first 10 years. Five-year estimate extrapolated by dividing the 10-year amount in half.
[13] The Klickitat plan uses a 50-year period to estimate its total project costs.
[14] The Rock Creek plan estimates cost for first 3 years and 10 years. The 5-year estimate is extrapolated from the 3-year value.

added during the implementation phase of this recovery plan. All cost estimates will be refined and updated over time.

Cost estimates from the draft cost chapters in the individual management plans were developed as consistently as possible, in that they all applied guidance provided by NMFS. However, the approaches vary to some degree given the local and independent nature of the planning groups. Costs developed in the management unit plans were estimated using several basic assumptions (i.e., neither baseline costs nor out-of-basin costs were included in the estimates) and used similar cost calculation methodologies. There are, however, differences in the timeframes for cost estimates.



Potential Effects of Proposed Recovery Actions

Chapter 9 in this plan presents an analysis of the potential effects of implementing all the proposed recovery actions – in all the "H" sectors – on the abundance and productivity of Middle Columbia River steelhead. This quantitative analysis provides an opportunity to evaluate the efficacy of proposed recovery strategies in light of current knowledge regarding population functioning, including relationships with habitat conditions. Equally important, the quantitative models used in the assessment provide a framework for productively targeting evaluation efforts as well as for revisiting key assumptions in the future as more information becomes available (e.g., from monitoring responses to initial implementation or from evaluation efforts targeting key uncertainties). Two models were used: Ecosystem Diagnosis and Treatment (EDT) and the All-H-Analyzer (AHA). Methods of analysis are explained in detail in Chapter 9 of this Plan.

The analysis indicates, based on the suites of proposed actions in all the sectors, that all Middle Columbia River steelhead populations for which there are adequate data are expected to achieve 95 percent probability of survival (less than 5 percent risk of extinction within 100 years) for abundance/productivity if the most intensive (major) restoration scenarios are implemented and the projected habitat changes are realized after 25 years of implementation. Under minimum restoration scenarios, three populations (Deschutes Westside, Satus, and Upper Yakima) may not achieve less than 5 percent risk for abundance/productivity. However, the Satus population would meet the recovery criteria identified in the Yakima Steelhead Recovery Plan, and even under poor ocean conditions and minimum restoration actions, the abundance and productivity of the other two populations are expected to increase considerably over the baseline.

Figure ES-6 shows the projected (modeled) abundance and productivity of the 14 populations for which there are adequate data (excluding the Rock Creek, Klickitat, and Touchet populations) after 25 years and major restoration actions. The curve represents the abundance and productivity needed to achieve 95 percent probability of survival for the next 100 years.

Figure ES-6. Predicted viability results for Middle Columbia Steelhead Populations after 25 years of major restoration efforts.

Research, Monitoring, and Evaluation

An important part of the strategy for achieving recovery is the development of a DPS-wide monitoring plan that will support implementation of the recovery plan and long-term adaptive management in response to changes and trends in the data. Two keys to effective implementation are targeting actions to specific areas and monitoring the results of the actions. To achieve these goals, a scientific technical team made up of local scientists, former ICTRT members, and managers will be necessary. The monitoring plan is discussed in more detail in Chapter 10. It is also important to explicitly address the many unknowns in salmon recovery – the "critical uncertainties" that make management decisions much harder. Critical uncertainty research will, in the long run, reduce monitoring and implementation costs. Critical uncertainties and data gaps are described in more detail in Sections 10.3 and 10.4.

Adaptive Management

Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. A plan for monitoring, evaluation, and feedback is incorporated into an overall implementation plan so that the results of actions can become feedback on design and implementation of future actions. Adaptive management works by coupling the decision-making process with collection of performance data and its evaluation. Most importantly, it works by offering an explicit process through which alternative strategies to achieve the same ends can be considered.

Within the Middle Columbia Basin, many different organizations, including Federal, state, tribal, local, and private entities, currently conduct programs and actions that could improve Middle Columbia steelhead survival. Development of Middle Columbia regional coordination will be essential for NMFS' future status reviews of the steelhead DPS. Establishing stable funding and staff for reporting data is also important. Management unit planners are developing detailed research, monitoring, evaluation, and adaptive management plans for each management unit based on the principles and concepts laid out in the NMFS draft guidance document, Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance (http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf). The individual RM&E and adaptive management plans will then be combined into a DPS RM&E and adaptive management plan by the Middle Columbia Science Team. This will ensure that, taken together, the monitoring and evaluation programs for each management unit, combined with monitoring components of the modules incorporated into the plans, address the needs of the entire DPS. The Mid-C Forum and others will use the RM&E and adaptive management plans to inform and guide projects and programs.

Setting Priorities

Priorities for recovery actions should be guided by DPS-, MPG-, and population-level recovery criteria and best available scientific information concerning DPS status, the role of the independent populations in meeting DPS and MPG viability, limiting factors and threats, and likelihood of effectiveness of actions. Protection of existing habitat is essential. Issues of funding and local, state, or national support for implementation will also inevitably come into play.

The management unit plans all address these issues in their implementation sections. For recovery actions in the tributaries, priorities will be settled largely at the local level. However, there should be ongoing technical review and support from DPS-level and management unit

science and technical committees. Coordination and communication in "out-of-subbasin" forums will be necessary for actions in the Columbia mainstem, estuary, and/or ocean.

Coordination/Governance

Coordination of actions and information-sharing among fisheries biologists, Tribes, local governments, citizen groups, and state and Federal agencies based in both Oregon and Washington is a key component of recovery for this DPS. Benefits of coordination include:

- Dealing with shared migration areas consistently
- Developing coherent MPG-level strategies where populations are in two states (Cascades Eastern Slope MPG; Umatilla/Walla Walla MPG), or the same population is in both states (Walla Walla population)
- Promoting consistent methods for setting recovery objectives, evaluating strategies, and monitoring progress across populations, MPGs, and the DPS

Such coordination is underway through the Middle Columbia Recovery Forum (Mid-C Forum), a group convened by NMFS to provide input on the DPS recovery plan.

Middle Columbia Recovery Forum

The recent creation of the Middle Columbia Recovery Forum (Mid-C Forum), to be convened regularly by NMFS, is intended to facilitate collaboration between scientists and recovery planners on both sides of the Columbia River. Figure ES-7 gives an overview of the relationships between these entities. Chapter 11 of this plan describes in more detail the proposed roles and responsibilities.

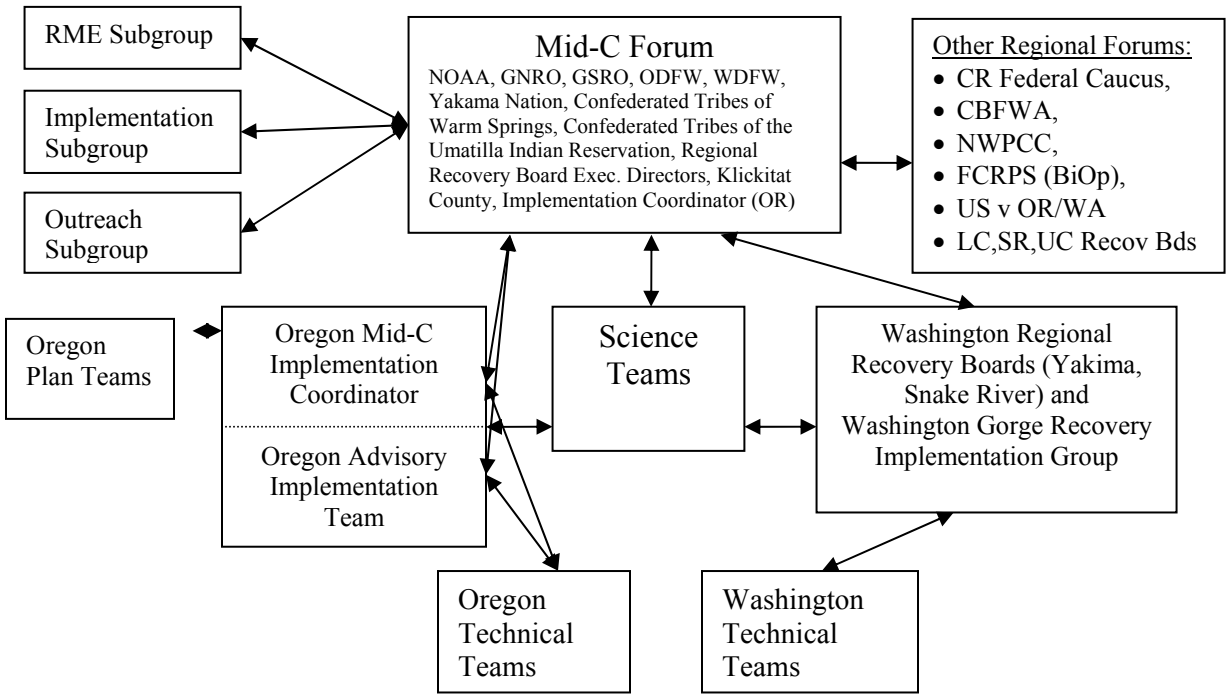


Figure ES-7. Mid-C Recovery Plan Implementation Organizational Structure.

Implementation Funding

Funding for project implementation is currently available from a variety of sources, but it will be an ongoing challenge. The role of the Mid-C Forum is to ensure that management unit plan implementers are aware of potential sources of funds and to advocate for the funding and implementation of actions that benefit all populations in the DPS. The Forum will not supersede decisions made by the individual management unit boards but will provide assistance and may promote funding of their projects and programs if requested. Sources of implementation funding include:

- Congressional appropriations to Federal agencies and to Pacific Coastal Salmon Recovery Fund (PCSRF) (through states and tribes)
- Salmon Recovery Funding Board (SRFB) (Washington)
- Oregon Watershed Enhancement Board (OWEB) (Oregon)
- State appropriations (state agencies)
- Northwest Power and Conservation Council Fish and Wildlife Program (states and tribes)
- Federal/state grants
- Non-profit organization programs and grants

How NMFS Intends to Use the Plan

Although recovery plans are not regulatory and their implementation is voluntary, they are important tools that help to do the following:

- Provide context for regulatory decisions.
- Guide decision making by Federal, state, Tribal, and local jurisdictions.
- Provide criteria for status reporting and delisting decisions.
- Organize, prioritize, and sequence recovery actions.
- Organize research, monitoring, and evaluation efforts.

NMFS will encourage Federal agencies and non-Federal jurisdictions to take recovery plans under serious consideration as they make the following sorts of decisions and allocate their resources:

- Actions carried out to meet section 7(a)(1) obligations to use their programs in furtherance of the purposes of the ESA and to carry out programs for the conservation of threatened and endangered species
- Actions that are subject to ESA sections 4d, 7(a)(2), or 10
- Hatchery and Genetic Management Plans and permit requests
- Harvest plans and permits
- Selection and prioritization of subbasin planning actions
- Development of research, monitoring, and evaluation programs
- Revision of land use and resource management plans
- Other natural resource decisions at the state, Tribal, and local levels

NMFS will emphasize recovery plan information in ESA section 7(a)(2) consultations, section 10 permit development, and application of the section 4(d) rule by considering:

- The importance of affected populations to listed species viability
- The importance of the action area to affected populations and species viability
- The relation of the action to recovery strategies and management actions
- The relation of the action to the research, monitoring, and evaluation plan for the affected species

In implementing these programs, recovery plans will be used as a reference and a source of context, expectations, and goals. NMFS staff will encourage the Federal action agencies to describe in their biological assessments how, within the action area, their proposed actions will affect individuals of specific populations and limiting factors identified in the recovery plans, and to describe any mitigating measures and voluntary recovery activities in the action area.

Middle Columbia River Steelhead ESA Recovery Plan

1. INTRODUCTION

This is a recovery plan (Plan) for the protection and restoration of Middle Columbia River steelhead (*Oncorhynchus mykiss*), which spawn and rear in tributaries to the Columbia River in central and eastern Washington and Oregon (Figure 1-1). The Middle Columbia River steelhead distinct population segment (DPS) was listed as threatened under the Endangered Species Act of 1973 (ESA) on January 5, 2006 (71 FR 834).

NOAA's National Marine Fisheries Service (NMFS) is required, pursuant to Section 4(f) of the Endangered Species Act (ESA) of 1973, to develop recovery plans for marine species listed under the Act. Recovery plans identify actions needed to restore threatened and endangered species to the point that they are again self-sustaining elements of their ecosystems and no longer need the protections of the ESA.

Nineteen of the 33 salmon and steelhead species in the Northwest region are listed as threatened or endangered. The Middle Columbia steelhead is among those with the best prospects of recovery, although it will require considerable political will and investment of long-term effort and funding. Modeling of the potential effects of the actions that are proposed in this plan (see Chapter 9) predicts that the DPS can achieve a "negligible" risk of extinction within a reasonable time frame – e.g. 25 to 50 years – if the actions are taken and if they have the predicted effects on steelhead habitat and survival. Cautious though this statement may be, it is a beacon of hope in the complex realm of salmonid recovery in the Northwest.

A recovery plan serves as a road map for species recovery—it lays out where we need to go and how best to get there. Without a plan to organize, coordinate and prioritize the many possible recovery actions on the part of Federal, state, and tribal agencies, local watershed councils and districts, and private citizens, our efforts may be inefficient or even ineffective. Prompt development and implementation of a recovery plan will help target limited resources effectively. Although recovery plans are guidance, not regulatory documents, the ESA clearly envisions recovery plans as the central organizing tool for guiding each species' recovery process.

Over the course of their life cycle, Middle Columbia River steelhead use habitats across a wide geographic range. They spawn and rear in the upper and middle reaches of freshwater tributaries, then migrate as juveniles through the lower tributary reaches and the mainstem Columbia River to the estuary and ocean. After one to five years in the ocean, the adults migrate upstream to their natal streams. The long-term biological success of steelhead is based on their ability to make use of these diverse habitats. Their resilience in the face of change depends on maintaining genetic, phenotypic, and behavioral diversity over a wide geographic area.

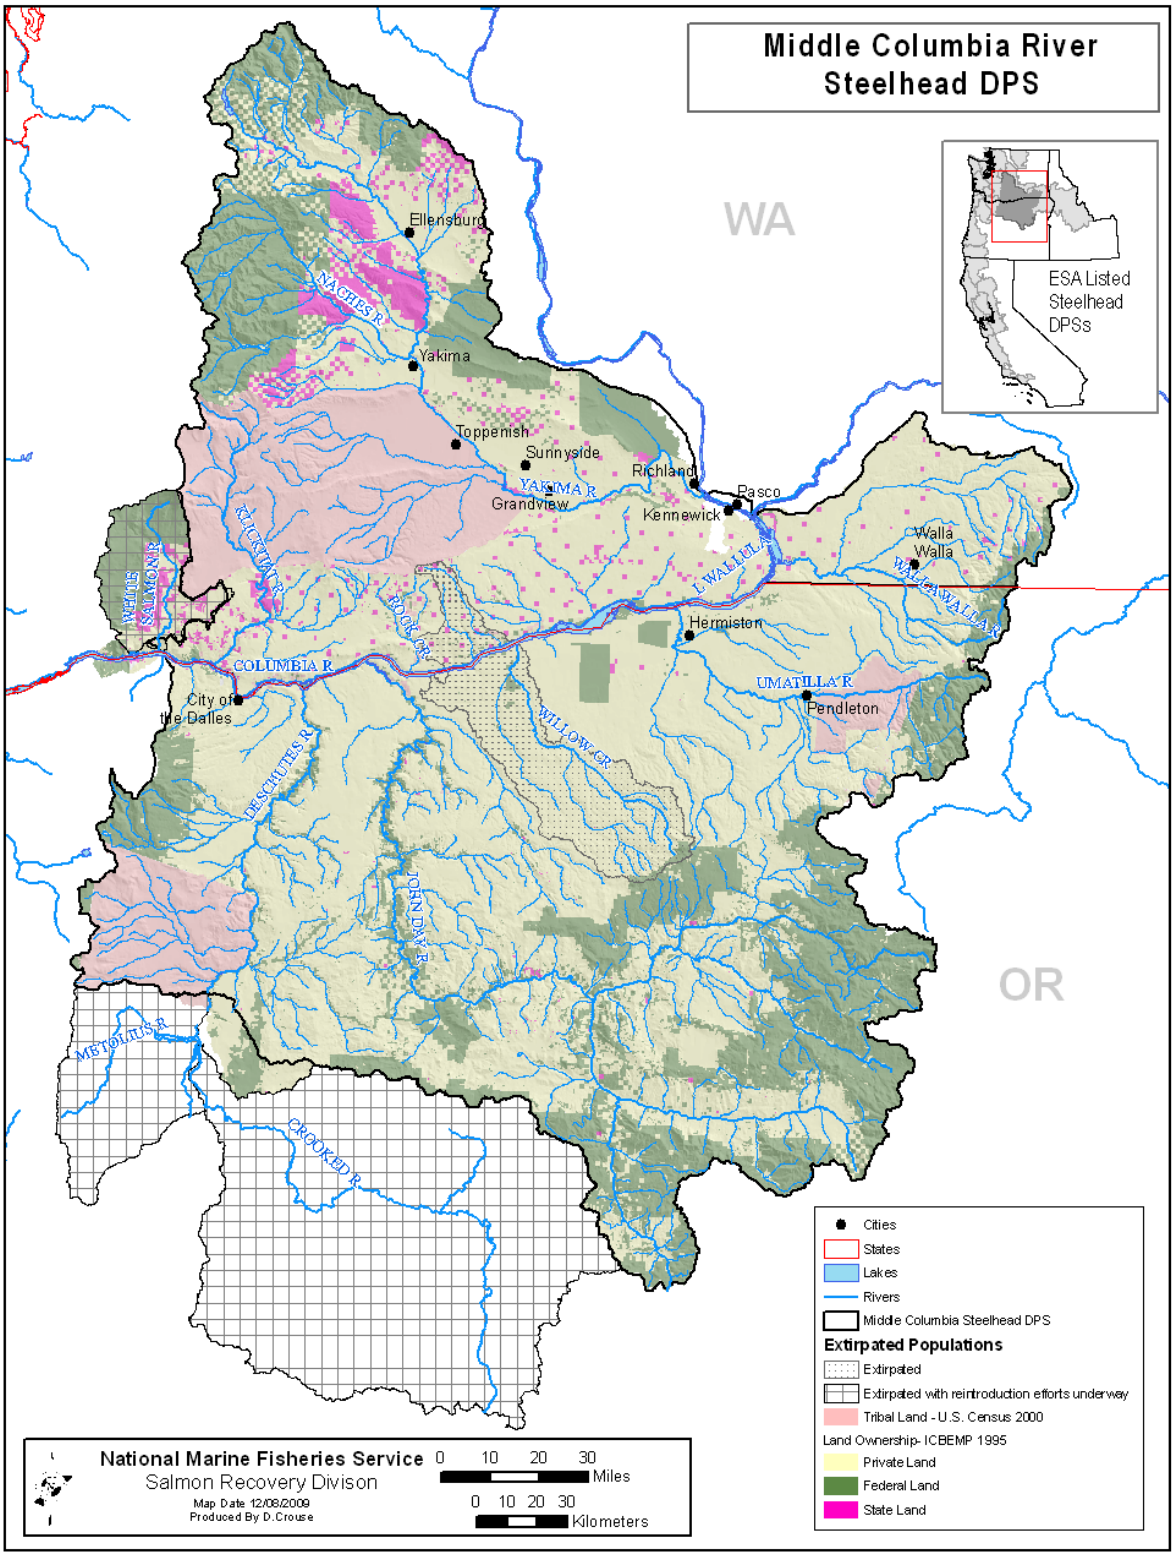

Figure 1-1. Geographic boundaries of the Middle Columbia River Steelhead DPS, showing land ownership.

Human activities have dramatically changed this geography. Although many of the deleterious effects on fish habitat are due to past practices, current human uses of the land and river systems continue to affect steelhead habitat and viability across much of its Middle Columbia range. A growing number of people now recognize the opportunities and benefits of actively protecting and restoring stream corridors, wetlands, stream flows, and other natural features that support native fish and wildlife populations. Management of upland areas is changing to protect or restore watershed function, and cities are undertaking urban watershed protection and restoration. Recovery planning is an opportunity to search for the common ground among affected parties, to organize protection and restoration of salmonid habitat, and to secure the economic and cultural benefits that accrue to human communities from healthy watersheds and rivers. While Federal, state, and tribal entities can make major contributions to the recovery of Middle Columbia steelhead, the actions of individuals on their land, as well as city and county codes and ordinances promoting conservation, are also essential.

The primary goal of ESA recovery plans is for the species to reach the point that it no longer needs the protection of the Act and can be delisted. Recovery plans may also contain "broad sense goals" that go beyond the requirements for delisting to address other legislative mandates or social, economic, and ecological values. The various locally produced plans contain broad sense goals adopted by local planning entities. These broad sense goals, while stated in slightly different ways, usually share some combination of the following elements: ensuring long-term persistence of viable populations of naturally produced steelhead distributed across their native range; enjoying the social and cultural benefits of meaningful harvest opportunities that are sustainable over the long term; and pursuing salmon recovery using an open and cooperative process that respects local customs and benefits local communities and economies. Recovery goals and delisting criteria are discussed in greater detail in Chapter 3.

1.1 ESA Requirements

Section 4(f) of the ESA requires that a recovery plan be developed and implemented for species listed as endangered or threatened under the statute.

ESA section 4(a)(1) lists factors for re-classification or delisting that are to be addressed in recovery plans:

A. The present or threatened destruction, modification, or curtailment of [the species'] habitat or range
B. Over-utilization for commercial, recreational, scientific or educational purposes
C. Disease or predation
D. The inadequacy of existing regulatory mechanisms
E. Other natural or human-made factors affecting its continued existence

ESA section 4(f)(1)(B) directs that recovery plans, to the extent practicable, incorporate:

1. a description of such site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species;
2. objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this chapter, that the species be removed from the list; and;

3. estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal.

In addition, it is important for recovery plans to provide the public and decision makers with a clear understanding of the goals and strategies needed to recover a listed species and the science underlying those conclusions (NMFS 2006).

Once a species is deemed recovered and therefore removed from a listed status, section 4(g) of the ESA requires the monitoring of the species for a period of not less than five years to ensure that it retains its recovered status.

1.2 How NMFS Intends to Use the Plan

Although recovery plans are not regulatory and their implementation is voluntary, they are important tools that help to do the following:

- Provide context for regulatory decisions.
- Guide decision making by Federal, state, Tribal, and local jurisdictions.
- Provide criteria for status reporting and delisting decisions.
- Organize, prioritize, and sequence recovery actions.
- Organize research, monitoring, and evaluation efforts.

NMFS will encourage Federal agencies and non-Federal jurisdictions to take recovery plans under serious consideration as they make the following sorts of decisions and allocate their resources:

- Actions carried out to meet section 7(a)(1) obligations to use their programs in furtherance of the purposes of the ESA and to carry out programs for the conservation of threatened and endangered species
- Actions that are subject to ESA sections 4d, 7(a)(2), or 10
- Hatchery and Genetic Management Plans and permit requests
- Harvest plans and permits
- Selection and prioritization of subbasin planning actions
- Development of research, monitoring, and evaluation programs
- Revision of land use and resource management plans
- Other natural resource decisions at the state, Tribal, and local levels

NMFS will emphasize recovery plan information in ESA section 7(a)(2) consultations, section 10 permit development, and application of the section 4(d) rule by considering:

- The importance of affected populations to listed species viability
- The importance of the action area to affected populations and species viability
- The relation of the action to recovery strategies and management actions
- The relation of the action to the research, monitoring, and evaluation plan for the affected species

In implementing these programs, recovery plans will be used as a reference and a source of context, expectations, and goals. NMFS staff will encourage the Federal "action agencies" to describe in their biological assessments how, within the action area, their proposed actions will

affect individuals of specific populations and limiting factors identified in the recovery plans, and to describe any mitigating measures and voluntary recovery activities in the action area.

1.3 Middle Columbia Steelhead DPS Geographic Setting

The range of the Middle Columbia steelhead DPS extends over approximately 35,000 square miles in the Columbia plateau of eastern Washington and eastern Oregon. The DPS includes all naturally spawned populations of steelhead in drainages upstream of the Wind River, Washington, and the Hood River, Oregon (exclusive), up to, and including, the Yakima River, Washington, but excluding steelhead from the Snake River Basin (64 FR 14517; 71 FR 849). Major drainages in this DPS are the Deschutes, John Day, Umatilla, Walla Walla, Yakima, and Klickitat river systems. The Cascade Mountains form the western border of the plateau in both Oregon and Washington, while the Blue Mountains form the eastern edge. The southern border is marked by the divides that separate the upper Deschutes and John Day basins from the Oregon high desert and drainages to the south. The Wenatchee Mountains and Palouse areas of eastern Washington border the Middle Columbia on the north.

Temperatures and precipitation vary widely, usually depending on elevation, with cooler and wetter climates in the mountainous areas at the western and eastern boundaries and warmer and drier climates in the lower portions of the watersheds that make up most of the province. The mountainous regions are predominately coniferous forests, while the arid regions are characterized by sagebrush steppe and grassland.

Most of the region is privately owned (64 percent), with the remaining area under Federal (23 percent), tribal (10 percent) and state (3 percent) ownership (Figure 1-1). The landscape, throughout the range of this DPS, is heavily modified for human use, even where populations are low. Most of the landscape consists of are rangeland and timberland, with significant concentrations of dryland agriculture in parts of the range. Irrigated agriculture and urban development are generally concentrated in valley bottoms. Populations in these regions are growing.

1.4 Relationship of Steelhead DPS to Resident *O. mykiss*

"Steelhead" is the name commonly applied to the anadromous (migratory) form of the biological species *Oncorhynchus mykiss*. The common names of the non-anadromous, or resident, form are rainbow trout and redband trout. When NMFS originally listed the Middle Columbia River steelhead as threatened on March 25, 1999 (64 FR 14517), it was classified as an "evolutionarily significant unit" (ESU) of salmonids that included both the anadromous and resident forms. Recently, NMFS revised its species determinations for West Coast steelhead under the ESA, delineating anadromous, steelhead-only "distinct population segments" (DPS). NMFS listed the Middle Columbia River steelhead DPS as threatened on January 5, 2006 (71 FR 834). Rainbow trout and redband trout are under the jurisdiction of the states unless they are listed, when they come under the jurisdiction of the U.S. Fish and Wildlife Service (USFWS). This recovery plan addresses steelhead and not rainbow trout, as is consistent with the 2006 ESA listing decision.

NMFS based its DPS determination on the fact that "despite the apparent reproductive exchange between resident and anadromous *O. mykiss*, the two life forms remain 'markedly separated' as a consequence of physical, physiological, ecological, and behavioral factors. . . . Steelhead differ

from resident rainbow trout physically in adult size and fecundity, physiologically by undergoing smoltification, ecologically in their preferred prey and principal predators, and behaviorally in their migratory strategy." (71 FR 838).

NMFS acknowledges that the data necessary to evaluate the current status and trends of resident populations are generally lacking, as well as historical data necessary to evaluate trends in abundance and distribution of the two life history forms. NMFS concluded that the collective contribution of the resident life history form to persistence of steelhead is unknown, and may not substantially reduce the overall extinction risk of the steelhead DPS (71 FR 834). Individual management unit plans may identify research and monitoring needs to better understand the status and trends of resident rainbow trout in order to address these data gaps.

1.5 Context of Plan Development

This plan is the product of a collaborative process initiated by NMFS that involves the State of Washington, regional salmon recovery organizations within Washington, the State of Oregon (led by the Oregon Department of Fish and Wildlife, with support from a collaborative sounding board), emerging regional sounding boards within Oregon, other Federal agencies, state agencies, Tribes, local governments, and the public.

While NMFS is directly responsible for ESA recovery planning for salmon and steelhead, NMFS believes that ESA recovery plans for salmon and steelhead should be based on the many state, regional, tribal, local, and private conservation efforts already underway throughout the region. Local support of recovery plans by those whose activities directly affect the listed species, and whose actions will be most affected by recovery efforts, is essential. NMFS therefore supports and participates in locally led collaborative efforts to develop recovery plans that involve local communities, state, tribal, and Federal entities, and other stakeholders.

NMFS developed the Middle Columbia Steelhead DPS ESA Recovery Plan with assistance from the Middle Columbia Recovery Forum (Mid-C Forum), a group convened by NMFS to provide input on the DPS recovery plan. NMFS developed this Plan by drawing upon the best available scientific information provided by the four regional recovery plans included as appendices to this Plan (i.e. the management unit plans, described below and in Section 1.6.), and by a regional team of scientists (the Interior Columbia Technical Recovery Team, described below). The draft plan went through repeated reviews and revisions in response to comments from both the scientific team and the Mid-C Forum. Participants in the Mid-C Forum include the Oregon Department of Fish and Wildlife (ODFW), Washington Department of Fish and Wildlife (WDFW), the Yakama Nation, Confederated Tribes of the Warm Springs Indian Reservation, Confederated Tribes of the Umatilla Indian Reservation, Washington Governor's Salmon Recovery Office, Oregon Governor's Natural Resources Office, Snake River Salmon Recovery Board, Yakima Basin Fish and Wildlife Recovery Board, US Bureau of Reclamation (BOR), US Fish and Wildlife Service (USFWS), US Forest Service (USFS), US Army Corps of Engineers (COE), Klickitat County, and NMFS Northwest Region.

The Draft Recovery Plan, including the four management unit plans and two scientific reports (McClure et al. 2003; ICTRT 2007a) that provide the scientific basis for the Plan, was made available for public review as a Proposed Recovery Plan. NMFS revised the Proposed Plan in

response to public comments, including comments from the ICTRT as peer reviewers. The responses to public comments are available on the NMFS website, at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/Recovery-Domains/Interior-Columbia/Mid-Columbia/upload/Mid-C-response.pdf

1.5.1 Recovery Domains and Technical Recovery Teams

Currently, there are 19 ESA-listed ESUs/DPSs of Pacific salmon and steelhead in the Pacific Northwest. NMFS Northwest Region also shares jurisdiction of an additional ESU, Southern Oregon/Northern California coho, with NMFS Southwest Region. For the purpose of recovery planning for these species, NMFS Northwest Region designated five geographically based "recovery domains": Interior Columbia; Willamette-Lower Columbia; Puget Sound and Washington Coast; the Oregon Coast; and the Southern Oregon/Northern California Coast (Figure 1-2). The range of the Middle Columbia River steelhead DPS is located in the Middle Columbia sub-domain of the Interior Columbia domain (the other Interior Columbia sub-domains are the Snake River and Upper Columbia).

For each domain, NMFS appointed a team of scientists, nominated for their geographic and species expertise, to provide a solid scientific foundation for recovery plans. The charge of each Technical Recovery Team (TRT) is to define ESU/DPS structures, develop recommendations on biological viability criteria for each ESU or DPS and its component populations, provide scientific support to local and regional recovery planning efforts, and provide scientific evaluations of proposed recovery plans. The Interior Columbia TRT (ICTRT) included biologists from NMFS, states, tribes, and academic institutions.

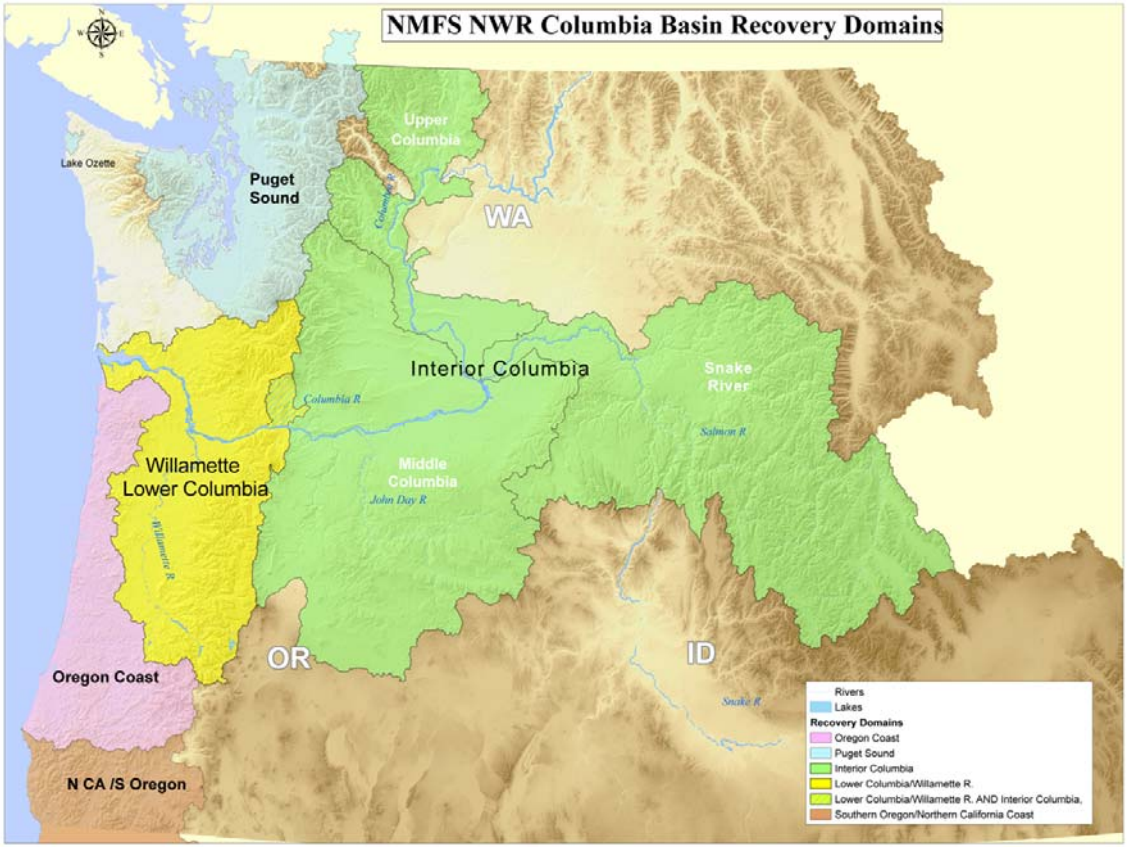

Figure 1-2. Columbia Basin Recovery Domains for NMFS Northwest Region.

All the TRTs used the same biological principles for developing their recommendations for ESU/DPS and population viability criteria – criteria to be used, along with criteria based on mitigation of the factors for decline, to determine whether a species has recovered sufficiently to be downlisted or delisted. These principles are described in a NMFS technical memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000). Viable salmonid populations (VSP) are defined in terms of four parameters: abundance, population productivity or growth rate, population spatial structure, and diversity. A viable ESU/DPS is naturally self-sustaining, with a high probability of persistence over a 100-year time period. Each TRT made recommendations using the VSP framework, based on data availability, the unique biological characteristics of the ESUs/DPSs and habitats in the domain, and the members' collective experience and expertise. Although NMFS encouraged the TRTs to develop regionally specific approaches for evaluating viability and identifying factors limiting recovery, all the TRTs worked from a common scientific foundation.

1.5.2 Management Units

In each domain, NMFS has worked with state, tribal, local and other Federal entities to develop planning forums that build to the extent possible on ongoing, locally led recovery efforts. NMFS defined "management units" based on jurisdictional boundaries as well as areas where local planning efforts were underway (Figure 1-3). It can be seen from the figure that the management units do not necessarily correspond to biological units, such as steelhead populations, but are defined for planning and administrative purposes. The Middle Columbia management units are

(1) Oregon; (2) Washington Gorge, which, in turn, is subdivided into three planning areas: White Salmon, Klickitat, and Rock Creek; (3) Yakima subbasin; and (4) Southeast Washington.

1.6 Management Unit Recovery Plans

Although NMFS has prepared this plan for the entire DPS, the management unit plans (Appendices A-E) are the work of local groups and county, state, Federal, and tribal entities within the Middle Columbia River region on both sides of the river. The management unit plans built on existing recovery plans, in particular, the Northwest Power and Conservation Council's subbasin plans, and targeted the specific ESA recovery needs of Middle Columbia steelhead.

- **Oregon Management Unit:** ***Conservation and Recovery Plan for Oregon Steelhead Populations in the Middle Columbia River Steelhead Distinct Population Segment (Oregon Steelhead Recovery Plan) (Appendix A).***

- **Washington Gorge Management Unit:** ***Recovery Plans for the Klickitat River (Appendix B) and Rock Creek (Appendix C) subbasin populations of Middle Columbia River steelhead. NMFS also prepared a draft plan for the White Salmon River extirpated population; however, the final White Salmon recovery plan will be incorporated into the Lower Columbia River domain plan.***

- **Southeast Washington Management Unit:** ***Snake River Salmon Recovery Plan for Southeast Washington (Southeast Washington Plan) (Appendix D)***

- **Yakima Management Unit:** ***Yakima Steelhead Recovery Plan (Appendix E)***

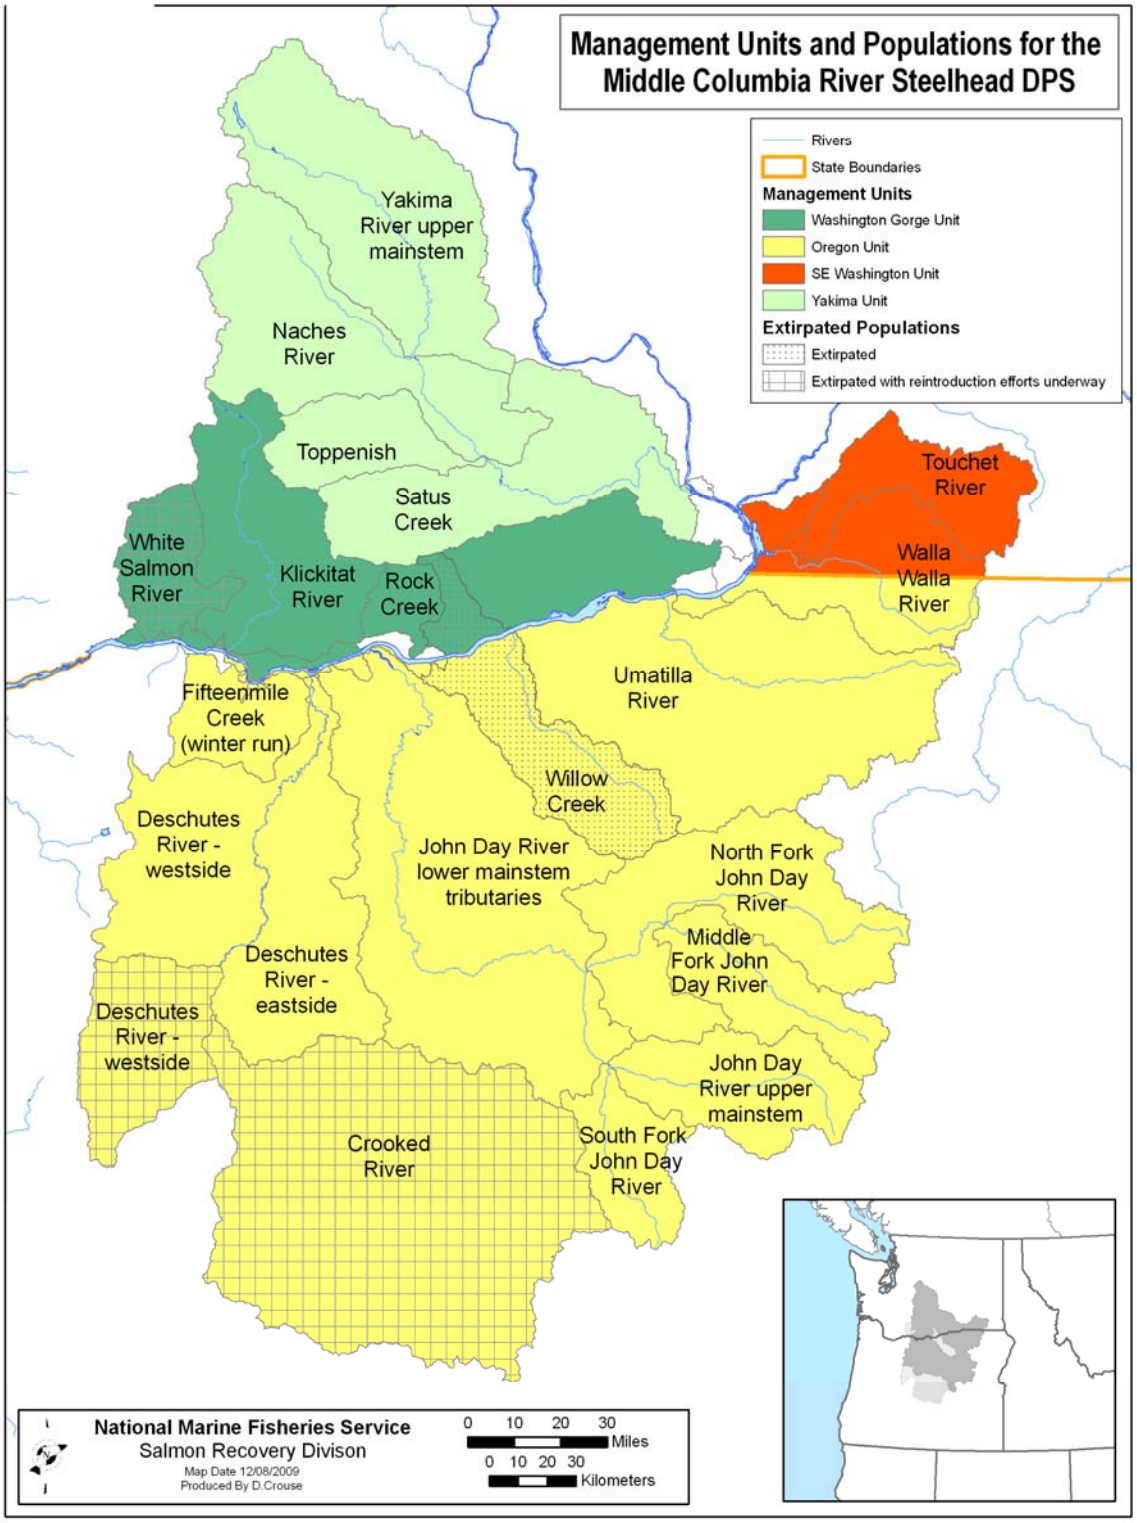

Figure 1-3. Management Units and Populations for the Middle Columbia River Steelhead DPS.

1.6.1 Oregon Steelhead Recovery Plan - Appendix A.

ODFW is the lead for the Conservation and Recovery Plan for Oregon Steelhead Populations in the Middle Columbia River Steelhead Distinct Population Segment (Oregon Steelhead Recovery Plan). ODFW drew together the Middle Columbia Recovery Planning Team, made up of ODFW staff biologists and representatives from eight other natural resource agencies, and a planning forum, the Mid-Columbia Sounding Board (MCSB). The MCSB is made up of representatives of local communities, agricultural water users, Federal and non-Federal land managers, governing bodies, Tribes, and industry and environmental interests. The role of the MCSB is to provide policy guidance in the development of all aspects of the plan and ensure locally appropriate and locally supported recovery actions needed to achieve species recovery goals. Population-specific management action development teams were drawn from the pool of natural resource agency staff on the Planning Team.

ODFW convened an "Expert Panel" of 12 biologists to examine limiting factors and threats for the 10 independent steelhead populations in Oregon. The recovery planning team also made its own evaluation. More detail on the Expert Panel process is available in the Oregon Steelhead Recovery Plan, Section 8, and in a report by the panel (Mid-Columbia Expert Panel 2006). The Oregon Steelhead Recovery Plan also drew on the relevant subbasin plans, ODEQ reports, NMFS' limiting factors modules, ODFW reports, and other sources.

Oregon Middle Columbia Steelhead Populations:
Fifteenmile Creek
Deschutes River Eastside
Deschutes River Westside
Deschutes/Crooked River (extirpated)
Lower Mainstem John Day
Upper Mainstem John Day
North Fork John Day
Middle Fork John Day
South Fork John Day
Umatilla River
Walla Walla River (also partially in Washington State)
Willow Creek (extirpated)

1.6.2 Washington Gorge Management Unit Recovery Plan (Appendices B and C)

The Washington Gorge Management Unit comprises three subbasins in south-central Washington: the areas drained by the Klickitat River, Rock Creek, and the White Salmon River. The steelhead populations in these subbasins are part of the Cascades Eastern Slope Tributaries major population group. The Washington Gorge Management Unit Recovery Plan (the Washington Gorge Plan) is actually made up of three separate plans, one for each subbasin. Since there is not presently a Washington-State sponsored salmon recovery planning board for this area, NMFS staff drafted the three plans in collaboration with the Yakama Nation, Washington Department of Fish and Wildlife, Klickitat County, the Washington State Governor's Salmon Recovery Office, other Federal agencies, state agencies, local governments, and the public.

The Columbia Gorge area within Washington State from Rock Creek east to Kennewick makes up Water Resource Inventory Area (WRIA) 31. The WRIA 31 planning unit is addressing steelhead habitat within the WRIA. The area contains Rock Creek and several smaller tributaries to the Columbia River with current and historical steelhead habitat. The ICTRT has designated steelhead in these smaller tributaries as part of the Willow Creek and Umatilla populations of the Middle Columbia steelhead DPS; however, there is very little further information currently available and no recovery plan was developed for them (see Appendix A to the Rock Creek management unit plan).

The Klickitat basin is in WRIA 30. The WRIA 30 planning unit is addressing steelhead habitat by reviewing water quality proposals developed primarily to fix flow and temperature problems in the Klickitat basin external to the Yakama Reservation. This recovery plan and the Klickitat Recovery Plan may be used by the WRIA 30 planning unit to help guide the review of proposals considered for funding.

The White Salmon River supported an historical population of Middle Columbia River steelhead, which was extirpated from its historical range in 1913 by the construction of Condit Dam at river mile 3.4. Condit Dam is scheduled for removal in 2010. In addition to steelhead, single populations of three listed ESUs of salmon (Lower Columbia River Chinook, Lower Columbia River Coho, and Columbia River Chum) spawn in the White Salmon River subbasin. The need for an ecosystem approach warrants addressing in one single plan all the listed salmonids that spawn in the White Salmon subbasin; for that reason, the White Salmon plan will be finalized as part of the Lower Columbia ESA Recovery Plan, scheduled to be completed in 2010. However, the delisting criteria, actions, and costs for Middle Columbia River steelhead in the White Salmon subbasin are included in this DPS plan in order to have all the information on the Middle Columbia DPS in one place.

Washington Gorge Steelhead Populations:
Rock Creek
Klickitat
White Salmon (functionally extirpated)[15]

1.6.3 Southeast Washington Plan (Appendix D)

The Snake River Salmon Recovery Board (SRSRB) developed the recovery plan for the Southeast Washington management unit, and entitled it the *Snake River Salmon Recovery Plan for Southeast Washington.* This plan is called the Southeast Washington Plan here in order to differentiate it from the forthcoming recovery plan for the five species of listed salmon and steelhead in the Snake River region (which includes parts of Washington, Oregon, and Idaho). The SRSRB is made up of government and tribal representatives, landowners, and private citizens, funded through the Washington Salmon Recovery Fund. The Board appointed a Regional Technical Team for technical and scientific assistance. In March 2006, NMFS accepted the SRSRB Plan, in combination with a NMFS Supplement regarding the Plan, as an Interim Regional Recovery Plan (March 14, 2006, 71 FR 13094).

[15] The ICTRT considers extirpated populations to be those that are entirely cut off from anadromy. Functionally extirpated populations are those of which there are so few remaining numbers that there are not enough fish or habitat in suitable condition to support a fully functional population.

Southeast Washington Steelhead Populations:
Walla Walla River (also partially in Oregon)
Touchet River

1.6.4 Yakima Steelhead Recovery Plan (Appendix E)

The Yakima Subbasin Fish and Wildlife Planning Board (YSPB) submitted the Draft Yakima Subbasin Salmon Recovery Plan to the Washington State Governor's Salmon Recovery Office on October 26, 2005. In May 2006, NMFS accepted the draft YSPB plan, in combination with a NMFS Supplement regarding the plan, as an Interim Regional Recovery Plan (May 3, 2006, 71 FR 26052). On April 5, 2006, the Yakima Subbasin Fish and Wildlife Planning Board and the Yakima River Basin Salmon Recovery Board were both dissolved by board resolutions. Their functions were then taken on by a new organization, the Yakima Basin Fish and Wildlife Recovery Board (YBFWRB), which includes representatives from the Yakama Nation, Benton, Kittitas, and Yakima counties, and 18 of the 24 municipalities in the Yakima Basin. Since the formation of the YBFWRB, revisions have been made to the original October 2005 draft to incorporate new information, improve clarity, and address issues identified in the NMFS supplement and comments received in response to publication in the Federal Register. A revised and updated portion of the draft plan, the Yakima Steelhead Recovery Plan, focuses on steelhead recovery needs, and was submitted to NMFS in early 2008 for inclusion in this Middle Columbia Steelhead Recovery Plan. (For more information see www.ybfwrb.org).

Yakima Basin Steelhead Populations:
Satus Creek
Toppenish Creek
Naches River
Upper Yakima River

1.7 Recovery Planning Modules

NMFS prepared two recovery planning "modules" to address system effects that transcend the geographic boundaries of individual subbasins, recovery domains, or management units. The modules provide detailed information on Columbia mainstem and estuary, through which Middle Columbia steelhead and other anadromous salmonids must pass as juveniles and returning adults.

1.7.1 Hydro Module

The Hydro Module summarizes the general effects of Columbia River mainstem hydropower projects on all 13 ESA-listed salmonids in the Columbia basin, including the limiting factors and threats and expected actions (including site-specific management actions), or strategy options, to address those threats. This module supports recovery plans for the Snake River, Upper Columbia, Middle Columbia, Lower Columbia, and Upper Willamette River species. It is a synthesis of information that has undergone public processes for review, including, but not limited to, the Federal Columbia River Power System (FCRPS) 2008 Biological Opinion, Federal Energy Regulatory Commission (FERC) licensing proceedings, and Habitat Conservation Plans (HCPs). This module may be updated as additional information becomes available.

1.7.2 Estuary Module

The Estuary Module, which NMFS prepared in collaboration with the Lower Columbia Estuary Partnership, focuses on habitat in the lower Columbia River below Bonneville Dam and how that habitat affects the survival of ESA-listed chum, steelhead, Chinook, and coho from throughout the Columbia River basin. It identifies and prioritizes limiting factors and threats in the estuary, then identifies 23 broad actions whose implementation would reduce the threats and thus increase survival of salmon and steelhead during their time in the estuary. The module also estimates the cost of implementing each action over a 25-year period. A description of monitoring, research, and evaluation needs that are appropriate to the management actions is included as an appendix to the module.

1.8 Tribal Trust and Treaty Responsibilities

Northwest Indian Tribes have legally enforceable rights reserving to them a share of the salmon harvest. In the Treaties of 1855 between the U.S. government and the Confederated Tribes of the Warm Springs Reservation of Oregon, the Confederated Tribes and Bands of the Yakama Indian Nation, the Confederated Tribes of the Umatilla Indian Reservation, and the Nez Perce Tribe, the tribes, in exchange for the preponderance of their lands, reserved the rights to fish within their reservations and "at all other usual and accustomed places." The usual and accustomed places are understood to include the millions of acres of aboriginal land ceded to the United States in the 1855 treaties, which extends to the Upper Columbia and Snake River basins, and includes most of the geographic range of the Middle Columbia steelhead DPS. A complex history of treaties, executive orders, legislation, and court decisions have culminated in the recognition of tribes as co-managers who share management responsibilities and rights for fisheries in the Columbia Basin.

Achieving the basic purpose of the ESA (to bring the species to the point that it no longer needs the protection of the Act) may not by itself fully meet these rights and expectations, although it will lead to major improvements in the current situation. Ensuring a sufficient abundance of salmon to sustain harvest can be an important element in fulfilling trust and treaty rights as well as garnering public support for these plans. ESA and tribal trust responsibilities complement one another. Both depend on a steady upward trend toward ESA recovery and delisting in the near term, while making aquatic habitat, harvest, and land management improvements for the long term.

It is appropriate for recovery plans to take these considerations into account and plan for a recovery strategy that includes harvest. In some cases, increases in the naturally spawning populations may be sufficient to support harvest. In others, the recovery strategy may include appropriate use of hatcheries to support a portion of the harvest. So long as the overall plan is likely to achieve the recovery of the listed ESU/DPS, it will be acceptable as a recovery plan.

The NMFS Regional Administrator, in testimony before the U.S. Senate Indian Affairs Committee (June 2003), emphasized the importance of this co-manager relationship: "We have repeatedly stressed to the region's leaders, tribal and non-tribal, the importance of our co-management and trust relationship to the tribes. NMFS enjoys a positive working relationship

with our Pacific Northwest tribal partners. We view that relationship as crucial to the region's future success in recovery of listed salmon."

2. BIOLOGICAL BACKGROUND

This chapter summarizes the distribution, life history, and habitat needs of Middle Columbia River steelhead and reviews the basic concepts in salmonid biology needed to understand recovery goals and criteria.

2.1 Steelhead Distribution, Life History, and Habitat

The present distribution of steelhead extends from Kamchatka in Asia, east to Alaska, and down to southern California (NMFS 1999a), although the historical range of *O. mykiss* extended at least to the Mexico border (Busby et al. 1996). Middle Columbia River steelhead historically occupied nine major river systems and numerous minor systems on the east side of the Cascades Mountains within the states of Oregon and Washington (see previous Figure 1-1). These major tributaries to the Columbia River are the White Salmon, Deschutes, John Day, Klickitat, Umatilla, Walla Walla, and Yakima Rivers and Fifteenmile Creek and Rock Creek. The John Day River of central Oregon supports the largest naturally spawning, native group of steelhead in the region.

Four artificial propagation programs are considered part of the DPS: the Touchet River Endemic Summer Steelhead Program, the Yakima River Kelt Reconditioning Program, and the Umatilla River and Deschutes River steelhead hatchery programs.

The species *Oncorhynchus mykiss* exhibits perhaps the most complex suite of life history traits of any species of Pacific salmonid. These fish can be anadromous or freshwater residents (and under some circumstances, apparently yield offspring of the opposite form). Steelhead, the anadromous form of *O. mykiss*, are under NMFS jurisdiction, while the resident freshwater forms, usually called "rainbow" or "redband" trout, are under the jurisdiction of the U.S. Fish and Wildlife Service (see further discussion in Section 1.4 of this plan).

Steelhead can spawn more than once (iteroparous), whereas all other *Oncorhynchus* except cutthroat trout (*O. clarki*) spawn once and then die (semelparous). Iteroparity for Columbia Basin steelhead ranges from reported rates of 2-4 percent above McNary Dam (Busby et al. 1996) up to 17 percent in the unimpounded tributaries below Bonneville Dam (at RM 146.1) (Leider et al. 1986).

Within the range of West Coast steelhead, spawning migrations occur throughout the year, with seasonal peaks of activity. The "runs" are usually named for the season in which the peak occurs. Most steelhead can be categorized as one of two run types, based on their sexual maturity when they re-enter freshwater and how far they go to spawn. In the Pacific Northwest, summer steelhead enter freshwater between May and October and require several months to mature before spawning; winter steelhead enter freshwater between November and April with well-developed gonads and spawn shortly thereafter. Summer steelhead usually spawn farther upstream than winter steelhead (Withler 1966, Roelofs 1983, Behnke 1992). Winter steelhead are also called ocean-maturing or coastal type, and summer steelhead, stream-maturing or inland type.

The Middle Columbia River steelhead DPS includes the only populations of inland winter steelhead in the United States, in the Klickitat River, White Salmon River, Fifteenmile Creek, and possibly Rock Creek.[16]

Steelhead spawn in clear, cool streams with suitable gravel size, depth, and current velocity. They may spawn in intermittent streams that provide appropriate conditions for spawning and incubation (Barnhart 1986, Everest 1973). Productive steelhead habitat is characterized by complexity, primarily in the form of large and small wood. Steelhead may enter streams and arrive at spawning grounds weeks or even months before they spawn and are therefore vulnerable to disturbance and predation. They need cover, in the form of overhanging vegetation, undercut banks, submerged vegetation, submerged objects such as logs and rocks, floating debris, deep water, turbulence, and turbidity. Summer rearing takes place primarily in the faster parts of pools, although young-of-the-year are abundant in glides and riffles. Winter rearing occurs more uniformly at lower densities across a wide range of fast and slow habitat types (Bambrick et al. 2004) (Table 2-1). Depending on water temperature, steelhead eggs may incubate for 1.5 to 4 months before hatching.

Table 2-1. Key habitat requirements by life stage and time period for steelhead.

Life Stage	Relevant Months	Key Habitat Descriptions
Spawning	Mar-Jun	Riffles, tailouts, and glides containing a mixture of gravel and cobble sizes with flow of sufficient depth for spawning activity.
Incubation	Mar-Jun	Riffles, tailouts, and glides as described for spawning, with sufficient flow for egg and alevin development.
Fry Colonization	May-Jul	Shallow, slow velocity areas within the stream channel, often associated with stream margins.
Active Rearing	0-age May-Jul; 1-age, Mar-Oct; 2+-age, Mar-Oct	Gravel and cobble substrates with sufficient depth and velocity, and boulder/large cobble/wood obstruction to reduce flow and concentrate food.
Inactive Rearing	0,1-age Oct-Mar	Stable cobble/boulder substrates with interstitial spaces.
Migrant	1-age, Mar-Jun 2+-age, Mar-Jun	All habitat types having sufficient flow for free movement of juvenile migrants.
Prespawning Migrant	Winter, Nov-Apr Summer, All	All habitat types having sufficient flow for free movement of sexually mature adult migrants.
Prespawning Holding	Winter, Dec-May Summer, All	Relatively slow, deep-water habitat types typically associated with (or immediately adjacent to) the main channel.

Young steelhead typically rear in streams for some time before migrating to the ocean as smolts. Steelhead smolts have been shown to migrate at ages ranging from 1 to 5 years throughout the

[16] See Rock Creek Recovery Plan

Columbia Basin, but most steelhead generally smolt after 2 years in freshwater (Busby et al. 1996). Some juveniles move downstream to rear in larger tributaries and mainstem rivers.

Based on catch data, juvenile steelhead tend to migrate directly offshore during their first summer, rather than migrating nearer to the coast. Maturing Columbia River steelhead are found off the coast of Northern British Columbia and west into the North Pacific Ocean (Busby et al. 1996). Available fin-mark and coded-wire tag data suggest that winter steelhead tend to migrate farther offshore but not as far north into the Gulf of Alaska as summer steelhead (Burgner et al. 1992). At the time adults are (re-)entering freshwater, tagging data indicate that immature Columbia River steelhead are out in the mid-North Pacific Ocean.

Most steelhead spend 2 years in the ocean (range 1 to 4 years) before migrating back to their natal streams (Shapovalov and Taft 1954; Ward and Slaney 1988). Once in the river, steelhead apparently rarely eat and grow little, if at all. These combined behaviors produce fish that range between 3 and 7 years of age at the time of spawning.

2.2 DPS Biological Structure

Salmonid species' homing propensity (their tendency to return to the locations where they originated) creates unique patterns of genetic variation and connectivity that mirror the distribution of their spawning areas across the landscape. Diverse genetic, life history, and morphological characteristics have evolved over generations, creating runs highly adapted to diverse environments. It is this variation that gives the species as a whole the resilience to persist over time.

Historically, a salmon ESU or, as in this case, steelhead DPS typically contained multiple populations connected by some small degree of genetic exchange by straying spawners. Thus, the overall biological structure of the ESU/DPS is hierarchical; spawners in the same area of the same stream will share more characteristics than those in the next stream over. Fish whose natal streams are separated by hundreds of miles will have less genetic similarity. The ESU or DPS is essentially a metapopulation defined by the common characteristics of populations within a geographic range. Recovery planning efforts focus on this biologically based hierarchy (Figure 2-1).

McElhany et al. (2000) formally identified two levels in this hierarchy for recovery planning purposes: the evolutionarily significant unit (ESU) or distinct population segment (DPS) and the independent population. The ICTRT identified an additional level between the population and ESU/DPS levels, which they call a major population group (MPG) (McClure et al. 2003).

2.2.1 Distinct Population Segments

An ESU or DPS is a distinctive group of Pacific salmon or steelhead that is uniquely adapted to a particular area or environment. Because of the hierarchical structure of salmonid populations, the concept of "distinctive group" has received considerable attention and refinement. An ESU is defined as a group of Pacific salmon that is "substantially reproductively isolated from other conspecific units and represents an important component of the evolutionary legacy of the species" (Waples et al. 1991). A "population segment" is considered distinct (a DPS and hence, like ESUs, considered a "species" for purposes of conservation under the ESA) if it is discrete

from and significant to the remainder of its species based on factors such as physical, behavioral, or genetic characteristics, or if it occupies an unusual or unique ecological setting, or if its loss would represent a significant gap in the species' range. ESUs/DPSs may contain multiple populations that are connected by some degree of migration, and hence may have a broad geographic range across watersheds and river basins.[17]

2.2.2 Major Population Groups

Within an ESU/DPS, independent populations can be grouped into larger populations that share similar genetic, geographic, and/or habitat characteristics (McClure et al. 2003). These "major groupings" of populations (MPGs) are isolated from one another over a longer time scale than that defining the individual populations, but retain some degree of connectivity greater than that between ESUs/DPSs. The relationship between ESU/DPS, MPG, and independent populations is depicted in Figure 2-1.

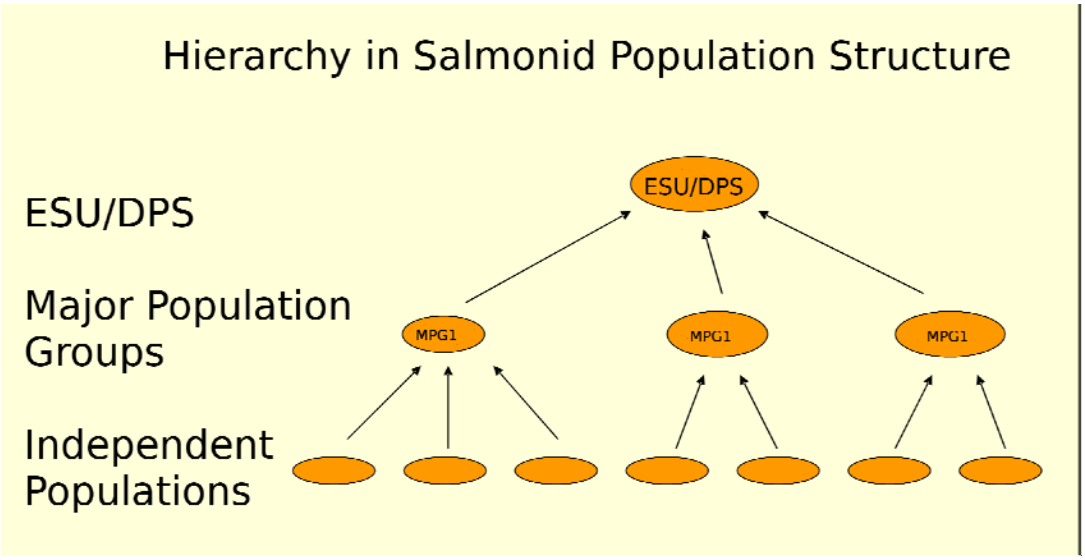

Figure 2-1 Hierarchical levels of salmonid species structure as defined by the TRTs for ESU/DPS recovery planning.

2.2.3 Independent Populations

McElhany et al. (2000) defined an independent population as follows:

> *"…a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season. For our purposes, not interbreeding to a 'substantial degree' means that two groups are considered to be independent populations if they are isolated to such an extent that exchanges of individuals among the populations do not*

[17] See Section 1.4 for discussion of the relationship of anadromous vs resident *O. mykiss.*

substantially affect the population dynamics or extinction risk of the independent populations over a 100-year time frame."

2.3 Middle Columbia River Steelhead MPGs and Populations

The ICTRT stratified the Middle Columbia River steelhead populations into MPGs based on ecoregion characteristics, life history types, and other geographic and genetic considerations. It identified four MPGs: Cascades Eastern Slope Tributaries, Yakima Basin, John Day Basin, and Umatilla/Walla Walla. The John Day River MPG is wholly within Oregon and the Yakima Basin MPG is wholly within Washington. The other two include populations on both sides of the Oregon/Washington boundary (see Figure 2-2). The management units that NMFS defined for planning purposes do not cross state boundaries; thus, the two bi-state MPGs have populations in different management units. The headwaters of the Walla Walla River are in Oregon and the river joins the Columbia in Washington, but the Walla Walla River steelhead are functionally one population, covered in two management unit plans.

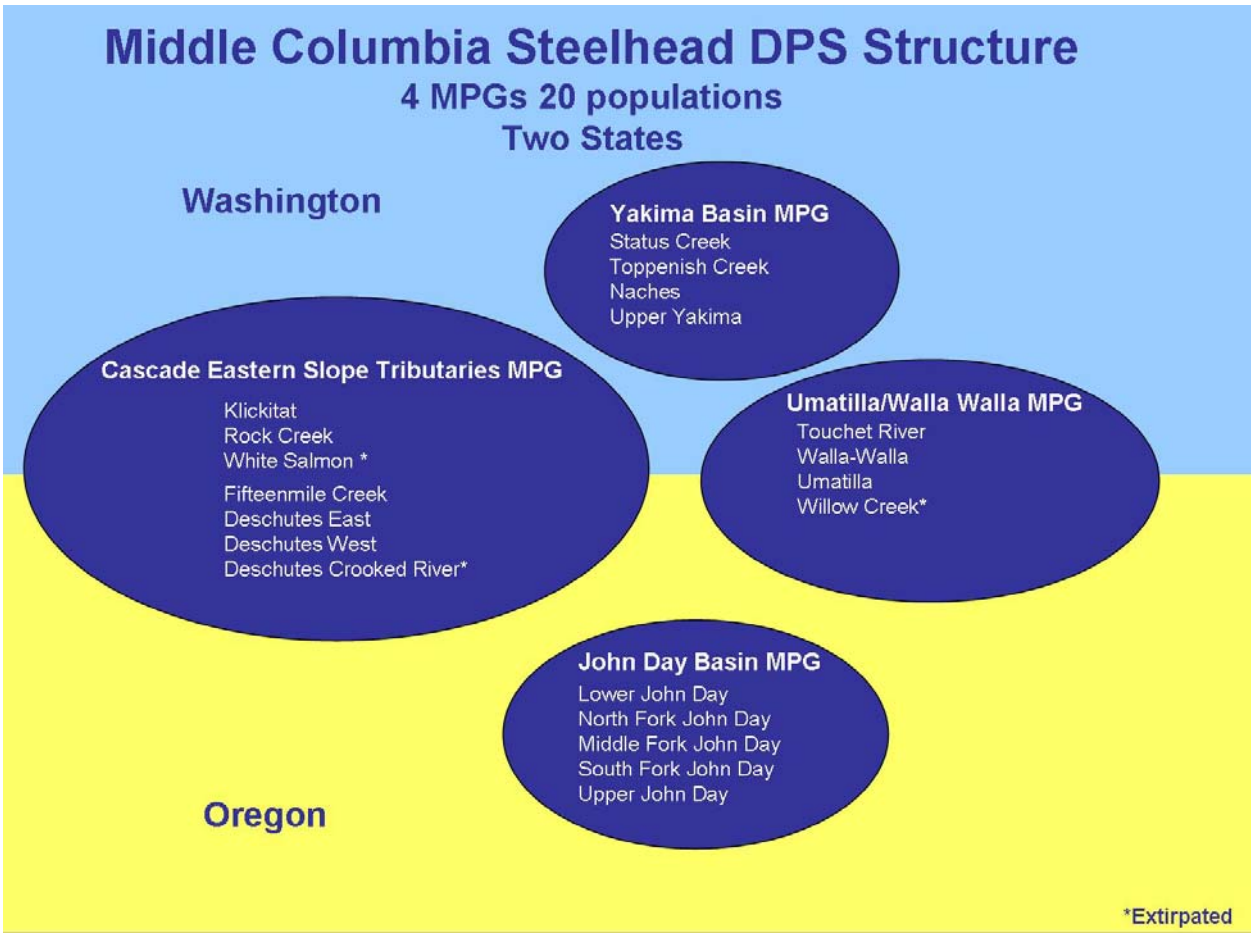

Figure 2-2 Middle Columbia Steelhead DPS Structure.

The ICTRT (McClure et al. 2003) identified 20 historical populations of Middle Columbia steelhead, shown in Figure 2-3. This identification was based on genetic information, geography, life history traits, morphological traits, and population dynamics. Seventeen of these populations

are extant, and three extirpated (White Salmon River, Deschutes Crooked River above Pelton Dam, and Willow Creek).

Three hatchery programs produce steelhead that are considered to be part of the DPS: the Round Butte hatchery program on the Deschutes River, the Umatilla River hatchery program, and the endemic summer steelhead program on the Touchet River (71 FR 834). In addition, a program to improve kelt (post-spawned adult) survival for the four Yakima Basin populations is also considered part of the DPS. Within the range of the Middle Columbia steelhead DPS, non-listed hatchery steelhead are released into the Klickitat basin, the Walla Walla (on the Washington side), the Touchet, and the White Salmon to support harvest.

2.3.1 Cascades Eastern Slope Tributaries MPG

The Cascades Eastern Slope Tributaries MPG includes three extant steelhead populations in Oregon and two in Washington, with one extirpated population in each state (Figure 2-3). This MPG has a geographically complex range, embracing one major river system – the Deschutes – and several smaller subbasins on both sides of the river. The Oregon populations are covered in the Oregon Steelhead Recovery Plan and the Washington populations in the Washington Gorge Management Unit plans. The Deschutes subbasin stretches over 10,700 square miles of land in central Oregon and covers 11 percent of Oregon's land area. Deschutes County, with the cities of Bend, Redmond, and Sisters, and Crook County, with Madras and Prineville, are among the fastest growing counties in the nation. The Confederated Tribes of Warm Springs Indian Reservation of approximately 641,000 acres includes several tributaries of the Deschutes and is bordered to the south and east by the mainstem Deschutes and the Round Butte dam complex. The Washington Gorge populations are in rural areas with agricultural development in the lowlands and forest uses in the uplands. The headwaters of the Klickitat River are within the Yakama Reservation.

2.3.2 John Day River MPG

The John Day River steelhead populations are currently managed entirely as wild populations. The John Day Basin is wholly within Oregon. The John Day River, which flows west from the Blue Mountains and then north through a deeply carved, basaltic landscape, is the second-longest free-flowing river in the continental United States. The towns within the subbasin with the largest populations are John Day, Prairie City, and Condon, all with less than 2000 residents. The largest tributary to the John Day River is the North Fork John Day, which originates in the Wallowa-Whitman National Forest in the Blue Mountains at elevations near 8000 feet. The North Fork John Day River flows westerly for 112 miles and joins the mainstem near Kimberly (RM 185), 15 miles below the town of Monument.

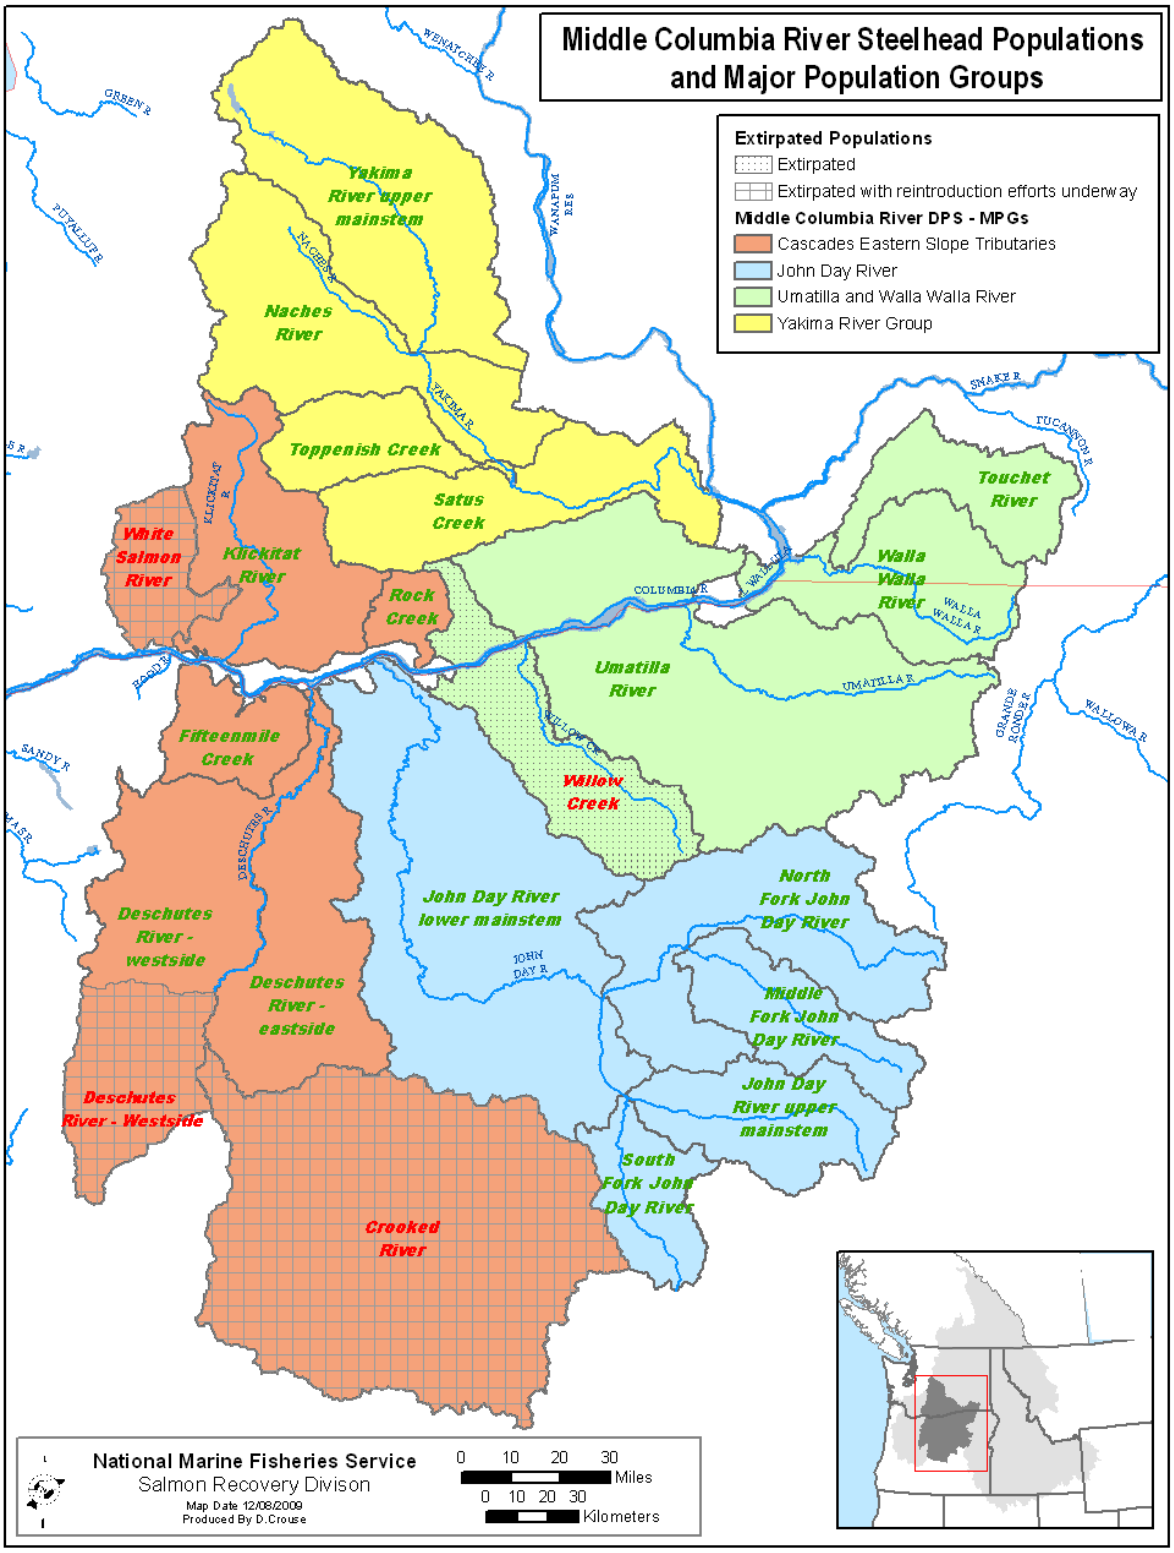

Figure 2-3 Middle Columbia River Steelhead Populations and Major Population Groups.

2.3.3 Umatilla/Walla Walla MPG

The Umatilla River is in Oregon, the Touchet River in Washington, and the Walla Walla River in both states. The Umatilla River originates in the Blue Mountains of northeastern Oregon and flows north and west to enter the Columbia River at river mile (RM) 289. The towns of Pendleton, Hermiston, and Umatilla are located along the Umatilla mainstem. The Confederated Tribes of the Umatilla Indian Reservation (CTUIR) comprises 271 square miles on both sides of the river. Aside from the towns, land use is mostly dryland and irrigated agriculture.

The Walla Walla River also originates in Oregon and flows northwest into Washington to join the Columbia, while the Touchet originates in the Blue Mountains on the Washington side and flows south and west into the Walla Walla. The river valley is extensively and intensively irrigated, with timber harvest in the high and mid elevations. Settlements include the city of Walla Walla, population 26,500, on Mill Creek, a tributary of the Walla Walla River, and the smaller towns of College Place, Dayton, and Waitsburg, Washington, and Milton Freewater, Oregon.

This MPG also includes several small tributaries (Chapman, Wood Gulch, Pine, Old Lady, Alder and Glade Creeks) located east of Rock Creek in Washington State that drain into the Columbia upstream of John Day Dam. The ICTRT has determined that four of these eastern Washington tributaries are minor spawning areas of the extirpated Willow Creek population – Pine Creek, Wood Creek, Old Lady Creek and Chapman Creek. Data needs to be collected regarding steelhead use in these small tributaries of the Columbia.

2.3.4 Yakima River MPG

The Yakima River MPG is wholly within Washington State. Cities and towns along the Yakima River include Cle Elum and Ellensburg in Kittitas County, Yakima and several smaller towns in Yakima County, and Prosser and Richland along the lower river in Benton County. The lowlands are extensively developed for irrigated agriculture, though significant amounts of complex floodplain habitat remain. Interstate highway 82 follows the river for about two-thirds of its length and scenic highways follow the Naches and Tieton rivers. The least developed areas are the uplands in the Eastern Cascade Mountains and the Satus Creek subbasin on the Yakama Indian Reservation. The population of the Yakima basin is approximately 300,000.

The Yakima subbasin is growing in population and most likely will continue to grow, and planners expect that the bulk of land use and development for future population growth will occur in proximity to the Yakima River mainstem and major tributary corridors where there is water, an existing core of rail and road transportation infrastructure, major concentrations of urban services, and high-value shoreline property.

Water storage and delivery systems have major impacts on the basin's hydrology. An extensive water supply system run by the Bureau of Reclamation's Yakima Irrigation Project stores and delivers water for over 400,000 acres of irrigated agriculture and, to a lesser degree, industrial, domestic, and hydropower use. Management of water storage and delivery systems results in streamflows across the subbasin that are often out of phase with the life history requirements of native salmonids (Fast et al. 1991; Stanford, Snyder et al. 2002) and riparian species such as cottonwoods (Braatne and Jamieson 2001).

2.4 Viable Salmonid Populations

NMFS scientists measure salmon recovery in terms of four parameters, called the viable salmonid population (VSP) parameters: abundance, productivity, spatial structure, and diversity (McElhany et al. 2000).

2.4.1 Abundance and Productivity

Abundance refers to spawners (adults on the spawning ground), measured over a time series, i.e. some number of years. The ICTRT often uses a recent 10- or 12-year geometric mean of natural spawners as a measure of current abundance.

The productivity of a population (the average number of surviving offspring per parent) is a measure of the population's ability to sustain itself. Productivity can be measured as spawner:spawner ratios (returns per spawner or recruits per spawner) (or adult progeny to parent), annual population growth rate, or trends in abundance. Population-specific estimates of abundance and productivity are derived from time series of annual estimates, typically subject to a high degree of annual variability and sampling-induced uncertainties. The ICTRT recommends estimating current intrinsic productivity using spawner-to-spawner return pairs from low to moderate escapements over a recent 20-year period.

Abundance and productivity are linked, as populations with low productivity can still persist if they are sufficiently large, and small populations can persist if they are sufficiently productive. A viable population needs sufficient abundance to maintain genetic health and to respond to normal environmental variation, and sufficient productivity to enable the population to quickly rebound from periods of poor ocean conditions or freshwater perturbations.

The VSP guidelines for abundance recommend that a viable population should be large enough to have a high probability of surviving environmental variation observed in the past and expected in the future; be resilient to environmental and anthropogenic disturbances; maintain genetic diversity; and support/provide ecosystem functions (McElhany et al. 2000).

Viable populations should demonstrate sufficient productivity to support a net replacement rate of 1:1 or higher at abundance levels established as long-term targets. Productivity rates at relatively low numbers of spawners should, on the average, be sufficiently greater than 1.0 to allow the population to rapidly return to abundance target levels (ICTRT 2005).

The ICTRT considers populations with fewer than 500 individuals at high risk for inbreeding depression and a variety of other genetic concerns (McClure et al. 2003). Because of this, it considers any population fewer than 500 individuals to be minimally viable, regardless of its intrinsic productivity.

Abundance should be high enough that 1) declines to critically low levels would be unlikely, assuming recent historical patterns of environmental variability and intrinsic productivity; 2) compensatory processes provide resilience to the effects of short-term perturbations; and 3) subpopulation structure is maintained (e.g., multiple spawning tributaries, spawning patches, life history patterns) (ICTRT 2005).

2.4.2 Spatial Structure and Diversity

Spatial structure and diversity considerations are combined in the evaluation of a salmonid population's status because they often overlap. A population's spatial structure is made up of both the geographic distribution of individuals in the population and the processes that generate that distribution (McElhany et al. 2000, p. 18). Diversity refers to the distribution of traits within and among populations. Some traits are completely genetically based, while others, including nearly all morphological, behavioral, and life history traits, vary as a result of a combination of genetic and environmental factors (ibid. p. 19).

Populations with restricted distribution and few spawning areas are at a higher risk of extinction as a result of catastrophic environmental events, such as a landslide, than are populations with more widespread and complex spatial structures. A population with a complex spatial structure, including multiple spawning areas, experiences more natural exchange of gene flow and life history characteristics.

Population-level diversity is similarly important for long-term persistence. Populations exhibiting greater diversity are generally more resilient to short-term and long-term environmental changes. Phenotypic diversity, which includes variation in morphology and life history traits, allows more diverse populations to use a wider array of environments, and protects populations against short-term temporal and spatial environmental changes. Underlying genetic diversity provides the ability to survive long-term environmental changes.

Because neither the precise role that diversity plays in salmonid population viability nor the relationship of spatial processes to viability is completely understood, the ICTRT adopted the principle from McElhany et al. that historical spatial structure and diversity should be taken as a "default benchmark," on the assumption that historical, natural populations did survive many environmental changes and therefore must have had adequate spatial structure and diversity.

2.5 Critical Habitat

The ESA requires the Federal government to designate "critical habitat" for any species it lists under the ESA. The Act defines critical habitat as areas that contain physical or biological features that are essential for the conservation of the species, and that may require special management or protection. Critical habitat designations must be based on the best scientific information available, in an open public process, within specific timeframes. On September 2, 2005 NMFS published a final rule (70 FR 52630, NMFS 2005b) to designate critical habitat for Middle Columbia River steelhead and 12 other ESUs/DPSs of salmon and steelhead (Figure 2-4). The final rule took effect on January 2, 2006.

A critical habitat designation does not set up a preserve or refuge, and critical habitat requirements do not apply to citizens engaged in activities on private land that do not involve a Federal agency. The designation applies only when Federal funding, permits, or projects are involved. Under section 7 of the ESA, all Federal agencies must ensure that any actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species, or destroy or adversely modify its designated critical habitat. Before critical habitat is designated, careful consideration must be given to its economic impacts, impacts on national security, and other relevant impacts. The Secretary of Commerce may exclude an area from

critical habitat if the benefits of exclusion outweigh the benefits of designation, unless excluding the area will result in the extinction of the species concerned.

For anadromous fish, the essential features of designated critical habitat include substrate, water quality, water quantity, water temperature, food, riparian vegetation, access, water, velocity, space, and safe passage. These features also describe the habitat factors associated with viability for all ESUs/DPSs. The specific habitat requirements for each ESU/DPS differ by life history type and life stage.

NMFS' Critical Habitat Assessment Review Team (Bambrick et al. 2004) rated the conservation value of all watersheds supporting populations of Middle Columbia River steelhead. The team identified the "primary constituent elements" of critical habitat for steelhead, i.e., the physical and biological elements that support one or more life stages and are considered essential to the conservation of the species (Table 2-2).

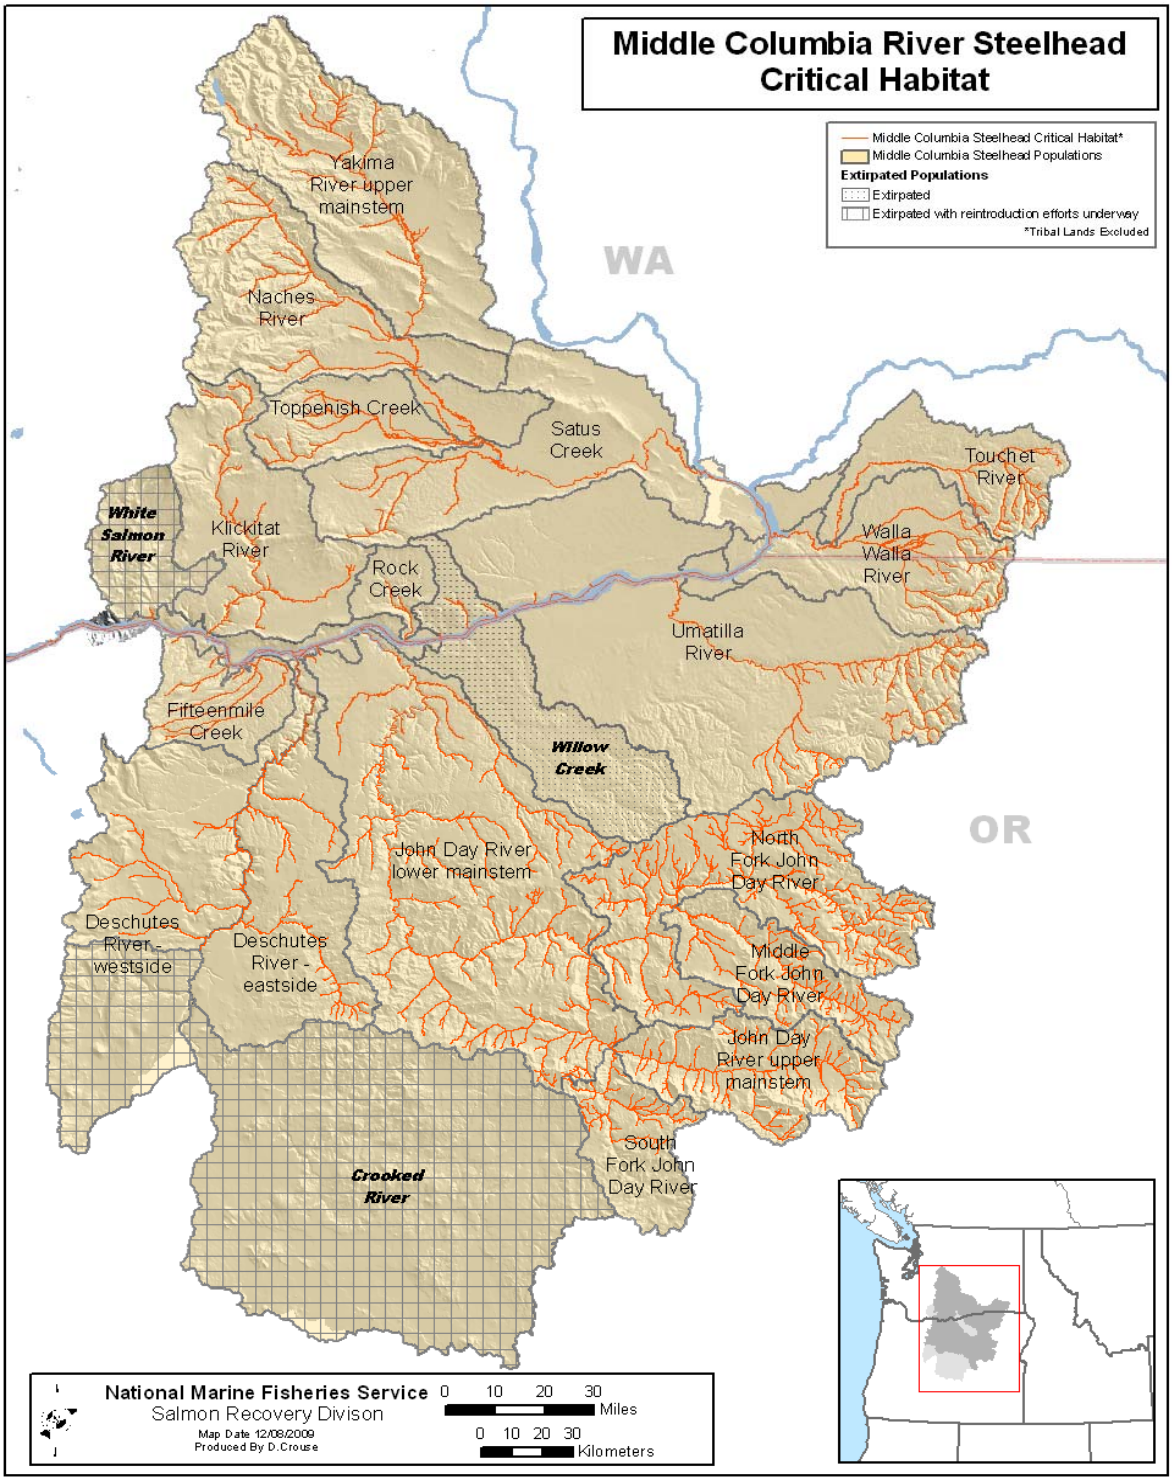

Figure 2-4. Middle Columbia Steelhead Critical Habitat[18] (NMFS 2005b)

[18] Critical habitat designation does not apply to the streams or stream reaches that are on tribal lands. However, the pattern of tribal vs nontribal ownership is too complex to differentiate at the scale of this map.

Table 2-2 Types of sites and essential physical and biological features designated as PCEs for steelhead, and the life stage each PCE supports.

Site	Essential Physical and Biological Features	ESU/DPS Life Stage
Freshwater spawning	Water quality, water quantity, and substrate	Spawning, incubation, and larval development
Freshwater rearing	Water quantity and floodplain connectivity	Juvenile growth and mobility
	Water quality and forage	Juvenile development
	Natural cover[a]	Juvenile mobility and survival
Freshwater migration	Free of artificial obstructions, water quality and quantity, and natural cover[b]	Juvenile and adult mobility and survival
Estuarine areas	Free of obstruction, water quality and quantity, and salinity	Juvenile and adult physiological transitions between salt and freshwater
	Natural cover,[a] forage,[b] and water quantity	Growth and maturation
Nearshore marine areas	Free of obstruction, water quality and quantity, natural cover,[a] and forage[b]	Growth and maturation, survival
Offshore marine areas	Water quality and forage[b]	Growth and maturation

[a] Natural cover includes shade, large wood, log jams, beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks.

[b] Forage includes aquatic invertebrate and fish species that support growth and maturation.

NMFS recognizes that salmon habitat is dynamic and that present understanding of areas important for conservation will likely change as recovery planning sheds light on areas that can and should be protected and restored, such as areas upstream of barriers where steelhead could be re-established into historical habitat. One example is the area upstream of Pelton Dam, of which the final rule designating critical habitat stated,

> " . . . the CHART agreed with the comments that areas upstream of Pelton Dam may be essential for this ESU as well, citing recent efforts to re-establish steelhead into historical habitat above this dam. However . . . at the present time we do not have information allowing us to determine that the specific areas within the geographical area occupied by the species are inadequate for conservation, such that we can make a determination that currently unoccupied areas above dams are essential for conservation. We will revise the designation if ongoing recovery planning indicates that specific areas above these dams warrant designation as critical habitat" (70 FR 52630, September 2, 2005, NMFS 2005a).

NMFS will update its critical habitat designations as needed, based on information developed during recovery plan implementation. Critical habitat designations are one element to consider in identifying and prioritizing recovery actions.

3. RECOVERY GOALS AND DELISTING CRITERIA

In this chapter we describe in greater detail the recovery goals in the management unit plans and the delisting criteria NMFS will use in future reviews of the Middle Columbia steelhead DPS. The recovery goals that are incorporated into a locally developed recovery plan may include delisting and other "broad sense" goals. The delisting criteria are a NMFS determination and may include both technical and policy considerations. Delisting criteria must meet the ESA requirements, while recovery may be defined more broadly. Broad sense recovery goals are goals defined in the recovery planning process that go beyond the requirements for delisting, to address, for example, other legislative mandates or social, economic, and ecological values. A third term used in this recovery plan is recovery "scenarios" (Section 3.3). Recovery scenarios are combinations of viability status for individual populations within the DPS that will meet the ICTRT criteria for overall DPS viability.

The ESA requires that recovery plans, to the maximum extent practicable, incorporate objective, measurable criteria which, when met, would result in a determination in accordance with the provisions of the ESA that the species be removed from the Federal List of Endangered and Threatened Wildlife and Plants (50 CFR 17.11 and 17.12). These criteria are of two kinds: the biological viability criteria, which deal with population or demographic parameters, and the "threats" criteria, which relate to the five listing factors detailed in the ESA (see Sections 1.1 and 3.3 of this Plan). The threats criteria define the conditions under which the listing factors, or threats, can be considered to be addressed or mitigated. Together these make up the "objective, measurable criteria" required under section 4(f)(1)(B) for the delisting decision.

The delisting criteria are based on the best available scientific information and incorporate the most current understanding of the DPS and the threats it faces. As this recovery plan is implemented, additional information will become available that can increase certainty about whether the threats have been abated, whether improvements in population and DPS status have occurred, and whether linkages between threats and changes in salmon status are understood. These criteria will be assessed through an adaptive management program under development for the Plan, and NMFS may review the criteria if appropriate during its 5-year reviews of the DPS.

For these status reviews, NMFS intends to rely strongly on the advice of the TRTs and recommendations of local recovery boards. However, NMFS has ultimate responsibility for final recovery plans and delisting decisions, and must take into account all relevant information, including, but not limited to, biological and policy considerations developed in the recovery planning process. NMFS has clarified, through Federal Register Notices on interim and proposed recovery plans, how it applies the TRT products to the plans (e.g., 71 FR 13094, Availability of ESA Draft Snake River Salmon Recovery Plan for Southeast Washington and Supplement to that draft; 71 FR 26052, Availability of Draft Yakima Subbasin Salmon Recovery Plan; 72 FR 57303, Adoption of ESA Recovery Plan for Upper Columbia Spring Chinook and Steelhead).

3.1 Biological Viability Criteria

In 2007, the ICTRT completed its Technical Review Draft of *Viability Criteria for Application to Interior Columbia Basin Salmonid ESUs* (ICTRT 2007a). Biological viability criteria are quantitative metrics that describe DPS characteristics associated with a low risk of extinction for

the foreseeable future. These criteria are based on the VSP parameters of abundance, productivity, spatial distribution, and diversity, according to guidelines developed by NOAA's Northwest Fisheries Science Center and published as a NOAA Technical Memorandum, *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units* (McElhany et al. 2000, ICTRT 2007a). The ICTRT calculated varying levels of risk of extinction and related the risk levels to their criteria.

3.1.1 DPS Viability Criterion

Since MPGs are geographically and genetically cohesive groups of populations, they are critical components of ESU/DPS spatial structure and diversity. Having all MPGs within an ESU/DPS at low risk provides the greatest probability of persistence for the ESU/DPS. The DPS viability criterion defined by the ICTRT (ICTRT 2007a) is as follows:

> **All extant MPGs and any extirpated MPGs critical for proper functioning of the ESU/DPS[19] should be at low risk.**

The ICTRT explains that the major objectives of the ESU/MPG-level viability criteria are to ensure preservation of basic historical metapopulation processes, including: 1) genetic exchange across populations within an ESU over a long time frame; 2) the opportunity for neighboring populations to serve as source areas in the event of local population extirpations; 3) populations distributed within an ESU so that they are not all susceptible to a specific localized catastrophic event. In addition, the presence of viable populations across MPGs would preserve a high level of diversity, promoting long-term evolutionary potential for adaptation to changing conditions (ICTRT 2007a; see also Section 2.4 of this plan, which explains the VSP parameters).

3.1.2 Major Population Group Viability Criteria

The ICTRT recommended MPG-level viability criteria that take into account the level of risk associated with the MPG's component populations (Figure 3-1). While individual populations meeting viability criteria are expected to have low risk of extinction, the MPG-level criteria ensure robust functioning of the metapopulation and provide resilience in case of catastrophic loss of one or more populations. MPG viability depends on the number, spatial arrangement, and diversity associated with its component populations. The ICTRT developed the following MPG-level criteria considering relatively simple and generalized assumptions about movement or exchange rates among individual populations. In developing these criteria, the ICTRT assumed that catastrophes do not increase dramatically in frequency, that populations are not lost permanently (because of catastrophe or anthropogenic impacts), and that permanent reductions in productivity, including long-term, gradual reductions in productivity, do not occur (ICTRT 2005).

[19] The Middle Columbia steelhead DPS has four extant and no extirpated MPGs. The three extirpated populations are addressed as part of the MPG-level criteria.

Major Population Group Viability Criteria (ICTRT 2007a)

The following five criteria should be met for an MPG to be regarded as at low risk (viable):

1. At least one-half of the populations historically within the MPG (with a minimum of two populations) should meet viability standards.

2. At least one population should be classified as "Highly Viable."

3. Viable populations within an MPG should include some populations classified (based on historical intrinsic potential) as "Very Large," "Large," or "Intermediate," generally reflecting the proportions historically present within the MPG. In particular, Very Large and Large populations should be at or above their composite historical fraction within each MPG.

4. All major life history strategies (e.g. spring and summer-run timing) that were present historically within the MPG should be represented in populations meeting viability requirements.

5. Remaining MPG populations should be maintained with sufficient abundance, productivity, spatial structure, and diversity to provide for ecological functions and to preserve options for ESU/DPS recovery.

Figure 3-1. Major Population Group Viability Criteria (ICTRT 2007a).

Specifically, the first criterion for one-half of the populations to meet "viability standards" refers to the "Viable" standard, or less than 5 percent risk of extinction within 100 years. In the second criterion, "Highly Viable" means less than 1 percent risk of extinction within 100 years. These criteria follow recommendations in McElhany et al. 2000. The presence of viable populations in each of the extant MPGs and some number of highly viable populations distributed throughout the DPS would result in sustainable production across a substantial range of environmental conditions. This distribution would preserve a high level of diversity within the DPS, and would promote long-term evolutionary potential for adaptation to changing conditions. The presence of multiple, relatively nearby, highly viable, viable, and maintained populations acts as protection against long-term impacts of localized catastrophic loss by serving as a source of re-colonization. These criteria are consistent with recommendations for other ESUs in the Pacific Northwest (e.g., McElhany et al. 2006, Ruckelshaus et al. 2002) (ICTRT 2007a).

3.1.3 Population-Level Viability Criteria

To be determined to be viable, populations should meet criteria for all four VSP parameters (abundance, productivity, spatial structure, and diversity). The abundance and productivity criteria are related to population size. The ICTRT developed criteria for characterizing the relative size and complexity of Interior Columbia Basin steelhead populations based on their analysis of the intrinsic or historical potential habitat available to the population (ICTRT 2005). This analysis used available Geographic Information System (GIS) data layers showing stream characteristics (e.g. channel width, gradient, valley confinement) and empirically derived relationships between habitat type, stream structure, landscape processes, and spawning. The ICTRT built a model that also incorporated information from local biologists and recovery planners to identify natural barriers to migration and other local variations (ICTRT 2007a).

Middle Columbia steelhead spawn in a wide range of tributary drainage areas, from small creeks, e.g. Fifteenmile Creek or Rock Creek, to very large rivers, such as the Lower John Day. The ICTRT categorized historical population sizes as Basic, Intermediate, Large, and Very Large, and set minimum abundance thresholds for viable steelhead populations of each type (Table 3-1). The abundance thresholds are associated with minimum productivity thresholds, based on modeling studies described in ICTRT 2007a and 2007b. As explained in Section 2.4.1, abundance and productivity are linked, within limits; above a certain threshold, higher productivity can compensate for lower abundance and vice versa.

Of the 20 Middle Columbia steelhead populations (including the three extirpated populations), five are categorized as Basic, eight as Intermediate, five as Large, and two as Very Large (ICTRT 2007a). Table 3-1 shows the minimum abundance and productivity thresholds for the Middle Columbia steelhead populations to have a 95 percent probability of persistence for the next 100 years.

Table 3-1. Abundance and Productivity Thresholds (ICTRT 2007).

Major Population Grouping	Population	Population Size	Abundance Threshold	Productivity Threshold
Cascades Eastern Slope Tributaries	White Salmon (functionally extirp.)	Basic	500	1.56
	Klickitat R.	Intermediate	1000	1.35
	Fifteenmile Cr.	Basic	500	1.56
	Deschutes R. East	Intermediate	1000	1.35
	Deschutes R. West	Large[1]	1500	1.26
	Rock Cr.	Basic	500	1.56
	Crooked River (Extirp.)	Very Large	2250	1.19
John Day River	Lower Mainstem JD	Very Large	2250	1.19
	North Fork John Day	Large	1500	1.26
	Middle Fork John Day	Intermediate	1000	1.35
	South Fork John Day	Basic	500	1.56
	Upper Mainstem JD	Intermediate	1000	1.35
Umatilla / Walla Walla Rivers	Umatilla R.	Large	1500	1.26
	Walla Walla R.	Intermediate	1000	1.35
	Touchet R.	Intermediate	1000	1.35
	Willow Crk. (Extirp.)	Intermediate	1000	1.35
Yakima River Group	Satus Cr.	Intermediate[20]	1000	1.35
	Toppenish Cr.	Basic	500	1.56
	Naches R.	Large	1500	1.26
	Upper Yakima	Large	1500	1.26

[1]This population is treated as Intermediate in size with respect to abundance and productivity criteria because of constraints to currently accessible habitat (i.e. Pelton Dam).

Abundance and productivity

[20] For the historical population analysis, the ICTRT included the mainstem Yakima habitat below the confluence of Satus Creek in the Satus Creek population, making it Intermediate in size. However, if the mainstem component is lumped instead with mainstem Yakima River habitat upstream of Satus, the Satus Creek population would drop to Basic size. The Yakima plan discusses this question in more detail in Section 4.1.1.

The ICTRT defined abundance and productivity criteria for Middle Columbia steelhead populations (ICTRT 2005 and 2007) based on analyses of the intrinsic potential of the historically available habitat, the locations and sizes of major and minor spawning areas, and, within these areas, the abundance and productivity relationships that would result in a probability of low risk of extinction within 100 years (see Table 3-1). The abundance "thresholds" shown in the table represent the number of spawners needed for a population of the given size category to achieve the 5 percent (low) risk level at a given productivity. Abundance thresholds are 500, 1000, 1500, and 2250 for population sizes of Basic, Intermediate, Large, and Very Large, respectively, with productivity of 1.56, 1.35, 1.26, and 1.19, respectively.

Spatial structure and diversity

Spatial structure and diversity criteria are more complex. The ICTRT cautions that there is a good deal of uncertainty in assessing the status of spatial structure and diversity in a population. These criteria are based on a set of biological goals and the mechanisms that achieve those goals, and are specific to each population.

The ICTRT defined two goals, or biological or ecological objectives, that spatial structure and diversity criteria should achieve:

- Maintaining natural rates and levels of spatially mediated processes. This goal serves (1) to minimize the likelihood that populations will be lost due to local catastrophe, (2) to maintain natural rates of recolonization within the population and between populations, and (3) to maintain other population functions that depend on the spatial arrangement of the population.

- Maintaining natural patterns of variation. This goal serves to ensure that populations can withstand environmental variation in the short and long terms (ICTRT 2007a).

3.1.4 Recovery Scenarios

Populations within the DPS are the units whose risk levels collectively determine MPG viability and the likely persistence of the DPS. The ICTRT recommended that all MPGs in an ESU/DPS should be viable before the ESU/DPS can be considered at low risk of extinction. However, it may not be necessary for all of the populations to attain low risk in order to provide sufficient viability for the DPS; the DPS-level viability criteria allow for some combination of risk status among the component populations. In other words, there is more than one way for an ESU/DPS to meet the viability criteria. The possible combinations of risk status for populations in each MPG that would allow the DPS to meet the viability criteria are called "recovery scenarios."

The ICTRT offered a detailed discussion of possible recovery scenarios for each MPG that would allow the DPS to meet the criteria (ICTRT 2007a). The ICTRT selected these combinations of risk status based on the populations' unique characteristics, such as run timing, population size, or genetics; major production areas in the MPG; and spatial distribution of the populations. Although the ICTRT criteria provide that at least one population in each MPG should reach Highly Viable status, the team did not indicate which population that should be, because of the uncertainties of any population's response to recovery efforts. The ICTRT cautioned against closing off the options for any population prematurely.

> Importantly, although not all populations in an MPG need to meet TRT viability criteria under most viable-MPG scenarios, it is strongly advisable to attempt to improve the status of more than the minimum number of populations to a low risk (viable) situation. There are two primary reasons for this: First, based on current population dynamic theory, the TRT has recommended that all extant populations be maintained with sufficient productivity that the overall MPG productivity does not fall below replacement (i.e. these areas should not serve as significant population sinks). Thus, it would be highly risky to allow the status of any population to degrade. In fact, many populations will need to be improved from their current status to be regarded as "maintained."
>
> Second, although the possible population sets suggested in [the ICTRT's] memo would meet TRT viability criteria for the ESUs, achieving recovery will likely require attempting recovery in more than just those populations because of the uncertainty of success of recovery efforts. A low risk strategy will thus target more populations than the minimum for viability (ICTRT 2007a).

Figure 3-2 shows how the ICTRT applied their MPG-level criteria to the 17 extant populations of the Middle Columbia River Steelhead DPS.

Figure 3-2. Recovery Scenarios: Application of ICTRT Viability Criteria to Middle Columbia River Steelhead MPGs: Options for Viability

MPG & Population	Size Category	Adult Life History Type	Role in Viability Scenario	Considerations
Cascades Eastern Slope MPG: Applying ICTRT viability criteria, for this MPG to be viable, four populations should meet viability criteria, and one should be highly viable.				
Klickitat River	Intermediate	Summer/Winter	Need for Viable status	Only summer/winter population in MPG, and is Intermediate
Fifteenmile Creek	Basic	Winter	Need for Viable status	Only winter population in MPG
Deschutes River East	Intermediate	Summer	Need for Viable status	Only Intermediate summer population
Deschutes River West	Large	Summer	Need for Viable status	Only extant Large population
Rock Creek	Basic	Summer	Maintain	Remaining population
White Salmon (functionally extirpated)	Basic	Summer/Winter		Functionally extirpated, blocked by a dam, abundant hatchery releases of Skamania stock
Crooked River (extirpated)	Very Large	Summer		

MPG & Population	Size Category	Adult Life History Type	Role in Viability Scenario	Considerations
John Day MPG: Applying ICTRT viability criteria, for this MPG to be viable, three populations should meet viability criteria, and one should be highly viable.				
Lower Mainstem John Day	Very Large	Summer	Need for Viable status	Only Very Large population – important for spatial structure because is the most downstream population
N. Fork John Day	Large	Summer	Need for Viable status	Only Large population – good candidate for highly viable because now at low risk. Also important to protect.
Middle Fork John Day	Intermediate	Summer	Option	Need one Intermediate population
Upper Mainstem John Day	Intermediate	Summer	Option	Need one Intermediate population
So. Fork John Day	Basic	Summer	Maintain	Remaining population

MPG & Population	Size Category	Adult Life History Type	Role in Viability Scenario	Considerations
Yakima River MPG: Applying ICTRT viability criteria, for this MPG to be viable, two populations should meet viability criteria, and one should be highly viable. In this case, the two viable populations could be BOTH Naches R. and Yakima Upper Mainstem, OR one of these and Satus Creek.				
Satus Creek	Intermediate	Summer	Option	Only Intermediate population
Naches River	Large	Summer	Option	Need one of two Large populations and one Intermediate OR both Large populations.
Yakima Upper Main	Large	Summer	Option	Need one of two Large populations and one Intermediate OR both Large populations. – This one would be good for spatial structure because it is at the upper end of drainage.
Toppenish Creek	Basic	Summer	Maintain	Remaining population

MPG & Population	Size Category	Adult Life History Type	Role in Viability Scenario	Considerations
Umatilla/Walla Walla MPG: Applying ICTRT viability criteria, for this MPG to be viable, two populations should meet viability criteria, and one should be highly viable.				
Umatilla River	Large	Summer	Need for Viable status	Only Large population
Walla Walla River	Intermediate	Summer	Option	Need one of two Intermediate populations – Walla Walla is now closer to meeting criteria than Touchet
Touchet River	Intermediate	Summer	Option	Need one of two Intermediate populations
Willow Creek (extirpated)	Intermediate	Summer		

3.2 Recovery Goals and Viability Criteria Adopted by Management Unit Plans

The management unit plans include locally determined recovery goals as well as viability criteria for the individual steelhead populations and MPGs in each management unit. All of the management unit plans used the ICTRT viability criteria and worked within the framework of the ICTRT-defined recovery scenarios. In some cases they set higher standards for one or more populations. Most of the plans also provide targets or objectives to measure progress within specified time frames, e.g. 10 to 50 years.

3.2.1 Oregon Steelhead Recovery Plan (Appendix A)

The Oregon Steelhead Recovery Plan for the Oregon portion of the Middle Columbia steelhead DPS states that the plan's primary goal is to support removal of the Middle Columbia Steelhead DPS from the threatened and endangered species list, and that this would require the Middle Columbia steelhead populations and MPGs in Oregon to reach the levels of biological viability defined by the ICTRT (Carmichael 2007).

3.2.1.1 Broad Sense Recovery Goal

The Oregon Steelhead Recovery Plan adds that a further goal, developed in collaboration with the Middle Columbia Sounding Board (described above in Section 1.6.1), is "to rebuild Oregon's Mid-C steelhead populations to levels that will provide for sustainable fisheries and other ecological, cultural, and social benefits . . . [incorporating] many of the traditional uses, as well as rural and Native American values, deemed important in the Pacific Northwest. . . . Recovery of Middle Columbia steelhead populations will require actions that preserve, enhance and restore healthy watershed conditions where ecosystem functions, processes and dynamics are intact ─ including instream conditions, riparian habitat diversity and complexity, and upland watershed health in concert with complementary management of harvest, hatcheries and hydropower. Recovery is a process that leads to steelhead populations that are not only viable, but that also provide a harvestable surplus for the treaty tribes and for all other citizens of the region" (ODFW 2007).

3.2.1.2 Recovery Objectives

The Oregon Steelhead Recovery Plan further states the following recovery objectives, to be achieved by the year 2050[21]:

"1. Middle Columbia steelhead are viable throughout the historical range and no longer need protection under the ESA;
"2. All currently extant Middle Columbia steelhead populations are highly viable;
"3. Extirpated populations (e.g. Willow Creek, Crooked River) are restored in a manner that engages landowner cooperation and does not subject landowners to ESA regulation based on the presence of previously extirpated populations until the introduced populations are self-sustaining and become part of the listed DPS;
"4. All extant populations of Middle Columbia steelhead are capable of contributing ecological, social, cultural, and economic benefits on a regular and sustainable basis;

[21] These objectives are in the Oregon Steelhead Recovery Plan. NMFS is not, by providing them here, committing itself to Oregon's interpretation of the applicability of ESA regulations to reintroduced steelhead in the upper Deschutes River basin, including the Crooked River.

"5. Working in concert with existing agreements and collaboratively with landowners and resource managers NOAA will define a suite of additional land and water resource management principles and practices that when followed will alleviate liability for possible ESA regulatory consequences to landowners and resource managers;
"6. Out-of-basin limiting factors are addressed equitably and in concert with in-basin limiting factors;
"7. Landowners, land managers and agencies are provided with guidance on the protection and management of habitats to promote the recovery of Middle Columbia River steelhead; and,
"8. Land and resource managers work with communities and other interests in a coordinated manner to achieve broad sense recovery through a shared vision of conservation where options and choices are preserved for future generations."

3.2.1.3 Viability Criteria

The Oregon Steelhead Recovery Plan adopts the ICTRT viability criteria for measuring progress toward delisting in terms of the four VSP parameters. Table 3-2 (Table 1-1 in Oregon Steelhead Recovery Plan Executive Summary) shows the minimum threshold abundance levels and minimum productivity required for Oregon Middle Columbia steelhead populations to achieve a 95 percent probability of persistence over 100 years.

Table 3-2. Oregon Mid-C steelhead population characteristics and minimum abundance and productivity values (at the threshold abundance level) needed to achieve a 95 percent probability of persistence over 100 years. (Source: ODFW 2009).

Population	Extant/ Extinct	Life History	Size	Threshold Abundance	Minimum Productivity
Fifteenmile Creek	Extant	Winter	Basic	500	1.56
Deschutes River E.	Extant	Summer	Intermediate	1,000	1.35
Deschutes River W.	Extant	Summer	Large (Inter.)[22]	1,500 (1,000)	1.35
Deschutes/Crooked	Extinct	Summer	Very Large	2,250	1.19
Lower Mainstem John Day R.	Extant	Summer	Very Large	2,250	1.19
North Fork John Day R.	Extant	Summer	Large	1,500	1.26
Middle Fork John Day R.	Extant	Summer	Intermediate	1,000	1.35
South Fork John Day R.	Extant	Summer	Basic	500	1.56
Upper Mainstem John Day R.	Extant	Summer	Intermediate	1,000	1.19
Willow Creek	Extinct	Summer	Intermediate	1,000	1.35
Umatilla River	Extant	Summer	Large	1,500	1.26
Walla Walla River	Extant	Summer	Intermediate	1,000	1.35

3.2.1.4 Recovery Scenario

The Oregon Steelhead Recovery Plan sets a higher standard for Oregon populations than the minimum identified by the ICTRT for DPS viability. Several scenarios or combinations of populations would satisfy the MPG-level viability criteria for the three MPGs containing Oregon Middle Columbia steelhead populations. But the Oregon Steelhead Recovery Plan states that "targeting only the minimum number of populations would likely result in failure to achieve our

[22] Large size category is for historically accessible area; intermediate size category is for currently accessible area.

goals," because of the uncertainty involved in predicting the biological response to management actions intended to aid recovery. "To hedge against this uncertainty, more than the minimum number of populations must be targeted for viable status. Therefore, we also seek to improve other extant Oregon populations to be maintained at sufficient levels to provide for ecological functions and to preserve options for DPS recovery" (ODFW 2009).

The following are the Oregon Steelhead Recovery Plan's delisting recommendations[23] for the three MPGs with Middle Columbia steelhead populations in Oregon:

Cascades Eastern Slope Tributaries MPG
To achieve viable status for this MPG, the Fifteenmile Creek, Deschutes River Eastside, Deschutes River Westside, and Klickitat populations must all achieve viable status. One of these populations must be highly viable. The Rock Creek population must be maintained.

John Day River MPG
To achieve viable status for this MPG, the Lower Mainstem John Day River, North Fork John Day River, and either the Middle Fork John Day River or Upper Mainstem John Day River populations must achieve viable status. One of these populations must be highly viable. The South Fork John Day River population must be maintained.

Umatilla/Walla Walla River MPG
To achieve viable status for this MPG, the Umatilla River population and either the Walla Walla River or Touchet River population must achieve viable status. One of these populations must be highly viable. All remaining extant populations must be maintained.

3.2.2 Washington Gorge Management Unit Plans (Appendices B and C)

The Klickitat River Plan's primary goal is to restore the Klickitat steelhead population to viable status and thus to support recovery of the Middle Columbia steelhead DPS (Appendix B). The Rock Creek Plan's primary goal is to achieve "maintained" status for the Rock Creek population as part of attaining viable status for the Cascades Eastern Slope Tributaries MPG (Appendix C). The White Salmon Plan's goal is to re-establish the White Salmon River population so that it can contribute to the conservation and survival of the DPS.

3.2.2.1 Broad Sense Recovery Goal

If a Washington Gorge Area regional recovery planning organization is created, it would have the option of developing broad sense goals for the area in a collaborative process with diverse stakeholders. In the meantime, the Yakama Nation has proposed, as a broad sense goal for the Klickitat steelhead population, the achievement of "highly viable" status, which corresponds to a one percent risk of extinction in a 100-year period. Achieving highly viable status for the population would provide for long-term, sustainable harvest and other social, cultural, and ceremonial needs, although it would likely exceed the minimum necessary to support delisting the DPS.

[23] The delisting decision is NMFS' responsibility, as described in Section 3.5.

3.2.2.2 Recovery Objectives

At this time NMFS is simply providing proposed ICTRT viability criteria for the Klickitat and Rock Creek populations.

3.2.2.3 Viability Criteria

The Klickitat and Rock Creek plans adopt the ICTRT viability criteria for their respective populations. The White Salmon plan recommends recovering the White Salmon extirpated population to viable status when passage is restored.

Klickitat Subbasin Recovery Plan (Appendix B): The ICTRT-recommended minimum abundance threshold for the Klickitat steelhead population to meet the criterion of a 5 percent or less risk of extinction over a 100-year time frame is 1000 naturally produced spawners at 1.3 spawner/spawner ratio. Regarding spatial structure and diversity, the Plan recommends research on the extent of the impacts of an outside stock (i.e. Skamania stock) hatchery program on natural spawning areas in the subbasin, and reducing these impacts if they are found to be substantial.

Rock Creek Subbasin Recovery Plan (Appendix C): The ICTRT-recommended minimum abundance threshold for the Rock Creek steelhead population to meet the criterion of a 5 percent or less risk of extinction over a 100-year timeframe is 500 naturally produced spawners. The current steelhead range in the Rock Creek watershed is believed to generally resemble the historical condition; therefore, the plan recommends maintaining current spatial structure.

White Salmon Subbasin Recovery Plan (to be included in the Lower Columbia River ESA Recovery Plan): The White Salmon steelhead population was functionally extirpated by the construction of Condit Dam. The dam is scheduled to be removed in 2010. The ICTRT recognizes that recovering this functionally extirpated population to a viable level may not be necessary to achieve viability at the MPG and DPS levels (ICTRT 2007a). When the dam is removed, the Plan recommends that this population eventually be recovered to a minimum abundance threshold of 500 spawners.

3.2.2.4 Recovery Scenario

The Klickitat and Rock Creek plans adopt the ICTRT-recommended scenario for their respective populations, i.e. to achieve viable status for the Klickitat population and maintained status for Rock Creek. The White Salmon plan recommends recovering the White Salmon extirpated population to viable status when passage is restored.

3.2.3 Southeast Washington Plan (Appendix D)

The Snake River Salmon Recovery Board (SRSRB) "defined salmon recovery at two levels: recovery and restoration. Recovery is defined as meeting ESA de-listing requirements based on VSP criteria. The goal of restoration is attainment of conditions that provide increased harvest opportunity for local communities and Tribes, thereby meeting [tribal] trust and treaty rights, as well as fisheries mitigation objectives for mainstem dams."

3.2.3.1 Broad Sense Goal

For the Southeast Washington plan, the equivalent of a broad sense goal is what this plan calls "restoration." Restoration means not simply harvestable levels of steelhead but also "a healthy ecosystem that fulfills the requirements of the key species and the people of the recovery region . . . [with] adequate and appropriate habitat for all salmonid life stages and free access to that habitat." Harvest must be at sustainable levels, hatcheries must contribute to recovery with minimal risk, and hydrosystems must not jeopardize the continued existence of the species.

The plan summarized restoration goals for abundance that were proposed by various agencies and Tribes, which include both naturally produced and hatchery returns (see Table 5-12, SRSRB Plan). Fisheries co-managers and the SRSRB are currently still in discussion regarding these longer-term goals.

3.2.3.2 Recovery Objectives – Planning Targets

The SRSRB set "short-term" (15-year) recovery planning targets for the Walla Walla and Touchet populations of the Walla Walla/Umatilla MPG, based on the ICTRT's viability curves for those populations. Both populations are classified as Intermediate size, and therefore their recovery goal is 1000 spawners each, with 1.35 spawner:spawner ratio.

The management unit plan also established general planning targets for spatial structure and diversity, as follows:

1. Where possible, expand current spawning distributions to match the historical condition as defined by the Major Spawning Areas in each subbasin.
2. Develop populations that are separated spatially so that risks due to catastrophic events are reduced.
3. Increase, insofar as the historical patterns can be reconstructed, the similarity between current and historical patterns of juvenile rearing distribution, habitat usage, and life history types.

The SRSRB plan also sets specific targets for habitat improvements, including criteria for such factors as large woody debris, riparian condition, water temperature, and channel confinement (Chapter 7, SRSRB Plan).

3.2.3.3 Viability Criteria

The SRSRB Plan used the ICTRT viability curves for each population to determine abundance and productivity values needed for delisting and also to identify the values needed for restoration of the populations under improved habitat conditions.

3.2.3.4 Recovery Scenario

The Southeast Washington Plan accepts the ICTRT recovery criteria and thus supports the scenario shown in Figure 3-1, which indicates that either the Walla Walla or Touchet Middle Columbia steelhead population should reach viable status for delisting. However, the SRSRB's long-term restoration goal is to achieve a healthy ecosystem that supports viability for both steelhead populations.

3.2.4 Yakima Steelhead Recovery Plan (Appendix E)

The Yakima Steelhead Recovery Plan was submitted to NMFS by the YBFWRB to address recovery issues for the Yakima MPG of Middle Columbia steelhead (see Section 1.6.4). This plan states that its "overall goal . . . is to ensure long-term persistence of viable populations of naturally produced steelhead distributed across their native range."

3.2.4.1 Broad Sense Recovery Goal

The Yakima Steelhead Recovery Plan sets a long-term, or broad sense, recovery goal to increase the abundance and productivity of Yakima Basin steelhead populations to levels that allow for harvest for recreational, commercial, and ceremonial purposes. This goal is articulated in the YBFWRB's Vision 2020 statement (Section 1.2 of the Yakima Steelhead Recovery Plan), which describes, in general terms, desired future conditions for the Yakima basin:

> *Yakima River basin communities have restored the Yakima River basin sufficiently to support self-sustaining and harvestable populations of indigenous fish and wildlife while enhancing the existing customs, cultures, and economies in the basin. Decisions that continuously improve the river basin ecosystem are made in an open and cooperative process that respects different points of view and varied statutory responsibilities and benefits current and future generations.*

3.2.4.2 Recovery Objectives/Scenarios

The Yakima Steelhead Recovery Plan defines three "thresholds" for assessing progress toward recovery: thresholds for ESA delisting, short-term recovery, and long-term (broad sense) recovery. As used in the Yakima Steelhead Recovery Plan, "threshold" combines two concepts that are differentiated in this DPS plan, i.e. recovery objectives and recovery scenario. The YBFWRB sees these three thresholds as points on a continuum and expects recovery actions to continue after delisting, even without the immediate motivation of the ESA. The long-term goals are less definite, but are meant to affirm that the Board and its partners believe that long-term recovery to significantly higher abundance levels is both feasible and desirable.

The delisting threshold is based on the ICTRT's MPG viability criteria: one population should be viable, one highly viable, and two should be at "maintained" status or better. The YBFWRB expected that the Satus population would be most likely to achieve "highly viable" status, the Naches population "viable," and the Toppenish and Upper Yakima populations "maintained."

The short-term recovery threshold also is based on the ICTRT criteria, but with continuing recovery actions, all four populations would be expected to achieve viable status. This would significantly reduce overall risk to the MPG.

The long-term recovery threshold is, as described above, a stable, long-term condition in which wild steelhead in the Yakima Basin are thriving and harvestable, based on restored access to as many of the historically accessible stream reaches as is consistent with the Board's commitment to sustaining local customs and economies.

3.2.4.3 Viability Criteria

The Yakima Steelhead Recovery Plan defines abundance and productivity criteria for the delisting, short-term, and long-term thresholds in terms of the ICTRT's viability criteria, as shown in Table 3-3.

Table 3-3 Yakima Steelhead Populations Abundance and Productivity Criteria (Source: Executive Summary, Yakima Steelhead Recovery Plan).

	Delisting Threshold		Short-Term Recovery		Long-term Recovery	
Population	**Avg. #**	**Prod.**	**Avg. #**	**Prod.**	**Avg. #**	**Prod.**
Satus: Satus Watershed[24] Mainstem Block	 500 500	 2.00[25] 1.65	 500 500	 1.56 1.56	 2,000	 1.2 1.2
Toppenish	250	1.2	500	1.56	1,500	1.2
Naches	1,500	1.26	1,500	1.26	5,400	1.2
Upper Yakima	500	1.2	1,500	1.26	7,700	1.2
Total	***3,250***		***4,500***		***16,600***	

The Yakima Steelhead Recovery Plan presents spatial structure and diversity criteria for the four Yakima steelhead populations. The spatial structure criteria are more complex, since several important historical spawning areas are either no longer accessible to steelhead or no longer feasible for spawning.

Satus
Naturally produced steelhead will occupy both major spawning areas in the Satus watershed (Satus and Dry Creek MSAs) and the Mule Dry minor spawning areas. Consistent spawning must occur in both major spawning areas.

Toppenish
Naturally produced steelhead will occupy both of the major spawning areas in the Toppenish watershed (upper Toppenish and Simcoe). Consistent spawning must occur in both major spawning areas.

Naches
Naturally produced steelhead will occupy at least seven of the eight major spawning areas for the delisting and short-term recovery thresholds. For the long-term recovery threshold, all eight will

[24] For its historical population analysis, the ICTRT included the mainstem Yakima habitat below the confluence of Satus Creek in the Satus Creek population, and therefore classified the Satus population as Intermediate in size. However, if the potential mainstem component is lumped instead with mainstem Yakima River habitat upstream of Satus, the population in the Satus Creek watershed alone would be Basic size. The Yakima plan discusses this question in more detail in Section 4.1.1.

[25] The Yakima Steelhead Recovery Plan calls for managing the Satus population in two blocks: the tributary block treated as a Basic population with the goal of high viability and the mainstem block treated with a simple abundance target that can be met within that portion of the mainstem Yakima or by additional production above and beyond the abundance targets for other areas.

be occupied. Consistent spawning must occur within the Naches mainstem, Ahtanum Creek, and Rattlesnake Creek to maintain distribution across habitat types and life histories.

Upper Yakima
Naturally produced steelhead will occupy at least 10 of the 14 major spawning areas for the delisting and short-term recovery thresholds. For the long-term recovery threshold, 12 of 14 MSAs will be occupied. Spawning must consistently occur within at least the Yakima mainstem, Umtanum Creek, Swauk Creek, Manashtash Creek, Taneum Creek and the Teanaway River (West and North Teanaway MSA and Lower Teanaway minor spawning area). While passage at Cle Elum, Kachess and/or Keechelus Dams is not specifically required to meet this threshold, providing passage can play an important role.

The diversity goal for all thresholds is to maintain and enhance both phenotypic (morphology, behavior, and life history traits) and genotypic diversity while limiting introgression of non-local genes.

3.3 Listing Factors/Threats Criteria

Listing factors are those features that are evaluated under section 4(a)(1) when initial determinations are made whether to list species for protection under the ESA. "Threats," in the context of salmon recovery, are understood as the activities or processes that cause the biological and physical conditions that limit salmon survival (the limiting factors). "Threats" also refer directly to the listing factors detailed in section 4(a)(1) of the ESA.

ESA section 4(a)(1) listing factors are the following:

A. Present or threatened destruction, modification, or curtailment of [the species'] habitat or range;
B. Over-utilization for commercial, recreational, scientific, or educational purposes;
C. Disease or predation;
D. Inadequacy of existing regulatory mechanisms; or
E. Other natural or human-made factors affecting [the species'] continued existence.

At the time of a delisting decision for the Middle Columbia steelhead, NMFS will examine whether the section 4(a)(1) listing factors have been addressed. To assist in this examination, NMFS will use the listing factors (or threats) criteria described below, in addition to evaluation of biological recovery criteria and other relevant data and policy considerations. The threats need to have been addressed to the point that delisting is not likely to result in their re-emergence. It is possible that currently perceived threats will become insignificant in the future due to changes in the natural environment or changes in the way threats affect the entire life cycle of salmon. Consequently, NMFS expects that the relative priority of threats will change over time and that new threats may be identified. During the 5-year reviews, NMFS may review the listing factor criteria as they apply at that time.

The specific criteria listed below for each of the relevant listing/delisting factors help to ensure that underlying causes of decline have been addressed and mitigated before a species is considered for delisting. NMFS expects that if the proposed actions described in the Plan are

implemented, they will make substantial progress toward meeting the following listing factor (threats) criteria for the Middle Columbia steelhead.

While NMFS appreciates that regional managers would like to have clear, more specifically defined targets for reducing threats, and accordingly a clear path to delisting, many scientific uncertainties remain. Building adaptive management into the recovery plan is an appropriate response to these uncertainties. Research, monitoring, and evaluation (RM&E) are necessary for adaptive management. The threats criteria listed in this section for each of the relevant listing/delisting factors are intended to help recovery planners formulate appropriate RM&E to ensure that underlying causes of decline have been addressed and mitigated before a species is considered for delisting. NMFS expects the appropriate metrics to be developed in the cooperative process of local and regional implementation, then fed back into adaptive management for steelhead recovery. In some cases, metrics or targets in certain categories have already been established by NMFS or by management unit planners and approved by NMFS. These will become part of the RM&E plan that will be developed after the DPS plan has been approved (see Chapter 10 of this Plan).

Factor A: The present or threatened destruction, modification, or curtailment of its habitat or range

To determine that the DPS is recovered, threats to habitat should be addressed as outlined below:

1. Passage obstructions (e.g., dams and culverts) are removed or modified to improve survival and restore access to historically accessible habitat where necessary to support recovery goals.

2. Flow conditions that support adequate rearing, spawning, and migration are achieved through management of mainstem and tributary irrigation and hydropower operations, and through increased efficiency and conservation in other consumptive water uses such as municipal supply.

3. Sufficient instream flows are protected to provide for steelhead in appropriate life stages.

4. Forest management practices that protect watershed and stream functions are implemented on Federal, state, tribal, and private lands.

5. Agricultural practices, including grazing, are managed in a manner that protects and restores riparian areas, floodplains, and stream channels, and protects water quality from sediment, pesticide, herbicide, and fertilizer runoff.

6. Urban and rural development, including land use conversion from agriculture and forestland to residential uses, does not reduce water quality or quantity, or impair natural stream conditions so as to impede achieving recovery goals.

7. The effects of toxic contaminants on salmonid fitness and survival are sufficiently limited so as not to affect recovery.

8. Channel function, including vegetated riparian areas, canopy cover, stream-bank stability, off-channel and side-channel habitats, natural substrate and sediment processes, and channel complexity are restored to provide adequate rearing and spawning habitat.

9. Floodplain function and the availability of floodplain habitats for salmon are restored to a degree sufficient to support a viable DPS. This restoration should include connectedness between river and floodplain and the restoration of impaired sediment delivery processes.

Factor B: Over-utilization for commercial, recreational, scientific or educational purposes

To determine that the DPS is recovered, any utilization for commercial, recreational, scientific, or educational purposes should be managed as outlined below:

1. Fishery management plans for steelhead are in place that (a) accurately account for total fishery mortality (i.e., both landed catch and non-landed mortalities) and constrain mortality rates to levels that are consistent with recovery; and (b) are implemented in such a way as to avoid deleterious genetic effects on populations or negative effects on the distribution of populations.

2. Federal, tribal and state rules and regulations are effectively enforced.

3. Technical tools accurately assess the effects of the harvest regimes so that harvest objectives are met but not exceeded.

4. Handling of fish is minimized to reduce indirect mortalities associated with educational or scientific programs, while recognizing that monitoring, research, and education are key actions for conservation of the species.

5. Routine construction and maintenance practices are managed to reduce or eliminate mortality of listed species.

Factor C: Disease or predation

To determine that the DPS is recovered, any disease or predation that threatens its continued existence should be addressed as outlined below:

1. Hatchery operations do not subject targeted populations to deleterious diseases and parasites and do not result in increased predation rates of wild fish.

2. Predation by avian predators is managed in a way that allows for recovery of salmon and steelhead populations.

3. The northern pikeminnow is managed to reduce predation on the targeted populations.

4. Populations of introduced exotic predators such as smallmouth bass, walleye and catfish are managed such that competition or predation does not impede recovery.

5. Predation of winter steelhead runs below Bonneville Dam by marine mammals does not impede achieving recovery.

6. Physiological stress and physical injury that may cause disease or increase susceptibility to pathogens during rearing or migration is reduced during critical low flow periods (e.g. low water years) or poor passage conditions (e.g. at diversion dams or bypasses).

Factor D: The inadequacy of existing regulatory mechanisms

To determine that the DPS is recovered, any inadequacy of existing regulatory mechanisms that threatens its continued existence should be addressed as outlined below:

1. Adequate resources, priorities, regulatory frameworks, and coordination mechanisms are established and/or maintained for effective enforcement of land and water use regulations that protect and restore habitats, including water quality and water quantity, and for the effective management of fisheries.
2. Habitat conditions and watershed functions are protected through land-use planning that guides human population growth and development.
3. Habitat conditions and watershed function are protected through regulations that govern resource extraction such as timber harvest and gravel mining.
4. Habitat conditions and watershed functions are protected through land protection agreements as appropriate, where existing policy or regulations do not provide adequate protection.
5. Regulatory, control, and education measures to prevent additional exotic plant and animal species invasions are in place.
6. Sufficient priority instream water rights for fish habitat are in place.

Factor E: Other natural or human-made factors affecting [the species'] continued existence

To determine that the DPS is recovered, other natural and man-made threats to its continued existence should be addressed as outlined below:

1. Hatchery programs are being operated in a manner that is consistent with individual watershed and region-wide recovery approaches; appropriate criteria are being used for integration of hatchery steelhead populations and extant natural populations inhabiting watersheds where the hatchery fish return.
2. Hatcheries operate using appropriate ecological, genetic, and demographic risk containment measures for (1) hatchery-origin adults returning to natural spawning areas, (2) release of hatchery juveniles, (3) handling of natural-origin adults at hatchery facilities, (4) withdrawal of water for hatchery use, (5) discharge of hatchery effluent, and (6) maintenance of fish health during their propagation in the hatchery.
3. Monitoring and Evaluation plans are implemented to measure population status, hatchery effectiveness, and ecological, genetic, and demographic risk containment measures.
4. Nutrient enrichment programs are implemented where it is determined that nutrient limitations are a significant limiting factor for steelhead production and that nutrient enrichment will not impair water quality.

3.4 Delisting Decision

NMFS concludes that the biological viability criteria as described in Sections 3.1 and 3.2, and the listing factor (threats) criteria (described in Section 3.3), define conditions that, when met, would result in a determination that the Middle Columbia steelhead DPS is not likely to become endangered within the foreseeable future throughout all or a significant portion of its range. These criteria could exceed the minimum necessary to delist the DPS.

In accordance with our responsibilities under section 4(c)(2) of the ESA, NMFS will conduct reviews of Middle Columbia steelhead every five years to evaluate the status of the DPS and determine whether it should be removed from the list or changed in status. Such evaluations will take into account the following:

- The biological recovery criteria (ICTRT 2007a) and listing factor (threats) criteria described above.
- The management programs in place to address the threats.
- Principles presented in the Viable Salmonid Populations paper (McElhany et al. 2000).
- Best available information on population and DPS status and new advances in risk evaluation methodologies.
- Other considerations, including: the number and status of extant spawning groups; the status of the major spawning groups; linkages and connectivity among groups; the diversity of life history and phenotypes expressed; and considerations regarding catastrophic risk.

4. CURRENT STATUS ASSESSMENT OF DPS

ICTRT scientists have aggregated a description of current Middle Columbia steelhead DPS status from information on the status of the component populations, using the VSP parameters of abundance, productivity, spatial structure, and diversity. Several related research reports from the ICTRT, including the most recent status assessment, are available on the Northwest Fisheries Science Center website, http://www.nwfsc.noaa.gov/trt/trt_columbia.cfm.

4.1 ICTRT Status Assessment of Middle Columbia Steelhead DPS

The status of a salmonid ESU or DPS is expressed in terms of likelihood of persistence over 100 years, or in terms of risk of extinction within 100 years. The ICTRT defines viability at two levels: less than 5 percent risk of extinction within 100 years (viable) and less than 1 percent risk of extinction within 100 years (highly viable). A third category, "maintained," represents a less than 25 percent risk. The risk level of the DPS is built up from the aggregate risk levels of the populations and MPGs. All four VSP parameters must be taken into account to determine the risk level.

Table 4-1 summarizes current status of the Middle Columbia steelhead populations, showing 10-year geometric mean abundance by population, estimated productivity (using a 20-year geometric mean), and the minimum abundance threshold needed for long-term viability. The table also includes the 10-year geometric mean proportion of hatchery spawners for the populations where data are available, and the risk ratings of high, moderate, low, and very low, for abundance and productivity combined, and spatial structure and diversity combined. In this chapter, two other ways of representing these findings are presented: graphs called "viability curves" showing the relationship of current abundance and productivity to that required for viability, and a matrix combining all four parameters to illustrate the overall risk rating of each population.

4.2 Viability Curves

The ICTRT developed viability criteria expressed as graphs showing the relationship between abundance and productivity. The result is a curve, called a "viability curve," running from high abundance/low productivity to high productivity/low abundance. The ICTRT then developed a method for adapting viability curves to population size categories, which, as described in Section 3.1.3, are based on estimated intrinsic production potential or capacity of the habitat. The actual current abundance and productivity are then plotted against this viability curve. Populations above the 5 percent risk curve are considered to have a low risk of extinction and below the 5 percent risk curve a higher risk of extinction.

Viability curves for Basic, Intermediate, Large, and Very Large Middle Columbia steelhead populations are depicted below in Figures 4-1 through 4-4, respectively. Only the Deschutes River East and Walla Walla populations (Intermediate) in Figure 4-2 and the North Fork John Day population (Large) in Figure 4-3 meet or exceed the 5 percent minimum risk of extinction in 100 years needed to meet the ICTRT viability criteria. The ovals about the point estimates of actual abundance and productivity represent one standard error of uncertainty about the points.

Table 4-1. Middle Columbia River steelhead DPS populations: summary of abundance, productivity, risk ratings, and minimum abundance thresholds (Source: ICTRT 2007a and 2008). (Numbers subject to periodic updates as additional information becomes available.)

4.3 Spatial Structure and Diversity

Although the Middle Columbia steelhead spawning range currently extends over an area of approximately 35,000 square miles, the viability of the DPS with regard to spatial structure and diversity (SS/D) depends on the spatial structure and diversity of each population. Given that one population is extinct and two functionally extirpated, and considering the status of the 17 extant populations, NMFS considers the DPS to be at moderate risk with regard to spatial structure and

diversity. NMFS considers only the Fifteenmile Creek and North Fork John Day populations to be at low SS/D risk. The Upper Yakima River is at high SS/D risk, and the 15 other populations are rated at moderate risk.

The ICTRT examined the steelhead's SS/D risk in terms of biological or ecological "goals," mechanisms that achieve those goals, and factors that influence the mechanisms. They identified two primary goals:

A. *Maintain natural rates and levels of spatially mediated processes*. Spatially mediated processes are, for example, population changes that result from local events such as landslides or other local catastrophes; recolonization within or between populations after such events; or "straying" of spawners away from home streams.

B. *Maintain natural patterns of variation*. Variation in the population – whether it is genetic, behavioral, or a matter of appearance or life history -- helps to ensure that populations can withstand environmental variation in both the short and long term.

The ICTRT defined *mechanisms* as biological or ecological processes that contribute to achieving the *goals*. For example, gene flow patterns are mechanisms that affect the distribution of genotypic and phenotypic variation in a population. *Factors* are characteristics of a population or its environment that influence mechanisms. For example, gaps in spawning distribution affect patterns of gene flow, which then affect patterns of genotypic and phenotypic variation.

In some cases the same factor can affect more than one mechanism or goal. The distribution of spawning areas, for example, can affect both patterns of gene flow and the patterns of spatially mediated processes such as catastrophes.

The ICTRT developed a method for scoring SS/D risk that considers these goals, mechanisms and factors. For example, maintaining natural patterns of gene flow is a mechanism that serves the goal of maintaining natural patterns of variation. The most relevant factor for maintaining natural patterns of gene flow is spawner composition. A high proportion of hatchery fish spawning naturally among wild fish can be a risk factor affecting genetic diversity, depending on the origin of the hatchery fish and other characteristics.

Using metrics and criteria developed for SS/D, the ICTRT scored the Mid-Columbia steelhead populations as shown in Table 4-1. The following is a narrative summary of the SS/D ratings for all four steelhead MPGs.

Cascades Eastern Slope MPG

Of the five extant populations in the Cascades Eastern Slope MPG, NMFS considers only the Fifteenmile Creek population to be at low risk of extinction with regard to spatial structure and diversity. The ICTRT rated the Klickitat River, Deschutes Eastside, and Deschutes Westside populations at moderate SS/D risk: these three have low risk for natural processes but moderate risk for diversity, because of the potential influence of naturally spawning, out-of-DPS hatchery fish. The Rock Creek population is assigned moderate SS/D risk, with the caution that more data are needed (ICTRT 2008).

John Day MPG

In the John Day MPG, only the North Fork John Day population has a low SS/D risk. The high proportion of out-of-population or out-of-DPS spawners puts the Middle and South Fork John Day populations at moderate risk. The high proportion of strays is a potential problem for all the John Day populations (ICTRT 2008).

All five populations in this group spawn across the historical range of tributary habitats and are rated at low or very low risk for spatial structure, or Goal A, maintaining natural rates and levels of spatially mediated processes (ICTRT 2008). The Lower Mainstem and Upper Mainstem populations are rated at moderate risk for life history diversity because of limitations and reductions in particular juvenile rearing time and area pathways, inferred from current temperature and flow conditions in the tributaries, the mainstem John Day River, and the mainstem Columbia River (ICTRT 2008). In addition, the Lower Mainstem John Day River population was rated at moderate risk for genetic diversity. Sport fishery and spawning ground sampling information indicates that a relatively high proportion of out-of-basin hatchery fish may be contributing to spawning, but no direct genetic sampling data are available.

In the Oregon Steelhead Recovery Plan, the Middle Fork and South Fork John Day populations are shown as having Low SS/D risk. The difference turns on the weight given in the integrated SS/D rating to the high proportion of out-of-population or out-of-DPS strays spawning naturally in these areas. The ICTRT rates both populations as at high risk for diversity, and therefore, overall moderate SS/D risk. The Oregon Conservation Plan rates the overall risk as low, "with the exception" of spawner composition.

Yakima River MPG

Three of the Yakima River steelhead populations are rated at moderate SS/D risk, and one, the Upper Yakima River, at high risk (ICTRT 2008). The SS/D risk for the Satus Creek, Toppenish Creek, and Naches River populations is moderate, because of changes related to Goal B – maintaining natural patterns of variation. These include changes in life history strategies – spawning, rearing, and migration timing – as well as changes in phenotypic or genetic traits, related to altered habitat, particularly flow regimes and water temperature. For the Satus Creek, Toppenish Creek, and Naches River populations, there are also changes in the distribution of spawning. The Upper Yakima River is at high risk for spatial structure and diversity because of loss of spawning areas, decreased life history variation, and possible genetic introgression with planted rainbow trout. All of these populations must pass four major dams in the mainstem Columbia River, and the ICTRT notes that characteristics of the hydropower system create selective pressures on various traits such as size and adult and juvenile migration timing, reducing variations that were likely present historically.

Umatilla/Walla Walla MPG

The ICTRT rated all three populations in the Umatilla/Walla Walla MPG as at moderate risk (ICTRT 2008). All three have lost spawning habitat, and the distances between occupied areas have increased. Phenotypic changes such as reduced variation in adult and juvenile migration patterns are inferred from changes in flow patterns and water temperature. For the Umatilla River, a high proportion of hatchery-origin fish spawning naturally represents a diversity risk.

For the Walla Walla River, a moderate risk is attributed to out-of-DPS strays spawning naturally. Water temperature and hydrograph changes as well as passage barriers have likely influenced life history diversity and phenotypic expression (ICTRT 2008). The Touchet population has good spatial distribution but was given a moderate risk rating because of assumed or inferred loss of life history and phenotypic variation. The ICTRT emphasized the need for more data for the Touchet (ICTRT 2008).

4.4 Population-Level Risk Rating

Given the hierarchical structure of salmonid biology (see Section 2.2, above), an overall assessment of risk of extinction for an ESU or DPS must be built up from assessments of risk for the component populations and then the MPGs.

The ICTRT integrated all four VSP parameters in a simple matrix (Figure 4-5). One side of the matrix is a series of risk levels for the combined abundance and productivity parameters (A/P): very low risk, i.e. less than a 1 percent risk of extinction within 100 years; low risk, less than a 5 percent risk of extinction within 100 years; moderate risk, less than a 25 percent risk of extinction within 100 years; and high risk, more than a 25 percent risk of extinction within 100 years. The A/P rating for each population is taken from the corresponding viability curve (see Section 4.2 above). A viable population is considered to have no more than a 5 percent A/P risk.

Across the top of the matrix is a series of risk levels for spatial structure and diversity (SS/D). The range of viable combinations of A/P and SS/D risks for a population can be seen in the top two rows combined with the first three columns. Populations with a Very Low risk rating for A/P and at least a Low rating for SS/D are considered to be "Highly Viable." Populations with a Low risk rating for A/P and a Moderate rating for SS/D are considered to be "Viable." Populations that fall into the cells outside this range cannot be considered viable by the standard set forth in the VSP paper (McElhany et al., 2000) and used by all of the TRTs. These individual scores are integrated to determine the viability of MPGs (ICTRT 2005), and the assessments of the component MPGs are aggregated to assess the DPS as a whole. The ICTRT used this approach to examine the viability of independent steelhead populations in the Middle Columbia DPS.

In Figure 4-5, five of the cells at higher risk are labeled "Candidate for maintained status." The ICTRT recognizes that some populations may not need to be fully viable to make the DPS viable, and yet maintaining them at some level will provide ecological functions and preserve options for DPS recovery. As a rule of thumb, populations that fall within cells adjacent to those regarded as viable in the risk matrix (Figure 4-5 in this recovery plan) can be regarded as "maintained."

The ICTRT (2007a) details how maintained populations contribute to the ecological functioning of the DPS and preserve recovery options in the event that efforts to recover other populations to viable levels fail.

Having populations meet maintained standards:

- Provides a hedge against the potential risk that the cumulative productivity across populations within an MPG may fall below replacement.
- Provides insurance against catastrophic events. For example, if a catastrophe impacts one or more of the functioning viable populations within the MPG, the other populations will

need to be at sufficient levels so that they can replenish those populations lost to or affected by the catastrophe.

- Allows these populations to serve as genetic or demographic "stepping stones" between populations, allowing natural patterns of gene flow and dispersal.
- Provides a buffer against uncertainty in the ICTRT population and MPG criteria. For example, having populations meet maintained standards preserves recovery options in the event that efforts to recover other populations to viable levels fail.

Although populations with specific combinations of A/P and SS/D ratings are candidates for Maintained status (Figure 4-5), the ICTRT cautions that it is difficult to capture all of the necessary attributes to meet the objectives for maintained populations in a simple set of integrated A/P and SS/D risk ratings. For each MPG, candidate populations should be reviewed individually and in context with the other populations against the above principles.

> "In general, populations with moderate abundance and productivity risk levels near 25% with high year-to-year variability or populations with high risk for multiple SS/D factors are less likely to be considered Maintained. A primary consideration in setting an abundance objective [for a] population in the smallest size category (Basic) would be uncertainty in current estimates of abundance and productivity. Given the levels of uncertainty in estimating recent geomean abundance and productivity, the abundance objectives for Basic populations should exceed 250 spawners [if they are] to be designated as Maintained status. Populations classified in any of the three largest size categories should be at abundance levels not less than 500, and will likely require average abundance levels approaching minimum threshold values to address demographic and genetic considerations." (ICTRT 2007a)

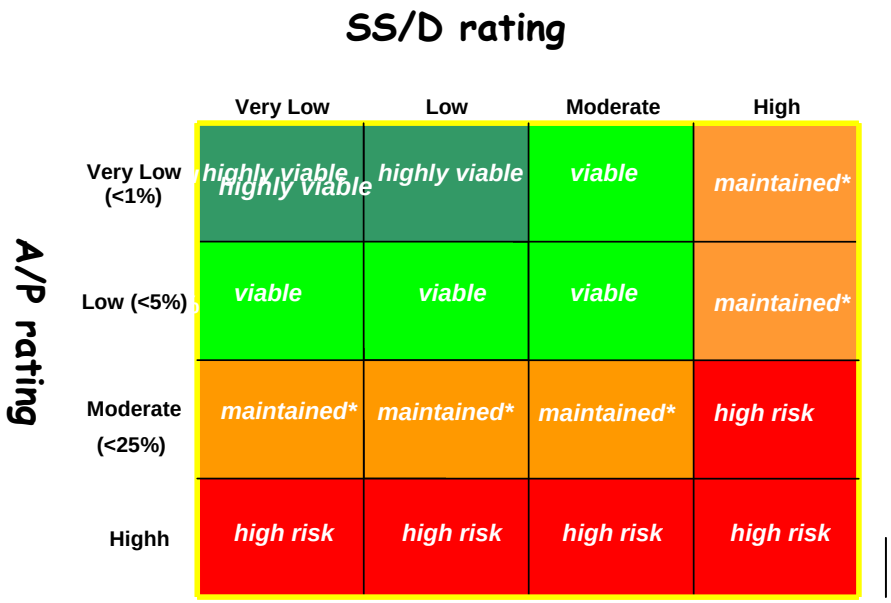

Figure 4-5. Assessing Population Viability Across VSP Criteria (ICTRT 2005).
***** Candidate for maintained status

4.5 Current Population Status

According to the ICTRT viability criteria, the majority of natural Middle Columbia steelhead populations are rated at moderate risk for abundance and productivity, but low to moderate risk for spatial structure and diversity (Table 4-1, Figure 4-6, and Figure 4-7). This DPS includes one highly viable population (North Fork John Day), two viable (Fifteenmile Creek and Deschutes River Eastside), five at high risk of extinction within 100 years (Deschutes Westside, Upper Yakima Mainstem, Naches River, Rock Creek, and Touchet[31]), and the remaining nine at moderate risk.

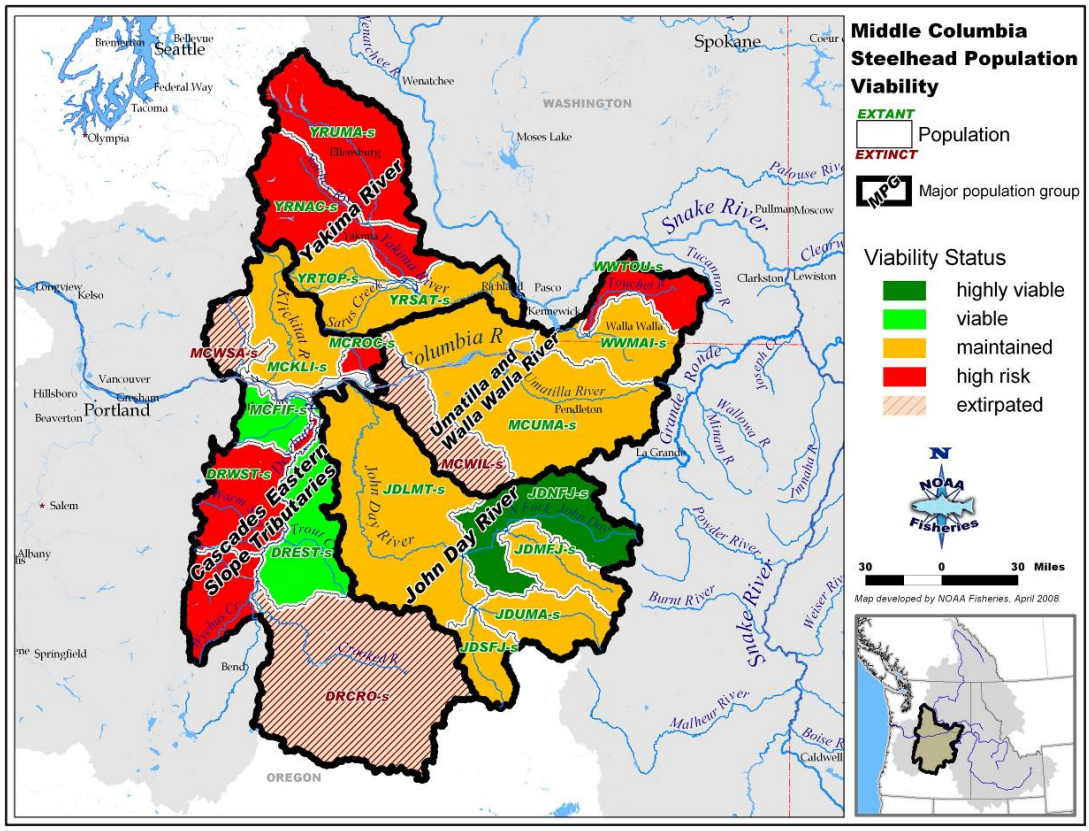

Figure 4-6. Middle Columbia Steelhead Population Viability (ICTRT, May 2008).

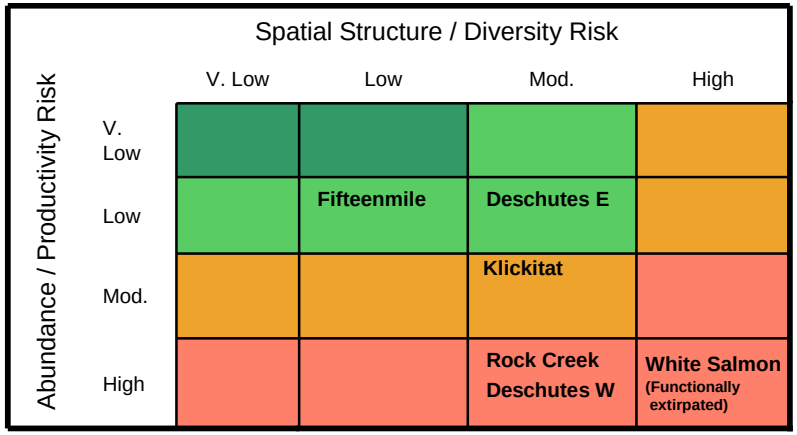
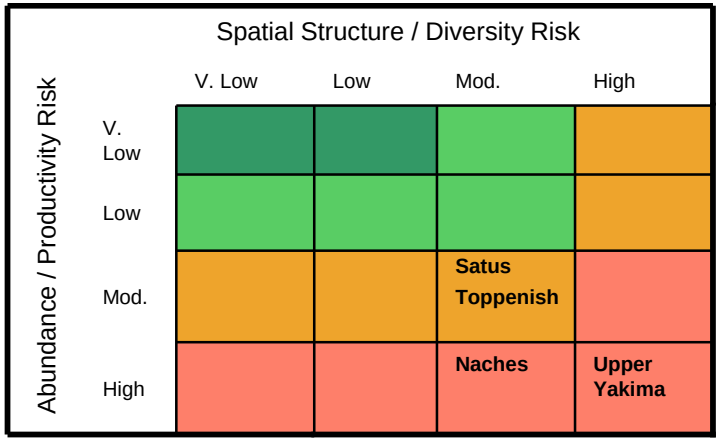


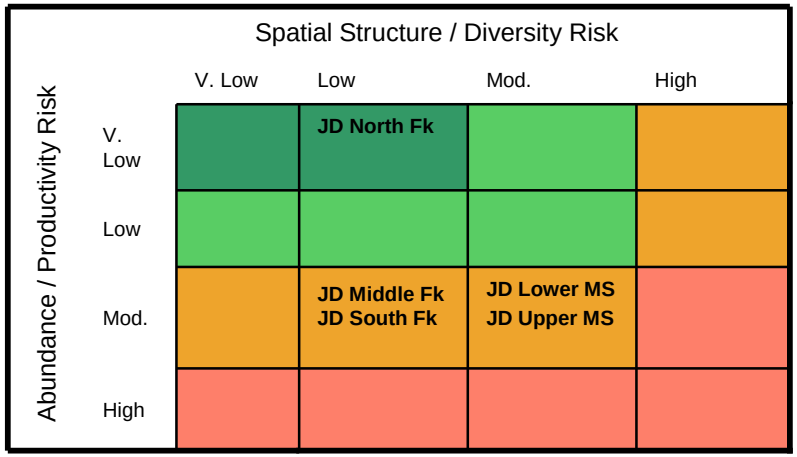
4.6 MPG Status

The ICTRT's viability ratings of the component populations of each Middle Columbia steelhead MPG are shown in the matrices below (Figure 4-7). None of the MPGs as a whole reaches low risk status according to the ICTRT's MPG-level criteria (shown in Figure 3-2).



4.7 DPS Status

The ICTRT's ESU-level viability criterion is the following: All extant MPGs and any extirpated MPGs critical for proper functioning of the ESU should be at low risk (ICTRT 2007a). Thus, the Middle Columbia steelhead DPS does not currently meet viability criteria based on the determination that the four component MPGs are not at low risk.



[31] The Rock Creek and Touchet populations are rated at High Risk because of uncertainty resulting from the limited set of annual return estimates (with significant missing years) currently available.

5. THE 'GAP' BETWEEN CURRENT AND DESIRED STATUS

The ICTRT assessed the difference between a listed species' or population's current abundance/productivity status and the viability criteria. This difference is called the "gap." The gap, as used in this plan, is a measure, although it is inevitably imprecise, of the improvement in survival needed to meet viability criteria. As such, it is also an indicator of the level of effort needed to achieve recovery. The following material is taken from the ICTRT's "Survival Gaps Report" (ICTRT 2007b) for the listed salmon and steelhead in the Interior Columbia Basin.

Although all four VSP parameters contribute to overall population and DPS viability, the gap is discussed quantitatively only in terms of abundance and productivity. Qualitative statements may be made about needed improvements to spatial structure and diversity, but the metrics—the methods of measurement—used to assess the risk levels of spatial structure and diversity are not easily summed up into a single statistic (See Section 4.3 of this Plan and ICTRT 2008).

A key part of the "gap" calculation is the productivity of the population. The ICTRT used a measure of productivity that directly relates to a population's potential to be self-sustaining, i.e., recruits per spawner, or the rate at which spawning adults in one generation are replaced by spawning adults in the next generation.

This measure of life-cycle productivity is affected by mortality and survival at all life stages, including juvenile mortality (such as the relative number or proportion of juveniles that die while migrating down river) and adult mortality (such as the relative proportion of adult fish harvested) (Figure 5-1).

The gap analysis itself does not identify or target a particular life stage for actions to achieve viability criteria. Gaps can be addressed by improvements to survival rates at any life stage (e.g., tributary residence, migration, estuary, early ocean, upstream migration), depending on the specific factors limiting the individual populations.

5.1 Gaps Using Abundance and Productivity Criteria

The ICTRT (2007c) estimated the minimal survival rate changes needed for Middle Columbia steelhead populations to meet the abundance and productivity viability criteria for a 5 percent risk of extinction in a 100-year time frame.

They used the following steps to estimate observed survival gaps:

1. Estimated current intrinsic productivity (defined by TRT as reproductive rate at low abundance) and natural spawner abundance (using the most recent 20 years of stock-recruit data).
2. Estimated current spawning level associated with achieving juvenile capacity.
3. Assigned each population to a risk category (very low, low, moderate, or high risk) based on its position relative to the viability curve for its size category.
4. Calculated gaps based on the minimum distance from the abundance/productivity point representing current status and the appropriate viability curve.

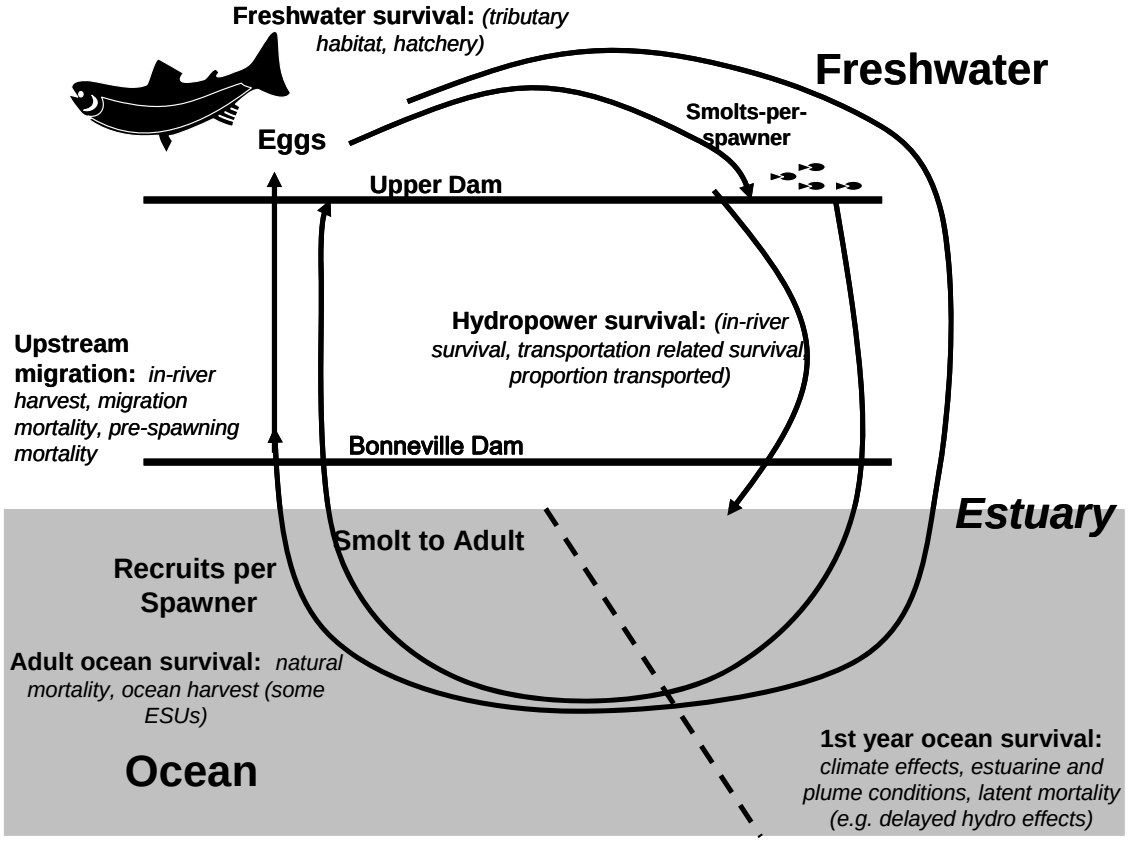

Figure 5-1. Survival and Mortality throughout Salmonid Life Cycle.

In addition, the ICTRT (2007b) estimated gaps under three different early-ocean survival scenarios; historical ocean conditions (ocean conditions that fish experienced over the past 60 years), pessimistic ocean conditions (ocean conditions experienced by the 1975-1997 brood years), and recent ocean conditions (ocean conditions experienced by fish during the 20-year assessment period). The ICTRT also estimated gaps assuming three different hydropower scenarios. However, only the base hydro condition, which assumed that survival rates from the most recent 20 years would continue into the future, is reported here. (See NMFS 2008a for details on survival through the FCRPS under proposed improvements.)

Changes in survivals of Middle Columbia steelhead needed to achieve the 5 percent risk criteria for abundance and productivity in a 100-year time period are presented in Table 5-1. The numbers in the table are expressed as a proportion of current survival. For example, in the table, an estimated gap of 0.09 for Umatilla steelhead requires increasing average life-cycle survival by 9 percent, or a 1.09 fold increase, to achieve 5 percent risk in a 100-year time period. A negative (minus) number means the population is viable.

The median survival gap (assuming recent ocean and base hydrosystem conditions and 5 percent risk) for the Cascades Eastern Slope MPG is 0.21, ranging from –0.34 (Deschutes Eastside) to 0.78 (Deschutes Westside). The Deschutes Eastside and Fifteen Mile populations

exceed the 5 percent abundance and productivity criteria under all ocean scenarios. In contrast, the Deschutes Westside fails to meet the criteria under all ocean scenarios. There was not enough information to estimate gaps for the Klickitat or Rock Creek populations.

The median survival gap for the John Day MPG is 0.09, ranging from –0.49 (North Fork) to 0.34 (South Fork). Two out of the five populations exceed the 5 percent abundance and productivity risk criteria under both the recent and historical ocean conditions. The North Fork population exceeds the 5 percent risk criteria under all ocean scenarios, while the South Fork population fails to meet the 5 percent criteria under all ocean scenarios.

There was sufficient information available to estimate gaps for only two of the three populations within the Umatilla/Walla Walla MPG. Assuming base hydrosystem and recent ocean conditions, the survival gaps for the Umatilla and Walla Walla populations are 0.09 and 0.34, respectively. The Umatilla population is projected to achieve the 5 percent risk criteria only under historical ocean conditions. The Walla Walla population fails to meet the 5 percent criteria under all ocean scenarios.

The median survival gap (assuming recent ocean and base hydrosystem conditions) for the Yakima MPG is 0.77, ranging from 0.22 (Satus—tributary only) to 1.15 (Upper Yakima). All populations in this MPG fail to meet the 5 percent criterion under all ocean scenarios.

5.2 Gaps using Spatial Structure and Diversity Criteria

As described in Section 4.3, the ICTRT analyzed a population's spatial structure and diversity in terms of two goals: maintaining natural rates and levels of spatially mediated processes, and maintaining natural patterns of variation. The team developed a scoring system, described in detail in Table 2-1 of Current Status Reviews, Vol. III (ICTRT 2008) to derive a composite spatial structure and diversity rating for each population. Using this method, the ICTRT rated only the Fifteenmile Creek and North Fork John Day populations at low risk of extinction with regard to spatial structure and diversity. The Upper Yakima River is at high SS/D risk, and the 15 other populations are rated at moderate risk.

It is important to include measures to address spatial structure and diversity risks in recovery planning. The Middle Columbia River steelhead DPS cannot reach viable status without closing these gaps as well as those identified in terms of abundance and productivity.

Summary

Using criteria for abundance and productivity, the ICTRT modeled a gaps analysis for each of the four MPGs in this DPS under three different ocean conditions and a base hydro condition (most recent 20-year survival rate). The results showed that none of the MPGs would be able to achieve a 5 percent or less risk of extinction over 100 years without recovery actions. It is important to consider that significant gaps in factors affecting spatial structure and diversity also contribute to the risk of extinction for these fish.

Table 5-1. Minimum changes in survival of Middle Columbia River steelhead needed to meet abundance and productivity criteria for 5 percent risk curves in a 100-year time period under base hydropower conditions and three different ocean scenarios. Gap estimates are expressed as a proportion of current survival (e.g., a gap of 0.50 requires increasing average life-cycle survival by 50 percent [multiplying by 1.5] over recent averages).

NOTE: A negative (minus) number means there is no gap – the population is viable. Data are from Table 6b in ICTRT (2007b); NA = not available.

Major Population Group	Population	Estimated abundance/productivity gaps (5% risk in a 100-year time period)		
		Recent ocean survival	Historical ocean survival	Pessimistic ocean survival
Cascades Eastern Slope	Deschutes W.	0.78	0.60	0.82
	Deschutes E.	No gap (-0.34)	No gap (-0.40)	No gap (-0.33)
	Klickitat	NA	NA	NA
	Fifteen Mile	No gap (-0.21)	No gap (-0.29)	No gap (-0.20)
	Rock Creek	NA	NA	NA
John Day	Lower Mainstem	0.11	0.00	0.14
	North Fork	No gap (-0.49)	No gap (-0.54)	No gap (-0.48)
	Upper Mainstem	0.00	No gap (-0.10)	0.02
	Middle Fork	0.09	No gap (-0.01)	0.12
	South Fork	0.34	0.21	0.37
Umatilla/Walla Walla	Umatilla	0.09	No gap (-0.01)	0.12
	Walla-Walla	0.34	0.21	0.37
	Touchet	NA	NA	NA
Yakima	Satus (tributary only)	0.22	0.10	0.25
	Toppenish	0.50	0.35	0.53
	Naches	1.03	0.83	1.08
	Upper Yakima	1.15	0.94	1.20

Note: These gaps do not constitute a legal determination of the status of Middle Columbia MPGs nor of the adequacy of any particular set of actions under the ESA. Rather, the gaps provide a sense of how much effort is needed for planning purposes.

6. LIMITING FACTORS AND THREATS

The reasons for a species' decline are generally described in terms of limiting factors and threats. NMFS defines limiting factors as the biological and physical conditions that limit a species' viability – e.g., high water temperature – and defines threats as those human activities or natural processes that cause the limiting factors. For example, removing the vegetation along the banks of a stream can cause higher water temperatures, because the stream is no longer shaded. Designing effective recovery strategies and actions requires understanding limiting factors and threats across the species' entire life cycle.

While the term "threats" carries a negative connotation, it does not mean that activities identified as threats are inherently undesirable. They are often legitimate human activities that may at times have unintended negative consequences on fish populations—and that can usually be managed in a manner that minimizes or eliminates the negative impacts.

For steelhead and other salmonids, survival to reproduce depends on a complex, interacting system of environmental conditions, with different conditions needed for each life stage. Optimal water temperature, for example, varies (within limits) for adult migration vs. egg incubation vs. juvenile rearing. In addition, the particular factors limiting production may vary across different sections of the tributary drainage used by a particular population. Data on a full range of potential limiting factors is rarely available at the reach level. As a result, the identification of limiting factors for salmonids often includes elements based on inference and expert opinion.

The list of limiting factors for the Middle Columbia steelhead DPS, as for the populations that make up the DPS, is based on a substantial body of research on salmonids, local field data and field observations, and the considered opinions of regional experts. These are implicitly hypothetical statements, made with the expectation that by taking action in the face of some degree of scientific uncertainty, monitoring the results, continuing to conduct research to resolve the uncertainties, and adapting our management actions in response, the state of our knowledge will improve and so will the survival of these fish, although not necessarily in a directly parallel process.

This plan describes limiting factors and threats for the Middle Columbia steelhead DPS as a whole at a general level, then describes the most salient specific conditions that affect individual populations and limit the viability of specific MPGs. More detail is available in the individual management unit plans and modules (Appendices A through G), as well as in the FCRPS BiOp (NMFS 2008a), particularly in the BiOp's Supplemental Comprehensive Analysis and Appendices, and in Appendix C of the Supplemental Comprehensive Analysis, Artificial Production for Pacific Salmon.

The discussion of out-of-subbasin limiting factors and threats that affect all the salmonid populations in the mainstem Columbia River corridor is excerpted from a "module" that NMFS prepared on the estuary and plume (NMFS 2007 and Appendix G of this Plan; available at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Other-Documents.cfm) and from the recently released 2008 FCRPS Biological Opinion (NMFS 2008a). NMFS also prepared a module to summarize FCRPS actions

contained in the Biological Opinion (Hydro Module, NMFS 2008c and Appendix F of this Plan), available at http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/Other-Documents.cfm. (The Estuary Module underwent public review; the Hydro Module, as a summary of the publicly reviewed BiOp actions, did not.) There is no hatchery module; hatchery programs are widespread throughout the Columbia Basin and their population-specific effects are described in the individual management unit plans.

6.1 Types of Limiting Factors

For recovery planning purposes, NMFS standardized descriptions of limiting factors into 12 categories or types. These are the categories of limiting factors used for the yearly Pacific Coast Salmon Recovery Fund (PCSRF) report to Congress in accordance with the PCSRF performance reporting framework (http://www.nwr.noaa.gov/Salmon-Recovery-Planning/PCSRF/upload/PCSRF-Perf-Framework.pdf). NMFS is working within the region to standardize definitions for monitoring and reporting. The descriptions of limiting factors in the management unit plans fit into these categories, although they may be lumped or split differently in the individual plan texts and also may be described slightly differently. However, Table 6-1 lists the 12 categories as "key" limiting factors, including the common characteristics used to describe them and the salmonid life stages they affect.

Table 6-1. Key limiting factors and common characteristics used to describe them.

Key Limiting Factors	Common Characteristics	Life Stages Affected
1. Degraded estuarine and nearshore marine habitat	Inadequate large woody debris; loss of estuary complexity; loss of off-channel habitats; loss of intertidal, salt marsh and other functional estuarine and marine vegetation.	egg-to-smolt survival, smolt migration, smolt-to-adult survival, adult migration
2. Degraded floodplain connectivity and function	Loss of off-channel habitat and floodplain connectivity, seasonal wetlands, wet meadows, side channels habitat; loss of connected and functional hyporheic zone.	egg-to-smolt survival, smolt migration, adult migration, pre-spawning
3. Degraded channel structure and complexity	Loss of pool frequency and quantity, large wood debris; channel straightening and confinement; simplified habitat; loss of spawning habitat structure, redd diversity; loss of sinuosity, insufficient instream complexity and roughness.	egg-to-smolt survival, smolt migration, adult migration, pre-spawning
4. Degraded riparian area and LWD recruitment	Degraded riparian condition; loss of vegetation, shade, overhead cover, terrestrial food sources; unstable or eroding stream banks.	egg-to-smolt survival, smolt migration, adult migration, pre-spawning
5. Altered hydrology	Higher peak flows, lower low flows; intermittent flow; increased stream energy; significant flow fluctuations on weekly, daily or hourly basis; dewatered channel.	egg-to-smolt survival, smolt migration, adult migration, pre-spawning
6. Degraded water quality	High water temperatures, high level of chemical contaminants, nutrients, oxygen, pathogens, pH, toxic mine waste.	egg-to-smolt survival, smolt migration, adult migration, pre-spawning
7. Altered sediment routing (degraded stream substrate)	Sedimentation; high levels of suspended sediment, turbidity, sediment load; increased fine sediments in spawning gravel; unnatural level of course-grained sediments; embedded substrate; contaminated sediment.	egg-to-parr survival
8. Impaired fish passage	Artificial barriers or obstructions, total or partially, obstructing habitat access (culverts, irrigation diversions, dams, seasonal push-up dams, unscreened diversions, and entrainment in irrigation diversions etc.).	smolt migration, adult migration, juvenile upstream migration due to thermal stress, water availability
9. Mainstem Columbia River hydro system effects	altered stream flows; impaired water quality, high water temperatures; impaired fish passage and survival; reduced mainstem spawning and rearing; increased predation and competition; degraded estuary and Columbia River plume habitat quality and quantity; degraded floodplains.	egg-to-smolt survival, smolt migration, adult migration
10. Hatchery-related adverse effects	Increased competition for food and space; increased predation; disease transfer; loss of genetic diversity.	egg-to-smolt survival, smolt migration, adult migration
11. Harvest-related adverse effects	Decreased adult abundance (number of spawners or adult recruits) and productivity; influenced diversity and spatial structure through selective removal based on size, age, distribution or run timing.	egg-to-smolt survival, adult survival
12. Predation/Competition/ Disease	Increase in predators; increased competition for food.	egg-to-smolt survival, smolt-to-adult survival, adult survival

6.2 Types of Threats

The threats contributing to the limiting factors and causes for a salmonid species' decline are often described in terms of the "four Hs" – habitat (usually relating to the effects of land use and tributary water use), hydropower, harvest, and hatcheries. Climate change also represents a potentially significant threat to salmon and steelhead.

6.3 Limiting Factors and Threats for the Middle Columbia Steelhead DPS

At the DPS level, based on information from the ICTRT and the four management unit plans, the major factors limiting the viability of Middle Columbia steelhead populations are *tributary habitat conditions (varying combinations of factors 2-7 listed in Table 6-1), impaired fish passage in the mainstem Columbia River and tributaries*, *hatchery-related effects, and predation/competition/disease*. Two factors, degradation of estuarine and nearshore marine habitat and harvest-related effects, pose some risk to steelhead viability for the entire DPS, but less than the other factors. Climate change could potentially affect habitat for all salmonids in the Columbia Basin.

Most of the management unit plans rate the importance of the limiting factors in their respective subbasins by population and also by smaller units such as stream reaches. There are some differences of opinion as to the general, relative importance of tributary habitat limiting factors vs. passage conditions in the mainstem Columbia. However, all of the plans list both as major limiting factors. Hatchery related effects on genetic diversity and productivity are considered a major limiting factor for populations in the Deschutes, John Day, and Umatilla basins, and possibly the Klickitat. The management unit plans provide detailed description and discussion of these factors as they apply to specific populations.

6.3.1 Tributary Habitat Conditions

For more than 10,000 years, habitat conditions favorable to salmonid survival were widespread in the Northwest. Over the last 150 years, human activities have significantly reduced the extent and quality of salmonid habitat. Tributary habitat degradation from past and/or present land use remains a key concern for all of the steelhead populations.

Historically, ecosystem conditions allowed steelhead populations in the spawning range of this DPS to grow and prosper. Extensive beaver activity created diverse instream habitats, with deep pools and strong connections to floodplains. Many stream channels contained abundant large wood from surrounding riparian forests, which included cottonwood, aspen, willow, and upstream conifers. Stream temperatures sufficient to support all steelhead life stages throughout the year were common. Upland and riparian conditions allowed for the storage and release of cool water during the dry, summer months and provided sufficient shade to keep water temperatures cool. Extensive and abundant riparian vegetation armored stream banks, providing protection against erosion and supporting an abundant food supply. Dynamic patterns of channel migration in floodplains continually created complex channel, side channel, and off-channel habitats.

Today, nearly all historical habitat lies in areas modified by human settlement and activities. Historical land use exerted a large and widespread impact on steelhead habitat quality and quantity across the DPS. Common historical practices included removal of wood from streams; removal of riparian vegetation; timber harvest, road construction, agricultural development, livestock grazing, urbanization, wetland draining, and gravel mining; alteration of channel structure through stream relocation, channel confinement and straightening; beaver removal; construction of dams for multiple purposes; and direct withdrawal of water for irrigation or human consumption.

While some streams and stream reaches retain highly functional habitat conditions, these various activities have degraded streams and stream reaches across the range of the Middle

Columbia steelhead DPS, leaving them with insufficient large wood in channels, insufficient instream complexity and roughness, and inadequate connectivity to associated wetlands and off-channel habitats. Many streams lack sinuosity and associated meanders and suffer from excessive streambank erosion and sedimentation, as well as altered flow regimes and higher summer water temperatures. In many areas, the contemporary watershed conditions created by past and current land use practices are so different from those under which native fish species evolved that they now pose a significant impediment to achieving recovery. The management unit plans contain detailed descriptions of tributary habitat threats and limiting factors.

6.3.2 Columbia River Mainstem Conditions

All populations of Middle Columbia steelhead use the mainstem Columbia River to migrate to and from the ocean, and all are affected by the mainstem Federal dams, as well as by other forms of development that alter the river environment. Mainstem Columbia River conditions include impaired fish passage, altered water temperature and thermal refuges, and changes in mainstem nearshore habitat.

6.3.2.1 Impaired Fish Passage

Development and operation of the mainstem Columbia River hydropower system significantly alters travel conditions in the mainstem Columbia River, resulting in direct mortality of both upstream migrating adults and downstream migrating steelhead kelts, and direct and indirect mortality for downstream migrating juveniles. The hydro system also changes the hydrograph, depleting historically available nutrients, changing water temperatures, and degrading rearing and food resources for both presmolts and smolts in the Columbia. Changes in the hydrograph leave steelhead more vulnerable to bird and fish predation in the Columbia River estuary and mainstem. In addition, broad deltas have been created at the mouths of tributaries where fine sediment has been deposited. These conditions have resulted in increased non-native piscivorous fish and avian predation on juveniles.

All these impacts increase somewhat for each population in direct relation to the number of dams that fish must pass during their migration to and from the Pacific Ocean. Middle Columbia steelhead populations pass one to four Columbia River dams. The Fifteenmile and Klickitat populations pass the Bonneville Dam; the Deschutes populations pass Bonneville and The Dalles dams; the John Day, Rock Creek, and Umatilla populations pass Bonneville, The Dalles, and John Day dams; and all four populations of the Yakima MPG as well as the Walla Walla and Touchet populations pass Bonneville, The Dalles, John Day, and McNary dams (Figure 6-1). While the hydropower system affects Middle Columbia steelhead less than the listed Interior Columbia salmonids that must pass up to nine mainstem dams, it still substantially affects most Middle Columbia populations.

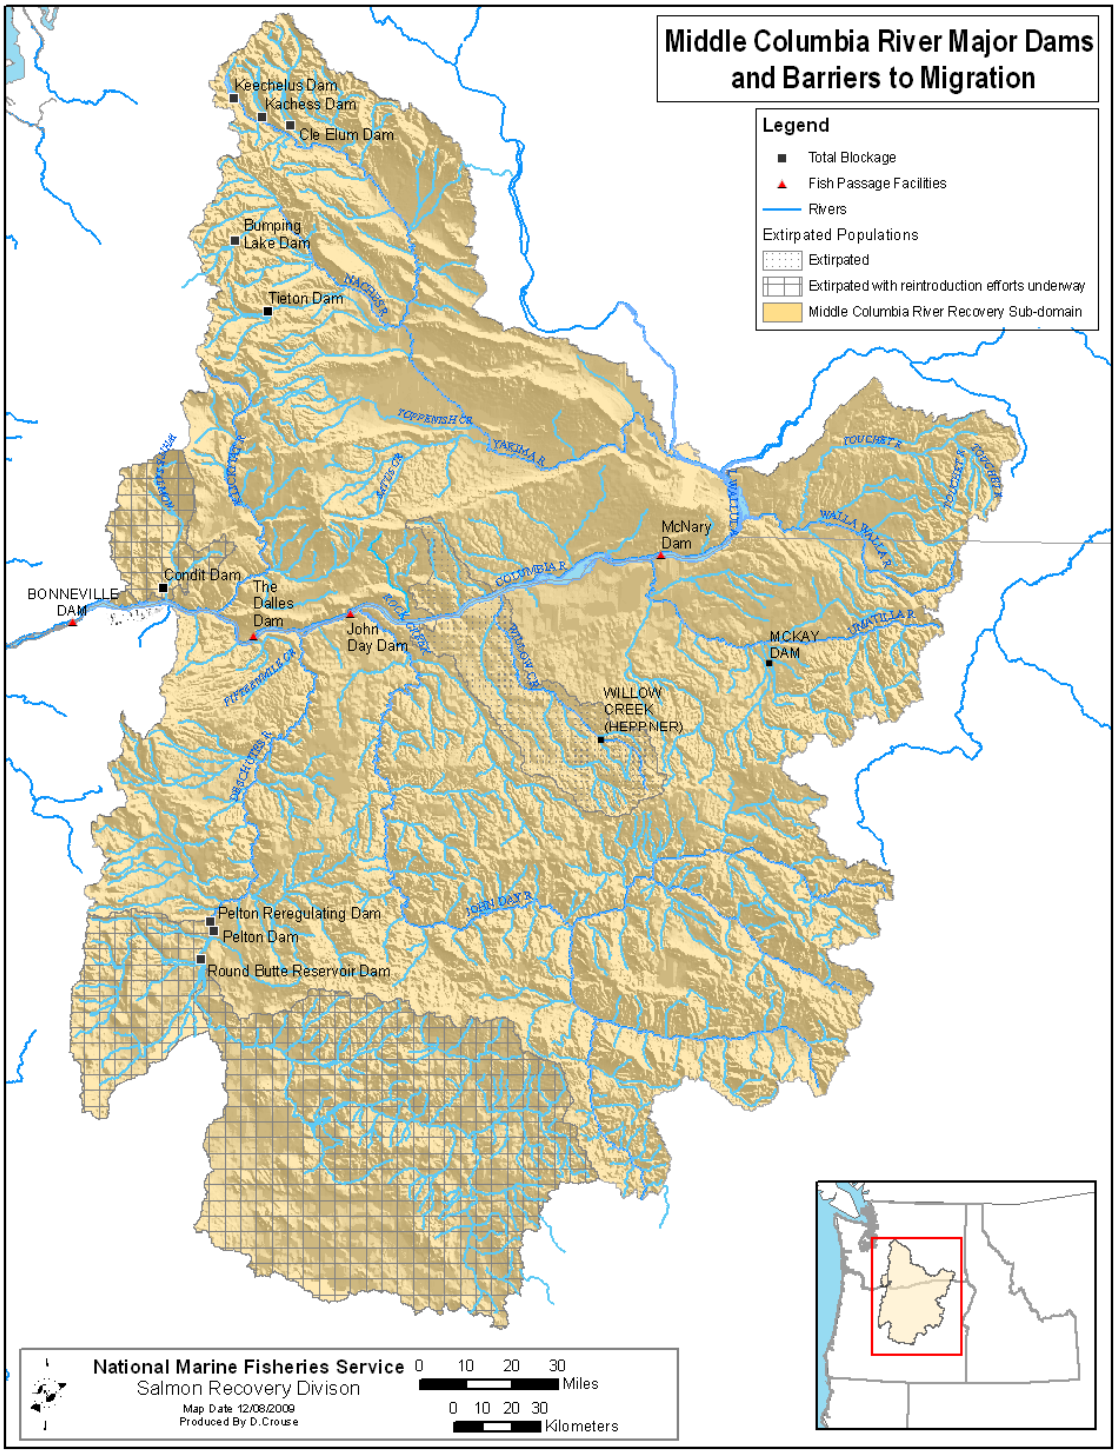

Figure 6-1. Major Dams and Barriers to Migration for Middle Columbia Steelhead.

Chapter 8 of the Oregon Steelhead Recovery Plan provides detailed information concerning the effects of the FCRPS on Middle Columbia steelhead; however, much must be inferred from studies of hatchery steelhead or Snake River steelhead because of a lack of specific survival data for the Middle Columbia steelhead DPS. Table 6-2 shows current estimates of survival of **juvenile** Middle Columbia steelhead migrating downstream through one to four dams. These estimates are based on COMPASS modeling of a 70-year water record (source: NMFS 2008a Supplemental Comprehensive Analysis—Hydro Modeling Appendix). They represent current conditions, reflecting improvements in the hydropower system made within the last decade. Juvenile survival is estimated at 90, 73, 54, and 48 percent, respectively, for passage through one to four dams. Juvenile mortality, conversely, is estimated at 10, 27, 46, and 52 percent.

Table 6-2. Middle Columbia River Steelhead DPS Juvenile Survival (migrating downstream) (Source: NMFS 2008a Supplemental Comprehensive Analysis—Hydro Modeling Appendix).

Population	Dams	% Survival
Fifteenmile	Bonneville	90
Klickitat		90
Deschutes West	The Dalles Bonneville	73
Deschutes East		73
Rock Creek	John Day The Dalles Bonneville	54
Lower Mainstem John Day		54
North Fork John Day		54
Upper Mainstem John Day		54
Middle Fork John Day		54
South Fork John Day		54
Umatilla		54
Walla Walla	McNary John Day The Dalles Bonneville	48
Touchet		48
Upper Yakima		48
Naches		48
Toppenish		48
Satus		48

Table 6-3 shows current estimates of **adult** survival for Middle Columbia steelhead migrating upstream through the dams.[32] These estimates are based on PIT-tagged steelhead from the Snake River as "surrogates." Adult steelhead survival is relatively high through the lower Columbia River dams and reservoirs as a result of dam operations and effective fish ladders.[33] There are known losses of adult fish approaching Bonneville Dam from marine mammal predation. For summer-run populations, this impact is likely minimal. For winter-run populations (Fifteenmile Creek, Klickitat, and possibly Rock Creek), the current impact may be as high as 22 percent (Source: NMFS 2008a Supplemental Comprehensive Analysis, Marine Mammal Predation Appendix).

Table 6-3. Middle Columbia River Steelhead DPS Adult Survival (migrating upstream) (Source: NMFS 2008a Supplemental Comprehensive Analysis, Adult Survival Estimates Appendix).

Population	Dams	% Survival
Fifteenmile	Bonneville	>98.5
Klickitat		>98.5
Deschutes West	Bonneville The Dalles	98.5
Deschutes East		98.5
Rock Creek	Bonneville The Dalles John Day	97
Lower Mainstem John Day		97
North Fork John Day		97
Upper Mainstem John Day		97
Middle Fork John Day		97
South Fork John Day		97
Umatilla		97
Walla Walla	Bonneville The Dalles John Day McNary	95
Touchet		95
Upper Yakima		95
Naches		95
Toppenish		95
Satus		95

[32] Adult steelhead detected at Bonneville Dam constitute the starting population for making survival rate estimates based on PIT tags. Consequently, no estimates of survival from the Bonneville tailrace to the detectors in the ladder are included in these estimates. However, based on the high inter-dam survival rates, this impact is likely small, except for winter-run populations, which may be substantially impacted by marine mammal predation in the Bonneville tailrace.

[33] It should be noted, however, that there are uncertainties in PIT-tag data for Upper Columbia steelhead compared to Snake River steelhead for the most recent two years, and it is not yet known how to interpret those data or how they apply to Middle Columbia steelhead adult survival estimates.

6.3.2.2 Water Temperature and Thermal Refuges

Optimal water temperatures for steelhead and salmon vary with life stage, but in general the optimal range is 11-15 °C (52-59 °F) and temperatures above 25 °C (77 °F) can be lethal. Alterations in water temperature affect the metabolism, growth rate, and disease resistance of salmonids, as well as the timing of adult migrations, fry emergence, and smoltification. As a result of the operation of the 14 FCRPS dams, in some areas and seasons the Columbia River is colder, and in others warmer, than before the dams (SCA Ch.5, NMFS 2008a). Since 1938, summer water temperatures at Bonneville Dam have increased 4 degrees on average (Lower Columbia Fish Recovery Board 2004). Among-year variability in temperature has been reduced by 63 percent since 1970 (Lower Columbia Fish Recovery Board 2004). Temperatures in the estuary exceed 20° C earlier in the year and more frequently than they did historically (National Research Council 2004). Coincident with and possibly due to climate change, average annual Columbia Basin air temperatures have increased by about 1 degree C over the past century and water temperatures in the mainstem Snake and Columbia rivers have been affected similarly (ISAB 2007). On the other hand, at some times of year temperatures in the lower Snake River may be lower than before, due to the release of colder water from the four lower Snake dams. This latter change has complex consequences; post-impoundment water temperatures may stay cooler longer into the spring and warmer later into the fall (called "thermal inertia"), and this in turn may affect adult migration, spawn timing, and juvenile emergence, rearing, and outmigration timing (SCA, NMFS 2008a).

When water temperatures are high, the fish may take refuge in cooler areas at the mouths of tributaries, and therefore delay migration and spawning or stray into the cooler rivers. It is possible that the Snake River hatchery steelhead that spawn in the Deschutes and John Day rivers are initially attracted to the thermal refuges at the mouths of these rivers.

6.3.2.3 Changes in Mainstem Columbia Nearshore Habitat

The mainstem nearshore environment has been changed by ports, population centers, railroad tracks, and highways, where riprap and docks have replaced riparian vegetation. Adverse effects include various contaminants, water temperature changes, loss of habitat complexity and associated rearing and refuge areas, loss of food resources, and stranding of juveniles. Relatively little information is available; more research is needed.

6.3.3 Impaired Fish Passage in Tributaries

Water management for agricultural irrigation alters seasonal flow patterns with serious consequences for steelhead rearing and both juvenile and adult migration in the Umatilla, Willow Creek, John Day, Deschutes, and especially the Yakima and Walla Walla basins. Dams, culverts, seasonal pushup dams, and unscreened diversions can directly prevent migration; seasonal areas of high water temperature, low flow, or dewatering can also function as barriers. In some tributary systems, local hydro-development blocks fish passage and results in flow modifications that affect water quality, habitat conditions, and predation rates. The Pelton-Round Butte Dam Complex on the Deschutes River blocks fish passage to upstream habitat on the Deschutes, Crooked, and Metolius rivers and smaller tributaries. Condit Dam blocks steelhead access to historical habitat on the White Salmon River. Five storage dams – Cle Elum, Kachess, Keechelus, Bumping Lake, and Tieton – block historical

habitat in the Yakima River basin. Bennington Dam, east of the City of Walla Walla on Mill Creek, a tributary of the Walla Walla River, was without fish passage until the 1980s. Subsequent improvements provide only partial passage, and Bennington Dam remains a significant passage obstruction that affects Walla Walla River steelhead. Numerous smaller barriers block or impair access to smaller tributaries throughout the basin.

In some tributary systems, local hydro-development also blocks fish passage (Pelton Dam on the Deschutes and Condit dam on the White Salmon) and results in flow modifications that affect water quality, habitat conditions, and predation rates (Pelton Dam on the Deschutes and Roza and Chandler Power Plants in the Yakima River system). Water management for agricultural irrigation alters seasonal flow patterns with serious consequences for steelhead rearing and both juvenile and adult migration in the Umatilla, Willow Creek, John Day, Deschutes, and especially the Yakima and Walla Walla basins.

6.3.4 Hatchery-Related Adverse Effects

Hatchery fish that stray into Middle Columbia tributaries and spawn naturally may represent a serious threat to steelhead recovery. More than 100 hatchery programs operate in the Columbia Basin above Bonneville Dam, mostly for the purpose of providing fish for harvest to mitigate losses caused by the FCRPS. Some hatchery programs may provide conservation benefits; however, hatchery programs also pose threats to natural-origin steelhead in some Middle Columbia watersheds. Hatchery-induced genetic change can reduce the fitness of both hatchery and natural-origin fish in the wild, and hatchery-induced ecological effects (competition for food and space) can reduce population productivity and abundance.

In particular, hatchery programs designed to return summer steelhead to upstream Columbia River tributaries result in substantial numbers of stray hatchery steelhead spawning naturally among several Middle Columbia populations. Concern exists regarding the continuing detrimental impact of these stray out-of-DPS hatchery fish in natural spawning areas on the genetic diversity and productivity of naturally produced Middle Columbia River steelhead populations. A large body of data indicates that steelhead of non-local origin can decrease the productivity and genetic diversity of natural populations (Fleming & Peterson 2001; McGinnity et al. 2003; Berejikian & Ford 2004, Myers et al. 2004). A recent study suggests that any interbreeding of hatchery-origin and naturally produced fish can pose risks to species fitness (Araki et al. 2007). The study suggested that use of natural-origin steelhead in a supplementation-type program is a possible strategy for increasing wild adults after one generation, but cautioned that long-term effects of supplementation are at present unknown and therefore a cause for concern in terms of potential impacts on fitness (Araki et al 2007).

The Oregon Steelhead Recovery Plan identifies hatchery practices and the effects of spawning stray hatchery fish as a key limiting factor and threat to the viability of the Deschutes River Eastside, Deschutes Westside, John Day, Umatilla, and Walla Walla populations. Out-of-DPS hatchery-origin spawners are estimated at 29 percent for Deschutes Eastside, 15.2 percent for Deschutes Westside, from 10 to 18 percent for Lower Mainstem John Day, and 5 percent for the Umatilla population (source: draft ICTRT Current Status Summary, Cooney 2008).

The Hatchery Scientific Review Group completed a review of hatchery programs in the Mid-Columbia steelhead DPS and released its recommendations in January 2009 (HSRG 2009).

The Oregon Steelhead Recovery Plan evaluates the hatchery strategies for each Oregon population to determine consistency with the HSRG recommendations.

Section 8.6 of the Oregon Steelhead Recovery Plan summarizes the specific hatchery programs and potential hatchery-related limiting factors for each of these populations. Within the Oregon portion of the Middle Columbia DPS, both the Round Butte hatchery program on the Deschutes River and the Umatilla hatchery program on the Umatilla River use endemic summer steelhead for broodstock. Out-of-basin hatchery smolts are released into the Walla Walla River as part of the Lower Snake River Compensation Plan. Washington Department of Fish and Wildlife operates the Lyons Ferry Hatchery, which is the only summer steelhead hatchery program in the Walla Walla basin. This hatchery program is being modified over time to reduce the impacts of non-endemic hatchery smolts released into the lower Walla Walla River with the goal of reducing genetic risks to the endemic steelhead population.

The John Day River steelhead populations are currently managed as wild populations and no hatchery production or supplementation occurs within the John Day River watershed. However, out-of-basin hatchery steelhead strays pose a primary threat to John Day steelhead populations. Hatchery steelhead coded-wire tag recoveries in the John Day subbasin from 1986 to 2003 identify 18 separate hatcheries as the sources of strays (Section 8.6.4 of the Oregon Steelhead Recovery Plan).

Releases of non-native Skamania stock hatchery fish in the Klickitat River may affect the Klickitat population. More data are needed to determine the effects of these hatchery fish on the productivity of the Klickitat population.

The Oregon Steelhead Recovery Plan notes that the number of out-of-basin hatchery-origin steelhead observed in the Deschutes River increased as mitigation programs developed in Columbia River watersheds (Section 8.6.3). A majority of these fish were produced in the Snake River Basin and at the Wallowa Hatchery. Both are funded under the Lower Snake River Compensation Plan.

More data are needed concerning the effect of all the combined hatchery releases on food supply and predation rates in the estuary (discussed further in Estuary Module). Pacific salmon at all abundance levels and at all life stages are subject to density dependent processes. Many factors influence these processes, including changes in habitat quality and quantity, prey base, the abundance and distribution of predators, natural fluctuations in environmental conditions (e.g., summer stream flows and ocean productivity), and interactions among species and between natural and hatchery fish that depend on the same natural environments. The question is how and to what extent hatchery-origin fish, in combination with these and other factors, affect density dependent processes and the growth and survival of natural-origin fish. There is increasing evidence of density dependent effects on salmon and steelhead growth and survival, but the underlying factor or factors remain poorly understood. Evaluating the factors that influence or drive density dependent effects under different freshwater (e.g., hydrosystem), estuarine, and ocean conditions is an important area of future research.

6.3.5 Predation/Competition/Disease

Anthropogenic changes in the Columbia River have altered the relationships between salmonids and other fish, bird, and pinniped species.

6.3.5.1 Pinnipeds

During the spring salmonid migration season, Steller sea lions, California sea lions, and harbor seals prey on salmon and steelhead in the Lower Columbia River as far upstream as the Bonneville Dam. California sea lions arrive in the greatest numbers (ranging from 31 to 111, 2002 to 2007, and averaging 82 individuals observed per year, compared to numbers in the single digits for Steller sea lions and harbor seals) (NMFS 2008d). They consume an estimated minimum of 1,000 to 4,000 (in-migrating adult) salmonids per year (ibid.). California sea lions and harbor seals are not ESA-listed, not considered depleted under the Marine Mammal Protection Act (MMPA), have increased in recent years and are considered to have stable populations that have reached carrying capacity for present ocean and breeding site conditions (Carretta et al. 2007, cited in NMFS 2008d). The Eastern United States stock of Steller sea lions (in this case, eastern refers to the eastern side of the Pacific Rim) is listed as threatened under the ESA and depleted under the MMPA. However, this population is stable or increasing throughout much of its range (ibid.).

The abundance of native pinnipeds has steadily increased since passage of the Marine Mammal Protection Act in 1972. The sea lions are estimated, based on visual observations and steelhead counts at Bonneville Dam, to consume 7.8 percent of winter-run steelhead (source: Marine Mammal Appendix, 2008 FCRPS BiOp). However, because of the difficulties of observing predation at the dam, comparisons of radio-telemetry data indicate that the consumption rate of spring Chinook salmon is likely 2.8 times higher (8.5 percent by radiotelemetry versus 3.0 by observation) than estimated using observational data alone. Applying this correction factor to winter-run steelhead would yield an estimate of 21.8 percent. Based on the relatively low numbers of steelhead passing Bonneville Dam during the winter months (0 to 140 individuals per day – Columbia River DART adult passage data for 2005 to 2008), even a small number of sea lions would be capable of consuming approximately 20 percent of the migrating winter steelhead (source: NMFS 2008a, Supplemental Comprehensive Analysis, Marine Mammal Appendix). This may represent a significant impact on the winter-run steelhead in the Middle Columbia DPS (primarily Fifteenmile Creek and Klickitat populations). Because of their migration timing, the summer-run steelhead populations that make up the bulk of the DPS are not likely substantially affected by pinniped predation.

6.3.5.2 Birds

Estuary habitat modifications have increased the number and/or predation effectiveness of Caspian terns, double-crested cormorants, and a variety of gull species. Juvenile steelhead, including Middle Columbia steelhead, are most vulnerable to predation by Caspian terns because they migrate at relatively shallow depths in deep water habitat channels that have relatively low turbidity and are close to island tern habitats (NMFS 2007; NMFS 2008a; Collis et al. 2007; Roby et al. 2008). They also tend to be larger than juveniles of other salmonid species. Caspian terns began nesting on East Sand Island in the Columbia estuary (RM 5) in 1984 and on Rice Island (RM 21) in 1986. The islands were formed by U.S. Army

Corps of Engineers' disposal of dredged material. On September 15, 1999, NMFS required the Corps to modify habitat on Rice Island to eliminate nesting habitat for Caspian terns. Since 2001, no Caspian terns have nested on Rice Island, resulting in reduced predation of juvenile salmonids from 11.7 million fish in 1999 to 6.5 million fish in 2002. Although total consumption of juvenile salmonids by terns was reduced considerably, a 2007 study found that predation rates on steelhead were 2-12 times higher than those for other salmonid species and run types (Roby et al. 2008). Based on smolt PIT tag recoveries on the East Sand Island Caspian tern colony, predation rates on steelhead smolts were particularly high during 2007, at about 12.5 percent for in-river migrant smolts and 7.7 percent for transported smolts.

Avian predation is also significant farther inland in the Middle Columbia region. Avian predator colonies on islands in the Columbia River include Caspian terns, double-crested cormorants, ring-billed and California gulls, and American white pelicans. The most significant populations of avian predators occur on Crescent Island (Caspian terns) and Foundation Island (cormorants), which are located in the Columbia near the mouth of the Snake River. In 2000 and 2001, bioenergetics modeling was used to estimate the smolt consumption rate of the Crescent Island tern colony at 465,000 and 679,000 smolts, respectively (Antolos et al. 2005). Approximately 25 percent of this consumption consisted of steelhead, including steelhead from the Yakima basin.

In 2005, an estimated 1 percent (22) of PIT tags from outmigrating Yakima River steelhead were subsequently recovered on the Crescent Island Caspian tern colony. In 2004, the figure was 2 percent (A. Evans, Real Time Research Inc., personal comm. 2006, as cited in the Yakima Recovery Plan). In 2005 only 0.1 percent (3 PIT tags) of PIT-tagged Yakima River steelhead were recovered on the Badger Island pelican colony (located just downstream from the mouth of the Yakima with more than 1057 adult birds present). PIT tag recoveries from the Foundation Island colony of double-crested cormorants, situated 8 km upstream of Crescent and Badger islands, indicated an overall steelhead predation rate about one-fifth as great as for the tern colony, though this is changing as tern numbers drop and cormorant numbers increase (Collis and Roby 2006). These rates do not account for ingested PIT tags deposited off the colonies, or for mortality (at least 50 percent for Yakima steelhead) of tagged fish between release sites and the Yakima River's mouth (Yakima Recovery Plan).

6.3.5.3 Piscivorous Fish

The dams on the Columbia River alter habitat conditions in several ways that are favorable to both native and nonnative fish species that prey on juvenile salmonids (NMFS 2008a). A recent report from the Independent Scientific Advisory Board, an appointed group of scientists advisory to the Northwest Power and Conservation Council, Columbia River Basin Indian Tribes, and NMFS, summarizes these effects and concludes that predation by nonnative species is as significant as habitat loss and degradation in imperiling native freshwater species (ISAB 2008). The primary resident fish predators are northern pikeminnow (native), smallmouth bass (introduced), and walleye (introduced) (NMFS 2008a). Other predatory resident fish are channel catfish (introduced), Pacific lamprey (native), yellow perch (introduced), largemouth bass (introduced), and bull trout (native).

Impacts of the northern pikeminnow are concentrated in the lower Columbia River from The Dalles reservoir downstream, where the estimated predation loss is 8 percent of the approximately 200 million hatchery and wild juvenile salmonid migrants in the system (NMFS 2008a). The highest densities of smallmouth bass in the Columbia and Snake Rivers occur in the Lower Granite forebay, tailrace, and reservoir, followed by the John Day Reservoir (NMFS 2000a). Throughout the John Day Reservoir study area, smallmouth bass consumed far fewer juvenile salmonids than did northern pikeminnow (Zimmerman 1999). Walleye are also most abundant in the tailraces of the dams (NMFS 2008a). In the 1983-1986 John Day Reservoir study that forms the basis for the current predator management program, Rieman et al. (1991) found that walleye consumed 13 percent of the estimated annual 2.7 million juvenile salmonids consumed by predatory fish. Northern pikeminnow accounted for 78 percent and smallmouth bass took 9 percent (cited in NMFS 2008a).

6.3.5.4 Competition

Changes in habitat and high numbers of hatchery fish releases can also affect competitive relationships, resulting in increased competition between steelhead and other species for food and habitat (NMFS 2008a; ISAB 2008). Competition is often discussed in terms of density dependence. Density dependence refers to changes in the size of a population that are themselves a result of the size of the population, such as when a population declines because it has exceeded the amount of resources available to support it (NMFS 2007). Density dependent mortality can occur through several mechanisms, such as direct competition for limited food and habitat and changes in the foraging activity of predators. With salmon and steelhead, density dependent mortality can occur at any stage in the animal's life cycle and may be exacerbated by the introduction of large numbers of hatchery fish released over a relatively short period of time.

How much density dependent mortality is taking place in the estuary compared to the ocean is unclear. There is some evidence that density dependent mortality is occurring in the open ocean. For example, during years when salmon are especially numerous in the ocean, their growth rates are reduced (Peterman 1984). However, another study found no connection between ocean conditions and density dependent mortality, which appeared to be occurring among wild Snake River Chinook as hatchery steelhead were released (Levin and Williams 2002). The authors suggested that the apparent density dependent mortality could be better explained by interactions in the tributaries or estuary than by interactions in the ocean.

There is growing awareness among scientists studying the Columbia River estuary that mechanisms related to density dependence may limit salmon and steelhead while they are using estuary and plume habitats. Scientists studying Skagit River fall Chinook have documented density dependence-related mortality as a result of loss of habitat in the Skagit estuary and believe that such mortality can be attributed to a 75 percent loss of tidal delta estuarine habitat (Beamer et al. 2005). With similar habitat losses in the Columbia River estuary, it is possible that too many fish are competing for limited habitat and associated resources in the estuary at key times, and that the resulting stressors translate into reduced salmonid survival. The NOAA/NMFS Northwest Fisheries Science Center currently is investigating potential density dependent mortality in the estuary.

6.3.5.5 Disease

Steelhead can be infected by a variety of bacterial, viral, fungal, and microparasitic pathogens. Numerous diseases may result from pathogens that occur naturally in the wild or that may be transmitted to wild fish via infected hatchery fish. Very little current or historical information exists to quantify changes in infection levels and mortality rates attributable to these diseases for steelhead. However, studies have shown that naturally spawned fish tend to be less susceptible to pathogens than hatchery-reared fish (Buchanon et al., 1983; Sanders et al., 1992). Native salmon populations have co-evolved with specific communities of these organisms, but the widespread use of artificial propagation has introduced exotic organisms not historically present in a particular watershed. Habitat conditions such as low water flows and high temperatures can exacerbate susceptibility to infectious diseases. Fish weakened by disease are more sensitive to other environmental stresses, and may become more vulnerable to predation or less able to compete with other species. Aggressive hatchery reforms implemented in some areas have reduced the magnitude and distribution of hatchery fish releases, and consequently the interactions between hatchery- and natural-origin fish and the potential transmission of infectious diseases. Additionally, regulations controlling hatchery effluent discharges into streams have reduced the potential of pathogens being released into steelhead habitats. There is little or no information on specific impacts or trends in disease among Middle Columbia steelhead.

6.3.6 Degradation of Estuarine and Nearshore Marine Habitat

The estuary serves an important role beyond simply providing a corridor that Interior Columbia populations use to migrate between freshwater and the ocean. The estuary is part of the continuum of ecosystems that salmon and steelhead use to complete their life cycles. A variety of anthropogenic factors and natural changes to the estuary have affected all VSP parameters, particularly alterations in flows, loss of emergent marsh, tidal swamp, and forested wetlands, shifts in organic matter important to estuarine food webs, and changes in the plume. Changes in the plume may have a greater effect than changes in shallow-water habitat on salmonids with yearling life history strategies such as the Middle Columbia steelhead DPS. Exposure to waterborne and sediment-associated chemical contaminants such as pesticides and dissolved metals can also affect productivity of salmon and steelhead. Finally, predation in the estuary is a major source of mortality on both adults and juveniles of all listed populations. These issues are discussed in greater detail in the Estuary Module (NMFS 2007).

6.3.7 Harvest

Fisheries that harvest salmon and steelhead of the Columbia River are established within the guidelines and constraints of the Pacific Salmon Treaty, the Pacific Fishery Management Council, the states of Oregon and Washington, the ESA administered by NMFS, and management agreements negotiated between the parties to *U.S. v. Oregon*. Fisheries management through these various organizations has resulted in the decline of total exploitation rates for Columbia River salmon and steelhead, especially since the 1970s. Because of these changes, the ICTRT currently considers harvest a secondary limiting factor for Oregon Middle Columbia steelhead populations.

6.3.7.1 Ocean Fisheries

It is assumed that steelhead are rarely caught in ocean fisheries because they tend to be distributed offshore of major fishing areas and are therefore not readily available. According to Rich (1942), Columbia River steelhead were historically taken along with Chinook and coho in ocean fisheries off the mouth of the Columbia River, but accounted for less than 0.1 percent of the catch and numbered only in the few hundreds of fish. Current ocean fisheries generally target Chinook and coho salmon, and interception of steelhead is believed to be rare. If caught, steelhead must be released. Creel surveys on recreational ocean fisheries recorded less than 100 steelhead (of any DPS) caught each year from 2003 to 2005. Of these, less than 10 were estimated to be released wild fish mortalities. Ocean fishing mortality on Middle Columbia River steelhead is assumed to be zero.

6.3.7.2 Mainstem Columbia Fisheries

Harvest rates on the Middle Columbia steelhead DPS in the past, e.g. prior to 1975, were estimated at 65 percent in fisheries occurring in the Columbia River. Current rates are much lower. There has been no direct freshwater non-tribal harvest on wild steelhead from the Middle Columbia DPS since 1992, when the last wild fish catch and release regulations on these populations became effective. Therefore, all current non-tribal harvest impacts on Middle Columbia DPS steelhead are due to incidental bycatch in commercial or recreational fisheries that target hatchery steelhead or other species. Monitoring these impacts is complex. Information assessing catch and release mortality of adult steelhead is limited. However, available information suggests that hook-and-release mortality is low. Hooton (1987) found catch and release mortality of adults in winter steelhead fisheries to be, on average, less than 5 percent when barbed and barbless hooks, bait and artificial lures were used; Hooton (1987) concluded that catch and release of adult steelhead was an effective mechanism for maintaining angling opportunity without negatively impacting stock recruitment. Reingold (1975) showed that adult steelhead hooked, played to exhaustion, and then released returned to their target spawning stream as well as steelhead not hooked and played to exhaustion. Similarly, Nelson et al. (2005) observed that the catch and release mortality for radio-tagged wild winter steelhead was 2.5 percent and that tagged steelhead survived to spawning even after being caught and released up to three times. Mongillo (1984) and Rawding (2000) reported a strong correlation between water temperature and catch and release mortality, with water temperatures below 50F (10C) providing optimal survival, while temperatures above 60F (15.5C) increase the mortality rate. Recreational fisheries are monitored by creel surveys. (Fisheries technicians interview anglers about their catch, gear, and wild steelhead releases.)

Tribal treaty fisheries are managed through the *U.S. v. Oregon* process. *U.S. v. Oregon* is the result of the Federal government intervening in Federal court to protect tribal treaty reserved fishing rights in the Columbia Basin. A 10-year agreement (through 2017) is now in place to govern mainstem Columbia River fishing (NMFS 2008a). Harvest impact is limited to ESA incidental mortality limits set by NMFS. Within these ESA limits, the states and tribes negotiate how harvest will be allocated, with the objective being to balance the catch between them. All of the fisheries are abundance-based, with higher harvest rates allowed as ESA-listed adult returns increase.

There is a standing technical committee, the TAC (Technical Advisory Committee), to help monitor the fisheries. The TAC, using models, develops pre-season estimates of adult returns, updates these estimates in-season based on dam counts, and monitors the fisheries in season. The fisheries (both state and tribal) are adjusted based on the in-season run forecasts to stay within the ESA impact limits. Most of the time the fisheries take less than the ESA impact limit. The states provide real time updates of the fisheries, accessible to the public via the Internet, during periods of fishing. There is usually a post-season review of the fishery. In summary, NMFS sets ESA limits; the states and tribes negotiate how the harvest will be allocated, with the objective being to balance the catch between them.

Three stocks of summer steelhead are used for management of treaty and non-treaty mainstem fisheries: lower river Skamania stock, upriver A-run stock, and upriver B-run stock. All Middle Columbia steelhead populations are designated A-run, with two populations being winter-run. In NOAA Biological Opinion for the 2008-2017 *U.S. v. Oregon* Fisheries Agreement (NMFS 2008b), the wild Middle Columbia steelhead DPS in the non-treaty winter, spring, and summer mainstem fisheries are subject to a 2 percent harvest rate limit (NMFS 2008b). Non-treaty fall fisheries are also limited to a 2 percent harvest rate for A-run summer steelhead. The total annual harvest rate limit for A-run steelhead in non-treaty fisheries is 4 percent and 2 percent for the summer-run and winter-run of the Middle Columbia steelhead DPS respectively. The expected actual harvest impacts from non-treaty fisheries are less than the limits proposed in the *U.S. v. Oregon* Fisheries Agreement. The yearly incidental catch of A-run steelhead in non-treaty fisheries has averaged 1.6 percent since 1999, and is not expected to change over the course of the Agreement (NMFS 2008b).

Tribal fishers in Zone 6 of the Columbia mainstem (between Bonneville Dam and McNary Dam) continue to retain wild steelhead for commercial sale or for personal use. The *U.S. v. Oregon* Fisheries Agreement does not establish specific harvest rate limits for treaty Indian fisheries on steelhead during the spring or summer seasons, which extend through July 31. Reported steelhead catch in Zone 6 winter and spring fisheries for 2003 to 2005 ranged from 0.7 percent to 7.9 percent of the winter steelhead run over Bonneville Dam. In 2004, reported and estimated non-reported steelhead catch together amounted to 4.8 percent of the run at Bonneville, with an unknown error around these numbers (Oregon Steelhead Recovery Plan, p. 8-98).

Impacts on Middle Columbia steelhead from Treaty Indian fall fisheries are limited by harvest rate limits for B-run steelhead and Upper Columbia River bright fall Chinook (NMFS 2008b). The harvest rate on Middle Columbia summer-run steelhead in spring, summer, and fall Zone 6 Treaty Indian fisheries combined averaged 11.7 percent since 1985 and 6.64 percent since 1998 (Table 8.8.5.5-1; NMFS 2008b). The impacts resulting from the Treaty Indian fisheries are expected to be similar to the 1998-2006 average of 6.64 percent. The harvest rate is less for populations that pass fewer dams in Zone 6 and are therefore subject to fewer non-Indian and treaty Indian fisheries (e.g. Klickitat steelhead pass only one dam and would experience a harvest rate less than 6.64 percent). Mainstem harvest rates are estimated to be less than 8.54 percent for natural Middle Columbia steelhead (NMFS 2008b).

Oregon and Washington have proposed regulations for tributary recreational fisheries in Fisheries Management and Evaluation Plans (FMEPs) submitted to NMFS for approval under the limit 4 of the 4(d) rule. All recreational steelhead fisheries are restricted to adipose fin-clipped hatchery steelhead only. WDFW estimates that in 2002 fisheries, the impacts on Middle Columbia steelhead from all fisheries were 7.5 percent for the Treaty Columbia River mainstem and tributary fisheries, less than 4.0 percent for the non-treaty Columbia River mainstem fisheries, and 0.3 percent in Washington tributaries, for a total impact of less than 12 percent (WDFW 2008).

ODFW performed a number of Population Viability Assessment model runs for 27 steelhead populations to assess the impact of fisheries mortality on the status and recovery of steelhead in Oregon (Chilcote 2001). The model looked at a range of fisheries mortalities from 0 percent to 75 percent. The results were stated in terms of the probability of the population becoming extinct in 50 years at each fisheries mortality rate. For most populations the modeling suggested that the probability of extinction was essentially zero as long as fisheries mortality rates remained less than 30 percent. As mortality rates became greater than 40 percent, the probability of extinction increased dramatically. Furthermore, once the probability of extinction increased beyond 0.05, the transition to an extinction probability of 1.00 was very rapid. In other words, once mortality rates increase sufficiently to cause the probability of extinction to exceed 0.05, any additional mortality would cause a rapid increase in the likelihood of extinction. Because the transition from low to high risk happens so rapidly, there is little room for error (in the model or the measurements of mortality rates). To address this concern, fisheries co-managers will manage steelhead fisheries not to exceed a maximum fisheries mortality limit to 20 percent. This conservative approach was used to provide a buffer for errors, even though the model results suggested that management under a 40 percent limit was unlikely to cause extinction.

6.3.8 Climate Change

The Independent Scientific Advisory Board (ISAB) for the Northwest Power and Conservation Council, Columbia River Basin Indian Tribes, and NMFS reviewed the potential effects of climate change on salmonids in the Columbia River basin (ISAB 2007). As described in that report, changes in climate in the Pacific Northwest have affected both habitats and species, and those effects are expected to continue in the future. Climate records show that the Pacific Northwest has warmed about 1.0 °C since 1900, or about 50 percent more than the global average warming over the same period. The warming rate for the Pacific Northwest over the next century is projected to be in the range of 0.1 to 0.6 °C per decade. While projected precipitation changes are predicted to be indistinguishable from natural variability until late in the 21st century, most models project long-term increases in winter precipitation and decreases in summer precipitation.

The ISAB report shows that changes in climate may adversely affect steelhead in freshwater habitats across the DPS by exacerbating existing problems with water quantity (lower summer stream flows) and water quality (higher summer water temperatures). Consistently identified types of impacts on snow pack, stream flow, and water quality in the Columbia Basin are the following (ISAB 2007):

- Warmer temperatures will result in more precipitation falling as rain rather than snow.
- Snow pack will diminish, and the timing of stream flows will be altered.
- Peak river flows will likely increase.
- Water temperatures will continue to rise.

These changes in air temperatures and river flows will cause changes to the physical and chemical habitat in the mainstem river and tributary streams, which will elicit a response in the biological communities living in those habitats. These changes will affect all salmonid life stages, and range from changes in run timing or movement because of warmer water temperatures, to changes in species composition with a shift toward species more tolerant of warmer water temperatures. ISAB (2007) predicts changes in interspecies interactions and increased physiological stressors on fish. These changes may affect steelhead more than other salmonids because of their long rearing period in freshwater. More detailed information on specific effects that climate change may have on Mid-Columbia steelhead at all their life stages is available in Section 8.8 of the Oregon Steelhead Recovery Plan (ODFW 2009).

Changing conditions could also affect salmonid health and survival in the ocean through a variety of mechanisms, including increased ocean temperatures, increased stratification of some waters, changes in the upwelling season, shifts in the distribution of salmonids, long-term variability in winds and ocean temperatures, increased acidity, and increased atmospheric and oceanic variability (NMFS 2007, 2008a; ISAB 2007).

All other threats and conditions remaining equal, future deterioration of water quality, water quantity, and/or physical habitat can be expected to cause a reduction in the number of naturally produced adult steelhead returning to these populations across the DPS. This possibility further reinforces the importance of achieving survival improvements throughout the entire steelhead life cycle. Recent research also indicates that neighboring populations with differences in habitat may show different responses to climate changes (Crozier and Zabel 2006; Crozier et al. 2008). This research reinforces the importance of maintaining habitat diversity. Ongoing efforts to develop models of future climate effects should be considered in adaptive management.

6.4 MPG Limiting Factors

The MPG-level summaries of limiting factors are based on population-level summaries compiled from the relevant management unit plans.

6.4.1 Cascades Eastern Slope Tributaries MPG

The following are major limiting factors for the Cascades Eastern Slope Tributaries MPG:

Tributary habitat. Degraded tributary habitat is a limiting factor to a greater or lesser degree throughout the area, including degraded riparian areas, reduced LWD recruitment, altered sediment routing, low or altered stream flows, degraded water quality (especially high water temperatures), impaired floodplain connectivity/function, altered channel structure/complexity, and impaired fish passage.

Mainstem passage. Mainstem Columbia River hydro system effects are least for the Fifteenmile Creek and Klickitat River populations, which pass only one mainstem dam. The Deschutes River populations pass two mainstem dams, and the Rock Creek population passes three.

Hatchery related effects. Influence from hatchery fish could be a significant factor for this MPG because of out-of-subbasin straying onto natural spawning grounds in the Deschutes River and also because of potential effects of hatchery releases on naturally produced steelhead in the Klickitat River. The Oregon Mid-C Expert Panel considered out-of-subbasin (and out-of-DPS) hatchery strays a primary threat to genetic traits and productivity of naturally produced Deschutes river steelhead populations. Out-of-DPS hatchery strays comprised an average of 29 percent of the Eastside population and 15.2 percent of the Westside population over the past three generations. This high fraction resulted in moderate risk ratings for spawner composition for both populations.

Blocked migration to historically accessible habitat. Historically, summer steelhead had free access to most of the Deschutes watershed, including the Crooked River, Metolius River, Deschutes River upstream to Big Falls, and Whychus Creek. Summer steelhead were historically present throughout much of the Crooked River basin, with the exception of the North Fork Crooked River above Upper and Lower Falls. Steelhead were still present in the Crooked River until the mid to late 1950s, and were occasionally caught by anglers. Now the Pelton-Round Butte Hydroelectric Project (Project), constructed at river mile (RM) 100 on the mainstem Deschutes River, creates the primary barrier to anadromous fish attempting to reach spawning and rearing areas in the upper basin. The project was completed in 1964 with upstream and downstream fish passage facilities. However, by 1966 it appeared that downstream passage through Lake Billy Chinook, the reservoir behind Round Butte Dam, could not be maintained because of poor guidance of out-migrating smolts. The last fish were passed in 1968. Currently, plans are underway to reinitiate fish passage facilities at the Pelton-Round Butte complex and reintroduce steelhead to the upper basin (details in Section 9.4.2 of the Oregon Steelhead Recovery Plan). The second large barrier to upstream fish migration into the Crooked River is Opal Springs Dam at RM 7. Agencies and stakeholders are working together to address fish passage issues (see Section 8.2.4 in the Oregon Steelhead Recovery Plan).

Historically, summer and winter steelhead spawned in the White Salmon subbasin. Condit Dam, constructed in 1913 on the mainstem White Salmon River, blocks all anadromous fish migration to historical habitats in the upper subbasin. Condit Dam is scheduled to be removed in 2010.

Predation/competition/disease. Predation, competition, and disease issues in mainstem and estuary affect all of the Middle Columbia steelhead populations (see Section 6.3.5). In addition, the Oregon Steelhead Recovery Plan hypothesizes that the abundance of the Deschutes River Westside population may be limited by competition with a large resident population of rainbow trout.

6.4.2 John Day River MPG

The following are major limiting factors for the John Day River MPG:

Mainstem passage. These populations must pass three dams; thus, limiting factors include direct mortality of pre-smolts and smolts at John Day, The Dalles, and Bonneville dams; delayed upstream migration of returning adults; false attraction of returning adults over McNary Dam; and cumulative impact of hydropower system on mainstem and estuary habitat (see Hydro Module, NMFS 2008c).

Hatchery related effects. Out-of-DPS hatchery fish straying into natural spawning areas (10 to 18 percent in the Lower Mainstem John Day) pose risks to genetic traits and productivity of naturally produced steelhead. Concern over competition for resources with wild fish and potential hybridization with natural-origin fish resulted in termination of all hatchery stocking of *O. mykiss* in the John Day River basin in 1997. Most hatchery stray recoveries occur in the Lower Mainstem John Day below the North Fork; however, strays have been observed in all populations.

Tributary habitat. For all five John Day populations, degraded floodplain and degraded channel structure (key habitat quantity and habitat diversity), altered sediment routing, water quality (temperature), and altered hydrology are limiting factors. For the Lower and Upper Mainstem and South Fork populations, passage obstructions in some of the smaller tributaries are also significant.

Predation/competition/disease. Predation, competition, and disease issues in mainstem and estuary affect all of the Middle Columbia steelhead populations.

6.4.3 Umatilla/Walla Walla MPG

The following are the major limiting factors for the Umatilla/Walla Walla MPG:

Mainstem passage. The Walla Walla and Touchet populations must pass four major dams; the Umatilla population must pass three.

Tributary habitat. For all three populations, water quality (temperature), sediment, blocked and impaired fish passage, degraded floodplain and channel structure (key habitat quantity and habitat diversity) and hydrologic alterations are limiting factors.

On the lower Umatilla River, six major irrigation diversions withdraw enough water to dewater the river in mid-summer. McKay Dam blocks fish passage to 108 miles of historically accessible habitat. Bennington Dam, east of the City of Walla Walla on Mill Creek, a tributary of the Walla Walla River, is a significant passage obstruction. The Mill Creek flood control channel through Walla Walla is also a significant passage obstruction.

Hatchery related effects. The hatchery program on the Umatilla River uses endemic (native) stock and is not currently considered a threat to wild steelhead; however, out-of-DPS strays pose a risk to spawner composition. The hatchery program on the Walla Walla and Touchet rivers uses non-endemic stock, but an endemic stock program is under development. Non-endemic-origin hatchery fish from mitigation releases into the lower Walla Walla River have been straying into upper river natural production areas at relatively low levels. Recent smolt releases in the program have been reduced. Future levels of straying are uncertain, and

additional actions may be necessary. Currently, data are insufficient to determine whether hatchery effects are a problem for wild steelhead in the Touchet River.

Predation/competition/disease. Predation, competition, and disease issues in mainstem and estuary affect all of the Middle Columbia steelhead populations.

6.4.4 Yakima River MPG

The following are the primary limiting factors for the Yakima MPG:

Mainstem passage. As the farthest upstream populations in the DPS, the Yakima populations must pass four dams and undergo higher exposure to altered habitat and avian and piscine predators in the mainstem Columbia.

Tributary habitat. Fish habitat in the Yakima subbasin is substantially influenced by the development of irrigation systems. Limiting factors include altered hydrology (low summer flow, scouring peak flows due to degraded watershed conditions, high summer delivery flows in mainstem Yakima and Naches rivers, reduced winter and spring flows due to irrigation storage, delivery, and withdrawals); degraded riparian area and LWD recruitment; impaired fish passage (dams, culverts, seasonal push-up dams, entrainment in unscreened diversions); altered sediment routing; degraded water quality; loss of historical habitat because of blocked or impaired fish passage; degraded floodplain connectivity and function (loss of off-channel habitat, side channels and connected hyporheic zone); degraded channel structure and complexity; reduced outmigrant survival in the mainstem Yakima.

Hatchery related effects. The Yakima populations have the lowest rates of hatchery strays in the DPS, and hatchery effects are not considered a significant limiting factor.

Predation/competition/disease. Of the Middle Columbia steelhead populations, the Yakima basin populations have the longest migration through the mainstem Columbia River. They may therefore be more vulnerable to some factors such as avian and piscivorous fish predation. For example, Yakima steelhead, but not the others, are consumed by Caspian tern and double-crested cormorants nesting on islands at the mouth of the Snake River.

7. RECOVERY STRATEGY

The preceding chapters summarize recovery goals, biological criteria and threats criteria, current status assessment, the gap between current status and desired viability, and the major limiting factors and threats identified for the Middle Columbia steelhead DPS. This information helps us understand what recovery would look like, but how will we get there?

NMFS' overall goal for DPS viability, as formulated by the ICTRT and described in Chapter 3 of this plan, is to have all four extant MPGs at viable (low risk) status, with representation of all the major life history strategies present historically, and with the abundance, productivity, spatial structure and diversity attributes required for long-term persistence.

The ICTRT's current status assessment for the Middle Columbia steelhead DPS and the gaps analysis show that for this DPS, the outlook is optimistic. One population, North Fork John Day, is currently at very low risk or "highly viable." Two populations are currently viable (Deschutes Eastside, Fifteenmile); eleven are at moderate risk, with good prospects for improving. However, the three large populations at high risk (Deschutes Westside, Naches, and Upper Yakima), are important to DPS viability; as a minimum, Deschutes Westside and one of the two large Yakima populations should also reach viable status, with the other large Yakima population at least reaching "maintained" status. These present significant, though not insuperable, challenges.

If, as we believe, the decline of the Middle Columbia River steelhead DPS is caused by widespread habitat degradation, impaired mainstem and tributary passage, hatchery effects, and predation/ competition/ disease, then actions taken to improve, change, mitigate, reduce those factors will result in reduced risks and increased survival. Because of the steelhead's complex life cycle and the many changes that have taken place in its environment, the factors limiting its survival must be addressed in concert, and in an integrated way. The work needs to occur at a regional level, in terms of commitment to actions and funding, and at the local level, population by population and site by site. Significant investments of research, planning, regional coordination, actions, and political will are already underway. The intent for the DPS plan is to build upon, help to coordinate, and add to the ongoing efforts.

NMFS' 2006 listing decision called upon Federal, state, and tribal entities to do their best to manage land, hydropower, hatchery, and harvest activities in a manner that would support steelhead recovery. This plan reaffirms those recommendations and adds to them the contributions of updated science, basinwide programs, and consensus building among stakeholders. While Federal, state, and tribal entities can make major contributions to the recovery of Middle Columbia steelhead, the actions of individuals on their land, as well as city and county codes and ordinances promoting conservation, are also essential.

The recovery strategy for the Middle Columbia steelhead DPS addresses both the basin-wide issues that affect all populations, such as conditions in the migratory corridor, and the subbasin and site-specific issues that are the focus of the management unit plans. The DPS Plan describes the overall strategy, summarizes the MPG-level strategies, and refers to Appendices A-G for more site-specific, population level actions.

7.1 DPS Level Recovery Strategy

The DPS-level recovery strategy for the Middle Columbia steelhead is made up of the following elements:

- Affirm and address the 2006 listing decision recommendations regarding the limiting factors for the DPS and populations.
- Protect and restore tributary habitat and Columbia River mainstem habitat, through strategies and actions at both the Basin/programmatic level and at the local level as detailed in the management unit plans.
- Address impaired fish passage through strategies and actions in the mainstem Columbia River, as detailed in the 2008 FCRPS Biological Opinion (as summarized in the Hydro Module) and in the tributaries as detailed in the management unit plans.
- Implement hatchery reforms at the population and site-specific level through Hatchery and Genetic Management Plans (HGMPs) as required by the 2008 FCRPS Biological Opinion and as described in Appendix C of the Supplemental Comprehensive Analysis (NMFS 2008a).
- Address ecosystem imbalances in predation, competition, and disease through the strategies and actions in the management unit plans, estuary module and FCRPS Biop.
- Maintain current low harvest levels, through fishery management planning for mainstem fisheries through the *U.S. v. Oregon* 10-year agreement, updated Fisheries Management Evaluation Plans and Tribal Resource Management Plans for tributary fisheries, and Pacific Salmon Treaty and Pacific Fishery Management Council processes.
- Protect and restore the estuary and Columbia River plume as detailed in the Columbia River Estuary module.
- Respond to climate change threats with a strategy based on the principle of preserving biodiversity.
- Implement the Plan through effective coordination and governance.
- Research critical uncertainties, monitor and evaluate implementation and effectiveness and adjust course as appropriate through adaptive management.

NMFS believes that if this strategy is implemented and the biological response is as expected, the Middle Columbia steelhead DPS is likely to achieve viable status within 25 to 50 years.

The following sections describe the recovery strategy elements in more detail. The chapter concludes with summaries of the MPG-level strategies.

7.1.1 NMFS 2006 Listing Decision Recommendations

In both NMFS' 2004 proposed listing decision (69 FR 33165) and its 2006 final listing decision (71 FR 834), NMFS listed 11 "conservation measures and commitments that if implemented might substantially address key limiting factors, ensure viability over the long

term, and likely bring Middle Columbia River steelhead to the point where the protections of the ESA are no longer necessary," as follows:

(1) Continued funding by the Bonneville Power Administration (BPA) of DPS-wide riparian zone and instream habitat restoration efforts, consistent with its Fish and Wildlife Program's portion of the subbasin and recovery plans being developed;

(2) Adherence by the BLM to best management practices for grazing, mining, and recreational activities DPS-wide;

(3) Adherence by the U.S. Forest Service to best management practices for grazing, forestry, and mining activities DPS-wide;

(4) Continued conservative fisheries management by the Washington Department of Fish and Wildlife within the range of this DPS, and development and implementation of a long-term approach that balances natural and hatchery production across the DPS;

(5) Continued conservative fisheries management by the Oregon Department of Fish and Wildlife (particularly in the John Day River subbasin), development and implementation of management approaches to reduce the straying of out-of-basin stocks into Deschutes and John Day spawning areas, and development and implementation of a long-term approach that balances natural and hatchery production across the DPS;

(6) Improved passage and flow management by the U.S. Bureau of Reclamation below all its facilities in the Yakima River and the Umatilla River subbasins, provision of fish passage into significant tributaries, and provision of passage over at least two of its storage dams in the Yakima Basin[34];

(7) Provision for passage in the Deschutes River subbasin above the Pelton/Round Butte complex by the Federal Energy Regulatory Commission (FERC); restoration of downstream water temperature regime to historical levels, and provision for upstream/downstream habitat enhancement and restoration;

(8) Improvement of fish passage, screening, and flow management in the Walla Walla River subbasin by the U.S. Army Corps of Engineers, and alteration of the flood operating rule for Mill Creek, or alternatively screening the diversion into Bennington Lake;

(9) Continued conservative hatchery and harvest management by the Yakama Nation and adherence to best land management practices;

(10) Continued conservative hatchery and harvest management by the Confederated Tribes of the Umatilla Reservation; and

[34] The conservation measures in NOAA's 2006 listing decision specifically identify the need for passage at two or more of the storage dams in the Yakima Basin. The Yakima Steelhead Recovery Plan strongly recommends the provision of passage at the storage dams, but notes that the geographic distribution criteria detailed in the plan provide for combinations of spawning areas that would meet delisting and short-term recovery thresholds without provision of access above the storage dams (See Appendix E, Section 4.3.7).

(11) Continued adherence to best land management practices by the Confederated Tribes of the Warm Springs Reservation in the Deschutes River subbasin.

These recommendations call upon Federal, state, and tribal entities to do their best to manage land, hydropower, hatchery and harvest activities in a manner that would support steelhead recovery. NMFS reaffirms these recommendations. Also, with two thirds of its range in private ownership, recovery for Middle Columbia River steelhead will depend on voluntary participation of landowners.

7.1.2 Tributary and Columbia Mainstem Habitat

Actions to protect and improve habitat in the tributaries and Columbia mainstem are essential to achieving recovery objectives for the Middle Columbia steelhead DPS. Unlike some other salmonid species, steelhead, which are "stream-type" salmonids, use mainstem tributary, upper tributary, and side channel habitats for spawning, juvenile rearing, and overwintering. Steelhead populations are particularly susceptible to the effects of degraded freshwater habitat because most steelhead spend one or more years in freshwater before migrating. While improving survival in the mainstem Columbia River and estuary is also an important part of DPS-wide strategy, and will benefit all salmonid populations, protecting existing high quality or good quality tributary habitat and restoring degraded habitat will specifically benefit Middle Columbia steelhead populations in the spawning and rearing life stages. Improved spawning and rearing means that more fish will reproduce, more juveniles will survive to migrate, and consequently more adults will return, even if the other factors remain as they are today.

The actions for tributary habitat include the following:

- Implementation of locally developed management unit plans to address protection and restoration of tributary habitat.
- Implementation of Federal, state, and tribal programs, such as, for example, U.S. Forest Service and BLM best management practices for grazing, mining, and recreation, and EPA and tribal programs to implement TMDLs and cold water refugia, in a manner that addresses primary habitat strategies and actions at the local level.

Relatively little information is available concerning Middle Columbia River steelhead use of mainstem Columbia River habitat above Bonneville, aside from passage through the dams. NMFS believes it is important to assess nearshore habitat and cold water refugia in the mainstem and to explore opportunities for, and potential benefits from, restoration and protection of these areas.

7.1.3 Impaired Fish Passage

Problems in migratory corridors for juvenile and adult steelhead in the mainstem Columbia River and tributaries should be addressed to improve survival.

7.1.3.1 Impaired Fish Passage in Mainstem Columbia River

Although the Federal Columbia River Power System (FCRPS) is a major limiting factor for steelhead in the mainstem Columbia River, changing it is a complex process. Three U.S. government agencies – the Bonneville Power Administration (BPA), the U.S. Army Corps of Engineers (COE) and the Bureau of Reclamation (Reclamation), also called, collectively, the "action agencies" – collaborate to run the FCRPS, under various congressional authorities, as a coordinated system for power production and flood control. The 31 federally owned multipurpose dams on the Columbia and its tributaries that make up the FCRPS provide about 60 percent of the Northwest's hydroelectric generating capacity. The dams supply irrigation water to more than a million acres of land in Washington, Oregon, Idaho and Montana. The river is used for barge navigation from the Pacific Ocean to Lewiston, Idaho, 465 miles inland.

NMFS has statutory responsibility under the ESA to consult with the FCRPS agencies and determine whether FCRPS effects on listed species are likely to jeopardize the continued existence of the species or cause adverse modification of critical habitat. NMFS summarizes its findings in a Biological Opinion, or BiOp. On May 26, 2005, the Federal District Court, in *National Wildlife Federation, et al., vs. National Marine Fisheries Service, et al.,* issued an opinion finding fault with the NMFS 2004 FCRPS BiOp (NMFS 2004). On October 7, 2005, the court ordered a "remand" of the BiOp, requiring NMFS and the three Federal agencies, called the action agencies, to engage in a collaborative process, which included input from affected States and Tribes, to develop proposed operational measures for analysis in a new biological opinion. The court's order, among other things, directed the action agencies to demonstrate how their proposed actions would contribute to recovery. A revised Biological Opinion was issued on May 5, 2008 (NMFS 2008a) and is available at http://www.nwr.noaa.gov/Salmon-Hydropower/Columbia-Snake-Basin/Final-BOs.cfm.

Current Columbia River hydropower programs and operations are the result of this and other completed or ongoing ESA section 7 consultation processes; habitat conservation plans (HCPs) pursuant to ESA section 10; FERC relicensing proceedings and other regulatory processes. In most cases, hydropower programs and operations are intended both to avoid jeopardy to listed species and to contribute to recovery.

The plan for current mainstem hydro operations, as summarized in the Hydro Module (NMFS 2008c), and any further improvements for fish survival that may result from the ongoing FCRPS collaborative process, represent the hydropower recovery strategy for all listed salmonids that migrate through the mainstem Columbia River, including the Middle Columbia steelhead populations.

The Reasonable and Prudent Alternative (RPA) for the FCRPS takes a comprehensive approach to ESA protection that includes hydro, habitat, hatchery, harvest and predation measures to address the biological needs of salmon and steelhead in every life stage. The RPA is the product of the collaboration between NMFS and the action agencies ordered by the court. It is based on a comprehensive analysis of the salmon life cycle conducted down to the level of the populations that make up the listed species. Section 8.8 and the "Reasonable

and Prudent Alternative Table" in the 2008 FCRPS Biological Opinion describe actions that should positively affect Middle Columbia River steelhead.

The current plan for operation of the FCRPS through 2018 (NMFS 2008a) contains the following actions intended to address the needs for survival and recovery of ESA-listed salmon and steelhead:

- Continue adult fish passage operations that have resulted in improved survival.
- Improve juvenile fish passage: install removable spillway weirs or similar surface bypass devices at John Day and McNary dams, an extended tailrace spill wall at The Dalles Dam, and various modifications at Bonneville Dam. Passage for steelhead smolts at each of the four Lower Columbia River mainstem projects must reach 96 percent survival.
- Continue and enhance spill for juvenile fish passage.
- Continue reservoir operations and river flows to benefit spring migrating juveniles.
- Develop dry water year operations to better protect migrating juveniles.
- Develop and implement a kelt management plan.

Dissenting View of State of Oregon Regarding Mainstem Operations

At the time the proposed recovery plan was finalized, August 2008, it was the position of the State of Oregon that additional or alternative actions should be taken in mainstem operations of the FCRPS for ESA-listed salmon and steelhead. Some additional or alternative actions recommended by Oregon, while considered, were not included in NOAA's FCRPS Biological Opinion. At this time, Oregon is a plaintiff in litigation against various federal agencies, including NOAA, challenging the adequacy of the measures contained in the current FCRPS Biological Opinion. NOAA is not in agreement with Oregon regarding the need for or efficacy of Oregon's additional or alternative actions. The actions sought by Oregon include:

- Draft storage reservoirs to help meet weekly and seasonal flow and velocity equivalent objectives for the lower Columbia and Snake rivers.
- Operate reservoirs at rule curves and seek additional flow augmentation volumes from Snake River and Canadian reservoirs for spring and summer flow and velocity objectives.
- Operate John Day reservoir at minimum operating pool (MOP) during spring and summer as long as barge transport and irrigation needs are met.
- Provide spill to total dissolved gas limits of water quality waivers or biological constraints at all dams, except maximize transportation at Snake River collector projects during lowest (10^{th} percentile) flow years.
- Maintain approximately 50/50 in-river and transportation proportions for spring and summer migrants in the Snake River by optimizing spill and surface-oriented routes of dam passage and transporting fish collected in the turbine screen bypass systems. Continue to provide spill and bypass all fish at McNary Dam at all flows during the spring migration period.
- Test removable spillway weirs and temporary spillway weirs to ensure they provide equal or better benefits of full spill before reducing spill.
- Establish more rigorous research, monitoring and evaluation to assure that fish survival is increasing and to inform adaptive management.
- Identify and prepare contingency actions for implementation if necessary to meet fish performance standards linked to the survival and recovery requirements of listed fish.

7.1.3.2 Impaired Fish Passage in Tributaries

Actions to improve fish passage in tributaries include:

- Implement locally developed management unit plans to improve fish passage.
- Implement recommendations regarding improved passage and flow management by the U.S. Bureau of Reclamation below all its facilities in the Yakima River and the Umatilla River subbasins, provision of fish passage into significant tributaries, and provision of passage over at least two of its storage dams in the Yakima Basin[35].
- Implement recommendations regarding improvement of fish passage, screening, and flow management in the Walla Walla River subbasin by the U.S. Army Corps of Engineers, and alteration of the flood operating rule for Mill Creek, or alternatively screening the diversion into Bennington Lake.
- Provide passage into the upper Deschutes River above Round Butte/Pelton complex and into the White Salmon River above Condit Dam according to multiparty agreements.

7.1.4 Hatchery Reforms

Influence from hatchery fish is a limiting factor for the Middle Columbia steelhead DPS because of out-of-basin hatchery fish straying onto natural spawning grounds in the John Day Basin, Deschutes River Eastside and Westside, and the Umatilla and Walla Walla rivers, as well as potential effects of hatchery releases and strays on naturally produced steelhead in the Klickitat subbasin. The hatchery programs in question are managed under the Mitchell Act, the Lower Snake River Compensation Plan, and the *U.S. v. Oregon* process involving the fisheries co-managers, and regulated by NMFS permits and section 7 consultations.

Hatchery reform actions are included in some of the management unit plans, and are also discussed in NMFS' Appendices C and D of the Supplemental Comprehensive Analysis of the FCRPS (NMFS 2008a). Additional actions are expected to be identified through the Hatchery Scientific Review Group's work and in hatchery management plans (e.g., Klickitat River Anadromous Fisheries Master Plan). These hatchery reform proposals will be addressed and implemented through the development of HGMPs, section 7 consultations, and the *U.S. v. Oregon* process.

NMFS is working with the funding agencies and hatchery operators to update and complete Hatchery and Genetic Management Plans (HGMPs) for every hatchery program in the Middle Columbia region, as well as for the hatchery programs that are part of the Lower Snake Compensation Plan and Mitchell Act and have been identified as producing the

[35] The conservation measures in NOAA's 2006 listing decision specifically identify the need for passage at two or more of the storage dams in the Yakima Basin. The Yakima Steelhead Recovery Plan strongly recommends the provision of passage at the storage dams, but notes that the geographic distribution criteria detailed in the plan do provide for combinations of spawning areas that would meet delisting and short-term recovery thresholds without provision of access above the storage dams (See Appendix E, Section 4.3.7)

problematic, out-of DPS hatchery strays. The HGMPs are the basis for NMFS' biological opinions on hatchery programs under sections 7 and 10 and the 4(d) rule, which all relate to incidental and direct take of listed species. The HGMPs describe each hatchery program's operations and the actions taken to support recovery and minimize ecological or genetic impacts, such as straying and other forms of competition with naturally produced fish. The revised FCRPS Biological Opinion (NMFS 2008a) requires the hatchery operators and the action agencies to submit to NMFS updated HGMPs describing site-specific applications of the "best management practices" for the hatchery programs as described in Appendices C and D of the Supplemental Comprehensive Analysis (SCA) of the Biological Opinion for those mitigation hatchery programs funded by the FCRPS action agencies.

Hatcheries are the subject of three major scientific reviews that are expected to provide important information that will be helpful in crafting specific hatchery actions that are consistent with salmon and steelhead recovery: the Mitchell Act Draft Environmental Impact Statement (DEIS) (in production), USFWS Hatchery Review, and the congressionally established Hatchery Scientific Review Group (HSRG). The HSRG recently published its recommendations (HSRG 2009.) Collectively, these scientific reviews will be scrutinizing every anadromous fish hatchery in the Columbia Basin. The schedule for updating hatchery actions is designed to allow consideration of information from the hatchery reviews. The updated HGMPs for programs in the range of the Middle Columbia steelhead DPS are all targeted to be submitted to NMFS in 2009, with section 7 consultations completed in 2010.

Oregon Steelhead Recovery Plan

The Oregon Steelhead Recovery Plan proposes a number of management strategies and actions to address the impacts of strays from hatchery programs outside the DPS that are a source of out-of-DPS strays. These recommendations include increased marking of Columbia Basin hatchery steelhead with coded-wire tags, and requiring mass marking of all hatchery steelhead releases with, at a minimum, an adipose fin-clip. In addition, for the hatchery programs that contribute significantly to the stray problem, develop alternative broodstocks that will stray at lower rates, and reduce the proportion of Snake River hatchery smolts that are transported from Lower Granite and Little Goose dams. Section 9.7.2 identifies proposed tributary hatchery strategies and actions for each population. The Oregon Sounding Board members did not reach consensus on all strategies and actions. For each proposed strategy and action, the Oregon Steelhead Recovery Plan lists the Sounding Board's views, and whether or not consensus was reached on the proposal. NMFS realizes these are regional issues that need to be addressed.

Klickitat Plan

The Klickitat population's moderate risk rating was assigned primarily on the basis of uncertainty and lack of data, particularly with respect to the influence of hatchery fish on the wild steelhead population. The plan recommends a targeted monitoring program to determine abundance and productivity of natural spawners, the proportion of hatchery and wild spawners in the Klickitat subbasin, and the adverse effects of Skamania broodstock on the Klickitat population, if any.

The Yakama Nation is also working with NMFS, WDFW, Tribal fish and wildlife leaders, and others to develop a master plan for an integrated hatchery program for the Lower Klickitat River with the purpose of minimizing adverse impacts on the natural steelhead spawning population. The same entities are considering the possibility of using a conservation hatchery program to accelerate recolonization of the Upper Klickitat watershed, since passage has been restored at Castile Falls. The hatchery program would not occur for at least 9 years after passage was restored, to allow for an evaluation of the natural recolonization management strategy.

Southeast Washington Plan

The Southeast Washington Plan does not propose new actions related to hatcheries but notes that as future hatchery strategies and scenarios are developed by the fisheries co-managers, the needs for achieving harvest objectives should be balanced with the risks to recovery of naturally spawning populations. In the Walla Walla basin, the plan says that the current segregated hatchery program could be transitioned to an integrated one using wild brood stock. For the Touchet River, the plan proposes intensified monitoring to determine whether strays from the segregated program pose an unacceptable risk to the genetic integrity of the natural population, and if so, to eliminate the segregated program. In the short term, both the integrated and segregated programs will be continued with increased monitoring of hatchery fish and removal of hatchery fish at the weir in Dayton. Based on monitoring of the impacts of the segregated program and the success of the integrated program it is anticipated that over the long term only the integrated program would continue.

Yakima Steelhead Plan

The Yakima Steelhead Plan does not indicate hatchery related effects as a limiting factor for steelhead, and states that hatchery steelhead have not been released in the Yakima River system since 1993. However, the plan does propose evaluating the use of small-scale supplementation to restore steelhead to watersheds with good habitat conditions where steelhead are not present or severely reduced because of passage barriers that have been or are being removed. The plan also recommends maintaining and evaluating the existing kelt reconditioning program, which uses hatchery techniques to increase the rate of repeat spawning of wild steelhead adults.

7.1.5 Predation, Competition and Disease

Predation, competition and disease are grouped together as a category of concern because ultimately these factors relate to balance and imbalance in the ecosystem. Improving habitat for salmonids throughout the life cycle is the best strategy for addressing these potential limiting factors (ISAB 2007). Specific measures can also be taken; the following is a summary of ongoing efforts and research.

7.1.5.1 Predation

Extensive research on predation and efforts at predator control, including piscivorous fish, avian predators, and marine mammals have been undertaken in the Columbia Basin for decades, and will continue. The FCRPS BiOp and the Estuary Module (73 FR 161, January 2, 2008), both of which are part of this recovery plan, provide extensive evaluations of these

issues as threats and limiting factors as well as specific strategies and actions for both monitoring and addressing them.

Piscivorous Fish

- Northern Pikeminnow Management Program - A multi-year, ongoing effort funded by BPA to reduce piscivorous predation on juvenile salmon through incentives to sports fishermen to remove predator-sized northern pikeminnow. From 1991 to 1996, three fisheries (sport-reward, dam angling, and gill net) harvested approximately 1.1 million northern pikeminnows greater than or equal to 250 mm fork length. Total exploitation averaged 12 percent (range, 8.1 to 15.5 percent) for 1991 to 1996 (Section 6.2.7.1 in NMFS 2000b). The annual harvest rate has averaged approximately 12 percent in the last few years.
- Non-native piscivores - Other sport fisheries target smallmouth bass, channel catfish, and walleye. However, the ISAB report states that state fisheries agencies in Washington, Oregon, and Idaho have simultaneously adopted management policies that in some cases seem aimed at perpetuating or even enhancing populations of these introduced predators. The ISAB recommends that the state agencies relax (or eliminate) fishing regulations that may be enhancing populations of non-native species (both predators and competitors), especially those that directly or indirectly interact with juvenile and adult salmonids (ISAB 2007). NMFS supports strategies and actions that would result in reduced populations of non-indigenous predators on juvenile steelhead.

Avian predation

- Altering Rice Island to prevent tern and cormorant nesting was effective in reducing avian predation in the estuary, and the current FCRPS Biological Opinion (NMFS 2008a) recommends further reduction in bird habitat on East Sand Island.
- The Biological Opinion also recommends development of plans to control Caspian terns and double-crested cormorants that nest in islands upstream of Bonneville Dam. The Army Corps of Engineers takes various "avian deterrent actions" at the lower Snake and Columbia River dams, and will continue to do so.

Marine Mammals

A pinniped hazing program has been implemented at Bonneville Dam since 2005, but the efforts have largely been ineffective against California sea lions, which are not listed as threatened or endangered. The animals may leave the area temporarily but return as soon as hazing stops. Under section 120 of the Marine Mammal Protection Act, states can ask for permission to kill individually identifiable sea lions or seals that are having a "significant negative impact" on at-risk salmon and steelhead, and NMFS can grant that permission, if certain legal standards are met. In March 2008, NMFS granted the request of the states of Oregon, Washington, and Idaho to lethally remove problem California sea lions. Any animals that are captured may be euthanized if no permanent holding facility can be found for them. NMFS and representatives of zoos and aquariums are compiling a list of pre-approved permanent holding facilities interested in receiving a limited number of captured sea lions as an alternative to euthanasia. NOAA has authorized the states to remove as many

as 85 animals annually, but estimates that only about 30 animals will be removed each year, given the conditions in its authorization.

In addition, non-lethal deterrence methods will be continued, including the following:

- Vessel chasing
- Cracker shells
- Aerial pyrotechnics (screamer rockets, banger rockets)
- Rubber projectiles
- Sea-lion exclusion devices
- Acoustic deterrents
- Underwater firecrackers
- Capture, marking, and relocation
- Temporary captive holding

Safety and training requirements for vessel use and deterrence measures (including firearms use) also would be continued.

Maintaining and restoring habitat

The ISAB report indicates that the methods of controlling non-native piscivores have not been sufficient, and that maintaining and restoring habitat is actually the better strategy. "When native species are provided with habitat for which they are best adapted, they have an improved chance of out-competing or persisting with non-native species," the ISAB report states (ISAB 2008). NMFS, as indicated elsewhere in this chapter, supports that conclusion.

Research and monitoring

NMFS supports the recommendations in the Yakima Steelhead Plan for research and monitoring to track trends in predator populations, understand their impacts on steelhead, and develop appropriate management techniques to reduce predation.

7.1.5.2 Competition – Density Dependent Mortality

As described in Section 6.3.5.4 of this Plan, density-dependent mortality can occur at any stage in salmon or steelhead life cycle and may be exacerbated by the introduction of, and/or cumulative effects of, large numbers of hatchery fish released over a relatively short period of time. Consistent with this concern NMFS, Salmon Recovery Division, and the Northwest Fisheries Science Center are planning to better define and describe the scientific uncertainty associated with ecological interactions of hatchery-origin and natural-origin salmonids. See also Appendix C of the 2008 FCRPS Biological Opinion (NMFS 2008a).

7.1.5.3 Disease

Disease in salmonids is caused by multiple factors and probably cannot be directly addressed by recovery actions except in specific instances of known causal factors. It is more likely that nearly all of the recommended recovery actions that improve spawning, rearing, and passage conditions for steelhead and increase the survival, abundance, and productivity of naturally produced fish will result in decreasing incidence of disease.

7.1.6 Harvest

Although in general harvest is not considered a major threat for the Middle Columbia steelhead DPS, it is important to ensure that impacts from fisheries do not impede recovery, and to perform monitoring and evaluation to verify impacts and reduce existing uncertainties.

- The *U.S. v. Oregon* agreement for 2008-2018 will maintain current low impacts on Middle Columbia steelhead in the lower mainstem and treaty mainstem fisheries. (See Section 6.3.7)
- The Fisheries Management and Evaluation Plans (FMEPs) submitted by the States of Oregon and Washington and approved by NMFS under the 4(d) rule of the ESA provide a mechanism for developing, implementing, and adjusting recreational fisheries to achieve management and conservation objectives. Under the FMEPs, recreational fisheries in the tributaries are expected to maintain the currently estimated low impacts on steelhead. Furthermore, NMFS requires the states to implement, monitor, and evaluate the effects of these plans and to report annually, including an assessment of the annual catch of natural fish, fishery mortality, the abundance of hatchery and natural fish for each tributary fishery area, and angler compliance. A comprehensive evaluation is required every five years. The continuing and additional monitoring and evaluation under the FMEPs is expected to further reduce uncertainties concerning fisheries impacts.
- Other increases in monitoring and evaluation will help to reduce uncertainties concerning fisheries impacts on steelhead:
    - Creel surveys or other methods of quantifying impacts in the more popular fisheries
    - In-basin monitoring of escapement from ocean into tributaries and onto the spawning grounds
    - Monitoring to verify the applicability of aggregate impact rates of mainstem fisheries on specific populations
- Other proposals in the management unit plans:
    - The Oregon Steelhead Recovery Plan proposes using selective fisheries to reduce the number of out-of-basin hatchery strays.
    - The Washington Gorge Management Unit plans recommend studies to determine the impacts of tributary fisheries and to determine the extent of illegal harvest, if any.

7.1.7 Estuary and Columbia River Plume

Although juvenile steelhead pass through the estuary on their way to the ocean, they tend to spend less residence time in the shallow parts of the estuary than other salmonids, and therefore the characteristics of the Columbia River plume and the deeper channels of the estuary are more important in determining their survival.

Flow changes in the estuary are primarily a result of dam operations, whereas habitat changes are a function of both hydropower operations and other, non-hydro issues, notably the

construction of dikes and levees in the estuary. The main effects of flow on Middle Columbia steelhead populations are associated with changes in the plume. Thus, actions that affect the plume, decrease exposure to toxicants, and decrease predation (especially Caspian tern predation) should improve the abundance/productivity and diversity of the Middle Columbia DPS.

NMFS' Estuary Module identifies 23 types of management actions that would improve estuary conditions for all salmonids. The following is a selection of these actions most beneficial to steelhead:

- Adjust the timing, magnitude and frequency of flows (especially spring freshets) entering the estuary and plume to provide better transport of sediments and access to habitats in the estuary, plume, and littoral cell.
- Manage pikeminnow, smallmouth bass, walleye, and channel catfish to prevent increases in abundance.
- Identify and implement actions to reduce salmonid predation by pinnipeds.
- Implement projects to redistribute part of the Caspian tern colony currently nesting on East Sand Island.
- Implement projects to reduce double-crested cormorant habitats and encourage dispersal to other locations.
- Implement pesticide and fertilizer best management practices to reduce estuary and upstream sources of toxic contaminants entering the estuary.
- Identify and reduce industrial, commercial, and public sources of pollutants.
- Monitor the estuary for contaminants and/or restore contaminated sites.
- Implement stormwater best management practices in cities and towns.

The module includes an evaluation of the "constraints" on implementation of these actions. Perhaps the most significant action would be to adjust the timing, magnitude and frequency of flows to return to a more natural hydrograph for the estuary; however, this is the least possible of the actions, given the constraints:
Constraints on hydrosystem operations prevent the return to a natural hydrograph in the estuary. Implementation of this action would be limited by international treaties, the need for flood control, fish management objectives systemwide, and power management (NMFS 2007).

7.1.8 Climate Change

A strategy for addressing the effects of climate change on Middle Columbia River steelhead needs to be based, broadly, on the principle of preserving biodiversity. Diversity in terms of both location and biological characteristics gives any species resilience in the face of environmental change. This principle underlies the viability criteria presented in Chapter 3 of this plan, as well as the strategies described in this chapter to address the factors limiting steelhead viability, as these are currently understood. NMFS supports the ISAB's recommendations for mitigating the effects of climate change (ISAB 2007), most of which are encompassed in Section 7.2 of this Plan.

The ISAB notes that "As climate and streams warm, tributary habitats will become increasingly important because they usually provide the cool waters for salmonids and other cool-water species in a watershed" (ISAB 2007). It follows that water temperature and stream flow are factors that will remain important throughout steelhead freshwater habitat. All strategies and actions that help to lower water temperature or prevent further increase will help to mitigate climate change. Protecting and/or restoring riparian areas to increase shade, as recommended in Section 7.2, is an important strategy for minimizing water temperature increases. Additional actions include purchasing water rights to leave more water in streams and restoration actions to improve channel complexity and establish side-channel rearing (FCRPS BiOp, NMFS 2008a). Specific recommendations from the ISAB include:

- Protect or restore riparian buffers along streams – especially in headwater tributaries where shading is crucial for maintaining cool water temperatures.

- Expand efforts to protect riparian areas from grazing, logging, development, or other activities that could impact riparian vegetation.

- Protect potential thermal refugia. Remove barriers to fish passage into thermal refugia.

The ISAB emphasizes the importance of identifying areas that may be most affected by climate change and establishing adequate protective measures, including "reserve" areas or strongholds of high productivity and diversity.

The ISAB also offers possible actions that could be taken on the mainstem Columbia River to address climate change impacts on Middle Columbia steelhead:

- Flow augmentation from cool/cold water storage reservoirs to reduce water temperatures or create cool water refugia in mainstem reservoirs and the estuary. Effective implementation of this strategy may require increasing the number of storage reservoirs.

Existing FCRPS operations result in cold water releases from Dworshak reservoir in late summer. Temperature control towers at other headwater reservoirs are under consideration through other processes. However, these actions are unlikely to have a significant impact on Middle Columbia steelhead because these water sources are too far away from this species' migration corridor. For Middle Columbia steelhead, new reservoirs would be needed in order to implement this option. Careful consideration of the benefits and negative impacts of increasing the number of storage facilities in the basin will be required. Such consideration should occur in the near future if storage capacity is to be increased in time to address climate change impacts.

- Use of removable surface weirs to reduce the time juvenile salmonids spend in the warm water of the forebay.

This Recovery Plan (through the FCRPS BiOp) includes operating all mainstem dams with removable surface weirs or other structures to quickly move juveniles downstream from dam forebays.

- Reduction of water temperatures in the ladders with water drawn from lower, cooler strata in the water column of the forebay.

Most mainstem reservoirs that Middle Columbia steelhead pass are isothermal during warm water periods, so pumping water from depth would not reduce ladder temperatures. However, stratification with warm surface water affecting fish ladders sometimes occurs at McNary Dam. A means of cooling fish ladder temperatures at this project should be investigated.

- Liberalization of harvest of introduced piscivorous species such as smallmouth bass, walleye, and channel catfish.

The recovery plan (through the FCRPS BiOp) calls for a plan to reduce predation of introduced fish species by the end of 2009.

- There are opportunities to mitigate for some climate change impacts in the estuary and plume with changes to hydrosystem operations. Possible actions would include reducing the frequency and magnitude of winter flows, extending the period of spring runoff later in the year, and increasing late summer and autumn flows.

The recovery plan (through the FCRPS BiOp) calls for estuary habitat restoration projects that include dike breaching and restoring access and tidal influence to marshes.

The recovery plan (through the FCRPS BiOp) includes new analyses to incorporate climate change predictions into mainstem Columbia River hydrology models with improved forecasting capabilities. The goal is better long-term operations planning, including patterns of reservoir storage and release for flood control and other purposes.

Climate change responses require significant monitoring information and additional research regarding effects of climate on key habitat variables and effects of habitat variables on fish survival. Research and monitoring related to climate change are described in Section 10.3.2.

7.1.9 Coordination/Governance

Coordination of actions and information-sharing among fisheries biologists, Tribes, local governments, citizen groups, and state and Federal agencies based in both Oregon and Washington is a key component of recovery for this DPS. Benefits of coordination include:

- Dealing with shared migration areas consistently.
- Developing coherent MPG-level strategies where populations are in two states (Cascades Eastern Slope MPG; Umatilla/Walla Walla MPG), or the same population is in both states (Walla Walla population).
- Promoting consistent methods for setting recovery objectives, evaluating strategies, and monitoring progress across populations, MPGs, and the DPS.

This coordination is under development. The recent creation of a Middle Columbia Recovery Forum, to be convened regularly by NMFS, is intended to facilitate such collaboration between scientists and recovery planners on both sides of the Columbia River. The Middle Columbia Recovery Forum is discussed further in Chapter 11, Implementation.

7.1.10 Research, Monitoring and Evaluation and Adaptive Management

An important part of the strategy for achieving recovery is the development of a monitoring plan that will support implementation of the recovery plan and long-term adaptive management in response to changes and trends in the data. Two keys to effective implementation are targeting actions to specific areas and monitoring the results of the actions. To achieve these goals, a scientific technical team made up of local scientists, former ICTRT members, and managers will be necessary. The monitoring plan is discussed in more detail in Chapter 10.

For each DPS-level, five-year status review, NMFS needs summarized information on each population derived from more detailed field assessments – at the least, monitoring data on abundance and productivity throughout the steelhead's range. The most efficient way to generate this information is through annual reports compiled by regional biologists. Currently, although basic data (e.g., redd surveys) are being gathered, funding and staff are lacking to turn this raw data into annual estimates of abundance/productivity in each river or stream in a timely fashion. Typically, each five-year status review starts with a time-consuming scramble to gather the information from the regional biologists and work with them to produce the metrics that are needed for the status assessment. These annual reports need to be funded, staffed, and standardized.

The Southeast Washington Plan proposes that the co-managers should be convened with NMFS and USFWS to better define the level (scale, frequency, location) of monitoring required to determine when recovery goals are achieved. The results of these conversations could be used to better define monitoring tasks and allow for the prioritization of expenditures.

In addition to the issue- and area-specific monitoring for adaptive management, research should be directed toward resolving the many uncertainties pertaining to ocean productivity, global climate change, hatchery effectiveness, effects of transportation, invasive species, effects of interacting strategies, and effects of human population growth on steelhead recovery. These are described in greater detail in Section 10.3 of this Plan.

7.2 Summary of Recovery Strategies for the MPGs

The following sections summarize the recovery strategy for each MPG. Tables 7-1 through 7-4 show more detail. The tables link the strategies with the limiting factors addressed.

7.2.1 Cascades Eastern Slope Tributaries MPG

Population	ICTRT Risk Status
Fifteenmile Creek	Viable
Deschutes Eastside	Viable
Klickitat	(provisional) Moderate risk – insufficient data, hatchery influence
Rock Creek	(provisional) High risk – insufficient data
Deschutes Westside	High risk
White Salmon	Functionally extirpated
Crooked River	Extinct

Two populations in this MPG meet the criteria for viable status (Fifteenmile Creek and Deschutes Eastside); one (Klickitat) is assigned a provisional moderate risk ("maintained" status) based on insufficient abundance/productivity data and an unknown degree of diversity risk from hatchery influence; one (Rock Creek) is assigned a provisional high risk status because of lack of data; one (Deschutes Westside) is at high risk for abundance/productivity and moderate risk for spatial structure/diversity, primarily because of blocked passage to a large amount of historically accessible habitat. Two populations in the MPG are extirpated (White Salmon and Crooked River); the Crooked River population was historically very large.

Recovery Scenario: For the Cascades Eastern Slope Tributaries MPG to be considered viable based on the currently extant populations, the Klickitat, Fifteenmile, and both the Deschutes Eastside and Westside populations should reach viable status, with one highly viable. The Rock Creek population should reach "maintained" status (25 percent or less risk level). MPG viability could be further bolstered if reintroduction of steelhead into the Crooked River succeeds and if the White Salmon population is successfully reintroduced to its historical habitat.

Gap: The median survival gap (assuming recent ocean and base hydrosystem conditions and 5 percent risk) for the Cascades Eastern Slope MPG is 0.21 (meaning that a 21 percent increase in average life-cycle survival is required to achieve 5 percent risk in a 100-year time period). The gap ranges from –0.34 (Deschutes Eastside) (no gap) to 0.78 (Deschutes Westside) (needs 78 percent improvement). There was not enough information to estimate gaps for the Klickitat or Rock Creek populations.

Key actions proposed (more detail in Table 7-1):

- Protect, improve, and increase freshwater habitat for steelhead production. Improvements to freshwater habitat should be targeted to address specific limiting factors in specific areas as described in the Oregon Steelhead Recovery Plan and the Washington Gorge plans.
- Reduce straying of out-of-DPS hatchery fish onto natural spawning grounds within the Deschutes subbasin.

- Restore historical passage to the upper Deschutes subbasin including the Westside tributaries and Crooked River above Pelton Round Butte dam complex and the White Salmon River above Condit Dam.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007) and FCRPS Biological Opinion (NMFS 2008a).
- Improve hatchery management to minimize impacts from hatchery releases on naturally produced steelhead within the Deschutes West and East and Klickitat subbasins.
- Fill data gaps for better assessment of Klickitat and Rock Creek steelhead populations.
- Coordinate between scientists, planners, and implementers of recovery actions on both sides of the river for sequencing of recovery actions and monitoring for adaptive management.

Summary of MPG Recovery Strategy: The proposed actions for the five extant populations in the Cascades Eastern Slope MPG are based on restoring important tributary habitat functions in areas that likely supported substantial steelhead production. The particular actions proposed for each population are predicated upon restoring natural conditions supporting summer rearing and overwintering in high potential reaches. For Cascades Eastern Slope populations, restoring degraded instream channel structure and the associated riparian habitats is a common element. For several populations, restoring sufficient flow, addressing high summer water temperatures, and other water quality issues are also key components. Quantitative modeling indicates that achieving the targeted levels of habitat improvement will translate into increases in both juvenile production capacity and survival rates through the key summer and winter juvenile rearing periods. Restoring access to tributaries with substantial amounts of high quality habitat is also a high priority across populations. Current and future increases in steelhead production from tributary habitats will be further bolstered by actions aimed at reducing mortalities during juvenile and adult migrations to and from the ocean.

The specific tributary habitat strategy for each population builds out from good habitat, targeting opportunities where there is substantial habitat potential. For the Fifteenmile Creek, Deschutes (eastside), Deschutes (Westside) and Rock Creek populations, restoring stream structure, riparian habitat, and water quality (temperature, sediments, etc.) in the lower reaches of major tributaries and the associated population mainstems are identified as high priorities. In the Klickitat, recent passage improvements at Castile Falls have reduced impediments to steelhead access into a substantial amount of habitat in the upper Klickitat River. Restoring stream channel structure and diversity and addressing tributary access problems in the Upper Klickitat is highlighted in the plan. Unique to the Westside Deschutes River population is a major effort to restore upstream and downstream passage at the Pelton/Round Butte Complex. This passage restoration combined with reintroductions using hatchery fish is designed to reestablish natural production in the blocked areas in the Westside population and in the extirpated Crooked River population. Section 9.7.2 in the Oregon Steelhead Recovery Plan gives details for these actions (ODFW 2009).

The recovery strategy for the two Deschutes River populations involves reducing the impacts and risks associated with chronically high levels of non-local stray hatchery spawners. While direct estimates of impacts on these particular populations are not available, steelhead field studies in nearby drainages and modeling of the proposed actions indicate that natural productivity may be significantly impaired, especially given the abundance of strays. The current steelhead hatchery program in the Klickitat River is intended to be a segregated program; an important objective is to minimize spawning interactions with natural-origin spawners. The Klickitat River strategy includes evaluating the performance of the current programs in the Klickitat (steelhead, Chinook and coho), adjusting to complement natural recovery efforts, and considering the use of artificial production in restoring production above Castile Falls.

An important element across all of the Middle Columbia steelhead populations is to continue to manage harvest in a manner that supports recovery efforts. Middle Columbia steelhead runs are subject to harvest in mainstem Columbia River fisheries and in hatchery-directed tributary fisheries. Fisheries in each of those geographic areas are currently managed under impact limits for natural-origin steelhead and all recreational fisheries prohibit retention of natural-origin fish.

Results of modeling management action effectiveness indicate that for most of the populations in the Cascades Eastern Slope Tributaries MPG, most of the productivity and capacity benefits from the proposed recovery actions will result from those focused on tributary habitat.

Table 7-1 Recovery Strategies and Actions for the Cascades Eastern Slope Tributaries MPG.

CASCADES EASTERN SLOPE TRIBUTARIES MPG				
Strategies (Not necessarily in order)	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
Tributary Habitat				
Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	All populations in MPG	• Protect highest quality habitats through acquisition and conservation. • Adopt and manage Cooperative Agreements. • Conserve rare and unique functioning habitats. • Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	All Parameters	Degradation of tributary habitat-forming processes and functions (loss of channel structure, floodplain connectivity, riparian vegetation and LWD recruitment)
Restore passage and connectivity to habitats blocked or impaired by artificial barriers.	Deschutes Westside Deschutes Eastside Crooked River Fifteenmile Creek White Salmon River Klickitat River Rock Creek	• Provide passage at Condit Dam. • Provide passage at Pelton-Round Butte Complex (PRBC). • Provide passage at Pine Creek confluence with Columbia River. • Improve steelhead passage at Lyle Falls Fishway. • Remove or replace barriers blocking or impairing passage including dams, dikes, road culverts and irrigation structures. • Provide screening at 100% of irrigation diversions. • Replace screens that do not meet criteria.	Abundance, Productivity, Spatial Structure	Loss of historical habitat because of blocked or impaired fish passage (dams, culverts, seasonal push-up dams, unscreened diversions)
Restore floodplain connectivity and function.	Fifteenmile Creek Deschutes Westside Deschutes Eastside White Salmon River Klickitat River Rock Creek Major Creek	• Reconnect side channels and off-channel habitats to stream channels. • Restore wet meadows. • Reconnect floodplain to channel. • Relocate or improve floodplain infrastructure and roads.	Abundance, Productivity, Spatial Structure	Degraded floodplain connectivity and function (loss of off-channel habitat, side channels and connected hyporheic zone)
Restore channel structure and complexity.	Fifteenmile Creek Deschutes Westside Deschutes Eastside White Salmon River Klickitat River Rock Creek Major Creek	• Place stable wood and other large organic debris in streambeds. • Stabilize stream banks. • Restore natural channel form.	Abundance, Productivity	Degraded channel structure and complexity (loss of spawning and rearing habitat, LWD, pools)
Restore riparian condition and LWD recruitment .	Fifteenmile Creek Deschutes Westside Deschutes Eastside White Salmon River Klickitat River Rock Creek Major Creek	• Restore natural riparian vegetative communities. • Develop grazing strategies that promote riparian recovery.	Abundance, Productivity	Degraded riparian condition (native riparian vegetative communities, LWD recruitment)

CASCADES EASTERN SLOPE TRIBUTARIES MPG				
Strategies (Not necessarily in order)	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
Restore altered hydrograph to provide appropriate flows during critical periods.	Fifteenmile Creek Deschutes Westside Deschutes Eastside Crooked River White Salmon River Klickitat River Rock Creek	• Implement agricultural water conservation measures. • Improve irrigation conveyance and efficiency. • Lease or acquire water rights and convert to instream. • Restore natural functions and processes through actions identified in strategies above. • Employ BMPs for forest, agriculture and grazing practices and road management. • Protect and/or rehabilitate springs.	Abundance, Productivity	Altered hydrology (low summer flow, scouring peak flows due to degraded watershed conditions and/or streamflow alterations and withdrawals for irrigation and other uses)
Improve degraded water quality.	Fifteenmile Creek Deschutes Westside Deschutes Eastside Crooked River White Salmon River Klickitat River Rock Creek	• Reduce chemical pollution inputs. • Restore natural functions and processes through actions identified in strategies above. • Employ BMPs for forest, agriculture and grazing practices and road management. • Upgrade or remove problem forest roads. • Conduct pathogen sampling and monitoring. • Construct water and sediment control basins.	Abundance, Productivity	Degraded water quality (abnormal temperatures or fine sediment, nutrients from runoff, pesticides and other chemicals, and/or degraded because of water withdrawals that reduce natural stream flows)
Harvest				
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	All populations in MPG	• Maintain current management regulations for low impact fisheries and adjust tributary harvest regulations in areas where harvest significantly impacts steelhead viability. • Monitor and evaluate effects of tributary harvest.	Abundance, Productivity	Not a primary limiting factor.
Use harvest to reduce abundance and proportion of stray hatchery spawners.	Deschutes Westside Deschutes Eastside	• Develop educational outreach program to promote retention of hatchery fish in selective recreational fisheries to reduce the number of out-of-basin hatchery strays.	Abundance, Productivity, Diversity	Straying of Out-of-DPS hatchery fish into natural spawning areas.
Reduce illegal harvest on ESA- listed species.	Klickitat River	• Eliminate illegal harvest by enforcing sport and Tribal regulations.	Abundance, Productivity	Not a primary limiting factor.
Provide better educational opportunities at the COE Park to preventing accidental catch of steelhead.	Rock Creek	• Increase outreach efforts to reduce the number of steelhead caught in recreational fisheries near the mouth of Rock Creek.	Abundance, Productivity	Not a primary limiting factor.
Hatchery				
Determine origin of hatchery strays and increase ability to recognize hatchery-origin fish.	Potential risk for all populations in MPG. Currently a significant risk to Deschutes Eastside and Deschutes Westside populations.	NOTE: The following measures are recommended in one or more management unit plans but have not been agreed upon by all co-managers. - Implement representative coded-wire-tagging (CWT) program so that all hatchery stocks have adequate	Diversity, Productivity	Straying of Out-of-DPS hatchery fish into natural spawning areas.

CASCADES EASTERN SLOPE TRIBUTARIES MPG				
Strategies (Not necessarily in order)	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
		CWT groups released annually. - Mark all hatchery steelhead releases in Columbia River Basin with, at a minimum, an adipose fin-clip. (An exception may be the proposed Klickitat hatchery program – a conservation hatchery program – that may use elastomer eye marking for evaluations.) - Recommend development of alternative broodstocks to reduce stray rates for programs that contribute significantly to stray problem. - Reduce proportion of Snake River hatchery smolts transported from Lower Granite and Little Goose dams.		
Reduce uncertainty in abundance and proportion of hatchery strays spawning naturally.	Fifteenmile Creek Deschutes Eastside Klickitat River, Rock Creek	• Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys and other methods.	Diversity, productivity	Out-of-DPS and Inside-DPS hatchery strays in tributary natural spawning grounds
Reduce abundance and proportion of stray hatchery fish that spawn naturally.	Deschutes Eastside Deschutes Westside	• Construct, improve trapping facilities and expand operations.	Abundance, Productivity, Diversity	Out-of-DPS and Inside-DPS hatchery strays in tributaries
Reduce genetic risks associated with Round Butte Hatchery Program.	Deschutes Westside	• Investigate opportunities and risks associated with incorporating naturally produced Deschutes River summer steelhead into Round Butte Hatchery (RBH) broodstock.	Diversity	Not a primary limiting factor
Restore natural production into historically utilized habitats, including blocked areas above Pelton-Round Butte Complex (Deschutes), Condit Dam (White Salmon) and Castile Falls (Klickitat).	Deschutes Westside Crooked River Klickitat River White Salmon River	• Develop plan for steelhead reintroductions into historical habitat when passage is restored. • Re-establish natural production in MaSAs and some minor spawning areas.	All Parameters	Not a primary limiting factor
Review effect of current hatchery practices and releases.	White Salmon River Klickitat River	• Review potential impact of Skamania stock steelhead on naturally producing steelhead.	Abundance, productivity, diversity	Not a primary limiting factor

7.2.2 John Day River MPG

Population	ICTRT Risk Status
North Fork John Day	Highly viable
Upper Mainstem John Day	Moderate risk
Lower Mainstem John Day	Moderate risk
Middle Fork John Day	Moderate risk
South Fork John Day	Moderate risk

This MPG does not meet viability criteria despite the fact that one of its populations, the North Fork John Day, is the only steelhead population in the Middle Columbia DPS classified as highly viable. The other four populations in the MPG are at maintained status. Both the Upper and Lower Mainstem John Day populations have moderate risk for diversity because of out-of-DPS hatchery strays. The Middle Fork population has moderate risk because of low abundance. The South Fork population has moderate risk for abundance and productivity, and there is also some uncertainty concerning the proportion of hatchery strays spawning.

Recovery Scenario: For the John Day River MPG to reach viable status, the Lower Mainstem John Day River, North Fork John Day River, and either the Middle Fork John Day River or Upper Mainstem John Day River populations should achieve viable status, with one highly viable.

Gap: The median survival gap for the John Day MPG is 0.09, ranging from –0.49 (North Fork) (no gap) to 0.34 (South Fork) (needs 34 percent improvement in average survival over the life cycle).

Key Actions proposed (more detail in Table 7-2):

- Protect and improve freshwater habitat conditions and connectivity for steelhead production. Improvements to freshwater habitat should be targeted to address specific factors in specific areas as described in the Oregon Steelhead Recovery Plan.
- Improve hatchery management to reduce straying from out-of-DPS hatchery fish onto natural spawning grounds within the John Day subbasin.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007) and FCRPS Biological Opinion (NMFS 2008a).

The Oregon Steelhead Recovery Plan identifies priority areas and actions for each population based on relative importance in meeting local and regional recovery objectives, and envisions local groups using the individual population action tables for development of specific implementation plans.

Summary of MPG Recovery Strategy: John Day River steelhead populations have been affected by changes across all the types of habitat they use in their complex life histories and across all their life stages. Of particular importance is the loss of rearing habitat quality and floodplain channel connectivity in the lower sections of major tributaries. Poor conditions in the downstream migration corridors affect both outmigrating juveniles and returning adults. For some populations, increased sedimentation and altered flow regimes have resulted in

increased mortality during incubation and early rearing. Higher summer water temperatures have significantly reduced the available rearing habitat.

Recovery strategies for John Day steelhead are designed to improve conditions across the range of habitats used for spawning, rearing, and migration. Actions projected to contribute the most would restore or maintain rearing habitat complexity and address sediment and temperature problems, especially in reaches that are adjacent to high quality habitats. Restoration of the associated riparian habitats will also contribute to sustaining natural stream functions. These actions will reduce sediment, restore a more normal hydrograph, and reduce water temperature. In addition, there are a significant number of actions to improve passage and connectivity of habitats for both juvenile and adult life stages.

The effect of improved tributary habitat will be enhanced if, in addition, migration conditions in the mainstem Columbia River and estuary are improved, fewer outside-origin hatchery fish spawn within the basin, and harvest is managed so that a high proportion of the increased numbers of steelhead return to spawn.

Table 7-2 Recovery Strategies and Actions for the John Day River MPG.

JOHN DAY RIVER MPG				
Strategies	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
Tributary Habitat				
Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	All populations in MPG	• Protect highest quality habitats through acquisition and conservation. • Adopt and manage Cooperative Agreements. • Conserve rare and unique functioning habitats. • Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	All Parameters	Degradation of tributary habitat-forming processes and functions (loss of channel structure, floodplain connectivity, riparian vegetation and LWD recruitment)
Restore passage and connectivity to habitats blocked or impaired by artificial barriers	All populations in MPG	• Remove or minimize use of push-up dams. • Remove or replace barriers blocking passage. • Provide screening at 100% of irrigation diversions. • Replace screens that do not meet criteria. • Improve passage at culverts on forest land.	Abundance, Productivity, Spatial Structure	Loss of historical habitat because of blocked or impaired fish passage (push-up dams, culverts, unscreened diversions)
Restore floodplain connectivity and function	Lower Main John Day South Fork John Day Upper Main John Day	• Reconnect side channels and off-channel habitats to stream channels. • Restore wet meadows. • Reconnect floodplain to channel.	Abundance, Productivity, Spatial Structure	Degraded floodplain connectivity and function (loss of off-channel habitat, side channels and connected hyporheic zone)
Restore channel structure and complexity	All populations in MPG	• Place stable wood and other large organic debris in streambeds. • Stabilize stream banks. • Restore natural channel form.	Abundance, Productivity	Degraded channel structure and complexity (loss of spawning and rearing habitat, LWD, pools)
Restore riparian condition and LWD recruitment	All populations in MPG	• Restore natural riparian vegetative communities. • Develop grazing strategies that promote riparian recovery. • Install/maintain fencing.	Abundance, Productivity	Degraded riparian condition (native riparian vegetative communities, LWD recruitment)
Restore altered hydrograph to provide appropriate flows during critical periods	All populations in MPG	• Implement agricultural water conservation measures. • Improve irrigation conveyance and efficiency. • Lease or acquire water rights and convert to instream. • Restore natural functions and processes through actions identified in strategies above. • Employ BMPs to forest, agriculture and grazing practices and to road management.	Abundance, Productivity	Altered hydrology (low summer flow, scouring peak flows due to degraded watershed conditions and/or streamflow alterations and withdrawals for irrigation and other uses.)
Improve degraded water quality	All populations in MPG	• Reduce chemical pollution inputs. • Reduce discharge from mining and dredging areas.	Abundance, Productivity	Degraded water quality (abnormal temperatures or fine sediment, nutrients from runoff, pesticides and

		• Restore natural functions and processes through actions identified in strategies above. • Employ BMPs to forest, agriculture and grazing practices and to road management.		other chemicals, and/or degraded because of water withdrawals that reduce natural stream flows)
Harvest				
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	All populations in MPG	• Maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	Abundance, Productivity	Not a primary limiting factor
Use harvest to reduce abundance and proportion of stray hatchery spawners.	All populations in MPG	• Develop educational outreach program to promote retention of hatchery fish in selective recreational fisheries to reduce the number of out-of-basin hatchery strays.	Abundance, Productivity, Diversity	Straying of out-of-basin hatchery fish into natural spawning areas
Reduce catch and release mortality on natural-origin fish	All populations in MPG	• Promote voluntary curtailment of fishing at higher water temperatures (above 21°C) to reduce hook-and-release mortality.	Abundance, Productivity	Not a primary limiting factor
Improve quality of harvest and natural-origin fish data.	All populations in MPG	• Expand the creel surveys to monitor fisheries effort and catch.	Abundance, Productivity	Not a primary limiting factor
Hatchery				
Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish.	Potential risk for all populations in MPG. Currently a primary risk to Lower John Day population.	NOTE: The following measures are recommended in one or more management unit plans but have not been agreed upon by all co-managers. - Implement representative coded-wire-tagging (CWT) program so all hatchery stocks have adequate CWT groups released annually. - Mark all hatchery steelhead releases in Columbia River Basin with, at a minimum, an adipose fin-clip. - Recommend development of alternative broodstocks to reduce stray rates for programs that contribute significantly to stray problem. - Reduce proportion of Snake River hatchery smolts that are transported from Lower Granite and Little Goose dams.	Productivity, Diversity	Straying of Out-of-DPS hatchery fish into natural spawning areas.
Reduce uncertainty in abundance and proportion of hatchery strays spawning naturally	Potential risk for all populations in MPG. Currently a primary risk to Lower John Day population.	• Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys and other methods.	Productivity, Diversity	Out-of-DPS and Inside-DPS hatchery strays in tributary natural spawning grounds

7.2.3 Umatilla/Walla Walla MPG

Population	ICTRT Risk Status
Umatilla River	Moderate Risk
Walla Walla River	Moderate Risk
Touchet River	High Risk (provisional because of insufficient data)

This MPG does not meet viability criteria because all three populations have moderate risk for both abundance/productivity and spatial structure/diversity and are assigned "maintained" status. The annual abundance data series for the Touchet River steelhead population is relatively short and has several missing years; the ICTRT cautions that the Touchet's status/risk rating is provisional and should be interpreted with caution.

Recovery Scenario: For the Umatilla/Walla Walla MPG to be viable, two populations should meet viability criteria, and of these one should be highly viable. The Umatilla River is the only large population, and therefore should be viable. Either the Walla Walla River or Touchet River population also should be viable.

Gap: There was sufficient information available to estimate gaps for only two of the three populations within the Umatilla/Walla Walla MPG. Assuming base hydrosystem and recent ocean conditions, the survival gaps for the Umatilla and Walla Walla populations are 0.09 and 0.34, respectively.

Key actions proposed (more details in Table 7-4):

- Coordinate between planners, scientists and those implementing recovery actions in Washington and Oregon for sequencing, monitoring, and adaptive management.
- Protect and improve freshwater habitat conditions and access for steelhead production. Improvements to freshwater habitat should be targeted to address specific factors in specific areas as described in the Southeast Washington Plan and the Oregon Steelhead Recovery Plan.
- Improve hatchery management to reduce straying from out-of-DPS hatchery fish onto natural spawning grounds within the Umatilla/Walla Walla subbasins.
- Improve survival in mainstem and estuary through actions detailed in NMFS Estuary Module (NMFS 2007) and FCRPS Biological Opinion (NMFS 2008a).

Summary of MPG Recovery Strategy: Natural steelhead production from the three populations in this MPG are projected to benefit from the combined effects of improved tributary habitats and enhanced survival through the migration corridor connecting upper tributary rearing habitats with the ocean. Tributary restoration strategies in these three populations put a high priority on building out from existing reaches of relatively good spawning and rearing habitat in the upper ends of major tributaries. The downriver tributary reaches targeted for restoration include a substantial amount of habitat projected to have historically supported steelhead production. Increased water temperatures during the summer rearing period, increased fine sediment levels, and loss of natural stream structure limit survival and capacity for summer rearing and overwintering in these reaches.

The plans summarize results of habitat assessments that document the distribution and relative magnitude of habitat degradation throughout the drainages. The projections of potential responses to the proposed habitat restoration actions were developed based upon considerations for the results of the habitat assessments in each population and past experiences with restoration efforts. Restoring juvenile rearing conditions in tributary mainstem rearing areas included as priorities in each population will increase the range of historically important life history patterns, increasing the resilience of the populations to fluctuations in environmental conditions. Action strategies are aimed at reducing temperatures and sedimentation by restoring riparian cover, natural bank conditions and flow regimes in targeted reaches.

An important element of the restoration strategy for each population in this MPG is to increase survivals during the smolt outmigration phase through improvements to the spring flow and temperature regimes in the tributary mainstems and the Columbia River. Actions proposed in the plans are designed to build upon the flow and passage improvements that have been gained in recent years. Hatchery programs designed to boost natural recovery efforts and to provide fish for harvest operate within each of the populations. The recovery plan includes strategies designed to limit long-term risks to natural production by controlling the distribution and level of hatchery contributions within each population.

Table 7-3 Recovery Strategies and Actions for the Umatilla/Walla Walla MPG.

UMATILLA/WALLA WALLA MPG				
Strategies	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
Tributary Habitat				
Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	All populations in MPG	• Protect highest quality habitats through acquisition and conservation. • Adopt and manage Cooperative Agreements. • Conserve rare and unique functioning habitats. • Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	All Parameters	Degradation of tributary habitat-forming processes and functions (loss of channel structure, floodplain connectivity, riparian vegetation and LWD recruitment)
Restore passage and connectivity to habitats blocked or impaired by artificial barriers.	Umatilla River, Walla Walla River, Touchet River	• Remove or replace culverts and/or other passage barriers. • Construct ladders over existing dams. • Provide adequate screening at 100% of irrigation diversions. • Replace screens that do not meet criteria.	Abundance, Productivity, Spatial Structure	Loss of historical habitat because of blocked or impaired fish passage (dams, culverts, unscreened diversions)
Restore floodplain connectivity and function.	Umatilla River, Walla Walla River, Touchet River	• Reconnect side channels and off-channel habitats to stream channels. • Restore wet meadows. • Reconnect floodplain to channel.	Abundance, Productivity, Spatial Structure	Degraded floodplain connectivity and function (loss of off-channel habitat, side channels and connected hyporheic zone)
Restore channel structure and complexity.	Umatilla River, Walla Walla River, Touchet River	• Place stable wood and other large organic debris in streambeds. • Stabilize stream banks. • Restore natural channel form.	Abundance, Productivity	Degraded channel structure and complexity (loss of spawning and rearing habitat, LWD, pools)
Restore riparian condition and LWD recruitment.	Umatilla River, Walla Walla River, Touchet River	• Restore natural riparian vegetative communities. • Develop grazing strategies that promote riparian recovery. • Install/maintain fencing.	Abundance, Productivity	Degraded riparian condition (native riparian vegetative communities, LWD recruitment)
Restore altered hydrograph to provide sufficient flow during critical periods.	Umatilla River, Walla Walla River, Touchet River	• Restore natural functions and processes through actions identified in strategies above. • Implement Umatilla Basin Project Phases I-III. • Implement water conservation measures. • Improve irrigation conveyance and efficiency. • Investigate feasibility of water storage and exchange (WW).	Abundance, Productivity	Altered hydrology (low summer flow, scouring peak flows due to degraded watershed condition and/or streamflow alterations and withdrawals for irrigation and other uses.)

UMATILLA/WALLA WALLA MPG				
Strategies	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
		• Employ BMPs to forest, agriculture and grazing practices and to road management.		
Improve degraded water quality.	Umatilla River	• Reduce chemical pollution inputs. • Reduce discharge from mining and dredging areas. • Restore natural functions and processes through actions identified in strategies above. • Employ BMPs to forest, agriculture and grazing practices and to road management.	Abundance, Productivity	Degraded water quality (abnormal temperatures or fine sediment, nutrients from runoff, pesticides and other chemicals and/or because of water withdrawals that reduce natural stream flows.)
Harvest				
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	Umatilla River, Walla Walla River, Touchet River	• Maintain current management regulations for low impact fisheries and adjust tributary harvest regulations in areas where harvest significantly impacts steelhead viability.	Abundance, Productivity	Not a primary limiting factor
Hatchery				
Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish.	Umatilla River, Walla Walla River	NOTE: The following measures are recommended in one or more management unit plan but have not been agreed upon by all co-managers. • Implement representative coded-wire-tagging (CWT) program so all hatchery steelhead stocks have adequate CWT groups released annually. • Mark all hatchery steelhead releases in Columbia River Basin with, at a minimum, an adipose fin-clip. • Recommend development of alternative broodstocks to reduce stray rates for programs that contribute significantly to stray problem. • Reduce proportion of Snake River hatchery smolts that are transported from lower Granite and Little Goose dams.	Productivity, Diversity	Straying of out-of-DPS hatchery fish into natural spawning areas.
Reduce abundance and proportion of out-of-basin hatchery strays spawning naturally.	Umatilla River	• Uniquely mark Umatilla Hatchery steelhead and remove out-of-basin hatchery strays at Three Mile Falls Dam.	Productivity, Diversity	Out-of-basin hatchery strays in tributary natural spawning grounds.
Reduce abundance and proportion of out-of-basin hatchery strays spawning naturally.	Walla Walla River	• (These actions are currently non-consensus recommendations.)	Productivity, Diversity	Genetic risks from out-of-basin hatchery strays spawning naturally

UMATILLA/WALLA WALLA MPG				
Strategies	**Populations Affected and Addressed**	**Key Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
		• Eliminate adult hatchery strays above Nursery Bridge Dam by resuming trapping operations and removing hatchery fish. • Alter release strategy of Lyons Ferry hatchery smolts released into lower Walla Walla River from direct stream to acclimated releases. Implement trap and removal near acclimation site. • Develop local broodstock to replace Lyons Ferry stock for use in harvest augmentation program and to initiate a natural production supplementation program.		
Reduce abundance and proportion of out-of-basin hatchery strays spawning naturally.	Touchet River	• Continue development of Endemic Touchet River summer steelhead program to replace current releases of Lyons Ferry hatchery summer steelhead smolts. • Improve adult trap at the Dayton Pons diversion dam to improve management of returning adult hatchery summer steelhead. • Install weir on Copei Creek to monitor escapement of summer steelhead and remove hatchery strays.	Diversity	Genetic risks from out-of-basin hatchery strays spawning naturally
Re-establish natural production in historically utilized habitats.	Umatilla River	• Re-establish natural production in Little Butter and Butter creek drainages by outplanting adults and/or juveniles into tributaries after habitat conditions are restored.	Abundance, Productivity, Spatial Structure, Diversity	Loss of natural production in Butter Creek system.
Reduce genetic influence of hatchery fish in hatchery broodstock.	Umatilla River	• Eliminate use of hatchery-produced adults in broodstock.	Diversity	Potential divergence in genetic and phenotypic traits between hatchery and natural-origin steelhead.
Reduce interactions between residual hatchery steelhead and natural steelhead.	Umatilla River	• Conduct volitional releases of steelhead smolts and remove fish that do not migrate.	Abundance, Productivity, Diversity	Risk of hatchery fish competing with and preying on natural steelhead juveniles
Reduce potential negative ecological interactions between coho salmon and natural steelhead.	Umatilla River	• Reduce number of hatchery coho released in Umatilla River and relocate releases downstream to areas not currently important for steelhead production.		Potential for coho smolts to compete with juvenile steelhead for prey resources and space.

7.2.4 Yakima River MPG

Population	ICTRT Risk Status
Upper Yakima River	High Risk
Naches River	High Risk
Satus Creek	Moderate Risk
Toppenish Creek	Moderate Risk

The Yakima MPG is currently rated at High Risk. The two largest populations in the drainage (Naches and Upper Yakima) are rated at High Risk; the Satus Creek and Toppenish Creek populations are rated as Maintained.

Recovery Scenario: For the Yakima River MPG to achieve viable status, two populations should be rated as Viable, including at least one of the two classified as Large - the Naches River and the Upper Yakima River. The remaining two populations should, at a minimum, meet the ICTRT's Maintained criteria.

Gap: The median survival gap (assuming recent ocean and base hydrosystem conditions) for the Yakima MPG is 0.77 (needs 77 percent improvement in average survival over the life cycle), ranging from 0.22 (Satus—tributary only) to 1.15 (Upper Yakima). This is the highest median survival gap of the four MPGs that make up the Middle Columbia River DPS.

Key actions proposed (more detail in Table 7-3):

- Protect and enhance habitat in key tributary watersheds in the Yakima Basin.
- Restore passage to blocked areas in the Naches and Upper Yakima population areas.
- Alter irrigation delivery and storage operations in the Yakima Basin to improve flow conditions for Middle Columbia steelhead and use managed high flows to maintain floodplain habitat.
- Improve channel and floodplain function and reduce predation through the mainstem Yakima and Naches Rivers.
- Improve survival in the mainstem Columbia and its estuary through actions detailed in NMFS Estuary Module (NMFS 2007) and FCRPS Biological Opinion (NMFS 2008a).

Summary of Recovery Strategy:

Tributary and mainstem habitats for steelhead in the Yakima basin have been substantially altered from historical conditions. High quality rearing habitat has been substantially reduced or rendered inaccessible. Especially in the Naches and Upper Yakima mainstem reaches, degraded conditions such as flow reductions, increased temperatures, and altered stream structure have reduced survival and the expression of life history diversity.

Recovery actions proposed to benefit Yakima River steelhead populations are aimed at improving conditions across the freshwater habitats the fish use in all life stages – from incubation and rearing to juvenile and adult migration – especially in the Yakima River mainstem. This has the highest potential to quickly make a difference by increasing

productivity in the areas where fish now spawn and restoring the pattern of extended rearing in the mainstem. It is also important to restore flow and temperature conditions conducive to steelhead rearing in mainstem reaches of the Naches River and the Upper Yakima, which are believed to have supported substantial production historically. Restoring anadromous access into tributaries with large amounts of relatively high quality habitat by targeting flow improvements and barrier removals is also a high priority, especially for the two large populations in the upper Yakima basin.

The Yakima River enters the Columbia upstream of four major hydroelectric dams. Actions to improve passage and migration survival in the mainstem Columbia River and the estuary will also contribute to achieving objectives for the Yakima populations. Since Yakima-origin steelhead are harvested in mainstem Columbia River fisheries primarily directed on fall Chinook, harvest management is another important component of the recovery strategy for these and all Middle Columbia steelhead populations.

Table 7-4 Recovery Strategies and Actions for the Yakima Basin MPG.

YAKIMA RIVER MPG				
Highest Priority Strategies	**Populations Affected and Addressed**	**Key Types of Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
Tributary Habitat				
Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	All populations in MPG: Upper Yakima Naches Toppenish Satus	• Protect highest quality habitats through long-term protection and conservation. • Adopt and manage Cooperative Agreements. • Conserve rare and unique functioning habitats. • Consistently apply BMPs and existing laws to protect and conserve natural ecological processes.	All Parameters	Degradation of tributary habitat-forming processes and functions (loss of channel structure, floodplain connectivity, riparian vegetation and LWD recruitment)
Restore passage and connectivity to habitats blocked or impaired by artificial barriers.	All Populations	• Provide passage at selected Yakima and Naches River Storage Dams as feasible. • Remove or replace barriers blocking or impairing passage including dams, dikes, road culverts and irrigation structures. • Provide screening at 100% of irrigation diversions. • Replace screens that do not meet criteria.	Abundance, Productivity, Spatial Structure	Loss of historical habitat because of blocked or impaired fish passage (dams, culverts, seasonal push-up dams, unscreened diversions) Reduced survival due to delay and mortality due to entrainment in water diversions
Improve conditions for outmigrating smolts at diversion structures.	Upper Yakima Lower Yakima migratory area (affects all populations)	• Improve smolt passage at Roza Dam. • Reduce mortality at Chandler, Roza and other Diversion Dams.	Abundance, Productivity	Increased travel time and decreased survival for outmigrating smolts
Restore floodplain connectivity and function.	All Populations	• Reconnect side channels and off-channel habitats to stream channels. • Restore wet meadows. • Reconnect floodplain to channel. • Relocate or improve floodplain infrastruct. & roads.	Abundance, Productivity, Spatial Structure	Degraded floodplain connectivity and function (loss of off-channel habitat, side channels and connected hyporheic zone)
Restore channel structure and complexity.	All Populations	• Place stable wood and other large organic debris in stream banks. • Stabilize stream banks. • Restore natural channel form.	Abundance, Productivity	Degraded channel structure and complexity (loss of spawning and rearing habitat, LWD, pools)
Restore riparian condition and LWD recruitment.	All Populations	• Restore natural riparian vegetative communities. • Develop grazing strategies that promote riparian recovery.	Abundance, Productivity	Degraded riparian condition (native riparian vegetative communities, LWD recruitment)
Restore altered hydrograph to provide appropriate flows during critical periods.	All Populations	• Implement agricultural water conservation measures. • Improve irrigation conveyance and efficiency. Lease or acquire water rights and convert to instream. • Restore natural functions and processes through actions	Abundance, Productivity	Altered hydrology (low summer flow, scouring peak flows due to degraded watershed conditions, high summer delivery flows in mainstem Yakima Tieton and Naches rivers. Reduced winter and spring flows due to irrigation storage,

YAKIMA RIVER MPG				
Highest Priority Strategies	**Populations Affected and Addressed**	**Key Types of Actions**	**VSP Parameters Addressed**	**Limiting Factors Addressed**
		identified in strategies above. • Employ BMPs to forest, agriculture and grazing practices, and to road management. • Protect and/or rehabilitate springs. • Increase irrigation storage as feasible.		delivery and withdrawals)
Improve degraded water quality.	All Populations	• Reduce chemical pollution inputs. • Restore natural functions and processes through actions identified in strategies above. • Employ BMPs to forest, agriculture and grazing practices and to road management. • Upgrade or remove problem forest roads. • Conduct pathogen sampling and monitoring. • Construct water and sediment control basins.	Abundance, Productivity	Degraded water quality (abnormal temperatures or fine sediment, nutrients fro runoff, pesticides and other chemicals and/or because of water withdrawals that reduce natural stream flows.
Harvest				
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	All Populations	• Maintain current management regulations for low impact fisheries and adjust tributary harvest regulations in areas where harvest significantly impacts steelhead viability.	Abundance, Productivity	Not a primary limiting factor
Reduce illegal harvest on ESA-listed species.	All Populations	• Ensure adequate enforcement to prevent illegal harvest of steelhead	Abundance, Productivity	Not a primary limiting factor
Hatchery				
Restore natural production into historically utilized habitats, including blocked areas in tributaries and above storage dams where passage is provided.	Naches, Upper Yakima	• Develop plan for steelhead reintroductions into historical habitat when passage is restored. • Use small scale supplementation to re-establish natural production in MaSAs and some MiSAs	All Parameters	Risks related to steelhead reintroductions to historical habitat using inside-DPS hatchery fish
Promote repeat spawning of kelts.	All Populations	• Use kelt reconditioning program	All Parameters	Reduced survival of kelts due to passage conditions in the Columbia and lower Yakima

7.3 Setting Priorities

Priorities for recovery actions should be guided by DPS-, MPG-, and population-level recovery criteria and best available scientific information concerning DPS status, the role of the independent populations in meeting DPS and MPG viability, limiting factors and threats, and likelihood of effectiveness of actions. Protection of existing habitat is essential. Issues of funding and local, state, or national support for implementation will also inevitably come into play.

The management unit plans all address these issues in their implementation sections. The Oregon Steelhead Recovery Plan offers detailed considerations for prioritization that are also adopted by the Washington Gorge Plans. The Southeast Washington Plan describes "strategic guidelines" for prioritization. The Yakima Steelhead Plan notes that the process of working out an implementation schedule with stakeholder participation will ultimately set the priorities.

See Chapter 11, Implementation, for discussion of the organization of ongoing technical review and support from DPS and management unit science and technical committees. Coordination and communication in the Mid-C Forum and other venues will be necessary for actions in the Columbia mainstem, estuary, and/or ocean.

7.3.1 Oregon Steelhead Recovery Plan

The Oregon Steelhead Recovery Plan offers an approach to steelhead recovery that attempts to integrate both the biological needs of the fish and the economic, political, social, and cultural context in which strategies must be implemented and actions chosen. The plan provides an overview of the links between threats and limiting factors, management strategies, and types of actions (Table 7-5). This is followed by detailed tables for each of the 10 Oregon steelhead populations, identifying specific proposed actions, locations, limiting factors and threats addressed, VSP parameters and life stages affected. The tables also include assessments of existing programs relevant to the proposed actions. The Oregon Steelhead Recovery Plan is included as Appendix A of this Plan.

Table 7-5. Integrated approach to address threats and factors limiting recovery of Oregon's Middle Columbia River steelhead populations.

Threats and Limiting Factors	Management Strategies	Types of Actions
All degraded habitat limiting factors	Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	Protect highest quality habitats through acquisition and conservation. Adopt and manage Cooperative Agreements. Conserve rare and unique functioning habitats. Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.
Degraded Habitat - Impaired fish passage	Restore passage and connectivity to habitats blocked or impaired by artificial barriers, and maintain unimpaired passage and connectivity	Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures. Provide screening at 100% of irrigation diversions. Replace screens that do not meet criteria.
Degraded habitat - floodplain connectivity and function	Restore floodplain connectivity and function, and maintain unimpaired floodplain connectivity and function	Reconnect side channels and off-channel habitats to stream channels. Restore wet meadows. Reconnect floodplain to channel.
Degraded habitat - channel structure and complexity	Restore channel structure and complexity, and maintain unimpaired structure and complexity	Place stable wood and other large organic debris in streambeds. Stabilize stream banks. Restore natural channel form.
Degraded habitat - riparian area and LWD recruitment	Restore riparian condition and LWD recruitment, and maintain unimpaired conditions	Restore natural riparian vegetative communities. Develop grazing strategies that promote riparian recovery.
Degraded habitat - altered hydrology	Restore altered hydrograph to provide sufficient flow during critical periods	Implement agricultural water conservation measures. Improve irrigation conveyance and efficiency. Lease or acquire water rights and convert to instream.
Degraded habitat - water quality	Improve degraded water quality and maintain unimpaired water quality	Reduce chemical pollution inputs. Apply BMPs to animal feeding operations. Restore natural functions and processes through actions identified in strategies 1,3,4,5,8
Degraded habitat - altered sediment routing	Restore degraded upland processes to minimize unnatural rates of erosion and runoff, and maintain unimpaired natural upland processes	Achieve 95% conversion to no till farming. Upgrade or remove problem forest roads. Restore native upland plant communities. Employ BMPs for forest practices, livestock grazing, road management and agricultural practices.
Degraded habitat - estuarine and Nearshore Marine	Restore degraded estuarine and nearshore habitat, and maintain unimpaired conditions	Protect/restore riparian areas Remove pile dikes Protect remaining high quality off-channel habitat Breach or lower dikes and levees Identify and reduce sources of pollutants Monitor and restore contaminated sites
Mainstem Columbia River hydro system	Improve salmonid migration and habitats, and reduce predation on and competition between salmonids in the mainstem Columbia River.	Adjust the timing, magnitude, and frequency of flows Mitigate/reduce reservoir heating Continue adult fish passage operations Improve juvenile fish passage Continue and enhance spill for juvenile fish passage Modify fish transportation to improve juvenile survival

Threats and Limiting Factors	Management Strategies	Types of Actions
Hatchery related adverse effects	Reduce hatchery related genetic and ecological effects on natural populations of Middle Columbia steelhead	Increase marking of Col. Basin hatchery steelhead with coded-wire tags. Require mass marking of all hatchery steelhead releases with, at a minimum, an adipose fin-clip. Increase efforts to monitor incidence of hatchery fish on spawning grounds. Develop plan for steelhead reintroduction into historical habitat when passage is restored. Eliminate the use of hatchery produced adults in the broodstock Construct trapping facilities
Harvest-related adverse effects	Manage fisheries to reduce harvest-related adverse effects	Use selective recreational fisheries to reduce the number of out-of-basin hatchery strays. Call for a voluntary curtailment of fishing at higher water temperatures (above 21°C) as a measure to reduce hook-and-release mortality Expand the creel surveys to monitor fisheries effort and catch
Predation, competition, disease	Reduce predation, competition and disease	Reduce predation by pinnipeds Redistribute Caspian terns Redistribute cormorants

The Oregon Steelhead Recovery Plan's recommendation for setting priorities is a list of "considerations," based on key principles derived from conservation biology and ecosystem management.

The principles for sound salmon recovery efforts:

1) Set aside or protect the highest quality habitat.
2) Do not let habitat conditions degrade further.
3) Maintain or restore critical ecological processes.
4) Develop goals and objectives based on deep understanding of ecological properties of the system.
5) Evolutionary processes must be conserved or restored.
6) Management must be adaptive and minimally intrusive.

The considerations for prioritizing actions:

We consider actions that achieve the following to be highest priority:

- *Actions that provide long-term protection of habitat conditions and conservation of natural ecological processes that support the viability of priority extant populations and their primary life history strategies throughout their entire life cycle. A population is considered a priority if it is critical for MPG or DPS viability.*
- *Actions that protect or enhance viability of multiple steelhead populations.*

- *Actions that support conservation of unique and rare functioning habitats, habitat diversity, life histories and genetic attributes.*
- *Actions that target the key limiting factors and that contribute the most to closing the gap between current status and desired future status of priority populations.*
- *Actions that provide critical information needed for assessing success and making adaptive management decisions.*

We consider the following types of actions to be high priority but less than highest:

- *Actions that enhance the habitat conditions and restore natural ecological processes of priority extant populations and their primary life history strategies throughout the entire life cycle.*
- *Actions that enhance the viability of priority extant populations.*
- *Actions that are required to protect and enhance habitats for populations that are not critical for MPG or ESU viability but must be maintained.*

Other things being equal, actions that demonstrate the following have enhanced priority:

- *Actions where opportunity for success is high (rather than those of limited feasibility).*
- *Actions that likely produce a large (rather than small) improvement in viability attributes.*
- *Actions that support restoration of normative ecological processes rather than short-term substitutions for normative processes.*
- *Actions that are complementary to other land management, water quality, environmental management and recreational objectives as specified in fish management, conservation, recovery or other plans developed with and supported by regional and subbasin stakeholders (rather than those that are isolated, stand-alone efforts).*
- *Actions that have regional and local support and generate increased participation.*
- *Actions that demonstrate cost effectiveness relative to alternative means of achieving the same objectives.*
- *Actions that have high degree of certainty in effectiveness and outcome. Source: ODFW 2009.*

The Oregon Steelhead Recovery Plan also proposes the following measures to address hatchery related genetic and ecological effects on natural populations of Middle Columbia steelhead:

- Increase efforts to monitor incidence of hatchery fish on spawning grounds.
- Develop and implement plan for steelhead reintroduction into historical habitat when passage is restored.
- Eliminate the use of hatchery-produced adults in the Umatilla River brood stock.
- Construct trapping facilities in the Deschutes River basin to remove stray hatchery fish.
- Use selective recreational fisheries to reduce the number of out-of-basin hatchery strays.

7.3.2 Washington Gorge Management Unit Plans

The Washington Gorge plans (White Salmon, Klickitat, and Rock Creek) identify recovery strategies in the same general order of importance as in the Oregon Steelhead Recovery Plan.

7.3.2.1 Klickitat Recovery Plan

The first priority for the Klickitat River steelhead population is to reduce the uncertainties and data gaps identified by the ICTRT. A targeted monitoring program will be designed to do the following:

- Determine abundance and productivity of natural steelhead spawners
- Determine the adverse effects of Skamania broodstock and out-of-subbasin strays on the Klickitat population, if any.
- Determine the effects of non-native coho and fall Chinook released from the hatcheries and naturalized in the river on naturally produced steelhead, if any.
- Continue study and further refine understanding of habitat limiting factors.

Further actions related to potential limiting factors:

- Minimize adverse impacts of large-scale hatchery releases of *U.S. v. Oregon* production stocks (coho and fall Chinook) on Klickitat steelhead. The satellite Wahkiacus Hatchery/Acclimation Facility at RM 17.0 is being developed so that existing U.S. v. Oregon production of fall Chinook and coho can be transferred from the Klickitat Hatchery 26 miles downstream to the Wahkiacus facility, transferring coho and fall Chinook production 26 miles downriver, to reduce and minimize the impacts of large-scale hatchery releases on wild spring Chinook and steelhead rearing between the two facilities.
- Determine and minimize impacts of hatchery trout releases in the subbasin.
- Improve steelhead passage at Lyle Falls Fishway.
- Assess steelhead natural recolonization of upper Klickitat watershed and the potential use of artificial propagation to accelerate recolonization.

To address habitat degradation in the Klickitat watershed, the plan proposes a strategy to protect and improve ecosystem functions and restore normative ecological processes. The components of the strategy are, first, to protect and maintain existing high quality and/or unimpaired habitats and ecosystem functions; and, second, to restore degraded habitat where appropriate, through passive and active measures.

Managing harvest for low impacts from both mainstem and tributary fisheries, and to reduce any adverse impacts that may be occurring, also is an important contribution to the population's viability.

7.3.2.2 Rock Creek Recovery Plan

The Rock Creek plan's recovery strategy aims to remove threats to the long-term survival of the population and improve population biological characteristics so it will, first, meet requirements for a Maintained population and support DPS recovery and, eventually, achieve viability and meet broader population goals. The recovery strategy focuses on (1) gaining information needed

to better assess population status and (2) removing key threats to population viability by improving freshwater habitat conditions.

7.3.2.3 White Salmon Recovery Plan

The White Salmon plan's recovery strategy contains two key parts: 1) a plan for reintroducing naturally produced steelhead into historical habitat after the removal of Condit Dam, and 2) improving and increasing freshwater habitat for steelhead production in the subbasin. The plan also recommends ensuring that harvest or hatchery actions do not impede efforts to improve steelhead viability. The White Salmon Technical Working Group is developing the reintroduction plan.

7.3.3 Southeast Washington Plan

The SRSRB developed its recovery strategies by means of a set of "strategic guidelines" weighed against proposed actions. However, for habitat protection and restoration actions, "imminent threats" to fish life in areas containing ESA-listed populations will receive the highest priority. Examples of imminent threats include adult fish passage barriers such as culverts or dams, unscreened or poorly screened irrigation diversions, stream crossings (fords or low water crossings) that are located in spawning areas and are used during the incubation period, dewatered reaches that strand or kill fish and act as passage barriers, and point sources of toxic pollutants. Removing imminent threats will likely result in the greatest increase in fish survival over the shortest time.

The overall strategic guidelines are as follows:

1. Emphasis will be placed on projects with long persistence time ("life span") and benefits distributed over the widest possible range of environmental attributes.
2. Recovery/restoration actions must include immediate measures in addition to long-term actions. Many actions that address the root causes of habitat degradation require a long time to achieve their goals. An example would be planting trees in riparian zones to: a) reduce instream temperatures, b) add large woody debris, and c) increase habitat complexity. Immediate actions that can "jump start" recovery can include such things as manual addition of large woody debris to stream channels, and creation of meanders in channelized streams.
3. The management strategy will involve "adaptive management"; that is, it will be a feedback system where changes in information or data detected through monitoring and evaluation will be used to adjust and modify plans and actions.
4. Identification of important areas and proposed actions is based substantially on information contained in the applicable subbasin plans.
5. Actions necessary to accomplish the recovery goals will be considered within the context of the four "Hs" (habitat, harvest, hatcheries, and hydroelectric).
6. Actions implemented within the region will be focused primarily on restoration and protection of habitat; actions pertinent to the other "Hs" will be addressed primarily through other planning processes, but the SRSRB may provide recommendations to these processes.
7. The EDT analysis tool, in combination with other analyses, empirical data and professional opinion, will be used to identify and prioritize habitat actions.

8. The final set of proposed actions will be subject to economic, social, and cultural constraints identified by the recovery region.
9. Priority actions are those that the SRSRB hopes to accomplish over the 15-year planning period of this plan.

In general, the habitat strategy is based on protection of high quality or productive habitat and restoration, preferably passive restoration, to revitalize degraded habitat. Specific habitat strategies were prioritized in the following way: Habitat characteristics or factors, such as substrate embeddedness, pools, or temperature, were correlated with general categories of appropriate action, such as improving riparian areas, improving channel and floodplain, or improving water quantity. The categories of action, called "approaches," were assigned priority in terms of effectiveness, technical feasibility, and cost/benefit. Objectives for restoration and protection were defined specifically; for example, the restoration objective for water temperature is to achieve a stream condition where the water temperature does not rise above 72° F for more than four days per month. The habitat factors were then arranged in order of importance for each major spawning area, and specific actions, funding sources, and potential costs were listed.

7.3.4 Yakima Steelhead Recovery Plan

Since the Yakima management unit encompasses all the populations of one MPG, the Yakima Steelhead Plan is structured to present a recovery strategy at the MPG-level. For this reason, the details of the Yakima recovery strategy are presented above in Section 7.2.4, Yakima River MPG.

8. SITE-SPECIFIC MANAGEMENT ACTIONS AND COST ESTIMATES

It is important to consider the unique characteristics and challenges of estimating time and cost for salmon and steelhead recovery, given the complex relationship of these fish to the environment and to human activities on land. NMFS estimates that recovery of the Middle Columbia steelhead DPS could take 25 to 50 years. The management unit plans (Appendices A through E) contain extensive lists of actions to recover the Middle Columbia steelhead DPS populations. These projects were developed using the most up-to-date assessment of Middle Columbia steelhead recovery needs. The management unit plans focus, for the most part, on actions within the next 5 to 15 years. There are many uncertainties involved in predicting the course of recovery and in estimating total costs. Such uncertainties include biological and ecosystem responses to recovery actions as well as long-term and future funding.

8.1 Site-Specific Management Actions

The proposed site-specific management actions at the population level are described in detail in Appendices A through E. It is possible that some of these actions will not be funded and that others will be proposed or added. It is important to note that the management unit plans are dynamic and subject to change through the adaptive management process. Implementation plans are often updated annually and generally cover a 3-to-10-year period. The reader is urged to refer to the management unit plans for up-to-date implementation schedules.

Proposed site-specific actions for the mainstem Columbia River and estuary are described in detail in the FCRPS Biological Opinion (NMFS 2008a) and the Hydro Module (NMFS 2008c), the Estuary Module (NMFS 2007), and *Artificial Propagation for Pacific Salmon*, Appendix C of the Supplemental Comprehensive Analysis of the FCRPS Biological Opinion (NMFS 2008a).

NMFS recognizes that to achieve recovery of ESA-listed salmon and steelhead in the Columbia River Basin, site-specific actions addressing all limiting factors and threats (habitat, hydropower, hatcheries, harvest, and ecological interactions including predation and competition) are necessary. In this recovery plan, the relative impacts of this full range of limiting factors and threats are identified and evaluated, although effective site-specific actions may be better developed or more feasible to implement in some sectors than in others. At this time, site-specific management actions are more fully developed for tributary habitat and mainstem hydropower than for hatcheries and harvest. Given that habitat protection and restoration actions generally take some time to yield ecosystem responses and improvements in fish populations, it is important to implement actions with more immediate benefits, as well as those whose benefits will accrue in the future.

Hatchery and harvest actions developed in other management processes will be important for recovery. For hatcheries, site-specific actions are being developed pursuant to the FCRPS consultation process, which requires Hatchery and Genetic Management Plans (HGMPs) for all facilities that affect listed salmon and steelhead in the Columbia Basin. Mainstem fisheries in the Columbia River will be implemented consistent with the recently completed U.S v. Oregon Agreement, which extends through 2017. Tributary fisheries are subject to Fishery Management and Evaluation Plans, many of which are now under review or scheduled for completion in the near future. Such plans have been and will be developed to be consistent with recovery plans, ESA

section 7(a)(2), and other ESA requirements. NMFS will continue to monitor these plans, using adaptive management, to assess implementation progress and consistency with recovery plans.

8.2 Cost Estimates

Cost estimates for recovery projects were provided by the management unit entities where available information was sufficient to do so. In some cases this was done in coordination with a NMFS economist at the Northwest Fisheries Science Center in Seattle using a regional recovery cost database, together with input and review from regional experts and representatives from the Middle Columbia Recovery Forum in 2007.

Cost estimates for proposed recovery projects were developed using the methods described in each management unit plan. No cost estimates are provided for (1) baseline actions (programs that are already in existence), which are listed as Not Applicable (N/A); or (2) actions that need costs to be developed, need unit costs, and/or need project scale estimates, which are listed as To Be Determined (TBD). Each management unit worked with regional experts to identify costs, scale, or unit costs for actions that required more information in the draft stage, and costs were updated to the extent possible for this final plan.

The total estimated cost of habitat recovery actions for the Middle Columbia steelhead DPS is approximately $235 million over the initial 5-year period, and approximately $996 million for all DPS-wide recovery actions for which sufficient information exists upon which to base an estimate (Table 8-1). This estimate includes expenditures by local, tribal, state, and Federal governments, private business, and individuals in implementing both capital projects and non-capital work. Administrative costs are embedded in the total management unit cost estimates in Table 8-1. However, they do not include costs associated with implementing actions within the lower Columbia River, estuary or Federal Columbia River Power System (FCRPS). Preliminary research, monitoring and evaluation costs have, in some cases, been estimated at the management unit level; however, these costs are not included at this time pending completion of research and monitoring plans and further development of each project.

Table 8-1 Summary of Cost Estimates for Habitat Projects for Middle Columbia Steelhead DPS.

Recovery Plan	First 5 Years ($M)	Total Cost ($M)
Oregon	$ 103.5	$ 512.8
Yakima Steelhead[36]	$ 91.9	$ 269.3
SE Washington[37]	$ 25.5	$ 76.4
Klickitat[38],[39]	$ 12.9	$ 129.4
Rock Creek[40]	$ 0.9	$ 1.8
White Salmon Steelhead	N/A	$ 6.5[41]
DPS Totals	**$ 234.7**	**$ 996.2**

Table 8-1 provides costs for implementing actions in the first five years for each management unit, together with total program costs in each management unit plan. The estimates in Table 8-1 do not include costs associated with baseline actions because these are actions categorized as part of ongoing, existing programs. The success of steelhead recovery is, however, dependent upon the continued support of ongoing baseline projects and programs.

There are several cautions that must be highlighted regarding these summary costs, because many of these estimates may be incomplete until actions are better defined. For example, the costs for potentially expensive projects such as land and water acquisition, water leasing, and research and monitoring have not yet been estimated for many populations. For other projects, unit cost estimates or determination of project scale may also still need to be calculated. Therefore, Table 8-1 presents preliminary summary costs for recovery that will likely increase when unit cost estimates, scale of projects, and costs for actions are determined and as projects are better defined.

These cost estimates do not include expenses associated with implementing actions within the lower Columbia River, estuary, or Federal Columbia River Power System (FCRPS), first, because of the basin-wide scope and applicability of these actions to all 13 Columbia Basin salmonid species listed

[36] The Yakima steelhead plan estimates costs for the first 6 years, and includes preliminary RME cost estimate of $300K/year. The 5-year estimate was extrapolated from the 6-year cost data.
[37] The SE Washington plan estimates annual steelhead implementation costs at about $5 million per year. The 5-year estimate was extrapolated by multiplying the annual amount by five.
[38] The Klickitat plan estimates costs for the first 10 years. The five-year estimate was extrapolated by dividing the 10-year amount in half.
[39] The Klickitat plan uses a 50-year period to estimate its total project costs.
[40] The Rock Creek plan estimates cost for the first 3 years and for years 4 to 10. The 5-year estimate was extrapolated by dividing the 10-year amount in half.
[41] Improvement of habitat in the White Salmon subbasin will likely improve conditions for all four listed salmonid species; however, there may be additional costs when recovery actions designed specifically for the three listed Lower Columbia salmon ESUs that spawn in the subbasin are figured in.

as threatened or endangered, and second, because they are considered "baseline actions" that are required through other processes such as section 7 consultations, FERC licensing agreements, and Habitat Conservation Plans. Cost estimates for estuary actions are included in a module that is incorporated into the Plan by reference, and is available on the NMFS website: www.nwr.noaa.gov/Salmon Recovery Planning/ESA Recovery Plans/Other Documents.cfm. The estuary recovery costs could be further refined following public comment on the module and on the ESA recovery plan for the three listed lower Columbia River ESUs and one listed lower Columbia River steelhead DPS in 2009. Costs for hatchery actions required through other processes such as consultations, permits, and 4(d) Rule implementation are not part of recovery costs reported here because the programs are already in existence or are undergoing required modifications. There are few estimated costs for recovery actions associated with harvest to report at this time. This is because no actions are currently proposed that go beyond those already being implemented through *U.S. v. Oregon* and other harvest management forums. In the event that additional harvest actions are implemented through these forums, those costs will be added during the implementation phase of this recovery plan. All cost estimates will be refined and updated over time.

Cost estimates from the draft cost chapters in the individual management plans were developed as consistently as possible, in that they all applied guidance provided by NMFS staff. However, the approaches vary to some degree given the local and independent nature of the planning groups. Costs developed in the management unit plans were estimated using several basic assumptions (i.e., neither baseline costs nor out-of-basin costs were included in the estimates) and used similar cost calculation methodologies. There are, however, differences in the timeframes for cost estimates.

8.2.1 Oregon Middle Columbia Steelhead Recovery Plan

Oregon's Middle Columbia Steelhead Recovery Plan presents extensive cost information for proposed recovery actions by strategies and populations in its Section 11 (Recovery Cost Summary Table) and two cost tables in Appendix I. Cost estimates for proposed recovery projects were developed using the unit cost method described in Section 11. Table I-1 (All Actions by Population, Strategy and Category) in Appendix I summarizes estimated total costs that can currently be identified for recovery actions in each Oregon population and strategy. These do not include certain high cost actions such as land and water acquisition or water leases. ODFW worked with regional experts to identify costs, scale or unit costs for actions that need more information during the public comment period. The Oregon Steelhead Recovery Plan's Appendix I, Table I-1 was updated with this new information for the final recovery plan. The total expected 5-year expenditure for all populations is $103,537,000. The overall total cost estimate for all proposed actions, where costs are available, for all populations is $512,843,328.

8.2.2 Washington Gorge Management Unit Plan

Costs are provided for the three smaller subbasin plans that make up the Washington Gorge management unit. Costs for steelhead habitat recovery for the White Salmon subbasin are included here; however, the White Salmon plan will be finalized as part of the Lower Columbia River ESA Recovery Plan because more than one species of listed salmonid spawns in the White Salmon subbasin.

8.2.2.1 Klickitat Recovery Plan

Costs for habitat recovery actions are estimated at approximately $26 million for years 1-10, approximately $104 million for years 11-50, and $130 million over a 50-year period. The funds to cover improvements at Lyle Falls and Castile Falls total $5.9 million (Klickitat Plan, Appendix B to this plan). Ongoing and expanded research monitoring and evaluation activities are estimated to cost roughly $4,484,402 total for years 1 to 3 and $15,142,783 total for years 4 through 10.

8.2.2.2 Rock Creek Recovery Plan

The plan estimates funding needs for habitat projects for the first 3 years at approximately $600,000. Total costs for recovery, expected to occur over a 10-year period, are approximately $1.8 million. Other costs will be developed as actions are proposed and implemented. The estimated cost for filling data gaps is roughly $3,350,000 over 10 years ($2,095,000 total for years 1 to 3 and $1,255,000 total for years 4 through 10).

8.2.2.3 White Salmon Steelhead Recovery Plan

The plan estimates costs for implementing the proposed habitat actions for the White Salmon drainage, based on the costs of specific reach actions identified in the plan. Habitat action costs for recovery over a 10-year time period are estimated to be $6.5 million ($2.17 million for years 1-3 and $4.33 million for years 4-10).

8.2.3 Southeast Washington Plan

The Southeast Washington Plan contains a 5-year implementation plan (2006-2011) with actions that can be carried out in the near future to reduce threats to listed fish. The plan's cost estimates are based on unit cost estimates for each type of project envisioned for seven major spawning areas (MaSA) in which listed fish reside. Of these, four MaSAs are home to Mid Columbia steelhead. For steelhead in these MaSAs, the plan estimates implementation cost as approximately $5 million per year and approximately $76 million for total costs to recovery, exclusive of monitoring and evaluation.

8.2.4 Yakima Steelhead Recovery Plan

The Yakima Steelhead Plan (Appendix E) identifies preliminary cost estimates for each action in accordance with NMFS' guidelines for developing cost estimates. The Plan categorizes each project's implementation as occurring over time spans of 0-3 years, 4-6 years, 6-10 years, or > 10 years. The estimate for projects expected to be completed within the first 6 years is approximately $110 million. The estimated total cost of recovery, for projects where sufficient information upon which to base an estimate exists, is approximately $211million.

8.3 Time Estimate

NMFS estimates that recovery of the Middle Columbia steelhead DPS could take 25 to 50 years. While the management unit plans contain extensive lists of actions to recover the Middle Columbia steelhead DPS populations, there are many uncertainties involved in predicting the course of recovery and in estimating total costs. Such uncertainties include biological and ecosystem responses to recovery actions as well as long-term and future funding. While continued programmatic actions in the management of habitat, hatcheries, hydro, and harvest will warrant additional expenditures beyond the first 10 years, NMFS believes it is impracticable to estimate all projected actions and

costs over 50 years, given the large number of economic, biological, and social variables involved. NMFS believes it is appropriate to focus on the first 5 years of implementation, with the proviso that before the end of the first implementation period, specific actions and costs will be estimated for subsequent years, to achieve long-term goals and to proceed until a determination is made that listing is no longer necessary.

9. POTENTIAL EFFECTS OF PROPOSED RECOVERY ACTIONS

This chapter presents an analysis of the potential effects of proposed recovery actions on the abundance and productivity of Middle Columbia River steelhead. Estimated levels of effectiveness for the proposed actions are generated and used as inputs into quantitative models to project the potential impacts of those changes on populations. In most cases, results are expressed as changes in steelhead abundance and productivity compared to the "baseline" abundance and productivity that the ICTRT calculated for the period 1980-2001. These quantitative analyses provide an opportunity to evaluate the efficacy of proposed recovery strategies in light of current knowledge regarding population functioning, including relationships with habitat conditions. Equally important, the quantitative models used in the assessment provide a framework for productively targeting evaluation efforts as well as for revisiting key assumptions in the future as more information becomes available (e.g., from monitoring responses to initial implementation or from evaluation efforts targeting key uncertainties).

The analyses were performed sequentially, first by projecting effects for tributary habitat actions alone, then sequentially adding in hatchery, hydro, predation, estuary, and harvest actions. The results at each step provide a means for comparing estimated relative benefits of the proposed suites of actions, and, finally, the potential benefit of all the proposed actions to the Middle Columbia steelhead DPS. Last, these results are compared to the gaps identified by the ICTRT (see Chapter 5 of this Plan).

Two models were used: Ecosystem Diagnosis and Treatment (EDT) and the All-H-Analyzer (AHA). The EDT model has commonly been used in regional planning efforts across the DPS to evaluate potential responses to tributary habitat restoration efforts. The EDT model uses derived relationships between habitat characteristics and fish survival to calculate changes in survival, abundance, and productivity that could result from changes in the habitat. Use of the EDT model requires a set of inputs that describe current habitat conditions and the expected changes in habitat conditions that would result from a proposed action scenario. This model could be used, for example, to calculate the improvement that would be expected from a 10 percent drop in water temperature during the period of egg incubation in a certain tributary reach. The AHA model encompasses prospective relationships between all the "H" factors: habitat, hatcheries, hydro, and harvest. Thus, the results of the EDT model become one set of information fed into the AHA model to produce an estimate of the benefits of all the proposed actions.

For the Oregon populations, modifications were made to the EDT and AHA models to improve their application for this analysis. These modifications or refinements are described in Chapter 10 of the Oregon Steelhead Recovery Plan (Appendix A), as follows:

"EDT and AHA address different life stages in the life cycle and thus the different limiting factors that affect salmonid population performance (Figure 10-1). We incorporated several refinements to the modeling procedures for each platform as they are usually employed in the region to improve application for our objectives. For EDT, we formulated an auxiliary tool for defining action effectiveness to better ensure that we considered the distinct elements of effectiveness consistently between actions and subbasins, and we incorporated an implementation timeframe element. For AHA, we disaggregated the life cycle into more segments than used in

the standard AHA in order to completely incorporate the effects of habitat conditions in the juvenile life stages following emigration from the subbasin through the adult life stages, until return to the subbasin. We also formulated a module for AHA to provide an efficient way of processing the large number of action combinations—both in tributaries and the mainstem Columbia—of interest to this analysis. In addition, we modified the default settings in AHA for genetic fitness to produce results that appear to be more consistent with how the populations of interest are currently performing" (ODFW 2008).

The models indicate, based on the suites of proposed actions in all the sectors, that all Middle Columbia River steelhead populations for which there are adequate data are expected to achieve less than 5 percent risk for abundance/productivity if the most intensive (major) restoration scenarios are implemented and the projected habitat changes are realized. Under minimum restoration scenarios, three populations (Deschutes Westside, Satus, and Upper Yakima) may not achieve less than 5 percent risk for abundance/productivity. However, even under poor ocean conditions and minimum restoration actions, the abundance and productivity of these three populations are expected to increase considerably over the baseline.

The results of the modeling analyses of the restoration scenarios are summarized by population in Section 9.2, by MPG in Section 9.3 and for the DPS in Section 9.4. Section 9.1 describes technical aspects of the analytical method.

It is important to note that the modeling results relative to recovery criteria are a function of the input information and key assumptions associated with the translation of actions into habitat changes, habitat and life-stage survival relationships, and population dynamics. Although the modeling provides valuable insight into the potential responses to recovery actions, the estimated potential responses are dependent on the assumptions and information put into the models.

9.1 Integration Approach

The analysis of action effectiveness for all populations except Rock Creek was performed using two modeling platforms: Ecosystem Diagnosis and Treatment (EDT) and the All-H-Analyzer (AHA). Linking the two models provided a way of projecting benefits measured at the end of the life cycle for a wide range of actions, regardless of what life stage an action affects.

For the Oregon Middle Columbia steelhead populations and for a description of the modeling approach, this chapter relies substantially on the analysis performed by ODFW biologists and detailed in Section 10 of the Oregon Steelhead Recovery Plan (ODFW 2008). The Oregon analyses considered tributary habitat changes projected for reach specific action strategies. The Yakima and SE Washington area population level model assessments incorporated results from more generic EDT tributary habitat restoration scenario analyses.

Estimates of the relative changes in population abundance and productivity associated with potential changes in tributary habitat conditions for the Touchet and the four Yakima populations were compiled in the regional recovery plans. A set of estimates for the Klickitat population was provided by Yakama Nation Fisheries biologists. All of these estimates for Washington area steelhead populations were based on EDT model runs generated for previous planning exercises (e.g., NWPPC 2004 Subbasin Plans).

Benefits associated with proposed actions for the Rock Creek steelhead population were estimated with the simple, multiplicative approach used in NMFS' 2008 FCRPS Biological Opinion (Comprehensive Analysis of Federal Columbia River Power System and Mainstem Effects of Upper Snake and Other Tributary Actions [CA]) and the Supplemental CA [SCA]). This approach estimated only density-independent survivals, unlike EDT and AHA, which modeled density dependent effects.

9.1.1 EDT Model

The EDT model was used to analyze the potential benefits of tributary habitat actions. In the Oregon Steelhead Recovery Plan, four scenarios were modeled for each Oregon Mid-C steelhead population, using EDT: (1) actions only in high priority areas at 25 years in the future; (2) actions only in high priority areas at 100 years in the future; (3) actions in all priority areas at 25 years in the future; and (4) actions in all priority areas at 100 years in the future. The expected change in habitat conditions assuming that the tributary protection and restoration actions are implemented following the general schedule described for each population was input into the EDT model for each scenario. The model results for a particular scenario represent the expected average performance of a population over a number of years given the specified habitat conditions. In addition, the Deschutes Westside population was modeled with and without passage at the Pelton-Round Butte Complex to estimate added benefits of passage and restoration of natural production in the blocked areas (see Oregon Steelhead Recovery Plan for more details).

Assessments of the potential response to tributary habitat changes resulting from implementation of the proposed actions for the Washington area populations were adapted from EDT analyses generated in developing the 2004/2005 NWPPC subbasin plans. Some modifications were made to reflect updates to the proposed tributary actions incorporated into the regional draft recovery plans. A single recovery action scenario was modeled for Washington populations, the model results represent the expected average performance of a population over a period of years given the projected changes in habitat conditions input into the EDT model corresponding to the proposed recovery strategy. For populations in Washington, no distinction was made between high priority actions and other actions; all actions were modeled, and future time horizons were only specified for the Walla Walla and Touchet populations (10-15 years future). Therefore, to complete the exercise for the Walla Walla population, which spawns in both states, the model combined Washington actions (10-15-year time horizon) with Oregon actions (all priority actions) using the 25-year time horizon.

Two different restoration scenarios were modeled for populations in the Yakima Basin. The first scenario, referred to as "minimum habitat restoration," used an updated version of the reference conditions from the Yakima Subbasin Plan, as described in the Yakima Steelhead Recovery Plan. The second scenario, referred to as "major habitat restoration," assumed that restoration actions will achieve about 50 percent of "properly functioning conditions" (a standardized set of criteria for watershed restoration [NMFS 1996]), across the basin. For both the Satus Creek and Toppenish River populations, the scenarios assumed that the basin consisted predominantly of anadromous life history types. For the Naches and Upper Yakima populations, the model was configured to partition habitat between resident and anadromous life history types and assume a steady-state abundance for resident fish. Performance of the Klickitat population was also

modeled under two different restoration scenarios. One included restoring conditions in areas already used by steelhead (i.e., it did not include recolonization of areas upstream from Castile Falls); the other included recolonization of the upper watershed (upstream from Castile Falls) and restoration of habitat throughout the basin. Both restoration scenarios assumed that major habitat limiting factors would be restored to 40 percent effectiveness.

For Oregon populations, the Oregon Steelhead Recovery Plan considered the influence of five factors for determining how effective an action may be in improving habitat conditions. The five factors were: (1) potential effectiveness – maximum effect of action type when fully implemented in targeted area; (2) intensity – scale of implementation within the targeted geographic area; (3) time lag – amount of potential effectiveness realized after 25 or 100 years; (4) schedule – delay in realizing potential effect due to implementation schedule; and (5) attribute – amount of reduced effectiveness associated with a specific attribute. The product of these scalars resulted in a "realized effectiveness" for each attribute (see Section 10.1.2 in the Oregon Steelhead Recovery Plan for more details).

9.1.2 AHA Model

The purpose of using the AHA model was to integrate the effects of various types of actions over the full life cycle of the fish. In the AHA model, the EDT analyses of tributary habitat actions were linked to prospective recovery actions involving hatchery fish and the mainstem Columbia River. This provided a way of projecting benefits measured at the end of the life cycle for a wide range of potential actions, regardless of what life stage an action affected. Section 10 in the Oregon Steelhead Recovery Plan describes in detail the AHA modeling approach.

For all populations except Rock Creek, AHA was used to model a set of scenarios representing baseline conditions (average conditions for migration years 1980-2001), current conditions (average conditions for migration years 2002-2006), and combinations of actions aimed at tributary habitat, mainstem Columbia River factors, and hatchery fish management. The model allowed the inclusion of potential effects of hatchery programs on the genetic fitness of the naturally produced populations. It also included several prospective actions to be implemented in the mainstem Columbia River, including: predator management – aimed at reducing predation rates caused by terns and northern pikeminnow; downstream juvenile passage improvements – measures to improve survival at each of the mainstem dams; Columbia estuary habitat improvements – measures to enhance habitat conditions within the Columbia estuary; and harvest – regulatory measures to reduce or hold harvest impacts in the mainstem Columbia River to current levels. The model incorporated survival improvement estimates for predation, hydrosystem, and estuary actions that were provided in the CA and SCA reports.

Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially. Using AHA, the effects of hatchery programs on genetic fitness of natural-origin fish were incorporated for each scenario. Actions intending to control the number of stray hatchery fish in subbasins were modeled as part of another set of scenarios. Finally, the effects of potential changes in marine survival were modeled. All of the scenarios were modeled using an average marine survival rate corresponding to the average during both the baseline and current periods. Then, two additional scenarios were modeled; one representing relatively good

ocean conditions (125 percent of the average condition) and the other representing relatively poor ocean conditions (75 percent of the average condition).

The output from AHA was expressed as Beverton-Holt population parameters, which represent the expectations of change for each population's abundance and productivity as a result of all the proposed actions. This change can be thought of as a percent change (e.g., 25 percent) or a ratio (e.g., 1.25). This needed to be "translated" into the same terms as the ICTRT's baseline abundance and productivity calculations for each population, which were derived empirically. Therefore, the ICTRT's baseline abundance and productivity values for each population were multiplied by the percent of change estimated by the AHA model. For example, if the AHA model indicated that abundance for a certain population will increase by 25 percent as a result of the proposed actions, then the ICTRT baseline abundance for that population was multiplied by 1.25 to get the projected estimate for abundance for that population under the recovery scenario. These calculations are described fully in Section 10.1 in the Oregon Steelhead Recovery Plan and shown in Figure 10-2 in the Oregon Steelhead Recovery Plan.

9.2 Effects of Recovery Actions

This section presents a summary of results of the benefits of proposed actions on Middle Columbia steelhead populations (see respective management unit recovery plans [Appendices A-E]for more detail). Changes in performance measures associated with each action scenario are presented for intrinsic productivity and spawner abundance. Except where noted otherwise, the results are comparable to population metrics for baseline performance, as derived empirically by the ICTRT, and to minimum productivity (at the threshold abundance level) and abundance viability thresholds at the 5 percent risk level in a 100-year time period. Performance measures are given for three periods: base period (1980-2001), base-current period (2002-2006), and the current-prospective period (2006-future). The latter varies depending on population. For those populations entirely within Oregon, the prospective period includes results at 25 and 100 years in the future. For Walla Walla and Touchet populations, results are projected ≤ 25 years in the future, while those in the Yakima and Klickitat have no defined future time horizon. A more detailed presentation of results for Oregon populations can be found in Sections 10.2 and 10.3 in the Oregon Steelhead Recovery Plan. Section 10.2 of the Oregon Steelhead Recovery Plan includes maps for each population showing the geographic areas that are currently in protected status, stream reaches where high priority actions are proposed, and restoration benefits from high priority actions for all reaches (ODFW 2009).

9.2.1 Cascades Eastern Slope Tributaries MPG

Deschutes River Westside Population

Abundance and productivity are projected to increase for all scenario combinations analyzed for Deschutes River Westside steelhead (Table 8.4; Oregon Steelhead Recovery Plan). The largest increases in population performance are associated with decreasing the number of stray hatchery fish and/or by providing passage at the Pelton-Round Butte Complex (including passage at Whychus Creek barriers). In the absence of the removal of strays or passage, benefits are much reduced. For those scenario combinations lacking removal of strays and passage, beneficial effects of tributary actions are greatest. However, predicted increases in abundance and productivity associated with habitat actions are less than 20 percent and between 35-55 percent, respectively.

Table 9-1 shows estimated abundance and productivity for the Deschutes River Westside population associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without passage at Pelton-Round Butte Dam Complex and with and without action to reduce the number of hatchery strays by 95 percent of those expected to enter the relevant area for the scenario. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25 percent represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario. Data are from Table 10-39 in the Oregon Steelhead Recovery Plan.

Table 9-1. Estimated Productivity and Abundance of Deschutes River Westside Steelhead with Proposed Actions.

Performance period	Scenario combination	Performance metric					
		Productivity			Abundance		
		No passage and no stray action	No passage with stray action	Passage with stray action	No passage and no stray action	No passage with stray action	Passage with stray action
Base		1.05			456		
Base-Current		1.17	1.84		514	557

	Hydro	1.67	2.57	2.52	610	641	925
	Predation	1.74	2.68	2.63	638	669	966
	Estuary	1.84	2.84	2.78	675	707	1,020
	Harvest	1.84	2.84	2.78	675	707	1,020
	Ocean ±25%	1.38-2.29	2.13-3.55	2.08-3.47	497-844	530-875	763-1,263
Current-Prospective (100 yrs future)	Habitat	1.82	2.78	2.74	630	660	931
	Hydro	1.92	2.92	2.88	665	694	978
	Predation	2.00	3.05	3.01	696	725	1,020
	Estuary	2.11	3.23	3.18	738	767	1,077
	Harvest	2.11	3.23	3.18	738	767	1,077
	Ocean ±25%	1.59-2.64	2.42-4.03	2.39-3.98	542-927	571-955	810-1,329

Deschutes River Eastside Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Deschutes River Eastside steelhead (Table 9.5; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with the greatest benefits accruing for the 100-year scenario. It is predicted that between 50-70 percent

of historical habitat potential for abundance will be achieved. The amount of habitat potential reflected in productivity, however, is somewhat less, being between 25-45 percent of potential. This means that the habitat actions will have a greater effect on habitat quantity than on habitat quality. Substantial benefits to both productivity and abundance are also expected to occur as a result of reducing the number of stray hatchery fish spawning with naturally produced fish.

Table 9-2 shows estimated population performance (productivity and abundance) of Deschutes River Eastside steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with and without action to reduce the number of hatchery strays by 95 percent of those expected to enter the relevant areas for the scenario. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25 percent represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario. Data are from Table 10-38 in the Oregon Steelhead Recovery Plan.

Table 9-2. Estimated Productivity and Abundance of Deschutes River Eastside Steelhead with Proposed Actions.

Performance period	Scenario combination	Performance metric			
		Productivity		Abundance	
		No stray action	With stray action	No stray action	With stray action
Base		1.89		1,599	
Base-Current		2.10	3.71	2,340	4,634
Current-Prospective (25 yrs future)	Habitat	4.26	6.80	6,973	8,323
	Hydro	4.47	7.15	7,471	8,818
	Predation	4.67	7.47	7,921	9,265
	Estuary	4.93	7.89	8,520	9,859
	Harvest	4.93	7.89	8,520	9,859
	Ocean ±25%	3.71-6.13	5.91-9.88	5,679-11,199	7,039-12,519
Current-Prospective (100 yrs future)	Habitat	5.97	9.20	8,643	9,619
	Hydro	6.26	9.67	9,174	10,151
	Predation	6.53	10.10	9,656	10,632
	Estuary	6.89	10.68	10,295	11,272
	Harvest	6.89	10.68	10,295	11,272
	Ocean ±25%	5.22-8.54	8.00-13.35	7,265-13,167	8,239-14,140

Klickitat River Population

Abundance and productivity are projected to increase for all scenario combinations analyzed for Klickitat River steelhead (Table 9-6; note that performance values in the table are direct output from EDT/AHA and have not been converted into ICTRT-equivalent performance values). The largest contribution to performance improvements results from the combination of tributary habitat actions throughout the basin and recolonization of the upper watershed (recolonization of the upper watershed is possible because of passage improvements at Castile Falls). In contrast, relatively small increases are attributable to mainstem actions.

Table 9-3 shows estimated population performance (productivity and abundance) of Klickitat River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly from EDT/AHA and were not converted to ICTRT-equivalent performance values (the ICTRT was unable to empirically estimate baseline performance measures for this population because of a lack of data). Results are shown with and without recolonization of the upper watershed. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario.

Table 9-3. Estimated Productivity and Abundance of Klickitat River steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric			
		Productivity		Abundance	
		Actions without recolonization of upper watershed	Actions with recolonization of upper watershed	Actions without recolonization of upper watershed	Actions with recolonization of upper watershed
Base		1.77		939	
Base-Current		1.92	1.92	1,118	1,118
Current-Prospective	Habitat	2.12	2.38	1,319	2,320
	Hydro	2.24	2.50	1,468	2,572
	Predation	2.29	2.56	1,538	2,692
	Estuary	2.36	2.62	1,630	2,850
	Harvest	2.36	2.62	1,630	2,850
	Ocean ±25%	2.01-2.64	2.27-2.90	1,181-2,026	2,088-3,539

Fifteenmile Creek Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Fifteenmile Creek steelhead (Table 9.7; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions. It is predicted that between 50-70 percent of historical habitat potential for both productivity and

abundance will be achieved. In contrast, relatively small increases are attributable to mainstem actions.

Table 9-4 shows estimated population performance (productivity and abundance) of Fifteenmile Creek steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario. Data are from Table 10-37 in the Oregon Steelhead Recovery Plan.

Table 9-4. Estimated Productivity and Abundance of Fifteenmile Creek Steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric	
		Productivity	Abundance
Base		1.82	703
Base-Current		1.96	764
Current-Prospective (25 yrs future)	Habitat	3.02	1,342
	Hydro	3.02	1,345
	Predation	3.16	1,410
	Estuary	3.34	1,496
	Harvest	3.34	1,496
	Ocean ±25%	2.50-4.17	1,095-1,898
Current-Prospective (100 yrs future)	Habitat	3.79	1,502
	Hydro	3.80	1,506
	Predation	3.96	1,577
	Estuary	4.19	1,672
	Harvest	4.19	1,672
	Ocean ±25%	3.14-5.24	1,230-2,114

Rock Creek Population

Because no ETD/AHA modeling was conducted for Rock Creek steelhead, potential benefits in productivity were estimated with the multiplicative approach used in the FCRPS BiOp (CA and SCA reports). This approach did not estimate productivity or abundance values. Rather, it estimated changes in productivity associated with actions within each sector (habitat, hatchery, hydrosystem, predation, estuary, and harvest). Values for habitat should be considered a minimum estimate, given that the FCRPS BiOp assumed no habitat restoration actions in the subbasin.

Based on the survival changes presented in the FCRPS BiOp for each sector, Rock Creek steelhead productivity was projected to increase about 13 percent during the base-current period (Table 9-8). For the current-prospective period, productivity is projected to increase about 21 percent. Most of this increase is associated with actions in the hydrosystem and estuary.

Table 9-5 shows estimated proportional changes in average base-period productivity of Rock Creek steelhead expected from completed actions and current human activities that are likely to continue in the future (base-current) and proposed future tributary and out-of-subbasin actions (current-prospective). Estimates greater than 1.00 result in higher survival (e.g., 1.134 indicates a 13.4 percent increase in survival, compared to the base period average); 1.00 indicates no change; and estimates less than 1.00 result in lower survival (e.g., 0.997 indicates a 0.3 percent reduction in survival, compared to the base period average. Because no EDT/AHA modeling was completed for Rock Creek steelhead, estimated changes in productivity are from the FCRPS BiOp (SCA and CA reports).

Table 9-5. Estimated Proportional Changes in Average Base-Period Productivity of Rock Creek Steelhead.

Performance period	Scenario combination*	Change in Productivity
Base-Current	Habitat	1.000
	Hydro	1.090
	Predation	0.997
	Estuary	1.003
	Harvest	1.040
	Hatchery	1.000
	Total	1.134
Current-Prospective	Habitat	1.000
	Hydro	1.100
	Predation	1.044
	Estuary	1.057
	Harvest	1.000
	Hatchery	1.000
	Total	1.214

Tributary habitat estimates are from CA Chapter 10, Table 10-9; hydro estimates are from SCA Hydro Modeling Appendix B; predation estimates are from CA Appendix F, Attachment F-1 (for pikeminnow predation), CA Appendix F, Attachment F-2, Table 4, based on the "Prospective 2 S/Current 2 S" approach (for bird predation), and SCA Marine Mammal Appendix (for marine mammal predation); and estuary estimates are from CA Appendix D, Attachment D-1, Table 6. The analyses assumed no survival changes associated with harvest or hatchery programs. Total survival improvement multipliers are the product of the survival improvement multipliers in each previous row.

9.2.2 John Day River MPG

Lower John Day River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Lower John Day River steelhead (Table 9.9; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100-year scenario. It is predicted that habitat actions can achieve about 31-40 percent of historical habitat potential for both productivity and abundance. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-6 shows estimated population performance (productivity and abundance) of Lower John Day River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions

sequentially, each being added to the previous scenario. Data are from Table 10-40 in the Oregon Steelhead Recovery Plan.

Table 9-6. Estimated Productivity and Abundance of Lower John Day River steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric	
		Productivity	Abundance
Base		2.99	1,800
Base-Current		3.44	2,423
Current-Prospective (25 yrs future)	Habitat	4.99	5,751
	Hydro	5.43	6,537
	Predation	5.65	6,918
	Estuary	5.94	7,427
	Harvest	5.94	7,427
	Ocean ±25%	4.61-7.33	5,047-9,722
Current-Prospective (100 yrs future)	Habitat	7.31	8,627
	Hydro	7.94	9,628
	Predation	8.25	10,112
	Estuary	8.67	10,758
	Harvest	8.67	10,758
	Ocean ±25%	6.77-10.66	7,728-13,667

North Fork John Day River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for North Fork John Day River steelhead (Table 9.10; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100-year scenario. It is predicted that habitat actions can achieve about 45-55 percent of historical habitat potential for both productivity and abundance. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-7 shows estimated population performance (productivity and abundance) of North Fork John Day River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25 percent represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in

actions sequentially, each being added to the previous scenario. Data are from Table 10-41 in the Oregon Steelhead Recovery Plan.

Table 9-7. Estimated Population Performance (Productivity and Abundance) of North Fork John Day River Steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric	
		Productivity	Abundance
Base		2.41	1,740
Base-Current		2.77	2,101
Current-Prospective (25 yrs future)	Habitat	3.44	2,762
	Hydro	3.77	3,090
	Predation	3.94	3,248

	Hydro	4.42	3,572
	Predation	4.61	3,747
	Estuary	4.87	3,980
	Harvest	4.87	3,980
	Ocean ±25%	3.69-6.06	2,880-5,028

Middle Fork John Day River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Middle Fork John Day River steelhead (Table 9.11; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100-year scenario. It is predicted that habitat actions can achieve about 40-55 percent of historical habitat potential for both productivity and abundance. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-8 shows estimated population performance (productivity and abundance) of Middle Fork John Day River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in

actions sequentially, each being added to the previous scenario. Data are from Table 10-42 in the Oregon Steelhead Recovery Plan.

Table 9-8. Estimated Population Performance (Productivity and Abundance) of Middle Fork John Day River Steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric	
		Productivity	Abundance
Base		2.45	756
Base-Current		2.82	921

	Harvest	6.57	2,084
	Ocean ±25%	5.00-8.15	1,528-2,616

South Fork John Day River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for South Fork John Day River steelhead (Table 9.12; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100-year scenario. It is predicted that habitat actions can achieve about 40-55 percent of historical habitat potential for both productivity and abundance. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-9 shows estimated population performance (productivity and abundance) of South Fork John Day River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in

actions sequentially, each being added to the previous scenario. Data are from Table 10-43 in the Oregon Steelhead Recovery Plan.

	Harvest	4.48	609
	Ocean ±25%	3.40-5.57	440-769

Upper John Day River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Upper John Day River steelhead (Table 9.13; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100-year scenario. It is predicted that habitat actions can achieve about 35-55 percent of historical habitat potential for both productivity and abundance. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-10 shows estimated population performance (productivity and abundance) of Upper John Day River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario. Data are from Table 10-44 in the Oregon Steelhead Recovery Plan.

	Ocean ±25%	4.91-7.95	1,411-2,431

9.2.3 Umatilla/Walla Walla MPG

Umatilla River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Umatilla River steelhead (Table 9.14; Oregon Steelhead Recovery Plan). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100-year scenario. It is predicted that habitat actions can achieve about 45-70 percent of historical habitat potential for both productivity and abundance. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-11 shows estimated population performance (productivity and abundance) of Umatilla River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario. Data are from Table 10-45 in the Oregon Steelhead Recovery Plan.

	Ocean ±25%	3.67-6.09	3,940-6,592

Walla Walla River Population

Abundance and productivity are projected to increase markedly for all scenario combinations analyzed for Walla Walla River steelhead (Table 9-12a and 9-12b). The largest contribution to performance improvements results from tributary habitat actions. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-12a shows estimated population performance (productivity and abundance) of Walla Walla River steelhead associated with combinations of all priority tributary and out-of-subbasin actions, including combined benefits of actions proposed in the Oregon portion of the Walla Walla basin with those proposed in the Washington portion of the basin. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario.

Table 9-12a. Estimated Productivity and Abundance of Walla Walla River Steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions, Including both Oregon and Washington.

	Harvest	3.41	2,136
	Ocean ±25%	2.56-4.27	1,599-2,590

Touchet River Population

Because of a lack of empirical data for the Touchet River steelhead population, base productivity was estimated as the median of the empirical series of estimates for the Walla Walla and Umatilla populations. This resulted in an estimated productivity of 1.42 for the Touchet population. It is important to note that this value is only a surrogate and will be replaced with an empirically derived estimate after there is a data series of sufficient length.

Abundance and productivity are projected to increase for Touchet River steelhead (Table 9-13). A relatively large contribution to performance improvements should result from tributary habitat actions. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-13 shows estimated population performance (productivity and abundance) of Touchet River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Base productivity was estimated as the median of the empirical series of productivity from the Walla Walla and Umatilla populations. All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario.

Table 9-13. Estimated productivity and abundance of Touchet River steelhead associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric	
		Productivity	Abundance
Base		1.42	310
Base-Current		1.69	387

	Harvest	3.67	1,139
	Ocean ±25%	2.57-4.59	609-1,402

9.2.4 Yakima MPG

Satus Creek Population (tributary only)

Abundance and productivity are projected to increase for all scenario combinations analyzed for Satus Creek steelhead (Table 9-14). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the major habitat restoration scenario, which assumes that restoration actions will achieve about 50 percent of Properly Functioning Conditions across the watershed. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-14 shows estimated population performance (productivity and abundance) of Satus Creek steelhead (tributary only) associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with minimum habitat restoration actions (using reference conditions described in the Yakima Steelhead Recovery Plan) and major habitat restoration actions (restoring 50 percent of Properly Functioning Conditions across the subbasin). All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25 percent represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario.

Table 9-14. Estimated Productivity and Abundance of Satus Creek Steelhead (Tributary only) associated with Combinations of all Priority Tributary and Out-of-Subbasin Actions.

Performance period	Scenario combination	Performance metric			
		Productivity		Abundance

	Harvest	2.78	6.19	682	1,793
	Ocean ±25%	2.09-3.46	4.70-7.70	478-870	1,338-2,225

Toppenish River Population

Abundance and productivity are projected to increase for all scenario combinations analyzed for Toppenish River steelhead (Table 9-15). The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the major habitat restoration scenario, which assumes that restoration actions will achieve about 50 percent of Properly Functioning Conditions across the watershed. Benefits associated with mainstem actions are cumulative with the sequential addition of actions.

Table 9-15 shows estimated population performance (productivity and abundance) of Toppenish River steelhead associated with combinations of all priority tributary and out-of-subbasin actions. Population performance measures are directly comparable to those derived empirically for baseline conditions by the ICTRT. Results are shown with minimum habitat restoration actions (using reference conditions described in the Yakima Steelhead Recovery Plan) and major habitat restoration actions (restoring 50 percent of Properly Functioning Conditions across the subbasin). All scenario combinations include average ocean conditions (average during baseline and current conditions); ocean ±25% represents performance of combined actions under relatively poor and good ocean conditions. Scenarios were run in a stepwise fashion, starting with baseline, then current conditions, and then adding in actions sequentially, each being added to the previous scenario.

9.3 Aggregate Analysis

This section describes the integration of total "base-to-current" and total "current-to-future" productivity and abundance improvements expected from recovery actions. For simplicity, improvements are based on the benefits of all priority actions projected at ≤ 25 years into the future. In addition, unless noted otherwise, benefits described in this section are based on the least intensive restoration scenarios (e.g., scenarios without passage, without stray actions, etc.). "Overall" abundance/productivity benefits are then compared to the 5 percent risk curves (in a 100-year time period). Information on expected changes to spatial structure and diversity are not currently available.

9.3.1 Cascades Eastern Slope MPG

Productivity. The combined effects of current and future recovery actions should result in productivity increases of at least 14 to 224 percent, compared to the "base" condition for Cascades Eastern Slope populations (Table 9-18). Productivity for the Deschutes Eastside population is expected to increase the most (base to future = 96-224 percent). These percentages do not account for possible increases in productivity that could be gained by reducing the number of stray hatchery fish spawning with naturally produced fish. Productivity for the Deschutes Westside population, which has the largest survival gap in this MPG, is expected to increase 31-118 percent (base-future). These percentages do not include actions for passage (at the Pelton-Round Butte Complex and Whychus Creek) or decreasing the numbers of stray hatchery fish spawning in the population. Including these actions, productivity could be expected to increase 98-230 percent. Productivities in the other populations are expected to increase 14-129 percent.

Abundance. The combined effects of current and future recovery actions should result in abundance increases of at least 9 to 600 percent, compared to the "base" condition for Cascades Eastern Slope populations (Table 9-19). Abundance for the Deschutes Eastside population should increase the most (base to future = 255-600 percent). Abundance in the Deschutes Westside population, which has the largest survival gap in this MPG, should increase 9-85 percent. Including passage and stray actions, the abundance of this population may increase 67-177 percent. The other populations in the MPG are expected to increase 26-170 percent in abundance.

Abundance/Productivity Risk. Only the Deschutes Westside population has an estimated survival gap (78 percent increase in survival needed to achieve 5 percent risk in a 100-year time period under base hydrosystem and recent ocean conditions). Gaps could not be estimated for the Klickitat or Rock Creek populations because of a lack of information. The other two populations (Deschutes Eastside and Fifteen Mile) had no survival gaps and the projected abundance/productivity estimates for these populations fell above the 5 percent risk curves (i.e., risk in a 100-year period was ≤ 5 percent) (Figure 9-1). The proposed actions for the Deschutes Westside population should result in ≤ 5 percent risk (in a 100-year time period) for abundance/productivity if actions intended to decrease the number of stray hatchery fish are implemented and passage is provided at the Pelton-Round Butte Complex. In the absence of stray actions and passage at Pelton-Round Butte, the projected benefit in abundance/productivity may not achieve ≤ 5 percent risk (Figure 9-1, bottom graph).

9.3.2 John Day River MPG

Productivity. The combined effects of current and future recovery actions should result in productivity increases of at least 30 to 188 percent, compared to the "base" condition for John Day populations (Table 9-18). Productivity is expected to increase the most for the Upper Mainstem population (base to future = 77-188 percent). For the South Fork population, which has the largest survival gap in this MPG, productivity is projected to increase 34-121 percent (base-future). For the Lower Mainstem and Middle Fork populations, which also have survival gaps, productivity is projected to increase 54-145 percent and 58-159 percent, respectively. Productivity for the North Fork population, which has no survival gap, is expected to increase 30-115 percent (base-future).

Abundance. The combined effects of current and future recovery actions should result in abundance increases of at least 42 to 440 percent, compared to the "base" condition for John Day populations (Table 9-19). Abundance is expected to increase the most for the Lower Mainstem population (base to future = 180-440 percent). For the South Fork population, which has the largest survival gap in this MPG, abundance is projected to increase 43-157 percent (base-future). For the Middle Fork population, which has a survival gap, abundance is projected to increase 64-189 percent. Abundance for the North Fork and Upper Mainstem populations is expected to increase 42-153 percent and 116-282 percent, respectively.

Abundance/Productivity Risk. The North Fork John Day population is the only population within the John Day MPG that is presently considered viable (at ≤ 5 percent risk in a 100-year period). The other populations within the MPG have survival gaps (Table 9-3). The proposed actions for all populations within this DPS should result in ≤ 5% risk (in a 100-year time period) for abundance/productivity (Figure 9-2).

9.3.3 Umatilla/Walla Walla MPG

Productivity. The combined effects of current and future recovery actions should result in productivity increases of at least 93 to 221 percent, compared to the "base" condition for the Umatilla and Walla Walla populations (Table 9-18). Productivity for the Walla Walla population, which has the largest survival gap in this MPG, is projected to increase 93-221 percent (base-future). For the Umatilla population, which has a survival gap, productivity is also expected to increase 93-221 percent. For the Touchet River, base productivity was estimated as the median of the empirical series of estimates for the Walla Walls and Umatilla populations. This is a surrogate value and will be replaced with an empirically derived estimate after there is a data series of sufficient length. Based on this interim value, productivity is expected to increase 52-172 percent (base-future).

Abundance. The combined effects of current and future recovery actions should result in abundance increases of at least 125 to 433 percent, compared to the "base" condition for Umatilla and Walla Walla populations (Table 9-19). Abundance for the Walla Walla population, which has the largest survival gap in this MPG, is projected to increase 213-433 percent (base-future). For the Umatilla population, which has a survival gap, abundance is also expected to increase 125-287 percent. Abundance for the Touchet population is expected to increase 57-262 percent.

Abundance/Productivity Risk. Of the three populations within the Umatilla/Walla Walla DPS, there are estimated survival gaps for the Umatilla and Walla Walla populations (Table 5-1). A gap for the Touchet population could not be estimated because of a lack of information. The proposed restoration actions for the Umatilla and Walla Walla populations should result in ≤ 5% risk (in a 100-year time period) for abundance/productivity (Figure 9-3). Assuming a base productivity of 1.42 for the Touchet population (this is the median of the Walla Walla and Umatilla populations) and a projected productivity and abundance of 3.67 and 1,139, respectively, the proposed restoration actions for the Touchet population should result in ≤ 5% risk.

9.3.4 Yakima MPG

Productivity. The combined effects of current and future recovery actions should result in productivity increases of at least 21 to 119 percent, compared to the "base" condition for Yakima populations (Table 9-18). Productivity is expected to increase the most for the Toppenish population (base to future = 33-119 percent). Productivity for the Upper Yakima, which has the largest survival gap in this MPG, is projected to increase 21-86 percent (base-future). For the other two populations, which also have survival gaps, productivity is expected to increase 21-100 percent for the Satus Creek population (tributary only) and 37-111 percent for the Naches population.

Abundance. The combined effects of current and future recovery actions should result in abundance increases of at least 26 to 2,558 percent, compared to the "base" condition for Yakima populations (Table 9-19). The largest increase in abundance is projected for the Upper Yakima population (base to future = 632-2,558 percent). Abundance for the Satus Creek population is projected to increase 26-130 percent (base-future). Abundance for the Toppenish and Naches populations should increase 55-185 percent and 185-547 percent, respectively.

Abundance/Productivity Risk. Under the major restoration scenario, all populations are expected to achieve ≤ 5% risk (in a 100-year time period) for abundance/productivity (Figure 9-4). Under the minimum restoration scenario, however, only the Naches and Toppenish populations are projected to achieve ≤ 5% risk for abundance/productivity.

9.4 Summary of Expected Benefits of Proposed Actions for Middle Columbia Steelhead DPS

Based on the proposed actions identified within the specific management unit plans, all Middle Columbia River steelhead populations for which there are adequate data are expected to achieve less than 5% risk for abundance/productivity if the most intensive (major) restoration scenarios are implemented (Figure 9-5). Under minimum restoration scenarios, three populations (Deschutes Westside, Satus (tributary only), and Upper Yakima populations) may not achieve ≤ 5% risk for abundance/productivity. However, even under poor ocean conditions and minimum restoration actions, the abundance and productivity of these three populations are expected to increase considerably over base conditions (Tables 9-18 and 9-19).

Table 9-18 shows total changes in productivity of Middle Columbia River steelhead expected from current and prospective recovery actions. For Oregon populations and the Walla Walla and Touchet, total changes in productivity are based on benefits projected at ≤ 25 years into the future. The range of benefits represents performance of combined actions under relatively poor (-25%) and good (+25%) ocean conditions. Estimates greater than 1.00 result in higher productivity (e.g., 1.114 indicates an 11.4% increase in productivity, compared to the base period average); 1.00 indicates no change; and estimates less than 1.00 result in lower productivity.

Table 9-18. Total changes in Productivity of Middle Columbia River Steelhead expected from Current and Prospective Recovery Actions.

Major Population Group	Population	Total Base-to-Current	Total Current-to-Future (±25% Ocean)	Total Base-Current and Current-Future[1] (±25% Ocean)
Cascades Eastern Slope	Deschutes W.[2]	1.114	1.179-1.957	1.313-2.180
	Deschutes E.[3]	1.111	1.767-2.919	1.963-3.243
	Klickitat[4]	1.085	1.047-1.375	1.136-1.492
	Fifteen Mile	1.077	1.276-2.128	1.374-2.291
	Rock Creek[5]	1.134	1.214	1.377
John Day	Lower Mainstem	1.151	1.340-2.131	1.542-2.452
	North Fork	1.149	1.134-1.870	1.303-2.149
	Middle Fork	1.151	1.376-2.252	1.584-2.592
	South Fork	1.150	1.165-1.920	1.340-2.209
	Upper Mainstem	1.150	1.541-2.504	1.771-2.879
Umatilla/Walla Walla	Umatilla	1.153	1.676-2.786	1.933-3.213
	Walla-Walla	1.194	1.613-2.688	1.925-3.209
	Touchet[6]	1.190	1.521-2.716	1.810-3.232

Major Population Group	Population	Total Base-to-Current	Total Current-to-Future (±25% Ocean)	Total Base-Current and Current-Future[1] (±25% Ocean)
Yakima	Satus (tributary only)[7]	1.191	1.015-1.680	1.208-2.000
	Toppenish[7]	1.281	1.034-1.712	1.325-2.193
	Naches[7]	1.196	1.142-1.761	1.366-2.107
	Upper Yakima[7]	1.193	1.015-1.562	1.211-1.862

[1] Calculated as the product of the Total Current-to-Future multiplier and the Total Base-to-Current multiplier.

[2] Represents the no passage and no stray action scenario.

[3] Represents the no stray action scenario.

[4] Represents actions without recolonization of the upper watershed.

[5] Benefits for Rock Creek steelhead were based on the FCRPS BiOp, which did not calculate survival changes under relatively good and poor ocean conditions.

[6] Base productivity for the Touchet population was estimated as the median of the empirical series of estimates for the Umatilla and Walla Walla populations. The base estimate for the Touchet is only a surrogate that will be replaced with an empirically derived estimate after there is a data series of sufficient length.

[7] Represents the minimum habitat restoration scenario.

Table 9-19 shows total changes in abundance of Middle Columbia River steelhead expected from current and prospective recovery actions. For Oregon populations and the Walla Walla and Touchet, total changes in abundance are based on benefits projected at ≤ 25 years into the future. The range of benefits represents performance of combined actions under relatively poor (-25%) and good (+25%) ocean conditions. Estimates greater than 1.00 result in higher abundance (e.g., 1.114 indicates an 11.4% increase in abundance, compared to the base period average); 1.00 indicates no change; and estimates less than 1.00 result in lower abundance. NA = information not available.

Table 9-19. Total changes in abundance of Middle Columbia River steelhead expected from current and prospective recovery actions.

Major Population Group	Population	Total Base-to-Current	Total Current-to-Future (±25% Ocean)	Total Base-Current and Current-Future[1] (±25% Ocean)
Cascades Eastern Slope	Deschutes W.[2]	1.127	0.967-1.642	1.090-1.851
	Deschutes E.[3]	1.463	2.427-4.786	3.552-7.004
	Klickitat[4]	1.191	1.056-1.812	1.258-2.158
	Fifteen Mile	1.087	1.433-2.484	1.558-2.699
	Rock Creek[5]	NA	NA	NA
John Day	Lower Mainstem	1.346	2.083-4.012	2.804-5.401
	North Fork	1.207	1.173-2.096	1.417-2.531
	Middle Fork	1.218	1.346-2.374	1.640-2.892
	South Fork	1.216	1.171-2.111	1.425-2.568
	Upper Mainstem	1.240	1.737-3.083	2.155-3.824
Umatilla/Walla Walla	Umatilla	1.236	1.820-3.128	2.251-3.868
	Walla-Walla	1.329	2.353-4.010	3.128-5.331
	Touchet	1.248	1.574-3.623	1.965-4.523
Yakima	Satus (tributary only)[6]	1.285	0.982-1.786	1.261-2.296
	Toppenish[6]	1.435	1.080-1.987	1.550-2.851
	Naches[6]	2.057	1.387-3.145	2.854-6.470
	Upper Yakima[6]	4.271	1.714-6.223	7.318-26.576

[1] Calculated as the product of the Total Current-to-Future multiplier and the Total Base-to-Current multiplier.

[2] Represents the no passage and no stray action scenario.

[3] Represents the no stray action scenario.

[4] Represents actions without recolonization of the upper watershed.

[5] Benefits for Rock Creek steelhead were based on the FCRPS BiOp, which did not calculate survival changes under relatively good and poor ocean conditions.

[6] Represents the minimum habitat restoration scenario.

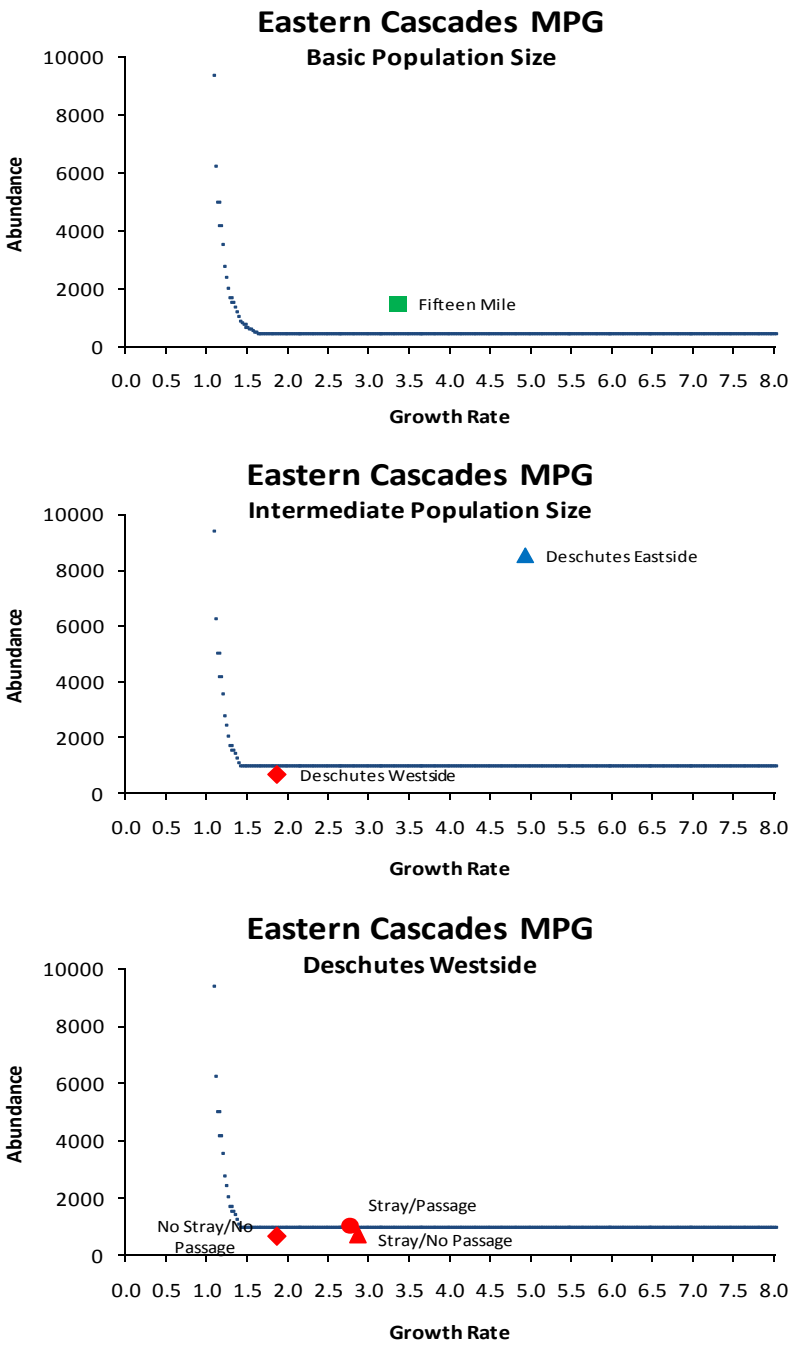

Figure 9-1. Relationship of Projected Abundance/Productivity Estimates to 5% Risk Curves (in a 100-year time period) for the different size Steelhead Populations within the Cascades Eastern Slope MPG.

In the top two graphs, estimated benefits (projected 25 years into the future) are associated with the least intensive restoration scenarios. The bottom figure shows the projected benefits associated with the different restoration scenarios for the Deschutes Westside population.

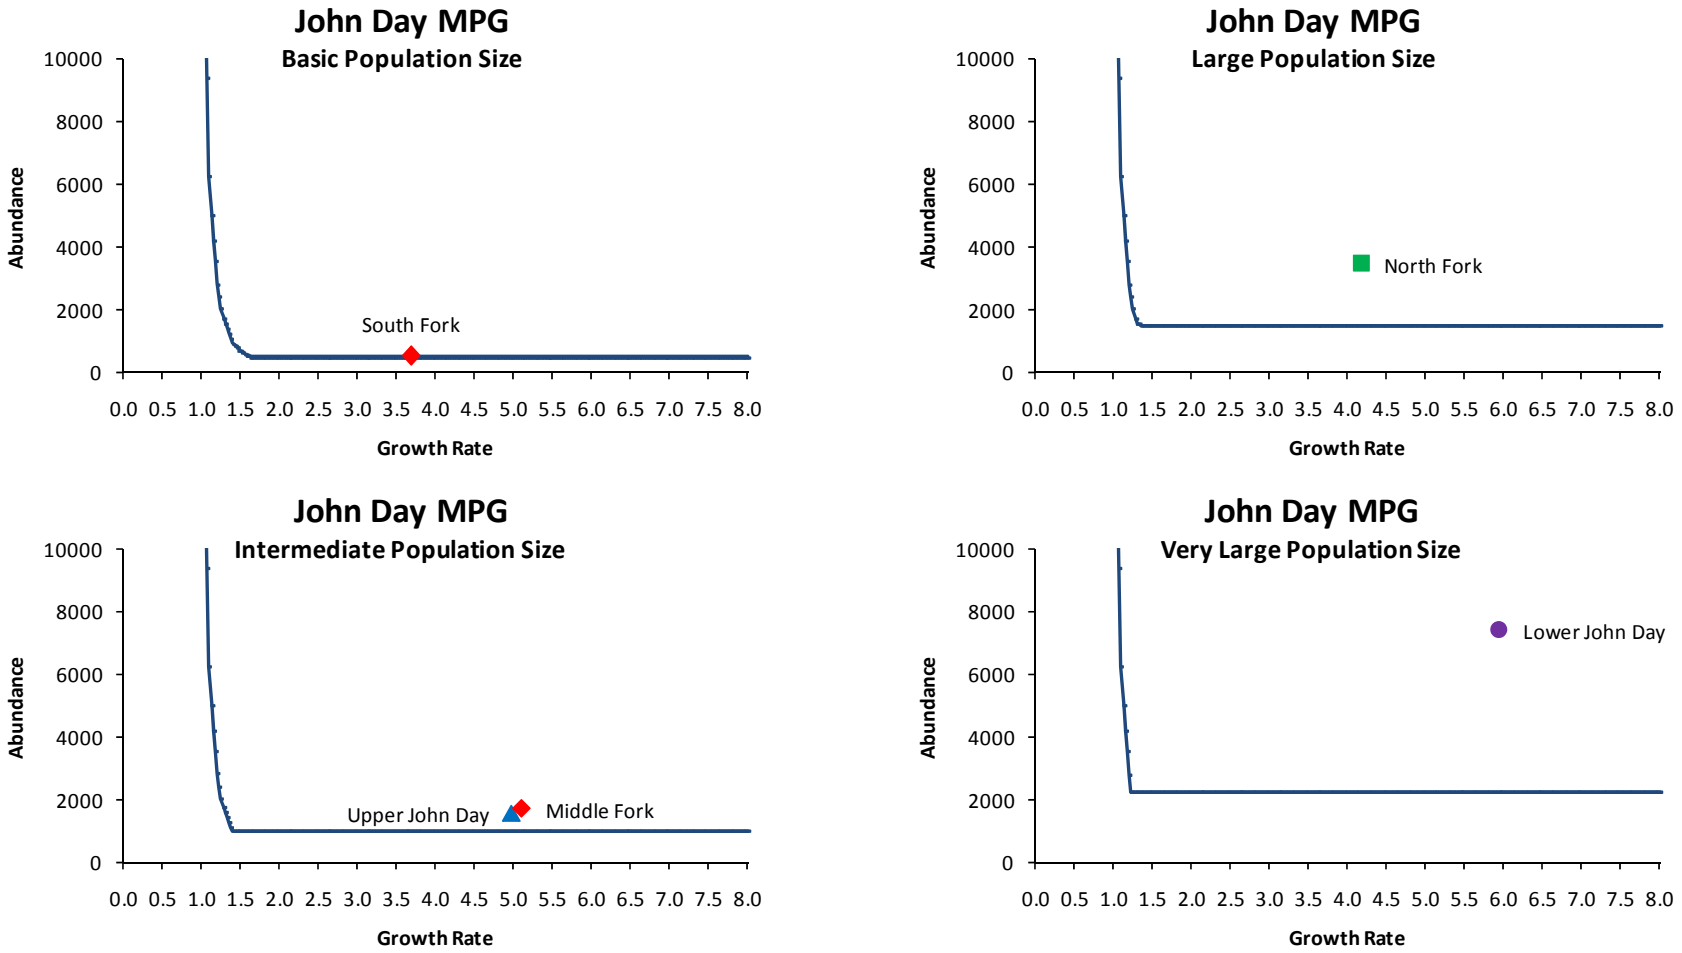

Figure 9-2. Relationship of Projected Abundance/Productivity Estimates to 5% Risk Curves (in a 100-year time period) for the different size Steelhead Populations within the John Day MPG. Estimates are projected at 25 years into the future. Populations are considered viable if the projected abundance/productivity estimates fall on or above the 5% risk curve.

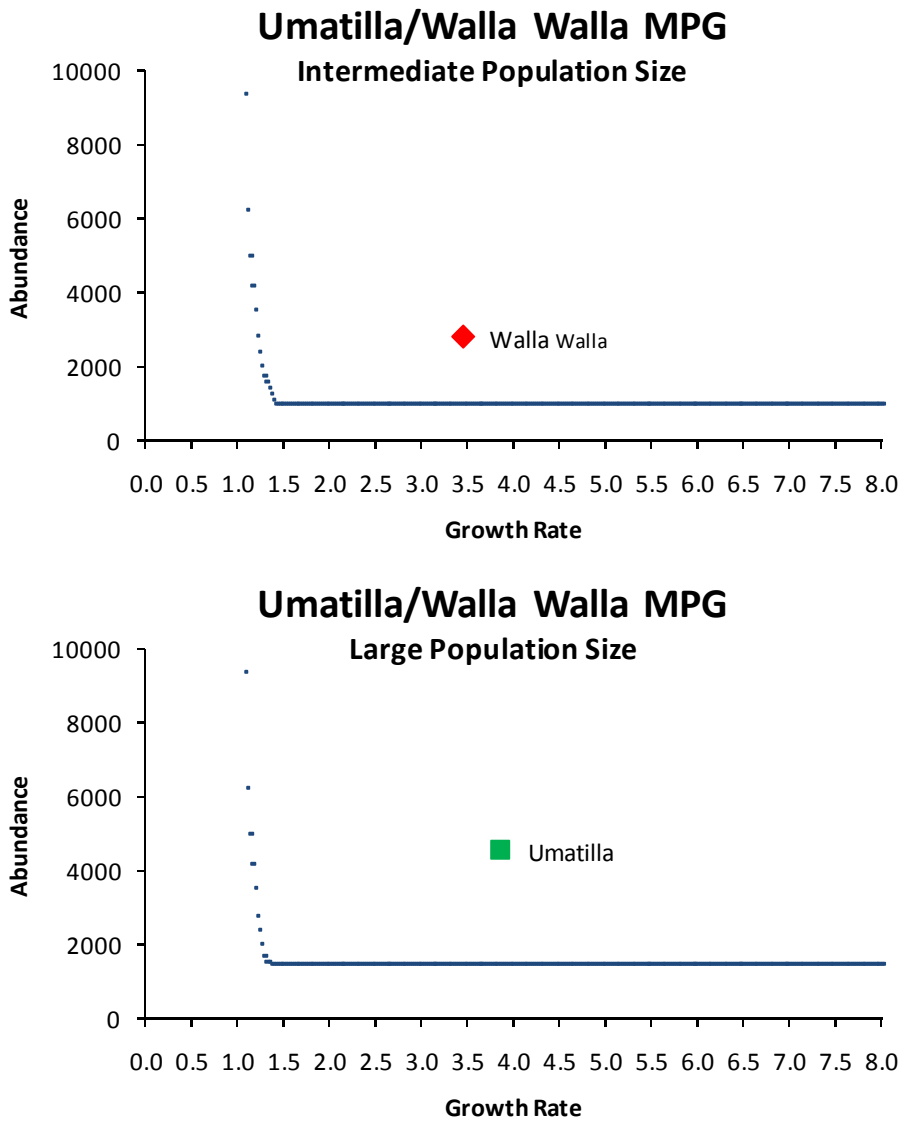

Figure 9-3. Relationship of Projected Abundance/Productivity Estimates to 5% Risk Curves (in a 100-year time period) for the different size Steelhead Populations within the Umatilla/Walla Walla MPG. The Walla Walla estimate includes restoration actions within both Oregon and Washington. Estimates are projected at 25 years into the future. Populations are considered viable if the projected abundance/productivity estimates fall on or above the 5% risk curve.

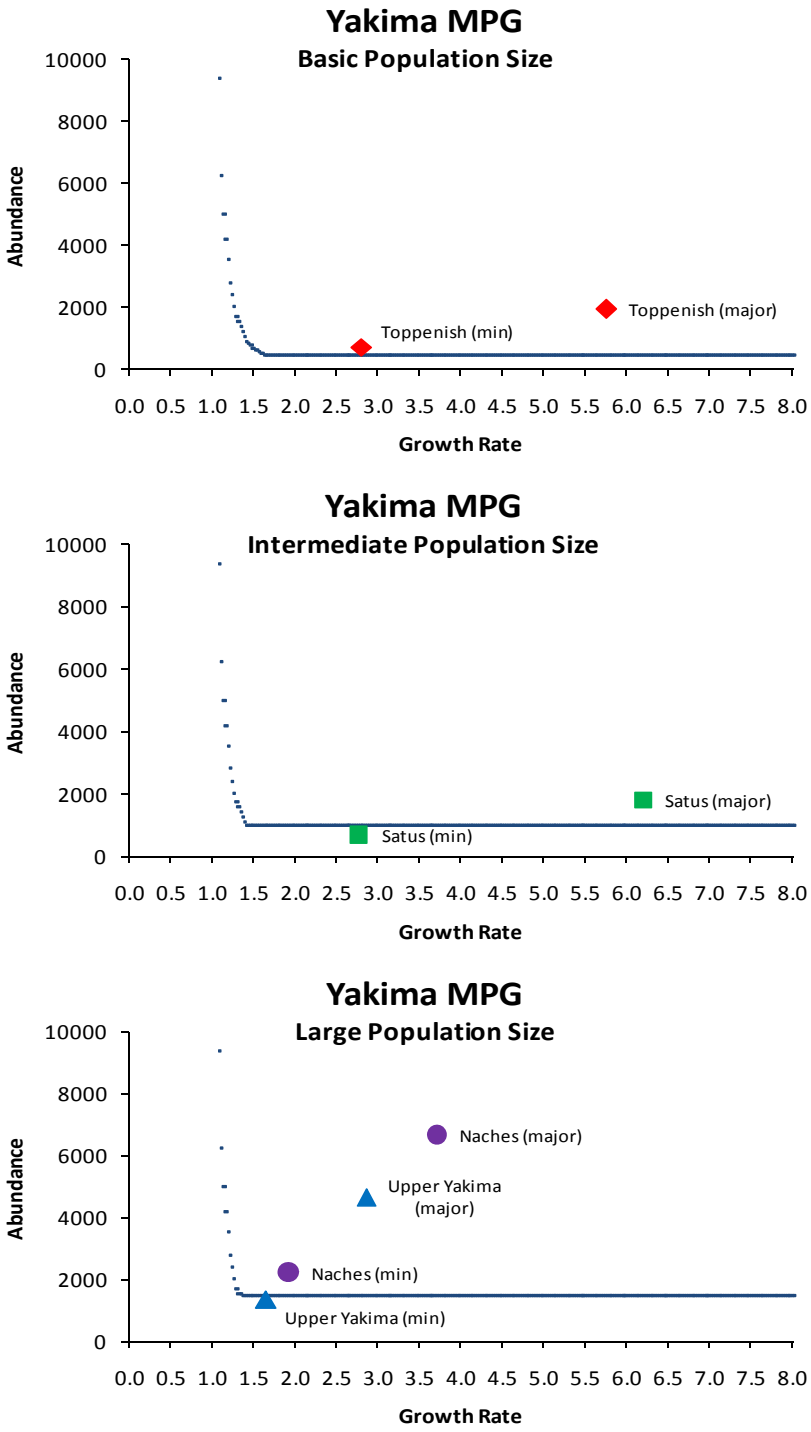

Figure 9-4. Relationship of Projected Abundance/Productivity estimates to 5% Risk Curves (in a 100-year time period) for the different size Steelhead Populations within the Yakima MPG. Estimates from both minimum and major restoration actions are shown for each population. Populations are considered viable if the Projected Abundance/Productivity Estimates fall on or above the 5% Risk Curve.

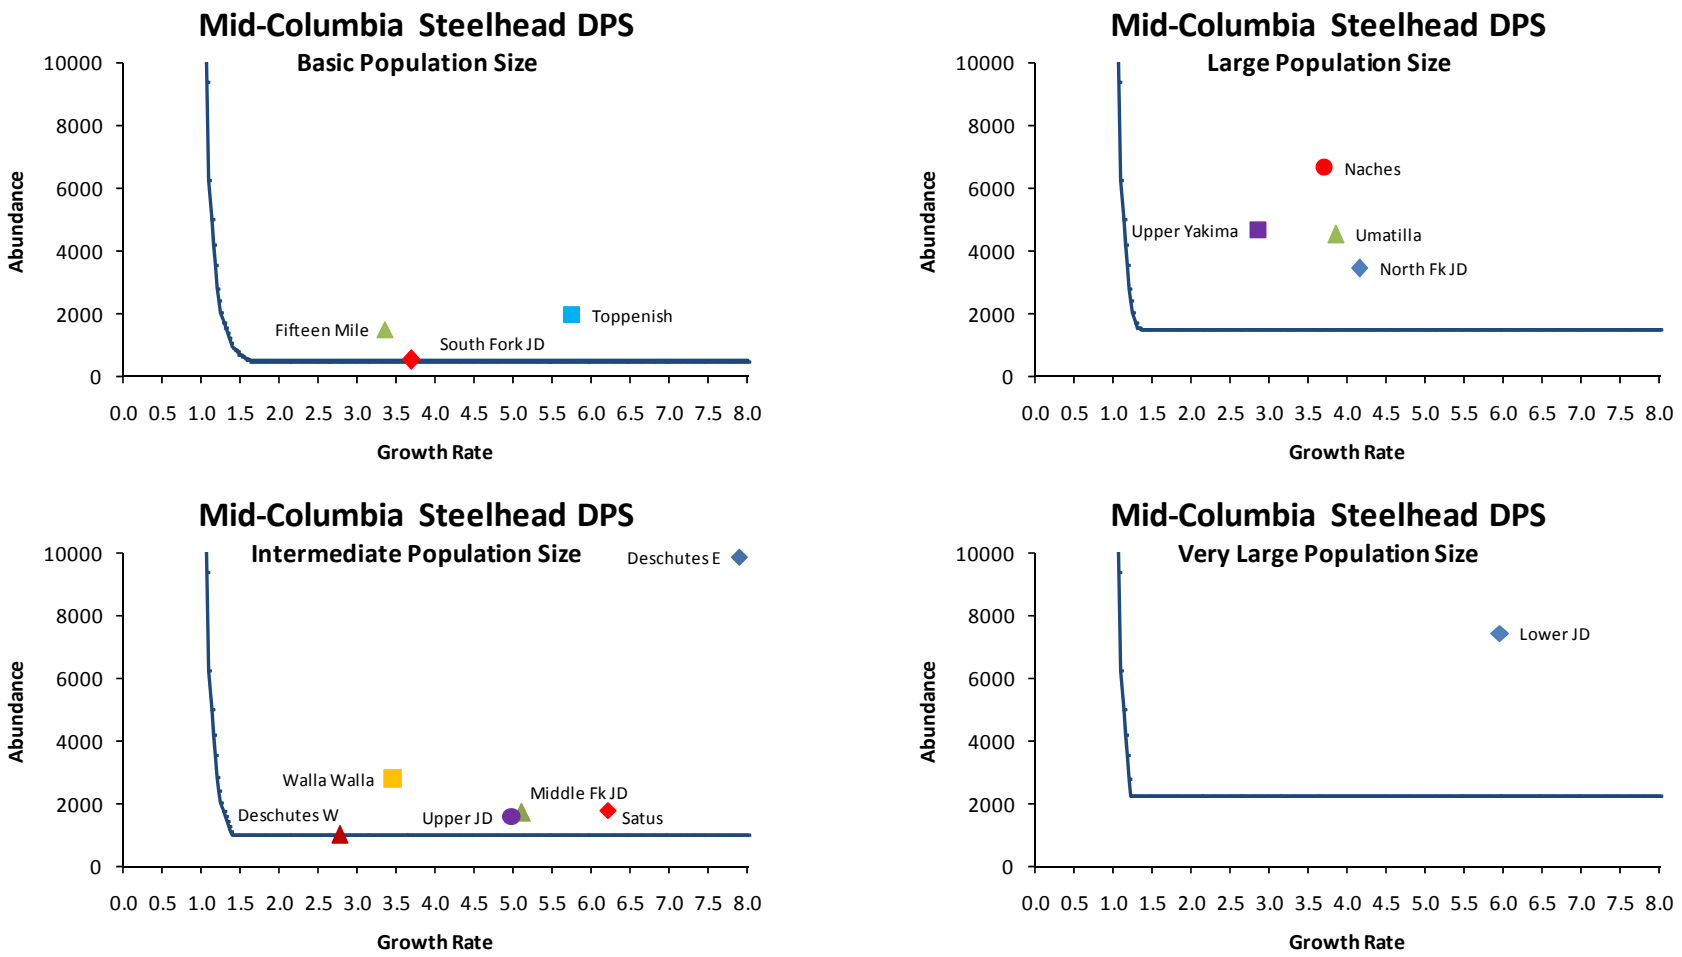

Figure 9-5. Relationship of Projected Abundance/Productivity Estimates to 5% Risk Curves (in a 100-year time period) for the different size Steelhead Populations within the Middle Columbia DPS. Estimates are projected at 25 years into the future and assume major restoration actions. Populations are considered viable if the projected abundance/productivity estimates fall on or above the 5% risk curve.

10. RESEARCH, MONITORING AND EVALUATION FOR ADAPTIVE MANAGEMENT

Because of the length and complexity of the salmonid life cycle and the habitat conditions these anadromous fish require, there are many uncertainties involved in improving salmon or steelhead survival. Simply identifying cause-and-effect relationships between any given management action and characteristics of fish populations can be a scientific challenge. It is essential to design a monitoring and evaluation program that will answer these basic questions: How will we know we are making progress? How will we get the information we need? And how will we use the information in decision-making?

Within the Middle Columbia Basin, many different organizations, including Federal, state, tribal, local, and private entities, currently conduct programs and actions designed to improve tributary fish habitat, and these entities also conduct various kinds of monitoring. Development of Middle Columbia regional coordination will be essential for NMFS' future status reviews of the steelhead DPS. Establishing stable funding and staff to produce annual reports is also important.

Detailed research, monitoring, and evaluation (RM&E) and adaptive management plans need to be developed for each management unit, based on the principles and concepts laid out in the NMFS draft guidance document, *Adaptive Management for Salmon Recovery: Evaluation Framework and Monitoring Guidance* (http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf). Each of the management unit Recovery Plans includes an RM&E component that follows or is generally consistent with the NMFS guidance document. The Oregon management unit plan is organized around a set of key RM&E questions applied to each MPG and includes a comprehensive set of recommendations addressing status monitoring, limiting factors assessments, and responses to recovery actions. The SE Washington management plan RM&E section is tailored after Washington state protocols, which share many of the principles included in the NMFS guidance document. The Yakima and Klickitat management unit plans explicitly incorporate the NMFS RM&E guidance principles and identify opportunities for improved status, limiting factors, and key uncertainty assessments. The Rock Creek Plan RM&E section recognizes that steelhead monitoring information has not been routinely collected in the basin and identifies a set of questions to inform monitoring implementation decisions. All of the management unit RM&E plans call for establishing a more detailed and specific RM&E implementation plan after the corresponding recovery plans are finalized.

The Middle Columbia Science Team will combine these management unit plans into an RM&E and adaptive management plan for the Middle Columbia steelhead DPS. This will ensure that, taken together, the monitoring and evaluation programs for each management unit, combined with monitoring components of the modules incorporated into the plans, address the needs of the entire DPS. The Mid-C Forum and others will use the RM&E and adaptive management plans to guide projects and programs during implementation.

10.1 Designing a Monitoring and Evaluation Program to Support Adaptive Management for Recovery Plans

Adaptive management in salmon recovery planning is a method of decision making in the face of uncertainty. It is a process of adjusting management actions and/or directions based on new information. To do this, it is essential to incorporate a plan for monitoring, evaluation, and feedback into an overall implementation plan for recovery. The plan should link results (intermediate or final) to feedback on design and implementation of actions. Adaptive management works by coupling the decision-making process with collection of performance data and its evaluation. Most importantly, it works by offering an explicit process through which alternative strategies to achieve the same ends are proposed, prioritized, and implemented when necessary.

An adaptive management plan must include the following elements (Anderson, 2003):

- Management strategies that are revisited regularly;
- The use of conceptual or quantitative models of the system being managed to develop and test hypotheses and to guide strategy and action planning;
- A range of potential management actions that could be used to meet the strategy;
- Monitoring and evaluation to track progress;
- Mechanisms for incorporating learning from monitoring and evaluation into decisions on actions and strategies; and
- A collaborative structure for stakeholder participation in adjusting management strategies and actions.

Adaptive management is crucial for salmonid recovery programs because of the length and complexity of the salmonid life cycle and the uncertainties involved in improving salmonid survival and status. The key is to build explicit links between management actions, monitoring data, and biological and physical responses.

Several types of monitoring are needed to support adaptive management:

- Implementation and compliance monitoring, used to evaluate whether the recovery plan is being implemented.
- Status and trend monitoring, which assesses changes in the status of an ESU and its component populations, and changes in status or significance of the threats to the ESU.
- Effectiveness monitoring, which tests hypotheses on cause-and-effect relationships and determines (via research) if an action is effective and should be continued.

It is essential to build effectiveness monitoring into the implementation plan at the outset, because it requires explicitly coupling the monitoring design and implementation with the action design and implementation in order to detect an effect. Recovery plan implementation should consist of action strategies that include the demonstration of effect.

It is also important to explicitly address the many unknowns in salmon recovery – the "critical uncertainties" that make management decisions much harder. Critical uncertainty research may seem expensive or unnecessary in light of basic information needs; however, in the long run, it

will reduce monitoring and implementation costs. Critical uncertainties are described in more detail in Section 10.3, below.

Implementation and compliance monitoring simply check on whether activities were carried out as planned, and whether specified criteria are being met as a direct result of an implemented action. For example, if a fence is planned for 20 miles of stream corridor to keep livestock off the stream banks so that riparian vegetation will rebound, implementation monitoring would verify the presence of the fence. Compliance monitoring would take note of the presence or absence of livestock in the fenced-off area.

Status and trend monitoring is a simple compilation of data-based descriptions of existing conditions. To be useful in decision-making, the raw data, or metrics, must be reduced to a more directly applicable form or indicator. For example, if the question is "What is the annual spawning population size of steelhead in the X River?" the indicator would be total spawning numbers of steelhead over one season for the entire river basin; however, the metric, or directly measured thing, would be something quite different, perhaps steelhead redds sighted on weekly passes over known spawning grounds. Thus, the metric must be processed to translate it from the metric data type (e.g., redds) into the indicator data type (e.g., spawners), and then reduced to generate the indicator required (e.g., list of weekly counts on spawning grounds to annual total for watershed). The ICTRT identified deficiencies in the currently available data and/or data-gathering techniques for Middle Columbia River steelhead. These are described in Section 10.4, below.

Effectiveness monitoring specifically addresses cause-and-effect questions. Demonstrating the direct and indirect impact of management actions requires supporting all steps in the logical chain that connects the action to its expected impact. This chain is rarely short and usually contains several hypotheses. For this reason, it's better to build the effectiveness monitoring into the recovery action strategies, with, for example, pilot-scale tests or other methods carefully thought out beforehand. Monitoring and evaluation will only provide the answers to the questions they were designed to address; they do not provide the framework for revising these questions if they are ill-posed, evaluating the assumptions upon which the strategy was built, or incorporating learning into future decisions on actions and strategies—this is the role of adaptive management.

NMFS' guidance document presents a decision framework that can guide the design of a research, monitoring, and evaluation plan. The framework (Figure 10-1) contains two basic sorts of questions: (1) questions regarding ESU status (biological viability criteria) and (2) questions regarding statutory listing factors and factors limiting recovery (limiting factor and threats criteria). Evaluating a species for potential delisting requires an explicit analysis of both types of criteria.

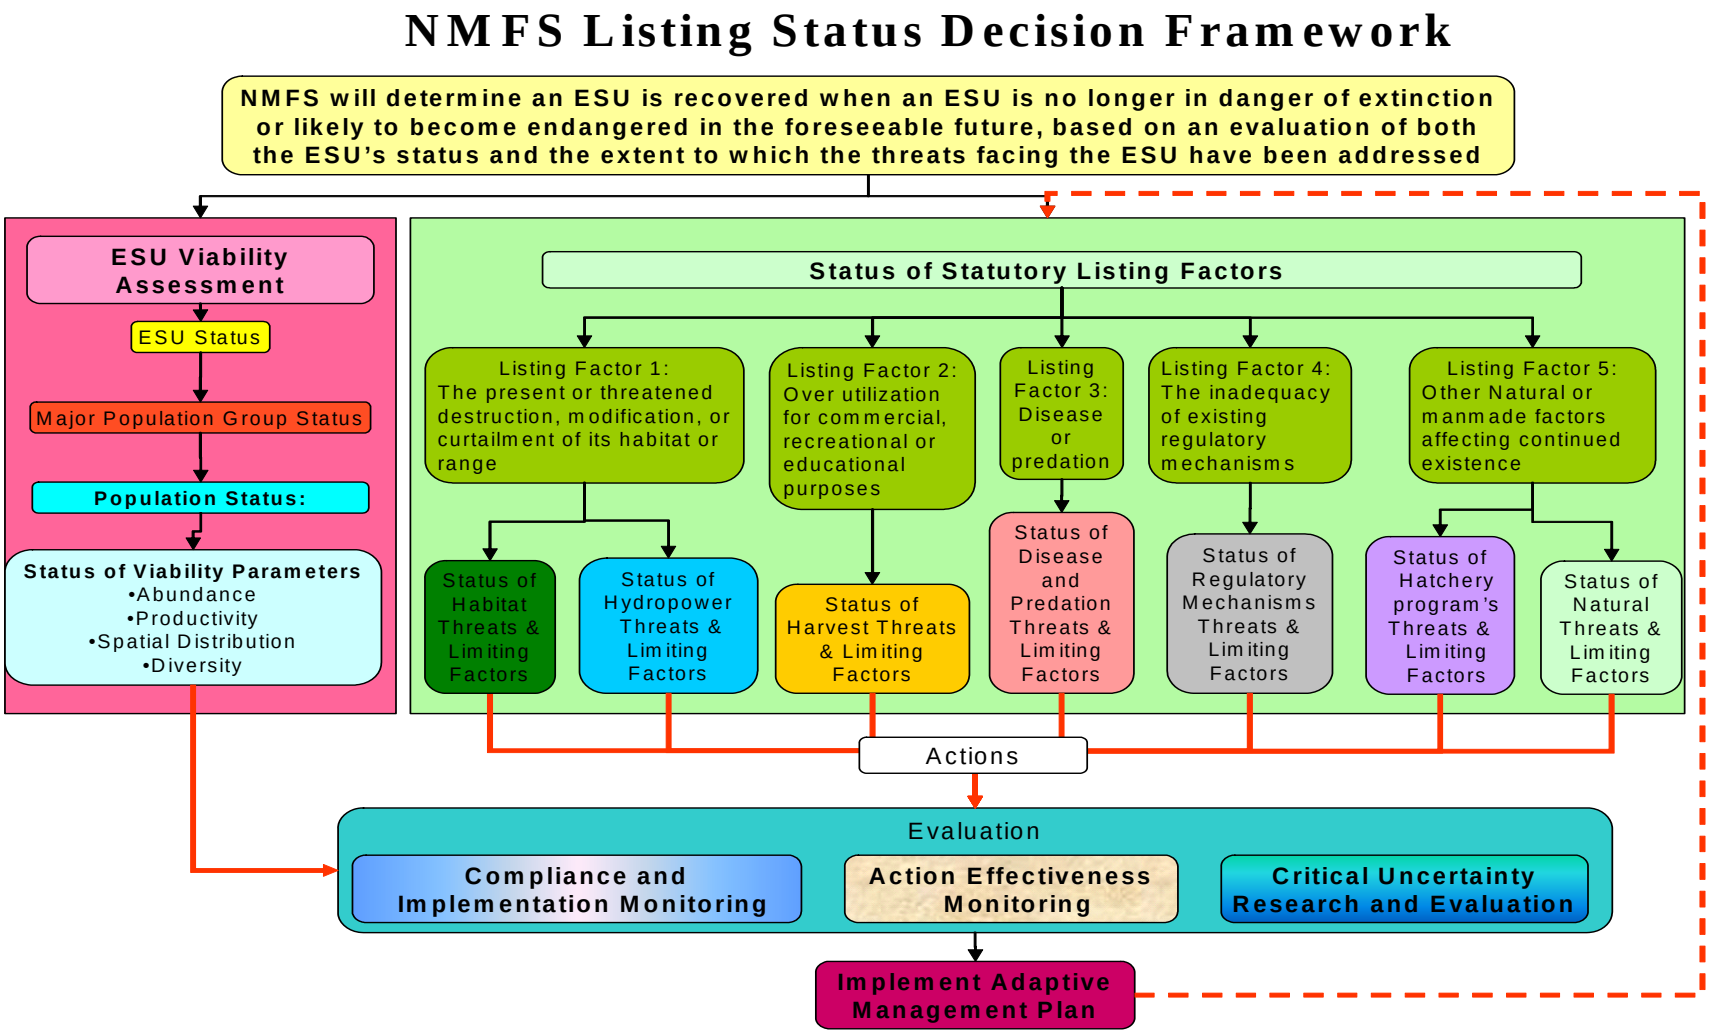

Figure 10-1. NMFS Listing Status Decision Framework

The guidance document contains a more detailed discussion of the framework and identifies the specific questions that must be answered to evaluate ESU status. These specific questions take the form of a series of decision-question sets that address the status and change in status of a salmonid ESU and the risks posed by threats to the ESU. The decision-question sets are designed to elicit the information NMFS needs to make delisting decisions. The framework can guide future decisions about strategies and actions aimed at achieving population, MPG, and ESU recovery goals.

Designing an effective monitoring program for salmon recovery involves the following initial steps:

1. Clarify the questions that need to be answered for policy and management decision-making. Include the full ESU and the full salmonid life cycle.
2. Identify entity or entities responsible for coordinating development of this program.
3. Identify:
    - Which populations and associated limiting factors to monitor
    - Metrics and indicators
    - Frequency, distribution, and intensity of monitoring
    - Tradeoffs and consequences of these choices
4. Assess the degree to which existing monitoring programs are consistent with NMFS guidance.
5. Identify needed adjustments in existing programs, additional monitoring needs, and strategy for filling those needs.
6. Develop a data management plan (See Appendix C of the NMFS guidance document).
7. Prioritize research needs for critical uncertainties, testing assumptions, etc.
8. Identify entities responsible for implementation.

Monitoring and evaluation programs will provide (1) a clear statement of the metrics and indicators by which progress toward achieving goals can be assessed, (2) a plan for tracking such metrics and indicators, and (3) a decision framework through which new information from monitoring and evaluation can be used to adjust strategies or actions aimed at achieving the Plan's goals.

10.2 Five-Year Reviews, ESU/DPS Status Assessments, and Adaptive Management

The ESA requires that, at least every 5 years, the Secretary shall conduct a review of all ESA-listed species and determine whether any species should: (1) be removed from such list; (2) be changed in status from an endangered species to a threatened species; or (3) be changed in status from a threatened species to an endangered species. Accordingly, at five-year intervals, NMFS will conduct reviews of the Middle Columbia steelhead DPS. These reviews will consider information that has become available since the most recent listing determinations, and make recommendations whether there is substantial information to suggest that a change in listing status may be warranted. If an ESU or DPS may warrant a change in status NMFS will conduct a formal, much more in-depth, ESA status review consistent with section 4(a) of the Act. Any formal status reviews will be based on the NMFS Listing Status Decision Framework and will be informed by the information obtained through implementation of the monitoring, research, and evaluation programs in each management unit plan and the recovery modules.

Similarly, new information considered during the five-year reviews may also compel more in-depth assessments of implementation and effectiveness monitoring and associated research to inform adaptive management decisions at the management unit and module level.

10.3 Research on Key Uncertainties

Chapter 6 described many of the important factors that have reduced, and continue to reduce, the abundance, productivity, spatial structure, and diversity of Middle Columbia River steelhead. It is clear that actions must be taken in all sectors (not just habitat) in order to recover listed populations. However, there are "key" areas of uncertainty identified in Biological Opinions (BiOp), PATH (Plan for Analyzing and Testing Hypotheses), and Northwest Power and Conservation Council documents that can affect the success of actions implemented within each of the sectors. Resolution of uncertainties will greatly improve chances of attaining recovery goals outlined in this plan. These "key" uncertainties are highlighted below.

10.3.1 Ocean Productivity and Natural Variation

Global-scale processes in the ocean and atmosphere can regulate the productivity of marine, estuarine, and freshwater habitats of steelhead. Although managers cannot control these processes, natural variability must be understood to correctly interpret the response of steelhead to management actions. For example, assessing needed survival improvements based on spawner returns during periods of below average climatic and other background conditions has the effect of projecting these generally poor ocean conditions into the future. If one were to add years representing better ocean conditions to the analysis, estimated required survival increases would decrease. Additional research is needed to help understand the mechanisms of ocean and climatic survival conditions, and to help improve forecasting and relating fisheries management capabilities and ensure that Middle Columbia steelhead populations persist over the full range of environmental conditions they are likely to encounter.

10.3.2 Global Climate Change

The potential impacts of global climate change are recognized at national and international levels. Many climate models project changes in regional snowpack and stream flows with global climate change. The effects of these changes could have significant effects on the success of recovery actions and the status of Middle Columbia steelhead. The risks of global climate change are potentially great for Middle Columbia stocks because many of the populations spawn and rear in snow-rain transitional zones that are likely to be impacted by climate change. It will be important to monitor key environmental variables such as summer and fall streamflow and temperature in tributaries (Crozier et al. 2008) and to perform research to better understand the relation between changes in those habitat factors and survival of Middle Columbia steelhead. Other useful freshwater monitoring includes assessment of existing areas of hyporheic flow comprising cold-water refuges and research to understand how those areas change with environmental conditions and human impacts such as water withdrawals. Steelhead stocks are also sensitive to climate-related shifts in ocean conditions, such as the position of the sub-arctic boundary, the strength of the California Current, the intensity of coastal upwelling, and the frequency and intensity of El Nino events (NPCC 2004). More research is needed to address the effects of climate change on ocean circulation patterns, freshwater habitat, and steelhead productivity.

10.3.3 Hatchery Effectiveness

Uncertainties exist regarding the potential for both benefits and harm of hatchery-produced fish on naturally spawning steelhead populations. A major uncertainty is whether it is possible to integrate natural and artificial production systems in the same subbasin to achieve sustainable long-term productivity. There is also uncertainty about the reproductive success of hatchery fish spawning in the wild. There is currently little data available and experimental methods for obtaining this information will take many years to get initial results and much longer before conclusions can be inferred from the empirical information. Although supplementation is considered a potential benefit to recovery, it carries risks as noted here.

10.3.4 Differential Delayed Mortality of Transported Steelhead (D Value)

The differential delayed mortality of transported steelhead (D value) is the estimated ratio of the post-Bonneville survival of transported fish relative to in-river migrating fish. This differential mortality can occur during any time from release downstream from Bonneville Dam, through the estuary and ocean life stage, and during adult upriver migration to the specific dam from which they were transported. The factors determining D are complex and poorly understood. This uncertainty has little effect under current conditions because few Middle Columbia steelhead are currently transported. However, an improved understanding of D will be necessary to determine the appropriate role of McNary transportation in the future. Furthermore, the future role of transportation and the potential benefit of major hydro-system configurations are highly sensitive to this uncertainty.

10.3.5 Invasive Species

Another critical uncertainty is the effect of invasive species on the viability of Middle Columbia steelhead. One such species, American shad, may affect the abundance and survival of steelhead in the lower Columbia River. It is possible that the growing population of shad is competing directly with juvenile steelhead by cropping food sources important to salmonids in the lower Columbia River. It is also possible that the large numbers of shad in the lower river contribute to the growth of northern pikeminnow, smallmouth bass, and walleye, which are important predators of steelhead. Shad may be sustaining large populations of predators during periods when steelhead are not available to the predators, and, as a result, more and larger predators are present during periods when steelhead are moving through the lower Columbia River.

10.3.6 Independent Populations

The Interior Columbia Basin Technical Recovery Team (ICBTRT) used a hierarchical approach to define DPS level viability, defining independent populations within each DPS and applying relatively simple rule sets to geographic groups of those populations to evaluate viability (ICBTRT 2003). The ICBTRT based their approach on the guidelines provided in McElhany et. al. (2000), including a specific definition of an independent population (see Section 2.2.3).

Following McElhany et al. (2000), the ICTRT assumed that spawning aggregations meeting a minimum size criteria were defined as independent if they were separated by a sufficient distance so that expected straying rates would be below 5-10 percent (ICBTRT 2003).

The ICBTRT DPS status evaluations were based on simplified demographic analyses of individual populations that implicitly assume that each population would function independently. The hierarchical model of DPS structure recognizes that relatively low (<10%) levels of exchange among independent populations within a DPS is also important to overall DPS viability.

The ICBTRT ESU/DPS level criteria were specifically designed to "... ensure preservation of basic historical metapopulation processes including:1) genetic exchange across populations within an ESU over a long time frame; 2) the opportunity for neighboring populations to serve as source areas in the event of local population extirpations; 3) populations distributed within an ESU so that they are not all susceptible to a specific localized catastrophic event. To meet these objectives a viable ESU will likely have some populations meeting viability standards close to each other AND some populations meeting viability standards relatively distant from each other (McElhany et al. 2000, Isaak et al. 2003)."

The ICBTRT viability criteria were specifically designed to implement the principles in McElhany et al. 2000 given the range of characteristics and data availability associated with listed Interior Columbia ESU/DPS. As the ICBTRT acknowledged, it may be possible to develop more detailed metapopulation models for DPS/ESUs where sufficient information is available. Continuing to explore each ESU/DPS from a metapopulation perspective could lead to improved criteria for assessing the risk at the DPS level. For that purpose, research is needed to further define population structures, natural straying, and movement among aggregations.

10.3.7 Effects of Interacting Strategies/Actions

A critical uncertainty associated with the implementation of this recovery plan will be the effect of management actions or strategies on the environment and on life-stage specific survival rate and population level responses. It is unclear how strategies implemented within each of the sectors (Harvest, Hatcheries, Hydropower, and Habitat) will interact and contribute to recovery. In particular, a high level of uncertainty exists for the magnitude and response time of habitat actions. Even if all habitat actions could be implemented immediately (which they cannot), there will be delays in the response to actions. Populations will likely respond more quickly to some actions (e.g., diversion screens and barrier removals) than they will to others (e.g., riparian plantings). Although the effects of interacting strategies on population VSP parameters remain unknown, monitoring will contribute substantially to resolving this uncertainty.

10.3.8 Effects of Human Population Growth

Human population growth in the Columbia Basin and its effects on recovery of listed species is a critical uncertainty. The size of the human population within the Columbia Basin will continue to increase and projected development will probably expand along streams and rivers at a greater rate than in upland areas. A high degree of coordination among agencies, tribes, and counties will be needed to maximize recovery efforts.

10.3.9 Resident-Anadromous *O. mykiss* Interactions

In the Middle Columbia region, only the anadromous life form (steelhead) of *O. mykiss* is listed. The resident life form (also known as rainbow trout or redband trout) is not listed, although these fish are genetically similar to steelhead, where they co-occur. In addition, where they co-occur,

individuals can occasionally produce progeny of the alternative life form. The nature of the relationship between resident and anadromous forms of *O. mykiss* is inherently complex, and an improved understanding of the range of interactions is needed.

10.4 Important Data Gaps

The management unit plans described monitoring and research needs for each steelhead population and/or area, and will do so in greater detail in the RM&E plans that will be completed after the DPS plan is approved. In its 2007 document, "Viability Criteria for Application to Interior Columbia Basin Salmonid ESUs," the ICTRT identified data gaps at the DPS/MPG level. The ICTRT said: "There is considerable variability in the quality and quantity of information to conduct viability assessments for Interior Columbia River salmon and steelhead populations. We have identified fairly large gaps in information for steelhead populations . . . We believe improving the quality and quantity of data is essential for monitoring future change in population status relative to viability criteria (ICTRT 2007)." Important information gaps the ICTRT listed for conducting population level viability assessments for Middle Columbia River steelhead include the following:

10.4.1 Abundance and Productivity

Mid Columbia Steelhead population abundance and productivity data: Most population abundance estimates are derived from standard index redd count surveys. Yakima population abundance is estimated from aggregate dam counts, and population-specific levels are apportioned using limited radio tag data. Abundance estimates need to be conducted using probabilistic sampling protocol for either redd counts or tagging studies (ICTRT 2007).

Mid Columbia steelhead population specific hatchery fraction and age structure data: A majority of populations had inadequate hatchery fraction information. Abundance and productivity assessments would improve with more detailed population level hatchery fraction data. A majority of populations had inadequate age structure information. Typically, average MPG aggregate age structure from a few years of data was used in most cases for the population level (ICTRT 2007).

Smolt-to-adult returns (SARs) and juvenile productivity estimates: Improve or collect information on SARs and juvenile productivity (i.e. smolts per spawner). SARs are essential for taking into account variability in survival during smolt outmigration and marine life stages in evaluating abundance and productivity criteria. The goal is to estimate SARs that are representative at the population level. There are a number of approaches to accomplish estimating these SARs (e.g. marking wild or hatchery smolts or estimating natural-origin smolts and adult production). In addition, measures representing survival from spawning to outmigrating smolts would aid in partitioning productivity between freshwater and marine life-stages (ICTRT 2007).

Population level effects of hatchery spawners on natural productivity: For populations with hatchery spawners, develop representative estimates of the effects of hatchery spawners on population-level productivity. Topics of interest include the effect of hatchery spawner contributions to the average natural productivity of a population and the relative effectiveness of hatchery spawners. In combination with adequate estimates of the relative levels of hatchery fish

contributing to natural spawning for a particular population, this information would allow for more representative estimates of current and potential natural productivity levels (ICTRT 2007).

10.4.2 Spatial Structure and Diversity

Steelhead population spawner distribution and habitat preference data: Many populations had inadequate spawner distribution information to assess spatial structure and diversity criteria. In addition, estimates of historical distribution are dependent upon habitat preferences derived from available empirical studies. Those studies are limited in scope and number. Additional information on habitat/steelhead preference or production relationships could improve the assessment of steelhead populations against SS/D criteria (ICTRT 2007).

Phenotypic characteristics for populations: Little information was available to assess phenotypic changes. Representative estimates of current morphological, life history, or behavioral traits are not available for many populations. Additional analysis of relationships between habitat characteristics and phenotypic traits would improve the ability to assess changes from historical patterns at the population level (ICTRT 2007).

Genetics information: Genetic baseline information and periodic follow-up surveys specifically designed to evaluate the level of variation or differentiation among subcomponents within populations and among populations. Periodic follow-ups would support evaluation of responses to management actions designed to promote restoration of natural patterns of population structure (ICTRT 2007).

Spawner composition for steelhead populations with hatchery spawners: Collect specific spawner composition information including proportion and source of hatchery spawners. Information on the relative distribution of hatchery spawners among production areas within populations would also improve the ability to assess status against ICTRT spatial structure criteria (ICTRT 2007).

Selective mortality effects: Little information was available to assess selective mortality resulting from differential impacts of human induced mortality. Additional information is needed to better assess human induced mortality effects in each of the four Hs (habitat, hatcheries, harvest and hydropower) (ICTRT 2007).

11. IMPLEMENTATION AND COORDINATION

This chapter describes how implementation of this recovery plan will be coordinated. It proposes that the Middle Columbia Recovery Forum (Mid-C Forum or Forum) will play a central role at the DPS-level.[42] The Forum is a voluntary organization of Federal agencies, states, tribes and other planning entities (see Chapter 1), that will coordinate implementation within the DPS. The function, membership, processes and organization of the Forum are described herein. State entities will play a central role in coordination plan implementation at the MU level. This chapter also describes the Oregon and Washington approaches to recovery implementation and the role of NMFS.

NMFS' vision[43] for recovery implementation is that the actions identified in salmon and steelhead recovery plans are carried out in a cooperative and collaborative manner and that recovery and delisting occur. NMFS' strategic goals to achieve that vision are to:

1. Sustain local support and momentum for recovery implementation.

2. Implement recovery plan actions within the time periods specified in each plan.

3. Ensure that the actions implemented contribute to achieving recovery.

4. Provide accurate assessments of species status and trends, limiting factors, and threats.

NMFS' strategic approach to achieving these goals is to:

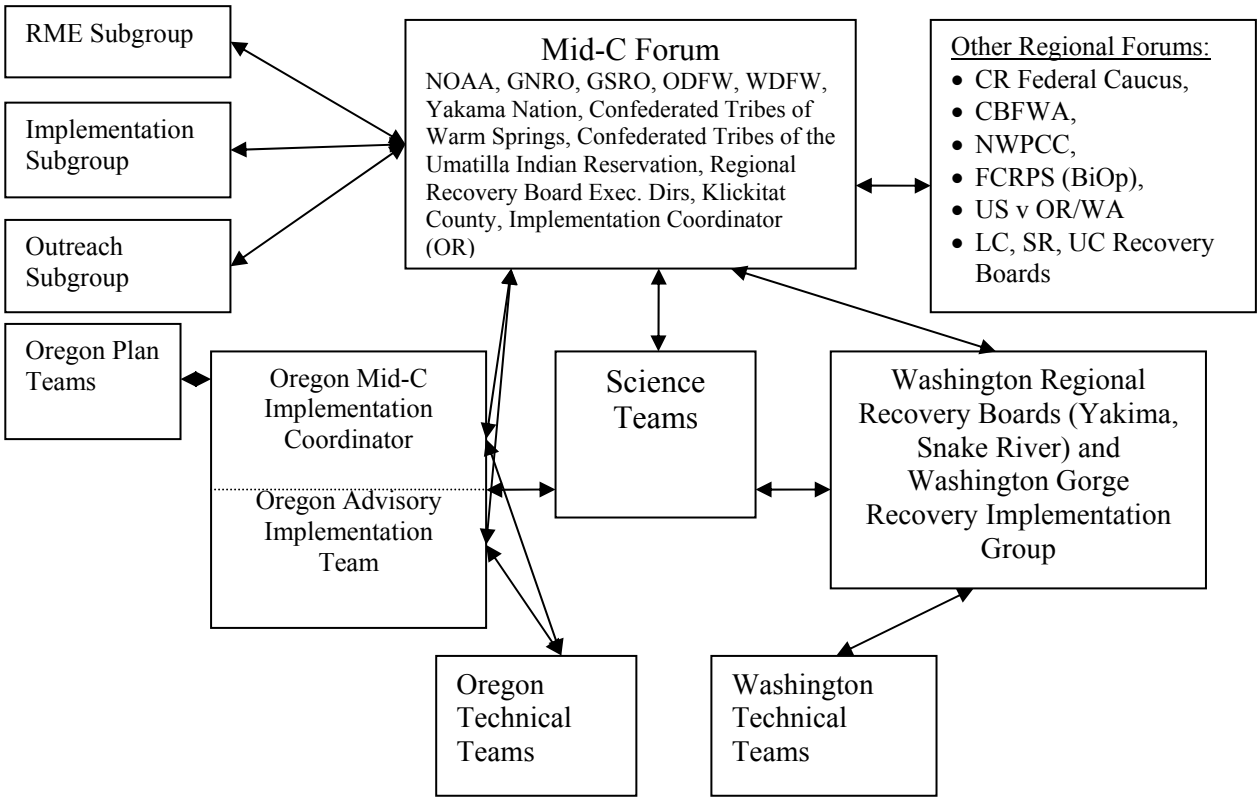
- Support local efforts by using Domain Teams[44] to coordinate (internally and externally) and encourage recovery plan implementation.

- Use recovery plans to guide internal and external regulatory decision-making.

- Use non-regulatory authorities and encourage others to use their authorities to implement recovery plans.

- Provide leadership to regional forums to develop research, monitoring, and evaluation (RME) processes that track action effectiveness and status and trends at the population and DPS levels.

- Provide periodic reports on species status and trends, limiting factors, threats, and plan implementation status.



[42] The Mid-C Forum was formed in March, 2007 to assist NMFS in completing this recovery plan.
[43] From NMFS Northwest Region Memo dated February 26, 2008, subject: Northwest Region Recovery Implementation Strategy.
[44] Domain Teams are an organizational structure internal to NMFS whose purpose is to coordinate recovery plan completion and the recovery implementation effort. The teams promote consistency in internal decision making and work with state, tribal, and local recovery parties to achieve recovery plan objectives.

NMFS will carry out its vision, goals, and strategic approach to recovery for Middle Columbia steelhead by working in partnership with the Mid-C Forum.

11.1 Implementation Roles and Responsibilities

Effectively implementing recovery actions for Mid-C steelhead will require coordinating the actions of diverse private, local, state and Federal parties spread across two states. In Washington, regional recovery boards have taken the lead on coordinating recovery implementation within the Yakima and Snake management units[45]. In Oregon, an implementation coordinator and reformed advisory board will lead recovery plan implementation, supported by the governance structure for the Oregon Plan for Salmon and Watersheds. Actions in the Columbia River, its estuary, and the ocean are implemented by a broad range of partners, including NMFS, the Northwest Power and Conservation Council, the Bonneville Power Administration, the Bureau of Reclamation, the Army Corps of Engineers, Federal land management agencies, state and tribal fisheries co-managers, the Columbia River Estuary Partnership, and local parties and jurisdictions interested in salmon recovery. The Mid-C Forum will take the lead in efforts to coordinate the actions of these many players at a DPS-level, supported by both local and regional Science Teams. Figure 11-1 gives an overview of the relationships between these entities.

Figure 11-1. Mid-C Recovery Plan Implementation Organizational Structure.

[45] Implementation structures for the Eastern Cascades populations within Washington have yet to be determined.

11.1.1 Mid-C Forum

The Mid-C Forum provides organizational structure for communication and coordination on a bi-state and multi-tribal level across the entire DPS.

Specific functions include:

- Facilitating coordination and communication between Federal agencies, the Northwest Power and Conservation Council, states, tribes, management unit leads, and local recovery boards.
- Advocating for the recovery of Mid-C steelhead.
- Promoting the application of adaptive management in the DPS.
- Providing recommendations for resource prioritization.
- Networking with other multi-jurisdictional Columbia recovery planning groups (e.g. Lower Columbia, Upper Columbia, and Snake River) and Northwest Power and Conservation Council subbasin planning efforts.
- Providing a scientific interface with the Recovery Implementation Science Team (RIST).
- Coordinating and synthesizing RME efforts and activities.

The Forum will coordinate with broader efforts to develop common indicators for measuring trends. The Mid-C Forum may also identify legislative, congressional, and other funding opportunities for management actions and RM&E within the DPS. Policy issues will be resolved within respective local, state, Federal and tribal authorities and agencies.

Organization/Membership:
The Mid-C Forum is guided by a Steering Committee. NMFS will serve as the convening partner and provide facilitation, venues, and guidance. Steering Committee membership includes management unit leads (or their representative) in Washington and Oregon and representatives from the Oregon and Washington governors' offices, NMFS, Yakama Nation, Confederated Tribes of Warm Springs, Confederated Tribes of the Umatilla Indian Reservation, Oregon Department of Fish and Wildlife, Washington Department of Fish and Wildlife, and Klickitat County.

There is no established membership for participation in the broader activities of the Forum. It is anticipated that participation in regular Forum meetings, as distinguished from meetings of the Steering committee, will vary depending on the topics and issues being addressed.

Operations:
The Mid-C Forum and Steering Committee will conduct regular meetings semi-annually, or as needed, and work to reach consensus on issues of dispute or discrepancy within the DPS.

Functional Topics:
The Forum will focus on four functional topics. For each topic the Forum may establish subgroups to organize, implement, and track progress. The decision to establish such subgroups will be determined based on the anticipated scope of work for each functional topic, Forum members' available staffing and funding, and other considerations as the Forum considers appropriate. The intent of these efforts is to support coordinated and effective implementation of the Mid-C Steelhead

Recovery Plan and to ensure that 5-year status reviews by NMFS are informed and efficient. The four functional topics are:

1. Research, Monitoring & Evaluation: RM&E will be coordinated by a Science Team which will be composed of RIST representatives, management unit technical representatives, ODFW/WDFW/tribal co-manager technical representatives, Klickitat County, etc. Focus areas may include:

    - Review/compile new information on VSP parameters and update stock status summaries accordingly.
    - Identify knowledge gaps that are high priorities across the DPS and review/coordinate efforts to address them.
    - Identify how to track threats criteria and provide annual summaries of applicable data.
    - Develop a DPS monitoring and evaluation and adaptive management plan.

2. Implementation: Subgroups may be composed of key project managers from management units, representatives from key funding programs (e.g., NMFS Restoration programs, Bonneville Power Administration, Columbia Basin Fish Accords[46], Northwest Power and Conservation Council, Oregon Watershed Enhancement Board, the Salmon Recovery Funding Board, and others), and key partners in recovery actions (such as USFS, BOR, and others). Their focus areas may include:

    - Review status of implementation scheduling for each management unit.
    - Share significant accomplishments by management units.
    - Promote technology transfer relevant to implementation across management units.
    - Communicate priorities for future actions to assist coordination across management units.
    - Identify opportunities where shared advocacy and coordination help implement key recovery actions (e.g., combine suitable proposals into single programmatic proposal; share technical resources for design review).

3. Outreach: Subgroups may be composed of representatives from state governors' staffs, co-manager policy leads, management unit representatives, and/or partner agency policy people. Their focus is to develop/support outreach related to Mid-C recovery, including reviewing/drafting NMFS two-year reports and updates to key decision makers (elected officials, agency heads, etc.).

[46] The Fish Accords consist of three Memorandums of Agreement (MOAs) entered into between the Federal Columbia River Power System (FCRPS) action agencies (Bonneville Power Administration, U.S. Army Corps of Engineers and the Bureau of Reclamation), four tribes, and one state. The most relevant MOA to the Middle Columbia River steelhead is with the Columbia River Inter-Tribal Fish Commission and the three treaty fishing tribes, Confederated Tribes of the Umatilla Indian Reservation; Confederated Tribes of the Warm Springs Reservation; and Confederated Tribes and Bands of the Yakama Nation. The MOAs are 10-year action agency commitments for projects to benefit fish affected by the FCRPS, with a focus on ESA-listed fish. The projects will be reviewed through the Northwest Power Act processes for implementing the Fish and Wildlife Program, administered by the Northwest Power and Conservation Council.

4. Policy: Policy issues will be managed by the Steering Committee, who may elect to organize subgroups for specific issues. Policy focus areas include:

    - Identify issues where joint advocacy supports Mid-C recovery action.
    - Track the status of Mid-C related activities in the Northwest Power and Conservation Council, Federal Caucus, FCRPS litigation, *U.S. v. Oregon*, *U.S. v. Washington*, and other regional forums.
    - Identify and, if appropriate, develop Mid-C policy proposals.

11.1.2 Management Unit Leads

The proposed organizational structure for plan implementation within Oregon and Washington is based on the structure used for development of the respective management unit recovery plans, with the note that these approaches differed, and will continue to differ, slightly. In Oregon, the Department of Fish and Wildlife (ODFW) led recovery plan development with assistance from the Governor's Natural Resources Office and NMFS. For implementation of the Oregon management unit recovery plan ODFW will seek an additional staff person (Implementation Coordinator) to facilitate implementation. In Washington, regional recovery boards, where they exist, developed the management unit plans and will coordinate plan implementation with guidance and support from the Governor's Salmon Recovery Office.

For the purposes of implementation, the term "management unit leads" (MU leads) refers to the Washington regional recovery boards, Oregon's recovery plan Implementation Coordinator (in conjunction with an Advisory Board) and, where no recovery board exists in Washington, NMFS. The MU leads have three primary responsibilities in regard to tributary-based implementation. Performance of these responsibilities will be influenced by MU lead capacity, authority, and MU priority, and will likely require other support structures or processes to fully accomplish these responsibilities. Not all of these duties can be accomplished initially with the current resources available. Prioritization of the initial duties will be guided by the statutory requirements of the ESA and the individual state's guidance.

The first responsibility for MU leads is to develop implementation schedules for the respective MUs, organized in a spreadsheet format consistent with NMFS interim recovery planning guidance (NMFS 2006). While all of the MU plans presently contain site-specific actions, priorities, and estimates of the time and cost sufficient to complete this DPS plan, further specificity will aid in local project selection and prioritization as well as in implementation reporting at the regional and national levels.

- Site-specific recovery actions specific to populations within the MUs.
- Limiting factor(s) addressed by each action.
- Priority for completing the action. Organize actions by priority level.
- Duration of and schedule for action, indicating also whether the action is new or already underway.
- Biological benefits of the action(s).
- Lead entity(ies) to implement each action.
- Estimated cost for each action over each of the next 5 years and a total cost for that action to recovery.

The second responsibility for MU leads is to coordinate implementation of recovery actions identified in the plan and implementation schedule. In this regard, they serve to facilitate two-way communication vertically (i.e., different spatial scales related to recovery plan governance) and horizontally (i.e., related programs, interests, and oversight outside of recovery plan governance). A key related program is the implementation of the Northwest Power and Conservation Council's Fish and Wildlife Program Subbasin Management Plans. The MU leads, in full coordination with the fishery agencies and tribes, should ensure that the project selection process for the Council's subbasin plans within the MU is consistent with implementing the ESA priority actions specified in this plan and the implementation schedules.

Specific responsibilities include:

- Coordinate with Federal and state agencies, Northwest Power and Conservation Council, tribes, local government, and other stakeholders, with an emphasis on implementing tributary habitat actions.

- Coordinate development of implementation strategies for voluntary actions requiring complex coordination among various entities, including:
    - local outreach
    - incentives
    - technical help
    - project funding
    - project management
    - monitoring/reporting

The third responsibility for MU leads is to track and report on progress of implementation in accordance with state and Federal reporting requirements. Specific responsibilities include:

- Coordinate plan monitoring within the MU.
    - Ensure appropriate tracking and reporting of recovery actions.

- Coordinate plan research within the MU.
    - Include results and reports in system information/outreach materials.

- Report on plan progress in relation to goals, strategies, and actions, using mechanisms and processes established for tracking progress.
    - Highlight plan successes and needs.

- Review and revise implementation schedules as necessary.
    - Use monitoring and research to guide actions.
    - Incorporate adaptive management, as needed.

- Represent the MU in the Mid-C Forum and Forum subgroups, as necessary.

11.1.3 Washington Regional Recovery Boards

Purpose and Function:
Regional Recovery Boards will be the MU Leads in Washington, and will serve those functions described under Section 11.1.2. In general, this entails overseeing, promoting, coordinating, and tracking actions and RM&E efforts within their respective management units (or within units that span two states) to ensure implementation of the Middle Columbia recovery plan. In addition, the Boards will coordinate data acquisition and sharing, seek funding opportunities for specific management unit actions, and track and ensure progress reporting to the Mid-C Forum on viability and threat trends for steelhead.

Regional Recovery Boards' regular operations are served by Executive Directors. The directors will coordinate Regional Recovery Board efforts, with assistance from the Governor's Salmon Recovery Office. Yakama Nation management and policy-level staff and other participants will coordinate with NMFS in areas not covered by a Recovery Board.

Organization/Membership:
Regional Recovery Boards include the Yakima Basin Fish and Wildlife Recovery Board and the Snake River Salmon Recovery Board. The Washington Gorge management unit will be served by the Yakama Nation, Klickitat County, and other participants NOAA brings into the recovery process. Where boards are in place, they are made up of government and tribal representatives and other local interests and are funded through the Washington Salmon Recovery Funding Board.

Operations:
Washington Regional Recovery Boards meet regularly, generally monthly or quarterly. Progress reporting will be done in coordination with existing "support" teams of Board and state/Federal/tribal agency staff.

The Yakima Basin and Snake River boards will report progress to the Mid-C Forum annually, including progress in management, conservation and RM&E actions, and trends in habitat health and salmonid viability.

Resources:
Washington's Recovery Boards will operate on existing funding sources.

11.1.4 Oregon Implementation Coordinator and Advisory Board

The Oregon Steelhead Recovery Plan proposes an updated implementation structure and approach in Section 12.1, Implementation and Adaptive Management. Figures 12.1 and 12.2 in the Oregon Steelhead Recovery Plan illustrate this new structure and working relationships to implement recovery actions and carry out adaptive management for the Oregon steelhead populations.

Implementation Coordinator: An ODFW implementation coordinator will serve as Oregon's "MU lead" for recovery plan implementation, under the advice and guidance of the Recovery Team. This individual will work with relevant teams, groups, entities and all relevant parties to implement the recovery plan. The Implementation Coordinator will work with the Implementation Team and Watershed Teams to plan, schedule, track and report on action implementation, and in coordination

with the Technical Team, develop, track and report on Adaptive Management activities (refer to Figure 12.1 in Oregon Steelhead Recovery Plan).

Recovery Team: The Recovery Team provides oversight and vision to recovery plan implementation. This team is responsible for reporting to NMFS and shares accountability for species recovery in the MU. The team provides overall coordination and guidance to the recovery plan teams, coordinates with other domain teams and the Oregon Plan Core Team, and serves as the state's representative at the bi-state Mid-C Forum. The Recovery Team is made up of representatives from the Governor's Natural Resource Office, the Oregon Department of Fish and Wildlife, Implementation Coordinator, Tribes, counties, and other major local entities.

Implementation Team: The Implementation Team provides advice, recommendations and support to the Implementation Coordinator. The Implementation Team is made up of Sounding Board members, watershed team representatives, NMFS, Tribes, Technical Team representative, and is chaired by the Implementation Coordinator.

Technical Team: The Technical Team provides advice and guidance on technical and science issues related to monitoring, research and evaluation, data analysis, and adaptive management that supports and strengthens effective implementation of the recovery plan. The Technical Team is made up of planning team representatives, other key Federal, state, local, tribal scientists, consultants, university professors and is chaired by a member of the Team or facilitator.

Watershed Teams: Watershed Teams are comprised of the various entities implementing local restoration and conservation actions via their respective organizations and entities. There will be a watershed team for each major watershed in the MU.

Figure 12.2 in the Oregon Steelhead Recovery Plan illustrates the relationships between these groups and how they will coordinate with each other. Oregon and NMFS will produce an implementation plan with a schedule to satisfy the requirements under the ESA.

11.1.5 NMFS

NMFS' role in Middle Columbia steelhead recovery is twofold. The first is to ensure that the agency's statutory responsibilities for recovery under the ESA are met. The second is to serve as the convening partner for the Mid-C Forum and to update forum members on issues relevant to recovery strategies. Forum meetings, for example, might contain standing agenda items where updates can be provided to the members on hatchery and harvest issues.

11.1.5.1 ESA Responsibilities

NMFS is responsible for the following tasks under the ESA:

- Ensure the recovery plan meets ESA statutory requirements, tribal trust and treaty obligations, and agency policy guidelines.
- Develop DPS-wide performance measures consistent with the recovery strategy outlined in Chapter 7.
- Conduct 5-year reviews (see Section 10.2).

- Make delisting determinations.
- Coordinate with other Federal agencies to ensure compliance under the ESA.
- Implement recovery plans.

11.1.5.2 Mid-C Convening Partner

As convening partner for the Mid-C Forum, the NMFS Northwest Regional Office, working through its Middle Columbia Recovery Coordinator and Domain Team, will:

- Convene Forum meetings on a regular basis (twice a year) and convene additional meetings as needed.
- Provide meeting facilitation services and manage the meeting process.
- Provide Forum meeting venues.
- Prepare and distribute meeting notes and follow up on tasks agreed to by the Forum.
- Serve as central clearinghouse for information, to include: DPS-wide stock status, relevant Federal scientific research, and DPS-wide gaps in recovery efforts.
- As requested by the Forum, establish and facilitate state, Federal and tribal meetings necessary for the coordination of recovery activities.

11.1.6 Technical Teams

Purpose and Function:
Technical teams are ad hoc work units or groups associated with supporting on-the-ground implementation of actions, monitoring and research, or technical analysis of data. The teams are a part of the foundation of implementation**.**

Organization/Membership:
Technical teams are composed of the members or staff of various watershed councils, soil and water conservation districts, non-governmental organizations, state agencies, Federal agencies, tribes, and others that conduct recovery plan actions, research, monitoring, or evaluation in the field or in the lab.

Operations:
Teams operate within their own internal structures, but will be requested to provide information and data to their respective MU Lead to ensure appropriate tracking and coordination within management units.

11.1.7 Science Team

Purpose and Function:
The Science Team will provide science input and advice to Mid-C actions, strategies, research designs, and RM&E priorities, including scoping science needs from RM&E needs at the MU and DPS-level. The Science Team will ensure that rigorous and "best available science" informs

implementation and is applied in RM&E for all "H's" within the DPS, and assist in translating information into status of species viability. The Science Team's input will be critical to 5-year reviews of the DPS.

Organization/Membership:
The Science Team will be a standing committee of the Forum and will be composed of RIST representatives, management unit technical representatives, ODFW/WDFW/tribal co-manager technical representatives, etc. The Science Team will select its own chair. It will coordinate with existing groups (e.g., the Recovery Implementation Science Team [RIST], Independent Science Advisory Board [ISAB], and/or the Independent Multidisciplinary Science Team [IMST]) or groups formed to provide scientific expertise for a specific purpose.

Operations:
The Science Team will operate on an ad hoc basis or on a regular schedule as determined by its members and will provide science oversight and guidance to the full DPS or to each management unit, as needed. The Science Team will coordinate with management unit technical teams where necessary.

11.2 Implementation Funding

Funding for project implementation is available from a variety of sources. The role of the Forum is to ensure MU plan implementers are aware of potential sources of funds and to advocate for the funding and implementation of actions that benefit all populations in the DPS. The Forum will not supersede decisions made by the individual management unit boards but may advocate for the funding of their projects and programs if requested.

Sources of implementation funding include:

- Pacific Coastal Salmon Recovery Fund (PCSRF) (States and tribes)
- Salmon Recovery Funding Board (SRFB) (Washington)
- Oregon Watershed Enhancement Board (OWEB) (Oregon)
- Columbia Basin Fish Accords
- Congressional appropriations (Federal agencies)
- State appropriations (State agencies)
- Northwest Power and Conservation Council Fish and Wildlife Program (States and tribes)
- Federal / state grants
- Non-profit organization programs and grants

11.3 Funding for Mid-C Forum Activities

Staff time for participation in the Mid-C Forum is to be funded by participating agencies and parties. NMFS will fund venues, facilitation, and other needs associated with convening Mid-C Forum meetings.

Conservation and Recovery Plan
for Oregon Steelhead Populations in the
Middle Columbia River Steelhead Distinct Population Segment

February 2010

Richard W. Carmichael
Oregon Department of Fish and Wildlife

and

Barbara J. Taylor
Planner – Editor

With contributions from: Tim Bailey, Ron Boyce, Paula Burgess, Will Cameron, Tom Cooney, Rod French, Rosemary Furfey, Mike Gauvin, Erin Gilbert, Richard Graves, Jerry Grant, Brett Hodgson, Scott Hoefer, Damon Holzer, Sue Knapp, Larry Lestelle, Kathryn Kostow, Don Matheson, Mark Plummer, Kathy Ramsey, Tom Rien, Jeff Rodgers, Jim Ruzycki, Jesse Schwartz, Eric Tinus, Rich Turner, Randy Tweten, Tim Unterwegner, Gary Wade

ACKNOWLEDGMENTS

The Oregon Middle Columbia River Steelhead Recovery Plan represents three years of intense effort by many people from multiple disciplines. There are far too many contributors to acknowledge and thank individually; however, special recognition is deserved for the Oregon Mid-Columbia Steelhead Sounding Board who provided excellent guidance, input and support throughout the planning process. The Mid-Columbia Planning Team and Management Action teams were instrumental in providing a solid science foundation for the plan and sound future management actions that will contribute greatly to steelhead recovery in Oregon. The Mid-Columbia Expert Panel provided a valuable report on limiting factors and threats, a key element of the plan. Members of each of these groups are identified in Appendix A.

We thank Larry Lestelle who led the difficult and innovative effort to model the biological effectiveness of the management actions and Erin Gilbert for his masterful GIS mapping. This plan would never have come together without the efforts of Trish Bell. We thank Trish who contributed so much to logistics and coordination of the teams, and was instrumental in processing, compiling, and distributing the document.

Our hope is that this plan will serve as a roadmap and a vehicle to facilitate the continuation of the sound work already underway as well as accelerate improvement in habitat conditions and steelhead management. Successful plan implementation will lead to abundant, diverse, and productive steelhead populations that provide significant ecological, social, and cultural benefits.

1-1	The Middle Columbia River Steelhead DPS. Areas marked as extirpated Represent absence of only the anadromous form of *O. mykiss*	1-3
1-2	Oregon populations in the Mid-C Steelhead DPS.	1-4
1-3	Mid-C Steelhead DPS major population groups and independent populations.	1-9
1-4	Example of Abundance/Productivity viability curve	1-15
1-5	Matrix used to integrate Viable Salmonid Population parameter risk ratings and determine overall viability level.	1-17
3-1	NMFS Management Units for the Middle Columbia River Steelhead DPS.	3-2
3-2	Geographic boundaries of the Middle Columbia River Steelhead DPS.	3-9
3-3	Interior Columbia River Basin steelhead populations including populations in the Middle Columbia River Steelhead DPS (ICTRT 2003)	3-10
3-4	Critical habitat designated for salmon and steelhead in Oregon.	3-13
4-1	Hierarchical population structure within ESA-listed ESUs/DPSs, as identified by the TRTs.	4-2
4-2	Middle Columbia River Steelhead DPS major population groups and populations.	4-4
4-3	Major Population Groups and populations of the Middle Columbia River Steelhead DPS.	4-4
4-4	Independent populations within the Middle Columbia River Steelhead DPS.	4-5
5-1	Example of Abundance/Productivity viability curves including Fifteenmile Creek current abundance productivity point estimate with standard error elipse and adjusted standard error bounds.	5-10
5-2	Viable salmonid population spatial structure and diversity guidelines (McElhany et al. 2000). .	5-11
5-3	Assessing population viability across VSP criteria (ICTRT 2007).	5-13
5-4	MPG-level viability criteria identified by the ICTRT (ICTRT 2007).	5-14

FIGURES (continued)

Number		Page
5-5	DPS-level viability criteria identified by the ICTRT (ICTRT 2007).	5-17
6-1	Fifteenmile Creek Winter Steelhead population abundance and productivity compared to the DPS viability curve.	6-1
6-2	Deschutes River Eastside Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-2
6-3	Deschutes River Westside Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-4
6-4	Lower Mainstem John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-5
6-5	North Fork John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-6
6-6	Middle Fork John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-8
6-7	South Fork John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-9
6-8	Upper Mainstem John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-10
6-9	Umatilla River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-12
6-10	Walla Walla River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.	6-13
8-1	Areas within Oregon Mid-C steelhead populations that have significantly altered fire regimes and vegetative attributes that are altered from the historical condition (USFS condition class 3).	8-18
8-2	Geographic areas used in the EDT analysis for the Umatilla River Subbasin (NPCC 2004c).	8-71

FIGURES (continued)

Number		Page
8-3	Reach survival from McNary Dam to Bonneville Dam for PIT-tagged steelhead detected at McNary Dam between May 11 and June 8 for years 1999 to 2005 plotted with average spill percent at John Day, The Dalles and Bonneville dams.	8-87
8-4	Reach survival from McNary Dam to Bonneville Dam for Pit-tagged steelhead detected at McNary Dam between May 11 and June 8 for years 1999 to 2005 plotted with average water transit time for the reach McNary Dam to Bonneville Dam.	8-87
8-5	Reach survival from McNary Dam to Bonneville Dam for PIT-tagged steelhead detected at McNary Dam between May 11 and June 8 for years 1999 to 2005 plotted with average water temperature(C) measured at tailwater TDGS monitors for the reach McNary Dam to Bonneville Dam.	8-88
8-6	Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2001.	8-90
8-7	Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2002.	8-91
8-8	Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2003.	8-91
8-9	Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2004.	8-92
8-10	Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2005.	8-92
8-11	Average escapement for adult spring/summer Chinook salmon, fall Chinook salmon, and steelhead through the Federal Columbia River Power System, adjusted for known commercial and sport harvests	8-95
8-12	Number of steelhead harvested each year in Mainstem Columbia River fisheries (1866-1936) (Craig and Hacker 1940).	8-104
8-13	Commercial harvest rates on steelhead, 1938-2002 (WDFW and ODFW 2002). Non-tribal commercial harvest was discontinued in 1975.	8-104

FIGURES (continued)

Number		Page
8-14	Recreational harvest rates on steelhead in the mainstem below Bonneville Dam, 1964-2002 (WDFW and ODFW 2002). Blue is summer steelhead while pink is winter steelhead. All Mainstem fisheries became catch-and-release in 1992 and the impacts since that year were calculated by the encounter rate and an estimated release mortality.	8-105
8-15	Run timing at Bonneville Dam of steelhead and other species that are targeted in Mainstem commercial fisheries.	8-109
8-16	Number of steelhead released per number of Chinook landed by mesh size, as observed during monitoring and test fishing in 2003-2005 spring Chinook fisheries.	8-111
8-17	Relationship of Bonneville Dam wild Group A steelhead counts to estimated escapement above Nursery Bridge Dam, Oregon for run years 1993-1994 through 1996-2000.	8-123
8-18	Proportion of steelhead that are Round Butte Hatchery and out-of-subbasin hatchery origin by trapping facility: (a) Sherars Falls, (b) Pelton Trap, (c) WSNFH.	8-127
8-19	Migration timing of natural and hatchery summer steelhead smolts counted at Three Mile Falls Dam. The percentages were from weekly totals of fish divided by the respective total for the out-migration period. Daily Flow data at the lower Umatilla River gauge (RM 2.1) was averaged on a weekly interval (from Chess et al. 2003a).	8-141
8-20	Percent change in springtime water availability (March-May) from baseline conditions (1971-2000) to future conditions (2040s) and projected future relative risk to Mid-Columbia River steelhead (6^{th} field hydrologic units)	8-160
8-21	Modeled current summer (July 21-August 3) stream temperatures and growth zone characterization for Mid-Columbia River steelhead (6^{th} field hydrologic units)	8-161
8-22	Modeled future (2080) summer (July 21-August 3) stream temperatures and growth zone characterization for Mid-Columbia River steelhead (6^{th} field hydrologic units)	8-162

FIGURES (continued)

Number		Page
8-23	Projected future relative risk to Mid-Columbia River steelhead habitat (6th field hydrologic units) due to changes in summer (July 21-August 3) stream temperatures from current (2010) to future (2080) conditions	8-163
8-24	Precipitation coefficient of variation for the period (1971-2007) and relative risk for Mid-Columbia River steelhead (6th field hydrologic units)	8-164
8-25	Integrated climate change potential vulnerability risk for Mid-Columbia River steelhead (6th field hydrologic units)	8-165
9-1	Flow chart illustrating the process for development of tributary habitat strategies, actions, and programs and their characteristics	9-10
10-1	Use of EDT and AHA modeling platforms for different segments of steelhead life cycle. The EDT model covers the life stages from adults to subbasin through smolt emigration and AHA covers smolt passage through adult entry	10-3
10-2	Action integration components	10-6
10-3	Action effectiveness elements	10-13
10-4	Change in fitness in relation to proportion of strays used in AHA modeling	10-20
10-5	Estimated percent changes in population performance of Fifteenmile Creek winter steelhead due to tributary habitat actions	10-24
10-6	Estimated amounts of tributary habitat potential achieved by population performance measures resulting from tributary habitat actions applied to Fifteenmile Creek winter steelhead	10-25
10-7	Map of the Fifteenmile Creek steelhead population showing geographic areas that are currently in protected status, reaches identified as high priority for proposed protection management actions, and relative restoration benefit from high priority (priority 1) proposed restoration actions for all reaches	10-26
10-8	Map of the Fifteenmile Creek steelhead population showing geographic areas that are currently in protected status, reaches identified for proposed protection management actions (priority 1 and priority 2), and reaches with high, moderate, low and very low restoration benefit from all (priority 1 and priority 2) proposed restoration actions	10-27

Section 1 Executive Summary

This plan serves as a blueprint for the recovery of ten Middle Columbia River (Mid-C) steelhead populations that occupy Oregon tributaries to the Columbia River. The steelhead populations spawn and rear in the Fifteenmile Creek, Deschutes, John Day, Umatilla and Walla Walla river basins and are part of the Mid-C steelhead (*Oncorhynchus mykiss)* Distinct Population Segment (DPS). The DPS, which is listed as threatened under the Endangered Species Act (ESA), includes all steelhead populations in Oregon and Washington tributaries to the Columbia River upstream of the Hood and Wind river systems, up to and including the Yakima River.

The plan seeks to remove or minimize threats to the long-term persistence of Oregon's Mid-C steelhead populations and improve their viability to levels that will allow removal of the DPS from the threatened and endangered species list. The long-term goals, however, reach well beyond achieving DPS delisting. They aim to recover the populations and their habitats to levels that are not only viable, but also provide sustainable fisheries and other ecological, cultural, social and economic benefits for future generations.

Improving the status of Oregon's Mid-C steelhead populations is critical to DPS recovery. The populations play essential roles in achieving viability for three of four major population groups within the DPS. Status of most of the populations needs to improve to achieve viability criteria. The plan's recovery strategies and actions seek to remove threats to the long-term persistence of the populations and improve biological status so the populations meet viability requirements and support DPS recovery. Strategies and actions focus primarily on addressing threats to the populations posed by tributary habitat degradation, out-of-DPS hatchery strays, and hydrosystem development and operations — considered the main obstacles to recovery.

The plan provides information required by NOAA's National Marine Fisheries Service (NMFS) to satisfy the requirements of section 4(f) of the ESA and the State of Oregon's Conservation Plan requirements. It describes: 1) recovery goals and objective, measurable criteria which, when met, will result in a determination that the species be removed from the threatened and endangered species list; 2) site-specific management actions necessary to achieve the plan's goals; 3) estimates of the time required and cost to carry out the actions needed to achieve the plan's goals; and 4) direction for monitoring and evaluation and adaptive management to fine-tune our course towards recovery when needed.

The document contains:

- The institutional framework and rationale for recovery plans
- How NOAA's National Marine Fisheries Service expects to use the plan
- The regional context within which recovery plans in the Columbia Basin are written
- The relation of this plan to other planning processes and other ESA mandates
- Desired status—delisting and broad sense recovery goals; viability criteria
- The current status of listed Oregon Mid-C steelhead populations
- Gaps between current status and viable status
- Limiting factors and threats
- Recovery strategies and actions for the Oregon portion of the Mid-C steelhead DPS
- Management action effectiveness and expected outcomes
- Cost analysis
- A framework for implementation, monitoring and evaluation, and adaptive management

Still, the plan is not a regulatory document. The ESA does not require any agency or entity to implement the recovery strategies or specific actions in the recovery plan unless otherwise legally mandated (NMFS 2006a). It depends on the social and regulatory structure that currently exists for habitat, hydropower, harvest, hatchery and predation management and models the existing and expected changes for these important factors in the future. The plan identifies actions deemed necessary to achieve recovery goals, focusing on where changes can be accomplished that build upon and adapt from the existing social and regulatory programs. This approach acknowledges the policy choices that have been made in the past to maintain hydropower in the Columbia Region as well as other choices to sustain social and economic interests, while identifying actions necessary to reach recovery goals. If and when there are major changes in the underlying policy choices, this plan will need to be updated to clearly reflect these changes. While this plan identifies needed actions and priority locations, it also gives implementing agencies and citizens the flexibility to design creative, yet scientifically sound approaches that reflect site-specific conditions and support local interests.

This conservation and recovery plan will be considered a "living document." As new information becomes available, such as the outcome of the Federal Columbia River Power System Biological Opinion process, or as new information reveals the need for adaptive change, revised and additional actions will be added to the plan.

1.1 Background and Regional Context

Historically, Mid-C steelhead spawned and reared throughout central Oregon and south-central Washington. They occupied nine major Columbia River tributaries draining the east side of the Cascades Mountains, as well as numerous smaller systems. Major river systems include the White Salmon, Deschutes, John Day, Klickitat, Umatilla, Walla Walla, and Yakima rivers and Fifteenmile, Rock, and Willow creeks (Figure 1-1).

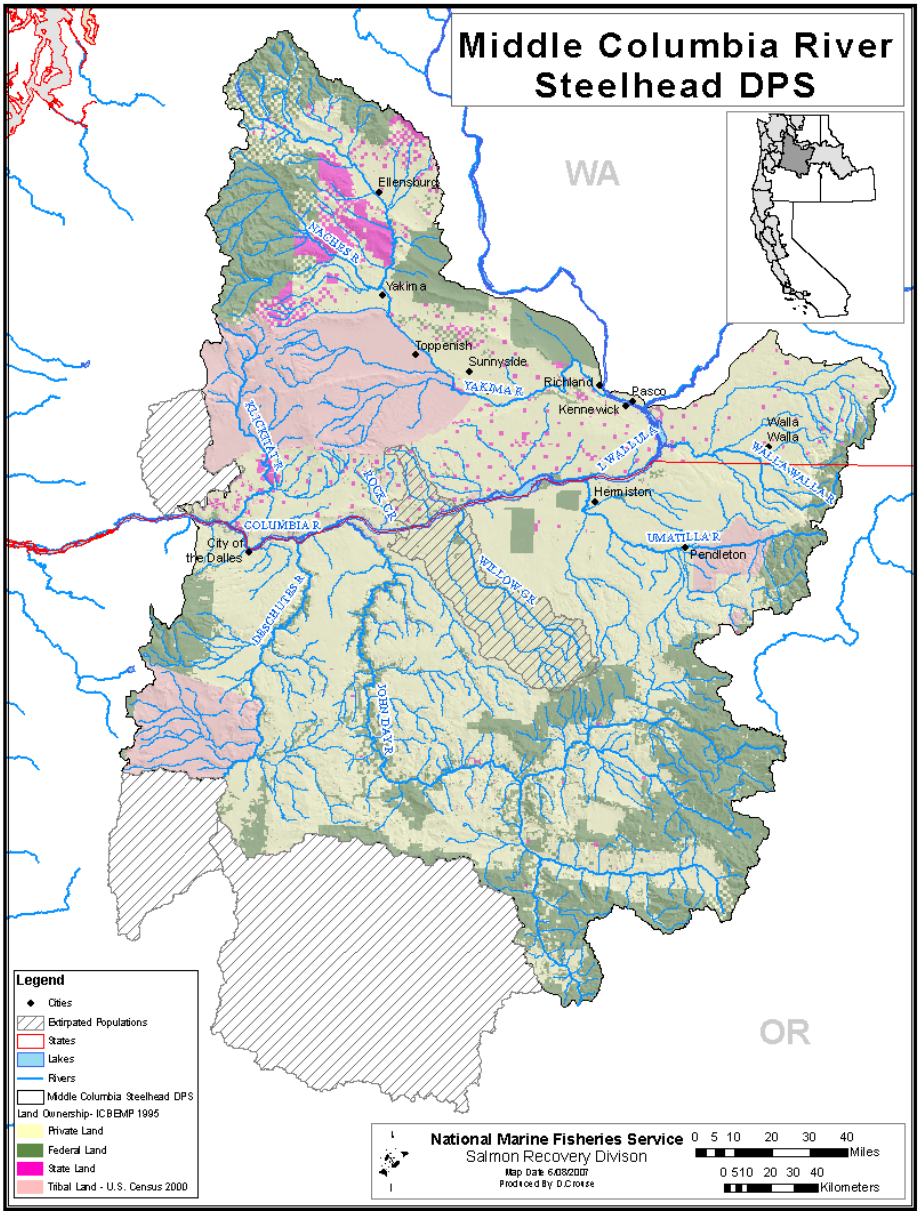

Figure 1-1. The Middle Columbia River Steelhead DPS. Areas marked as extirpated represent absence of only the anadromous form of *O. mykiss*.

By the late 1900s, Mid-C steelhead populations had experienced significant declines in abundance as a result of loss, damage or change to their natural environment. On March 25, 1999, NMFS listed Oregon's Mid-C steelhead populations as threatened under the Endangered Species Act as part of the Middle Columbia River steelhead Evolutionarily Significant Unit (ESU) (69 FR 33101). The ESU included both anadromous and resident forms of the biological species *Oncorhynchus mykiss (O.mykiss).* Recently, NMFS revised its species determinations for West Coast steelhead under the ESA, delineating anadromous, steelhead-only "distinct population segments" (DPS). NMFS listed the Middle Columbia River steelhead DPS as threatened on January 5, 2006 (71 FR 834). The DPS consists of all historical steelhead populations in Oregon and Washington tributaries of the Columbia River upstream of the Hood

and Wind river systems, up to and including the Yakima River. It is one of 17 ESUs and DPSs of salmon and steelhead in the Pacific Northwest listed under the ESA.

The populations remain highly valued by Native Americans and many other people in the Pacific Northwest. The steelhead populations have long had important tribal subsistence, ceremonial and commercial values for Native Americans, including the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes and Bands of the Yakama Nation, and the Confederated Tribes of the Warm Springs Reservation of Oregon. Native Americans continue to maintain strong cultural values for steelhead and salmon species. Northwest Indian tribes hold legally enforceable treaty rights reserving to them a share of the salmon harvest. Local communities and others in the region also treasure the steelhead populations and their habitats as important resources, and want to see them rebuilt to sustainable, harvestable levels. All of these rights and expectations will not necessarily be fully met by achieving only the basic purpose of the ESA and delisting of the species, although it will lead to major improvements in the current situation. The recovery plan's broad sense goals and objectives address these and other issues.

1.2 A Cooperative Effort

This conservation and recovery plan is one piece of a larger, integrated recovery plan for the entire DPS. It addresses factors limiting the viability of Mid-C steelhead populations within the State of Oregon (Figure 1-2). The DPS-level recovery plan also includes individual recovery plans for the other areas in the DPS.

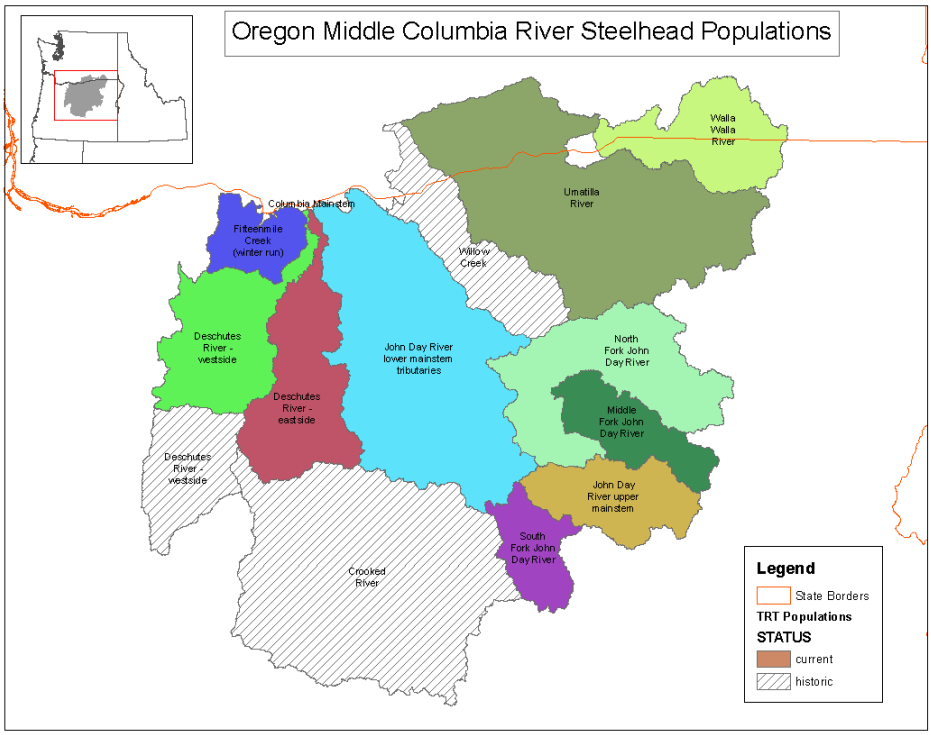

Figure 1-2. Oregon populations in the Mid-C Steelhead DPS.

State of Oregon Recovery Planning

The State of Oregon led the development of this recovery plan for Oregon Mid-C steelhead in partnership with NMFS, other natural resource agencies, the tribes, and local communities. The State's approach to recovery planning is grounded in an understanding that the challenges of steelhead recovery are immense—particularly in the face of growing human populations and demands for clean water and other precious resources. The recovery plan was developed to parallel and build from the Oregon Plan and the Oregon Conservation Strategy.

The Oregon Department of Fish and Wildlife facilitated the plan's development through a collaborative process with broad technical, stakeholder and public involvement. We have involved critical players at each stage in the decision-making process. Oregon's recovery planning forums include the Middle Columbia Sounding Board, the Mid-Columbia Recovery Planning Team, and Management Action Teams. We are relying heavily on these different players to make sure that our recovery strategy for Oregon Mid-C steelhead in scientifically sound and defendable. This involvement is vital for the plan's successful implementation.

- *Middle Columbia Sounding Board (MCSB).* The MCSB consists of representatives of local communities, agricultural and timber interests, land managers, governing bodies, tribes, and industry and environmental interests. The MCSB provides policy guidance in the development of all aspects of the plan and ensures selection of locally appropriate and locally supported recovery actions needed to achieve species recovery goals. The MCSB was particularly instrumental in the development of broad sense recovery goals, recovery scenarios, recovery strategies, strategic guidance for development and prioritization of management actions, and implementation planning.

- *Mid-Columbia Recovery Planning Team.* The recovery planning team includes state, Federal, Tribal, and watershed council technical representatives across the DPS. The team provided technical guidance and writing for all aspects of the plan.

- *Management Action Teams.* The three management action teams include local experts representing state and federal natural resource agencies, the tribes, watershed councils and Portland General Electric. The teams developed management actions for the ten steelhead populations.

Oregon recovery planners also incorporated findings from groups with broader areas of responsibility than the Mid-Columbia, including the Interior Columbia Technical Recovery Team and the Oregon Expert Panel.

- *Interior Columbia Technical Recovery Team (ICTRT).* The ICTRT, appointed by NMFS, provides geographic and species expertise for the entire Interior Columbia domain. The team includes biologists from NMFS, state, tribal and local entities, academic institutions, and private consulting firms. The ICTRT plays an important role in recovery planning, including developing ESU/DPS and population viability criteria that will be used, along with threats-based criteria, to determine whether a species has recovered sufficiently to be downlisted to threatened (if endangered) or delisted.

- *Oregon Expert Panel.* The Expert Panel was created by the Oregon Department of Fish and Wildlife for purposes of recovery planning and consisted of biologists with significant knowledge of the limiting factors and threats influencing Oregon's listed salmon and steelhead populations. Panelists identified common key and secondary threat themes for the populations.

Involvement by these different entities helps ensure that recovery goals and actions are consistent and compatible with the goals and direction adopted in related efforts. This integrated approach establishes partnerships that allow actions to be implemented effectively and efficiently.

1.3 Delisting the DPS

The overarching aim of this recovery plan is removal of the Middle Columbia River steelhead DPS from the threatened and endangered species list. Section 4(a) (1) of the ESA and NMFS implementing regulations (50 CFR part 424) establish procedures for listing species. According to this direction, the Secretary of Commerce must determine if a species is endangered or threatened because of any one or a combination of the following factors: (1) the present or threatened destruction, modification, or curtailment of its habitat or range; (2) overutilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) inadequacy of existing regulatory mechanisms; or (5) other natural or human-made factors affecting its continued existence.

Listing Factors

In its initial determination to list the species, NMFS found (1996, 1997) that all five listing factors had played a role in the decline of the West Coast salmon and steelhead ESUs. These factors may or may not still be limiting recovery in the future when NMFS reevaluates the status of the species to determine whether the protections of the ESA are no longer warranted and the species may be "delisted." Findings leading to the listing of West Coast salmon and steelhead, including Mid-C steelhead, include:

1. *The present or threatened destruction, modification, or curtailment of its habitat or range*. Salmon and steelhead have experienced declines in abundance over the past several decades as a result of loss, damage or change to their natural environment. Water diversions, forestry, agriculture, mining, and urbanization have eliminated, degraded, simplified, and fragmented habitat. Hydroelectric development on the mainstem Columbia River modified natural flow regimes and impaired fish passage. Tributary obstructions also restrict or block salmon and steelhead access to historical habitats.

2. *Overutilization for commercial, recreational, scientific, or educational purposes.* Overfishing in the early days of European settlement led to the depletion of many salmonid stocks before extensive modifications and degradation of natural habitats, and exploitation rates following the degradation of many aquatic and riparian ecosystems were higher than many populations could sustain. Today, steelhead harvest continues on

the Columbia River, tributaries and Pacific Ocean; however, fishery impacts have declined significantly because of changes in fishery management.

3. *Disease or predation.* Introductions of non-native species and habitat modifications have resulted in increased predator populations in numerous rivers. Predators on adult and juvenile steelhead include seabirds, such as Caspian terns, walleye and California sea lions.

4. *Inadequacy of existing regulatory mechanisms.* Various federal, state, county and tribal regulatory mechanisms are in place to reduce habitat loss and degradation caused by human use and development. Many of these mechanisms have been improved over the years to slow the habitat degradation and destruction. Protective efforts directed toward addressing the many factors that adversely impact Mid-C steelhead and habitat—water quality and quantity, safe migration, riparian vegetation, food, predation dynamics and complex stream channels, and floodplain connectivity—will aid in improving these factors.

5. *Other natural or human-made factors affecting its continued existence*. Variability in ocean and freshwater conditions can have profound impacts on the productivity of salmonid populations and, at different times, have exacerbated or mitigated the problems associated with degraded and altered riverine and estuarine habitats.

NMFS listed the Middle Columbia River ESU in response to a biological review that concluded that summer steelhead in the ESU were "likely to become endangered in the foreseeable future" (NMFS 1999). Prominent features leading NMFS to list the ESU included: (1) declines in abundance of wild steelhead populations, (2) levels of abundance well below historical levels, (3) large numbers of hatchery-origin steelhead entering the Deschutes River basin, and a lack of information regarding this phenomenon, (4) large numbers of hatchery steelhead relative to wild steelhead and a general lack of information regarding the impacts of hatchery steelhead on wild steelhead populations throughout the region, (5) a lack of information regarding the interactions between resident rainbow trout and anadromous steelhead, and (6) habitat alterations in the region resulting in a loss of spawning and rearing habitat for steelhead, including habitat changes that have exterminated some steelhead runs (Busby et al. 1996; NMFS 1999).

Critical Habitat

NMFS designated critical habitat for Mid-C steelhead and 12 other ESUs of salmon and steelhead in a final rule that took effect on January 2, 2006. Essential features of designated critical habitat include substrate, water quality, water quantity, water temperature, food, riparian vegetation, access, water, velocity, space, and safe passage. The Critical Habitat Assessment Review Team (CHART) has rated the conservation value of all 5th-field HUCs supporting populations of Mid-C steelhead. Section 3 of the draft recovery plan discusses the physical and biological primary constituent elements (PCEs) identified as essential to the conservation of the species and shows streams designated critical habitat for Mid-C steelhead.

1.4 DPS Structure — A Hierarchical Steelhead Organization

Our approach to recovery recognizes that a hierarchical steelhead organization structure exists in the DPS. This hierarchical structure extends from the DPS level to a level below the independent population, with individual steelhead in the DPS often sharing more genetic and life history similarities with their closest neighbors than with steelhead from other parts of the DPS. The homing propensity, distribution across the landscape, and the diverse genetic, life history and morphological characteristics that evolve contribute significantly to this hierarchical structure and the species long-term persistence.

The ICTRT has identified three levels in this hierarchy that reflect genetic, geographic (hydrographic) and habitat considerations in the DPS (ICTRT 2003). The State of Oregon adopted this biological hierarchy for purposes of Mid-C steelhead recovery planning.

- *Evolutionarily Significant Units and Distinct Population Segments* listed under the ESA must be substantially reproductively isolated from other nonspecific units, and represent an important component of the evolutionary legacy of the species (Waples 1991).

- *Major Population Groups (MPGs)* are independent populations in an ESU or DPS that share similar genetic, geographic (hydrographic and ecoregion), and/or habitat characteristics (ICTRT 2003). The ICTRT defined a grouping as a Major Population Group (MPG), which is analogous to "strata" as defined by the Lower Columbia-Upper Willamette TRT and "geographic region" described by the Puget Sound TRT.

- *Independent Population* as defined by McElhany et al. (2000) is "a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season. For our purposes, not interbreeding to a 'substantial degree' means that two groups are considered to be independent populations if they are isolated to such an extent that exchanges of individuals among the populations do not substantially affect the population dynamics or extinction risk of the independent populations over a 100-year time frame."

The ICTRT divided the Mid-Columbia steelhead DPS into four major population groups: Cascades Eastern Slope Tributaries MPG, Yakima River MPG, John Day River MPG and Umatilla/Walla Walla Rivers MPG (Figure 1-3). Three of these MPGs contain Mid-C steelhead from Oregon tributaries.

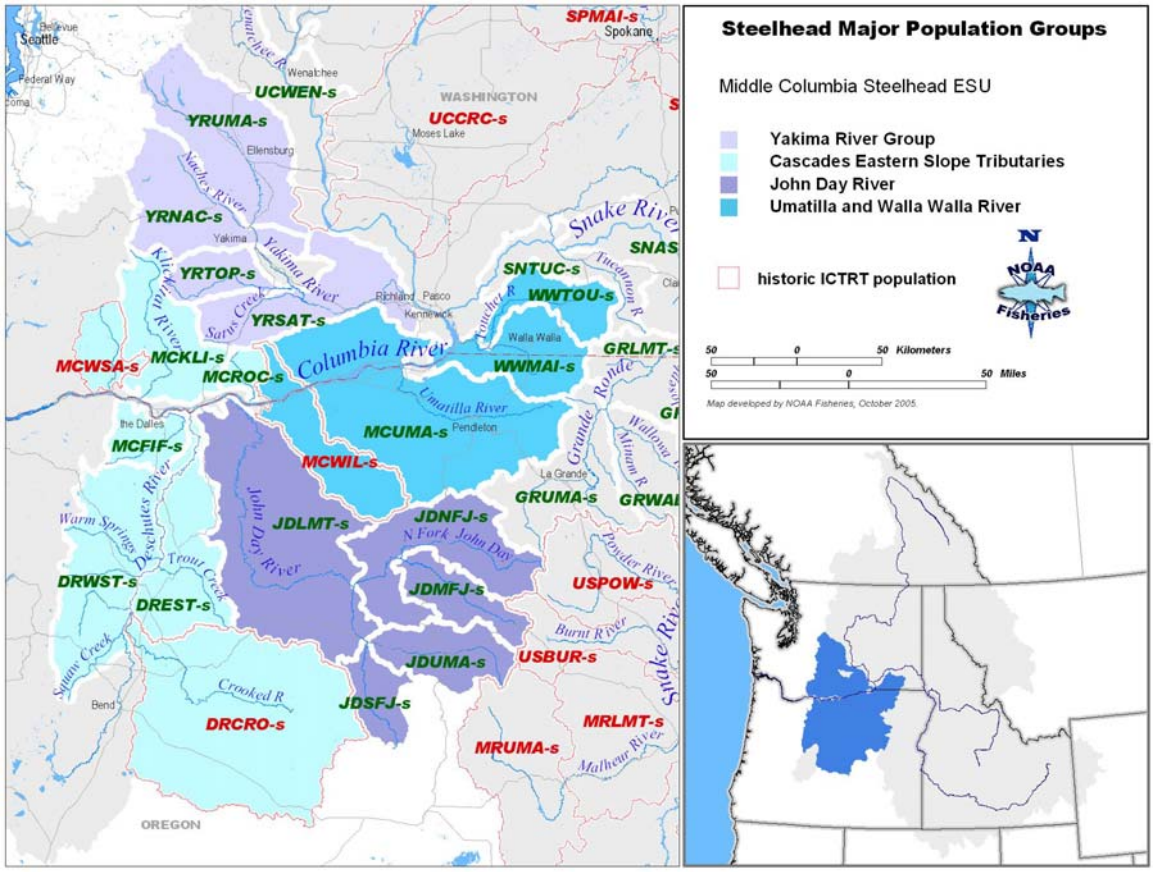

Figure 1-3. Mid-C Steelhead DPS major population groups and independent populations.

Major Population Groups and Oregon Populations

The three MPGs that support Oregon Mid-C steelhead, and the Oregon populations within them, are the focus of this recovery plan and are discussed below. Independent populations are the units that will be combined to form alternative recovery scenarios for MPG and DPS viability.

Cascades Eastern Slope Tributaries MPG

The Cascades Eastern Slope Tributaries MPG contains five extant populations (Fifteenmile Creek, Deschutes River Westside, Deschutes River Eastside, Klickitat and Rock Creek) and two extinct populations (White Salmon and Crooked River). Populations in this MPG are united primarily by geographic proximity. The Columbia River tributaries that support them generally drain the eastern slope of the Cascades and the dry Columbia Plateau, and display varied habitat conditions. The MPG supports summer and winter run life history forms of steelhead. It contains three extant and one extinct Oregon populations:

1. The *Fifteenmile Creek* population occupies Fifteenmile Creek and its tributaries, Fivemile, Eightmile and Ramsey creeks. It also includes five drainages outside of the Fifteenmile Creek watershed, Threemile, Mill, Chenoweth, Mosier, and Rock creeks, that flow directly into the Columbia River. Fifteenmile Creek steelhead are exclusively

winter run fish and are considered the easternmost distribution of winter steelhead in the Columbia basin.

2. The *Deschutes River Eastside* population encompasses the mainstem Deschutes River from its mouth to the confluence of Trout Creek and the tributaries entering the Deschutes from the east, including Buck Hollow, Bakeoven, and Trout creeks. Steelhead in this population are exclusively summer run fish.

3. The *Deschutes River Westside* population covers the mainstem Deschutes River upstream from the mouth of Trout Creek and tributaries entering the Deschutes from the west. Current steelhead access extends from Trout Creek to the Pelton Re-regulating Dam on the mainstem Deschutes and into the Warm Springs River, Shitike Creek and several smaller tributaries. Pelton Dam, a hydroelectric dam at RM 100 on the Deschutes River, blocks all anadromous fish passage to historical habitat above the dam, including areas in the Metolius River and Whychus Creek. The population is a summer run. It is separated from the eastside tributary population based on habitat and life history characteristics.

4. The *Deschutes Crooked River* population once occupied the Crooked River drainage, a major watershed in the Deschutes basin. The population is now extinct because of the lack of passage above Pelton Dam. A current management agreement and plan aim to re-establish steelhead production within the population's boundaries.

John Day River MPG

The John Day River MPG covers Oregon's John Day River drainage. The MPG contains five extant populations (Lower Mainstem John Day, North Fork John Day, Middle Fork John Day, South Fork John Day and Upper Mainstem John Day). Steelhead in these populations are exclusively summer steelhead. The MPG is one of the few remaining summer steelhead groups in the Interior Columbia basin that has had no intentional influence from introduced hatchery steelhead and that has recently been classified as strong or healthy (Lee et al. 1997; Huntington et al. 1994). Spawning is widely distributed across tributary and mainstem habitats.

1. The *Lower Mainstem John Day River* population includes tributaries to the John Day River downstream of the South Fork John Day River. This widespread population is the most differentiated ecologically from other populations, occupying the lower, drier, Columbia Plateau ecoregion.

2. The *North Fork John Day River* population occupies the highest elevation, wettest area in the John Day basin. Population boundaries include the main stem and tributaries of the North Fork John Day River. The population was defined based on habitat characteristics, basin topography, and demographic patterns.

3. The *Middle Fork John Day River* population resides in the Middle Fork John Day and all its tributaries. Spawning areas in the Middle Fork John Day River are separated substantially from all other spawning areas; except for those in the North Fork John Day, that exhibit different habitat characteristics.

4. The *South Fork John Day River* population occupies the South Fork John Day River drainage. The independent population was defined based on genetic information and basin topography.

5. The *Upper Mainstem John Day River* population includes the mainstem John Day River and tributaries upstream from the South Fork. It is separated from the lower mainstem based on habitat differences and from the South Fork because of topography.

Umatilla/Walla Walla Rivers MPG
This major group includes three extant populations (Umatilla River, Walla Walla River and the Touchet River, a tributary of the Walla Walla River in Washington State) and one extinct population (Willow Creek). The Umatilla and Walla Walla rivers drain the northwestern slopes of the Blue Mountains, with lower reaches in the warmer, drier habitats of the Columbia Plateau. Genetic information, distance between spawning aggregates and ecoregional classifications contributed to ICTRT population delineations within this major group. The entire Umatilla drainage and part of the Walla Walla lie within the State of Oregon's borders and are addressed in this plan.

1. The *Umatilla River* population spawns and rears in the Umatilla watershed and several small tributaries to the Columbia River in eastern Washington State. The population is separated from the Walla Walla River based on genetic analysis and distance.

2. The *Walla Walla River* population occupies much of the Walla Walla drainage. One major tributary to the Walla Walla River, the Touchet River, is considered a separate population based on genetic analyses.

3. The *Willow Creek* population is extinct. It was designated as an independent population based on geographic distance from other populations and capacity sufficient to support an independent population.

1.5 Desired Status — Delisting and Broad Sense Recovery

The desired status for Oregon's Mid-C steelhead populations is two-tiered. First, the populations must reach desired levels of biological viability to support removal of the DPS from the threatened and endangered species list. Second, the State of Oregon and the Middle Columbia Sounding Board seek to rebuild the populations to provide for sustainable fisheries and other ecological, cultural, social and economic benefits. The recovery goals, viability criteria and potential recovery scenarios described in the plan are summarized below.

Delisting Goal

Our primary goal is to support removal of the Mid-C steelhead DPS from the threatened and endangered species list. This requires that the populations must reach the levels of biological viability defined by the ICTRT and adopted by the State of Oregon in this plan as delisting criteria. In the context of recovery, delisting criteria and viability criteria are considered

synonymous. Achieving ICTRT biological viability status at the population and MPG levels is needed before the DPS can be considered at low risk of extinction and a candidate for delisting.

To attain viability at the MPG level, the populations included in the viable MPG-level scenarios must be at or above viable status as defined by the ICTRT's viability criteria (ICTRT 2006). In addition, the criteria require that other extant populations within a MPG must be maintained at sufficient levels to provide for ecological functions and to preserve options for DPS recovery so that overall MPG productivity does not fall below replacement. Further, this plan recommends a staged, adaptive approach to recovery planning and implementation. Such an approach gives highest priory initially to implementing actions within currently occupied areas and, thus, to improving the status of extant populations and MPGs.

Broad Sense Recovery Goal

After achieving steelhead recovery under the ESA, the State of Oregon aims to rebuild Oregon's Mid-C steelhead populations to levels that will provide for sustainable fisheries and other ecological, cultural and social benefits consistent with achievement of the goals of the Oregon Plan for Salmon and Watersheds. Although broader than the definition of delisting provided by the ESA, these broad sense goals incorporate many of the traditional uses, as well as rural and Native American values, deemed important in the Pacific Northwest.

Oregon's broad sense recovery goal for Mid-C steelhead is founded on a belief that citizens throughout the region value and enjoy the substantial ecological, cultural, social, and economic benefits that are derived from having healthy, diverse populations of steelhead. The Middle Columbia Sounding Board (2006) identified the following broad sense recovery goal:

> *Oregon's Mid-Columbia River natural steelhead populations are sufficiently abundant, productive, and diverse (in terms of life histories and geographic distribution) so that they provide significant ecological, social, cultural, and economic benefits.*

Recovery of Mid-Columbia steelhead populations will require actions that preserve, enhance and restore healthy watershed conditions where ecosystem functions, processes and dynamics are intact, including instream conditions, riparian habitat diversity and complexity, and upland watershed health, in concert with complementary management of harvest, hatcheries and hydropower. Recovery is a process that leads to steelhead populations that are not only viable, but that also provide a harvestable surplus for the treaty tribes and for all other citizens of the region.

This vision for broad-sense recovery incorporates ESA delisting goals in the sense that delisting would be achieved *first* during an extended and stepwise process of achieving broad sense recovery goals. ESA delisting criteria are entirely science-based and establish the biologically-based standards required to sustain the DPS. In contrast, broad-sense recovery represents a level of population and DPS performance that will considerably exceed the delisting level.

Recovery Objectives

By the year 2050, proponents of Oregon's Mid-Columbia River Steelhead Recovery Plan intend to achieve the following objectives:

1. Middle Columbia steelhead are viable throughout the historical range and no longer need protection under the ESA;
2. All currently extant Middle Columbia steelhead populations are highly viable;
3. Extirpated populations (e.g. Willow Creek, Crooked River) are restored in a manner that engages landowner cooperation and does not subject landowners to ESA regulation based on the presence of previously extirpated populations until the introduced populations are self-sustaining and become part of the listed DPS;
4. All extant populations of Middle Columbia steelhead are capable of contributing ecological, social, cultural, and economic benefits on a regular and sustainable basis;
5. Working in concert with existing agreements and collaboratively with landowners and resource managers NOAA will define a suite of additional land and water resource management principles and practices that when followed will alleviate liability for possible ESA regulatory consequences to landowners and resource managers;
6. Out-of-basin limiting factors are addressed equitably and in concert with in-basin limiting factors;
7. Landowners, land managers and agencies are provided with guidance on the protection and management of habitats to promote the recovery of Mid-C steelhead; and,
8. Land and resource managers work with communities and other interests in a coordinated manner to achieve broad sense recovery through a shared vision of conservation where options and choices are preserved for future generations.

Viability Criteria and Approach

The ICTRT's biologically based viability criteria provided the stepping stones for assessing the status of populations in the DPS and identifying future conditions that, when met, would describe viable populations. The State of Oregon adopted the ICTRT's viability criteria as its delisting criteria.

Under the approach, viability assessments are first conducted for the independent populations. The population-level assessments provide the basis for evaluating viability at the next hierarchical level, the MPG. The MPGs then need to meet viability criteria for the DPS to be rated as viable. This approach is consistent with the Viable Salmonid Populations (VSP) guidelines (McElhany et al. 2000), as well as related applications by the Puget Sound and Willamette/Lower Columbia TRTs and the Upper Columbia QAR, and information reviewed for listed Interior Columbia ESU and DPS populations. Section 5.1 describes the ICTRT's viability criteria that address these abundance, productivity, spatial structure and diversity considerations. The ICTRT recommends that the criteria be met to remove the DPS from its listed status under the ESA.

Population-level Viability Criteria

According to McElhany et al. (2000): "*A viable population should be large enough to: 1) have high probability of surviving environmental variation observed in the past and expected in the future; 2) be resilient to environmental and anthropogenic disturbances; 3) maintain genetic diversity; and, 4) support/provide ecosystem functions.*"

The viability criteria address four VSP parameters at the population level:

- *Abundance* – the average number of spawners in a population over a generation or more,
- *Productivity* – the performance of a population over time in terms of recruits produced per spawner,
- *Spatial Structure* – a population's geographic distribution and the processes that affect that distribution, and
- *Diversity* – the distribution of genetic, life history and phenotypic variation within and among populations.

The ICTRT grouped these parameters into two categories: measures addressing abundance and productivity, and measures addressing spatial structure and diversity. The viability of an independent population is determined by integrating risks across the four VSP parameters.

Population Abundance and Productivity Parameters

The ICTRT's objective for abundance and productivity criteria is that: abundance should be high enough that 1) in combination with intrinsic productivity, declines to critically low levels would be unlikely assuming recent historical patterns of environmental variability; 2) compensatory processes provide resilience to the effects of short term perturbations; and, 3) subpopulation structure is maintained (e.g., multiple spawning tributaries, spawning patches, life history patterns) (ICTRT 2007).

The ICTRT used the viability curve concept (e.g., LC/W TRT 2003) as a framework for defining population-specific abundance and productivity levels to meet the objective. A viability curve shows the extinction risks posed by different combinations of abundance and productivity. The ICTRT generated viability curves for each population to identify the combinations of abundance and productivity corresponding to a range of extinction risks—1% (very low), 5% (low), and 25% (moderate) over a 100-year period (Figure 1-4). It targeted population level recovery strategies to achieve less than a 5% (low) risk of extinction in a 100-year period. This is consistent with the VSP guidelines and conservation literature (McElhany et al. 2000; NRC 1995).

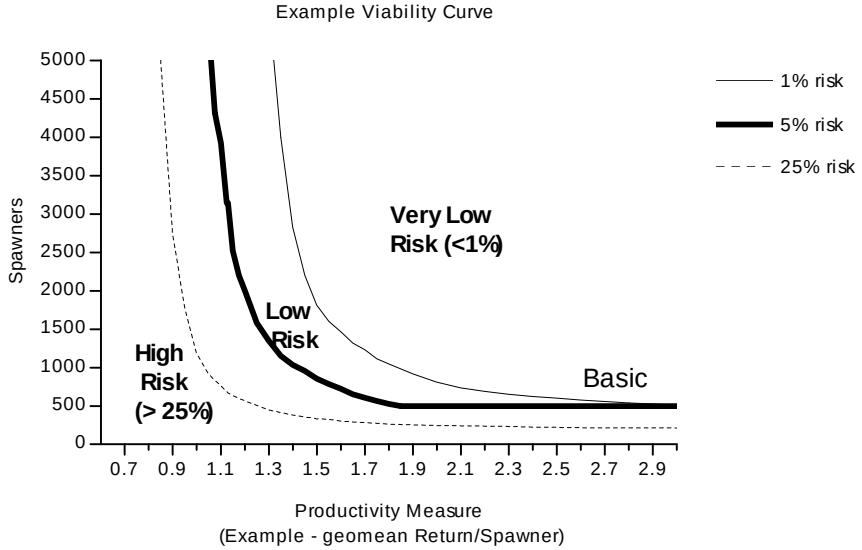

Figure 1-4. Example of Abundance/Productivity viability curve.

The ICTRT established a minimum abundance threshold of 500 individuals for a Basic size population based on its determination that abundance levels below 500 individuals for any population would pose unacceptable risk for inbreeding depression and other genetic concerns. It established higher minimum abundance thresholds incrementally for the three larger population sizes — Intermediate (1,000 spawners), Large (1,500 spawners) and Very Large (2,250 spawners). Viability curves for all four size categories were truncated at the minimum abundance threshold level. The ICTRT also categorized the populations by historical spatial distribution pattern and complexity (Table 1-1).

Table 1-1. Population characteristics and minimum abundance and productivity (at the threshold abundance level) values that represent levels needed to achieve a 95% probability of persistence over 100 years for Oregon Mid-C steelhead populations.

Population	Extant/ Extinct	Life History	Size	Spatial Category	Threshold Abundance	Minimum Productivity
Cascades Eastern Slope Tributaries MPG						
Fifteenmile Creek	Extant	Winter	Basic	C-Trellis	500	1.56
Deschutes River E.	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35
Deschutes River W.	Extant	Summer	Large (Inter.) [a]	B-Dendritic	1,500 (1,000)	1.35
Deschutes/Crooked	Extinct	Summer	Very Large	B-Dendritic	2,250	1.19
John Day River MPG						
L. Main John Day R.	Extant	Summer	Very Large	B-Dendritic	2,250	1.19
NF John Day R.	Extant	Summer	Large	B-Dendritic	1,500	1.26
MF John Day R.	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35
SF John Day R.	Extant	Summer	Basic	B-Dendritic	500	1.56
U. Main John Day R.	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35
Umatilla/Walla Walla Rivers MPG						
Willow Creek	Extinct	Summer	Intermediate	B-Dendritic	1,000	1.35
Umatilla River	Extant	Summer	Large	B-Dendritic	1,500	1.26
Walla Walla River	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35

[a] Large size category is for historically accessible area; intermediate size category is for currently accessible area.

Spatial Structure and Diversity Parameters

The ICTRT identified two primary goals that spatial structure and diversity criteria should address: 1) maintain natural rates and levels of spatially mediated processes, and 2) maintain natural patterns of variation. It also identified mechanisms, factors and metrics for assessing a population's spatial structure and diversity. Mechanisms are biological or ecological processes that contribute to achieving the goals, factors are characteristics of a population or its environment that influence mechanisms, and metrics are conditions that can be measured and assessed at regular intervals to determine whether a population has achieved goals or to evaluate its current risk level.

Goal 1: *Maintain natural rates and levels of spatially-mediated processes.*
Metrics:

a. Number and distribution of spawning areas
b. Spatial extent and range relative to historical
c. Changes in gaps between spawning areas

Goal 2: *Maintain natural levels of variation.*
Metrics:

a. Changes and loss of major life history strategies
b. Variation and loss of phenotypic traits, run timing
c. Genetic variation
d. Spawner composition, proportion and origin of natural spawning hatchery fish
e. Changes in use of major habitat types (ecoregions)
f. Selective mortality factors: Hydrosystem, Hatcheries, Harvest, Habitat

Section 5.1 provides a more detailed discussion of these goals and the mechanisms, factors and metrics for rating spatial structure and diversity risks.

Integrating the Four Parameters

The ICTRT's population level criteria allowed us to identify populations performing at Viable or Highly Viable levels. We identified these populations by using a simple matrix approach that integrates all four viable salmonid population parameters. The abundance/productivity (A/P) risk level combines the abundance and productivity criteria using a viability curve. The spatial structure/diversity (SS/D) risk level integrates across the measures of spatial structure and diversity.

Under this approach, Viable and Highly Viable populations are rated directly as specific combinations of A/P and SS/D risk ratings (Figure 1-5). Populations with a Very Low rating for A/P and at least a Low rating for SS/D are considered to be Highly Viable. Population rated at Moderate or High risk for A/P, or High risk for SS/D have a risk of extinction greater than 5% and are not considered Viable. These individual population ratings are then integrated to determine viability at the MPG level. ICTRT criteria require a minimum number of populations within an MPG to be at or above viable status, with additional MPG populations maintained at sufficient levels to provide for ecological functions and to preserve options for DPS recovery.

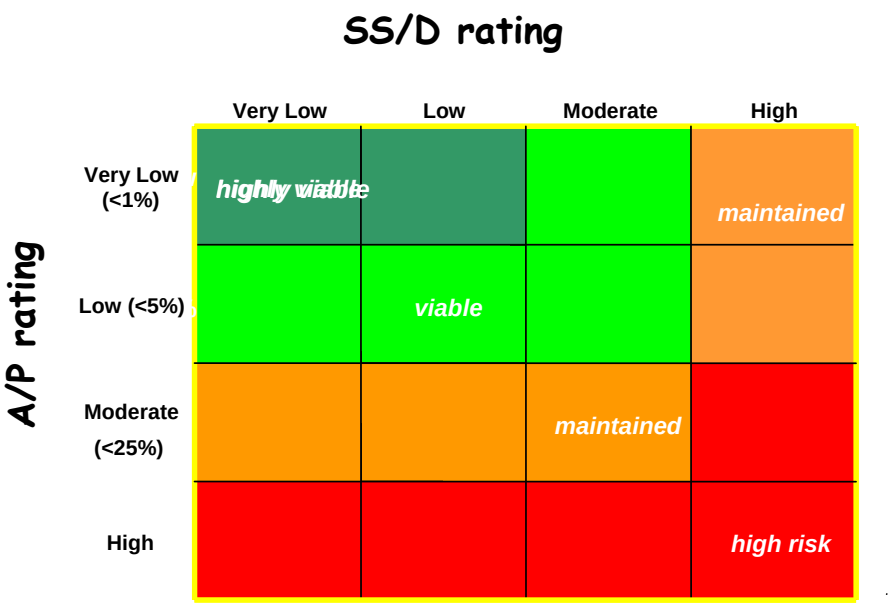

Figure 1-5. Matrix used to integrate Viable Salmonid Population parameter risk ratings and determine overall viability level.

DPS and MPG-level Viability Criteria

The ICTRT framed its ESU/DPS and MPG-level viability criteria to ensure preservation of basic historical metapopulation processes within the DPS, including 1) genetic exchange across populations over a long time frame; 2) the opportunity for neighboring populations to serve as source areas in the event of local population extirpations; 3) population distribution so that they are not all susceptible to a specific localized catastrophic event (ICTRT 2007). Its ESU/DPS-level viability criterion recognizes that MPGs within the DPS likely functioned historically as metapopulations.

DPS-level viability criteria

The ICTRT provided the following criterion to describe the biological characteristics of a viable ESU or DPS:

> All extant MPGs and any extirpated MPGs critical for proper functioning of the ESU or DPS should be at low risk.

MPG-level viability criteria

The ICTRT defined five criteria that a MPG must meet to be regarded as at low risk:

1. At least one-half of the populations historically within the MPG (with a minimum of two populations) must meet viability standards.
2. At least one population must be categorized as being "Highly Viable."
3. Viable populations within an MPG must include some populations classified (based on historical intrinsic potential) as "Very Large", "Large" or "Intermediate" generally

reflecting the proportions historically present within the MPG. In particular, Very Large and Large populations should be at or above their composite historical fraction within each MPG.

4. Populations not meeting viability standards should be maintained with a) sufficient productivity so the overall MPG productivity does not fall below replacement, and b) sufficient spatial structure and diversity demonstrated by achieving Maintained standards.
5. All major life history strategies (e.g., summer and winter run-timing) that were present historically within the MPG must be represented in populations meeting viability requirements.

The population level assessments provide the basis for evaluating viability at the MPG level and, in turn, the DPS as a whole. The combined effects of requiring each MPG to sustain a minimum number of viable populations, a representation of larger size classes of populations and major life history patterns, and the maintenance requirement provide for a network of populations that would sustain the DPS. Revisiting population delineation and viability criteria when new information becomes available is considered an essential element of the adaptive management plan that guides implementation.

Threats Criteria

The listing factor (threats) criteria are the measures that NMFS will use to reevaluate the status of the Mid-C steelhead DPS. They are based on the features that were evaluated under section 4(a)(1) when the initial determination was made to list the species for protection under the ESA. Recovery plans are required to contain these criteria. At the time of a delisting decision, NMFS will use the criteria to determine whether the section 4(a)(1) listing factors have been adequately addressed, i.e., whether the underlying causes of decline have been addressed and mitigated and are not likely to re-emerge. The listing factor (threats) criteria, which will be used to reevaluate the status of Oregon's Mid-C steelhead, are included in the DPS-level recovery plan for Mid-C steelhead and are not repeated in this plan. Threats criteria are described in detail in NOAA's Mid-C DPS Recovery Plan.

Potential MPG-level Recovery Scenarios

Several scenarios or combinations of populations would satisfy the MPG level viability criteria for the three MPGs containing Oregon Mid-C steelhead populations. The populations included in each of these scenarios were selected based on unique characteristics (e.g. run timing, population size, genetic characteristics), major production areas in the MPG, and spatial distribution of the populations.

The State of Oregon aims to improve more than the minimum number of populations identified in the recovery scenarios for viability. We acknowledge that targeting only the minimum number of populations would likely result in failure to achieve our goals. There is considerable uncertainty in the management actions and how effective they will be in improving population viability. This uncertainty will result in some targeted populations not achieving the desired status. To hedge against this uncertainty, more than the minimum number of populations must be targeted for viable status. Therefore, we also seek to improve all extant Oregon populations

in the MPGs to be maintained at sufficient levels to provide for ecological functions and to preserve options for DPS recovery. This is consistent with ICTRT criteria that recommend that more than the minimum number of populations be improved to a viable status.

Cascades Eastern Slope Tributaries MPG
The following recovery scenario exists for the Cascades Eastern Slope Tributaries MPG:

Population Characteristics:

Independent Populations	Size Category	Life History Type
White Salmon (extirpated)	Basic	Unknown
Klickitat River	Intermediate	Summer/winter
Deschutes River Eastside	Intermediate	Summer
Deschutes River Westside	Large	Summer
Crooked River (extirpated)	Very Large	Summer
Fifteenmile Creek	Basic	Winter
Rock Creek	Basic	summer

Recovery Scenario:

- Four populations must meet viability criteria, one of which must meet highly viable criteria.
- Fifteenmile Creek is the only winter population and thus must meet viability criteria.
- One Large or Very Large population must meet viability criteria. Deschutes River Westside is the only extant population that can meet this criterion.
- Two Intermediate populations must meet viability criteria. Deschutes River Eastside and Klickitat River are the only populations that can meet this criterion.

Recommendations: To achieve viable status in the Cascades Eastern Slope Tributaries MPG, the Fifteenmile Creek, Deschutes River Eastside, Deschutes River Westside, and Klickitat populations must all achieve viable status. One of these populations must be highly viable. The Rock Creek population must be maintained.

John Day River MPG
Recovery scenarios for the John Day River MPG are presented below:

Population Characteristics:

Independent Populations	Size Category	Life History Type
Lower Mainstem John Day River	Very Large	Summer
South Fork John Day River	Basic	Summer
Middle Fork John Day River	Intermediate	Summer
North Fork John Day River	Large	Summer
Upper Mainstem John Day River	Intermediate	Summer

Recovery Scenario:

- Three populations must meet viability criteria, one of which must meet highly viable criteria.

- Two Large or Very Large populations must meet viability criteria. Lower John Day and North Fork John Day are the only populations that can meet this criterion.
- One Intermediate population must meet viability criteria. The Upper Mainstem John Day or Middle Fork John Day populations could meet this criterion.

Recommendations: To achieve viable status in the John Day River MPG, the Lower Mainstem John Day River, North Fork John Day River, and either the Middle Fork John Day River or Upper Mainstem John Day River populations must achieve viable status. One of these populations must be highly viable. The South Fork John Day River population must be maintained.

Umatilla/Walla Walla Rivers MPG
The following recovery scenarios exist for the Umatilla/Walla Walla MPG:

Population Characteristics:

Independent Populations	Size Category	Life History Type
Willow Creek (extirpated)		
Umatilla River	Large	Summer
Walla Walla River	Intermediate	Summer
Touchet River	Intermediate	Summer

Recovery Scenario:
- Two populations must meet viability criteria, one of which must meet highly viable criteria.
- One Large or Very Large population must meet viability criteria. The Umatilla River is the only population that can meet this criterion.

Recommendations: To achieve viable status in the Umatilla/Walla Walla Rivers MPG, the Umatilla River population and either the Walla Walla River or Touchet River population must achieve viable status. One of these populations must be highly viable. All remaining extant populations must be maintained.

1.6 Current Population Status

Assessing the current status of the populations according to the viability criteria is a critical first step in determining a path towards MPG and DPS viability. Following ICTRT guidelines, we completed viability assessments for Oregon's ten extant Mid-C steelhead populations. The assessments describe the current status of the populations relative to the abundance/productivity and spatial structure/diversity viability criteria.

Overall, the viability assessments show that only three of Oregon's Mid-C steelhead populations currently meet the viability criteria. The North Fork John Day population is highly viable and the Fifteenmile Creek and Deschutes River Eastside populations are viable. The remaining populations rated as either maintained or extinct. Assessment findings are provided for each of the ten populations in the population summaries (later in this section-1.14) and in Section 6 of

the recovery plan. Appendix B contains the detailed individual population viability assessments, including population-specific data sources and methods used to estimate abundance.

We also completed viability assessments for the three MPGs containing the Oregon populations. The assessment findings indicate that the three MPGs are currently below viable status based on the status of the constituent populations. These findings are shown below in Tables 1-2 through 1-4.

Cascades Eastern Slope Tributaries MPG

Findings: The Cascades Eastern Slope Tributaries MPG is currently below viable status. The Fifteenmile Creek and the Deschutes River Eastside are viable. The Deschutes River Westside population does not meet viability criteria. The Deschutes Crooked River population is extinct.

Table 1-2. Viability assessment results for Mid-C steelhead populations in the Cascades Eastern Slope Tributaries MPG.

Population	Extant/ Extinct	Abundance		Productivity		A/P Risk	Goal A Natural Processes Risk	Goal B Diversity Risk	Integrated SS/D Risk	Overall Population Viability Rating
		Mean	Lower 90% CI	Mean	Lower 90% CI					
Fifteenmile Creek	Extant	703	481	1.82	1.23	Low	Very Low	Low	Low	Viable
Deschutes River Eastside	Extant	1,599	896	1.89	1.10	Low	Low	Moderate	Moderate	Viable
Deschutes River Westside	Extant	456	306	1.05	0.76	High	Low	Moderate	Moderate	High Risk
Deschutes Crooked River	Extinct	0	NA	0	NA	Extinct	NA	NA	NA	Extinct

John Day River MPG

Findings: The John Day River MPG is currently below viable status. The North Fork population is highly viable; however, all of the other John Day River populations were below viable status.

Table 1-3. Viability assessment results for Mid-C steelhead populations in the John Day River MPG.

Population	Extant/ Extinct	Abundance		Productivity		A/P Risk	Goal A Natural Processes Risk	Goal B Diversity Risk	Integrated SS/D Risk	Overall Population Viability Rating
		Mean	Lower 90% CI	Mean	Lower 90% CI					
Lower Mainstem John Day River	Extant	1,800	1,065	2.99	1.91	Moderate	Very Low	Moderate	Moderate	Maintained
North Fork John Day River	Extant	1,740	1,375	2.41	1.62	Very Low	Very Low	Low	Low	Highly Viable
Middle Fork John Day River	Extant	756	508	2.45	1.81	Moderate	Low	Low	Low	Maintained
South Fork John Day River	Extant	259	168	2.06	1.26	Moderate	Very Low	Low	Low	Maintained
Upper Mainstem John Day River	Extant	524	399	2.14	1.15	Moderate	Very Low	Moderate	Moderate	Maintained

Umatilla/Walla Walla Rivers MPG

Findings: The Umatilla/Walla Walla Rivers MPG is currently below viable status because the Umatilla and Walla Walla populations do not meet viability criteria.

Table 1-4. Viability assessment results for Mid-C steelhead populations in the Umatilla/Walla Walla Rivers MPG.

Population	Extant/ Extinct	Abundance		Productivity		A/P Risk	Goal A Natural Processes Risk	Goal B Diversity Risk	Integrated SS/D Risk	Overall Population Viability Rating
		Mean	Lower 90% CI	Mean	Lower 90% CI					
Willow Creek	Extinct	0	NA	0	NA	Extinct	NA	NA	NA	Extinct
Umatilla River	Extant	1,472	988	1.50	1.11	Moderate	Moderate	Moderate	Moderate	Maintained
Walla Walla River	Extant	650	459	1.34	1.05	Moderate	Low	Moderate	Moderate	Maintained

1.7 Gap Analysis

The viability assessment results were used to determine the "gap" between the current status and the status required to meet the viability criteria. The gap analysis addresses the four VSP parameters: abundance, productivity, spatial structure and diversity. This analysis allowed us to identify viability impairments at the population level and inform development of appropriate actions to address impairments and, thus, "close the gaps."

The ICTRT conducted the abundance/productivity gap analyses for Mid-Columbia steelhead populations. The ICTRT defined the abundance/productivity gap as the quantitative relative amount of change in survival or capacity that is required for a population to improve from current status to a specific viability level. The gap analysis provides estimates of the magnitude of survival or capacity change that are needed to reach viability criteria for 25%, 5% and 1% probability of extinction over a 100-year timeframe as defined by the viability curves.

Our recovery planners performed the spatial structure/diversity gap analyses for the Oregon populations. The analyses included several steps: 1) for each population, we identified all spatial structure and diversity metrics with ratings of moderate or high risk; 2) for the metrics rated moderate, we determined if the rating was a result of changed status from intrinsic conditions or if the rating was a result of an intrinsic moderate risk for the metric; and 3) we characterized spatial structure and diversity gaps for each population as those metrics that rated high risk and those metrics that rated moderate risk because the current status is impaired relative to the intrinsic condition.

Gap analysis results for individual populations are provided in the population summaries (later in this section-1.14) and in Section 7.

1.8 Limiting Factors and Threats

Section 8 describes limiting factors and threats to the viability of Mid-C steelhead in Oregon. The findings were identified based on many sources of information, including the Mid-C steelhead Expert Panel's report, subbasin plans, ODEQ reports, ICTRT reports, NOAA's limiting factors modules, ODFW reports, hydrosystem biological opinion remand documents, and numerous other sources. The limiting factors and threats analyses serve as an essential foundation for the development and prioritization of management actions across the entire lifecycle. We used the following definitions of limiting factors and threats for our assessment.

> *Limiting Factors*: The physical, biological, or chemical conditions of the environment and associated ecological processes and interactions (e.g., habitat connectivity, water quality, physical habitat quality, etc.) that influence Mid-C steelhead viable salmonid population parameters, including abundance, productivity, spatial structure, and diversity.
>
> *Threats:* Threats are human actions (e.g., fishing, operation of hatcheries, operation of hydrosystem, land use practices, etc.) or natural events (e.g., flood, drought, volcano, etc.) that cause or contribute to limiting factors. Threats may influence one or multiple life stages and may occur in the present or future or have occurred in the past.

Key findings are summarized below and population-specific limiting factors and threats are identified in the population summaries in Section 1.14. Section 8.1 provides a broad level perspective of the primary limiting factors and threats across and within Oregon's Mid-C steelhead populations. This broader look is followed by more detailed, in-depth discussions of limiting factors and threats in Section 8.2 (Tributary Habitat), 8.3 (Hydrosystem), 8.4 (Estuarine and Plume Habitat), 8.5 (Harvest), 8.6 (Hatchery), and 8.7 (Predation and Competition).

Land Use

Tributary habitat degradation from past and/or present land use remains a key concern for all populations. Steelhead have been adversely affected by modified and reduced streamflows, impaired water quality due to elevated water temperatures and agricultural chemicals, impaired upstream and downstream fish passage, degraded channel structure and complexity (including riffles, pools and large woody debris), loss of riparian vegetation, reduced floodplain connectivity, and excessive levels of fine sediments caused by altered sediment routing. Threats contributing to these factors include agricultural, forestry and grazing practices that negatively impact steelhead growth and survival, dams and other barriers, water withdrawals, roads and channel manipulations. The Mid-C Expert Panel identified land use as having the most key concerns of any of the threat categories because, for most populations, the greatest impairment to viability has resulted from changes to the tributary spawning, rearing, and migration habitats.

We examined seven general types of tributary habitat limiting factors during our analysis. The factors are often interrelated.

- *Degraded floodplain connectivity and function*: Loss, impairment or degradation of floodplain connectivity; access to previously available habitats (seasonal wetlands, off-

channel habitat, side channels); and a connected and functional hypotheic zone. Includes reduced overwinter habitat and channel habitat. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

- *Degraded channel structure and complexity*: Loss, impairment or degradation of channels; a suitable distribution of riffles and functional pools; functional amounts and sizes of large woody debris or other channel structure. Includes reduced summer rearing habitat, degraded spawning habitat, reduced diversity and structure (wood, boulders, etc.), inadequate quantity or depth of pools, loss of side and braided channels. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

- *Degraded riparian areas and LWD recruitment*: Loss, degradation or impairment of riparian conditions important for production of food organisms and organic material, shading, bank stabilizing by roots, nutrient and chemical mediation, control of surface erosion, and production of large-sized woody material. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

- *Altered hydrology*: Changes in the hydrograph that alter the natural pattern of flows over the seasons, causing inadequate flow, scouring flow, or other flow conditions that inhibit the development and survival of salmonids. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

- *Degraded water quality*: Degraded or impaired water quality due to abnormal temperature, or levels of suspended fine sediment, dissolved oxygen, nutrients from agricultural runoff, heavy metals, pesticides, herbicides and other contaminants (toxics). Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

- *Altered sediment routing*: Altered sediment routing leading to an overabundance of fine-grained sediments, excess of course-grained sediments, inadequate course-grained sediments and/or contaminated sediment. Includes excessive fine sediment that reduces spawning gravel or increases embeddedness. Life stages affected: egg-to-parr survival.

- *Impaired fish passage*: The total or partial human-caused blockage to previously accessible habitat that eliminates or decreases migration ability or alters the range of conditions under which migration is possible. This may include seasonal or periodic total migration blockage. Includes dams, culverts, seasonal push up dams, unscreened diversions, and entrainment in irrigation diversions. Life stages affected: smolt migration, adult migration, juvenile upstream migration due to thermal blockage or water availability.

Climate change is expected to increase the loss and degradation of steelhead habitat. Many of the environmental attributes that will be influenced by climate change (temperature and hydrograph) are those that have already been influenced significantly by past land use and are currently considered key limiting factors. Environmental changes associated with climate change that pose particular threats to salmonid viability include: increased air and stream

temperatures; reduced snow pack and a shift in precipitation from snow to rain; altered hydrographs with earlier and higher peak flows, and lower summer-fall flows; more frequent extreme storm events; increased periods of drought; changing ocean temperatures and current patterns; and more frequent and severe fire events (O'Neal 2002; Mote et al. 2003; ISAB 2007a; Michael and O'Brien 2008). Such environmental changes will impact all life stages of Oregon's Mid-Columbia River steelhead. The magnitude of environmental change will vary considerable across ecoregions; however, habitats at lower elevations east of the Cascade Mountains in the southern portion of the Columbia River basin will generally experience the greatest level of change (ISAB 2007a).

Hydrosystem

The mainstem Columbia River hydrosystem is considered a primary threat to the viability of Oregon's Mid-C steelhead populations. Specific viability concerns identified by the Mid-C Expert Panel related primarily to effects of delayed upstream passage (adults), direct and indirect mortality on downstream migrants (juveniles), alteration of the hydrograph (mainstem and estuary flow regime), depletion of historically available nutrients, and degraded rearing and food resources for both presmolts and smolts in the Columbia River.

Results of the BiOp Framework Work Group support this conclusion. NMFS created the work group to provide scientific expertise during development of its Biological Opinion (BiOp) evaluating effects of operations of the FCRPS — including estimating the relative magnitude of human-caused mortality factors influencing Mid-C steelhead and other Interior Columbia River salmon and steelhead populations. During this evaluation, the work group found that the FCRPS hydrosystem had the greatest relative impact on the Mid-C steelhead populations compared with other human-induced mortality effects (Step 4 Report 2006) (Table 8-1). The ICTRT reached a similar conclusion in September 2006, when members rated the mainstem Columbia River hydrosystem as a major limiting factor for all populations in the DPS. Oregon's recovery planning team also determined that the mainstem hydropower system represents a primary threat to the viability of Oregon Mid-C steelhead populations. The Expert Panel's findings were generally consistent with the BiOp Framework Work Group's findings on magnitude of human-induced mortality, however, the Expert Panel considered the mainstem Columbia hydrosystem a threat of moderate concern to the populations and generally considered legacy and current land use as a greater threat than the hydrosystem.

Impacts from the mainstem Columbia River hydrosystem increase somewhat for each of the populations in direct relation to the number of dams the fish must pass during their migration to and from the Pacific Ocean. Mid-Columbia steelhead populations pass one to four Columbia River dams: the Fifteenmile Creek population passes one dam; Deschutes River populations pass two dams; John Day River and Umatilla River populations pass three dams; and the Walla Walla River population passes four dams.

Several hydroelectric dams on Columbia River tributaries also pose significant threats to the viability of specific populations. The Pelton-Round Butte Complex on the Deschutes River at RM 100 significantly affects the Deschutes Westside population and to a lesser extent the Deschutes Eastside population. It blocks all passage to historical habitat above the dam,

particularly in Whychus Creek, Metolius River and Crooked River. The Boyd Hydro Project on the Umatilla River and Twin Reservoirs Hydro Project on Mill Creek, a tributary to the Walla Walla River affect the Umatilla and Walla Walla steelhead populations.

Estuarine and Plume Habitat

The Columbia River estuary and plume have changed considerably over the last 200 years. The estuary tidal prism is now about 20% smaller, due mostly to dike and filling practices used to convert the floodplain to agricultural, industrial, commercial, and residential uses. Instream flows entering the estuary also have changed dramatically—there has been a 44% decrease in spring freshets or floods, and the annual timing, magnitude, and duration of flows no longer resemble those of the historical hydrograph in the Columbia River (Jay and Kukulka 2002).

Scientists generally believe that steelhead and other stream-type salmonids are particularly affected by changes in plume habitat conditions and by predation in the estuary and plume (Lower Columbia River Estuary Partnership (LCREP) 2006). The plume is believed to function as habitat, as a transitional saltwater area, and as refugia for juvenile salmonids as they prepare for ocean life (Fresh et al. 2005; LCREP 2006). Changes in the Columbia River hydrograph alter both the size and structure of the plume during the spring and summer months (NPCC 2000). Changes in the hydrograph also affect plume habitat by reducing fine-sediment inputs leaving the estuary.

Harvest

Steelhead are affected by harvest during several life stages from pre-smolts taken in trout fisheries to adults taken in commercial, recreational and tribal fisheries primarily in the mainstem Columbia River and tributaries. However, given current management regulations for mainstem Columbia River and tributary fisheries, harvest is not considered a primary or secondary threat due to the low impact on viability. The ICTRT identified harvest-related effects as a secondary level limiting factor and the Mid-C Expert Panel did not identify harvest as either a key or secondary concern for Oregon's Mid-C steelhead populations. The panel, however, did express concerns over the impact that mortality associated with catch and release fisheries have on Westside and Eastside Deschutes populations.

Hatcheries

Out-of-DPS hatchery strays pose significant risk to many of Oregon's Mid-C steelhead populations, particularly to the Eastside and Westside Deschutes and John Day populations. Viability assessments, summarized in Section 6 of this document and presented in Appendix B, identified that a significant proportion of spawners in the Deschutes River and John Day River populations were out-of-DPS strays. In addition, these populations were rated at high risk for spawner composition due to the abundance of strays. Biologists remain especially concerned regarding the continuing detrimental impact of stray out-of-DPS hatchery fish in natural spawning areas on the genetic traits and productivity of these natural populations. Hatchery programs operated within the Mid-C steelhead DPS — including the Umatilla, Walla Walla and Westside Deschutes subbasins — also create some risks. The Mid-C Expert Panel ranked the

impact of hatchery strays as a key concern to the Eastside and Westside Deschutes and Lower John Day populations, and as a secondary concern to the Umatilla and Walla Walla populations.

Predation

The Expert Panel listed predation is a primary concern for juvenile and adult steelhead in the Columbia River estuary and plume. Estuary habitat modifications have increased the number and/or predation effectiveness of Caspian terns, cormorants, and gull species (Fresh et al. 2005). The increasing abundance of native pinnipeds has resulted in increased predation on adult salmonids to a point of concern. Panelists identified predation by non-native piscivorous fish on pre-smolts and smolts in the mainstem Columbia as a secondary concern for all Mid-C steelhead populations.

Climate Change

Climate change will alter environmental conditions across the entire life cycle for all life stages of Oregon's Mid-Columbia River steelhead. There remains considerable uncertainty regarding the magnitude of loss and degradation of salmonid habitat in the Columbia Basin that will result from climate change. The magnitude of environmental change will vary considerable across ecoregions and thus will have different impacts on viability of steelhead populations within the Mid-C DPS. In general, habitats at lower elevations east of the Cascade Mountains in the southern portion of the Columbia River basin, which encompasses the Oregon Mid-C area, will experience the greatest level of change (ISAB 2007a).

Many of the environmental attributes that will be influenced by climate change (temperature and hydrograph) are those that have already been influenced significantly by past land use and are currently considered key limiting factors. The degree to which climate change will impact a given population is partially dependent on the degree to which natural processes have already been altered. A number of reviews have recently been completed that characterize potential climate change impacts in the Pacific Northwest (O'Neal 2002; Mote et al. 2003; ISAB 2007a; Michael and O'Brien 2008). The environmental changes most often described as significant threats to salmonid viability include:

- Increased air and stream temperatures
- Reduced snow pack and a shift in precipitation from snow to rain
- Altered hydrographs with earlier and higher peak flows, and lower summer-fall flows
- More frequent extreme storm events
- Increased periods of drought
- Changing ocean temperatures and current patterns
- More frequent and severe fire events

We conducted an analysis to assess population-specific vulnerability to climate change impacts. We developed a climate change potential vulnerability risk index based on projected future springtime water availability, projected future stream temperatures, and historical variation in precipitation. Our analysis indicates that few of the HUC6s in Oregon's Mid-C populations are at low or very low risk. Many populations have the entire geographic area within the population

boundaries rated as moderate or high risk. The combination of environmental characteristics that are forecasted to change under future climate scenarios will threaten capacity, productivity, diversity, and spatial structure from both lower elevations upward and higher elevations downward. Temperature changes will influence lower elevation areas significantly while higher elevation areas will be influenced most by hydrograph changes.

1.9 Recovery Strategies and Actions

Achieving recovery for the DPS will depend on restoring the viability of extant populations in major population groups to levels that support the proper functioning of the DPS. Recovery strategies for Oregon's Mid-C steelhead populations involve substantial reductions in the threats across all categories (tributary habitat, hydrosystem, estuary and plume habitat, harvest, hatcheries, and predation and competition).

An Integrated Approach

The delisting and broad sense recovery goals, assessments of current status and viability gaps, and limiting factors and threats analysis served as essential building blocks for identifying recovery strategies and actions. The plan's strategies and actions address the multiple limiting factors and threats that affect steelhead viability throughout their life cycle:

- Tributary habitat strategies and actions (Section 9.3) call for the protection of the highest quality habitats, maintenance of existing unimpaired habitats and ecosystem functions that support population viability, and habitat restoration through passive and active measures. Restoration strategies are linked directly to the limiting factors and aim to improve tributary spawning, rearing and migration conditions by restoring instream, riparian and upland habitat conditions, providing passage and floodplain connectivity, and addressing water quality and flow concerns. Actions identified under each strategy define the specific work needed to fill the gap between current conditions and what is needed in the long term to fully achieve the strategy. Actions differ from strategies in that they address specific needs for a specified geographic area, program deficiencies, as well as biophysical habitat impairments and threats. Together, the strategies and actions represent a complete list of needs, somewhat unconstrained by logistic and financial concerns.

- Hydrosystem strategies and actions (Section 9.4) primarily address configurations and operations of the Columbia River hydropower system. They range from improving juvenile and adult steelhead passage and survival at particular dams to addressing flow and temperature issues. These strategies and actions may be revised before completion of the final recovery plan to be consistent with adopted revisions of the 2004 FCRPS BiOp Remand.

  The section also identifies strategies and actions to adjust hydropower operations and facilities in the Umatilla and Walla Walla river systems, and to increase the quantity of spawning and rearing habitat available to Deschutes River Westside steelhead, and to a lesser extent Deschutes River Eastside steelhead, by restoring passage to historical

habitats in the middle and upper Deschutes drainage. Strategies and actions will also restore steelhead access to blocked historical habitats in the Crooked River area.

- Estuarine and plume habitat strategies and actions (Section 9.5) improve steelhead rearing conditions and survival in the Columbia River estuary and plume by restoring estuarine riparian conditions, removing dikes and protecting off-channel habitats.

- Harvest strategies and actions (Section 9.6) protect steelhead in the ocean, mainstem Columbia River and tributaries by maintaining low impact fisheries and attempting to increase harvest of stray hatchery spawners, thus reducing abundance of out-of-DPS hatchery strays.

- Hatchery strategies and actions (Section 9.7) address ecological and genetic effects on Oregon Mid-C steelhead from hatchery management programs in and outside the DPS. They include reducing the abundance and proportion of out-of-DPS hatchery strays spawning naturally in Oregon's Mid-C steelhead populations. They also help restore natural production in historically utilized habitats of the Deschutes Westside, Crooked River, and Umatilla River population areas.

- Predation and competition strategies and actions (Section 9.8) seek to reduce predation by pinnipeds, birds, and piscivorous fish on salmon and steelhead in the Columbia River estuary and mainstem.

Together, the strategies and actions are framed to close viability gaps, reach delisting status, and progress toward broad sense recovery goals. Table 1-5 shows the strategies and types of actions that will be implemented to address all factors limiting recovery of Oregon Mid-C steelhead populations throughout their lifecycle. The highest priority tributary-level strategies, actions and priority areas are also identified for each population (later in this section-1.14).

Table 1-5. Integrated approach to address all factors limiting recovery of Oregon's Mid-C steelhead populations.

Strategies	Populations Addressed	Types of Actions	Limiting Factors and Threats Addressed
Tributary Habitat			
Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	All populations	Protect highest quality habitats through acquisition and conservation. Adopt and manage Cooperative Agreements. Conserve rare and unique functioning habitats. Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	Degradation of tributary habitat-forming processes and functions (loss of channel structure, floodplain connectivity, riparian vegetation, and LWD recruitment)
Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	All populations	Provide passage at Pelton-Round Butte Complex. Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures. Provide screening at 100% of irrigation diversions. Replace screens that do not meet criteria.	Loss of historical habitat because of blocked or impaired fish passage (dams, culverts, unscreened diversions)
Maintain and restore floodplain connectivity and function.	All populations	Reconnect side channels and off-channel habitats to stream channels. Restore wet meadows. Reconnect floodplain to channel.	Degraded floodplain connectivity and function (loss of off-channel habitat, side channels, connected hypotheic zone)

Strategies	Populations Addressed	Types of Actions	Limiting Factors and Threats Addressed
Restore degraded and maintain properly functioning channel structure and complexity.	All populations	Place stable wood and other large organic debris in streambeds. Stabilize streambanks. Restore natural channel form.	Degraded channel structure and complexity (loss of spawning and rearing habitat, LWD, pools)
Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	All populations	Restore natural riparian vegetative communities. Develop grazing strategies that promote riparian recovery.	Degraded riparian condition (native riparian vegetative communities, LWD recruitment)
Restore natural hydrograph to provide sufficient flow during critical periods	All populations	Implement agricultural water conservation measures. Improve irrigation conveyance and efficiency. Lease or acquire water rights and convert to instream.	Altered hydrology (low flow, scouring peak flows due to degraded watershed conditions, streamflow alterations and/or withdrawals for irrigation and other uses)
Improve degraded water quality and maintain unimpaired water quality	All populations	Reduce chemical pollution inputs. Apply BMPs to animal feeding operations. Restore natural functions and processes through above remediation actions.	Degraded water quality (high temperatures, nutrients, pesticides and other chemicals)
Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	All populations	Achieve 95% conversion to no till farming. Upgrade or remove problem forest roads. Restore native upland plant communities. Employ BMPs to forest practices, livestock grazing, road management and agricultural practices.	Altered sediment routing and runoff patterns due to upland management activities.
Estuarine and Plume Habitat			
Restore degraded estuarine and plume habitats and associated ecological processes.	All populations	Protect/restore riparian areas Remove pile dikes Protect remaining high-quality off-channel habitat Breach or lower dikes and levees Identify and reduce sources of pollutants Monitor and restore contaminated sites	Degraded estuarine and nearshore marine habitat reduces refugia available to juvenile steelhead in Columbia River estuary and plume as they prepare for ocean life.
Hydropower Systems			
Operate the FCRPS to more closely approximate the shape of the natural hydrograph to enhance flows and water quality to improve juvenile and adult fish survival.	All populations	Draft storage reservoirs (Libby, Hungry Horse, Grand Coulee, and Dworshak) in attempt to meet seasonal and weekly flow objectives in the lower Columbia River during July and August. Pursue negotiations with Canada to provide 1 million acre feet of storage to augment summer flows. Meet Non-Treaty storage refill responsibilities and pursue a new long-term agreement on use of non-treaty space in Canadian reservoirs. Implement drafts and other measures to improve flows during the lowest 20th percentile years. Implement Water Quality Plan for Total Dissolved Gas and Water Temperature in the Mainstem Columbia and Snake rivers.	Altered steelhead migration conditions and delayed passage due to hydrosystem development and operations in mainstem Columbia River.
Modify Columbia and Snake River dams to maximize juvenile and adult survival.	All populations.	Implement project specific configurations and operations at the eight mainstem dams on the lower Snake and Columbia rivers.	Altered juvenile and adult steelhead migration conditions due to mainstem Columbia River hydrosystem.
Implement spill and juvenile transportation improvements at Columbia and Snake rivers dams.	All populations.	Provide spill to improve juvenile fish passage. Implement interim transportation program to improve survival of transported fish.	Altered juvenile and adult steelhead migration conditions due to mainstem Columbia River hydrosystem.
Operate and maintain juvenile and adult fish passage facilities at Corps mainstem projects to maintain biological performance.	All populations.	Corps will operate juvenile and adult passage facilities year around with the regionally coordinate Fish Passage Plan.	Altered juvenile and adult steelhead migration conditions due to mainstem Columbia River hydrosystem.
Restore sustainable natural steelhead production to	Deschutes Westside Deschutes Eastside	Develop downstream collection and passage through Pelton-Round Butte Complex.	Tributary hydrosystem operations and configurations block access

Strategies	Populations Addressed	Types of Actions	Limiting Factors and Threats Addressed
blocked habitats in the Deschutes River Westside, Deschutes River Eastside and extinct Crooked River populations.	Crooked River	Improve flow patterns through reservoir for juvenile migration. Modify hydro operations to restore water quality.	to historical habitats and alter habitat conditions.
Improve hydrosystem operations and facilities to enhance steelhead survival and viability.	Umatilla River Walla Walla River	Modify bypass flows at Boyd Project as needed to mimic instream water right. Modify fish passage facilities at Boyd Project to meet current standards. Remove weir panels from diversion dam at Boyd Project during non-operation. Maintain trash racks at Boyd Project. Modify fishway at Twin Reservoirs Project to meet juvenile fish passage standards.	Tributary hydrosystem operations and configurations impair passage and alter habitat conditions.
Harvest			
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	All populations	Maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	Commercial, recreational and tribal fisheries in ocean, mainstem Columbia River and tributaries
Utilize tributary harvest to reduce abundance and proportion of stray hatchery spawners.	Deschutes Westside Deschutes Eastside John Day MPG	Develop educational outreach program to promote use of selective recreational fisheries to reduce the number of out-of-basin hatchery strays.	Straying of out-of-DPS hatchery spawners into tributary spawning grounds.
Reduce catch and release mortality on natural-origin fish in John Day Basin.	John Day MPG	Promote voluntary curtailment of fishing at higher water temperatures (above 21°C) to reduce hook-and-release mortality	Adverse effects of tributary harvest on natural steelhead.
Improve quality of harvest information and impacts on natural-origin fish in John Day Basin.	John Day MPG	Expand the creel surveys to monitor fisheries effort and catch.	Adverse effects of tributary harvest on natural steelhead.
Hatchery			
Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish.	Potential risk for all populations. Significant risk for Deschutes Eastside, Deschutes Westside and Lower John Day populations.	Implement representative coded-wire-tagging program so all hatchery stocks have adequate CWT groups released annually.	Straying of out-of-DPS hatchery fish into natural spawning grounds.
Reduce uncertainty in abundance and proportion of hatchery strays spawning naturally.	Fifteenmile Creek Deschutes Eastside All John Day populations	Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys and other methods.	Straying of out-of-DPS hatchery fish into natural spawning areas.
Reduce abundance and proportion of stray hatchery fish that spawn naturally.	Deschutes Eastside Deschutes Westside Umatilla River Walla Walla River	Construct, improve trapping facilities and expand operations to remove strays. Eliminate adult hatchery strays above Nursery Bridge Dam. Recommend development of alternative broodstocks to reduce stray rates for programs that contribute significantly to stray problem.	Straying of out-of-DPS hatchery fish into natural spawning areas.
Reduce genetic risks associated with Round Butte Hatchery Program.	Deschutes Westside	Investigate opportunities and risks associated with incorporating naturally produced Deschutes River summer steelhead into RBH broodstock.	Inside-DPS hatchery genetic risks
Restore natural production into historically utilized habitats.	Deschutes Westside Crooked River Umatilla River	Develop plan for steelhead reintroduction into historical habitat above Pelton-Round Butte Complex when passage is restored. Re-establish natural production in Little Butter and Butter creeks and some minor spawning areas.	Risks related to steelhead reintroductions to historical habitat using inside-DPS hatchery fish.
Reduce genetic influence of hatchery fish in hatchery	Umatilla River	Eliminate use of hatchery produced adults in the broodstock.	Potential divergence in genetic and phenotypic traits between

Strategies	Populations Addressed	Types of Actions	Limiting Factors and Threats Addressed
broodstock.			hatchery and natural-origin steelhead.
Reduce interactions between residual hatchery steelhead and natural steelhead.	Umatilla River	Assess degree of impact.	Risk of hatchery fish competing with and preying on natural steelhead juveniles
Reduce potential negative ecological interactions between coho salmon and natural steelhead.	Umatilla River	Reduce number of hatchery coho released in Umatilla River and relocate releases downstream to areas not currently important to steelhead production.	Potential for coho smolts to compete with juvenile steelhead for prey resources and space
Predation and Competition			
Reduce predation and competition in the Columbia River mainstem, estuary and plume.	All populations	Reduce predation by pinnipeds Redistribute Caspian terms Redistribute cormorants	Increased predation on steelhead due to degraded estuarine and plume habitats, and to hydrosystem development and operations in mainstem Columbia River.

Building on Current Efforts

We recognize that reversing the decline of populations, life histories and habitats requires use of well-formulated, scientifically sound approaches. In many areas, effective steps have already been taken or are currently underway that will improve the status of different Oregon Mid-C steelhead populations. In tributary watersheds state and federal natural resource managers, tribes, local governments, watershed councils, soil and water conservation districts, non-profit organizations, local land owners and others continue to improve stream conditions to enhance steelhead populations throughout their freshwater life stages. They are also improving land use practices on uplands and floodplains that are allowing natural ecosystem functions and processes to recover.

Similar efforts are underway to address other threats. In the Columbia River estuary, various parties are working to improve estuarine and plume habitat conditions and reduce predation. In the mainstem Columbia River, hydrosystem managers and fish resource managers continue to refine hydropower system operations to address some needs for survival and recovery of the Mid-C steelhead DPS and other ESA-listed salmon and steelhead. Hatchery programs operated within the DPS have also been modified over the past 10 years to reduce threats and improve contribution to recovery. In addition, extensive harvest management changes in both the mainstem and tributaries have been implemented to reduce the impacts of fisheries.

This plan is designed to build on these past and current efforts. Section 9 identifies many of these efforts along with their sufficiency and areas in need of improvement so that future actions expand from and improve their effectiveness. Spreading the responsibility among a range of parties lessens the cost to any one group, increases the certainty of success, and compounds the benefits of moderate improvements in each factor.

Strategic Guidance and Prioritization Considerations for Plan Implementation

Achieving recovery for the Mid-C steelhead DPS will require intensive effort by individuals at the regional, watershed and local levels. Many recovery efforts will need to be conducted in concert to address overlapping causes that impair population viability and disrupt ecosystem functions.

Unfortunately, all of the management actions needed to reach recovery goals cannot be implemented at the same time due to various constraints. In addition, setting priorities can often be difficult because of the scientific complexity and diverse policy strategies. Although priorities must be science based, they are ultimately policy choices. Section 9.1 provides guidance for the development and implementation of management strategies and actions to recover Oregon's Mid-C steelhead populations. This guidance was adopted by Oregon's Middle Columbia Sounding Board. The characteristics of highest priority actions are identified below. Section 9.1 identifies other high priority actions, though less than highest, as well as other prioritization considerations.

Highest Priority Actions

- Provide long-term protection of habitat conditions and conservation of natural ecological processes that support the viability of priority extant populations and their primary life history strategies throughout their entire life cycle. A population is considered a priority if it is critical for MPG or DPS viability.

- Protect or enhance viability of multiple steelhead populations.

- Support conservation of unique and rare functioning habitats, habitat diversity, life histories and genetic attributes.

- Target the key limiting factors and that contribute the most to closing the gap between current status and desired future status of priority populations.

- Provide critical information needed for assessing success and making adaptive management decisions.

1.10 Management Action Effectiveness

Section 10 presents an analysis of the effects of the proposed actions on the performance of Oregon populations in the Mid-Columbia River steelhead DPS. The analysis was performed in sequential steps, first by projecting outcomes for tributary actions alone, then sequentially adding in hatchery fish genetic effects, then types of out-of-subbasin actions, and finally actions to manage stray hatchery fish. The results at each step provided a means for comparing relative benefits of the proposed actions.

Approach

The analysis of action effectiveness was performed using two modeling platforms, Ecosystem Diagnosis and Treatment (EDT) and the All-H-Analyzer (AHA), that address different types of

limiting factors affecting salmonid population performance during the life cycle. Linking the two models provided a way of projecting benefits measured at the end of the life cycle for a wide range of potential actions, regardless of what life stage an action affects. We made a number of changes to both models to improve the application to our analyses.

Modified EDT Model

The EDT model was used to analyze the potential benefits of tributary habitat actions. The model is designed to estimate salmonid population performance based on characteristics of the aquatic habitat. Four scenarios were modeled using the EDT model, reflecting two priorities for where actions would be implemented at two future times: 1) High priority actions and locations only at 25 years in the future; 2) High priority actions and locations only at 100 years in the future; 3) All actions and locations at 25 years in the future; and 4) All actions and locations at 100 years in the future. In addition, the Deschutes Westside population was modeled with and without passage/reintroduction at the Pelton-Round Butte Complex to illustrate the added benefit of providing passage.

A two-part process was used to determine action effectiveness. Part 1 asked the question: What stream reaches would be affected by each of the actions? This was answered by linking stream reaches in each of the five subbasins to the actions. Part 2 consisted of explicitly defining distinct elements—or factors—that are used to compose the overall effectiveness value applied in the analysis. Five elements of action effectiveness were recognized, each acting as a scalar to determine how effective an action would be in moving an attribute's current baseline rating back toward the undeveloped state: *Effect*, the potential effectiveness of action; *Intensity,* the scale at which an action is to be applied; *Lag,* how much of the potential effectiveness of an action will be achieved at a time in the future (25 or 100 years in the future); *Schedule,* an implementation schedule effect, i.e., whether implementation is delayed to some point in the future, whereby the amount of the potential effectiveness of an action would be reduced at a time in the future; and A*ttribute,* the potential effectiveness of an action due to an attribute effect.

Modified AHA Model

The AHA model linked the analyses of tributary habitat actions to prospective recovery actions involving hatchery fish and the mainstem Columbia River; integrating the effects of various types of actions over the full life cycle. A set of scenarios was modeled using AHA, representing baseline conditions, current conditions, and combinations of actions aimed at tributary habitat, mainstem Columbia River factors, and hatchery fish management. AHA scenarios were run in a stepwise fashion, starting with baseline, then current condition, then adding in actions sequentially, each being added to the previous scenario.

Importantly, the AHA model allowed incorporation of potential effects of hatchery programs on the genetic fitness of the natural populations. The model incorporates key concepts and assumptions about the effects of genetic interactions between hatchery and natural fish built on the work of Lynch and O'Hely (2001) and Ford (2002), with further development of those ideas by geneticists working with the Hatchery Scientific Review Group (HSRG)(Mobrand – Jones & Stokes 2005). Fitness is computed in the model using Ford's (2002) modeling equations. It was used to evaluate potential genetic effects on the natural populations due to interactions between out-of-DPS stray hatchery fish and from the Umatilla supplementation hatchery program.

Several prospective actions to be taken in the mainstem Columbia River were also modeled using AHA, including: predator management – aimed at reducing predation rates caused by terns and northern pikeminnow; downstream juvenile passage improvements – measures to improve survival at each of the mainstem dams; Columbia estuary habitat improvements – measures to enhance habitat conditions within the Columbia estuary; and harvest – regulatory measures to reduce or hold harvest impacts in the mainstem Columbia River to current levels. We used survival improvement estimates provided in the recent BiOp (NOAA Fisheries 2007a) for predation, hydrosystem, and estuary actions. The use of these values in no way implies endorsement of the validity of the estimates or the adequacy of the actions. At this time, these are the only estimates available for the proposed actions.

The output from AHA, also expressed as Beverton-Holt population parameters, represents the expectation for population performance when all actions are integrated together. These parameters were then converted to the percent change in each parameter value compared to baseline conditions and multiplied by the ICTRT's baseline population measures to compute expected ICTRT-equivalent parameter values reflecting the effects of all actions.

Summary of Findings

Overall, analysis results show that population performance, as measured by both productivity and spawner abundance, increases markedly for all populations under the recovery action scenarios.

Results of All-H integration analysis are summarized below for each population and presented in Section 10. Changes in performance measures associated with each action scenario are presented for intrinsic productivity and equilibrium spawner abundance. The results are comparable to population metrics presented in Section 6 for baseline performance, as derived empirically by the ICTRT, and to minimum productivity (at the threshold abundance level) and abundance viability thresholds at the 5% risk level.

Fifteenmile Creek Population
Population performance is increased markedly for all scenario combinations analyzed. By far, the largest contribution to performance improvements results from tributary habitat actions. Relatively small increases are attributable to mainstem actions. Viability thresholds are exceeded for all scenarios.

Deschutes River Eastside Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements result from tributary habitat actions, with greatest benefits accruing for the 100 year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Very substantial benefits to both population productivity and natural-origin spawner abundance also occur as a result of reducing the number of stray hatchery fish spawning with natural-origin fish. Viability thresholds are exceeded for all scenarios.

Deschutes River Westside Population
The largest increases in population performance associated with the range of scenario combinations analyzed occur as a result of decreasing the number of stray hatchery fish and/or by providing passage at the Pelton-Round Butte Complex (includes passage at Whychus Creek barriers). In the absence of the removal of strays or passage, benefits are much reduced. For those scenario combinations lacking removal of strays and passage, beneficial effects of tributary actions are greatest, though beneficial cumulative effects of adding in mainstem actions are clearly evident. The viability threshold for productivity is exceeded for all action scenarios. The minimum abundance threshold was not achieved for any scenario.

Lower Mainstem John Day River Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements result from tributary habitat actions, with greatest benefits accruing for the 100 year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Viability thresholds are exceeded for all scenarios.

North Fork John Day River Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements result from tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Viability thresholds are exceeded for all scenarios.

Middle Fork John Day River Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements result from tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Viability thresholds are exceeded for all scenarios.

South Fork John Day River Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements result from tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. The viability threshold for productivity is exceeded for all action scenarios. The abundance threshold is reached in about 30% of the action scenarios.

Upper Mainstem John Day River Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements result from tributary habitat actions, with greatest benefits accruing for the 100-year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Viability thresholds are exceeded for all scenarios.

Umatilla River Population
Population performance is increased markedly for all scenario combinations analyzed. The largest contribution to performance improvements results from tributary habitat actions, with greatest benefits accruing for the 100 year scenarios. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Viability thresholds are exceeded for all scenarios.

Walla Walla River Population
Population performance is increased markedly for all scenario combinations analyzed. Relatively small differences exist between scenario results at 25 and 100 years. The largest contribution to performance improvements is estimated to be due to tributary habitat actions. Benefits associated with mainstem actions are seen to be cumulative with the sequential addition of actions. Viability thresholds are exceeded for all scenarios.

1.11 Time and Cost Estimates

Section 11 summarizes the time and partial costs expected for recovery of Oregon Mid-C steelhead populations. Appendix I discusses the costs of implementing the various actions identified in Section 9 in more detail.

Currently, we estimate the overall total cost for implementation of proposed actions that we were able to estimate for all ten Oregon Mid-C steelhead populations at $512,843,328. This estimate reflects preliminary summary partial costs for recovery of the populations based on implementation of identified management actions, where available information was sufficient to do so. The draft cost estimates (Table I-1) were prepared by a NMFS economist at the Northwest Fisheries Science Center in Seattle using a regional recovery cost database, together with input and review from ODFW, regional experts, and the Mid-Columbia Sounding Board in 2007. The total cost will increase when unit cost estimates, scale of projects, and costs for all actions are determined. Costs for some of the expensive actions like land acquisition, flow enhancement, land leases, and RM&E have yet to be determined.

Estimated costs for different projects range widely from relatively less expensive fish passage projects to more expensive projects, such as restoring stream channel structure and complexity. The Lower John Day ($116,192,806) and Deschutes River Westside ($114,110,501) populations have the most expensive estimated total project costs, while the South Fork John Day ($8,656,103) and Fifteenmile ($28,358,906) populations have the smallest total costs. These total cost differences may be due to many factors such as size of the population, extent to which current conditions need to be improved, scale of projects, number of projects identified, and the availability of recovery action cost information by population at this time.

NMFS estimates that implementation of the recovery actions for the Mid-Columbia steelhead DPS, like recovery for most of the ESA-listed Pacific Northwest salmon and steelhead, could take 50 to 100 years. While this recovery plan contains an extensive list of actions that need to be undertaken to recover Oregon's Mid-Columbia steelhead populations, there are many uncertainties involved in predicting the course of recovery and in estimating total costs. These include uncertainties regarding biological and ecosystem responses to recovery actions, as well

as uncertainties regarding long-term and future funding. Given the uncertainties in developing recovery cost estimates, Oregon is not able to estimate total or 10-year implementation costs to recover Oregon's populations in the Mid-Columbia steelhead DPS. Table I-2 in Appendix I, however, provides current average expenditures on habitat projects expected during the next five-year period. These projected five-year habitat project expenditures total approximately $102 million.

In early 2008, Oregon, NOAA, and other partners will develop a plan for recovery project implementation that will include project cost estimates. The implementation plan will identify what entity or individual will carry out the recovery actions and the timeline for implementation. Recovery costs will be revised in the future as specific project budgets are completed.

1.12 Implementation Plan and Adaptive Management Framework

The successful implementation of the Oregon Mid-Columbia Steelhead Conservation and Recovery Plan recovery actions, research, monitoring and evaluation, and adaptive management process will require significant funds and the coordinated work of ODFW, State agencies, tribes, counties, irrigation districts, agriculture and private forest land managers, NMFS, U.S. Forest Service, BLM, other Federal agencies, local residents, citizen groups, utilities, other agencies, and individuals. ODFW, in coordination with the Oregon Governor's Office and NMFS, has taken the lead in developing this recovery plan; all will continue to be instrumental in its implementation.

Oregon's recovery plan implementation framework is intended to provide a collaborative approach to implementation, science guidance and policy direction, as well as facilitate information exchange and coordination from local-level action entities to upper level decision makers and provide linkage to state, DPS and regional forums. Existing forums, groups, partnerships and involved citizens make this implementation structure possible, but additional resources and funding will be needed to make it work effectively and successfully. The basic components of Oregon's implementation framework include a Recovery Team, an Implementation Coordinator, an Implementation Team, a Technical Team, and Watershed Teams. These teams will interface with and potentially strengthen the various state agency teams associated with the Oregon Plan for Salmon and Watersheds that provide for policy, management, and monitoring of interagency Oregon Plan programs for the conservation and restoration of habitat, water quality, and salmon. In addition, these teams will function to coordinate within the DPS implementation and adaptive management framework. The implementation framework will adapt and change as necessary to adjust to funding, available resources, and implementation needs.

Mid-C steelhead have a complex life cycle that traverses habitats from high elevation tributaries to the open ocean. Life history strategies and life stage specific habitat requirements are complex. There are many limiting factors and threats that influence the viability of Oregon's Mid-C steelhead at all life stages. The suite of proposed management actions to address primary limiting factors and threats across the entire life cycle is extensive and diverse. Although the limiting factors and threats, as well as the management actions, have been developed based on the best available science, there remains considerable uncertainty regarding the outcomes and

effectiveness of the proposed management actions as well as the status of the populations. It is this uncertainty which generates the essential need for an effective adaptive management process.

A successful adaptive management process requires that we understand how and why steelhead and their associated habitats respond to the management actions we take to address key limiting factors and threats. In addition, success requires a decision framework and process which considers new information in the development and implementation of future management actions.

One of the great challenges facing the development and implementation of an effective adaptive management strategy for Oregon's Mid-C steelhead is the extensive number of organizations that implement management actions, as well as the complexity in jurisdictional and management decision authority. There are many different organizations including state agencies, tribes, counties, irrigation districts, agriculture and private forest land managers, NOAA, U.S. Forest Service, BLM, other federal agencies, local residents, citizen groups, utilities and others that implement management actions.

Along with this implementation complexity is a parallel level of jurisdictional, management decision authority, and process complexity. There is no one single decision body that holds decision authority for management actions across all the H's. Decision authority for management actions resides across many entities including state, tribal, federal, county as well as others. Those diverse decision frameworks and processes, many independent of others, create coordination and collaboration challenges. We acknowledge that it is unreasonable to expect centralization and integration of all authorities and decision processes into a single decision framework. Our approach is to develop a collaboration and coordination process that uses the implementation structures and allows for sharing of information and decisions that influence recovery of Mid-C steelhead.

1.13 Research, Monitoring, and Evaluation

Section 13 presents a detailed monitoring and evaluation (M&E) plan that covers the Oregon portion of the Mid-C steelhead DPS. It describes the types of monitoring approaches that are used, current efforts underway, and additional M&E recommended for assessing the status and trends in population viability and for evaluating the success of management actions implemented to recover these steelhead populations. Logistical and monetary limitations are understood to exist; however, a comprehensive M&E plan should help to focus efforts towards the common goal of assessing success in population and DPS recovery.

The M&E plan is based in part on principles and concepts laid out in the NMFS guidance document, *Adaptive Management for ESA-Listed Salmon and Steelhead Recovery: Decision Framework and Monitoring Guidance (May 1, 2007)* http://www.nwr.noaa.gov/Salmon-Recovery-Planning/ESA-Recovery-Plans/upload/Adaptive_Mngmnt.pdf. It also borrows from RM&E plans that were developed for Mid-Columbia subbasins and other Columbia Basin regions.

The plan also follows the principles of adaptive management, the process of adjusting management actions and/or directions based on new information. Adaptive management is considered crucial for salmonid recovery programs because of the length and complexity of the salmonid life cycle, and the uncertainties involved in improving salmonid survival and status. The plan addresses adaptive management by linking monitoring and evaluation to biological and physical responses, and using these results to better design and implement of management actions.

Types of Monitoring Programs

Several types of monitoring are needed to support adaptive management and to allow managers to make sound decisions:

- **Status and Trends Monitoring.** Status monitoring includes measures of the current state or condition of the population at any given time. Trend monitoring tracks these conditions to provide a measure of the increasing, decreasing, or steady state of a status measure through time. Status and trends monitoring includes the collection of standardized basic information used to monitor broad-scale trends over time in the status of fish populations, habitat conditions, and other ecosystem factors affecting fish. This information is the basis for evaluating the cumulative effects of management actions on fish and the aquatic and terrestrial ecosystem.

- **Action Effectiveness Monitoring.** Action effectiveness monitoring involves project-scale monitoring of local conditions to determine if implemented actions were effective in creating the desired proximate change. Action effectiveness monitoring typically is used to determine whether project- or program-specific goals were met. This type of monitoring also includes post-project monitoring to see whether the actions continue to function as they were designed or intended. Note that status and trend monitoring may be appropriate for fulfilling these needs but that project effectiveness monitoring generally requires focused evaluations of more specific parameters directly associated with actions. Specific indicators and metrics need to be developed in plans for each category of action. Specific plans will include measurable variables or parameters to address each objective, study design (spatial and temporal scale, tests and controls, statistical criteria, etc.), data collection methods and reference examples, and analyses and decisions in response to results.

- **Implementation and Compliance Monitoring.** Implementation and compliance monitoring involves monitoring of management actions to determine if they were implemented as planned and meet established benchmarks. This monitoring is typically conducted by the groups implementing the management and restoration actions.

- **Uncertainties Research.** Uncertainties research includes scientific investigations of critical assumptions and unknowns that constrain effective recovery plan implementation. Uncertainties include unavailable pieces of information required for informed decision making as well as studies to establish or verify cause-and-effect and identification and analysis of limiting factors.

Population-Specific Research, Monitoring, and Evaluation Needs

The plan addresses each major population group separately. In some cases, specific objectives are provided at the population scale to characterize unique monitoring needs. Specific approaches are presented that address each objective. A brief sampling design, including the spatial and temporal scale of application, is provided for each objective. Measurement variables protocols and a description of the analysis are presented. Existing and potential funding sources are identified and finally, implementation and coordination details are discussed. The techniques described for each population are not necessarily exhaustive, but are meant to be representative of those actions considered to have potential while recognizing logistical and monetary constraints.

In general, population research, monitoring and evaluation activities are designed to gain information needed to improve knowledge of population viability. They examine status and trends in abundance and productivity of natural spawners; status of spatial structure based on current and historically utilized habitat; status and trend in condition of current and historically utilized habitat; freshwater and full life cycle productivity, and primary factors limiting freshwater production; current status, and change in future status of population life history and phenotypic diversity; effect of disease and predation on population abundance, productivity, diversity, and distribution; effect of harvest on population abundance, productivity, and diversity; effect of hydropower on population abundance, productivity, diversity, and distribution; and effect of habitat degradation and habitat restoration activities on population abundance, productivity, and distribution.

Following are specific research, monitoring and evaluation needs for each population in addition to the general types of activities described above:

Fifteenmile Creek population

- Improved estimates of abundance of stray hatchery fish
- Determine life history characteristics

Deschutes River Eastside and Westside populations

- Effectiveness of passage at Pelton-Round Butte Complex
- Effectiveness of reintroduction into Whychus Creek and the Crooked River population
- Extent of mainstem spawning
- Impact of Snake River strays on viability
- Fall back rate of natural and hatchery fish that pass Sherars Falls
- Spawning distribution of hatchery-origin strays
- Genetic characteristics of natural populations and the degree of introgression of hatchery strays
- Steelhead-resident rainbow relationship in Westside population and impact on steelhead capacity

Crooked River population

- Assess the success of restoring natural production within the Crooked River population boundaries

John Day River populations

- Improved estimates of abundance of hatchery-origin strays
- Spawning distribution of hatchery-origin strays

Umatilla River population

- Hatchery supplementation effectiveness
- Relative reproductive success of hatchery fish
- Spawning distribution of hatchery-origin fish
- Effectiveness of major flow enhancement actions (Phase 3)

Walla Walla River population

- Improved estimates of abundance of hatchery-origin strays
- Spawning distribution of hatchery-origin strays
- Proportion of population spawning below Nursery Bridge
- Effectiveness of major flow enhancement and passage improvement actions

Out of Basin Research, Monitoring and Evaluation Needs

The following types of RM&E actions are needed to support assessment of recovery of the Mid-C steelhead DPS and its Oregon populations:

- Survival improvements from hydrosystem actions
- Survival improvements from predator control actions
- Survival improvements from estuary actions
- Population specific mainstem harvest rates
- Marine survival estimates and variation through time
- Influence of transportation on Snake River hatchery steelhead straying

1.14 Population Summaries

Tables 1-6 through 1-16 summarize vital information related to the recovery of each of Oregon's ten Mid-C steelhead populations. For each population, the summaries identify: key population attributes, minimum viability levels for a low risk recovery scenario, viability assessment results, the viability gap, major limiting factors and threats, and the highest priority tributary habitat strategies and actions.

Table 1-6. Summary of Recovery Information for Fifteenmile Creek Population.

Key Population Attributes
The population occupies the entire Fifteenmile Subbasin and several smaller subbasins—including the Rock, Mosier, Chenoweth, Mill, and Threemile watersheds—which enter the Columbia River directly downstream from Fifteenmile Creek. Current spawning distribution is similar to historical with major production areas in Fifteenmile, Ramsey, Eightmile, and Fivemile creeks.
Recent year natural spawners include only natural-origin fish. Hatchery strays in the Fifteenmile Creek population have rarely been documented.
The population contains three MaSAs, all located in the Fifteenmile Creek watershed: Upper Fifteenmile, Eightmile and Fivemile. It also contains five MiSAs: Mill, Chenoweth, Threemile, Mosier and Lower Fifteenmile.
It is the only Mid-C steelhead population that is classified as an entirely winter run life history type. It is part of the Cascade Eastern Slope Tributaries MPG.
The population is considered a Basic size population with a mean minimum abundance threshold of 500 spawners.
Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)
Abundance: Minimum abundance threshold of 500 spawners.
Productivity: Minimum productivity level of 1.56 recruits per spawner at the threshold abundance.
Viability Assessment Results
Abundance/Productivity: Population is at low risk based on current abundance and productivity. The Abundance/Productivity point estimate resides above the 1% risk curve, but the population is not considered to be at very low risk because of uncertainty criteria, the 98% confidence interval (CI) extends below the 25% risk curve. These A/P results should be viewed with caution, as abundance and productivity estimates for the Fifteenmile population are based on 15 years of spawner/recruit data.
Spatial Structure/Diversity: The integrated SS/D rating is low risk for the population. There has been little change in distribution relative to the historical distribution. The absence of major reductions in distribution resulted in a rating of very low risk for spatial structure metrics. There have likely been minor reductions in life history diversity and phenotypic variation, but these changes are not severe enough to raise risk levels to moderate. There are few hatchery fish in the population resulting in low risk for spawner composition.
Overall Viability Rating: Population *currently meets viability criteria* because both A/P and SS/D are rated at low risk. A relatively small increase in productivity is required to move this population into "highly viable" status. Monitoring should be continued to allow analysis of a longer data time series.
Viability Gap
Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 703 exceeds the minimum threshold abundance of 500. The current productivity estimate of 1.82 recruits per spawner resides between the 5% and 1% risk curves. There is no observed gap or uncertainty gap for the 5% risk level. The observed and uncertainty gaps for the 1% risk level are 0.03 and 0.09 respectively.
Spatial Structure/Diversity: There are no gaps for SS/D since all the SS/D metrics rated very low or low risk.
Limiting Factors and Threats
Primary Limiting Factors: Tributary Habitat: low flows, high water temperatures, degraded riparian condition, sediment routing, degraded floodplain, degraded channel structure (channel confinement and overall habitat diversity); *Hydro:* mainstem passage.
Primary Threats: Current land use practices (including roads, residential development, and agricultural and forest practices) and the Columbia River mainstem hydrosystem.
Primary Life Stages Affected: Fry, summer parr, winter parr, smolts.
VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.
Tributary Management Strategies and Actions (Highest Priority)
Habitat Strategies
Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs.
Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water

conservation measures, improve irrigation conveyance and efficiency.

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, riparian fencing.

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, and stabilize streambanks.

High Priority Areas for all strategies: Fifteenmile Cr - Mouth to FS boundary; Ramsey Cr - Mouth to new FS boundary; Eightmile Cr - Hwy 197 to FS boundary; Fivemile Cr - Mouth to FS boundary.

Harvest Strategies

Strategy: Manage harvest to maintain current low impact fisheries. *Key actions:* Maintain current low impact fisheries.

Hatchery Strategies

Strategy: Reduce uncertainty in abundance and proportion of stray hatchery fish spawning naturally. *Key actions*: increased monitoring of hatchery fish on spawning grounds.

Table 1-7. Summary of Recovery Information for Deschutes River Eastside Population.

Key Population Attributes
The Deschutes River Eastside population occupies the Deschutes River from its mouth to Trout Creek and all tributaries flowing in from the east side, including Willow Creek above Pelton Dam.
Spawners in the population include natural-origin returns, hatchery returns from Deschutes River-origin fish produced at Round Butte Hatchery and out-of-DPS hatchery strays primarily from the Snake River Basin. Hatchery-origin fish comprise a significant proportion of the natural spawners.
The population contains six MaSAs: Buck Hollow, Bakeoven, Ward/Antelope/Cold, Lower Trout, Upper Trout and Willow. It contains two MiSAs: Jones Canyon and Campbell.
The population exhibits a summer life history strategy and is part of the Cascade Eastern Slope Tributaries MPG.
The ICTRT considers it an Intermediate population with a mean minimum abundance threshold of 1,000 spawners.
Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)
Abundance: Minimum abundance threshold of 1,000 spawners.
Productivity: Minimum productivity level of 1.35 recruits per spawner at the threshold abundance.
Viability Assessment Results
Abundance/Productivity: The population is at low risk based on current abundance and productivity. The point estimate on the viability curve resides above the 1% curve, but the population is not considered to be at very low risk since the 99% CI extends below the 25% risk curve.
Spatial Structure/Diversity: The integrated SS/D rating is moderate risk for the population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was low risk. However, the population's spawning distribution is reduced from the historical distribution, primarily from loss of spawning in the Willow Creek drainage. The population remains broadly distributed with little changes in gaps and good continuity within the current accessible habitat. The rating for Goal B "maintaining natural levels of variation" was moderate risk. Habitat changes in key tributary production areas have likely resulted in limitations to life history diversity and reduction in phenotypic expression. Also, a significant proportion of natural spawners are out-of-DPS strays which resulted in a high risk rating for spawner composition.
Overall Viability Rating: The Deschutes River Eastside population *currently meets the recommendation for viable status.* The SS/D rating is moderate risk primarily because of the influence of habitat changes on life history and phenotypic expression, as well as out-of-DPS hatchery spawners.
Viability Gap
Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 1,599 substantially exceeds the minimum threshold abundance of 1,000. The current productivity estimate of 1.89 resides in the very low risk zone and thus there are no observed abundance/productivity gaps. The lower end of the productivity 99% confidence interval is below the 25% risk curve resulting in a 0.05 gap to meet uncertainty criteria for 1% risk level. The abundance/productivity dataset is a relatively short time series which results in a larger 90% CI than is typical of most other Oregon Mid-C populations.

Spatial Structure/Diversity: Spatial structure/diversity gaps were identified for the following metrics: *Phenotypic variation*: moderate risk due to likely reduction in juvenile and adult migration patterns resulting from flow and temperature changes in tributary production areas; *Spawner composition*: Out-of-DPS spawners rated high risk due to the high proportion of Snake River strays spawning naturally in the population. Out-of-population within MPG spawners rated moderate risk due to the proportion of Round Butte Hatchery fish spawning naturally in the population.
Limiting Factors and Threats *Primary Limiting Factors: Tributary Habitat:* degraded riparian condition, low flows, high water temperatures, degraded channel structure/complexity and floodplain connectivity, impaired fish passage. *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage. *Primary Threats:* Hatchery production which results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (grazing, roads, residences, forestry and agricultural practices that simplify habitats and irrigation withdrawals); the Columbia River mainstem hydrosystem. *Primary Life Stages Affected:* Spawners, fry, summer parr, winter parr, smolts. *VSP Characteristics Impacted:* Abundance, productivity, spatial structure, diversity.
Tributary Management Strategies and Actions (Highest Priority) *Habitat Strategies* *Strategy:* Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: Bakeoven Cr (mouth to Deep Cr), Buck Hollow Cr (mouth to Macken Canyon), Trout Cr (Little Trout Cr. to headwaters) *Strategy*: Restore passage and connectivity. *Key actions*: Remove/replace barriers, adequate screening of irrigation diversions. *Priority areas*: Bakeoven Cr, Mud Springs Cr., Hay Cr *Strategy*: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures, improve irrigation conveyance and efficiency. *Priority areas:* Trout Cr (mouth to Clover Cr), Antelope Cr *Strategy:* Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Trout Cr (Little Trout Cr to Clover Cr, sections from mouth to Antelope Cr), Antelope Cr, Hay Cr *Strategy:* Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, and stabilize streambanks. *Priority areas*: same as for riparian strategy. *Hydrosystem Strategies* *Strategy:* Improve flow patterns through Pelton-Round Butte Complex (PRBC), restore water quality below PRBC. *Priority areas*: Deschutes R. (at and below PRBC). *Harvest Strategies* *Strategy:* Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries. *Hatchery Strategies* *Strategy:* Reduce uncertainty regarding hatchery strays and reduce abundance and proportion of stray hatchery fish spawning naturally. *Key actions*: coded-wire-tagging program, development of alternative broodstocks for programs contributing strays, increased monitoring on spawning grounds and trap and removal of strays.

Table 1-8. Summary of Recovery Information for Deschutes River Westside Population.

Key Population Attributes The Deschutes River Westside population occupies the mainstem Deschutes River from Trout Creek to the Pelton-Round Butte Complex (PRBC) at RM 100 and tributaries joining the Deschutes from the Westside, including the Warm Springs River and Shitike Creek below the hydroelectric complex and the Metolius River and Whychus Creek drainages above the complex. The Warm Springs watershed and Shitike Creek currently provide most spawning habitat. Whychus Creek was once a major steelhead producer for the population. Recent year natural spawners include returns originating from naturally spawning parents, strays from the Deschutes Subbasin Round Butte Hatchery program, and a significant number of out-of-DPS hatchery strays from the Snake

River. Natural-origin spawners have comprised an average of 82% of natural spawning fish since 1978.

The population contains six MaSAs: Upper Warm Springs, Whychus, Upper Metolius, Mill, Beaver and Shitike; and nine MiSAs.

The population exhibits a summer life history strategy and is part of the Cascades Eastern Slope Tributaries MPG.

The ICTRT considers it a 'large' population with a mean minimum abundance threshold of 1,500 spawners. Access to a considerable amount of historical habitat is blocked by PRBC, with current spawning only below the barrier. The minimum abundance threshold is 1,000 spawners for currently available habitat.

Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)

Abundance: Minimum abundance threshold of 1,500 spawners (1,000 for currently accessible habitat).

Productivity: Minimum productivity level of 1.35 recruits per spawner at the threshold level.

Viability Assessment Results

Abundance/Productivity: Population is at high risk based on current abundance and productivity. The point estimate on the viability curve resides below the 25% risk curve.

Spatial Structure/Diversity: The integrated spatial structure/diversity rating is high risk for the population. It rates at moderate risk for two of the spatial distribution metrics because the current distribution is substantially reduced from the historical intrinsic distribution due to blocked passages to areas above the Pelton-Round Butte Complex. Ratings for two metrics related to Goal B "maintaining natural patterns of variation" resulted in a moderate rating for Goal B and the overall moderate rating. Genetic variation rated moderate due to limited data and the lack of differentiation between the Deschutes samples and outside-basin hatchery samples. Samples collected in 2005-2007 will better inform the risk associated with genetic variation. The proportion of out-of-DPS hatchery strays resulted in a high risk rating for spawner composition. Most of these strays originate from the Snake River Basin.

Overall Viability Rating: The Deschutes River Westside *population does not currently meet recommendations for viability and is below maintained status*. However, it is the only extant Large or Very Large population in the MPG and should be recovered to meet the viability criteria. A substantial increase in productivity will be required to raise the A/P values to the low risk level. Genetics information presently being collected will better inform the genetics variation risk level in the future. A reduction in the out-of-ESU hatchery stray proportion will be needed to reduce the risk rating for the spawner composition metric.

Viability Gap

Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 456 is well below the abundance threshold of 1,000, the threshold abundance for currently available habitat. The current productivity estimate of 1.05 recruits per spawner is well below the minimum of 1.35 required at the threshold abundance. The observed gaps, which are greater than uncertainty gaps, for the 5% and 1% risk levels are 0.78 and 0.92 respectively. This gap is by far the largest observed gap of all the Oregon Mid-C populations. The large gap results from the substantial difference in the equilibrium abundance (448) and the threshold abundance, as well as the low productivity.

Spatial Structure/Diversity: Spatial structure/diversity gaps were identified for the following metrics: *Spatial extent and range of population*: moderate risk because spawner distribution is substantially reduced from historical due to blocked access to Whychus Creek and the Metolius River; *Genetic variation:* moderate risk because there are limited genetics data available and the samples that have been analyzed show similarity to out-of-DPS hatchery strays; *Spawner composition: O*ut-of-DPS spawners rated high risk because out-of-DPS strays have comprised a significant proportion of the natural spawners in this population for many generations.

Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: degraded channel structure and complexity, altered sediment routing, high water temperature, low flows and lack of fish passage over PRBC; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage and tributary passage to blocked areas above Pelton-Round Butte Complex.

Primary Threats: Hatchery production that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (grazing, roads, residences, forestry and agricultural practices that simplify habitats and irrigation withdrawals); the Columbia River mainstem hydrosystem, Pelton-Round Butte Complex.

Primary Life Stages Affected: Spawners, fry, summer parr, winter parr, smolts.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

Tributary Management Strategies and Actions (Highest Priority)
Habitat Strategies
Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas:* Spawning areas in mainstem Deschutes R. below PRBC.
Strategy: Restore passage and connectivity. *Key actions*: Restore passage at PRBC, remove/replace barriers, adequate screening of irrigation diversions. *Priority areas*: Deschutes R. (RM 100), Warm Springs R, Shitike Cr, Beaver Cr.
Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures, improve irrigation conveyance and efficiency. *Priority areas:* Whychus Cr.
Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Deschutes R. (Eagle Cr to Shitike Cr), Deschutes R (Trout Cr to PBR), Warm Springs R., Shitike Cr., Beaver Cr., Whychus Cr.
Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, and stabilize streambanks. *Priority areas*: Deschutes R. (Eagle Cr to Shitike Cr), Deschutes R. (Trout Cr to PBRC), Warm Springs R. (mouth to Badger Cr), Shitike Cr. (mouth to road crossing), Beaver Cr. (mouth to Robinson Park Bridge)
Hydrosystem Strategies
Strategy: Restore steelhead production in historical habitats. *Key actions*: develop juvenile collection and passage through PRBC, improve flow patterns through PRBC, restore water quality below PRBC. *Priority areas*: Deschutes R. (at and below PRBC).
Harvest Strategies
Strategy: Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries.
Hatchery Strategies
Strategy: Reduce uncertainty regarding hatchery strays and reduce abundance and proportion of stray hatchery fish spawning naturally. *Key actions:* coded-wire-tagging program, development of alternative broodstocks, increased monitoring on spawning grounds and trap and removal of strays.
Strategy: Reduce genetic risks associated with Round Butte Hatchery Program. *Key actions*: investigate incorporating naturally produced local steelhead into RBH broodstock.
Strategy: Restore natural production in historically utilized habitats. Key actions: develop plan for steelhead reintroductions above PRBC. *Priority areas*: Metolius R, Whychus Cr, Deschutes R.

Table 1-9. Summary of Recovery Information for Deschutes/Crooked River Population.

Key Population Attributes
The Deschutes/Crooked River population once occupied the Crooked River drainage, a major watershed in the Deschutes basin.
The population is now extinct because of the lack of passage above Pelton Dam.
The population exhibited a summer life history strategy and is part of the Cascade Eastern Slope Tributaries MPG.
The ICTRT considers it a very large population with a mean minimum abundance threshold of 2,250 spawners.
Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)
Abundance: Minimum abundance threshold of 2,250 spawners.
Productivity: Minimum productivity level of 1.19 recruits per spawner at the threshold abundance.
Viability Assessment Results
The ICTRT did not complete a viability assessment for the population because it is currently extinct.
Overall Viability Rating: The Deschutes/Crooked River population is currently considered extinct.
Viability Gap
A gaps analysis was not completed for the Deschutes/Crooked River population because it is currently extinct.
Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: degraded channel structure and complexity and floodplain connectivity, degraded riparian condition, high water temperature, low flows, altered hydrology sediment routing, and lack of fish passage; *Hydro:* Impaired upstream and downstream migration.

Primary Threats: grazing and agricultural practices, urban development, off highway vehicle (OHV) use, irrigation withdrawal, dams, lack of floodplain connectivity; Pelton-Round Butte Complex on the mainstem Deschutes blocks fish passage.

Primary Life Stages Affected: All life stages.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

Tributary Management Strategies and Actions (Highest Priority)

Habitat Strategies

Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: Crooked River (RM 6-14, RM 55-70), McKay Cr, Ochoco Cr (below Ochoco Dam)

Strategy: Restore passage and connectivity. *Key actions*: Remove/replace barriers including dams, road culverts, irrigation structures, infiltration galleries; provide adequate screening of irrigation diversions. *Priority areas*: Rice Baldwin Dam, Stearns Dam, Seamus Dam, Parga Dam, Peoples irrigation diversion

Strategy: Restore floodplain connectivity and function. *Key actions*: Reconnect floodplain and side channels to channel. *Priority areas:* Crooked River (RM 31-51), McKay Cr

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures, improve irrigation conveyance and efficiency, lease/purchase water rights and convert to instream. *Priority areas:* Crooked River (RM 14-55), McKay Cr, Allen Cr, Ochoco Cr (below Ochoco Dam)

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Crooked River (RM 14-55), McKay Cr, Ochoco Cr (below Ochoco Dam), Allen Cr

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, and stabilize streambanks. *Priority areas*: Crooked River (RM 31-51), McKay Cr.

Hydrosystem Strategies

Strategy: Restore steelhead production in historical habitats. *Key actions*: develop juvenile collection and passage through PRBC, improve flow patterns through PRBC, restore water quality below PRBC. *Priority areas*: Deschutes R. (at and below PRBC).

Hatchery Strategies

Strategy: Restore natural production to blocked areas above PRBC. *Key actions*: Develop and implement a comprehensive plan for the reintroduction of steelhead into the Crooked River population area.

Table 1-10. Summary of Recovery Information for Lower Mainstem John Day River Population.

Key Population Attributes

The population occupies the Lower John Day watershed below the mouth of the South Fork John Day River and the town of Dayville. Steelhead in this population spawn in tributary streams connected to the lower John Day River including Bridge, Butte, Thirtymile, Hay and Rock creeks.

Recent year natural spawners include returns originating from naturally spawning parents, and a small fraction of strays from the Snake River and Columbia River hatchery programs.

The population contains 11 MaSAs and 19 MiSAs. Major spawning areas include Bridge, Mountain, Cottonwood, Hay, Middle Rock, Upper Rock, Pine Hollow, Long Rock (Lower John Day) Thirtymile, Butte, and Grass Valley. All 11 MaSAs are currently occupied and 11 of the 19 MiSAs are occupied.

The population exhibits a summer life history strategy and is part of the John Day River MPG.

It is considered a Very Large population with a mean minimum abundance threshold of 2,250 spawners.

Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)

Abundance: Minimum abundance threshold of 2,250 spawners.

Productivity: Minimum productivity level of 1.19 recruits per spawner at the threshold abundance.

Viability Assessment Results

Abundance/Productivity: The population is at moderate risk based on current A/P. The productivity is very low risk because the point estimate is above very low risk and the lower end of the adjusted standard error is above the 5% risk level. The abundance is moderate risk because it resides between the 5% and 25% risk levels.

Spatial Structure/Diversity: The integrated rating is moderate risk for the population. The rating for Goal A "allowing natural rates and level of spatially mediated processes" was very low. The current spawner distribution is similar to historical with all MaSAs occupied. The MiSAs that are currently unoccupied have little influence on gaps and continuity, and spawners are spread over a very broad geographic area. The rating for Goal B "maintaining natural levels of variation" was moderate risk. This rating was a result of moderate risk for life history and genetic variation and high risk for spawner composition out-of-DPS hatchery strays. The magnitude and trend in out-of-DPS hatchery strays are of significant concern. Analysis of genetics information will yield considerable insight into the genetic variation and characteristics of this population.

Overall Viability Rating: The Lower Mainstem John Day River population *does not currently meet recommendations for viability*, although it does meet criteria for a "maintained" population. To achieve a viable rating, this population must improve in both A/P and SS/D. Out-of-DPS origin spawners are the most influential factor on diversity risk. Additional population specific data are needed to better quantify the spawner composition in this population to reduce the uncertainty associated with this risk metric.

Viability Gap

Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 1,800 is 72% of the threshold abundance of 2,250 natural spawners. The current productivity of 2.99 recruits per spawner is well above the minimum required to meet the 1% risk level. The lower end of the 99% CI also resides above the minimum needed to meet the 1% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.11. This gap is a result of the difference in the equilibrium abundance (2,019) and the threshold abundance.

Spatial Structure/Diversity: Gaps were identified for the following spatial structure/diversity metrics: *Major life history strategies:* moderate risk because habitat changes have resulted in reduced juvenile life history diversity and restricted summer rearing distribution. *Genetic variation*: moderate risk because there are no genetics data and due to potential genetic effects of the high proportion of out-of-DPS spawners. *Spawner composition:* Out-of-DPS spawners rated high risk due to high proportion and increasing trend of out-of-DPS spawners.

Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: degraded channel structure and complexity (habitat quantity and diversity), altered sediment routing, water temperature, and altered hydrology. Impaired fish passage is also a high priority limiting factor in Bridge, Butte, Kahler, Muddy, Rock, and Thirtymile creeks. *Hatchery*: effects of naturally spawning stray hatchery fish on viability. *Hydro:* mainstem passage.

Primary Threats: Hatchery production that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (agricultural and grazing practices, removal of overstory trees and bank vegetation from the riparian corridor, water withdrawals, wetland draining and conversion, and stream channelization and diking; the Columbia River mainstem hydro system.

Primary Life Stages Affected: Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, smolts.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

Tributary Management Strategies and Actions (Highest Priority)

Habitat Strategies

Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: Pine, Bridge, Cottonwood creeks.

Strategy: Restore passage and connectivity. *Key actions*: Remove/replace barriers, adequate screening of irrigation diversions. *Priority areas*: Rock, Upper Rock, Middle Rock, Lone Rock, Thirtymile, Butte, and Bridge creeks.

Strategy Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, stabilize streambanks. *Priority areas*: Rock, Middle Rock, Thirtymile and Butte creeks.

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water

conservation measures, improve irrigation conveyance and efficiency. *Priority areas:* Rock, Bridge, Rock Mountain, lower Parrish and Kahler creeks

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas:* Lone Rock, Mountain Cr (Wheeler Co), Parrish Cr, Cherry Cr, Kahler Cr, Bridge Cr, Thirtymile Cr, Butte Cr, and upper reaches of Pine Hollow Canyon Cr.

Strategy: Restore passage and connectivity: *Key actions:* Remove or minimize use of push up dams; remove or replace barriers blocking passage; provide screening at all irrigation diversions; replace screens that do not meet criteria. *Priority areas*: Rock, Upper Rock, Middle Rock, Lone Rock, Thirtymile, Butte, and Bridge creeks.

Harvest Strategies

Strategy: Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries.

Strategy: Reduce catch and release mortality on natural steelhead spawner. *Key actions*: voluntary curtailment of fishing at higher water temperatures.

Strategy: Improve quality of harvest information. *Key actions*: expand creel surveys.

Hatchery Strategies

Strategy: Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* coded-wire-tagging program, development of alternative broodstocks.

Strategy: Reduce uncertainty in abundance and proportion of stray hatchery fish spawning naturally. *Key actions:* increased monitoring on spawning grounds and possibly trapping.

Table 1-11. Summary of Recovery Information for North Fork John Day River Population.

Key Population Attributes

The population occupies the North Fork John Day watershed excluding the Middle Fork drainage. The North Fork John Day is the largest tributary to the John Day River, draining approximately 1,800 mi^2.

Recent year natural spawners include returns originating from naturally spawning parents, and a small fraction of strays from the Snake and Columbia River hatchery programs.

The population contains 8 MaSAs (Lower North Fork John Day, Potamus, Big Wall, Big, Upper North Fork John Day, Desolation, Granite, and Owens) and seven MiSAs (Bridge, Meadow Brook, two Cabins, Fivemile, Meadow and Ditch).

The population exhibits a summer life history strategy and is part of the John Day River MPG.

The population is considered a Large population with a mean minimum abundance threshold of 1,500 spawners.

Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)

Abundance: Minimum abundance threshold of 1,500 spawners.

Productivity: Minimum productivity level of 1.26 recruits per spawner at the threshold abundance.

Viability Assessment Results

Abundance/Productivity: The North Fork John Day River population is at very low risk based on current abundance and productivity. The point estimate for abundance and productivity resides above the 1% risk curve and the 99% confidence interval for productivity is above the 25% risk curve.

Spatial Structure/Diversity: The combined integrated SS/D rating is low risk for the population. The rating for Goal A "allowing natural rates and level of spatially mediated processes" was very low. Current spawner distribution mimics the intrinsic distribution. The population is distributed broadly across the landscape in numerous MaSAs and MiSAs. Good continuity exists between spawning areas and current gaps between spawning areas are similar to historical gaps. The rating for Goal B "maintaining natural levels of variation" was low risk. However, there remains considerable uncertainty about the ratings for genetic variation and out-of-DPS hatchery strays in the natural spawners. Additional genetic analyses and interpretation is needed to determine if the genetic variation is similar to historical conditions and to examine evidence for degree of stray hatchery fish introgression. The metric for out-of-DPS hatchery strays rated very high. The data used for this rating are a composite from four John Day populations. Additional population specific spawner composition data are needed to improve the certainty of the out-of-DPS stray hatchery risk rating. If there is

significant hatchery introgression that is affecting the genetic variation through time then the risk rating for "genetic variation" will increase and the overall risk rating for Goal B and SS/D will also increase.

Overall Viability Rating: The overall viability rating for the North Fork John Day steelhead population *is considered highly viable* as a result of the A/P rating of very low risk, and the SS/D rating of low risk. There remains considerable uncertainty regarding the genetic effect of out-of-DPS strays, as well as the actual proportion of natural spawners that are hatchery strays. Enhanced monitoring efforts should be undertaken to develop better estimates of the composition of North Fork John Day spawners.

Viability Gap

Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 1,740 exceeds the threshold abundance of 1,500. The current productivity of 2.41 recruits per spawner is well above the value needed to meet the 1% risk level. The lower end of the 90% CI resides above the 1% risk level. No abundance/productivity gaps exist for the 5% or 1% risk levels.

Spatial Structure/Diversity: All metrics rated very low or low risk except for the following: *Spawner composition:* Out-of-DPS spawners rated high risk due to the high estimated proportion of Snake River hatchery strays within this population. There is also considerable uncertainty regarding the hatchery fraction estimates for this population.

Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: degraded floodplain connectivity and function, degraded channel structure and complexity (key habitat quantity, habitat diversity, channel stability), altered sediment routing, water temperature, and low flows; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.

Primary Threats: Hatchery management that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, irrigation withdrawals, mining and dredging); the Columbia River mainstem hydro system.

Primary Life Stages Affected: Parr-to-smolt survival, egg-to-fry survival, smolts.

VSP Characteristics Impacted: Abundance, productivity, diversity.

Tributary Management Strategies and Actions (Highest Priority)

Habitat Strategies

Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: tributaries within the NF John Day Wilderness, NF John Day River (Big Cr to headwaters), SF Desolation Cr, upper Clear Cr

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Cottonwood Cr below Fox Cr, Camas Cr above Wilkins Cr

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, stabilize streambanks. *Priority areas*: Camas Cr (Wilkins Cr to Cable Cr), Clear Cr below Ruby Cr, Olive Cr below Beaver Cr, Bull Run Cr, Cottonwood Cr below EF Cottonwood

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures; improve irrigation conveyance and efficiency. *Priority areas:* Cottonwood/Fox, Rudio, Camas Cr above Wilkins Cr

Harvest Strategies

Strategy: Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries.

Strategy: Reduce catch and release mortality on natural steelhead spawner. *Key actions*: voluntary curtailment of fishing at higher water temperatures.

Strategy: Improve quality of harvest information. *Key actions*: expand creel surveys.

Hatchery Strategies

Strategy: Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* coded-wire-tagging program, marking of all hatchery steelhead in Columbia River Basin, development of alternative broodstocks, reduced transport of hatchery smolts from Snake River.

Strategy: Reduce uncertainty in abundance and proportion of stray hatchery fish spawning naturally. *Key actions:* increased monitoring on spawning grounds and possibly trapping.

Table 1-12. Summary of Recovery Information for Middle Fork John Day River Population.

Key Population Attributes
The population occupies the Middle Fork drainage, which contains five watersheds, all used by steelhead.
Recent year natural spawners include returns originating from naturally spawning parents, and a small fraction of strays from the Snake and Columbia River hatchery programs.
Two MaSAs exist in the Middle Fork John Day River population, including Middle Fork John Day and Long Creek, and no MiSAs.
The population exhibits a summer life history strategy and is part of the John Day River MPG.
It is considered an Intermediate population with a mean minimum abundance threshold of 1,000 spawners.
Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)
Abundance: Minimum abundance threshold of 1,000 spawners.
Productivity: Minimum productivity level of 1.35 recruits per spawner at the threshold abundance.
Viability Assessment Results
Abundance/Productivity: The population is at moderate risk based on current abundance and productivity. The point estimate is between 5% and 25% risk curves.
Spatial Structure/Diversity: The integrated SS/D rating is low risk for the population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was between very low and low risk. Current spawner distribution mimics the intrinsic distribution. The population is distributed broadly across the landscape, in multiple MaSAs with adequate gaps and good continuity between spawning areas. The rating for Goal B "maintaining natural levels of variation" was low risk; however, additional genetics analyses are needed to better assess genetic variation and hatchery introgression. The population rated high risk for proportion of out-of-DPS hatchery strays based on a limited time series of composite John Day population data. Better population specific spawner composition data are needed to better understand the out-of-DPS hatchery stray influence. If significant hatchery introgression affects genetic variation through time, then the risk rating will increase, thus raising the overall risk rating for Goal B and the overall SS/D rating.
Overall Viability Rating: The population *does not currently meet the recommended viability criteria*, although it does meet criteria for a "maintained" population. Increased annual abundance would allow this population to achieve a risk rating of low for A/P and raise the overall viability rating to viable.
Viability Gap
Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 756 is 75.6% of the threshold abundance of 1,000. The current productivity of 2.45 recruits per spawner is above the minimum needed at threshold abundance. The lower end of the 90% CI is well above the 25% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.08. This gap is a result of the difference in equilibrium abundance (928) and the threshold abundance.
Spatial Structure/Diversity: All metrics rated very low or low risk except for the following: *Spawner composition:* Out-of-DPS spawners rated high risk due to the high estimated proportion of out-of-DPS strays within this population.
Limiting Factors and Threats
Primary Limiting Factors: Tributary Habitat: degraded channel structure and complexity (habitat quantity and diversity), degraded floodplain function and connectivity, altered sediment routing, altered hydrology, and water temperature; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.
Primary Threats: Hatchery management that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, passage barriers, irrigation withdrawals, mining and dredging); the Columbia River mainstem hydro system.
Primary Life Stages Affected: fry-to-smolt, egg incubation; egg-to-parr, smolts, adult spawning.
VSP Characteristics Impacted: Abundance, productivity, diversity.
Tributary Management Strategies and Actions (Highest Priority)
Habitat Strategies
Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs.

Priority areas: Upper reaches of Big, Big Boulder, and Granite Boulder creeks that originate in the Vinegar Hill-Indian Rock Scenic Area.

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Mainstem Middle Fork John Day (Crawford to Bridge Cr, Horse to Camp Cr, Long Cr, Camp Cr).

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, stabilize streambanks. *Priority areas*: Middle Fork from mouth of Granite Boulder Cr to Ragged Cr, between Big Boulder Cr and Camp Cr, and near the mouth of Mosquito Cr

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures; improve irrigation conveyance and efficiency. *Priority areas:* Long Cr and tributaries

Harvest Strategies

Strategy: Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries.

Strategy: Reduce catch and release mortality on natural steelhead spawner. *Key actions*: voluntary curtailment of fishing at higher water temperatures.

Strategy: Improve quality of harvest. *Key actions*: expand creel surveys.

Hatchery Strategies

Strategy: Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* coded-wire-tagging program, development of alternative broodstocks.

Strategy: Reduce uncertainty in abundance and proportion of stray hatchery fish spawning naturally. *Key actions:* increased monitoring on spawning grounds and possibly trapping.

Table 1-13. Summary of Recovery Information for South Fork John Day River Population.

Key Population Attributes

The population occupies the South Fork drainage in the John Day River Basin. Steelhead spawn and rear through the lower South Fork John Day up to Izee Falls at RM 28.5 and in Murderers Creek and other South Fork tributaries.

Recent year natural spawners include returns originating from naturally spawning parents, and a small fraction of strays from the Snake River and Columbia River hatchery programs.

The population includes three MaSAs: Upper South Fork, Lower South Fork and Murderers Creek.

It exhibits a summer life history strategy and is part of the John Day River MPG.

The population is considered a Basic population with a mean minimum abundance threshold of 500 spawners.

Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)

Abundance: Minimum abundance threshold of 500 spawners.

Productivity: Minimum productivity level of 1.56 recruits per spawner at the threshold abundance.

Viability Assessment Results

Abundance/Productivity: The population is at moderate risk based on current abundance and productivity. The point estimate resides between the 25% and 5% viability curves. The lower bound of the adjusted standard error for both the productivity and abundance extend below the 25% risk level.

Spatial Structure/Diversity: The integrated SS/D rating is low risk for the population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" rated midway between very low and low risk. Although the current spawner distribution mimics the intrinsic distribution, only three MaSAs exist within the population. Good continuity exists between spawning areas and gaps between areas have remained relatively unchanged. The rating for Goal B "maintaining natural levels of variation" is low risk. As is the case for all John Day steelhead populations, there is uncertainty in ratings of metrics "genetic variation" and "proportion of spawners that are out-of-DPS strays." Limited genetics data for South Fork steelhead restrict efforts to determine if the current population variation is similar to historical conditions and to examine the degree of hatchery fish introgression. The metric for proportion of out-of-DPS strays rated as high risk. However, the analyses relied on composite data from four John Day populations. Additional population specific spawner composition data are needed to better inform the risk rating and to reduce the associated uncertainty.

Overall Viability Rating: The population *does not currently meet the recommended viability criteria*, although it does meet

criteria for a "maintained" population. Improvement in abundance will allow this population to achieve viable status. However, while the population received a SS/D rating of low risk, there is considerable uncertainty surrounding the spawner composition data. Enhanced monitoring of the hatchery-wild ratios on the South Fork spawning grounds should be conducted to improve the hatchery fraction estimate and reduce the degree of uncertainty.

Viability Gap

Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 259 is 51.8% of the threshold abundance of 500. The current productivity of 2.00 recruits per spawner is greater than the minimum required at the abundance threshold. The lower end of the 90% CI extends well below the 25% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.22. The uncertainty gap for the 1% risk level is 0.23. The gaps are primarily a result of the difference between the equilibrium abundance (409) and the threshold abundance.

Spatial Structure/Diversity: All metrics rated very low or low risk except the following: *Spawner composition*: Out-of-DPS spawners rated high risk due to the high estimated proportion of out-of-DPS strays within this population.

Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: altered sediment routing, degraded channel structure and complexity (habitat quantity and diversity), altered hydrology and low flow, water temperature, and impaired fish passage; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.

Primary Threats: Hatchery management that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, fish passage barriers (culverts, and other seasonal barriers), and irrigation withdrawals); the Columbia River mainstem hydro system.

Primary Life Stages Affected: Juvenile rearing, adult spawning, egg incubation, egg-to-parr survival, smolts.

VSP Characteristics Impacted: Abundance, productivity, diversity.

Tributary Management Strategies and Actions (Highest Priority)

Habitat Strategies

Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: Lower Murderers Cr tributaries draining the south side of Aldrich Mountain.

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Upper South Fork River above Izee Falls, SF Murderers Cr, Deer Cr

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, stabilize streambanks. *Priority areas*: same as for riparian strategy.

Strategy: Restore degraded floodplain connectivity and function. *Key actions*: Reconnect floodplain to channel, reconnect side channels and off-channel habitats, restore wet meadows. *Priority areas:* SF Murderers Cr, Deer Cr, Upper South Fork River above Izee Falls.

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures; improve irrigation conveyance/efficiency. *Priority areas:* SF Murderers Cr, Deer Cr, Upper South Fork River above Izee Falls.

Harvest Strategies

Strategy: Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries.

Strategy: Reduce catch and release mortality on natural steelhead spawner. *Key actions*: voluntary curtailment of fishing at higher water temperatures.

Strategy: Improve quality of harvest information. *Key actions*: expand creel surveys.

Hatchery Strategies

Strategy: Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* enhance coded-wire-tagging program, development of alternative broodstock.

Strategy: Reduce uncertainty in abundance and proportion of stray hatchery fish spawning naturally. *Key actions:* increased monitoring on spawning grounds and trapping.

Table 1-14. Summary of Recovery Information for Upper Mainstem John Day River Population.

Key Population Attributes
The population occupies the John Day River drainage above the town of Dayville and the mouth of the South Fork John Day River.
Recent year natural spawners include returns originating from naturally spawning parents and a small fraction of strays from the Snake River and Columbia River hatchery programs.
The population includes five MaSAs, Upper John Day, Upper Middle Mainstem John Day, Laycock, Beech and Canyon, and no MiSAs. The MaSAs are located primarily in the upper portions of the population boundaries.
The population exhibits a summer life history strategy and is part of the John Day River MPG.
It is considered an Intermediate population with a mean minimum abundance threshold of 1,000 spawners.
Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)
Abundance: Minimum abundance threshold of 1,000 spawners.
Productivity: Minimum productivity level of 1.35 recruits per spawner at the threshold abundance.
Viability Assessment Results
Abundance/Productivity: The population is at moderate risk based on current abundance and productivity. The point estimate for abundance and productivity resides between the 5% and 25% risk curves.
Spatial Structure/Diversity: The integrated SS/D rating is moderate risk for the Upper Mainstem John Day River population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was very low because the current distribution is nearly identical to the historical distribution. The rating for Goal B "maintaining natural levels of variation" was moderate risk. This risk rating was a result of a moderate rating for changes in major life history strategies. Additional genetics information needs to be assessed to determine current genetic variation and to examine for the degree of introgression of hatchery fish. The population was rated as high risk for out-of-DPS hatchery strays based on a limited time series of composite John Day population hatchery fish observation data. Better population specific spawner composition data are needed to better determine the out-of-DPS hatchery fraction. If there is significant hatchery introgression that affects the genetic variation of this population through time, then the risk rating for Goal B will increase, and the overall risk rating for SS/D will increase.
Overall Viability Rating: The population *does not currently meet the recommended viability criteria*, although it does meet criteria for a "maintained" population. An increase in abundance is needed for this population to achieve viable A/P criteria. In addition, the SS/D rating was moderate due to loss in life history diversity and high risk for spawner composition.
Viability Gap
Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 524 is only 52.4% of the threshold abundance of 1,000. The current productivity of 2.14 recruits per spawner is well above the minimum required at the threshold abundance. The lower end of the 90% CI resides above the 25% risk level. The observed A/P gap to reach the 5% and 1% risk levels is 0.37. The uncertainty gaps are less than the observed gaps. The gap is primarily a result of the difference in the equilibrium abundance (730) and the threshold abundance.
Spatial Structure/Diversity: Gaps were identified for the following SS/D metrics: *Major life history strategies:* moderate risk due to reduced opportunities for juvenile movement patterns and reduced summer rearing distribution that has resulted from altered mainstem and tributary habitats. *Spawner composition:* Out-of-DPS spawners rated high risk due to the high proportion of out-of-DPS strays and uncertainty in the estimates of hatchery fraction.
Limiting Factors and Threats
Primary Limiting Factors: Tributary Habitat: degraded channel structure and complexity (habitat quantity and diversity), degraded riparian areas and LWD recruitment, altered sediment routing, water temperatures, altered hydrology and degraded floodplain function and connectivity. Impaired fish passage is also a priority limiting factor in Beech and Laycock creeks. *Hatchery:* effects of naturally spawning stray hatchery fish on viability. *Hydro:* mainstem passage.
Primary Threats: Hatchery production that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (agricultural practices, livestock overgrazing, removal of large trees from the riparian corridor, wetland draining/conversion, stream channelization/diking); the Columbia River mainstem hydro system.
Primary Life Stages Affected: Juvenile rearing, egg incubation, egg-to-parr survival, smolts, adult spawning.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.
Tributary Management Strategies and Actions (Highest Priority) *Habitat Strategies* *Strategy*: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: EF and Middle Fork of Canyon Cr, John Day River above Blue Mt. Hot Springs. *Strategy*: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Upper mainstem John Day River, Beech Cr, Bear Cr, lower reaches of Fields Cr, Belshaw Cr and Riley Cr. *Strategy:* Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, stabilize streambanks. *Priority areas*: Mainstem John Day River (Dayville to Blue Mt. Hot Springs), Indian Cr, Pine Cr, lower Beech Cr, middle Canyon Cr, lower Strawberry Cr *Strategy*: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement water conservation measures; improve irrigation conveyance/efficiency. *Priority areas:* Fields, Indian, Pine, Beech, Strawberry and Laycock creeks, John Day River (Dayville to Mt. Vernon). *Strategy*: Restore passage and connectivity. *Key actions*: Remove or minimize use of push up dams, remove or replace culverts and/or other passage barriers. *Priority areas*: Beech, Canyon, Strawberry, Dixie, and Reynolds creeks. *Harvest Strategies* *Strategy:* Use harvest to reduce stray hatchery spawners. *Key actions*: selective fisheries. *Strategy:* Reduce catch and release mortality on natural steelhead spawner. *Key actions*: voluntary curtailment of fishing at higher water temperatures. *Strategy:* Improve quality of harvest information. *Key actions*: expand creel surveys. *Hatchery Strategies* *Strategy:* Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* enhance coded-wire-tagging program, development of alternative broodstocks. *Strategy:* Reduce uncertainty in abundance and proportion of stray hatchery fish spawning naturally. *Key actions:* increased monitoring on spawning grounds and trapping.

Table 1-15. Summary of Recovery Information for Umatilla River Population.

Key Population Attributes The Umatilla River steelhead population occupies the Umatilla watershed and a few smaller streams in Washington State that flow directly into the Columbia River. Recent year natural spawners include returns originating from naturally spawning parents, Umatilla River hatchery-origin fish and out-of-DPS strays, primarily from the Snake River Basin. The ICTRT has identified 13 MaSAs for this steelhead population. Eleven of the MaSAs are within the Umatilla drainage in Oregon: Butter, East Birch, McKay, Meacham, Middle Umatilla, Upper Umatilla, Lower Middle Umatilla, Lower Birch, Lower Umatilla, Wildhorse and West Birch. The population also has three MiSAs: Alkali, Fourmile Canyon, and Cottonwood. Two of the MaSAs, Alder Creek and Glade Creek, are included in the Umatilla population, but are direct tributaries to the Columbia River on the Washington side. Currently only eight of the 13 MaSAs are occupied. The population exhibits a summer life history strategy and is part of the Umatilla/Walla Walla Rivers MPG. It is considered a Large population with a mean minimum abundance threshold of 1,500 spawners.
Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk) *Abundance:* Minimum abundance threshold of 1,500 spawners. *Productivity:* Minimum productivity level of 1.26 recruits per spawner at the threshold abundance.
Viability Assessment Results *Abundance/Productivity*: The population is at moderate risk. The productivity is at low risk because the point estimate is above 5% risk level and the adjusted standard error is above the 25% risk level. Abundance is moderate because the point estimate is slightly below the 5% risk level.

Spatial Structure/Diversity: The integrated SS/D rating is moderate risk for the population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was moderate risk. There has been significant reduction in spawner distribution relative to intrinsic potential distribution. This reduction has caused significant increases in gaps between spawning areas as well as disrupted continuity. The rating for Goal B "maintaining natural levels of variation" was moderate risk. Habitat changes have been significant in the Umatilla Basin resulting in changes to flow profiles and elevated temperatures. These changes have resulted in impacts to life history diversity and phenotypic trait variation. The out-of-DPS strays in combination with local origin hatchery fish spawning naturally put the population at high risk for spawner composition. Within basin habitat changes have likely resulted in selective mortality of specific components of juvenile and adult life stages resulting in a moderate risk rating.

Overall Viability Rating: The population *does not currently meet the recommended viability criteria* because A/P and SS/D risks ratings are both moderate. It does meet criteria for a "maintained" population. Improvement in many of the SS/D metrics and a small increase in the average abundance will raise the population to viable status.

Viability Gap

Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 1,472 is 98.1% of the threshold abundance of 1,500. The current productivity of 1.50 recruits per spawner is above the minimum of 1.26 required at the threshold abundance. The lower end of the 90% CI resides slightly above the 25% risk level. The observed A/P gap for the 5% and 1% risk levels is 0.09. The uncertainty gap for the 1% risk level is less than the observed gap.

Spatial Structure/Diversity: Gaps were identified for the following SS/D metrics: *Spatial Extent or Range of Population*: moderate risk because the current spawner distribution is substantially reduced from the historical distribution. Loss of spawning in the Butter and McKay watersheds has resulted in the reduced distribution. *Increase or decrease in gaps and continuities*: moderate risk because of the increased gaps and changed continuity resulting from losses of occupancy in the Butter and McKay watersheds. *Major life history strategies:* moderate risk as a result of reduced opportunity for life history expression for juvenile and adult life stages. This reduced opportunity has resulted from significant habitat changes in the Umatilla Basin. *Phenotypic variation:* moderate risk due to effects of flow and temperature on adult and juvenile migration characteristics. *Spawner composition*: Overall rating is high risk due to two moderate ratings for the component metrics. Out-of-DPS spawners rated as moderate risk due to the estimated level of strays observed at Three-mile Falls Dam over the last three generations. Within-population spawners rated moderate risk due to the proportion and duration of Umatilla Hatchery fish spawning in the basin. *Selective change in Natural Processes-Habitat:* moderate risk due to the selective effects of temperature and flow changes on juvenile and adult characteristics.

Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: high water temperature, sediment routing, impaired fish passage, degraded channel structure and complexity and low flows; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.

Primary Threats: Hatchery production that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices that reduce habitat quality, quantity and disrupt ecosystem functions; the Columbia River mainstem hydrosystem.

Primary Life Stages Affected: fry, summer parr, winter parr, smolts.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

Tributary Management Strategies and Actions (Highest Priority)

Habitat Strategies

Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas:* North Fork Umatilla R, Umatilla R (Meacham Cr. to forks), Buck Cr, NF Meacham Cr, E. Meacham Cr, Thomas Cr, W. Birch Cr (Bear Cr to headwaters), E. Birch Cr (California Gulch to headwaters), SF Umatilla R (mouth to Thomas Cr).

Strategy: Restore passage and connectivity. *Key actions*: Remove or replace culverts and/or other passage barriers, construct ladders over existing dams, provide adequate screening at all irrigation diversions. *Priority areas*: Birch Cr, W. Birch Cr, Bridge Cr, and diversions within current steelhead distribution.

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Umatilla R (Mission Br to forks), Meacham Cr (mouth to headwaters), Birch Cr, West Birch Cr (mouth to Gorge), East Birch Cr,

Bear Cr, Iskuulpa Cr.

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, stabilize streambanks. *Priority areas*: Umatilla R (Mission Br. to forks), Meacham Cr, NF Meacham Cr, Birch Cr, West Birch Cr (mouth to Gorge), East Birch Cr, Bear Cr.

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Implement Umatilla Basin Project Phases I-IIII, implement water conservation measures, improve irrigation conveyance/efficiency. *Priority areas:* Umatilla R (mouth to Thornhollow), Birch C, West Birch Cr (mouth to Gorge), East Birch Cr, Bear Cr.

Hydrosystem Strategies

Strategy: Improve hydrosystem operations and facilities at Boyd Project to enhance steelhead survival and viability. *Key actions:* Modify bypass flows at Project if possible to mimic instream water right, modify fish passage facilities to meet current standards, remove weir panels from diversion dam during non-operation, maintain trash racks. *Priority areas:* At and below Boyd Project.

Harvest Strategies

Strategy: Manage harvest to maintain current low impact fisheries. *Key actions:* Maintain current low impact fisheries.

Hatchery Strategies

Strategy: Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* coded-wire-tagging program, development of alternative broodstocks for the hatchery programs that produce the strays.

Strategy: Reduce abundance and proportion of out-of-basin stray hatchery fish spawning naturally. *Key actions:* no consensus actions.

Strategy: Re-establish natural production in historically utilized areas. *Key actions*: re-establish natural production in Little Butter and Butter creeks and some MiSAs through adult outplanting and juvenile releases.

Strategy: Reduce genetic influence of hatchery fish in broodstock. *Key actions*: Eliminate use of hatchery produced adults in broodstock.

Strategy: Reduce interactions between residual hatchery steelhead and natural steelhead. *Key actions*: no consensus actions.

Strategy: Reduce potential ecological interactions between coho and natural steelhead. *Key actions*: reduce number of hatchery coho released in Umatilla R. and relocate releases downstream of areas important to steelhead production.

Table 1-16. Summary of Recovery Information for Walla Walla River Population.

Key Population Attributes

The Walla Walla River steelhead population occupies the Walla Walla watershed, with the exception of the Touchet River drainage, which is considered a separate independent steelhead population. The main tributaries of the Walla Walla River are the North and South forks and Couse, Pine, Birch, Cottonwood and Mill creeks. The North and South forks and Couse Creek are entirely within Oregon, but the remaining tributaries span the state line. Two small watersheds that empty directly into the Columbia River below the Walla Walla River confluence are included in the Walla Walla population boundaries.

Recent years natural spawners include returns originating from naturally spawning adults and from outside-DPS strays that originate from Lyons Ferry Hatchery releases in the lower Walla Walla River.

The population is comprised of three MaSAs (Mill, Pine, and Walla Walla) and two MiSAs (Dry and Switzler). Currently two of three MaSAs are occupied, including Walla Walla and Mill. Spawning and rearing occur in the lower reaches of the Pine Creek MaSA.

The population exhibits a summer life history strategy and is part of the Umatilla/Walla Walla Rivers MPG.

It is considered an Intermediate size population with a mean minimum abundance threshold of 1,000 spawners.

Minimum Viability Levels For Low Risk Recovery Scenario (5% extinction risk)

Abundance: Minimum abundance threshold of 1,000 spawners.

Productivity: Minimum productivity level of 1.35 recruits per spawner at the threshold abundance.

Viability Assessment Results

Abundance/Productivity: The population is at moderate risk based on current abundance and productivity. The point estimate falls between the 5% and 25% risk curves. The risk rating should be viewed with caution given two considerations. First, the time series is short, with only eight complete brood years. Second, there is considerable uncertainty associated with the amount of spawning and production that occurs within the population outside of the area above Nursery Bridge Dam, particularly in Mill Creek. Better information relating abundance above Nursery Bridge Dam to the remaining area in the population is needed to reduce these data uncertainties.

Spatial Structure/Diversity: The integrated SS/D rating for the population is moderate risk. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was moderate risk. There has been significant reduction in spawner distribution which has resulted in increased gaps and loss of continuity within the population, as well as between the Walla Walla population and other Mid-Columbia steelhead populations. The rating for Goal B "maintaining natural levels of variation" was moderate risk. Water temperature and hydrograph changes, as well as barriers have likely influenced life history diversity and phenotypic expression. Out-of-DPS strays have put the population in the moderate risk category for the spawner composition metric. Within basin habitat changes have likely resulted in selective mortality at multiple life stages resulting in a moderate risk rating.

Overall Viability Rating: The population *does not currently meet the recommended viability criteria*, although it does meet criteria for a "maintained" population. The A/P values are at moderate risk and the time series is short resulting in considerable uncertainty. Additional brood years are needed to demonstrate sustained recruits per spawner and abundance values above the low risk criteria level. Significant improvements to spatial structure and diversity are needed to improve the risk level.

Viability Gap

Abundance/Productivity: The recent 10-year geomean natural-origin abundance of 650 is well below the threshold abundance of 1,000. The current productivity of 1.34 recruits per spawner is slightly less than the minimum of 1.35 required at the threshold abundance. The lower end of the 95% CI extends well below the 25% risk level. The observed gaps for A/P at the 5% and 1% risk levels were 0.34 and 0.45 respectively. The uncertainty gaps at the 5% and 1% risk levels were less than the observed gaps. These gaps should be viewed cautiously because there is only a short data series available to estimate productivity.

Spatial Structure/Diversity: Gaps were identified for the following SS/D metrics: *Major life history strategies:* moderate risk due to changes in juvenile and adult movement patterns as well as reduced juvenile rearing distribution relative to historical opportunities. The reduced life history strategies have resulted from significant flow and temperature changes within the basin. *Phenotypic variation:* moderate risk due to the effect of flow and temperature changes on phenotypic variation. Adult and juvenile migration patterns have been significantly altered due to these habitat changes. *Spawner composition:* Out-of-DPS spawners rated moderate risk due to the proportion and duration of out-of-DPS spawners in the population. *Selective change in Natural Processes-Habitat:* moderate risk due primarily flow and temperature effects on migration, movement and rearing patterns.

Limiting Factors and Threats

Primary Limiting Factors: Tributary Habitat: high water temperature, sediment routing, impaired fish passage, degraded channel structure and complexity, degraded floodplain connectivity and function, and low flow; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.

Primary Threats: Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices that reduce habitat quality, quantity and disrupt ecosystem functions; the Columbia River mainstem hydrosystem.

Primary Life Stages Affected: fry, summer parr, winter parr, smolts.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

Tributary Management Strategies and Actions (Highest Priority)

Habitat Strategies

Strategy: Protect and conserve natural ecological processes. *Key actions*: Protect highest quality habitats; apply BMPs. *Priority areas*: SF Walla Walla (Elbow to headwaters), SF Walla Walla Tribs, NF Walla Walla (Little Meadows to headwaters).

Strategy: Restore passage and connectivity. *Key actions*: Remove or replace culverts and/or other passage barriers, construct ladders over existing dams, provide adequate screening at all irrigation diversions. *Priority areas*: Mill Cr., Birch Cr, Couse Cr, and unscreened irrigation diversions within current steelhead distribution.

Strategy: Restore riparian condition and LWD recruitment. *Key actions*: restore natural plant communities, maintain fencing, adjust grazing strategies (new fencing may be part of an adjusted strategy). *Priority areas*: Walla Walla R (Mill Cr. to forks), SF Walla Walla (mouth to Elbow Cr), NF Walla Walla R (mouth to Little Meadows Cyn).

Strategy: Restore degraded and maintain properly functioning channel structure and complexity. *Key actions*: restore natural channel form, increase LWD, and stabilize streambanks. *Priority Areas*: Walla Walla R (Mill Cr. to forks), SF Walla Walla (mouth to Elbow Cr), NF Walla Walla R (mouth to Little Meadows Cyn).

Strategy: Restore natural hydrograph to provide sufficient flow during critical periods. *Key actions*: Investigate feasibility of water storage or exchange, implement water conservation measures, and improve irrigation conveyance/efficiency. *Priority Areas:* Walla Walla R (mouth to Little Walla Walla diversion), Walla Walla R. (Mill Cr to forks), NF Walla Walla R (mouth to Little Meadows Cyn).

Hydrosystem Strategies

Strategy: Improve hydro operations and facilities at Twin Reservoirs Project. *Key actions:* Conduct assessment of fishway and modify to meet juvenile fish passage standards.

Harvest Strategies

Strategy: Manage harvest to maintain current low impact fisheries. *Key actions:* Maintain current low impact fisheries.

Hatchery Strategies

Strategy: Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery fish. *Key actions:* enhance coded-wire-tagging program, development of alternative broodstocks for the hatchery programs producing strays.

Strategy: Reduce abundance and proportion of hatchery strays spawning naturally. *Key actions:* no consensus actions.

Section 2 Introduction

This plan provides a framework and roadmap for the conservation and recovery of Middle Columbia River (Mid-C) steelhead (*Oncorhynchus mykiss)* in the State of Oregon. Mid-C steelhead currently occupy habitat in five major Oregon subbasins: Fifteenmile Creek and the Deschutes, John Day, Umatilla and Walla Walla rivers, as well as a number of small tributaries that flow directly into the Columbia River. The plan focuses on the recovery of Mid-C steelhead populations in these subbasins.

Oregon Mid-C steelhead were originally listed as threatened under the Endangered Species Act (ESA) as part of the Middle Columbia River steelhead Evolutionarily Significant Unit (ESU) on March 25, 1999 (69 FR 33101). After NOAA Fisheries' National Marine Fisheries Service (NMFS) revised its species determinations for West Coast steelhead, Mid-C steelhead populations were listed as threatened on January 5, 2006 (71 FR 834) as the Middle Columbia River steelhead Distinct Population Segment (DPS). The DPS includes all steelhead populations in Oregon and Washington tributaries of the Columbia River upstream of the Hood and Wind River systems, up to and including the Yakima River. The Snake River is not part of the DPS.

The draft recovery plan describes a process to remove or minimize the threats to the long-term survival and recovery of Mid-C steelhead and improve the viability to the level that protection under the ESA is not required.

The document describes:

- The institutional framework and rationale for recovery plans
- How NOAA's National Marine Fisheries Service expects to use the plan
- The regional domains of the Columbia Basin within which the recovery plans are written
- The relation of this plan to other planning processes and other ESA mandates
- Desired status--delisting (viability) criteria and broad sense recovery goals
- The current status of listed Mid-C steelhead
- Gaps between current status and viable status
- Limiting factors and threats
- Recovery strategies, management strategies and actions
- Management action effectiveness
- Cost analysis
- Research, monitoring and evaluation
- A framework for implementation and adaptive management

2.1 Species Recovery under ESA

Section 4(f) of the ESA requires NMFS to develop and implement recovery plans for species listed as endangered or threatened under the Act. These plans must, at a minimum, contain (1) a description of site-specific management actions necessary to achieve the plan's goal for the conservation and survival of the species; (2) objective, measurable criteria that, when met, would result in a determination that the species be removed from the list; and, (3) estimates of the time

required and cost to carry out the measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal. Recovery plans are guidance and not regulatory documents, thus no agency or entity is required by the ESA to implement the recovery strategies or actions in the plans unless otherwise legally mandated (NMFS 2006a). Although not regulatory, the authors of the ESA clearly saw recovery plans as a central guiding vehicle for the recovery of listed species.

NMFS is the agency responsible for recovery planning for salmon and steelhead, and also for decisions to list and delist marine species as endangered or threatened. Nevertheless, NMFS recognizes that local support of recovery plans is essential to their successful implementation. It is committed to involving local citizens and groups — those whose activities directly affect the listed species, and whose activities are most affected by recovery requirements — in development of the plans. The State of Oregon has taken the lead, in collaboration with NMFS and many other agencies, in developing the recovery plan for Oregon Mid-C steelhead. This plan fulfills the initial ESA recovery planning requirements for Mid-C steelhead, and represents the participation and leadership of tribal and non-tribal citizen groups.

As a template for listed species recovery, a recovery plan describes a process to remove the threats to long-term survival and persistence by reversing the decline of a listed species and its habitat so that they initially become viable and eventually achieve their historical role in the natural-cultural system of the Columbia Basin. A recovery plan provides the necessary information that Federal agencies (NMFS and the U.S. Fish and Wildlife Service (USFWS)) have determined will lead to recovery of listed species and their associated habitats. The plan describes the current species status, the 'gap' that needs addressing to reach recovery, as well as ongoing or proposed actions designed to aid in the recovery of the species. The plan also provides estimated timeframe and costs for the overall effort. The final recovery plan will be considered a "living document." As new information becomes available, such as the outcome of the Federal Columbia River Power System Biological Opinion process, better understanding of climate change, or as monitoring and adaptive management reveal the need for change, revised and additional actions will be added to the plan.

Once a species is deemed recovered, and therefore removed from a 'listed status,' section 4(g) of the ESA requires the monitoring of the species for a period of not less than five years to ensure that it retains its recovered status and does not decline to such a state that requires the need to again list it as either a threatened or endangered species under the ESA.

2.2 State of Oregon Recovery Planning

The State of Oregon considers this plan its conservation plan for the Oregon portion of the Middle Columbia River steelhead DPS. The plan supports the State of Oregon's Plan for Salmon and Watersheds (Oregon Plan) and meets the requirements of Oregon's Native Fish Conservation Policy (NFCP) (OAR 635-007-0502 to 0509). The Oregon Plan is a comprehensive partnership between government, communities, private landowners, industry and citizens funded by the Oregon Legislature. The Oregon Plan mission is:

> *To restore the watersheds of Oregon and to recover the fish and wildlife populations of those watersheds to productive and sustainable levels in a manner that provides substantial environmental, cultural and economic benefits.*

The Native Fish Conservation Policy, adopted in 2002 by the Oregon Fish and Wildlife Commission, provides refined policy to support implementation of the Oregon Plan. The NFCP is Oregon's policy for managing native fish and determining restoration priorities that improve the effectiveness of conservation efforts under the Oregon Plan. The NFCP focuses on the conservation of naturally produced fish because they are the basis for Federal ESA listings and are the foundation for productive fisheries programs.

The NFCP uses conservation plans as a means to identify and implement strategies and actions to restore and maintain native fish in Oregon. The conservation plans describe commitments by the State of Oregon that will conserve the sustainability of ESUs/DPSs and restore biological attributes necessary to achieve desired status goals that will provide significant ecological, economic and cultural benefits for all Oregonians. The plans are developed through a sequential process, nearly identical to the one used for this recovery planning effort:

1. Determine the management unit, ESU or DPS
2. Determine its current status
3. Define a desired status (viability and broad sense goals)
4. Determine any gap between the two and the factors causing the gap (limiting factors)
5. Identify strategies and actions that address the limiting factors
6. Monitor and evaluate the ESU (or DPS) status and actions implemented and use adaptive management to make adjustments.

Status assessments conducted under the NFCP resemble assessments for ESA recovery in that they focus on groups of populations from a common geographic area with similar genetic and life history traits called Species Management Units (SMUs). Oregon, however, believes there are ecological and adaptive differences between summer and winter forms of steelhead and separates them into different SMUs. Populations delineated within Oregon's Mid-C summer steelhead SMU are similar to those defined for the Cascade Eastern Slope Tributaries MPG, except that the Deschutes Eastside and Westside populations are combined into a single population and the Fifteenmile Creek winter steelhead population is included in the Lower Columbia winter steelhead SMU. Oregon currently considers both SMUs as "At Risk" (ODFW 2005d). We chose to use the ICTRT population delineations because they were developed based on more recent information. We do not believe that the delisting criteria or management actions would differ if the Oregon NFCP populations or SMU boundaries were used because of the close similarity to the ICTRT boundaries.

As a conservation plan under the NFCP, this plan for Oregon Mid-C steelhead populations goes beyond achieving ESA recovery requirements. Its desired status includes achievement of 'broad sense goals', including meeting social and cultural benefits. This approach to species recovery includes development of goals for harvestable population levels viewed essential by all the parties involved. Although somewhat broader than the definition of recovery provided by the

ESA, these broad sense recovery goals incorporate many of the traditional uses as well as rural and Native American values deemed important in Oregon and throughout the Pacific Northwest.

Consistent with the Oregon Plan and NFCP — as well as the ESA — this plan provides structure and guidance to efforts to protect and restore Oregon Mid-Columbia steelhead and their habitats, while providing flexibility for actions to be determined by appropriate parties. It is designed to support and build on the existing conservation network across Oregon's portion of the DPS. This partnership of regulatory and non-regulatory entities, private landowners, and others represents an effective means for achieving viability targets and broader recovery goals.

This Recovery Plan was developed to parallel and build from the Oregon Conservation Strategy. The Oregon Conservation Strategy (Conservation Strategy) was developed by ODFW in response to a national effort guided by the U.S. Congress and the U.S. Fish and Wildlife Service to encourage states to develop comprehensive wildlife conservation plans. The Oregon Fish and Wildlife Commission approved the Conservation Strategy in August 2005 and the strategy was approved by the USFWS in March 2006. The Conservation Strategy provides a long-term, big picture "blueprint" for conserving Oregon's natural resources. The strategy is designed to maintain and improve environmental health for today and future generations. The principle goal is to "maintain healthy fish and wildlife populations by maintaining and restoring functioning habitats, prevent declines of at-risk species, and reverse declines in these resources where possible." Like the Recovery Plan, the Conservation Strategy is not a regulatory document and relies on voluntary conservation actions. Mid-Columbia River steelhead are identified as a "Strategy Species" that are distributed throughout three ecoregions specified as critical for achieving the goals of the Conservation Strategy. The Conservation Strategy identifies six key issues for which specific goals and actions are presented. All of the actions identified within this Recovery Plan align with the key issues and goals identified in the Conservation Strategy. The limiting factors and management actions described in this Recovery Plan are more spatially and temporally explicit than the actions in the Conservation Strategy. In addition, this plan addresses a wider array of issues such as hydrosystem, harvest, hatcheries and predation.

2.3 Tribal Treaty/Trust Obligations

Northwest Indian tribes have legally enforceable treaty rights reserving to them a share of the salmon harvest, and they are "co-managers" with state and federal agencies in regulating salmon harvest. These rights and expectations may not necessarily be fully met by achieving the basic purposes of the ESA and delisting of the species, although it will lead to major improvements in the current situation.

Historically, Mid-C steelhead were found throughout central Oregon and south-central Washington. Mid-C steelhead were important to Native Americans of the interior west, including the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes and Bands of the Yakama Nation, and the Confederated Tribes of the Warm Springs Reservation. Native Americans throughout the Pacific Northwest maintain strong cultural values for steelhead and salmon species. These fish have long had important tribal subsistence, ceremonial and commercial value. Steelhead have also been, and continue to be, of importance to the recreational fishing industry of the region.

Several treaty tribes exist within the area considered the range of Mid-C steelhead; the Yakama, Umatilla, Walla Walla, and Warm Springs tribes. The Treaty of June 9, 1855 was between the United States and the Walla Walla, Cayuse, and Umatilla Tribes, now the Confederated Tribes of the Umatilla Indian Reservation (CTUIR). In 1855 the Warm Springs and Wasco tribes signed with the United States in the Treaty with the Middle Oregon Tribes of Oregon. The Confederated Tribes of the Warm Springs (CTWSRO) consists of the Warm Springs, Wasco and Paiute tribes. The Confederated Tribes of the Yakama represent 14 bands and tribes that were a party of the 1855 Treaty with the Yakamas and United States.

Ensuring a sufficient abundance of salmon and steelhead to sustain harvest can be an important element in fulfilling treaty rights. NMFS is committed to meeting Federal treaty and trust obligations to the tribes. These obligations are described in a July 21, 1998 letter from Terry D. Garcia, Assistant Secretary for Oceans and Atmosphere, U.S. Dept of Commerce, to Mr. Ted Strong, Executive Director of the Columbia River Inter-Tribal Fish Commission. This letter states that recovery *"…must achieve two goals; 1) the recovery and delisting of salmonids listed under the provisions of the ESA; and 2) the restoration of salmonid populations over time, to a level to provide a sustainable harvest sufficient to allow for the meaningful exercise of tribal fishing rights."* Thus it is appropriate for recovery plans to take these conditions into account and plan for a recovery strategy that includes harvest.

The ESA and tribal trust responsibilities complement one another. Both depend on a steady upward trend toward ESA recovery and delisting in the near term, while making river, harvest, and land management improvements for the long term. Furthermore, ESA delisting cannot occur until both biological objectives and the listing factors are considered and NMFS determines, based on an evaluation of the listing factors, that the DPS is no longer likely to require the protection of the Act. Therefore, NMFS will make no delisting decision until it is clear that the threats to the DPS have been addressed and that the status and trends of both the fish and their habitats will be healthy and sustainable in the long term.

Section 3 Background and Regional Context

Section 3 describes the context of Oregon's recovery plan for Mid-C steelhead within the framework of NMFS's larger recovery planning efforts. It also describes the State of Oregon's process led by the Oregon Department of Fish and Wildlife to develop a scientifically sound, realistic road map for recovery through broad technical, stakeholder, and public involvement. In addition it identifies the recovery goals for the DPS, discusses the listing of Mid-C steelhead, and provides a short description of the population's life history characteristics and critical habitat.

3.1 Context of Plan Development

This recovery plan is one piece of a larger recovery planning effort for listed species across the Pacific Northwest, as well as in other parts of the Mid-C DPS. It is also part of a broader planning effort by the State of Oregon to conserve and rebuild Oregon's native salmon and steelhead runs. These overlapping processes are discussed in this section.

3.1.1 NMFS's Regional Process

Currently, 17 ESUs and DPSs of Pacific salmon and steelhead in the Pacific Northwest are listed under the ESA. NMFS has designated five geographically-based recovery domains for preparing recovery plans for the listed species. The Mid-C steelhead DPS falls within the Interior Columbia domain (which is divided into three sub-domains: the Snake River, Mid-Columbia, and Upper Columbia). The other domains are the Willamette-Lower Columbia; Puget Sound and Washington Coast; Oregon Coast; and the Southern Oregon/ Northern California Coast domains. Opportunities exist for technical and stakeholder involvement in each domain.

Technical Recovery Team
For each domain, NMFS appointed an independent Technical Recovery Team (TRT) that has geographic and species expertise for the domain and can provide a solid scientific foundation for recovery plans. The charge of each TRT is to define ESU/DPS structures, develop recommendations on biological viability criteria for ESUs/DPSs and populations, to provide scientific support to local and regional recovery planning efforts, and to provide scientific evaluations of recovery plans. The TRTs include biologists from NMFS, state, tribal, and local entities, agencies, academic institutions, and private consulting groups. All the TRTs operate from a common scientific foundation. Each TRT has used the same biological principles for developing its recommended ESU/DPS and population viability criteria — criteria that will be used, along with threats-based criteria, to determine whether a species has recovered sufficiently to be downlisted to threatened (if endangered) or delisted — although they have developed regionally specific approaches to these criteria. Each TRT's recommendations are assessed using the Viable Salmonid Population (VSP) framework, with viability criteria expressed in terms of abundance, productivity (population growth rate), spatial distribution, and diversity (McElhany et al. 2000).

Planning Forums

In each domain, NMFS has worked with state, tribal, local and other Federal stakeholders to develop planning forums appropriate to the domain, which builds to the extent possible on ongoing, locally led efforts. NMFS separated the Mid-Columbia River steelhead DPS into four management units (Figure 3-1) that reflect its diverse human and physical landscape: the Oregon Unit, Yakima Unit, Columbia Gorge Unit (Klickitat/White Salmon/Rock Creek), and Southeastern Washington Unit (Touchet and the Washington portion of the Walla Walla River).

Individual recovery plans developed by local forums for the four management units form the foundation of the DPS-level recovery plan. This recovery plan is for the Oregon management unit. The State of Washington took responsibility for recovery planning for the portion of the Mid-Columbia DPS within its borders. The State of Washington's Salmon Recovery Act established six regional boards that are comprised of government and tribal representatives, landowners, and private citizens. With substantial funding from Washington's Salmon Recovery Board and the Northwest Power and Conservation Council (NPCC), these groups produced the June 2005 Draft Snake River Salmon Recovery Plan for SE Washington, and the October 2005 Draft Yakima Subbasin Salmon Recovery Plan that address the drainages within the State of Washington regarding Mid-C steelhead. NMFS and representatives from the four management units worked together to develop DPS-level direction that identified the viability scenarios for Cascades Eastern Slope Tributaries and Umatilla/Walla Walla MPGs that overlap parts of Oregon and Washington states.

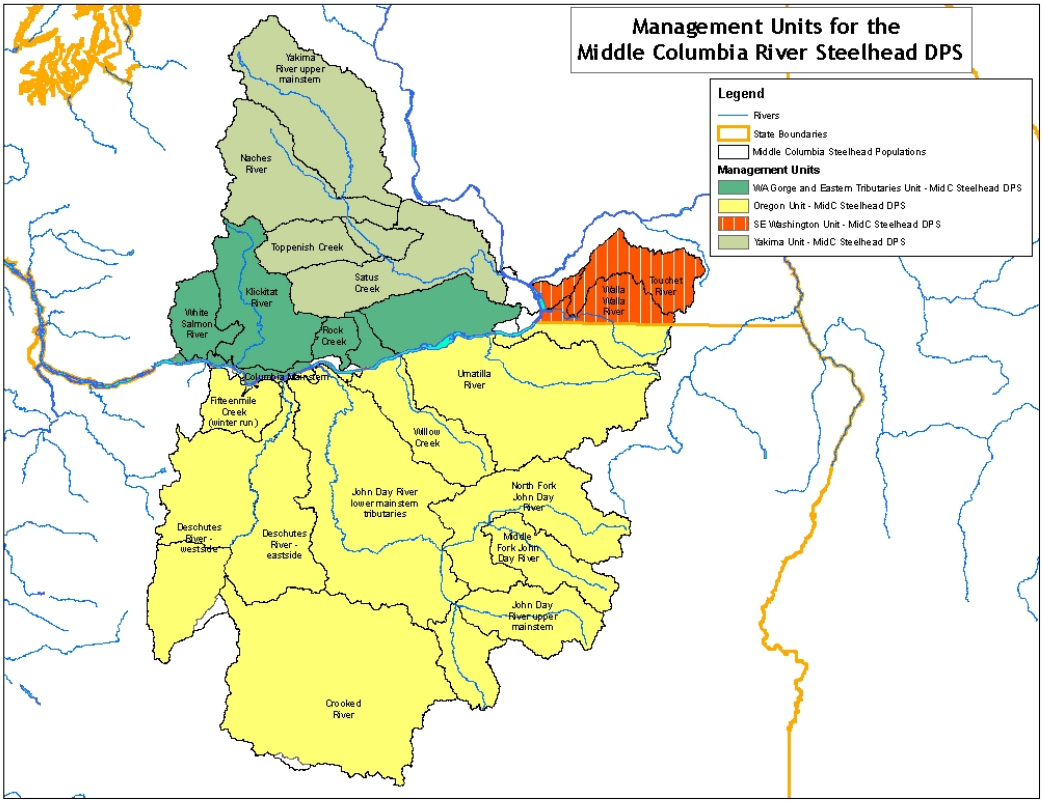

Figure 3-1. NMFS Management Units for the Middle Columbia River Steelhead DPS.

For more information about NMFS, the domains, and the TRTs, see the following Internet site: http://www.nwr.noaa.gov/Salmon-Recovery-Planning/index.cfm.

3.1.2 State of Oregon Recovery Planning Process

The State of Oregon developed this plan in partnership with other state and Federal natural resources agencies, the tribes, and local communities. The plan took shape through a collaborative process with broad technical, stakeholder and public involvement. The planning process drew on direction developed through related planning processes, included the NPCC subbasin plans, the Oregon Plan and Native Fish Conservation Policy planning. ODFW took the lead in drafting the Oregon Mid-C steelhead recovery plan with the assistance of a cadre of other entities. Members of ODFW, NMFS, Tribes, and many other contributors compiled the information for the Oregon portion of the Mid-Columbia River basin from multiple sources, including federal, state, tribal, private, and local watershed organizations that are involved in salmon recovery.

ODFW has involved critical players in the plan's development at each stage in the decision-making process. The plan reflects substantial the review, discussion, critique and recommendations of four primary forums: a State-level Expert Panel, a diverse public sounding board, a recovery planning team, and population-specific management action teams. Appendix A lists the members of each of these groups. The Interior Columbia TRT was also involved in the process. This involvement is vital to the plan's success and will help ensure that it is both scientifically and technically sound and supported by various stakeholders and private landowners.

- *Oregon Mid-Columbia Expert Panel*. The Expert Panel was created by the Oregon Department of Fish and Wildlife for purposes of recovery planning and consisted of biologists with significant knowledge of the limiting factors and threats influencing Oregon's listed salmon and steelhead populations. Panelists identified common key and secondary threat themes and limiting factors for the populations.

- *Mid-Columbia Sounding Board.* The Mid-Columbia Sounding Board (MCSB) consists of representatives of local communities, agricultural and timber interests, water users, land managers, governing bodies, tribes, and industry and environmental interests. The MCSB provides policy guidance in the development of all aspects of the plan and ensures locally appropriate and locally supported recovery actions needed to achieve species recovery goals. The MCSB was particularly instrumental in the development of broad sense recovery goals, recovery scenarios, recovery strategies, and strategic guidance for development and prioritization of management actions.

- *Mid-Columbia Recovery Planning Team.* The recovery planning team includes state, Federal, Tribal, and watershed council technical representatives across the DPS. The team provided technical guidance and assisted in writing different aspects of the plan.

- *Management Action Teams.* The three management action teams include local experts representing state and federal natural resource agencies, the tribes, watershed councils and Portland General Electric. The teams developed management actions for the ten steelhead populations.

Involvement by these different entities helps ensure that recovery goals and actions are consistent and compatible with the goals and direction adopted in related efforts. This integrated approach establishes partnerships that allow actions to be implemented effectively and efficiently.

Plan Review, Revision, Adoption and Implementation
Drafts of the Oregon Mid-C steelhead recovery plan were posted on the NMFS Web site to provide an opportunity for informal public response during the development phase. The initial 2005 draft was a framework and progress report intended to keep the interested reader abreast of the development of the draft plan. The 2007 draft was the first complete draft available for review.

This is the second complete draft of the recovery plan. It will be refined following extensive review, including a formal period of public comment through Federal and State processes, by public agencies, environmental organizations, landowners, interested public and other stakeholders. In spring 2009 the draft recovery plan will be revised and published in final form for public reference and use.

Once this recovery plan is approved, all federal and nonfederal funding entities should develop a coordinated, prioritized, and accountable funding strategy. To facilitate implementation, NMFS intends to provide streamlined regulatory assurances for actions that are undertaken to implement recovery. Adaptive management including a comprehensive monitoring, evaluation and research component will be a high priority during the recovery effort. Adjustments to on the ground actions in response to new information will be incorporated as we learn from our successes and failures. The challenges of salmon recovery are immense, particularly in the face of increasing human populations and heavy demand for precious resources such as sufficient clean water. It will be important to monitor the benefits and costs of completed actions and to work in a collaborative forum to tackle the hard issues to come.

3.2 Overview of Recovery Goals

A simplified way of looking at species recovery includes addressing those factors that lead to the species being listed. Section 4(a) (1) of the ESA and NMFS' implementing regulations (50 CFR part 424) set forth procedures for listing species. The Secretary of Commerce (Secretary) must determine, through the regulatory process, if a species is endangered or threatened because of any one or a combination of the following factors: (1) The present or threatened destruction, modification, or curtailment of its habitat or range; (2) overutilization for commercial, recreational, scientific, or educational purposes; (3) disease or predation; (4) inadequacy of existing regulatory mechanisms; or (5) other natural or human-made factors affecting its continued existence. NMFS has previously detailed the impacts of various factors contributing to the decline of Pacific salmon and *O. mykiss* (e.g., citations for ESU listing determinations;

NMFS 1997c, ‘‘Factors Contributing to the Decline of Chinook Salmon—An Addendum to the 1996 West Coast Steelhead Factors for Decline Report;’’ NMFS 1996a, ‘‘Factors for Decline—A Supplement to the Notice of Determination for West Coast Steelhead Under the Endangered Species Act’’). The Federal Register notices and technical reports concluded that all of the factors identified in section 4(a)(1) of the ESA have played a role in the decline of West Coast salmon and *O. mykiss* ESUs/DPSs. The Federal Register notices and technical reports provide a more detailed treatment of the relevant factors for decline for specific ESUs/DPSs. The following discussion briefly summarizes findings regarding the principal factors for decline across the range of West Coast salmon and *O. mykiss*. While these factors are treated in general terms, it is important to underscore that impacts from certain factors are more acute for specific ESUs/DPSs.

1. *The present or threatened destruction, modification, or curtailment of its habitat or range*: West Coast salmon and *O. mykiss* have experienced declines in abundance over the past several decades as a result of loss, damage or change to their natural environment. Water diversions for agriculture, flood control, domestic, and hydropower purposes have greatly reduced or eliminated historically accessible habitat and degraded remaining habitat. Forestry, agriculture, mining, and urbanization have degraded, simplified, and fragmented habitat. Studies indicate that in most western states, about 80 to 90 percent of the historical riparian habitat has been eliminated (Botkin et al. 1995). The destruction or modification of estuarine areas has resulted in the loss of important rearing and migration habitats. Losses of habitat complexity and habitat fragmentation have also contributed to the decline of West Coast salmonids. Sedimentation from extensive and intensive land use activities (e.g., forest practices, roads, livestock grazing, and urbanization) is recognized as a primary cause of habitat degradation throughout the range of West Coast salmon and *O. mykiss*.

   Water quality impairment that affects spawning, migration and rearing is a problem in many areas that were historically suitable rearing and spawning habitat. Summer stream temperature is the primary water quality problem for Mid-C steelhead, and many stream reaches are listed on the Clean Water Act (CWA) 303(d) list for water temperature. Contaminants such as insecticides and herbicides from agricultural run-off and heavy metals from mine waste are common in some areas of designated critical habitat for this DPS.

   Low summer streamflows are also a common characteristic affecting spawning, rearing, and migration. Withdrawal and storage of natural streamflow—and land use practices that reduced water storage on uplands, floodplains and riparian areas—have altered the natural pattern of flows over the seasons and caused inadequate flow, scouring flows, or other flow conditions that inhibit steelhead distribution and survival. Many stream reaches are over-appropriated under state water law at low summer flow, with more allocated water rights than existing streamflow conditions can support.
   Depending upon their natal watershed, adult and out-migrating juvenile steelhead from the Oregon portion of the Mid-Columbia River DPS encounter between one and four mainstem Columbia River dams migrating to and from the ocean. Hydroelectric development has modified natural flow regimes resulting in higher water temperatures,

changes in fish community structure, and increased travel time for migrating adults and juvenile salmonids. Physical features of dams such as turbines also kill migrating fish. The only substantial habitat blockages at present in this DPS are Pelton Dam on the Deschutes River and Condit Dam on the White Salmon River. However, smaller dams, impassable culverts, irrigation dams, and other small passage barriers occur throughout the region.

2. *Overutilization for commercial, recreational, scientific, or educational purposes*: Historically, salmon and *O. mykiss* were abundant in many western coastal and interior waters of the United States. These species have supported, and continue to support, important tribal, commercial and recreational fisheries throughout their range, contributing millions of dollars to numerous local economies, as well as providing important cultural and subsistence needs for Native Americans. Overfishing in the early days of European settlement led to the depletion of many stocks of salmonids, prior to extensive modifications and degradation of natural habitats. However, following the degradation of many west coast aquatic and riparian ecosystems, exploitation rates were higher than many populations could sustain. Therefore, harvest may have contributed to the further decline of some populations.

   Steelhead harvest or fishery impact occurs in Columbia River and tributaries sport fisheries, Columbia River Treaty Indian gillnet fisheries, Columbia River Treaty Indian subsistence fisheries, and tributary Treaty Indian subsistence fisheries. Landing records and coded wire tag analyses indicate that steelhead are not taken in significant numbers in any ocean fishery, apparently because of an offshore, high-seas distribution pattern. Non-Indian commercial fisheries for steelhead in the Columbia River have been prohibited beginning in 1975 and incidental impacts of non-Indian commercial fisheries for other species are minimal because no significant fisheries occur in the group A (see Life History section below) migration time frame.

   Columbia River sport fisheries above and below Bonneville Dam keep only marked (hatchery) fish since the late 1970's. Significant sport fisheries for steelhead between Bonneville Dam and the Deschutes River occur primarily from July through September when fish seek refuge from warm Columbia River temperatures in cool tributary mouths, primarily in Bonneville Reservoir. Steelhead are taken by treaty Indian fisheries in the Columbia River mainstem primarily in fall gillnet fisheries that target Chinook salmon from late August through October. Current steelhead harvest rates in fall treaty Indian fisheries are limited in number and through the use of large mesh gillnets, which target the larger fall Chinook. Small numbers of steelhead are also taken in various ceremonial and subsistence fisheries during the remainder of the year. These fisheries primarily occur by hook-and-line or from platforms with dip nets. Treaty Indian fisheries occur from Bonneville to McNary dams, but most of the effort is between Bonneville Dam and the Deschutes River mouth.

   Steelhead harvest or fishery impact also occurs in the Deschutes Basin sport and tribal dipnet fisheries (which occurs immediately below Sherars Falls in years when fall salmon runs are significant). The required release of wild fish, catch of many non-local fish, and

the reliance on catch record card data for catches above Sherars Falls make estimation of fishery impacts on natural-origin Deschutes River steelhead difficult.

3. *Disease or predation***:** Introductions of non-native species and habitat modifications have resulted in increased predator populations in numerous rivers and lakes. Predation by seabirds can influence the survival of juvenile salmon and *O. mykiss* in some locations. For example, it is estimated that Caspian terns (*Sterna caspia*) in the lower Columbia River and estuary consume approximately 13 percent of the outmigrating smolts reaching the estuary in some years (Collis et al. 2001). Other mainstem predation occurs from walleye (*Stizostedion Vitreum*) and California sea lions (*Zalophus californianus*) of juveniles and adults, respectively.

   Infectious disease is one of many factors that can influence adult and juvenile salmon and *O. mykiss* survival. In general, very little current or historical information exists to quantify changes in infection levels and mortality rates attributable to these diseases. Native *O. mykiss* populations have co-evolved with specific communities of these organisms, but the widespread use of artificial propagation has introduced exotic organisms not historically present in a particular watershed. Habitat conditions such as low water flows and high temperatures can exacerbate susceptibility to infectious diseases.

4. *The inadequacy of existing regulatory mechanisms*: The ESA listings of salmon ESUs and *O. mykiss* DPSs have provided the incentive for numerous protective efforts. While many causes of decline in salmon ESUs and *O. mykiss* DPSs are being addressed (e.g., providing fish passage above artificial barriers), habitat degradation and destruction have been slowed but not prevented. The protective efforts are directed toward addressing the numerous factors that adversely impact Mid-C steelhead and its habitat — water quality and quantity, safe migration, riparian vegetation, food, predation dynamics and complex stream channels, and floodplain connectivity. These actions all will aid in improving these factors within the area of each project. The recovery planning process addresses the cumulative effects of these and other protective efforts, and any additional measures necessary to address the species' factors for decline and extinction risk.

5. *Other natural or manmade factors affecting its continued existence*: Variability in ocean and freshwater conditions can have profound impacts on the productivity of salmon and *O. mykiss* populations. Natural climatic conditions have at different times exacerbated or mitigated the problems associated with degraded and altered riverine and estuarine habitats.

   Widespread presence of hatchery fish throughout the DPS was also identified as contributing to declines in population abundance. Extensive hatchery programs have been implemented throughout the range of West Coast salmon and *O. mykiss*. The Umatilla and Deschutes river systems have ongoing hatchery production programs based on locally derived broodstock. The straying of hatchery steelhead from out-of-DPS production programs poses a significant threat to several steelhead populations in the DPS. Straying of out-of-basin hatchery fish into the Deschutes River has been identified as a chronic occurrence.

3.3 Description and Taxonomy

The March 25, 1999 (64 FR 14517) listing of Mid-Columbia River steelhead was developed in response to a biological review that concluded that summer steelhead in the Mid-Columbia River ESU were "likely to become endangered in the foreseeable future" (NMFS 1999). Protective regulations for Mid-C steelhead were issued under section 4(d) of the ESA on July 10, 2000 (65 FR 42422).

The most prominent factors leading to NMFS' conclusion that Mid-C steelhead were threatened included: (1) declines in abundance of wild steelhead populations, (2) levels of abundance well below historical levels, (3) large numbers of hatchery-origin steelhead entering the Deschutes River basin, and a lack of information regarding this phenomenon, (4) large numbers of hatchery steelhead relative to wild steelhead, and a general lack of information regarding the impacts of hatchery steelhead on wild steelhead populations throughout the region, (5) a lack of information regarding the interactions between resident rainbow trout and anadromous steelhead, and (6) habitat alterations in the region resulting in a loss of spawning and rearing habitat for steelhead, including habitat changes that have exterminated some steelhead runs (Busby et al. 1996; NMFS 1999).

The Mid-Columbia River steelhead ESU included all natural populations of steelhead in streams within the Columbia River basin from above the Wind River in Washington and the Hood River in Oregon upstream to, and including, the Yakima River in Washington, excluding steelhead from the Snake River Basin. It also included resident trout populations of *O. mykiss* below impassible barriers (natural and manmade) that co-occurred with anadromous population in the Mid-Columbia River steelhead ESU (69 FR 33101 June 14, 2004). However, in January 2006, NMFS revised its species determinations for West Coast steelhead under the ESA, delineating steelhead-only Distinct Population Segments (DPSs). NMFS listed the Mid-Columbia River steelhead DPS as threatened on January 5, 2006 (71 FR 834). The Federal Register Notice contains a more complete explanation of this listing decision.

This recovery plan focuses on the anadromous from of *O. mykiss*. However, the strategic focus to restore natural ecological processes throughout the subbasins through habitat restoration and protection will provide productivity and capacity benefits for all *O. mykiss* life history forms. Protection and restoration of natural ecological processes will contribute significantly to restoring a natural balance among *O. mykiss* resident and anadromous life history forms.

Mid-C steelhead historically occupied nine major river systems within the states of Oregon and Washington on the east side of the Cascades Mountains (Figure 3-2) and numerous minor systems. These major tributaries to the Columbia River include the White Salmon, Fifteenmile Creek, Deschutes, John Day, Klickitat, Rock Creek, Umatilla, Walla Walla, and Yakima River systems. The John Day River of central Oregon probably represents the largest naturally spawning, native group of steelhead in the region.

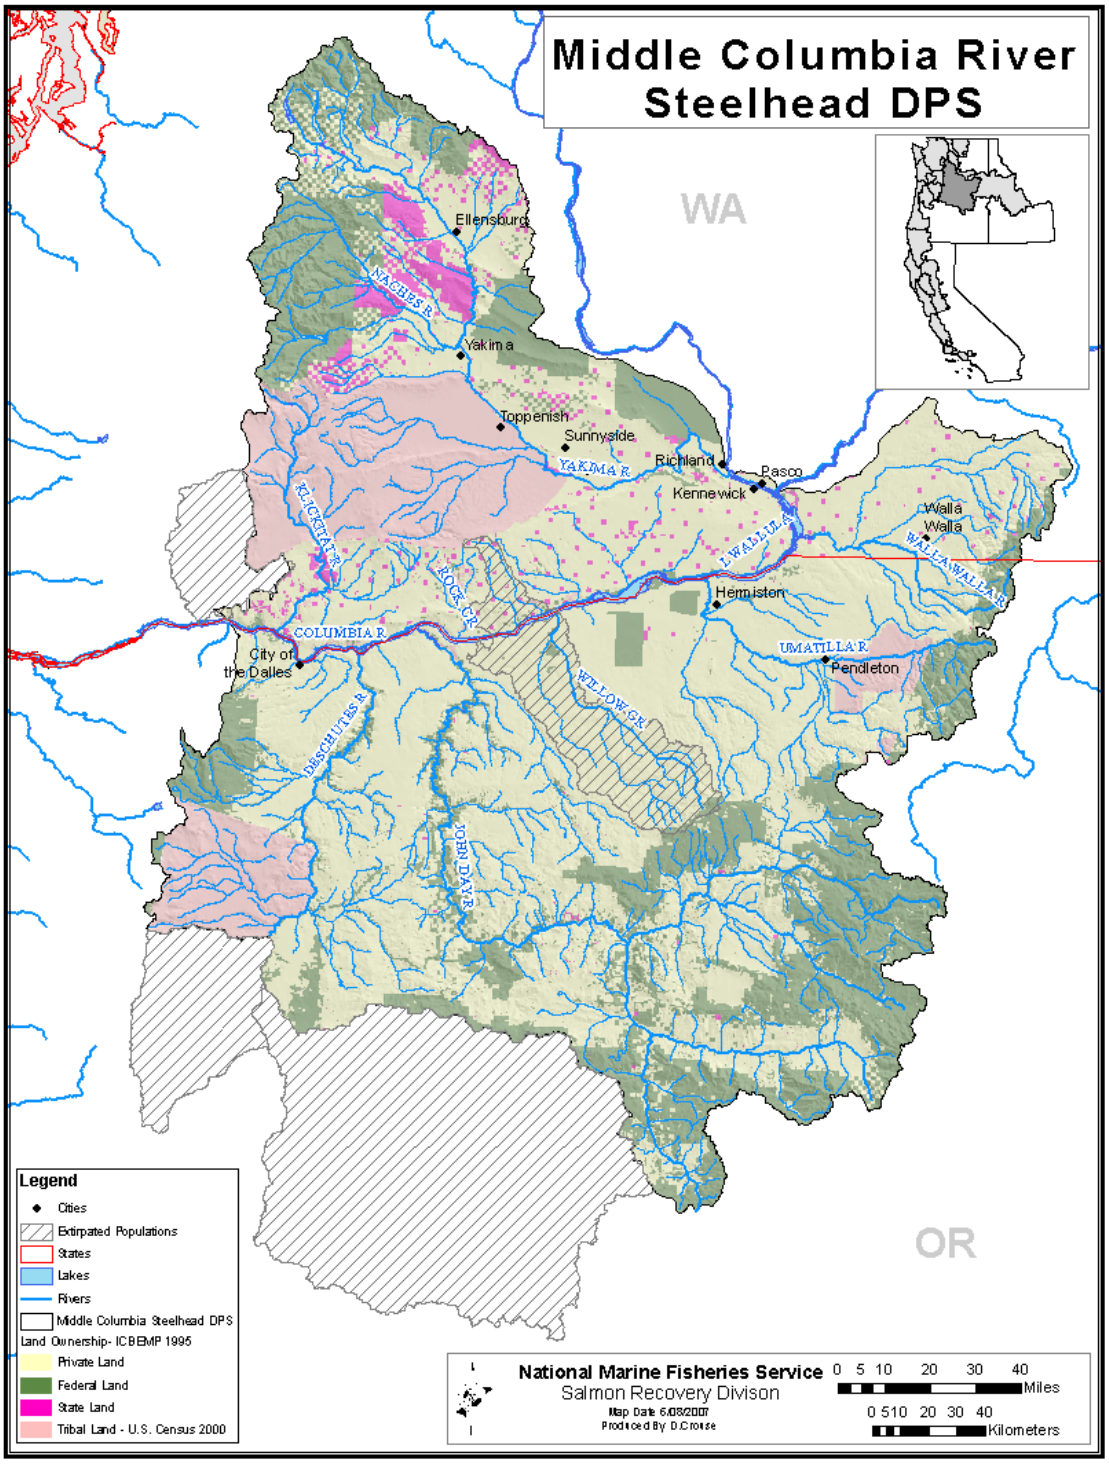

Figure 3-2. Geographic boundaries of the Middle Columbia River Steelhead DPS.

The Interior Columbia Basin Technical Recovery Team (ICTRT 2003) identified historical populations throughout the Interior Columbia River Basin (Figure 3-3). There are 17 extant populations. There are two extinct populations in the Cascades Eastern Slope Major Population

Group (MPG): the White Salmon River and Deschutes Crooked River above Pelton Dam, and one extinct population in the Umatilla/Walla Walla MPG: Willow Creek.

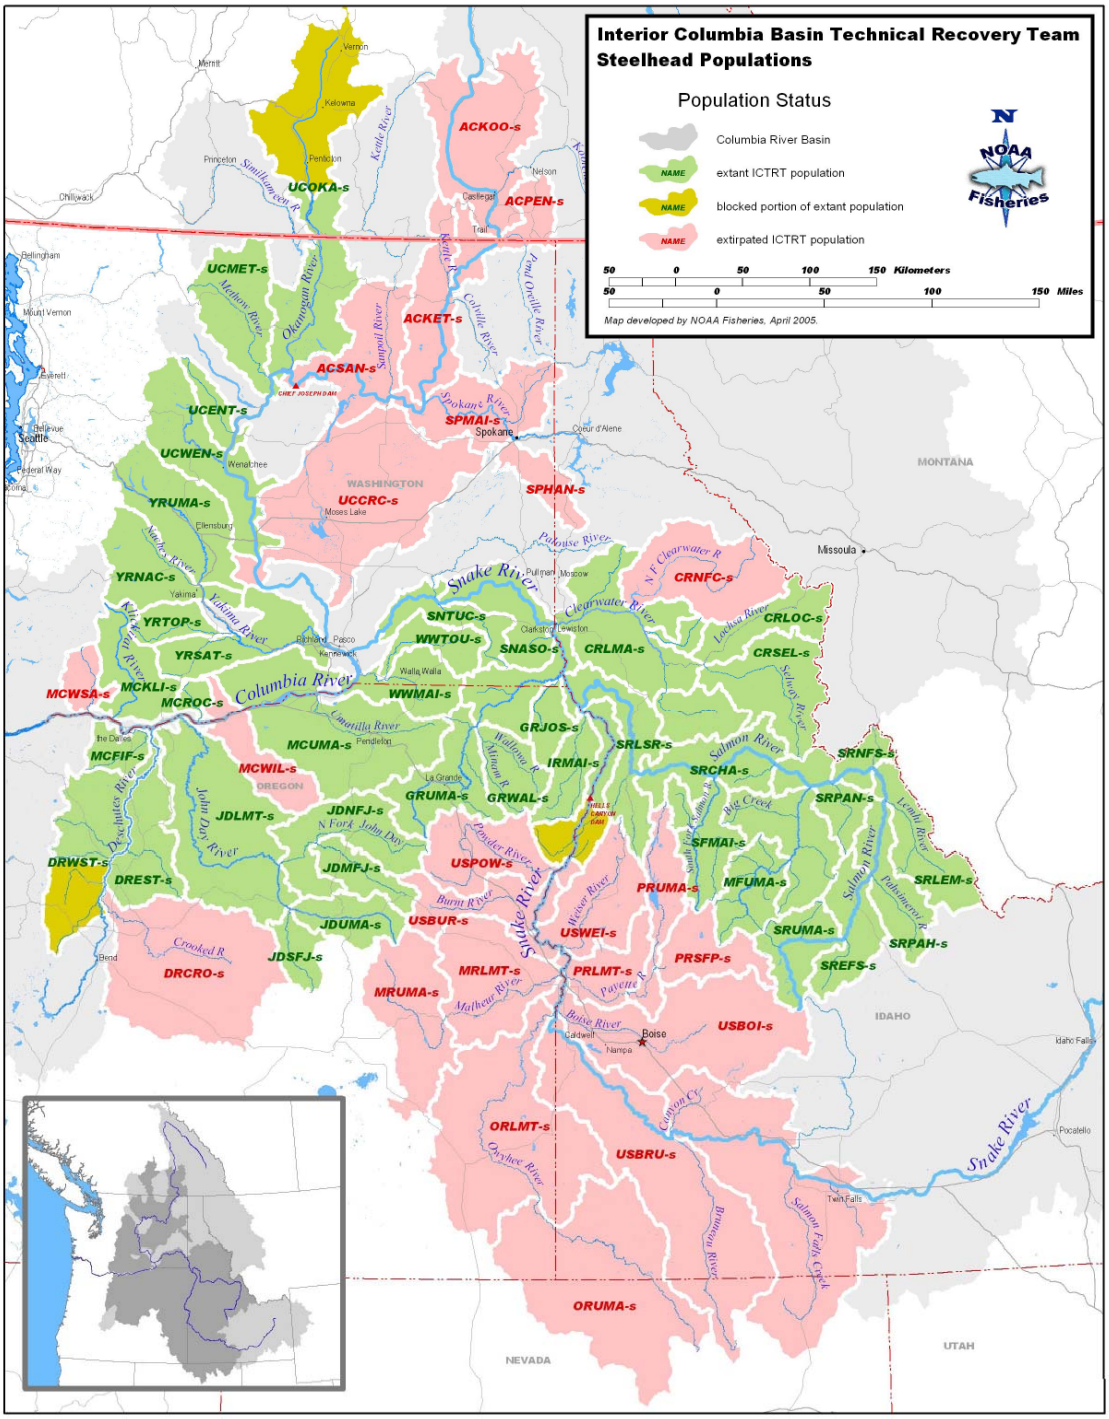

Figure 3-3. Interior Columbia River Basin steelhead populations including populations in the Middle Columbia River Steelhead DPS (ICTRT 2003).

Hatchery programs propagate steelhead in three populations and improve kelt (post spawned adult) survival in one population. No artificial programs produce the winter-run life history in the Klickitat River and Fifteenmile Creek populations. All of the DPS hatchery programs are designed to produce fish for harvest, although two are also implemented to augment the naturally spawning populations in the basins where the fish are released.

3.4 Life History

'Steelhead' is the name commonly applied to the anadromous form of the biological species *O. mykiss*. The present distribution of steelhead extends from Kamchatka in Asia, east to Alaska, and down to southern California (NMFS 1999c), although the historical range of *O. mykiss* extended at least to the Mexico border (Busby et al. 1996). *O. mykiss* exhibit perhaps the most complex suite of life history traits of any species of Pacific salmonid. They can be anadromous or freshwater residents (and under some circumstances, yield offspring of the opposite form). Those that are anadromous can spend up to seven years in fresh water before smoltification, and then spend up to three years in salt water before first spawning. This species can also spawn more than once (iteroparous), whereas all other species of Oncorhynchus except cutthroat trout (*O. clarki*) spawn once and then die (semelparous). The anadromous form of *O. mykiss* is presently under NMFS jurisdiction, while the resident freshwater forms, usually called "rainbow" or "redband" trout, are under the jurisdiction of the U.S. Fish and Wildlife Service.

Within the range of West Coast steelhead, spawning migrations occur throughout the year, with seasonal peaks of activity. In a given river basin there may be one or more peaks in migration activity; since these "runs" are usually named for the season in which the peak occurs, some rivers may have runs known as winter, spring, summer, or fall steelhead. For example, large rivers, such as the Columbia, Rogue, and Klamath rivers, have migrating adult steelhead at all times of the year. There are local variations in the names used to identify the seasonal runs of steelhead; in Northern California, some biologists have retained the use of the terms spring and fall steelhead to describe what others would call summer steelhead.

Steelhead can be divided into two basic reproductive ecotypes, based on the state of sexual maturity at the time of river entry, and duration of spawning migration (Burgner et al. 1992). The "stream-maturing" type (summer steelhead in the Pacific Northwest and Northern California) enters fresh water in a sexually immature condition between May and October and requires several months to mature and spawn. The "ocean-maturing" type (winter steelhead in the Pacific Northwest and Northern California) enters fresh water between November and April with well-developed gonads and spawns shortly thereafter. In basins with both summer and winter steelhead runs, it appears that the summer run occurs where habitat is not fully utilized by the winter run or a seasonal hydrologic barrier, such as a waterfall, separates them. Summer steelhead usually spawn farther upstream than winter steelhead (Withler 1966, Roelofs 1983, Behnke 1992). Coastal streams are dominated by winter steelhead, whereas inland steelhead of the Columbia River Basin are almost exclusively summer steelhead. Winter steelhead may have been excluded from inland areas of the Columbia River Basin by Celilo Falls or by the considerable migration distance from the ocean. The Sacramento-San Joaquin River Basin may have historically had multiple runs of steelhead that probably included both ocean-maturing and stream-maturing stocks (CDFG 1995, McEwan and Jackson 1996). These steelhead are referred

to as winter steelhead by the California Department of Fish and Game (CDFG); however, some biologists call them fall steelhead (Cramer et. al 1995). Fifteenmile Creek and the Klickitat River support the populations of winter steelhead that are furthest inland in the Columbia Basin.

Inland summer steelhead of the Columbia River Basin, especially the Snake River Subbasin, are commonly referred to as either "A-run" or "B-run." These designations are based on a bimodal migration of adult steelhead at Bonneville Dam (235 km from the mouth of the Columbia River), and differences in age (1 versus 2 years in the ocean) and adult size observed among Snake River steelhead. It is unclear, however, to what degree the life history and body size differences observed upstream are correlated back to the groups forming the bimodal migration observed at Bonneville Dam. A-run steelhead are believed to occur throughout the steelhead-bearing streams of the Snake River Basin and the inland Columbia River. B-run steelhead are thought to be produced only in the Clearwater, Middle Fork Salmon, and South Fork Salmon rivers (IDFG 1994).

Life history characteristics for Mid-C steelhead are similar to those of other inland steelhead DPSs. Most fish smolt at two years and spend one to two years in salt water before reentering freshwater, where they may remain up to a year before spawning. All steelhead upstream of The Dalles Dam are summer-run fish that enter the Columbia River from June to August. Adult steelhead ascend mainstem rivers and their tributaries throughout the winter, spawning in the late winter and early spring. Fry emergence typically occurs between May and the end of June. A nonanadromous form of *O. mykiss* co-occurs with the anadromous form in this DPS; information suggests that the two forms may not be isolated reproductively.

3.5 Critical Habitat

Critical habitat was designated on February 16, 2000 [65 FR 7764], but vacated (undesignated) by court order on April 30, 2002. On September 2, 2005, NMFS published a final rule (70 FR 52630) to designate critical habitat for Mid-C steelhead and 12 other ESUs/DPSs of salmon and steelhead. The final rule took effect on January 2, 2006. The Critical Habitat Assessment Review Team (CHART) (NMFS 2004c) rated the conservation value of all 5th-field HUCs supporting populations of Mid-C steelhead.

Essential features of designated critical habitat include substrate, water quality, water quantity, water temperature, food, riparian vegetation, access, water, velocity, space, and safe passage. These features also describe the habitat factors associated with viability for all ESUs and DPSs. The specific habitat requirements for each ESU or DPS differ by life history type and life stage.

Primary constituent elements (PCEs) consist of the physical and biological elements identified as essential to the conservation of the species in the documents identifying critical habitat (Table 3-1). Figure 3-4 depicts those streams designated critical habitat for Mid-C steelhead.

Table 3-1. Types of sites and essential physical and biological features designated as PCEs, and the life stage each PCE supports.

Site	Essential Physical and Biological Features	ESU Life Stage
Freshwater spawning	Water quality, water quantity, and substrate	Spawning, incubation, and larval development
Freshwater rearing	Water quantity and floodplain connectivity	Juvenile growth and mobility
	Water quality and forage	Juvenile development
	Natural cover[a]	Juvenile mobility and survival
Freshwater migration	Free of artificial obstructions, water quality and quantity, and natural cover[b]	Juvenile and adult mobility and survival
Estuarine areas	Free of obstruction, water quality and quantity, and salinity	Juvenile and adult physiological transitions between salt and freshwater
	Natural cover,[a] forage,[b] and water quantity	Growth and maturation
Nearshore marine areas	Free of obstruction, water quality and quantity, natural cover,[a] and forage[b]	Growth and maturation, survival
Offshore marine areas	Water quality and forage[b]	Growth and maturation

[a] Natural cover includes shade, large wood, log jams, beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks.

[b] Forage includes aquatic invertebrate and fish species that support growth and maturation.

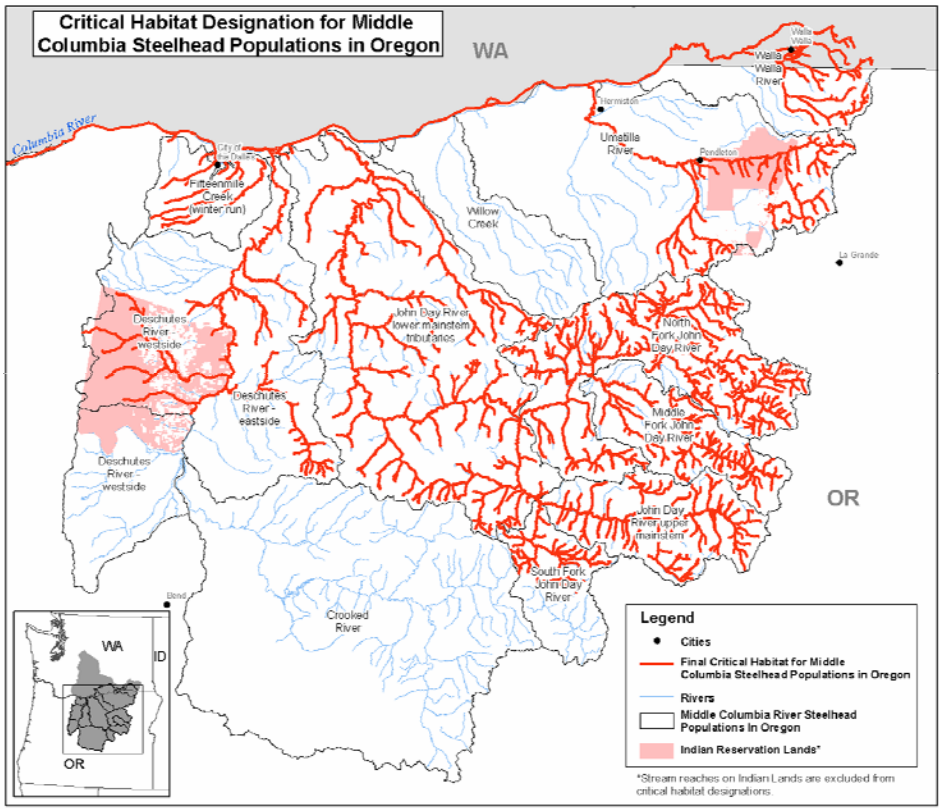

Figure 3-4. Critical habitat designated for salmon and steelhead in Oregon.

Section 4 DPS Structure

This section describes the biological hierarchical organization for the Mid-Columbia River Steelhead DPS, including major population groups and independent populations. It also discusses the characteristics that define the Mid-C steelhead populations in Oregon subbasins.

4.1 Steelhead Population Structure: A Biologically-Based Hierarchy

Steelhead organizational structure is hierarchical from the species level to a level below the population. The homing propensity, distribution across the landscape, and the diverse genetic, life history and morphological characteristics that evolve contribute significantly to the hierarchical structure and long-term persistence.

Recovery planning efforts focus on this biologically based hierarchy that spans DPSs, major groups, populations and substructure within populations, and reflects the apparent degree of connectivity between the fish in each of these hierarchical levels (Figure 4-1). Two levels in this hierarchy, the ESU or DPS and population, were formally defined for listing, delisting, and recovery planning purposes. The ICTRT identified an additional level in the hierarchy between the population and ESU levels. These three levels in the hierarchy are described below.

- **Evolutionarily Significant Unit or Distinct Population Segment:** Two criteria define a salmon ESU or steelhead DPS listed under the ESA: 1) it must be substantially reproductively isolated from other nonspecific units, and 2) it must represent an important component of the evolutionary legacy of the species (Waples 1991). ESUs and DPSs may contain multiple populations that are connected by some degree of migration, and hence may have broad geographic areas, transcending political borders.

- **Major Population Groups:** Within ESUs and DPSs, independent populations can be grouped into larger aggregates that share similar genetic, geographic (hydrographic and ecoregion), and/or habitat characteristics (ICTRT 2003). These "major groupings" are groups of populations that are isolated from one another over a longer time scale than that defining the individual populations, but which retain some degree of connectivity greater than that between ESUs or DPSs. The ICTRT defines this level in the hierarchy as Major Population Groups. These MPGs are analogous to “strata” as defined by the Lower Columbia-Upper Willamette TRT and “geographic regions” described by the Puget Sound TRT.

- **Independent Populations:** McElhany et al. (2000) defined an independent population as: *“…a group of fish of the same species that spawns in a particular lake or stream (or portion thereof) at a particular season and which, to a substantial degree, does not interbreed with fish from any other group spawning in a different place or in the same place at a different season. For our purposes, not interbreeding to a ‘substantial degree’ means that two groups are considered to be independent populations if they are isolated to such an extent that exchanges of individuals among the populations do not*

substantially affect the population dynamics or extinction risk of the independent populations over a 100-year time frame."

Independent populations are the units that will be combined to form alternative recovery scenarios for MPG and DPS viability. Ultimately, the populations are the primary units of recovery actions.

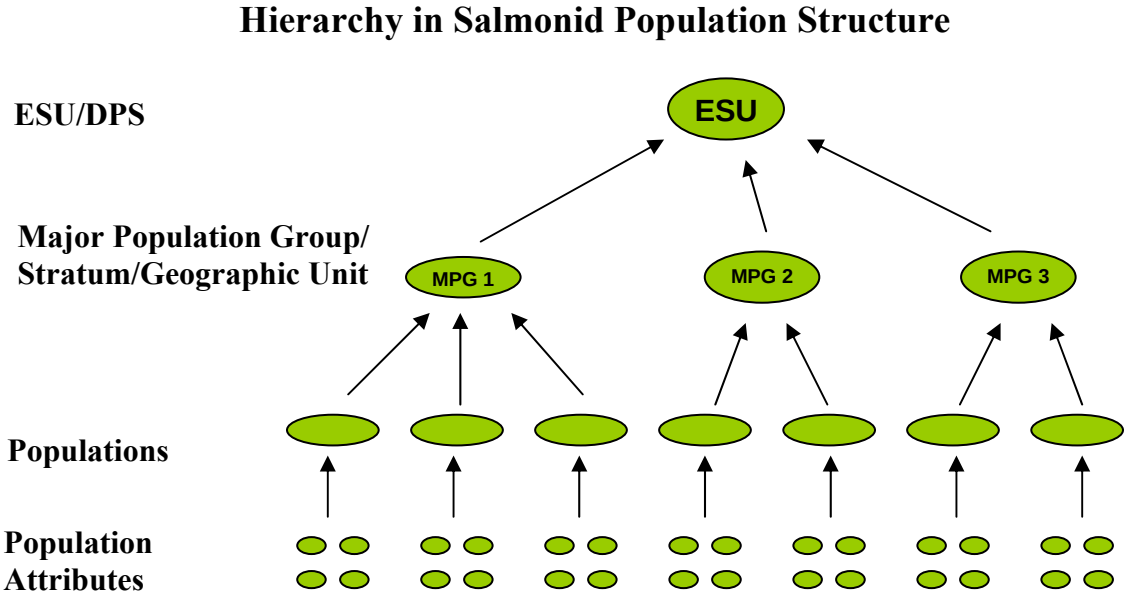

Figure 4-1. Hierarchical population structure within ESA-listed ESUs/DPSs, as identified by the TRTs.

4.1.1 Population Structure Adopted for Recovery Planning

The Oregon Department of Fish and Wildlife has adopted the DPS, Major Population Groups and population structure defined by the ICTRT for purposes of Mid-C steelhead recovery planning. These groups were defined based on genetic, geographic (hydrographic) and habitat considerations (ICTRT 2003) with guidance provided by the Viable Salmonid Populations document (McElhany et al. 2000).

Population Identification
As one of its first tasks in recovery planning, the ICTRT delineated independent populations within the listed ESUs in the Interior Columbia Basin, including those in the Mid-Columbia River steelhead DPS. This delineation of population boundaries is critical for effective conservation planning, since incorrect lumping or splitting of populations (or portions of populations) can provide an inaccurate picture of population status. Over- or underestimating the true status (Abundance/Productivity, Spatial Structure/Diversity) may lead to failed recovery efforts. Similarly, if two "true" populations are treated as a single unit, the status of one may mask the other, potentially leading to the loss of one of the populations (ICTRT 2003).

The ICTRT assessed a variety of information sources to delineate independent populations (ICTRT 2003). It initially classified major groups of populations within ESUs, and then identified independent populations within major groups. It used a variety of data types to define MPGs and independent populations; however, in no case was the entire array of desired information available to inform its decision process. It relied heavily on genetic information, distances between spawning areas related to dispersal (straying distance) as evidence of reproductive isolation, and habitat characteristics. Phenotypic (life history and morphological) characteristics were also considered for distinction at the population level. In addition, it considered two demographic factors. First, because the goal was to identify demographically independent populations, it examined the correlation in abundance time series between areas. Second, it considered historical population size in determining potential population capacity (ICTRT 2003).

Mid-Columbia River Steelhead DPS Populations

The Mid-Columbia River steelhead (*Onchorhynchus mykiss*) DPS includes all natural steelhead populations in streams within the Columbia River basin from above the Wind River in Washington and the Hood River in Oregon (exclusive), upstream to, and including, the Yakima River in Washington, excluding steelhead from the Snake River basin (71 FR 834 January 5, 2006; 64 FR 14517 March 25, 1999). Stream systems in the DPS include Rock Creek and the White Salmon, Klickitat, and Yakima rivers on the northern side of the Columbia and Fifteenmile Creek, and the Deschutes, John Day, Umatilla and Walla Walla rivers and Willow Creek on the southern side (Figure 4-2).

The ICTRT identified four Major Population Groups in the Mid-Columbia River steelhead DPS ─ Cascades Eastern Slope Tributaries, Yakima River, John Day River and Umatilla/Walla Walla Rivers (ICTRT 2003). Figure 4-3 shows these major population groups. Three of these major population groups contain Mid-C steelhead from Oregon tributaries and are addressed in this recovery plan.

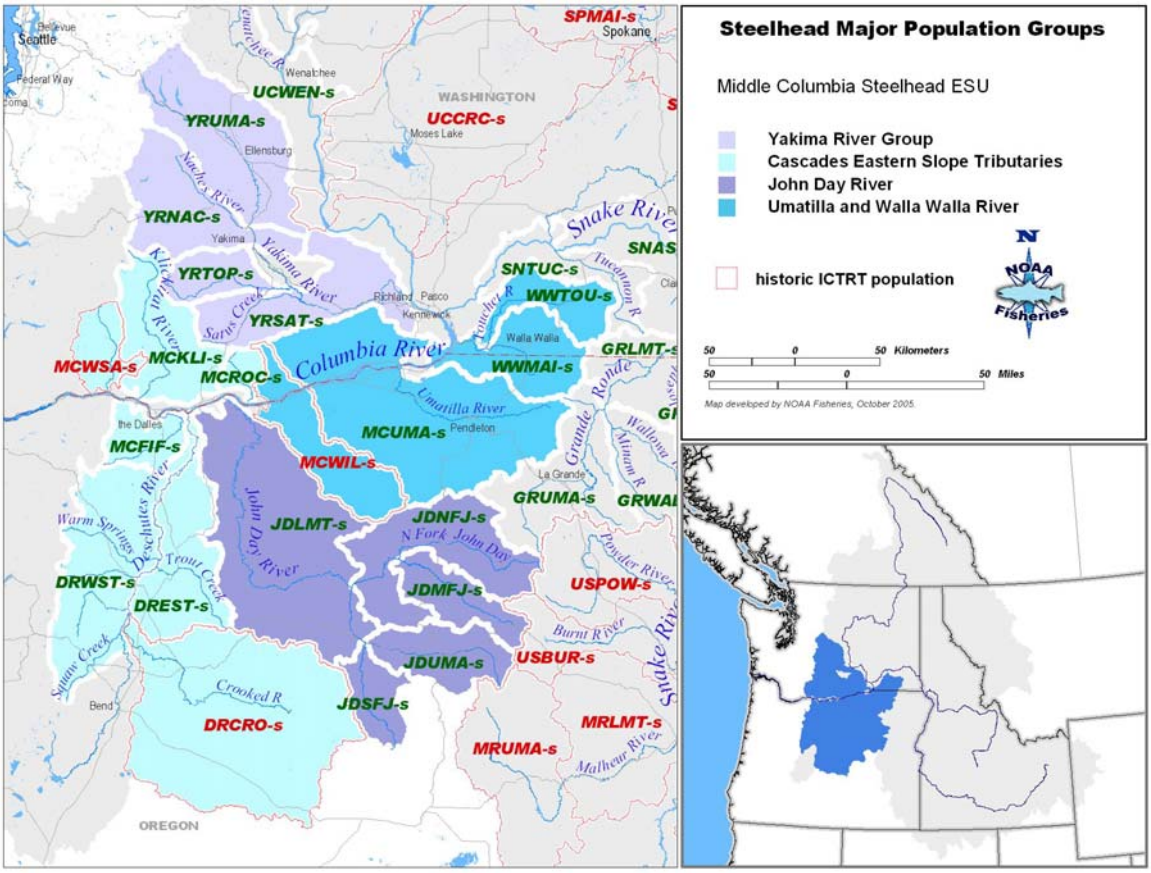

Figure 4-2. Middle Columbia River Steelhead DPS major population groups and populations.

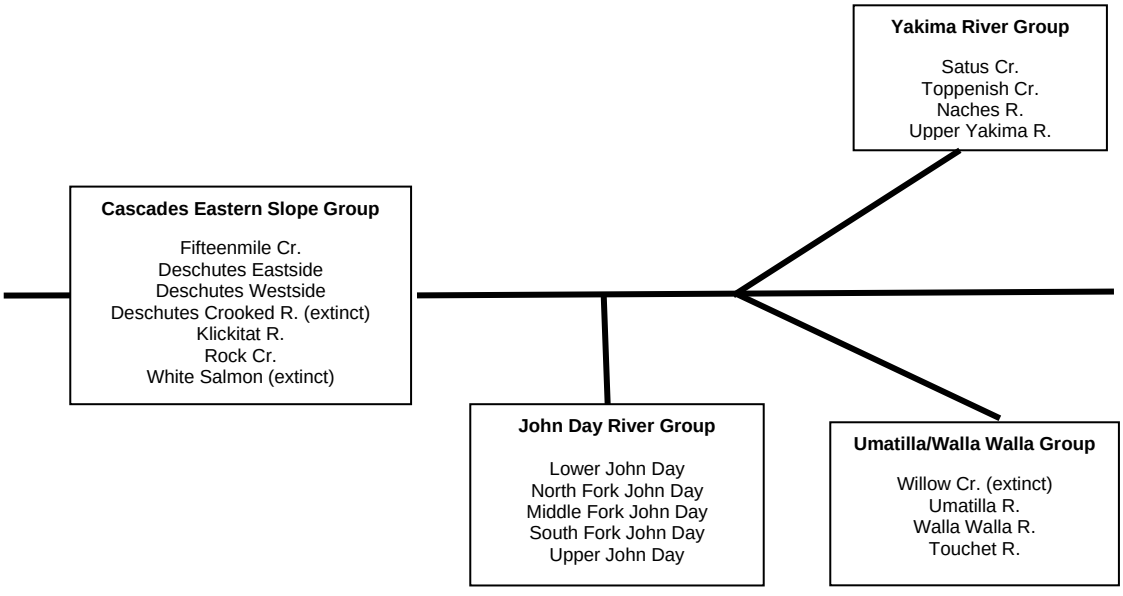

Figure 4-3. Major Population Groups and populations of the Middle Columbia River Steelhead DPS.

Together, the four major population groups in the DPS contain 17 extant and 3 extinct independent populations (ICTRT 2003). Subbasins on the Oregon side of the Columbia River historically supported 12 of the 20 populations in the Mid-Columbia River steelhead DPS. These 12 populations, the subject of this plan, include 10 extant populations: Fifteenmile Creek, Deschutes River Westside, Deschutes River Eastside, Lower Mainstem John Day, North Fork John Day, Upper Mainstem John Day, Middle Fork John Day, South Fork John Day, Umatilla River, and Walla Walla River; and 2 extinct populations: Deschutes/Crooked River and Willow Creek. Five extant populations and one extinct population of Mid-C steelhead reside on the Washington side of the Columbia River and are addressed in other recovery plans. Figure 4-4 shows the independent steelhead populations in the DPS.

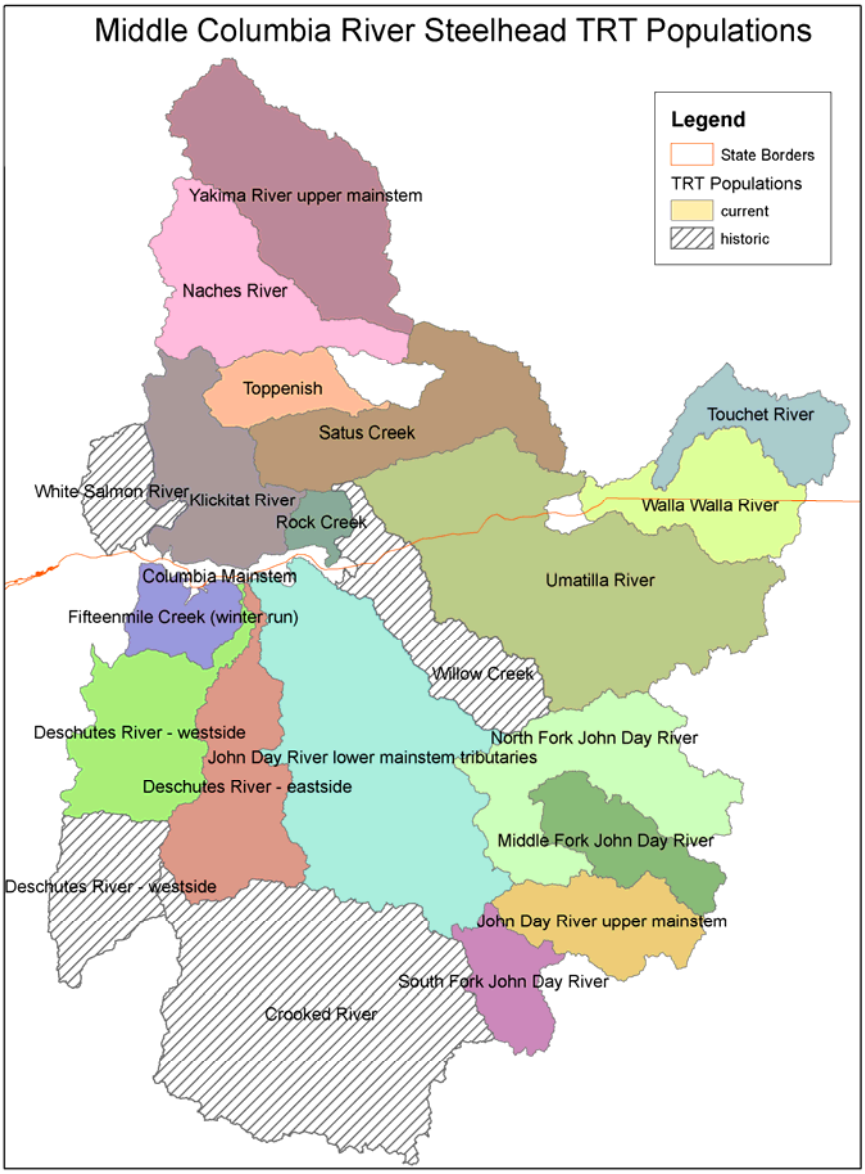

Figure 4-4. Independent populations within the Middle Columbia River Steelhead DPS.

The three major population groups that contain independent Mid-Columbia steelhead populations in Oregon subbasins are described below. These MPGs include the Cascades Eastern Slope Tributaries MPG, John Day River MPG and Walla Walla and Umatilla rivers MPG. Descriptions of the MPGs and independent populations summarize information provided in the ICTRT report *Independent Populations of Chinook, Steelhead, and Sockeye for Listed Evolutionarily Significant Units within the Interior Columbia River Domain* (ICTRT 2003) and the updated population delineation in the interior Columbia Basin memorandum (ICTRT May 11, 2005). Mid-C steelhead populations from Washington tributaries are not discussed in this document.

Cascades Eastern Slope Tributaries MPG

The Cascades Eastern Slope Tributaries MPG contains five extant populations and two extinct populations. Oregon subbasins support three of the extant populations ─ Deschutes River Westside, Deschutes River Eastside, and Fifteenmile Creek ― and historically supported the extinct Deschutes/Crooked River. Populations in the Cascades Eastern Slope Tributaries MPG are united primarily by geographic proximity. The habitats they occupy are diverse, but the constituent rivers generally drain the eastern slope of the Cascades and the dry Columbia Plateau. The MPG supports summer and winter run life history forms of steelhead.

1. *Fifteenmile Creek*: This population occupies Fifteenmile Creek and its tributaries, Fivemile, Eightmile and Ramsey creeks. It also includes five drainages outside of the Fifteenmile Creek watershed ― Threemile, Mill, Chenoweth, Mosier, and Rock creeks ― that flow directly into the Columbia River. The population is moderately segregated from other populations (22 km from the Klickitat and 37 km from the nearest spawning in the Deschutes River), and occupies somewhat different habitat. Fifteenmile Creek steelhead are exclusively winter run fish and are considered the easternmost distribution of winter steelhead in the Columbia basin. These characteristics, coupled with genetic differentiation and capacity, lead to designation as an independent population.

2. *Deschutes River Eastside*: The Deschutes River Eastside summer steelhead population occupies the mainstem Deschutes River from its mouth to the confluence of Trout Creek, and the tributaries entering the Deschutes from the east: Buck Hollow, Bakeoven, and Trout Creeks. Because of uncertainty concerning the relationship of mainstem spawners in the Deschutes River and tributaries, mainstem reaches were grouped with their respective tributary population. The population is separated from the Fifteenmile Creek population by geographic distance (37 km) and run timing (Fifteenmile steelhead are exclusively winter run fish), and from the Deschutes River Westside population because of significant habitat and life history differences. Eastside tributaries drain drier, lower elevation areas than the Westside tributaries, resulting in quite different flow and temperature patterns.

3. *Deschutes River Westside*: The Deschutes River Westside summer steelhead population boundaries encompass the mainstem Deschutes River from the mouth of Trout Creek upstream to Big Falls (current upstream barrier to anadromous fish), and tributaries entering the Deschutes from the west, including the Warm Springs River, Shitike Creek, Whychus Creek and the Metolius River. The current occupied area only includes the

mainstem from the mouth of Trout Creek upstream to Pelton Dam, the Warm Springs River, and Shitike Creek. The remaining area is blocked by the Pelton-Round Butte Complex. The population is separated from the eastside population based on habitat and life history characteristics. Nearly 50% of the habitat resides in the Ponderosa Pine-Bitterbrush Woodland ecoregion. None of the habitat in the Eastside population resides in this ecoregion.

4. *Deschutes Crooked River*: This historical population once occupied the Crooked River drainage, a major watershed in the Deschutes basin. The populations is now extinct as Pelton Dam, a hydroelectric dam at RM 100 on the Deschutes River, blocks all anadromous fish passage. The population boundaries include Crooked River and its tributaries. The population was designated based on historical capacity and distance from other populations. Ochoco Dam built on Ochoco Creek (RM 10) in 1922 and Bowman Dam built on the Crooked River mainstem in 1961 (RM 70) without passage facilities blocked migration to the upper portion of the Basin (Nehlsen 1995). Passage was abandoned at the Pelton-Round Butte Complex in 1968, and anadromous fish passage is now blocked at the Pelton Reregulating Dam (RM 100). There is a current management agreement and plan to re-establish steelhead production within the Crooked River population boundaries up to Ochoco and Bowman dams.

   There is currently (March 2007) a barrier at Opal Springs Dam on the Crooked River immediately upstream from Lake Billy Chinook (LBC) that will need to have safe upstream passage before any production of steelhead is possible within the Crooked River Basin. Opal Springs Dam is not scheduled for federal relicensing for many years. However, state and federal biologists are currently working with the licensee, Deschutes Valley Water District, to work out a plan to provide upstream passage.

John Day River MPG

The ICTRT defined the John Day River MPG as a major grouping based primarily on basin topography and distance from other MPGs. The MPG covers Oregon's John Day River drainage. It is one of the few remaining summer steelhead groups in the Interior Columbia Basin that has had no intentional influence from introduced hatchery steelhead and that has recently been classified as strong or healthy (Huntington et al.1994, Lee et al.1997). The ICTRT identified five populations in this MPG based on genetic information, demographic correlations, and habitat/ecoregion data. Spawning areas are widely distributed across tributary and mainstem habitats.

1. *Lower Mainstem John Day River*: This summer steelhead population includes tributaries to the John Day River downstream of the South Fork John Day River. This widespread population is the most differentiated ecologically from other populations, occupying the lower, drier Columbia Plateau ecoregion. Habitat divergence and distance to other populations are the primary factors in delineating this population.

2. *North Fork John Day River*: The North Fork summer steelhead population occupies the highest elevation, wettest area in the John Day basin. Population boundaries include the main stem and tributaries of the North Fork John Day River. The ICTRT defined the

population based on habitat characteristics, basin topography, and demographic patterns. The population also encompasses sufficient habitat to support an independent population. Chilcote (2001) found that the upper North Fork index count was the most divergent of the John Day stocks, indicating demographic independence.

3. *Middle Fork John Day River*: This summer steelhead population occupies the Middle Fork John Day River and all its tributaries. Spawning areas in the Middle Fork John Day River are separated substantially from all other spawning areas, except for those in the North Fork John Day. The distance between spawning habitat in this population and others combined with habitat differences between this population and the North Fork population, as well as general basin topography, led to independent population designation.

4. *South Fork John Day River*: This summer steelhead population occupies the South Fork John Day River drainage. Genetic data from South Fork John Day River *O. mykiss* samples, which likely includes the anadromous form, indicate that the population is differentiated from those in other parts of the John Day (Currens et al. 1985). This independent population was defined based on genetic information and basin topography.

5. *Upper Mainstem John Day River*: The Upper Mainstem John Day River summer steelhead population includes the mainstem John Day River and tributaries upstream from the South Fork. It is separated from the lower mainstem based on habitat differences, and from the South Fork because of topography.

Walla Walla and Umatilla Rivers MPG

The Walla Walla and Umatilla rivers form a major grouping based on shared ecological characteristics and geographic proximity. They both drain the northwestern slopes of the Blue Mountains, with lower reaches in the warmer, drier habitats of the Columbia Plateau. Within this major group, genetic information, distance between spawning aggregates and ecoregional classifications contributed to ICTRT population delineations.

1. *Umatilla River*: The Umatilla River and its tributaries are considered an independent population. Both genetic analysis (Narum and Powell 2002) and distance from other populations supports separation of this subbasin from the Walla Walla River. There is little genetic differentiation between areas within the Umatilla River subbasin and substantial connectivity between spawning areas in the subbasin.

2. *Walla Walla River*: The Walla Walla River and its tributaries (except the Touchet River) are designated as an independent population. One major tributary to the Walla Walla River, the Touchet River, was identified as a separate population. Several genetic analyses indicate that *O. mykiss* in the Touchet River are genetically distinct from other *O. mykiss* in the Walla Walla basin (Currens 1985, Currens 1997, Narum et al. 2004, Kassler et al. in review). In addition, spawners in the mainstem Walla Walla River and its tributaries are geographically distant (101 km) from those in the Touchet and those in the Umatilla River.

3. *Touchet River*: The ICTRT identified the Touchet River, which flows into the Walla Walla River, as an independent population based on genetic and geographic separation.

4. *Willow Creek*: Willow Creek is an extinct population. It was designated as an independent population based on geographic distance from other populations and capacity sufficient to support an independent population.

Section 5 Desired Status
Delisting and Broad Sense Recovery

Under the ESA, a species no longer requires protection when it is no longer in danger of extinction or likely to become endangered within the foreseeable future based on evaluation of the listing factors specified in ESA Section 4(a)(1). To remove the Mid-Columbia River Steelhead DPS from the Federal ESA list, NMFS must determine that the DPS, as evaluated under the ESA listing factors, is no longer likely to become endangered. Any new factors identified since listing must also be addressed to ensure that the species no longer requires protection as a threatened species.

The desired status for Oregon's steelhead populations in the Mid-Columbia River steelhead DPS is two-fold. First, the populations must reach desired levels of biological viability to support removal of the DPS from the threatened and endangered species list. Second, the State of Oregon and the Mid-C Sounding Board seek to rebuild the populations to provide for sustainable fisheries and other ecological, cultural and social benefits. Broader than the definition of delisting provided by the ESA, these broad sense goals incorporate many of the traditional uses, as well as rural and Native American values, deemed important in the Pacific Northwest.

This section identifies the biological viability levels and criteria Oregon Mid-C steelhead populations need to achieve to support delisting of the DPS. It discusses the approach used by the ICTRT (2007) to define these levels and the viability criteria that we applied to assess viability characteristics for each population, MPG, and the DPS. It also describes our broad sense recovery goal and objectives for the Oregon portion of the Mid-Columbia River steelhead DPS.

5.1 Delisting Goal and Criteria

Our primary goal is to support removal of the Mid-C steelhead DPS from the threatened and endangered species list. This requires that the populations must reach the levels of biological viability defined by the ICTRT and adopted by the State of Oregon in this plan as delisting criteria. In the context of recovery, delisting criteria and viability criteria are considered synonymous. Achieving ICTRT biological viability status at the population and MPG levels is needed before the DPS can be considered at low risk of extinction and a candidate for delisting.

5.1.1 Overall Approach

The ESA requires that recovery plans, to the maximum extent practicable, incorporate objective, measurable criteria that, when met, would result in a determination in accordance with the provisions of the ESA that the species be removed from the Federal List of Endangered and Threatened Wildlife and Plants (50 CFR 17.11 and 17.12). The recovery criteria comprise the core standards that NMFS believes will lead to conditions upon which the decision to de-list a species will be based. The ESA's listing factors, and not the recovery plan, are the legal basis for making de-listing decisions.

One of the main tasks assigned to the NMFS's technical recovery teams for recovery planning was to recommend biologically based viability criteria for application to salmon and steelhead ESUs/DPSs listed under the ESA. Viability criteria identify characteristics and conditions that, when met, would describe viable populations and a viable ESU or DPS that no longer warrants listing. Viability criteria identify the metrics and thresholds that will be used to determine the status of a population and the viability risk.

The ICTRT's approach to recovery is based on guidance from the NMFS Technical Memorandum *Viable Salmonid Populations and the Recovery of Evolutionarily Significant Units (*McElhany et al. 2000). This memorandum provides general direction for setting viability objectives at the ESU and component population levels. Viable salmonid population (VSP) guidelines provided by McElhany et al. (2000) address four major considerations: abundance, productivity, spatial structure and diversity. ESU or DPS level viability criteria consider the appropriate distribution and characteristics of component populations to maintain a viable ESU or DPS in the face of longer-term ecological and evolutionary processes. The Independent Scientific Advisory Board (ISAB 2007b) recently reviewed the ICTRT criteria and concluded "The proposed criteria are based on a well-reasoned and well-supported set of scientific principles and are laid out in a relatively transparent fashion with clear guidelines and examples of their application. The general approach employed by the ICTRT and the underlying understanding of conservation biology and salmon biology are scientifically defensible with no apparent conceptual gaps that might negate the defensibility of the approach."

The ICTRT's approach is consistent with related applications by the Puget Sound and Lower Columbia/Willamette TRTs and the Upper Columbia QAR, and the review of specific information for listed Interior Columbia ESU and DPS populations. The general approach identified for viability criteria has five essential elements:

Stratified Approach: Life history and ecological complexity that historically existed should have a high probability of persistence. The ICTRT stratified the Mid-Columbia River steelhead DPS into groups based on ecoregion characteristics (Eastern Cascades, Columbia plateau, John Day and Yakima), life history types (summer, winter, and summer/winter) and other geographic and genetic considerations.

Viable Populations: Some individual populations within a MPG should have persistence probabilities consistent with a high probability of MPG persistence. The ICTRT defined high persistence probability based on the presence of at least two or one-half of historical populations, whichever is greater, with a negligible risk of extinction.

Representative Populations: Representative populations need to achieve viability criteria or be maintained, but not every historical population needs to meet viability criteria. Viable combinations of populations should include "core" populations that are highly productive, "legacy" populations that represent historical genetic diversity, and dispersed populations that minimize susceptibility to catastrophic events.

Non-deterioration: No population should be allowed to deteriorate until DPS recovery is assured, and all extant populations must be maintained. The ICTRT provided specific

criteria for maintained population status. Current populations and subpopulation structure must be preserved. Recovery measures will be needed in most areas to stop further decline and offset the effects of future impacts.

Safety Factors: Higher levels of recovery should be attempted in more populations than the minimum needed to achieve DPS viability because not all attempts will be successful. Recovery efforts should target all populations, and more than the minimum population viability levels thought to ensure viability. Some populations should be highly viable.

During recovery planning, the ICTRT defined biological viability objectives at the DPS, MPG, and component population levels (McClure et al. 2003). Assessments of viability at these different levels follow guidelines and approaches recommended by the ICTRT. The ICTRT's ESU/DPS-level viability criteria are designed to assess risk for Abundance/Productivity and Spatial Structure/Diversity at the population level. Assessments are then rolled-up to the MPG and ESU levels.

5.1.2 Independent Population-level Viability Criteria

Guidelines for population-level viability (McElhany et al. 2000) state that a viable population should be large enough to:

1. have high probability of surviving environmental variation observed in the past and expected in the future;
2. be resilient to environmental and anthropogenic disturbances;
3. maintain genetic diversity; and,
4. support/provide ecosystem functions.

To address these guidelines, the ICTRT grouped specific population level criteria into two categories: measures addressing abundance and productivity, and measures addressing spatial structure/diversity considerations. It also developed a framework for compiling an aggregate risk score for a population based on the results of applying the individual criteria.

Population Abundance and Productivity

These two population performance characteristics are linked to drive extinction risk. Abundance refers to the average number of spawners in a population over a generation or more. Productivity, or population growth rate, refers to the performance of the population over time in terms of recruits produced per spawner.

Viable populations should demonstrate sufficient productivity to support a net replacement rate of 1:1 or higher at abundance levels established as long-term targets. Productivity rates at relatively low numbers of spawners should, on average, be sufficiently greater that 1.0 to allow the population to rapidly return to abundance target levels. Following guidelines from McElhany et al. (2000), the ICTRT identified the following objective for population abundance and productivity:

Abundance should be high enough that 1) in combination with intrinsic productivity, declines to critically low levels would be unlikely assuming recent historical patterns of

environmental variability; 2) compensatory processes provide resilience to the effects of short-term perturbations; and, 3) subpopulation structure is maintained (e.g., multiple spawning tributaries, spawning patches, life history patterns).

The ICTRT used the Viability Curve concept (McElhaney et al. 2003) as a framework for defining population specific abundance and productivity criteria. A viability curve describes those combinations of abundance and productivity that yield a particular extinction risk threshold. The two parameters are linked relative to extinction risks associated with environmental variability. This approach recognizes that relatively large populations are more resilient in the face of year-to-year variability in overall survival rates than smaller populations. Populations with relatively high intrinsic productivity ─ the expected ratio of spawners to their parent spawners at low levels of spawner abundance ─ are also more robust at a given level of abundance than populations with lower intrinsic productivity. Combinations of abundance and productivity are characterized by viability curves that represent specific extinction risks. Table 5-1 shows combinations of abundance and productivity that represent the 5% extinction risk viability curves for Mid-C steelhead (ICTRT 2007).

Table 5-1. Mid-Columbia River steelhead population viability curves in tabular format (return per spawner and population growth rate versions)[a] (ICTRT 2007).

Middle Columbia Steelhead Growth Rate (S/S)	Spawner to Spawner Measure Minimum Abundance by Population Size Categories				Population Growth Rate (Lambda) Measure Minimum Abundance by Population Size Categories				
	Basic	*Intermediate*	*Large*	*Very Large*	*Population Growth Rate*	*Basic*	*Intermediate*	*Large*	*Very Large*
1.1	5650	5650	5650	5650	**1.02**	48000	48000	48000	48000

1.4	800	1000	1500	2250	**1.16**	830	1000	1500	2250
1.45	660	1000	1500	2250	**1.18**	580	1000	1500	2250
1.5	570	1000	1500	2250	**1.2**	510	1000	1500	2250
1.55	520	1000	1500	2250	**1.21**	500	1000	1500	2250
1.6	500	1000	1500	2250	**1.22**	500	1000	1500	2250
1.65	500	1000	1500	2250	**1.24**	500	1000	1500	2250
1.7	500	1000	1500	2250	**1.26**	500	1000	1500	2250
1.75	500	1000	1500	2250	**1.28**	500	1000	1500	2250
1.8	500	1000	1500	2250	**1.3**	500	1000	1500	2250
1.9	500	1000	1500	2250					
2	500	1000	1500	2250					
2.1	500	1000	1500	2250					

[a] Combinations of abundance and productivity exceeding these combinations would have a projected extinction risk of less than 5% in 100 years, assuming continuation of recent (1978-present) variation in return rates. Spawner to spawner estimates generated using Hockey-Stick recruitment function and average variance (0.18), autocorrelation (0.74) and age structure (0.03 age 3; 0.46 age 4; 0.43 age 5; 0.04 age 6) for populations in the ESU. Population growth rate based estimates generated using average running sums based variance (0.17) for ESU populations.

Methodology and Analysis

The ICTRT developed viability curves representing 1%, 5%, and 25% extinction risk. Populations were grouped into four size categories ― Basic, Intermediate, Large or Very Large ― based on historical capacity, represented by the weighted intrinsic potential area within the population boundaries. The team developed a model to calculate the intrinsic spawning habitat

potential within defined populations. This approach quantified potential habitat based on the relationship of spawning use, landscape characteristics, and stream structure. A Geographic Information System (GIS) was used to compile ecological data, and for model development and output. Datasets describing spawning distribution, geomorphological features and instream habitat characteristics were crucial in developing the relationships. After spatial data acquisition, model parameters were formulated by comparing mapped salmon and steelhead spawning distribution to stream physiography and adjacent landforms.

In general, the ICTRT used spawning and habitat surveys to describe a species spatial structure by locality and density. Additionally, where site specific spawning locations were not available, we used general salmonid distributional GIS data produced by state agencies. The team then evaluated the mapped distributions against stream attributes and spatially coincident landscape features calculated from common spatial data themes. These included United States Geological Service (USGS) digital elevation models, the National Hydrography Dataset (NHD), soil data from the Natural Resources Conservation Service (NRCS), and climatic data from the National Climatic Data Center (NCDC). The 1:100,000 scale NHD layer was subdivided into a continuous series of 200-meter reaches, and this became the basic analysis unit. Using information modeled from the digital elevation models, NCDC precipitation grids, and NHD data, the ICTRT computed stream gradient, wetted and bankful width, and channel confinement, and then assigned this information to each 200-meter segment within the stream network. These attributes were concentrated into groups representing all observed combinations, which included 4 width classes, 6 gradient classes, and 3 confinement classes. Each discrete category was assessed by using statistical methods to compare the relative density of spawners observed within each group. Each habitat class was then assigned a rating of "high", "moderate", "low", or "none" in regards to spawning habitat potential (Table 5-2).

Two additional modifiers were applied to the habitat classes described in Table 5-2. First, there were some instances where stream width did not adequately address flow conditions. We found that certain streams that met general size requirements did not have appropriate flow parameters. Therefore, we assigned NHD stream velocities to our reach level data (200-meter segments) and compared these values to salmon and steelhead distributions. Where velocities fell below or above values observed within spawning locations we dropped intrinsic habitat ratings to "low." Our second qualifier incorporated sedimentation. Again, we observed streams where "moderate" or "high" intrinsic reaches (those with preferred widths, gradients, and confinement) were limited by natural environmental features. Soil erodibility was found to exhibit a negative relationship with spawning preferences. Generally, low gradient reaches within highly erodible soil complexes contain a greater potential for fine particle deposition, and hence poor spawning substrates. We identified low gradient reaches from our reach coverage and highly erodible soils from NRCS soils data. Calculations were also developed to assign mean soil erodibility to each 200-meter segment for the contributing watershed. From these assessments, we dropped low gradient reaches within highly erodible soils to a "low" intrinsic spawning potential. From the analyses described above , the ICTRT generated similar categories for all stream segments within the Interior Columbia ESUs/DPSs and assigned their corresponding habitat ratings. Reach length and width values were used to compute habitat area for all streams and we weighted the values by intrinsic spawning potential, so that "good" = (area * 1.0), "moderate" = (area * 0.5), "low" = (area * 0.25), and "none" = (area * 0.0). The ICTRT identified areas above

natural barriers and assigned these reaches a rating of "none." Natural barriers were identified through surveys from field biologists and gradient breaks computed from the DEM. Once calculated, the ICTRT summarized the weighted stream area for each population and generated size categories based on these values.

The ICTRT analyzed how weighted habitat was aggregated within populations, and labeled reaches with continuous high and moderate ratings as spawning branches. A spawning branch was defined as a stream reach with enough habitat to support 50 spawners. The accumulation of branches within populations then became the basis for defining major spawning areas (MaSAs). It also developed a process for aggregating MaSAs by evaluating the continuity of branch habitat and the spatial composition of stream junctions. A MaSA was required to have enough weighted habitat to support 500 spawners. MaSAs are an important habitat unit for assessing ecological complexity within populations, and for the spatial structure/diversity viability assessment.

The ICTRT determined that abundance levels below 500 individuals for any population would pose unacceptable risk for inbreeding depression and other genetic concerns (ICTRT 2007), and established a minimum abundance threshold of 500 individuals for the basic size populations. Higher spawning threshold sizes were established incrementally for the three larger population sizes. Viability curves for all four size categories were truncated at the minimum abundance threshold level. Table 5-1 shows the combination of abundance and productivity values for all four size categories that yield a 5% risk of extinction. Populations were also categorized by their historical spatial distribution pattern and complexity. Table 5-3 shows population characteristics, spatial complexity designation, minimum abundance thresholds, and minimum productivity at threshold escapement needed to achieve a 95% probability of persistence over 100 years.

Table 5-3. Population characteristics and minimum abundance and productivity (at the threshold abundance level) values that represent levels needed to achieve a 95% probability of persistence over 100 years for Mid-Columbia steelhead populations in Oregon.

Population	Extant/ Extinct	Life History	Size	Spatial Category	Threshold[a] Abundance	Minimum Productivity
Cascades Eastern Slope Tributaries MPG						
Fifteenmile Creek	Extant	Winter	Basic	C-Trellis	500	1.56
Deschutes River Eastside	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35
Deschutes River Westside	Extant	Summer	Large (Inter.)[b]	B-Dendritic	1,500 (1,000)	1.26 (1.35)
Deschutes Crooked River	Extinct	Summer	Very Large	B-Dendritic	2,250	1.19
John Day River MPG						
Lower Mainstem John Day River	Extant	Summer	Very Large	B-Dendritic	2,250	1.19
North Fork John Day River	Extant	Summer	Large	B-Dendritic	1,500	1.26
Middle Fork John Day River	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35
South Fork John Day River	Extant	Summer	Basic	B-Dendritic	500	1.56
Upper Mainstem John Day River	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35
Umatilla/Walla Walla Rivers MPG						
Willow Creek	Extinct	Summer	Intermediate	B-Dendritic	1,000	1.35
Umatilla River	Extant	Summer	Large	B-Dendritic	1,500	1.26
Walla Walla River	Extant	Summer	Intermediate	B-Dendritic	1,000	1.35

[a]Threshold abundance is the minimum abundance criteria to achieve a 5% or less risk of extinction at the minimum productivity.

[b] Large size category is for historically accessible area; intermediate size category is for currently accessible area.

The ICTRT also developed specific guidance for assessing current status relative to the Abundance/Productivity viability risk curves (ICTRT 2006). Using this guidance, mean abundance and standard error were calculated as the most recent 10-year geometric mean of natural-origin spawners. Productivity was calculated as recruits per spawner (spawner to spawner) from the 20 most recent completed brood years (less if only that was available). Only natural-origin fish were counted as recruits, and both natural-origin and hatchery-origin fish spawning naturally were counted as parents. No relative reproductive success factors were applied to hatchery parents. The team determined low abundance/productivity by limiting the data series to only include the low abundance parent population sizes. This delimiting was conducted to address the influence of density on recruits-per-spawner. It determined the median parent abundance level, and used the values equal to or less than the median in most cases. In those cases where the median was not used, it censused at 75% of the threshold. In most cases, this resulted in ten recruits-per-spawner data points. To further increase the accuracy and precision of the productivity estimate, the recruits-per-spawner values were adjusted to represent average smolt-to-adult return rates (SAR), thus reducing the variation resulting from variable smolt out-migration and marine survival. The ICTRT calculated a geometric mean and standard error from the censused, SAR adjusted recruits per spawner dataset. It used an aggregate SAR developed from Deschutes, Umatilla, Snake, and Columbia rivers SAR data sets.

The Oregon technical team used the following approach to consider uncertainty in the risk rating. The approach we selected was one of three options presented by the ICTRT (2007). Under this approach, a lower 90% confidence interval bounds was determined to compare against the viability curves. When the lower end of the 90% CI for productivity resides above the 25% risk curve, there is a 95% probability that the true value is above the 25% risk level. To be considered low risk, the point estimate must reside above the 5% risk level for abundance and productivity and the lower 90% CI bound for productivity must reside above the 25% risk level. To be considered very low risk, the point estimate for abundance and productivity must reside above the 1% risk level and there must be less than 1 in 100 chance (the lower end of the 98% CI resides above the 25% risk curve) that the true productivity value is below the 25% risk level. If the point estimate for abundance and productivity falls between the 5% and 25% risk level, then the population is considered at moderate risk regardless of where the 90% CI resides, which equates to a minimum of 50% probability that the true value is above the 25% risk level. Figure 5-1 provides an example of an Abundance/Productivity viability curve.

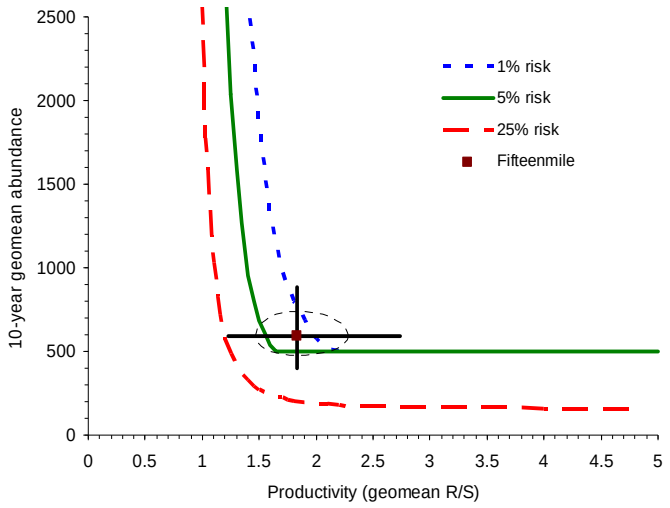

Figure 5-1. Example of Abundance/Productivity viability curves including Fifteenmile Creek current abundance productivity point estimate with standard error elipse and adjusted standard error bounds.

Population Spatial Structure and Diversity

Spatial structure and diversity considerations are combined in the evaluation because they are closely integrated. Spatial structure concerns a population's geographic distribution and the processes that affect that distribution. Diversity refers to the distribution of genetic, life history and phenotypic variation within and among populations.

Distribution influences a population's viability because populations with restricted distribution and few spawning areas are at a higher risk of extinction due to catastrophic environmental events than are populations with more widespread and complex spatial structures. A population with a complex spatial structure, including multiple spawning areas, may experience more opportunity for gene flow, developmental substructure, and life history diversity.

Population-level diversity is similarly important for long-term persistence. Populations exhibiting greater diversity are generally more resilient to short-term and long-term environmental changes. Phenotypic and life history diversity allow populations to use a wider array of environments and protect populations against short-term temporal and spatial environmental changes. Underlying diversity provides the ability to survive long-term environmental changes.

McElhany et al. (2000) provide a number of guidelines for the spatial structure and diversity of viable salmonid populations that consider these principles (Figure 5-2).

Spatial Structure

1. Habitat patches should not be destroyed faster than they are naturally created.
2. Natural rates of straying among subpopulations should not be substantially increased or decreased by human actions.
3. Some habitat patches should be maintained that appear to be suitable or marginally suitable, but currently contain no fish.
4. Source subpopulations should be maintained.
5. Analyses of population spatial processes should take uncertainty into account.

Diversity

1. Human-caused factors such as habitat changes, harvest pressures, artificial propagation, and exotic species introduction should not substantially alter variation in traits such as run timing, age structure, size, fecundity, morphology, behavior, and molecular genetic characteristics.
2. Natural processes of dispersal should be maintained. Human-caused factors should not substantially alter the rate of gene flow among populations.
3. Natural processes that cause ecological variation should be maintained.
4. Population status evaluations should take uncertainty about requisite levels of diversity into account.

Figure 5-2. Viable salmonid population spatial structure and diversity guidelines (McElhany et al. 2000).

The ICTRT identified two primary goals that spatial structure and diversity criteria should address:

1. maintain natural rates and levels of spatially mediated processes, and
2. maintain natural patterns of variation.

The ICTRT also provided a format outlining guidelines for achieving these goals. The format identifies mechanisms, factors and metrics appropriate for assessing population status. Mechanisms are biological or ecological processes that contribute to achieving the goals (e.g., gene flow patterns affect the distribution of genotypic and phenotypic variation in a population.) Factors are characteristics of a population or its environment that influence mechanisms (e.g., gaps in spawning distribution affect patterns in gene flow.) Metrics are measured and assessed at regular intervals to determine whether a population has achieved goals or to evaluate its current risk level. Some viability metrics include variable criteria that are dependent on the spatial complexity designation of the population. Table 5-4 summarizes the associations between these goals, mechanisms, factors and metrics. Spatial complexity designations are also presented in Table 5-4.

Table 5-4. Organization of goals, mechanisms, factors and metrics for spatial structure and diversity risk rating (ICTRT 2007).

Goal	Mechanism	Factor	Metrics
A. Allowing natural rates and levels of spatially-mediated processes.	1. Maintain natural distribution of spawning areas.	a. Number and spatial arrangement of spawning areas.	Number of MaSAs, distribution of MaSAs, and quantity of habitat outside MaSAs.
		b. Spatial extent or range of population.	Proportion of historical range occupied and presence/absence of spawners in MaSAs.
		c. Increase or decrease gaps or continuities between spawning areas.	Change in occupancy of MaSAs that affects connectivity within the population.
B. Maintaining natural levels of variation.	1. Maintain natural patterns of phenotypic and genotypic expression.	a. Major life history strategies.	Distribution of major life history expression within a population.
		b. Phenotypic variation.	Reduction in variability of traits, shift in mean value of trait, loss of traits.
		c. Genetic variation.	Analysis addressing within and between population genetic variation.
	2. Maintain natural patterns of gene flow.	a. Spawner composition.	(1) Proportion of natural spawners that are unnatural out-of ESU spawners.
			(2) Proportion of natural spawners that are unnatural out-of MPG spawners.
			(3) Proportion of hatchery origin natural spawners derived from a within MPG brood stock program, or within population (not best practices) program.
			(4) Proportion of hatchery origin natural spawners derived from a local (within population) broodstock program using best management practices.
	3. Maintain occupancy in a natural variety of available habitat types.	a. Distribution of population across habitat types.	Change in occupancy across ecoregion types.
	4. Maintain integrity of natural systems.	a. Selective change in natural processes or impacts.	Ongoing anthropogenic activities inducing selective mortality or habitat change within- or out-of-population boundary.

Integrating the Four VSP Parameters

These abundance/productivity and spatial structure/diversity considerations form the centerpiece of the ICTRT's framework for assessing ESU viability (ICTRT 2007). The approach is based on guidelines in McElhany et al. (2000), the results of previous applications (i.e., Puget Sound and Lower Columbia/Willamette TRTs and Upper Columbia Qualitative Analysis Review), and a review of specific information available relative to listed Interior Columbia ESU populations.

The ICTRT integrates all four VSP parameters using a simple matrix approach (Figure 5-3). The abundance/productivity (A/P) risk level combines the abundance and productivity VSP criteria

using a viability curve. The spatial structure/diversity (SS/D) risk level integrates across 12 measures of spatial structure and diversity. The overall diversity viability rating for any population is determined using two guiding principles. First, the VSP concept (McElhany et al. 2000) provides a 5% risk criterion to define a viable population. Therefore, any population scored moderate or high risk in the abundance/productivity criteria would not meet the recommended viable standards. In addition, any population that is high risk in SS/D would not be considered viable. Second, populations with a very low rating for A/P and at least a low rating for SS/D are considered to be "Highly Viable." Populations with a low rating for A/P and a very low, low, or moderate rating for SS/D are considered "Viable." In addition, populations with a very low risk rating for A/P and a moderate rating for SS/D are also considered "Viable." This integration approach places greater emphasis on the abundance/productivity criteria. These individual ratings are then integrated to determine the viability of major population groups. The assessments of individual MPGs are aggregated to assess the DPS as a whole (ICTRT 2007).

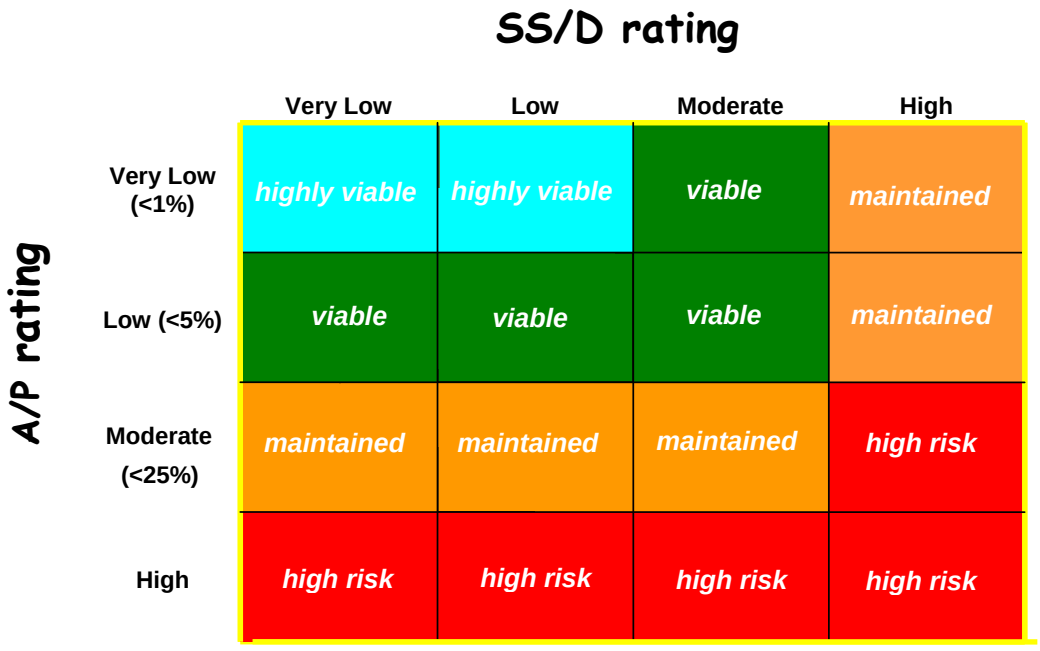

Figure 5-3. Assessing population viability across VSP criteria (ICTRT 2007).

Percentages for abundance and productivity scores represent the probability of extinction in a 100-year time period. The ICTRT used the analysis approach discussed in this section to examine the viability of independent populations in the Mid-Columbia River steelhead DPS.

5.1.3 Major Population Group Viability Criteria

The ICTRT recommended MPG-level risk criteria that assess the level of risk associated with its component populations. While individual populations meeting viability criteria are expected to have low risk of extinction, these additional MPG-level criteria ensure robust functioning of the population group and provide resilience to catastrophic loss of one or more populations. In developing these criteria, the ICTRT assumed that catastrophes do not increase dramatically in frequency, that populations are not lost permanently (due to catastrophe or anthropogenic

impacts) and that permanent reductions in productivity, including long-term, gradual reductions in productivity do not occur (ICTRT 2007). Figure 5-4 shows MPG-level viability criteria identified by the ICTRT.

MPG Viability Criteria (ICTRT 2007)

The following six criteria must be met for an MPG to be regarded as low risk (viable):

1. One-half of the populations historically within the MPG (with a minimum of two populations) must meet at least minimum viability standards.
2. At least one population must be categorized as being "Highly Viable".
3. Viable populations within an MPG must include some populations classified (based on historical intrinsic potential) as "Very Large," or "Large," and "Intermediate" in the same proportion as were present within the MPG historically.
4. Populations not meeting viability standards should be maintained with sufficient productivity that the overall MPG productivity does not fall below replacement (i.e., these areas should not serve as significant population sinks).
5. Where possible, given other MPG viability requirements, some populations meeting viability standards should be contiguous AND some populations meeting viability standards should be disjunct from each other.
6. All major life history strategies (e.g. spring and summer run timing) that were present historically within the MPG must be represented in populations meeting at least the minimum viability requirements.

Figure 5-4. MPG-level viability criteria identified by the ICTRT (ICTRT 2007).

MPG Recovery Scenarios Options

We identified the following options for the three MPGs containing Oregon Mid-C steelhead populations. The Cascades Eastern Slope Tributaries and the Umatilla/Walla Walla MPGs contain populations that reside in Oregon and Washington. Although this recovery plan deals specifically with Oregon populations, we present MPG recovery scenarios considering all populations within each MPG.

Cascades Eastern Slope Tributaries Major Population Group

This MPG contains seven populations, including four Oregon populations, shown in Table 5-5.

Table 5-5. Characteristics of steelhead populations in Cascades Eastern Slope Tributaries MPG.

Population	Extant/Extinct	Life History	Size Category
Fifteenmile Creek	Extant	Winter Run	Basic
Deschutes River Eastside	Extant	Summer Run	Intermediate
Deschutes River Westside	Extant	Summer Run	Large
Deschutes Crooked River	Extinct	Summer Run	Very Large
Klickitat River	Extant	Winter/Summer Run	Intermediate
White Salmon	Extinct	Summer Run	Intermediate
Rock Creek	Extant	Summer Run	Basic

The following ICTRT criteria are recommended for this MPG to be regarded as viable:

1. Four of the seven historical populations in the MPG meet viable criteria standards.
2. One very large/large and two intermediate size populations must be included for the MPG to have proportional representation of the Very Large/Large and Intermediate sizes. The fourth population can be any size from basic to very large.
3. At least one summer run, one winter run, and one population with winter/summer combination must be included for all of the historical major life history strategies to be represented.
4. One of the four viable populations must be highly viable.
5. All populations that do not meet viable status have to meet maintained status.

Given the above criteria, the only viability scenario for this MPG must include the following populations:

- Fifteenmile Creek—represents a winter run requirement and small size.
- Deschutes River Eastside—represents a summer run and intermediate size requirement.
- Deschutes River Westside—represents a summer run and large size requirement.
- Klickitat River—represents a winter/summer run and an intermediate size requirement.
- Rock Creek—must be maintained.

John Day River Major Population Group

This MPG contains five populations. Their characteristics are described in Table 5-6.

Table 5-6. Characteristics of steelhead populations in the John Day River MPG.

Population	Extant/Extinct	Life History	Size Category
Lower Mainstem John Day	Extant	Summer Run	Very Large
North Fork John Day	Extant	Summer Run	Large
Middle Fork John Day	Extant	Summer Run	Intermediate
South Fork John Day	Extant	Summer Run	Basic
Upper Mainstem John Day	Extant	Summer Run	Intermediate

The following ICTRT criteria are recommended for this MPG to be regarded as viable:

1. Three of the five historical populations in the MPG must meet viable criteria standards.
2. Viable populations within the MPG must include two very large/large and one intermediate size population to have proportional representation of the population sizes.
3. All major life history strategies present historically must be represented. There are only summer-run life histories.
4. One of the three viable populations must be highly viable.

5. All populations that do not meet viable status must be maintained.

Given the above criteria, a viability scenario for this MPG must include the following populations:

- Lower Mainstem John Day—represents the only population that meets the very large size requirement.
- North Fork John Day—represents a highly viable population and a large size requirement.
- Middle Fork John Day or Upper Mainstem John Day—either population could meet the second intermediate size requirement.
- South Fork John Day—must be maintained.

Umatilla/Walla Walla Rivers Major Population Group

This MPG contains four populations, including three Oregon populations, shown in Table 5-7.

Table 5-7. Characteristics of steelhead populations in Umatilla/Walla Walla Rivers MPG.

Population	Extant/Extinct	Life History	Size Category
Willow Creek	Extinct	Summer Run	Intermediate
Umatilla River	Extant	Summer Run	Large
Walla Walla River	Extant	Summer Run	Intermediate
Touchet River	Extant	Summer Run	Intermediate

The following ICTRT criteria are recommended for this MPG to be regarded as viable:

1. Two of the four historical populations in the MPG must meet viable criteria standards.
2. Viable populations within the MPG must include one large and one intermediate size populations.
3. All major life history strategies present historically must be represented. There are only summer-run life histories.
4. One of the two viable populations must be highly viable.
5. All populations that do not meet viable status must be maintained.

Given the above criteria, the following two viability scenarios are options:

- Umatilla River—this population is required to meet the large size requirement because it is the only large size population.
- Walla Walla River or Touchet River—either population could meet the second population requirement at intermediate size.

5.1.4 DPS Viability Criteria

The ICTRT determined that, because MPGs are geographically and genetically cohesive groups of populations, they are critical components of ESU/DPS-level spatial structure and diversity. Having all MPGs within the DPS at low risk provides the greatest probability of persistence for the DPS. Figure 5-5 shows DPS-level viability criteria defined by the ICTRT.

DPS-Level Viability Criteria (from Cooney et al. 2005)

1. All extant MPGs and any extirpated MPGs critical for proper functioning of the DPS must be at low risk.

2. DPSs that contained only one MPG historically or that include only one MPG critical for proper function must meet the following criteria:
    a. The single MPG must meet all the requirements to be at low risk (see above). In addition:
    b. Two-thirds or more of the populations within the MPG historically must meet minimum viability standards; AND
    c. At least two populations must meet the criteria to be "Highly Viable."

These extirpated areas will be evaluated to determine whether extirpated MPGs are critical for proper functioning of the DPS using the following considerations:

- Likely demographic (abundance and productivity) contribution of the MPG and its component populations to the DPS.
- Spatial role of the MPG in the DPS (e.g. does the extirpated MPG create a gap in the distribution of the DPS?)
- Likely contribution to overall DPS diversity (e.g. does the extirpated MPG occupy habitats that are substantially different from other habitats currently occupied in the DPS?)

Figure 5-5. DPS-level viability criteria identified by the ICTRT (ICTRT 2007).

5.2 Broad Sense Recovery Goal and Objectives

After achieving steelhead recovery under the ESA, the State of Oregon aims to rebuild Oregon's Mid-C steelhead populations to levels that will provide for sustainable fisheries and other ecological, cultural and social benefits. Although broader than the definition of delisting provided by the ESA, these broad sense goals incorporate many of the traditional uses, as well as rural and Native American values, deemed important in the Pacific Northwest.

During the recovery planning effort, the Oregon Middle Columbia Steelhead Sounding Board led the development of broad sense recovery goals for the region. The Sounding Board included citizens from all Oregon subbasins within the Mid-Columbia steelhead DPS. During the process, the board members worked with recovery planners to identify goals and objectives that would provide abundance, productivity, and diversity well above delisting levels to allow for sustainable fisheries and other cultural uses. The Sounding Board (2006) identified the following broad sense recovery goal and objectives.

Broad Sense Recovery Goal

Oregon's broad sense recovery goal for the Mid-C Steelhead is founded on a belief that citizens throughout the region value and enjoy the substantial ecological, cultural, social, and economic benefits that are derived from having healthy, diverse populations of steelhead.

Oregon's Mid-Columbia River natural steelhead populations are sufficiently abundant, productive, and diverse (in terms of life histories and geographic distribution) so that they provide significant ecological, social, cultural, and economic benefits.

To achieve these benefits for current and future generations, this recovery plan aims to restore Mid-C steelhead in Oregon subbasins to the point where their protection under the ESA is no longer needed and a range of societal benefits are met. Recovery of Mid-Columbia steelhead populations will require actions that preserve, enhance and restore healthy watershed conditions where ecosystem functions, processes and dynamics are intact ─ including instream conditions, riparian habitat diversity and complexity, and upland watershed health in concert with complementary management of harvest, hatcheries and hydropower. Recovery is a process that leads to steelhead populations that are not only viable, but that also provide a harvestable surplus for the treaty tribes and for all other citizens of the region.

This vision for broad-sense recovery incorporates ESA delisting goals in the sense that delisting would be achieved *first* during an extended and stepwise process of achieving broad sense recovery goals. ESA delisting criteria are entirely science-based and establish the biologically-based standards required to sustain the DPS. In contrast, broad-sense recovery represents a level of population performance that will considerably exceed the delisting level.

Recovery Objectives
By the year 2050, proponents of the Middle Columbia River Steelhead Recovery Plan intend to achieve the following objectives:

1. Middle Columbia steelhead are viable throughout the historical range and no longer need protection under the ESA;

2. All currently extant Middle Columbia steelhead populations are highly viable;

3. Extirpated populations (e.g. Willow Creek, Crooked River) are restored in a manner that engages landowner cooperation and does not subject landowners to ESA regulation based on the presence of previously extirpated populations until the introduced populations are self-sustaining and become part of the listed DPS;

4. All extant populations of Middle Columbia steelhead are capable of contributing ecological, social, cultural, and economic benefits on a regular and sustainable basis;

5. Working in concert with existing agreements and collaboratively with landowners and resource managers NOAA will define a suite of additional land and water resource management principles and practices that when followed will alleviate liability for possible ESA regulatory consequences to landowners and resource managers;

6. Out-of-basin limiting factors are addressed equitably and in concert with in-basin limiting factors;

7. Landowners, land managers and agencies are provided with guidance on the protection and management of habitats to promote the recovery of Mid-C steelhead; and,

8. Land and resource managers work with communities and other interests in a coordinated manner to achieve broad sense recovery through a shared vision of conservation where options and choices are preserved for future generations.

A number of actions are needed to accomplish the goal and objectives:

1. Collaborative management processes and approaches, including both volunteer and incentive-based programs, encourage restoration of habitat.

2. Management actions are based on a strategic priority framework that recognizes the importance of protection, enhancement, and restoration throughout the life cycle of the species.

3. Agencies and residents employ a diversity of management approaches across the DPS that meet both social and biological objectives.

4. Landowners and resource managers are provided with information and assistance on how to accomplish recovery goals and objectives.

5. A coordinated research, monitoring, and evaluation program is in place that will facilitate periodic assessments of implementation effectiveness, population status, habitat status, and advise the need, if any, to modify future recovery management actions within an adaptive management framework.

Section 6 Current Status — Viability Assessments

This section summarizes the current status of Oregon's ten independent populations of Mid-C steelhead based on viability assessment results. It also describes the role of each population in achieving viable status at the MPG level. Detailed individual population viability assessments are presented in Appendix B. Section 5 describes the ICTRT's approach and criteria for assessing population viability. All error bars shown represent 90% confidence intervals (CI) unless otherwise indicated. In those cases where 98% CIs are shown is for the purpose of determining if uncertainty criteria for highly viable status has been met.

6.1 Fifteenmile Creek Winter Steelhead Population

The Fifteenmile Creek population occupies the Fifteenmile watershed and several smaller drainages — Rock, Mosier, Chenoweth, Mill, and Threemile — outside the Fifteenmile watershed. The population contains three MaSAs, located in the Fifteenmile Creek watershed: Upper Fifteenmile, Eightmile, and Fivemile. It also occupies five MiSAs: lower Fifteenmile, Threemile, Mill, Chenoweth, and Mosier.

The Fifteenmile Creek Winter Steelhead population is at low risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 703. During the period 1985-1999, returns per spawner in the Fifteenmile Creek population ranged from 0.37 (1987) to 5.58 (1998). The most recent 15-year (1985-1999) SAR adjusted and delimited geomean of returns per spawner was 1.82 (Appendix B).

Figure 6-1 shows the viability curve for the Fifteenmile Creek population. The Abundance/Productivity (A/P) point estimate resides above the 1% risk curve, but the population is not considered to be at very low risk because of uncertainty criteria, the 98% confidence interval (CI) extends below the 25% risk curve. However, since the 90% CI is above the 25% risk curve, the population is rated at low risk. These A/P results should be viewed with caution, as abundance and productivity estimates for the population are based on 15 years of spawner/recruit data.

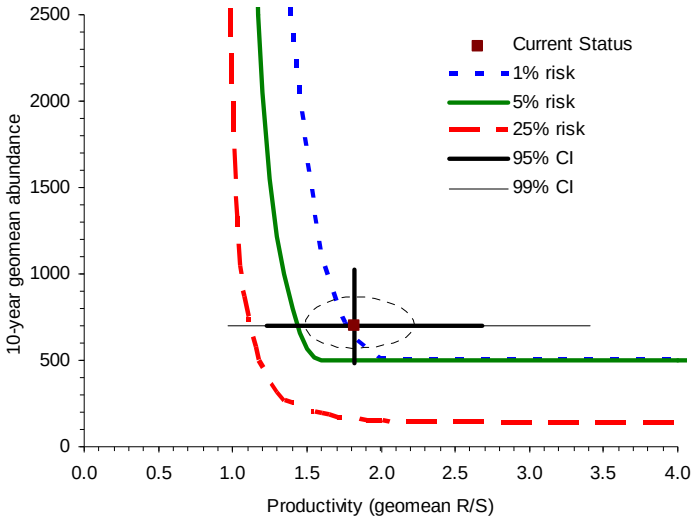

Figure 6-1. Fifteenmile Creek Winter Steelhead population abundance and productivity compared to the DPS viability curve.

The integrated Spatial Structure/Diversity (SS/D) rating is low risk for the Fifteenmile population. There has been little change in distribution relative to the historical distribution. The absence of major reductions in distribution resulted in a rating of very low risk for the spatial structure metrics. We hypothesize that there have been minor reductions in life history diversity and phenotypic variation, but these changes are not severe enough to raise risk levels to moderate. There are few hatchery fish in the population resulting in low risk for spawner composition.

Overall Risk Rating

The Fifteenmile Creek population currently meets criteria for viable status because both Abundance/Productivity and Spatial Structure/Diversity are rated at low risk. The productivity value of 1.82 is above the minimum 1.65 required at the threshold abundance, and the 10-year geomean of natural-origin spawners is well above the viable threshold of 500 for a "basic" size population. A relatively small increase in productivity and reduction in the CI are required to move this population into "highly viable" status. Additional data points will likely decrease the standard error and move the 98% confidence interval out of the high risk region. Monitoring should be continued to allow analysis of a longer data time series.

6.2 Deschutes River Eastside Summer Steelhead Population

The Deschutes River Eastside population includes the mainstem Deschutes River from the mouth to above the Pelton-Round Butte Complex at RM 100, and tributaries joining the Deschutes from the Eastside. Areas above the complex, including Willow Creek, are currently inaccessible. The population contains six MaSAs: Buck Hollow, Bakeoven, Ward/Antelope/Cold/Carp, Lower Trout, Upper Trout and Willow. It contains two MiSAs: Jones Canyon and Campbell. The Willow Creek MaSA and Campbell MiSA are in the inaccessible area above the complex.

The Deschutes River Eastside Summer Steelhead population is at low risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 1,599. During the period 1990-1999, returns per spawner for steelhead in the Deschutes River Eastside ranged from 0.24 (1991) to 3.97 (1996). The most recent 10-year (1990-1999) geomean of returns per spawner SAR adjusted and median delimited was 1.89 (Appendix B).

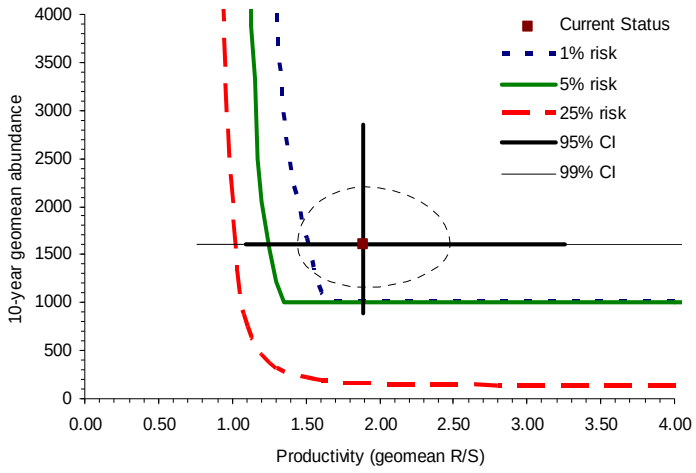

Figure 6-2. Deschutes River Eastside Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The current point estimate for productivity on the viability curve for the Deschutes River Eastside Summer Steelhead population resides above the 1% curve, but the population is not considered to be at very low risk since the 98% CI extends below the 25% risk curve (Figure 6-2). Since the 90% CI is above the 25% risk curve, the population is rated at low risk.

The integrated Spatial Structure/Diversity rating is moderate risk for the Deschutes Eastside population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was low risk. Although the overall rating for this goal was low, spawning distribution is reduced significantly from the historical distribution with loss of spawning in the Willow Creek drainage being the primary factor. The population remains broadly distributed with little change in gaps and good continuity within the currently accessible habitat.

The rating for Goal B "maintaining natural levels of variation" was moderate risk. Habitat changes in key tributary production areas have likely resulted in limitations to life history diversity and reduction in phenotypic expression. In addition, a significant proportion of natural spawners are out-of-DPS strays that resulted in a high risk rating for the spawner composition metric. Additional genetics information is needed to assess within and between population differentiations, and to improve our understanding of the degree of introgression of out-of-DPS strays. The ongoing genetics work of the USFWS and co-managers will provide the information needed to better assess the genetic health of this population.

Overall Risk Rating
The Deschutes River Eastside population currently meets the ICTRT recommendation for viable status. The 10-year geomean of natural fish abundance of 1,599 is well above the threshold of 1,000. The point estimate of productivity (1.89) puts the population into the very low risk region; however the 90% CI extends well below the 25% risk level. This wide standard error results in a low risk level for abundance/productivity. The spatial structure/diversity rating is moderate risk, primarily because of the influence of habitat changes on life history and phenotypic expression as well as out-of-DPS hatchery spawners.

6.3 Deschutes River Westside Summer Steelhead Population

The Deschutes River Westside population includes the mainstem Deschutes River from Trout Creek to the Pelton-Round Butte Complex at RM 100, and tributaries joining the Deschutes from the Westside. Current distribution is reduced significantly from the historical distribution because of loss of accessibility to the Metolius River and Whychus Creek drainages. Spawning is currently concentrated in the Warm Springs River and Shitike Creek, and in the mainstem Deschutes River between Trout Creek and Pelton Dam. The population contains six MaSAs (Upper Warm Springs, Mill, Beaver, Shitike, Upper Metolius and Whychus) and nine MiSAs (Lower Warm Springs, Oak Canyon, Seekseekqua, Wapinitia, Lower Warm Springs Tribs, Trahan, Eagle, Skookum, and Dry) in the historically accessible habitat.

The Deschutes River Westside Summer Steelhead population is at high risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 456, which is below the minimum abundance threshold of 1,000 spawners for an "intermediate" size population. During

the period 1980-1999, returns per spawner for steelhead in the Deschutes River Westside population ranged from 0.24 (1987) to 3.72 (1996). The most recent 20-year (1979-1998) geomean of returns per spawner SAR adjusted and delimited at 75% of threshold was 1.05 (Appendix B).

The current point estimate for Abundance/Productivity on the viability curve for the Deschutes River Westside Summer Steelhead population resides below the 25% risk curve (Figure 6-3).

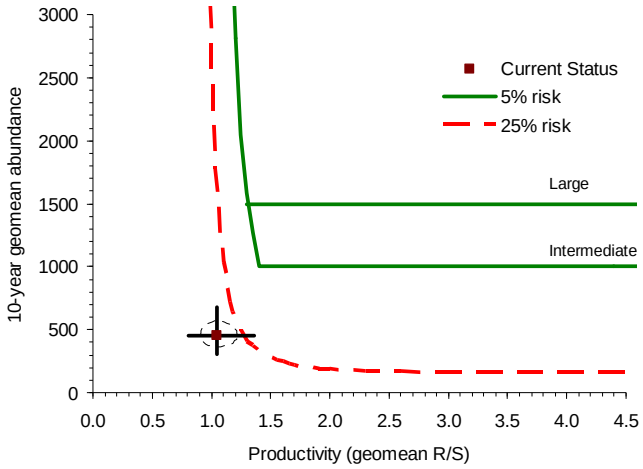

Figure 6-3. Deschutes River Westside Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The integrated Spatial Structure/Diversity rating is high risk for the Deschutes River Westside population. The population rates at moderate risk for two of the spatial distribution metrics because the current distribution is substantially reduced from the historical intrinsic distribution due to blocked passages to areas above the Pelton-Round Butte Complex. Ratings for two metrics related to Goal B "maintaining natural patterns of variation" resulted in a moderate rating for Goal B and the overall moderate rating. Genetic variation rated moderate due to limited data and the lack of differentiation between the Deschutes samples and outside-basin hatchery samples. Samples collected in 2005-2006 will better inform the risk associated with genetic variation. The proportion of out-of-DPS hatchery strays resulted in a high risk rating for spawner composition. Most of these strays originate from the Snake River Basin.

Overall Risk Rating

The Deschutes River Westside steelhead population does not currently meet the ICTRT recommended viability criteria and is currently high risk status because the Abundance/Productivity is rated at high risk, and the Spatial Structure/Diversity rating is moderate risk. The 10-year geometric mean abundance of 456 is well below the minimum threshold of 1,000 required for an intermediate size population. The abundance of 456 is slightly below the minimum 500 recommended by the ICTRT for maintained status. A substantial increase in productivity will be required to raise the abundance/productivity values to the low risk level. The genetics information that is presently being collected will better inform the genetics variation risk level in the future. A reduction in the out-of-ESU hatchery stray proportion will be needed to reduce the risk rating for the spawner composition metric.

6.4 Lower Mainstem John Day River Summer Steelhead Population

The Lower Mainstem John Day River population occupies the Lower John Day watershed below the town of Dayville at the mouth of the South Fork John Day River. Steelhead in the Lower Mainstem John Day River population spawn in tributary streams connected by the lower John Day River, including Bridge, Butte, Thirtymile, Service, Mountain and Rock creeks. Multiple smaller drainages also support production. The population contains 11 MaSAs and 19 MiSAs. MaSAs include: Bridge, Mountain, Cottonwood, Middle Rock, Upper Rock, Pine Hollow, Lone Rock, Thirtymile, Butte, Hay, and Grass Valley. MiSAs include: Esau Canyon, Kahler, Jackknife, Pine (John Day), Service, Ferry, Rhodes Canyon, Rowe, Currant, Johnson (John Day), Shoofly, Girds, Cherry, Bologna, Buckhorn, Cottonwood Canyon, Lower Rock 1, Lower Rock 2, and Haystack.

The Lower Mainstem John Day River Summer Steelhead population is at moderate risk based on current abundance and productivity. Spawner abundance in recent years has been highly variable; the most recent 10-year geomean number of natural-origin spawners was 1,800. During the period 1975-1997, returns per spawner for steelhead in the population ranged from 0.14 (1987) to 17.5 (1979). The most recent 19-year (1980-1998) SAR adjusted and delimited geomean of returns per spawner was 2.99 (Appendix B).

The population's productivity is at very low risk. The current point estimate for productivity on the viability curve is above very low risk and the lower end of the adjusted standard error is above the 5% risk level. The abundance is moderate risk because it resides between the 5% and 25% risk levels (Figure 6-4).

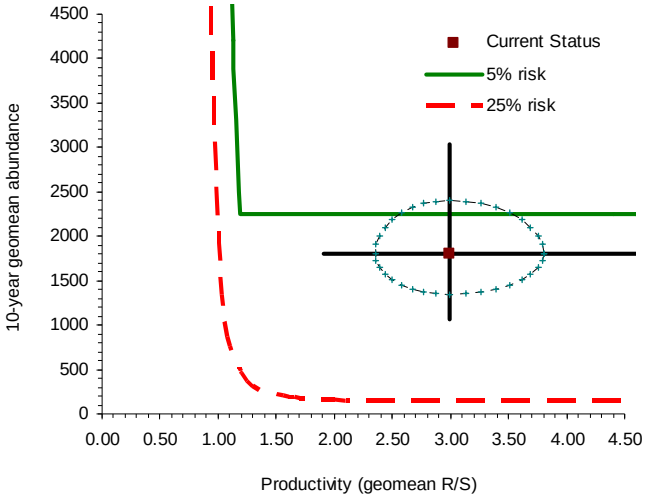

Figure 6-4. Lower Mainstem John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The integrated Spatial Structure/Diversity rating is moderate risk for the Lower Mainstem John Day River population. The rating for Goal A "allowing natural rates and level of spatially mediated processes" was very low. The current spawner distribution is similar to historical with all MaSAs occupied. The MiSAs that are currently unoccupied have little influence on gaps and continuity, and spawners are spread over a very broad geographic area. The rating for Goal B "maintaining natural levels of variation" was moderate risk. This rating was a result of moderate risk for life history and genetic variation, and high risk for spawner composition out-of-DPS hatchery strays. The magnitude and trend in out-of-DPS hatchery strays are of significant

concern. Analysis of genetics information will yield considerable insight into the population's genetic variation and characteristics. Examining genetics data for evidence of hatchery introgression will be useful for future spatial structure/diversity risk assessments.

Overall Risk Rating

With a moderate rating for Abundance/Productivity and a moderate rating for Spatial Structure/Diversity, the Lower Mainstem John Day River Summer Steelhead population does not currently achieve an overall rating of viable according to ICTRT criteria, although it does meet the criteria for a "maintained" population with abundance well above the 500 minimum recommended by the ICTRT for maintained status. To achieve a viable rating, this population must improve in both Abundance/Productivity and Spatial Structure/Diversity. Out-of-DPS origin spawners are the most influential factor on Diversity Risk. Additional population specific data are needed to better quantify the spawner composition in this population to reduce the uncertainty associated with this risk metric.

6.5 North Fork John Day River Summer Steelhead Population

The North Fork John Day is the largest tributary to the John Day River. The North Fork John Day River population contains eight MaSAs: Lower North Fork John Day, Potamus, Big Wall, Big, Upper North Fork John Day, Desolation, Granite and Owens. It contains seven MiSAs: Meadow Brook, Fivemile (North Fork), Ditch, Cabin, Meadow (North Fork), Cabin (North Fork) and Bridge (North Fork). Spawning is distributed broadly throughout the population boundaries including mainstem areas of Cottonwood, Camas, Desolation, and Granite creeks, and the Upper North Fork John Day River, as well as in many tributaries.

The North Fork John Day River Summer Steelhead population is at very low risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 1,740 (1,898 total spawners). During the period 1973-1997, returns per spawner for steelhead in the North Fork John Day River ranged from 0.10 (1985) to 3.07 (1991). The most recent 20-year (1978-1997) SAR adjusted and delimited geomean of returns per spawner was 2.41 (Appendix B).

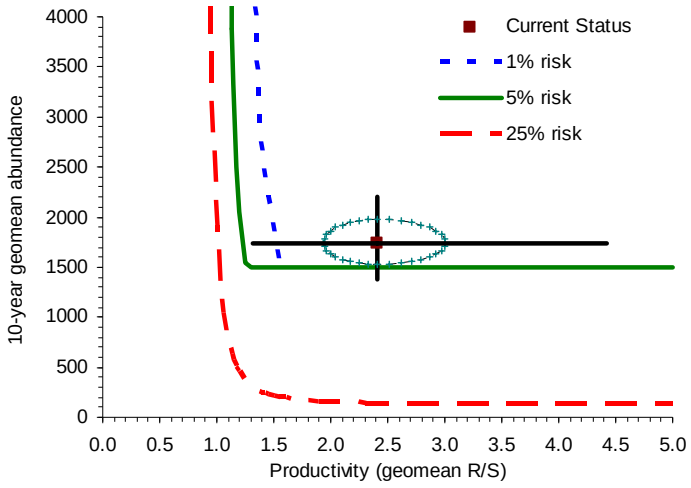

Figure 6-5. North Fork John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The current point estimate for Abundance/Productivity on the viability curve for the population resides above the 1% risk curve and the 98% confidence interval for productivity is above the 25% risk curve (Figure 6-5). The productivity value of 2.41 is well above the minimum needed at threshold abundance, and the abundance of 1,740 is above the 1,500 threshold for a "large" size population.

The combined integrated Spatial Structure/Diversity rating is low risk for the North Fork John Day population. The rating for Goal A "allowing natural rates and level of spatially mediated processes" was very low. The current spawner distribution mimics the intrinsic distribution. The population is distributed broadly across the landscape in numerous MaSAs and MiSAs. Good continuity exists between spawning areas and current gaps between spawning areas are similar to historical gaps. The rating for Goal B "maintaining natural levels of variation" was low risk. However, there remains considerable uncertainty about the ratings for genetic variation and out-of-DPS hatchery strays in the natural spawners. Additional genetic analyses and interpretation is needed to determine if the genetic variation is similar to historical conditions and to examine evidence for degree of stray hatchery fish introgression. We rated the metric for out-of-DPS hatchery strays as very high. The data used for this rating are a composite from four John Day populations. Additional population specific spawner composition data are needed to improve the certainty of the out-of-DPS stray hatchery risk rating. If there is significant hatchery introgression that is affecting the genetic variation through time, the risk rating for "genetic variation" will increase and the overall risk rating for Goal B and Spatial Structure/Diversity will also increase.

Overall Risk Rating
The overall viability rating for the North Fork John Day River Summer Steelhead population is highly viable as a result of the Abundance/Productivity rating of very low risk, and the Spatial Structure/Diversity rating of low risk. The productivity value of 2.41 is well above the minimum needed at threshold abundance, and the abundance of 1,740 is above the minimum of 1,500 natural-origin spawners for a large size population. The Spatial Structure/Diversity metric ratings for genetic variation and out-of-DPS hatchery-origin spawner composition were the most influential on the overall Spatial Structure/Diversity assessment. There is considerable uncertainty regarding the genetic effect of out-of-DPS strays as well as the actual proportion of natural spawners that are hatchery strays. Enhanced monitoring efforts should be undertaken to develop better estimates of the composition of North Fork John Day spawners.

6.6 Middle Fork John Day River Summer Steelhead Population

The Middle Fork John Day population contains two MaSAs, Middle Fork John Day and Long Creek; it does not contain any MiSAs. Spawning is distributed broadly throughout the population boundaries, including mainstem areas in the lower and upper Middle Fork John Day and Long Creek. There are numerous tributary spawning streams distributed from the lower end of the population boundary to the uppermost reaches.

The Middle Fork John Day River Summer Steelhead population is at moderate risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 756. During

the period 1969-1998, returns per spawner for steelhead in the Middle Fork John Day River ranged from 0.17 (1992) to 3.84 (1997). The most recent 20-year (1979-1998) geomean of returns per spawner SAR adjusted and delimited was 2.45 (Appendix B).

The current point estimate for Abundance/Productivity on the viability curve for the Middle Fork John Day River summer steelhead population is between 5% and 25% risk curves. This productivity is well above the minimum required at threshold abundance; however, abundance is below the threshold (Figure 6-6).

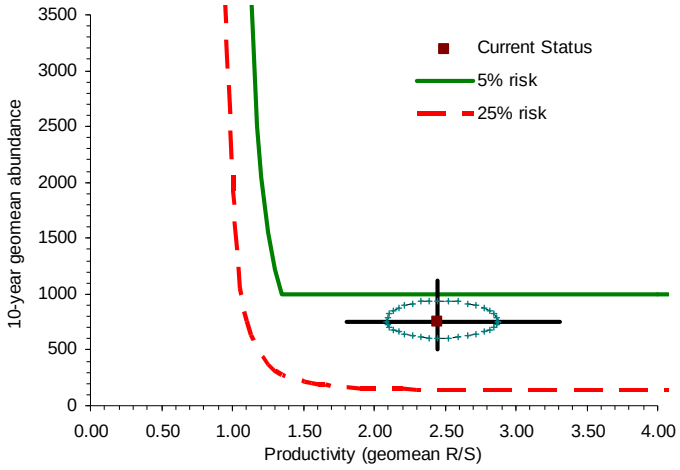

Figure 6-6. Middle Fork John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The integrated Spatial Structure/Diversity rating is low risk for the Middle Fork population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was between very low and low risk. The current spawner distribution of the Middle Fork population mimics the intrinsic distribution. The population is distributed broadly across the landscape, in both MaSAs with adequate gaps and good continuity between spawning areas. The rating for Goal B "maintaining natural levels of variation" was low risk. However, additional genetics analyses are needed to better assess genetic variation and hatchery introgression. This population was rated high risk for proportion of out-of-DPS hatchery strays based on a limited time series of composite John Day population data. Better population specific spawner composition data are needed to better understand the out-of-DPS hatchery stray influence. If there is significant hatchery introgression that affects genetic variation through time, then the risk rating will increase, thus raising the overall risk rating for Goal B and the overall rating for Spatial Structure/Diversity.

Overall Risk Rating

The Middle Fork John Day River Summer Steelhead population does not currently meet the ICTRT criteria for viable status, although it does meet the criteria for a "maintained" population because the abundance is well above the minimum of 500 natural-origin spawners for maintained status. The productivity point estimate of 2.45, as well as the lower end of the adjusted standard error, met the low risk criteria. The abundance of 756 is only 75.6% of the minimum threshold criteria of 1,000 natural-origin spawners for an intermediate size population. Increased annual abundance would allow this population to achieve a risk rating of low for abundance/productivity and raise the overall viability rating to viable.

6.7 South Fork John Day River Summer Steelhead Population

Steelhead spawn, rear, and migrate through the lower South Fork John Day River up to Izee Falls, a natural barrier at RM 28.5, and into Murderers Creek, Canyon Creek and other tributaries. The population contains three MaSAs (Upper South Fork John Day, Lower South Fork John Day and Murderers Creek) and no MiSAs.

The South Fork John Day River Steelhead population is at moderate risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 259. During the period 1961-1998, returns per spawner for steelhead in the South Fork John Day River ranged from 0.20 (1987) to 13.54 (1968). The most recent 20-year (1979-1998) geomean of returns per spawner, adjusted for marine survival and delimited, was 2.06 (Appendix B).

The current point estimate for Abundance/Productivity on the viability curve for the South Fork John Day River summer steelhead population resides between the 25% and 5% viability curves. The lower bound of the adjusted standard error for both the productivity and abundance extend below the 25% risk level (Figure 6-7).

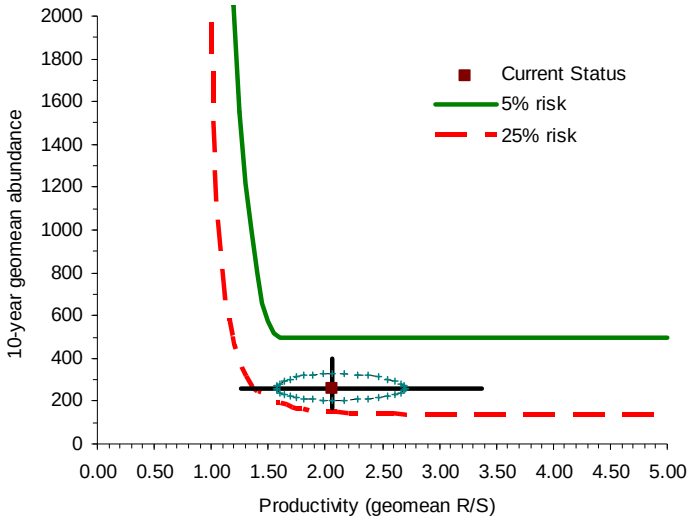

Figure 6-7. South Fork John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The integrated Spatial Structure/Diversity rating is low risk for the South Fork John Day River population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" rated midway between very low and low risk. Although the current spawner distribution mimics the intrinsic distribution, only three MaSAs exist within the population. Good continuity exists between spawning areas and gaps between areas have remained relatively unchanged. The rating for Goal B "maintaining natural levels of variation" is low risk. As is the case for all John Day steelhead populations there is uncertainty in ratings of metrics "genetic variation" and "proportion of spawners that are out-of-DPS strays." We have limited genetics data for South Fork steelhead to determine if the current population variation is similar to historical conditions and to examine the degree of hatchery fish introgression. The metric for proportion of out-of-DPS strays rated as high risk. However, the analyses relied on composite data from four John Day populations. Additional population specific spawner composition data are needed to better inform the risk rating and to reduce the associated uncertainty.

Overall Risk Rating

The South Fork John Day River steelhead population does not currently meet the ICTRT criteria for viable status. The population does meet criteria for a "maintained" population because the abundance exceeds the minimum of 250 natural-origin spawners for maintained status. The recent 10-year geomean abundance of 259 is only 52% of the minimum goal of 500 for viable status of a "basic" size population. The 20-year delimited recruit per spawner point estimate resides above the minimum value required at a 500 abundance level; however, the lower end of the adjusted standard error is below the 25% risk level. Increased productivity in combination with abundance will allow this population to achieve viable status as the Spatial Structure/Diversity criteria achieved a low risk rating. While the population received a Spatial Structure/Diversity rating of low risk, there is considerable uncertainty surrounding the spawner composition data. Enhanced monitoring of the hatchery-wild ratios on the South Fork spawning grounds will improve the hatchery fraction estimate and reduce the degree of uncertainty.

6.8 Upper Mainstem John Day River Summer Steelhead Population

The Upper Mainstem John Day River steelhead population occupies the John Day Basin above the mouth of the South Fork John Day River at Dayville. The population has five MaSAs: Upper John Day, Upper Middle Mainstem John Day, Beech, Laycock, and Canyon. It does not have any MiSAs. Spawning is distributed broadly across the population including mainstem reaches in the Upper John Day River, Canyon Creek, and Beech Creek, as well as in numerous tributaries from Dayville upstream to the headwaters.

The Upper Mainstem John Day River Summer Steelhead population is at moderate risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable, the most recent 10-year geomean number of natural-origin spawners was 524 (572 total spawners). During the period 1969-1998, returns per spawner for steelhead in the Upper Mainstem John Day River ranged from 0.19 (1992) to 5.43 (1979). The most recent 20-year (1979-1998) SAR adjusted and delimited geomean of returns per spawner was 2.14 (Appendix B).

The current point estimate for Abundance/Productivity on the viability curve for the Upper Mainstem John Day River summer steelhead population resides between the 5% and 25% risk curves (Figure 6-8).

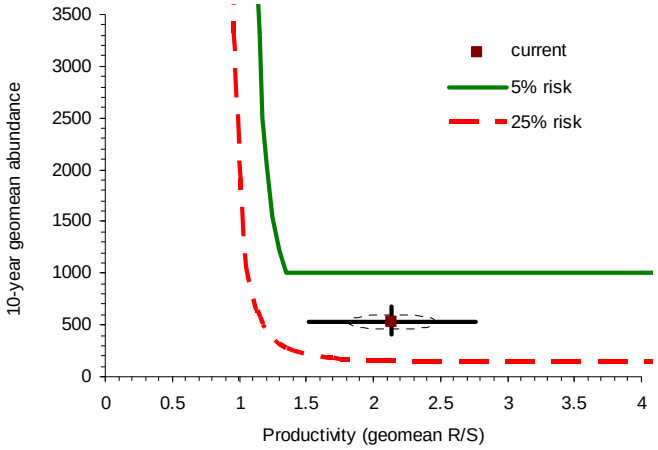

Figure 6-8. Upper Mainstem John Day River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The integrated Spatial Structure/Diversity rating is moderate risk for the Upper Mainstem John Day River population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was very low risk. A rating of "very low" was achieved because the current distribution is nearly identical to the historical distribution. The rating for Goal B "maintaining natural levels of variation" was moderate risk. This risk rating was a result of a moderate rating for changes in major life history strategies. Additional genetics information needs to be assessed to determine current genetic variation and to examine for the degree of introgression of hatchery fish. The population was rated as high risk for out-of-DPS hatchery strays based on a limited time series of composite John Day population hatchery fish observation data. Better population specific spawner composition data are needed to better determine the out-of-DPS hatchery fraction. If there is significant hatchery introgression that affects the genetic variation of this population through time, then the risk rating for Goal B will increase, and the overall risk rating for Spatial Structure/Diversity will increase.

Overall Risk Rating
The Upper Mainstem John Day River Summer Steelhead population does not currently meet the ICTRT criteria for viable status, although it does meet criteria for a "maintained" population. The 10-year geomean abundance of 524 is well below the viable goal of 1,000 natural-origin spawners for an "intermediated" size population; however, the abundance is above the 500 minimum recommended for maintained status of an intermediate size population. The productivity point estimate of 2.14 is above the minimum needed at an abundance of 1,000, and the lower end of the adjusted standard error is above the 25% risk level. An increase in abundance is needed for this population to achieve viable Abundance/Productivity criteria. In addition, the Spatial Structure/Diversity rating was moderate risk due to loss in life history diversity and high risk for spawner composition.

6.9 Umatilla River Summer Steelhead Population

The Umatilla River steelhead population includes thirteen historical MaSAs: Butter, East Birch, West Birch, McKay, Meacham, Middle Umatilla, Lower Middle Umatilla, Upper Umatilla, Lower Umatilla, Lower Birch, Alder, Glade and Wildhorse. It contains three historical MiSAs: Alkali, Fourmile Canyon, and Cottonwood (Umatilla). Two of the MaSAs (Alder Creek and Glade Creek) and one MiSA (Fourmile Canyon) that are included in the Umatilla River population are direct tributaries to the Columbia River on the Washington side of the Columbia. These areas are considered in our assessment of spatial structure/diversity for the Umatilla steelhead population, but are not considered for abundance/productivity because no abundance data are available. Current spawning distribution is somewhat limited relative to historical and is concentrated in Birch Creek, Iskuulpa Creek, Meacham Creek, Upper Umatilla River, and the North and South Forks of the Umatilla River.

The Umatilla River Summer Steelhead population is at moderate risk based on current spawner abundance and productivity. Spawner abundance in recent years has been moderately variable, the most recent 10-year geomean number of natural-origin spawners was 1,472 (2,347 total spawners). During the period 1967-2000, returns per spawner for steelhead in the Umatilla River

ranged from 0.3 (1978) to 4.98 (1998). The most recent 20-year (1981-2000) geomean of returns per spawner SAR adjusted and delimited at 75% of the threshold was 1.50 (Appendix B).

The productivity rating for the Umatilla River summer steelhead population is in the low risk zone because the current point estimate on the viability curve for the population is above 5% risk level and the adjusted standard error is above the 25% risk level. Abundance is moderate because the point estimate is slightly below the 5% risk level (Figure 6-9).

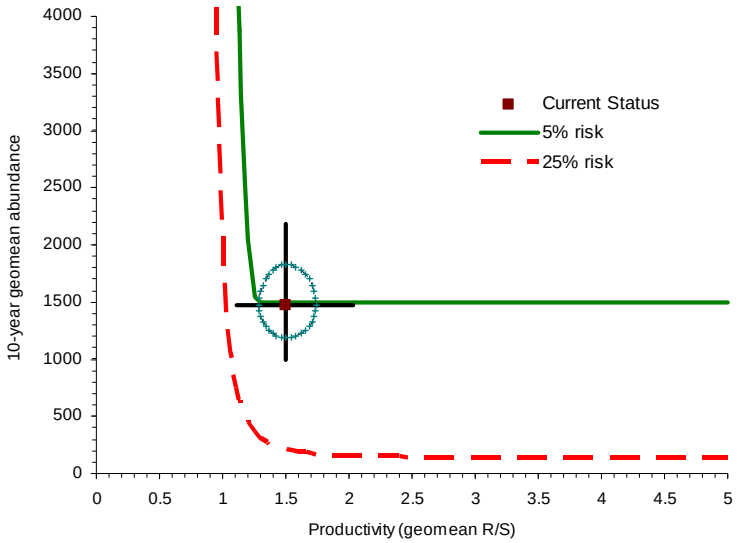

Figure 6-9. Umatilla River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The combined integrated Spatial Structure/Diversity rating is moderate risk for the Umatilla River population. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was moderate risk. There has been significant reduction in spawner distribution relative to intrinsic potential distribution. This reduction has caused significant increases in gaps between spawning areas as well as disrupted continuity. The rating for Goal B "maintaining natural levels of variation" was moderate risk. Habitat changes have been significant in the Umatilla Basin resulting in changes to flow profiles and elevated temperatures. These changes have resulted in impacts to life history diversity and phenotypic trait variation. The out-of-DPS spawners in combination with local-origin hatchery fish spawning naturally put the population at high risk for spawner composition. Hydrosystem effects and within basin habitat changes have likely resulted in selective mortality of specific components of juvenile and adult life stages resulting in a moderate risk rating.

Overall Risk Rating

The Umatilla River Summer Steelhead population does not currently meet the ICTRT criteria for viable status because Abundance/Productivity and Spatial Structure/Diversity risks ratings are both moderate risk. However, the population does meet criteria for a "maintained" population because the abundance level is well above the minimum 500 required for maintained status. The 20-year delimited recruit per spawner point estimate is 1.50 with the lower end of the adjusted standard error above the 25% risk level, thus placing the productivity at low risk. The 10-year mean abundance of 1,472 is 98.1% of the minimum threshold of 1,500. Improvement in many of the Spatial Structure/Diversity metrics and a small increase in the average abundance will raise the population to viable status.

6.10 Walla Walla River Summer Steelhead Population

The Walla Walla Basin spans the Oregon-Washington border east of the Columbia River. The main tributaries of the Walla Walla River are the North and South forks and Couse, Pine, Birch, Cottonwood and Mill creeks. The North and South forks and Couse Creek are entirely within Oregon, but the remaining tributaries span the state line. Birch and Pine creeks originate in Oregon, but their confluence with the Walla Walla River is in Washington. Cottonwood Creek flows into Yellowhawk Creek in Washington. Mill Creek originates in Washington, flows through Oregon for approximately six miles and enters the Walla Walla River in Washington, just west of the City of Walla Walla.

The Walla Walla River population is comprised of three historical MaSAs (Walla Walla, Mill and Pine) and two historical MiSAs (Dry and Switzler). Current spawning distribution is substantially reduced relative to the historical intrinsic distribution and is concentrated in the North and South forks of the Walla Walla River, Couse Creek, Mill Creek and Dry Creek (WA).

The Walla Walla Summer Steelhead population is at moderate risk based on current abundance and productivity. Spawner abundance in recent years has been moderately variable; the most recent 10-year geomean number of natural-origin spawners was 650. During the period 1993-2000, returns per spawner for steelhead in the Walla Walla River ranged from 0.39 (1993) to 2.65 (1998). The most recent 8-year (1993-2000) geomean of returns per spawner, delimited at the median and SAR adjusted was 1.34 (Appendix B).

The current point estimate for Abundance/Productivity on the viability curve for the Walla Walla River summer steelhead population falls between the 5% and 25% risk curves (Figure 6-10). This risk rating is based on a short data series, and should be viewed with caution.

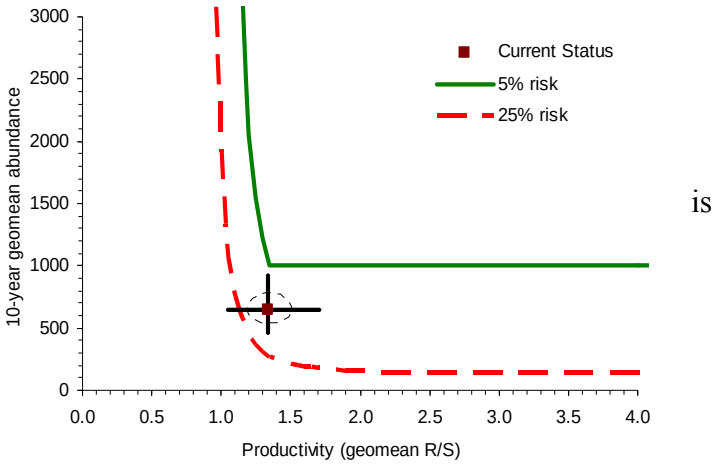

Figure 6-10. Walla Walla River Summer Steelhead population abundance and productivity compared to the viability curve for the DPS.

The integrated Spatial Structure/Diversity rating for the Walla Walla population is moderate risk. The rating for Goal A "allowing natural rates and levels of spatially mediated processes" was moderate risk. There has been significant reduction in spawner distribution that has resulted in increased gaps and loss of continuity within the population and between the Walla Walla population and other Mid-Columbia steelhead populations. The rating for Goal B "maintaining natural levels of variation" was moderate risk. Water temperature and hydrograph changes as well as barriers have likely influenced life history diversity and phenotypic expression. Out-of-

DPS spawners have put the population in the moderate risk category for the spawner composition metric. Within basin habitat changes have likely resulted in selective mortality at multiple life stages resulting in a moderate risk rating.

Overall Risk Rating
The Walla Walla Summer Steelhead population does not currently meet ICTRT criteria for viable status, although it does meet the criteria for a "maintained" population. The abundance/productivity values are at moderate risk and the time series is short resulting in considerable uncertainty. The 10-year geomean abundance of 650 is well below the minimum threshold of 1,000 for viable status. However, current abundance exceeds the 500 minimum recommended by the ICTRT for maintained status of an "intermediate" size population. We need additional brood years to demonstrate sustained recruits per spawner and abundance values above the low risk criteria level. Significant improvements to spatial structure and diversity are needed to improve the risk level.

6.11 Major Population Groups Viability Assessments

The status of each MPG is assessed based on the status of the constituent populations. Viability assessment findings for the three Mid-C steelhead MPGs that contain Oregon populations are summarized below.

Cascades Eastern Slope Tributaries MPG
To achieve viable status in the Cascades Eastern Slope Tributaries MPG, the Fifteenmile Creek, Deschutes River Eastside, Deschutes River Westside, and Klickitat populations must all achieve viable status. The Cascades Eastern Slope Tributaries MPG is below viable status because the Deschutes River Westside population did not meet viability criteria, and the Deschutes Crooked River population is extinct. (Table 6-1).

Table 6-1. Viability assessment results for Mid-C steelhead populations in the Cascades Eastern Slope Tributaries MPG.

Population	Extant/ Extinct	Abundance		Productivity		A/P Risk	Goal A Natural Processes Risk	Goal B Diversity Risk	Integrated SS/D Risk	Overall Population Viability Rating
		Mean	Lower 90% CI	Mean	Lower 90% CI					
Fifteenmile Creek	Extant	703	481	1.82	1.23	Low	Very Low	Low	Low	Viable
Deschutes River Eastside	Extant	1,599	896	1.89	1.10	Low	Low	Moderate	Moderate	Viable
Deschutes River Westside	Extant	456	306	1.05	0.76	High	Low	Moderate	Moderate	High Risk
Deschutes Crooked River	Extinct	0	NA	0	NA	Extinct	NA	NA	NA	Extinct

John Day River MPG
To achieve viable status in the John Day River MPG, the Lower Mainstem John Day River, North Fork John Day River, and either the Middle Fork John Day River or Upper Mainstem John Day River populations must achieve viable status. The John Day River MPG is below viable

status. The North Fork population is highly viable, however all of the other John Day River populations were below viable status (Table 6-2).

Table 6-2. Viability assessment results for Mid-C steelhead populations in the John Day River MPG.

Population	Extant/ Extinct	Abundance		Productivity		A/P Risk	Goal A Natural Processes Risk	Goal B Diversity Risk	Integrated SS/D Risk	Overall Population Viability Rating
		Mean	Lower 90% CI	Mean	Lower 90% CI					
Lower Mainstem John Day River	Extant	1,800	1,065	2.99	1.91	Moderate	Very Low	Moderate	Moderate	Maintained
North Fork John Day River	Extant	1,740	1,375	2.41	1.62	Very Low	Very Low	Low	Low	Highly Viable
Middle Fork John Day River	Extant	756	508	2.45	1.81	Moderate	Low	Low	Low	Maintained
South Fork John Day River	Extant	259	168	2.06	1.26	Moderate	Very Low	Low	Low	Maintained
Upper Mainstem John Day River	Extant	524	399	2.14	1.15	Moderate	Very Low	Moderate	Moderate	Maintained

Umatilla/Walla Walla Rivers MPG

To achieve viable status in the Umatilla/Walla Walla Rivers MPG, the Umatilla River population and either the Walla Walla River or Touchet River population must achieve viable status. The Umatilla/Walla Walla Rivers MPG is below viable status because neither the Umatilla River or Walla Walla River populations meet viability criteria (Table 6-3).

Table 6-3. Viability assessment results for Mid-C steelhead populations in the Umatilla/Walla Walla Rivers MPG.

Population	Extant/ Extinct	Abundance		Productivity		A/P Risk	Goal A Natural Processes Risk	Goal B Diversity Risk	Integrated SS/D Risk	Overall Population Viability Rating
		Mean	Lower 90% CI	Mean	Lower 90% CI					
Willow Creek	Extinct	0	NA	0	NA	Extinct	NA	NA	NA	Extinct
Umatilla River	Extant	1,472	988	1.50	1.11	Moderate	Moderate	Moderate	Moderate	Maintained
Walla Walla River	Extant	650	459	1.34	1.05	Moderate	Low	Moderate	Moderate	Maintained

6.12 DPS Viability Assessment

All major population groups must achieve viable status for the DPS to be considerable viable. The Mid-C steelhead DPS is below viable status because none of the MPGs currently achieve viable status.

Section 7 Viability Gaps

In the previous two sections we described viability criteria and presented results of the current status assessments. The status assessments provide a visual and narrative comparison of the current status relative to the abundance/productivity and spatial structure/diversity criteria. In this section, we present the results of ICTRT (2007a) abundance/productivity gap analysis and our spatial structure/diversity gap analyses.

7.1 Gaps Approach

This section provides a brief overview of the methods to establish a general understanding of the approach. Detailed methods for abundance/productivity gaps determination are provided in ICTRT (2007a).

The abundance/productivity gap is defined as the quantitative relative amount of change in survival or capacity that is required for a population to improve from current status to a specific viability level. The purpose of determining gaps is to inform planners and managers how much change is required to improve current status to a specific viability level. Observed gaps represent the amount of improvement needed assuming that the climate/environmental conditions and average survivals that occurred during the time period of the status assessments (generally 1980-2001) will be the same in the future. The gap analysis provides estimates of the magnitude of survival or capacity change that are needed to reach viability criteria for 25% (moderate risk), 5% (low risk) and 1% (very low risk) probability of extinction over a 100-year timeframe as defined by the viability curves. Beyond estimating observed gaps, the ICTRT used a modeling approach to evaluate the influence of alternative climate regimes and hydrosystem scenarios on observed gaps.

We only present observed gaps in this section. The influence of alternative ocean survival scenarios, hydrosystem scenarios, and other management actions on observed gaps is presented in Section 10 "Management Action Effectiveness." In addition to the gaps calculated for the current A/P status point estimate, gaps are also calculated to address the uncertainty criteria. Estimates of current abundance and productivity of a population are based on sampling data and are therefore subject to statistical uncertainty. The level of uncertainty, especially for the productivity, can have a substantial impact relative to confidence in the empirical difference between current status and specific risk levels. We incorporate an uncertainty gap into our analyses to minimize the potential of a substantial underestimate in the gap between the current A/P estimate and the specific risk levels. For Mid-C steelhead, we applied the following uncertainty criteria in our viability assessments: To achieve the 5% risk criteria (low risk), the lower end of the productivity 90% confidence interval needed to be above the 25% risk curve; and, to meet the 1% risk criteria (very low risk), the lower end of the 98% confidence interval needed to be above the 25% risk curve. We calculated gaps for both the 5% and 1% uncertainty criteria.

The ICTRT described a four-step process for determining observed abundance/productivity gaps. We summarize the steps below and encourage readers to view ICTRT (2007a) for a more extensive explanation.

1. *Estimate current intrinsic productivity and natural-origin abundance* (method previously described).

2. *Estimate adult spawner population size that achieves juvenile production capacity*. The ICTRT used population specific stock recruitment data fitted to a Hockey-Stick function to estimate current capacity. The full range of data for each population was used in the analyses. Simple cohort analyses were used to generate broodyear specific estimates of spawners. Spawner numbers were standardized to reflect average recent SARs and harvest rates to remove the substantial variation in ocean survival and harvest rates. Population specific estimates of spawners at capacity were highly variable. To address the effects of sampling variability, populations were grouped by species and the estimated capacity was regressed against the independent estimates of capacity derived from the intrinsic habitat potential analyses. The ultimate estimate of capacity was derived as the mean of the population specific stock-recruitment estimate and the corresponding regression-based estimate. This estimate is referred to as Model Capacity in the equations below.

3. *Assign populations to categories based on the point estimate position relative to the abundance/productivity variability curve*. Many of the Oregon Mid-C steelhead populations clustered together in a zone (ICTRT Zone C) where the abundance/productivity point estimates fell below the viability curve, substantially to the right (greater than) of the minimum productivity values. Those Mid-C steelhead populations that did not reside in Zone C were populations that had either abundance/productivity point estimates above the viability curve including Fifteenmile Creek, Deschutes River Eastside, and North Fork John Day River, or productivity and abundance values below the minimum criteria including the Deschutes River Westside population.

4. *Calculate the gap as the minimum distance for the current abundance/productivity point estimate (observed gap) to each viability curve and from the lower end of the 90% and 98% CI's to the 25% risk curve*. In cases where the uncertainty criteria gap was greater than the A/P point estimate gap, the uncertainty criteria gap was used. All of the Oregon Mid-C populations that did not meet A/P viability criteria, except the Deschutes River Westside population, exhibited current productivity above minimums needed at threshold abundance with recent average abundance below the threshold. The ICTRT concluded that these populations were strongly affected by density dependence.

The method for calculating gaps for populations with moderate to high productivity and relatively low abundance is detailed in ICTRT 2007a. The gaps are estimated based on estimated difference in observed abundance and estimated capacity relative to the threshold abundance level specific to the population.

The gap was calculated as:

Survival Gap = Threshold Abundance ÷ EQ capacity – 1
where EQ Capacity = Model Capacity + 10-year geomean abundance ÷ 2

The calculated gaps are expressed as the proportional increase in productivity, but can also be considered the proportional increases needed in effective capacity of the population. Because the threshold abundance levels are equal at the 5% and 1% risk levels, populations that reside in Zone C have the same point estimate gaps at these two risk levels.

Uncertainty gaps are calculated in a different way because they only address required changes in productivity. Uncertainty gaps are calculated as the relative proportional change in productivity required to move the lower end of the 90% confidence interval to the 25% risk curve for the low risk criteria, and to move the lower end of the 98% confidence interval to the 25% risk curve for the very low risk criteria.

The ICTRT has not provided specific guidance on how to define Spatial Structure/Diversity gaps; therefore we developed the following steps and criteria for identifying these gaps.

1) Identify for each population all spatial structure and diversity metrics with ratings of moderate or high risk.
2) For the metrics rated moderate, determine if the rating is a result of changed status from intrinsic conditions or if the rating is a result of an intrinsic moderate risk for the metric.
3) Characterize spatial structure and diversity gaps for each population as those metrics that are rated high risk and those metrics that are rated moderate risk because the current status is impaired relative to the intrinsic condition.

7.2 Population Specific Viability Gaps

The results of gaps analyses for Oregon Mid-C steelhead populations are discussed below and shown in Table 7-1.

7.2.1 Fifteenmile Creek Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 703 spawners exceeds the minimum threshold abundance of 500. The current productivity estimate of 1.82 recruits per spawner resides between the 5% and 1% risk curves. There is no observed gap or uncertainty gap for the 5% risk level. The observed and uncertainty gaps for the 1% risk level are 0.03 and 0.09 respectively (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was low risk. All of the Spatial Structure and Diversity metrics were rated very low or low risk, therefore there are no Spatial Structure/Diversity gaps for this population.

Table 7-1. Abundance/Productivity statistics, risk ratings, and observed and uncertainty gaps for Oregon Mid-C Steelhead populations. Observed gaps are calculated from current status point estimates. Uncertainty gaps are for achieving uncertainty criteria and are only presented when they exceed the observed gaps. Negative gaps indicate that current abundance/productivity exceeds the criteria. Gap data are from ICTRT (2007a).

	Current Status		Equilibrium	A/P Risk	SS/D Risk	Gaps				
						Observed (point estimate)			Uncertainty	
Population	Abundance	Productivity	Abundance	Rating	Rating	25%	5%	1%	5%	1%
Fifteenmile Cr.	703	1.82	632	Low	Low	-.41	-.21	.03		.09
Deschutes R. Eastside	1,599	1.89	1,501	Low	Moderate	-.46	-.34	-.20		.05
Deschutes R. Westside	456	1.05	448	High	Moderate	.14	.78	.92		
Lower Mainstem John Day R.	1,800	2.99	2,019	Moderate	Moderate	.00	.11	.11		
North Fork John Day R.	1,740	2.41	1,689	Very Low	Low	-.58	-.49	-.38		
Middle Fork John Day R.	756	2.45	928	Moderate	Low	.00	.08	.08		
South Fork John Day R.	259	2.00	409	Moderate	Low	-.02	.22	.22		.23
Upper Mainstem John Day R.	524	2.14	730	Moderate	Moderate	-.02	.37	.37		
Umatilla River	1,472	1.50	1,371	Moderate	Moderate	-.32	.09	.09		
Walla Walla River	650	1.34	625	Moderate	Moderate	-.08	.34	.45		

7.2.2 Deschutes River Eastside Population Gaps

Abundance/Productivity

The recent 10-year geomean natural-origin abundance of 1,599 spawners substantially exceeds the minimum threshold abundance of 1,000. The current productivity estimate of 1.89 resides in the very low risk zone and, thus, there are no observed abundance/productivity gaps. The lower end of the productivity 98% confidence interval is below the 25% risk curve resulting in a 0.05 gap to meet uncertainty criteria for 1% risk level. The abundance/productivity dataset is a relatively short time series which results in a larger 90% CI than is typical of most other Oregon Mid-C populations. Additional brood years will likely decrease the uncertainty around the productivity point estimate (Table 7-1).

Spatial Structure/Diversity

The overall Spatial Structure/Diversity rating was moderate risk. Spatial structure/diversity gaps were identified for the following metrics:

Phenotypic variation

Metric rated moderate risk due to likely reduction in juvenile and adult migration patterns resulting from flow and temperature changes in tributary production areas.

Spawner composition

Out-of-DPS spawners. Metric rated high risk due to the high proportion of Snake River strays spawning naturally in the population.

Out-of-population spawners within the MPG. Metric rated moderate risk due to the proportion of Round Butte Hatchery fish spawning naturally in the population.

7.2.3 Deschutes River Westside Population Gaps

Abundance/Productivity

The recent 10-year geomean natural-origin abundance of 456 spawners is well below the abundance threshold of 1,000, the threshold abundance for currently available habitat. The current productivity estimate of 1.05 recruits per spawner is well below the minimum of 1.35 required at the threshold abundance. The observed gaps, that are greater than uncertainty gaps, for the 5% and 1% risk levels are 0.78 and 0.92 respectively. This gap is by far the largest observed gap of all the Oregon Mid-C populations. The large gap results from the substantial difference in the equilibrium abundance (448) and the threshold abundance, as well as the low productivity (Table 7-1).

Spatial Structure/Diversity

The overall Spatial Structure/Diversity rating was moderate risk. Spatial Structure/Diversity gaps were identified for the following metrics:

Spatial extent or range of population

Metric rated moderate risk because spawner distribution is substantially reduced from historical due to blocked access to Whychus Creek and the Metolius River.

Increase or decrease in gaps or continuity

Metric rated moderate risk due to loss of occupancy in areas above Pelton-Round Butte Complex.

Genetic variation

Metric rated moderate risk because there are limited genetics data available and the samples that have been analyzed show similarity to out-of-DPS hatchery strays.

Spawner composition

Out-of-DPS spawners. Metric rated high risk because out-of-DPS strays have comprised a significant proportion of the natural spawners in this population for many generations.

7.2.4 Lower Mainstem John Day River Population Gaps

Abundance/Productivity

The recent 10-year geomean natural-origin abundance of 1,800 spawners is 72% of the threshold abundance of 2,250. The current productivity of 2.99 recruits per spawner is well above the minimum required at threshold abundance to meet the 1% risk level. The lower end of the 98%

CI also resides above the minimum needed to meet the 1% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.11. This gap is a result of the difference in the equilibrium abundance (2,019) and the threshold abundance (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was moderate risk. Gaps were identified for the following Spatial Structure/Diversity metrics:

Major life history strategies
Metric rated moderate risk because habitat changes have resulted in reduced juvenile life history diversity and restricted summer rearing distribution.

Genetic variation
Metric rated moderate risk because there are no genetics data and due to potential genetic effects of the high proportion of out-of-DPS spawners.

Spawner composition
Out-of-DPS spawners. Metric rated high risk due to high proportion and increasing trend of out-of-DPS spawners.

7.2.5 North Fork John Day River Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 1,740 spawners exceeds the threshold abundance of 1,500. The current productivity of 2.41 recruits per spawner is well above the value needed to meet the 1% risk level. The lower end of the 90% CI resides above the 1% risk level. There are no abundance/productivity gaps for the 5% or 1% risk levels (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was low risk. All metrics were rated very low or low risk, except for the following:

Spawner composition
Out-of-DPS spawners. Metric rated high risk due to the high estimated proportion of Snake River hatchery strays within this population. In addition, there is considerable uncertainty regarding the hatchery fraction estimates for this population.

7.2.6 Middle Fork John Day River Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 756 spawners is 75.6% of the threshold abundance of 1,000. The current productivity of 2.45 recruits per spawner is above the minimum needed at threshold abundance. The lower end of the 90% CI is well above the 25% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.08. This gap is a result of the difference in equilibrium abundance (928) and threshold abundance (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was low risk. All metrics were rated very low or low risk, except for the following:

Spawner composition
Out-of-DPS spawners. Metric rated high risk due to the high estimated proportion of out-of-DPS strays within this population.

7.2.7 South Fork John Day River Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 259 spawners is 51.8% of the threshold abundance of 500. The current productivity of 2.00 recruits per spawner is greater than the minimum required at the abundance threshold. The lower end of the 90% CI extends well below the 25% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.22. Uncertainty gap for the 1% risk level is 0.23. The gaps are primarily a result of the difference between the equilibrium abundance (409) and the threshold abundance (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was low risk. All metrics were rated very low or low risk, except the following:

Spawner composition
Out-of-DPS spawners. Metric rated high risk due to the high estimated proportion of out-of-DPS strays within this population.

7.2.8 Upper Mainstem John Day River Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 524 spawners is only 52.4% of the threshold abundance of 1,000. The current productivity of 2.14 recruits per spawner is well above the minimum required at the threshold abundance. The lower end of the 90% CI resides above the 25% risk level. The observed abundance/productivity gap to reach the 5% and 1% risk levels is 0.37. The uncertainty gaps are less than the observed gaps. The gap is primarily a result of the difference in the equilibrium abundance (730) and threshold abundance (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was moderate risk. Gaps were identified for the following Spatial Structure/Diversity metrics:

Major life history strategies
Metric rated moderate risk due to reduced opportunities for juvenile movement patterns and reduced summer rearing distribution that has resulted from altered mainstem and tributary habitats.

Spawner composition
Out-of-DPS spawners. Metric rated high risk due to the high proportion of out-of-DPS strays and uncertainty in the estimates of hatchery fraction.

7.2.9 Umatilla River Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 1,472 spawners is 98.1% of the threshold abundance of 1,500. The current productivity of 1.50 recruits per spawner is above the minimum of 1.26 required at the threshold abundance. The lower end of the 90% CI resides slightly above the 25% risk level. The observed abundance/productivity gap for the 5% and 1% risk levels is 0.09. The uncertainty gaps are less than the observed gaps (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was moderate risk. Gaps were identified for the following Spatial Structure/Diversity metrics:

Spatial extent or range of population
Metric rated moderate risk because the current spawner distribution is substantially reduced from the historical distribution. Loss of spawning in the Butter Creek and McKay Creek watersheds has resulted in the reduced distribution. There is considerable uncertainty regarding occupancy of the Alder and Glade MaSAs.

Increase or decrease in gaps and continuity
Metric rated moderate risk because of increased gaps and changed continuity resulting from losses of occupancy in the Butter Creek and McKay Creek watersheds.

Major life history strategies
Metric rated moderate risk as a result of reduced opportunity for life history expression for juvenile and adult life stages. This reduced opportunity has resulted from significant habitat changes in the Umatilla Basin.

Phenotypic variation
Metric rated moderate risk due to effects of flow and temperature on adult and juvenile migration characteristics.

Spawner composition
Overall rating is high risk due to two moderate ratings for the component metrics.

Out-of-DPS spawners. Metric rated moderate risk due to the estimated level of strays observed at Three-mile Falls Dam over the last three generations.

Within-population spawners. Metric rated moderate risk due to the proportion and duration of Umatilla Hatchery fish spawning in the basin.

Selective change in Natural Processes-Habitat
Metric rated moderate risk due to the selective effects of tributary temperature and flow changes on juvenile and adult migration characteristics and the effect of mainstem Columbia River temperature and flow on adult migration, survival, and straying.

7.2.10 Walla Walla River Population Gaps

Abundance/Productivity
The recent 10-year geomean natural-origin abundance of 650 spawners is well below the threshold abundance of 1,000. The current productivity of 1.34 recruits per spawner is slightly less than the minimum of 1.35 required at the threshold abundance. The lower end of the 90% CI extends well below the 25% risk level. The observed gaps for abundance/productivity at the 5% and 1% risk levels were 0.34 and 0.45 respectively. The uncertainty gaps at the 5% and 1% risk levels were less than the observed gaps. These gaps should be viewed cautiously because there is only a short data series available to estimate productivity (Table 7-1).

Spatial Structure/Diversity
The overall Spatial Structure/Diversity rating was moderate risk. Gaps were identified for the following Spatial Structure/Diversity metrics:

Spatial extent or range of population
Metric rated moderate risk because the current distribution is substantially reduced from the historical distribution. Loss of spawning in the Pine Creek MaSA and Switzler MiSA has resulted in reduced distribution.

Increase or decrease in gaps and continuity
Metric rated moderate risk because of increased gaps and changed continuity resulting from loss of occupancy in the Pine Creek MaSA.

Major life history strategies
Metric rated moderate risk due to changes in juvenile and adult movement patterns as well as reduced juvenile rearing distribution relative to historical opportunities. The reduced life history strategies have resulted from significant flow and temperature changes within the basin.

Phenotypic variation
Metric rated moderate risk due to effect of flow and temperature changes on phenotypic variation. Adult and juvenile migration patterns have been significantly altered due to these habitat changes.

Spawner composition
Out-of-DPS spawners. Metric rated moderate risk due to the proportion and duration of out-of-DPS spawners in the population.

Selective change in Natural Processes-Habitat

Metric rated moderate risk due primarily to tributary flow and temperature effects on juvenile and adult migration and movement patterns and the effect of mainstem Columbia River temperature and flow effects on adult migration, survival, and straying.

Section 8 Limiting Factors and Threats

This section describes limiting factors and threats to the viability of Mid-C steelhead in Oregon. The limiting factors and threats analyses serve as an essential foundation for the development and prioritization of management actions across the entire lifecycle. Findings were identified based on many sources of information, including the Mid-C steelhead Expert Panel's report, subbasin plans, ODEQ reports, ICTRT reports, NOAA's limiting factors modules, ODFW reports, hydrosystem biological opinion remand documents, and numerous other sources.

Section 8.1 provides a broad level perspective of the primary limiting factors and threats across and within Oregon's Mid-C steelhead populations. This broader look is followed by more detailed, in-depth discussions of limiting factors and threats in Section 8.2 (Tributary Habitat), 8.3 (Hydrosystem), 8.4 (Estuarine and Plume Habitat), 8.5 (Harvest), 8.6 (Hatchery), 8.7 (Predation and Competition) and 8.8 (Climate Change).

8.1 Primary Limiting Factors and Threats Across and Within Populations

This section describes the primary factors and threats constraining the viability of Oregon's Mid-C steelhead populations throughout their life cycles. It summarizes the findings of the Mid-C Expert Panel, the Mid-C recovery planning team, other groups and published information regarding the significance of these various factors and threats both across and within the populations. We used the following definitions of limiting factors and threats for our assessment:

> **Limiting factors:** The physical, biological, or chemical conditions of the environment and associated ecological processes and interactions (e.g., habitat connectivity, water quality, physical habitat quality, etc.) that influence Mid-C steelhead viable salmonid population parameters, including abundance, productivity, spatial structure, and diversity.
>
> **Threats:** Human actions (e.g., fishing, operation of hatcheries, operation of hydrosystem, land use practices, etc.) or natural events (e.g., flood, drought, volcano, etc.) that cause or contribute to limiting factors. Threats may influence one or multiple life stages and may occur in the present or future or have occurred in the past.

The Mid-C Expert Panel, created by ODFW for this purpose, consisted of 12 biologists with significant knowledge of the limiting factors and threats influencing steelhead production in the Mid-C steelhead DPS. Panelists examined limiting factors and threats for the ten independent steelhead populations, and then identified common key and secondary threat themes for all of the populations. They used a systematic process, similar to a Delphi process, during their deliberations. The Panel's approach in their deliberations and findings are discussed in the report Limiting Factors and Threats to the Recovery of Steelhead in the Oregon Portion of the Mid-Columbia Distinct Population Segment: Results of Expert Panel Deliberations (Mid-C Expert Panel 2006).

8.1.1 Primary Limiting Factors and Threats across Populations

Several factors and threats play a critical role in restricting viability across Oregon's Mid-C steelhead populations.

Land Use
We acknowledge that land use practices have improved significantly over the past few decades. In the tributary watersheds land managers, local land owners, and others have improved habitat management in an effort to enhance watershed conditions to support steelhead recovery. Actions to improve watershed conditions from the uplands to the floodplain are allowing, in some cases, natural ecosystem functions to recover. Although many steps have been taken, there are many more needed to achieve recovery goals. Tributary habitat degradation from past and/or present land use remains a key concern for all of the populations. Steelhead have been adversely affected by modified and reduced streamflows, impaired water quality due to elevated water temperatures and agricultural chemicals, impaired upstream and downstream fish passage, degraded channel structure and complexity (including riffles, pools and large woody debris), loss of riparian vegetation, reduced floodplain connectivity, and excessive levels of fine sediments caused by altered sediment routing. Threats contributing to these factors include agricultural, forestry and grazing practices that negatively impact steelhead growth and survival, dams and other barriers, water withdrawals, roads and channel manipulations.

The Mid-C Expert Panel identified land use as having the most key concerns of any of the threat categories. Depending on the population, the Panel listed the following as either key or secondary concerns attributable to land use: 1) impaired upstream and downstream movement of juvenile and adult steelhead; 3) impaired physical habitat quality; 4) impaired water quality due to elevated water temperatures and agricultural chemicals; 5) reduced water quantity and/or modified hydrologic processes. Listed as secondary concerns for all populations were the impacts of fine sediment on steelhead eggs and alevins, and the impact of predation by birds on pre-smolts and smolts in the estuary as a result of habitat alterations resulting from the creation of dredge spoil islands. Panelists noted that current land use practices are considerably improved over historical practices.

Hatcheries
Out-of-DPS hatchery strays pose significant risk to several of Oregon's Mid-C steelhead populations, particularly to the Eastside and Westside Deschutes and John Day populations. Viability assessments, summarized in Section 6 of this document and presented in Appendix B, identified that a significant proportion of spawners in the Deschutes River and John Day River populations were out-of-DPS strays. In addition, these populations were rated at high risk for spawner composition due to the abundance of strays. Biologists remain especially concerned regarding the continuing detrimental impact of stray out-of-DPS hatchery fish in natural spawning areas on the genetic traits and productivity of these natural populations. Hatchery programs operated within the Mid-C steelhead DPS — including the Umatilla, Walla Walla and Westside Deschutes subbasins — also create some risks. The Mid-C Expert Panel ranked the impact of hatchery strays as a key concern to the Eastside and Westside Deschutes and Lower John Day populations, and as a secondary concern to the Umatilla and Walla Walla populations.

Hydrosystem
The mainstem Columbia River hydrosystem is considered a primary threat to the viability of Oregon's Mid-C steelhead populations. Specific viability concerns identified by the Mid-C Expert Panel related primarily to effects of delayed upstream passage (adults), direct and indirect mortality on downstream migrants (juveniles), alteration of the hydrograph (mainstem and estuary flow regime), depletion of historically available nutrients, and degraded rearing and food resources for both presmolts and smolts in the Columbia.

Results of the BiOp Framework Work Group support this conclusion. This work group was created by NMFS to provide scientific expertise during development of its Biological Opinion (BiOp) evaluating effects of operations of the FCRPS. One work group task was to estimate the relative magnitude of human-caused mortality factors influencing Interior Columbia River salmon and steelhead populations, including Mid-C steelhead. During this evaluation, the work group found that the FCRPS hydrosystem had the greatest relative impact on the Mid-C steelhead populations compared with other human-induced mortality effects (Step 4 Report 2006) (Table 8-1). The ICTRT reached a similar conclusion in September 2006, when members rated the mainstem Columbia River hydrosystem as a major limiting factor for all populations in the DPS. Oregon's recovery planning team also determined that the mainstem hydropower system represents a primary threat to the viability of Oregon Mid-C steelhead populations. The Expert Panel's findings were generally consistent with the BiOp Framework Work Group's findings on magnitude of human-induced mortality, however, the Expert Panel considered the mainstem Columbia hydrosystem a threat of moderate concern to the populations and generally considered legacy and current land use as a greater threat than the hydrosystem.

Impacts from the mainstem Columbia River hydrosystem increase somewhat for each of the populations in direct relation to the number of dams the fish must pass during their migration to and from the Pacific Ocean. Oregon's Mid-C steelhead populations pass from one to four Columbia River dams: the Fifteenmile Creek population passes one dam; Deschutes River populations pass two dams; John Day River and Umatilla River populations pass three dams; and the Walla Walla River population passes four dams.

Several hydroelectric dams on Columbia River tributaries also pose significant threats to the viability of specific populations. The Expert Panel listed the impact of the Pelton-Round Butte Complex as a key concern for Westside Deschutes and Crooked River populations

Harvest
Given current management regulations for mainstem Columbia River and tributary fisheries, harvest is not considered a primary or secondary threat due to the low impact on viability. The ICTRT identified harvest-related effects as a secondary level limiting factor and the Mid-C Expert panel did not identify harvest as either a key or secondary concern for Oregon's Mid-C steelhead populations. The panel, however, did express concerns over the impact that mortality associated with catch and release fisheries have on Westside and Eastside Deschutes populations.

Predation
Predation by non-native piscivorous fish on pre-smolts and smolts in the mainstem Columbia was listed by the Expert panel as a secondary concern for all Mid-C steelhead populations.

Predation is a primary concern for juvenile and adult steelhead in the Columbia River estuary and plume. Estuary habitat modifications have increased the number and/or predation effectiveness of Caspian terns, cormorants, and gull species (Fresh et al. 2005). The increasing abundance of native pinnipeds has resulted in increased predation on adult salmonids to a point of concern.

Table 8-1. Ranges of proportional reduction in survival for human-induced mortality factors that influence Oregon's Mid-Columbia River steelhead. Negative values are truncated to zero (Step 4 Report 2006).

Location Population	FCRPS Hydro (juvenile)	FCRPS Hydro Latent	FCRPS Hydro (adult)	Tribal In-River Harvest	Non-Tribal In-River Harvest	Indirect and Additional Harvest	Tributary Habitat	Tributary Habitat Delayed	Hatchery	Estuary	Avian Estuary Predation (smolts)	Pinniped Predation (adult)

8.1.2 Primary Limiting Factors and Threats Within Populations

During the recovery planning process, the recovery planning team and the Mid-C Expert Panel conducted separate evaluations of limiting factors and threats for the ten independent steelhead populations throughout their life cycles, and then identified the primary, or key and secondary, constraints limiting population viability. The limiting factors and threats assessment in this plan reflects information gained from many sources including subbasin plans, water quality reports, ICTRT assessments, NOAA limiting factors modules and ODFW reports. The results from the two evaluations, which are generally similar, are summarized below.

Fifteenmile Creek Winter Steelhead Population
The Mid-C recovery planning team identified the following limiting factors and threats to the Fifteenmile Creek steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat*: low flows, high water temperatures, degraded riparian condition, sediment routing, degraded floodplain, degraded channel structure (channel confinement and overall habitat diversity); *Hydro:* mainstem passage.
>
> **Primary Threats:** Current land use practices (including roads, residential development, agricultural practices and forest practices) and the Columbia River mainstem hydropower system.
>
> **Primary Life Stages Affected:** Fry, summer parr, winter parr, smolts.
>
> **VSP Characteristics Impacted:** Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current land use practices are the primary threat to the viability of the Fifteenmile Creek steelhead population (Table 8-2).

Table 8-2. Key and secondary threats to viability of the Fifteenmile Creek steelhead population (Mid-C Expert Panel 2006).

Fifteenmile Creek
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected:* Impaired physical habitat quality; elevated water temperatures; agricultural chemicals in tributaries; reduced water quantity and/or modified hydrograph. • *Life stage(s) primarily affected:* fry, summer parr and winter parr. • *Specific threat(s):* Current land use practices (agriculture, and forest practices, road maintenance) that negatively impact steelhead growth and survival in tributary streams. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: Direct mortality of pre-smolts and smolts at dams; delayed upstream migration of returning adults over dams; cumulative impact of system on mainstem and estuary habitat for pre-smolts and smolts. **Land Use Practices:** Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary because of creation of dredge spoil islands; increased fine sediment from past and present agricultural and forestry practices reduces survival of eggs and alevins in tributary streams. **Introduced Species:** Predation by non-native piscivorous fish on pre-smolts and smolts in mainstem Columbia.

Deschutes River Eastside Summer Steelhead Population
The Mid-C recovery planning team identified the following limiting factors and threats to the Deschutes River Eastside steelhead population:

> **Primary Limiting Factors**: *Tributary Habitat*: degraded riparian condition, low flows, high water temperatures, degraded channel structure/complexity and floodplain connectivity, impaired fish passage; *Hatchery*: effects of naturally spawning stray hatchery fish on viability; *Hydro*: mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high proportions of stray hatchery fish in natural spawning areas; current land use practices (grazing, roads, residences, forestry and agricultural practices that simplify habitats and irrigation withdrawals); the Columbia River mainstem hydropower system.
>
> **Primary Life Stages Affected:** Spawners, fry, summer parr, winter parr, smolts.
>
> **VSP Characteristics Impacted:** Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current hatchery and land use practices are the primary threats to the viability of the Deschutes River Eastside steelhead population (Table 8-3).

Table 8-3. Key and secondary threats to viability of the Deschutes River Eastside steelhead population (Mid-C Expert Panel 2006).

Deschutes – Eastside Tributaries
Key Threats
Current Hatchery Practices • *Limiting factor(s) primarily affected:* Straying of hatchery steelhead into spawning grounds. • *Life stage(s) primarily affected:* Spawners. • *Specific threat(s):* Management designed to produce returns of hatchery summer steelhead to the Deschutes and many other upstream Columbia River tributaries results in significant proportions of stray hatchery steelhead spawning naturally in this population. The principal concern relates to a continuing detrimental impact of stray hatchery fish in natural spawning areas on the genetic traits and productivity of naturally produced steelhead. **Current Land Use Practices** • *Limiting factor(s) primarily affected:* Reduced water quantity and/or modified hydrograph; impaired physical habitat quality; elevated water temperatures. • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Current land use practices (agriculture, grazing, forest practices, road maintenance, etc.) that impact steelhead growth and survival, or modify natural hydrographs during critical periods in tributary streams. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: (See discussion for Fifteenmile Creek population.) **Land Use Practices:** (See discussion for Fifteenmile Creek population.) **Harvest:** Mortality of returning adults in tributary streams from catch and release fishery. **Introduced Species***:* (See discussion for Fifteenmile Creek population.)

Deschutes River Westside Summer Steelhead Population
The Mid-C recovery planning team identified the following limiting factors and threats to the Deschutes River Westside steelhead population:

Primary Limiting Factors: *Tributary Habitat:* degraded channel structure and complexity, altered sediment routing, high water temperature, low flows and lack of fish passage over PRBC; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage and tributary passage to blocked areas above Pelton-Round Butte Complex.

Primary Threats: Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices (grazing, roads, residences, forestry and agricultural practices that simplify habitats and irrigation withdrawals); the Columbia River mainstem hydropower system.

Primary Life Stages Affected: Spawners, fry, summer parr, winter parr, smolts.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current hatchery practices, hydropower influences, and land use practices are the primary threats to the viability of the Deschutes River Westside steelhead population (Table 8-4).

Table 8-4. Key and secondary threats to viability of the Deschutes River Westside steelhead population (Mid-C Expert Panel 2006).

Deschutes – Westside Tributaries
Key Threats
Current Hatchery Practices • *Limiting factor(s) primarily affected:* Stray hatchery steelhead spawn with wild population. • *Life stage(s) primarily affected:* Spawners. • *Specific threat(s):* Management designed to produce returns of hatchery summer steelhead to the Deschutes and many other upstream Columbia River tributaries results in significant proportions of stray hatchery steelhead spawning naturally in this population. Straying of these hatchery fish into natural spawning areas threatens the genetic traits and productivity of naturally produced steelhead. **Current Hydropower:** • *Limiting factor(s) primarily affected:* Impaired downstream migration through Lake Billy Chinook; blocked migration above Pelton Dam. • *Life stage(s) primarily affected:* Smolts and returning adults. • *Specific threat(s):* Fish passage currently blocked at Pelton Dam on the Deschutes, eliminating access by steelhead to a significant portion of the historical distribution of this population. **Current Land Use Practices** • *Limiting factor(s) primarily affected:* Impaired physical habitat quality. • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Current land use practices (agriculture, grazing, forestry, road maintenance) that negatively impact steelhead growth and survival in tributary streams. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: (See discussion for Fifteenmile Creek population.) **Land Use Practices***:* Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary because of creation of dredge spoil islands; elevated water temperatures and increased fine sediment from past and present agricultural and forestry practices reduce survival of eggs and alevins in tributary streams; reduced water quantity and/or modified hydrograph impacts growth and survival of fry and summer parr in tributaries. **Harvest***:* Mortality of returning adults in tributary streams from catch and release fishery. **Introduced Species***:* (See discussion for Fifteenmile Creek population.)

Crooked River Summer Steelhead Population

Members of the Mid-C recovery planning team identified the following limiting factors and threats to the Crooked River steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat*: degraded channel structure and complexity, floodplain connectivity, degraded riparian condition, altered sediment routing, high water temperatures, low flows, and passage barriers. *Hydro*: mainstem Columbia river passage and passage in the Deschutes River mainstem to blocked areas above Pelton-Round Butte Complex.
>
> **Primary Threats:** Current land use practices (including grazing, roads, residential development, forestry and agricultural practices that simplify habitats and irrigation withdrawals); the Pelton-Round Butte Complex and the Columbia River mainstem hydropower system; passage barriers that block access to tributary spawning and rearing habitat.
>
> **Primary Life Stages Affected:** Spawners, fry, summer parr, winter parr, smolts and adult migrants.
>
> **VSP Characteristics Impacted:** Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current land use practices and the Pelton-Round Butte Complex are primary threats to viability of the Crooked River steelhead population (Table 8-5).

Table 8-5. Key and secondary threats to viability of the extinct Deschutes Crooked River steelhead population (Mid-C Expert Panel 2006).

Deschutes – Crooked River (Extinct population)
Key Threats
Current Hydropower • *Limiting factor(s) primarily affected:* Impaired downstream migration; blocked upstream migration, hydrograph, water quantity. • *Life stage(s) primarily affected:* smolts and returning adults. • *Specific threat(s):* Fish passage is currently blocked at Pelton Dam on the mainstem Deschutes, thereby entirely eliminating access by steelhead to the historic distribution of this population. **Current Land Use Practices/Irrigation System** • *Limiting factor(s) primarily affected*: Fish migration; impaired physical habitat quality; elevated water temperatures; reduced water quantity and/or modified hydrograph, population traits. • *Life stage(s) primarily affected:* fry, summer parr, winter parr, adults. • *Specific threat(s):* Current land use practices (agriculture, grazing, forestry, road maintenance, etc.) that impact steelhead growth and survival in tributaries; irrigation diversions. These conditions would impair the likelihood of re-establishing a self-sustaining population of steelhead in the future. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historic practices. Maintenance of an irrigation water storage system in the Crooked River alters the seasonal hydrograph (lower summer flows, higher autumn flows) and increases summer water temperatures. These conditions would impair the likelihood of re-establishing a self-sustaining population of steelhead in the future.
Secondary Threats
Current Mainstem Columbia Hydropower System: Direct mortality of pre-smolts and smolts at The Dalles and Bonneville dams; delayed upstream migration of returning adults over dams; cumulative impact of system on mainstem and estuary habitat for pre-smolts and smolts. **Land Use Practices***:* Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary because of creation of dredge spoil islands; increased fine sediment from past and present agricultural and forestry practices reduce survival of eggs and alevins in tributary streams. **Introduced Species:** Predation by non-native piscivorous fish on pre-smolts and smolts in mainstem Columbia.

Lower Mainstem John Day River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the Lower Mainstem John Day River steelhead population:

Primary Limiting Factors: *Tributary Habitat*: degraded channel structure and complexity (habitat quantity and diversity), altered sediment routing, water temperature, and altered hydrology. Impaired fish passage is also a high priority limiting factor in Bridge, Butte, Kahler, Muddy, Rock, and Thirtymile creeks; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.

Primary Threats: Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices (agricultural and grazing practices, removal of overstory trees and bank vegetation from the riparian corridor, water withdrawals, wetland draining and conversion, and stream channelization and diking; the Columbia River mainstem hydropower system.

Primary Life Stages Affected: Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, smolts.

VSP Characteristics Impacted: Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current hatchery and land use practices are the primary threats to viability of the Lower Mainstem John Day River steelhead population (Table 8-6).

Table 8-6. Key and secondary threats to viability of the Lower Mainstem John Day River steelhead population (Mid-C Expert Panel 2006).

John Day River – Lower Mainstem
Key Threats
Current Hatchery Practices • *Limiting factor(s) primarily affected:* Straying of hatchery steelhead into tributaries. • *Life stage(s) primarily affected:* Spawners. • *Specific threat(s):* Management designed to produce returns of hatchery summer steelhead to upstream Columbia River tributaries results in significant proportions of stray hatchery steelhead spawning naturally in this population. Straying of hatchery fish into natural spawning areas poses risks to the genetic traits and productivity of naturally produced steelhead. **Current Land Use Practices** • *Limiting factor(s) primarily affected:* Impaired physical habitat quality; elevated water temperatures. • *Life stage(s) primarily affected:* Fry, summer parr and winter parr. • *Specific threat(s):* Past and/or current land use practices (agriculture, grazing, forest practices) that impart steelhead growth and survival in tributaries. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: Direct mortality of pre-smolts and smolts at John Day, The Dalles and Bonneville dams; delayed upstream migration of returning adults over dams; false attraction of returning adults over Mc Nary Dam; cumulative impact of system on mainstem and estuary habitat for pre-smolts and smolts. **Land Use Practices**: Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary from creation of dredge spoil islands; increased fine sediment from agricultural and forestry practices reduces egg and alevin survival tributaries; reduced water quantity and/or modified hydrograph that impact growth and survival of fry and summer parr in tributaries. **Introduced Species**: Predation by non-native piscivorous fish on pre-smolts and smolts in mainstem Columbia.

North Fork John Day River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the North Fork John Day River steelhead population:

> **Primary Limiting Factors**: *Tributary Habitat*: degraded floodplain connectivity and function, degraded channel structure and complexity (key habitat quantity, habitat diversity, channel stability), altered sediment routing, water temperature, and low flows; *Hatchery*: effects of naturally spawning stray hatchery fish on viability; *Hydro*: mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices (riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, irrigation withdrawals, mining and dredging); the Columbia River mainstem hydropower system.
>
> **Primary Life Stages Affected:** Parr-to-smolt survival, egg-to-fry survival, smolts.
>
> **VSP Characteristics Impacted:** Abundance, productivity, diversity.

The Mid-C Expert Panel (2006) concluded that current land use practices are the primary threat to viability of the North Fork John Day River steelhead population (Table 8-7).

Table 8-7. Key and secondary threats to viability of the North Fork John Day River steelhead population (Mid-C Expert Panel 2006).

John Day River – North Fork
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected*: Impaired physical habitat quality; elevated water temperatures. • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Past and current land use practices (agriculture, grazing, forestry, road maintenance) that impact steelhead growth and survival in tributary streams. Improvement of some habitat conditions is expected in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: (See discussion for Lower Mainstem John Day population.) **Land Use Practices**: (See discussion for Lower Mainstem John Day population.) **Introduced Species**: (See discussion for Lower Mainstem John Day population.)

Middle Fork John Day River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the Middle Fork John Day River steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat:* degraded channel structure and complexity (habitat quantity and diversity), degraded floodplain function and connectivity, altered sediment routing, altered hydrology, and water temperature; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices (riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, passage barriers, irrigation withdrawals, mining and dredging); the Columbia River mainstem hydropower system.
>
> **Primary Life Stages Affected:** fry-to-smolt, egg incubation; egg-to-parr, smolts, adult spawning.
>
> **VSP Characteristics Impacted:** Abundance, productivity, diversity.

The Mid-C Expert Panel (2006) concluded that current land use practices are the primary threat to viability of the Middle Fork John Day River steelhead population (Table 8-8).

Table 8-8. Key and secondary threats to viability of the Middle Fork John Day River steelhead population (Mid-C Expert Panel 2006).

John Day River – Middle Fork
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected*: Impaired physical habitat quality; elevated water temperatures • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Past and current practices (grazing, forest practices, road maintenance) that impact steelhead growth and survival in tributaries. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: (See discussion for Lower Mainstem John Day population.) **Land Use Practices**: (Factors identified in discussion for Lower Mainstem John Day population, plus push-up dams that impair upstream passage of returning adults and upstream and downstream movement of fry and summer parr.) **Introduced Species**: (See discussion for Lower Mainstem John Day population.)

South Fork John Day River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the South Fork John Day River steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat*: altered sediment routing, degraded channel structure and complexity (habitat quantity and diversity), altered hydrology and low flow, water temperature, and impaired fish passage; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices (riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, fish passage barriers (culverts, and other seasonal barriers), and irrigation withdrawals); the Columbia River mainstem hydropower system.
>
> **Primary Life Stages Affected:** Juvenile rearing, adult spawning, egg incubation, egg-to-parr survival, smolts.
>
> **VSP Characteristics Impacted:** Abundance, productivity, diversity.

The Mid-C Expert Panel (2006) determined that current land use practices pose the primary threat to viability of the South Fork John Day River steelhead population (Table 8-9).

Table 8-9. Key and secondary threats to viability of the South Fork John Day River steelhead population (Mid-C Expert Panel 2006).

John Day River – South Fork
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected:* Reduced water quantity and/or modified hydrograph; impaired physical habitat quality; impaired fish passage; elevated water temperatures. • *Life stage(s) primarily affected:* fry, summer parr, winter parr, returning adults. • *Specific threat(s):* Current land use practices (agriculture, push-up dams that provide irrigation water, grazing, etc.) that impact steelhead growth and survival in tributaries; push-up dams that block or impair fish movement. Improvement of some habitat conditions is expected in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: (See discussion for Lower Mainstem John Day population.) **Land Use Practices**: Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary because of creation of dredge spoil islands; increased fine sediment from agricultural and forestry practices reduces egg and alevin survival tributaries. **Introduced Species**: (See discussion for Lower Mainstem John Day population.)

Upper Mainstem John Day River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the Upper Mainstem John Day River steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat:* degraded channel structure and complexity (habitat quantity and diversity), degraded riparian areas and LWD recruitment, altered sediment routing, water temperatures, altered hydrology and degraded floodplain function and connectivity. Impaired fish passage is also a priority limiting factor in Beech and Laycock creeks; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices (agricultural practices, livestock overgrazing, removal of large trees from the riparian corridor, wetland draining and conversion, stream channelization/diking); the Columbia River mainstem hydropower system.
>
> **Primary Life Stages Affected:** Juvenile rearing, egg incubation, egg-to-parr survival, smolts, adult spawning.
>
> **VSP Characteristics Impacted:** Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current land use practices pose the primary threat to viability of the Upper Mainstem John Day River steelhead population (Table 8-10).

Table 8-10. Key and secondary threats to viability of the Upper Mainstem John Day River steelhead population (Mid-C Expert Panel 2006).

John Day River – Upper Mainstem
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected:* Reduced water quantity and/or modified hydrograph; impaired physical habitat quality; elevated water temperatures. • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Current land use practices (agriculture, forestry, push-up dams that provide irrigation water, grazing, etc.) that impact steelhead growth and survival in tributaries. Improvement of some habitat conditions is expected in the future due to current practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: (See discussion for Lower Mainstem John Day population.) **Land Use Practices**: (See discussion for South Fork John Day population.). **Introduced Species**: (See discussion for Lower Mainstem John Day population.)

Umatilla River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the Umatilla River steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat*: high water temperature, sediment routing, impaired fish passage, degraded channel structure and complexity and low flows; *Hatchery*: effects of naturally spawning stray hatchery fish on viability; *Hydro*: mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices that reduce habitat quality, quantity and disrupt ecosystem functions; the Columbia River hydropower system.
>
> **Primary Life Stages Affected:** fry, summer parr, winter parr, smolts.
>
> **VSP Characteristics Impacted:** Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current land use practices pose the primary threat to viability of the Umatilla steelhead population (Table 8-11).

Table 8-11. Key and secondary threats to viability of the Umatilla River steelhead population (Mid-C Expert Panel 2006).

Umatilla
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected:* Reduced water quantity and/or modified hydrograph; impaired physical habitat quality; impaired fish movement and habitat access; elevated water temperatures. • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Current land use practices (agriculture, un-screened irrigation diversions, maintenance of the irrigation impoundment system that provides irrigation water and flow control, forest practices, grazing) that impact steelhead growth and survival in tributaries. Improvement of some habitat conditions is expected to occur in the future, based on current land use practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: Direct mortality of pre-smolts and smolts at John Day, The Dalles and Bonneville dams; delayed upstream migration of returning adults over dams; cumulative impact of system on mainstem and estuary habitat for pre-smolts and smolts. **Hatchery Practices**: Stray hatchery steelhead spawn in tributaries with wild population creating a risk of genetic introgression. **Land Use Practices**: Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary because of creation of dredge spoil islands; increased fine sediment from agricultural and forestry practices reduces egg and alevin survival in tributaries. **Introduced Species**: Predation by non-native piscivorous fish on pre-smolts and smolts in mainstem Columbia.

Walla Walla River Summer Steelhead Population

The Mid-C recovery planning team identified the following limiting factors and threats to the Walla Walla River steelhead population:

> **Primary Limiting Factors:** *Tributary Habitat*: high water temperature, sediment routing, impaired fish passage, degraded channel structure and complexity, degraded floodplain connectivity and function, and low flow; *Hatchery:* effects of naturally spawning stray hatchery fish on viability; *Hydro:* mainstem passage.
>
> **Primary Threats:** Hatchery management that results in high rates of straying hatchery fish in natural spawning areas; current land use practices that reduce habitat quality, quantity and disrupt ecosystem functions; the Columbia River mainstem hydrosystem.
>
> **Primary Life Stages Affected:** fry, summer parr, winter parr, smolts.
>
> **VSP Characteristics Impacted:** Abundance, productivity, spatial structure, diversity.

The Mid-C Expert Panel (2006) determined that current land use practices pose the primary threat to viability of the Walla Walla River steelhead population (Table 8-12).

Table 8-12. Key and secondary threats to viability of the Walla Walla River steelhead population (Mid-C Expert Panel 2006).

Walla Walla
Key Threats
Current Land Use Practices • *Limiting factor(s) primarily affected*: Reduced water quantity and/or modified hydrograph; impaired physical habitat quality; impaired fish movement and habitat access; elevated water temperatures. • *Life stage(s) primarily affected:* fry, summer parr, winter parr. • *Specific threat(s):* Current land use practices (agriculture, un-screened irrigation diversions, push-up dams, maintenance of the irrigation impoundment system that provides irrigation water and flow control, forest practices, grazing) that impair steelhead growth and survival in tributaries. Improvement of some habitat conditions is expected in the future, based on current practices that are much improved over historical practices.
Secondary Threats
Current Mainstem Columbia Hydropower System: Direct mortality of pre-smolts and smolts at John Day, The Dalles and Bonneville dams; delayed upstream migration of returning adults over dams; cumulative impact of system on mainstem and estuary habitat for pre-smolts and smolts. **Hatchery Practices**: Stray hatchery steelhead spawn in tributaries with wild population creating a risk of genetic introgression. **Land Use Practices**: Cumulative impact of past and present activities on estuarine habitat for pre-smolts and smolts; predation by birds on pre-smolts and smolts in estuary because of creation of dredge spoil islands; increased fine sediment from agricultural and forestry practices reduces egg and alevin survival in tributaries. **Introduced Species**: Predation by non-native piscivorous fish on pre-smolts and smolts in mainstem Columbia.

8.2 Tributary Habitat

Historically, habitat conditions in the Fifteenmile, Deschutes, John Day, Umatilla, and Walla Walla subbasins supported productive and viable steelhead populations. Natural processes created diverse instream habitats with deep pools and strong connections to floodplains. Many stream channels contained abundant large wood from surrounding riparian hardwood galleries, including cottonwood, aspen, willow, and upstream conifer forests. Stream temperatures were generally sufficient to support all steelhead life stages throughout the year, as upland and riparian conditions allowed for the storage and release of cool water during the dry, summer months and provided shaded sufficient to keep water temperatures cool. Extensive and abundant riparian vegetation armored streambanks, providing protection against erosion.

Conditions in these tributary drainages have changed considerably over the last 150 years. Together, past land use practices across the region contributed significantly to causing the factors now limiting abundance, productivity, and diversity of Mid-C steelhead. As noted by the Expert Panel, and indicated by the EDT limiting factors analyses, historical spawning and rearing areas are now often degraded restricting steelhead abundance, productivity, spatial structure and diversity. However, while harmful land use practices continue today, many landowners now understand the advantages of good conservation practices and have changed their approaches to farming, grazing, forest practices and other activities so that important ecosystem processes and functions can recover. In addition, a suite of regulatory programs have been implemented to protect and restore steelhead habitat conditions. Many people are also voluntarily protecting and restoring stream corridors, wetlands, and other natural features that influence the viability of salmonid populations. Such changes are slowly improving habitat conditions for Mid-C steelhead and other species, while also restoring overall watershed health.

Nevertheless, two emerging threats — forest health and land use conversion — need to be acknowledged. Management actions of the past, including unregulated forest practices, poorly managed livestock grazing, and fire suppression have modified patterns of vegetation in forest and range habitats. These changes have resulted in alteration of important ecosystem processes such as fire, insects and succession. In some cases, current conditions are a significant departure from historical. Fire suppression and silvicultural practices in some Mid-C forests have modified the historical fire regimes and contributed to unnaturally heavy fuel loads. A significant proportion of the forested landscape in the Westside Deschutes, North Fork John Day, Middle Fork John Day, and Upper Mainstem John Day populations is now characterized by such conditions and is classified by the USFS (Schmidt et al. 2002) as condition class 3 with severely altered fire regimes and vegetation attributes significantly altered from the historical conditions (Figure 8-1). Unless improved, areas within these significantly altered landscapes will likely experience intensive wild fires that can impact steelhead recovery efforts, at least in the short term.

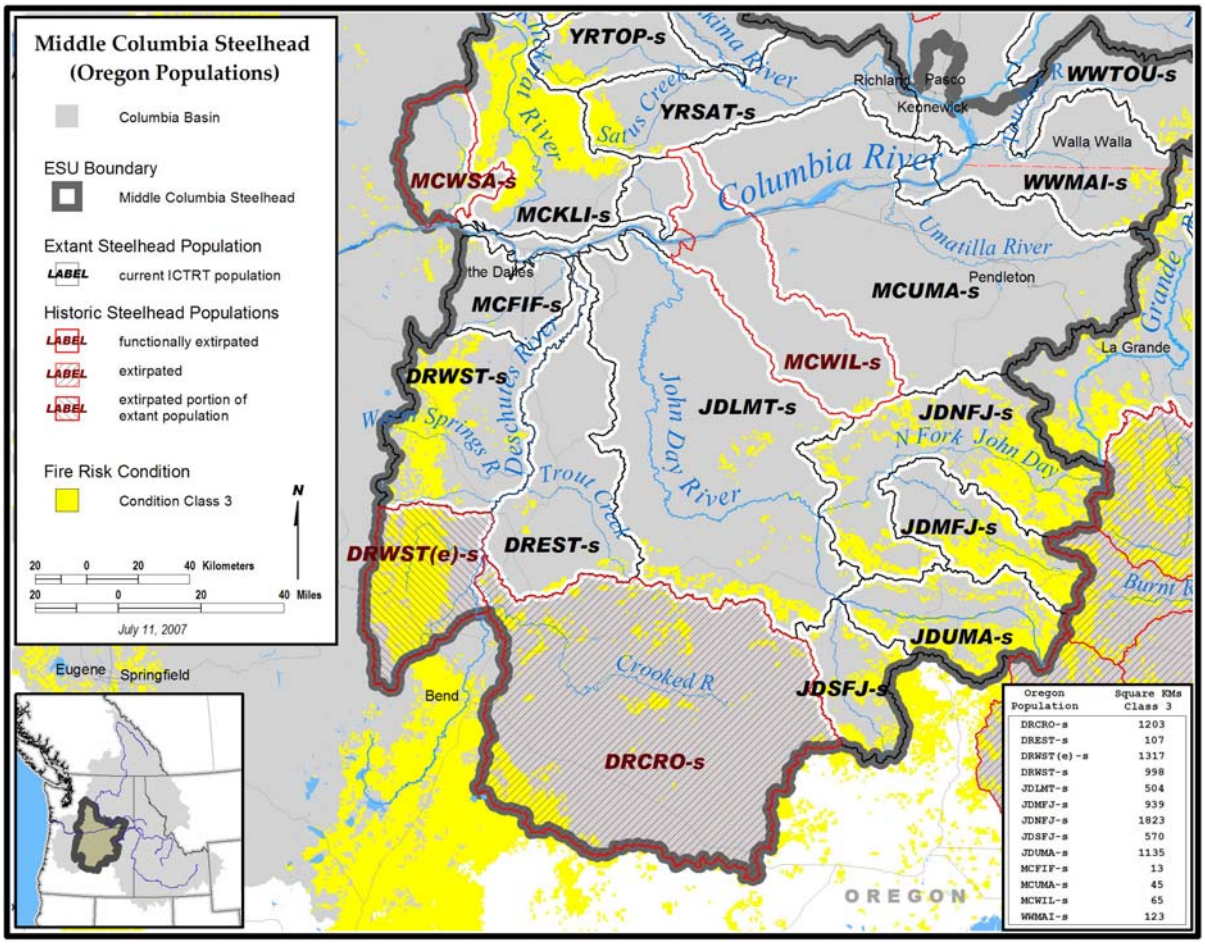

Figure 8-1. Areas within Oregon Mid-C steelhead populations that have significantly altered fire regimes and vegetative attributes that are altered from the historical condition (USFS condition class 3).

Although significant proportions of the forested landscape in these four populations are classified as condition class 3, the degree of threat to the viability of steelhead is uncertain. Much of the research over the past 15 years has demonstrated that, in general, episodic wildfires and post-fire flood events tend to produce long-term habitat benefits for salmonids. The immediate adverse impacts, when they occur, are relatively short term in duration (Howell, 2006; Rieman et al. 1997; Sestrick, 2005; Dunham et al. 2003). However, particularly after large intensive wildfires, water temperatures may increase where streamwide vegetation is destroyed and post-fire channel reorganizing flood events occur, though this does not occur in all cases. In cases where temperatures rise, they can remain elevated for periods of ten years or longer, but rainbow trout quickly repopulate such areas post-fire when fish passage has not been obstructed, and populations maintain their distributions (Dunham et al. 2007). Soil erosion and sediment losses may also increase significantly after intense wildfires, depending on area topography, precipitation, and restoration efforts, adversely impacting spawning and rearing habitats and increasing the short-term risks to viability of some populations (Rieman et al. 2000).

Strategic restoration efforts aimed at restoring such landscapes back to their natural vegetative conditions and their historical fire regimes could help enhance watershed function and forest health. Such approaches will most likely be effective only in areas where existing road systems can facilitate restoration activities without additional disturbance or impact (Rieman et al. 2000).

Rieman et al. (2000 and 2001) concluded that alteration of fire regimes did little to affect outcomes at the scale of the Interior Columbia River Basin and that aggressive active management could result in short-term fish habitat degradation. Specific to Mid-C steelhead populations in Oregon, Rieman et al. (2000) concluded that only in the Westside Deschutes River population and a few other locations would intensive forest restoration activities be potentially compatible with restoration of aquatic conditions, and only under very specific guidelines. The USFS specifically addressed the issue of fuels treatment as an action contributing to recovery of ESA listed salmonids. They concluded that any evaluation of trade-offs to ESA listed salmonids from fuel treatments will be dependent on local conditions and successful integration of both forest and aquatic system restoration objectives. Site specific multi-scale analyses to evaluate benefits and risks of fuels treatments are necessary to assess potential value or detriment to recovery (Appendix J).

In addition to previously described forest health issues, western juniper has expanded across a large area within the DPS. The estimated acres of juniper forest and savanna in Oregon increased since the 1930's from about 1.5 million acres to 6.5 million acres. The expansion of juniper across the landscape has had an uncertain and unquantified affect on aquatic habitat. Junipers may use more water than other vegetation and can outcompete native vegetation. The overall results are potential reduction in streamflow and altered hydrological processes.

Land use conversion is also an emerging threat. Oregon has had a statewide land use program since 1973. In spite of this effort, areas within the Mid-C DPS, such as the Deschutes subbasin, have experienced a high rate of conversion from resource land to developed land. Deschutes County has been one of the fastest growing counties in the Northwest. The extent to which this conversion has influenced aquatic habitat in the recent past, and the future impact of land use conversion on Mid-C steelhead has not been quantified. Although we did not identify forest

health and land use conversion as primary or secondary threats, there are a number of management actions to address these threats in the management actions section.

We defined seven general types of tributary habitat factors that limit the viability of Oregon's ten steelhead populations in the Mid-C DPS and listed the key contemporary threats to each population at specific life stages.

Degraded floodplain connectivity and function: The loss, impairment or degradation of floodplain connectivity; access to previously available habitats (seasonal wetlands, off-channel habitat, side channels); and a connected and functional hyporheic zone. This factor includes reduced overwinter habitat and channel habitat. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

Degraded channel structure and complexity: The loss, impairment or degradation of channels; a suitable distribution of riffles and functional pools; functional amounts and sizes of large woody debris or other channel structure. Includes reduced summer rearing habitat, degraded spawning habitat, reduced diversity and structure (wood, boulders, etc.), inadequate quantity or depth of pools, loss of side and braided channels. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

Degraded riparian areas and LWD recruitment: The loss, degradation or impairment of riparian conditions important for production of food organisms and organic material, shading, bank stabilizing by roots, nutrient and chemical mediation, control of surface erosion, and production of large-sized woody material. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

Altered hydrologic processes: Changes in the hydrograph that alter the natural pattern of flows over the seasons, causing inadequate flow, scouring flow, or other flow conditions that inhibit the development and survival of salmonids. Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

Degraded water quality: Degraded or impaired water quality due to abnormal temperature, or levels of suspended fine sediment, dissolved oxygen, nutrients from agricultural runoff, heavy metals, pesticides, herbicides and other contaminants (toxics). Life stages affected: egg-to-smolt survival, smolt migration, adult migration, pre-spawning.

Altered sediment routing: Altered sediment routing leading to an overabundance of fine-grained sediments, excess of course-grained sediments, inadequate course-grained sediments and/or contaminated sediment. Includes excessive fine sediment that reduces spawning gravel or increases embeddedness. Life stages affected: egg-to-parr survival.

Impaired fish passage: The total or partial human-caused blockage to previously accessible habitat that eliminates or decreases migration ability or alters the range of conditions under which migration is possible. This may include seasonal or periodic total migration blockage. Includes dams, culverts, seasonal push up dams, unscreened

diversions, and entrainment in irrigation diversions. Life stages affected: smolt migration, adult migration, juvenile upstream migration due to thermal blockage or water availability.

These habitat limiting factors are often interrelated. For example, degraded riparian condition often results in channel straightening, elimination of off-channel habitat, loss of large woody debris, reduced channel roughness, increased water temperatures, and increased sedimentation. Changes in the hydrograph — such as through loss of storage on connected riparian areas, floodplains and uplands — often lead to higher peak flows and lower summer flows, which can impair water conditions and temperatures, or restrict fish movement between habitat reaches.

8.2.1 Fifteenmile Creek Winter Steelhead, Tributary Habitat Limiting Factors

The primary habitat-related limiting factors identified by the recovery planning team for the Fifteenmile Creek steelhead population are low flows, high water temperatures, sedimentation, channel confinement and overall habitat loss due to degraded channel structure and complexity.

Degraded floodplain connectivity and function
By 1910, irrigated farms and pastures occupied the floodplains of Fifteenmile, Eightmile, and Fivemile creeks. Development of irrigated farms and pastures on the floodplain and throughout the valley floor, and associated channel straightening and confinement, reduced available off-channel habitat and floodplain connectivity within the Fifteenmile subbasin. Off-channel habitat and floodplain connectivity declined further with the loss of beaver and from channel straightening and debris removal associated with flood restoration (NPCC 2004a). Stream straightening and debris removal increased stream energy and channel downcutting, causing streams to abandon floodplains and associated off-channels.

Degraded channel structure and complexity
In-channel large wood in the subbasin has declined considerably from historical levels due to channel cleanout and removal of source trees, and resulted in reduced pool frequency and quality. Stream straightening and debris removal led to increased bank erosion and a higher width/depth ratio. Streambank erosion has increased considerably over background levels resulting in direct input of large volumes of sediment and a corresponding increase in width/depth ratio. EDT analysis shows that habitat complexity ─ including habitat diversity, key habitat quantity, and channel stability ─ have been degraded by the straightening and channelization of streams, and other factors. EDT results rated most of the Fifteenmile Creek watershed, except Dry Creek, as a moderate priority for restoring habitat diversity for spawning, active rearing of all age-classes, juvenile migration, winter inactivity, and prespawning holding (NPCC 2004a).

Habitat conditions in the Fifteenmile Creek watershed have begun to improve because of habitat restoration projects conducted since the 1980s. Recent large wood placement and riparian restoration within the Fifteenmile Creek watershed will increase off-channel habitat and floodplain connectivity by encouraging channels to aggrade, but more work is needed. Large wood placement will function to restore processes in the short term, and riparian restoration will help stabilize streambanks and restore ecological processes over the long term. As more large

wood is placed or is naturally recruited, structures that can accommodate movement of large wood will be needed.

Impaired fish passage
While many physical barriers in the Fifteenmile Creek watershed have at least been partially fixed, some remain. Fish screens have been installed on 80 diversions and 5 fish ladders have been installed at diversion structures. Although the fish ladders are no longer barriers to adults, they may still be barriers to upstream juvenile migration (NPCC 2004a). A 1998 ODFW culvert survey identified 11 culverts not meeting fish passage criteria on intermittent streams.

Degraded riparian communities and large wood recruitment
Development of farms, pastures and residential areas in the Fifteenmile subbasin considerably impacted riparian condition and connectivity. Roads were also located in many riparian areas, confining stream channels and eliminating riparian vegetation. Below the forested areas, riparian vegetation and large woody debris was nearly gone well before 1980 due to extensive management associated with residences, agriculture, flood control, livestock grazing, and roads (NPCC 2004a). Riparian impacts were also present in forested areas, but to a lesser extent.

Riparian buffer programs and various restoration projects have been implemented to protect and restore riparian habitat. Timber harvest on national forest land has declined sharply since adoption of the Northwest Forest Plan in 1990. Since 1980, the Forest Service has been working to replace large wood in channels and on floodplains (NPCC 2004a). Roads have largely been eliminated in riparian area on national forest lands, though the middle and lower portions of the watershed still contain extensive riparian roads. In addition, riparian buffers have been established in many parts of the Fifteenmile Creek watershed, areas. Riparian conditions are improving in the lower parts of the watershed through ODFW and USDA programs, and beavers have started re-colonizing the lower watershed. Approximately 126 miles of stream in the watershed has some protection through some form of riparian buffer, either through the NWFP on federal lands, the Forest Practices Act on private forest lands, or programs available to private landowners. Currently, about 30 miles of anadromous habitat lack a forested buffer in the watershed.

Degraded water quality
High water temperatures restrict steelhead production in the Fifteenmile Creek subbasin, particularly in the lower watershed. While spawning occurs in most presettlement spawning areas, temperatures become too high to support one or more life stages. Portions of the middle and lower watershed cannot support any steelhead life stages during late summer due to high water temperatures or dry streams (NPCC 2004a). Water temperatures can also create thermal barriers that prevent fish from moving to cooler reaches. Water temperatures in late summer in lower Fifteenmile Creek, Eightmile Creek, and Fivemile Creek are too high to allow for passage of any life stages. Several reaches in the subbasin are on the 303(d) list for temperature, including Fifteenmile, Ramsey, Dry, Eightmile and Fivemile creeks. Some areas in the watershed exceed the cold-water and rearing standards and are believed to exceed the spawning standard as well, although most of the temperature monitoring has occurred during the summer.

Water quality in the Fifteenmile Creek watershed is also degraded by suspended sediment associated with erosion from land management activities, and possibly chemical contaminants and nutrients. While there is currently not enough data to determine if chemical contaminants and nutrient are a problem, both are likely above presettlement levels because of fertilizer and pesticide use for agriculture.

Altered hydrologic processes

Forest practices, conversion of shrub-steppe habitat to agricultural land, loss of beaver, and road development in the Fifteenmile Creek drainage have affected the subbasin's natural hydrologic regime, resulting in higher peak flows and lower base flows. Peak flows increased by as much as 600% between 1850 and 1950 as very little water was being retained in the soil. On forest lands, runoff increased by 1 to 6% due to forest practices and roads (NPCC 2004a). Below the forest boundary, irrigation withdrawals and the dry climate result in very low flows in most Fifteenmile subbasin streams during the summer. At the time of low summer flow, streamflow has been nearly fully appropriated for irrigation since the early 1900s. The change in base flows causes most lower elevation tributaries to become intermittent during summer months, with flows in some smaller tributaries drying up completely. The shallow water depths can prevent fish passage. The lower portions of Fifteenmile, Eightmile, and Fivemile creeks have been the most impacted by low flows, high water temperatures, and overall habitat loss.

Peak flows have the greatest potential for recovering native vegetation; however, peak flows have partially recovered with the adoption of no-till techniques. Over half of the agricultural land in the watershed has been converted to direct-seed/no-till systems that reduce runoff and erosion by increasing infiltration, leaving 50,000 to 60,000 acres that could be converted (NPCC 2004a).

Altered sediment routing

The geology in the Fifteenmile Creek subbasin lends itself to erosion so any management that disturbs the soil increases fine sediment production. Fine sediment in spawning gravel is a primary concern in the subbasin. Extensive soil loss associated with tilled agriculture has contributed to increased fine sediment in spawning gravel. By 1950, soil loss due to water erosion associated with tilled agriculture in the Fifteenmile Creek watershed was as high as 20 tons per acre per year. Steep slopes and clean tillage were largely responsible for the soil loss (NPCC 2004a). Fifteenmile and Ramsey creeks are on the 303(d) list for sedimentation, and EDT modeling identified sedimentation as one of the key factors inhibiting steelhead production (NPCC 2004a). The adoption of minimum-till and no-till techniques on well over half of the tilled acreage in the watershed has reduced erosion and fine sediment delivery to streams in recent years. Rates of erosion and sediment delivery, however, remain elevated above presettlement rates.

In addition, riparian road densities are highest on private land adjacent to Fivemile, Eightmile, and lower Fifteenmile creeks, with more than a half mile of road per mile of stream within 200 feet of the stream. Forest Service pebble counts have found elevated levels of sand and fine sediment in streams throughout the watershed (NPCC 2004a).

Table 8-13 shows the primary limiting factors identified in the EDT Diagnostic Report for the Fifteenmile Creek winter steelhead population. A summary of the major limiting factors and threats by geographic area is presented in Table 8-14.

Table 8-14. Habitat limiting factors summary for the Fifteenmile Creek steelhead population.

Population MaSA and MiSA	Major Limiting Factors	Sites Affected*	VSP Characteristics Impacted	Threats	Life Stages Affected
FIFTEENMILE CREEK POPULATION					
Fifteenmile Creek Population	Altered hydrology (low flows); Water quality (temps); altered sediment routing; degraded floodplain; degraded channel structure (channel confinement, overall habitat loss), degraded riparian condition	MaSAs and MiSAs	Productivity, abundance, spatial structure, diversity	Roads, residential development, agricultural practices and forest practices, irrigation diversions, and loss of beaver	All life stages
Upper Fifteenmile Creek MaSA	Degraded floodplain and channel structure (shorter/steeper, diversity, stability); degraded riparian community; altered sediment routing; altered hydrology; degraded water quality (temp); blocked or impaired fish passage	Fifteenmile [F, CS, R, T (RM 0-40), H (mouth to Pine Cr.), S (RM 0-52.7)]; Dry Creek [F, CS, T (RM 0-16.6),H]; Ramsey Creek [F, CS, BP (on Mt. Hood NF block 2,357 feet of habitat), T (RM 0-5.4), H, S (RM 0-13.2)]; Long Hollow, Douglas Hollow, Standard Hollow, Mays Canyon [IP (culverts)]	Productivity, abundance, spatial structure and diversity	Roads, residential development, agricultural and forest practices, irrigation diversions, and loss of beaver	All life stages are affected.
Eightmile Creek MaSA	Water quality (temp); altered hydrology; degraded riparian communities; altered sediment routing; impaired fish passage	Eightmile Cr. [F, CS, IP (culverts at campground and RM 10), T (RM 0-22), R, H, S (RM 0-34.5)]; Japanese Hollow [IP]	Productivity, abundance, spatial structure and diversity	Roads, residential development, agricultural and forest practices, irrigation diversions, and loss of beaver	All life stages are affected.
Fivemile Creek MaSA	Water quality (temp); altered hydrology; altered sediment routing; degraded riparian communities; impaired fish passage	Fivemile Creek [F, CS, R, T, H, S]; Middle Fork Fivemile Cr [F, CS, BP (culvert), IP,T, R, H]	Productivity, abundance, spatial structure and diversity	Road building, legacy forest roads, residential development, agricultural and forest practices, irrigation diversions, and loss of beaver	All life stages are affected.

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F), degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), high water temperatures (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.2 Deschutes River Eastside Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for the Deschutes Eastside steelhead population are degraded riparian condition, low flows, high water temperatures, degraded channel structure/complexity and floodplain connectivity, impaired fish passage.

Degraded floodplain connectivity and function
Off-channel habitats, including wet meadows, oxbows and backwater areas have been reduced by floodplain degradation and loss of beaver. These areas provided juvenile rearing habitat and helped moderate streamflows and water temperature alterations.

Degraded channel structure and complexity
Habitat complexity is generally impaired in most stream reaches used by the Deschutes Eastside steelhead population. Large wood and pool habitat is lacking, thus limiting salmonid production. During summer low flows, a small number of pools with little cover provide the only available habitat for juveniles and adults. The lack of pool habitat confines large numbers of fish to small areas with very little cover, exposing them to potential predation (NPCC 2004b).

EDT results identified reduced habitat diversity as a major factor limiting steelhead in the Buck Hollow, Bakeoven, and Trout creek systems. Reduced habitat diversity ranked as extreme or high for several reaches. Other major limiting for these streams include the loss of instream habitat complexity and pool habitat for rearing, reduced spawning habitat diversity and high temperatures for egg incubation and 0-age rearing, and low flow for 0- to 2-age rearing (NPCC 2004b). EDT results also identified habitat diversity for spawning and rearing and channel stability as major habitat constraints in the smaller tributaries (NPCC 2004b).

Degraded riparian communities and large wood recruitment
Streams on the lower eastside of the Deschutes have been considerably impacted by beaver harvest, irrigation, roads, and cattle grazing; particularly since soils in many eastside stream systems are not very permeable and are prone to landslides. With the loss of riparian vegetation, streams began eroding vertically and horizontally during storm events. Roads were located in many of the riparian areas within the subbasin (NPCC 2004b). Channel downcutting contributed to lowering the water table, which exacerbated the loss of riparian vegetation (NPCC 2004b). Riparian vegetation is recovering in many areas because the impacts associated with grazing have been reduced through improved livestock management practices, including early season use, better livestock distribution, shorter use duration, lower intensity of use, and installation of livestock exclosures (NPCC 2004b). With the recovery of riparian vegetation, beavers have started recolonizing the eastside tributaries (NPCC 2004b).

Degraded water quality
Water temperatures in the eastside tributaries naturally rise more quickly and reach higher levels than westside tributaries because of warmer air temperatures and more arid conditions (NPCC 2004b). Temperatures have increased because of land use practices, and now typically exceed State water quality criteria for salmonid rearing during summer months. Buck Hollow Creek (RM 0-37.7) is on the 303(d) list for temperature and Trout Creek (RM 0-50.7) and tributaries Tenmile, Auger, Big Log, Bull Cartwright, Dick, Dutchman and Potlid creeks are on the 303(d) list for temperature and sedimentation. In Buck Hollow Creek, summer water temperatures often rise above 75° F, except in areas of cool water refuge where seeps and springs enter the channel, or where widely scattered deep pools are recharged with cool subsurface flow. In Trout Creek, water temperatures usually surpass recommended levels by late May and can remain high through October (NPCC 2004b). Bakeoven Creek also experiences high water temperatures and other water quality problems, including turbidity, low dissolved oxygen and nutrients.

Altered hydrologic processes
The eastside streams are very flashy due to their high average slope, high drainage densities, and occasional severe thunderstorms (NPCC 2004b). The uplands are generally degraded by grazing and agriculture; reducing the soil's ability to collect and store moisture, contributing to the flashy nature of the streams. Approximately 370,000 acres of contiguous interior grassland that existed in the upper Bakeoven, Buck Hollow, and Antelope watersheds has been lost to encroachment by other habitat types and land use (NPCC 2004b). There has also been an increase in the drainage network due to roads. Roads and ditches increase runoff by intercepting ground water from cut slopes and collecting precipitation and routing it directly to stream channels.

Combined upland and riparian degradation has resulted in an altered flow regime with higher peak flows and lower base flows. In places where juniper encroachment has resulted in woodland stands, hydrologic processes have likely been altered. The Natural Resource Conservation Service estimates that current peak flows in some segments of the Trout Creek system are two to three times greater than under pre-settlement conditions (Jefferson County SWCD 1996). Some streams are intermittent in summer months. EDT results identified low flows for 0- to 1-age rearing as a major habitat constraint in the smaller tributaries (NPCC 2004b).

Altered sediment routing
Substrate has been degraded by fine sediment deposition from tilling practices associate with dry cropland farming. However, no-till techniques, which have greatly reduced erosion and sediment delivery to substrate, are being adopted (NPCC 2004b). EDT results identified sediment during egg incubation as a major habitat constraint in the smaller tributaries (NPCC 2004b). Buck Hollow is a gravel-rich system, but fine sediment levels are elevated.

Blocked or impaired fish passage
A road crossing on Stag Canyon impairs fish passage. On the Trout Creek system, numerous push-up dams block fish passage during the irrigation season, including on Trout Creek between Little Trout Creek and Board Hollow Creek, on Antelope Creek between the mouth and Ward Creek, and on Clover Creek. Most irrigation diversions have been screened or replaced with infiltration galleries. Road culverts affect fish passage. Mud Springs Creek contains a high gradient concrete box culvert in section 15 that is a barrier, and a culvert just upstream of Gateway that is a barrier. Relocation of Hay Creek has created a barrier cascade in the SW corner of section 17 near the mouth of Hay Creek. Other barriers in Hay Creek include storage reservoirs (NPCC 2004b).

Table 8-15 shows limiting factors and priorities identified by EDT Diagnostic Reports for the Deschutes Eastside steelhead population. A summary of major limiting factors and threats by geographic area is presented in Table 8-16.

Table 8-16. Habitat limiting factors summary for the Deschutes River Eastside steelhead population.

Population MaSA and MiSA	Major Limiting Factors	Sites Affected*	VSP Characteristics Impacted	Potential Causes/Threats	Life Stages Affected
DESCHUTES EASTSIDE POPULATION					
Deschutes River Eastside Population	Degraded floodplain and channel structure (complexity, deep pools, diversity); degraded riparian communities; water quality (temp, chemical contaminants and nutrients); altered hydrology (higher peak, lower low flows); altered sediment routing	MaSAs and MiSAs	Productivity, abundance, spatial structure and diversity	Livestock grazing, roads, residences, agricultural practices that simplify habitat, irrigation withdrawals, dams and other barriers	All life stages
Buck Hollow MaSA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology, degraded water quality (temp); altered sediment routing	Buck Hollow [F, CS (mouth to Thorn Hollow), T (RM 0-37.7); H; S]; Thorn Hollow Cr. [R, F, CS (mouth to spring in section 23), S]	Productivity, abundance, spatial structure and diversity	Livestock grazing, upland agricultural practices	All life stages are affected.
Bakeoven MaSA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp); altered sediment routing; impaired fish passage	Bakeoven [F, CS, T, H, S (mouth to Deep Cr.), IP (road crossing at Stag Canyon)]; Deep Cr. [F, CS (especially mouth to Cottonwood Cr)]; Cottonwood Cr. [F, CS (mouth to Ochoco Cr)]	Productivity, abundance, spatial structure and diversity	Livestock grazing, upland agricultural practices, irrigation, roads	All life stages are affected.
Ward/ Antelope/Cold MaSA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; blocked and impaired fish passage	Most drainages [F, CS, H]; Antelope Cr. [BP (push-up dams]	Productivity, abundance, spatial structure and diversity	Irrigation withdrawals, agricultural practices	All life stages are affected.
Lower Trout Cr. MaSA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp); altered sediment routing; blocked and impaired fish passage	Trout Cr. [H (especially below Willowdale), T (RM 0-50.7), F, CS, R, S, PB (Mud Springs Cr., Hay Cr.)]; Tenmile Cr. [T (RM 0-5.9)]; Mud Cr. [IP (culvert in section 15 and just above Gateway)]; Hay Cr. [IP (cascade near mouth, storage reservoirs, diversions)]	Productivity, abundance, spatial structure and diversity	Agricultural practices, channel simplification following flood, roads, irrigation storage reservoirs and diversions, livestock grazing	All life stages are affected.
Upper Trout Cr. MaSA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp); altered sediment routing; blocked and impaired fish passage	Trout Cr. [F, CS (mouth to 4,800-ft level, especially below NF boundary), R, T, S (RM 0-50.7), H (especially below Ashwood), IP (Little Trout to Board Hollow)]; Big Log Cr. [T and S (RM 0-5.5)]; Cartwright Cr. [T and S (RM 0-4.3)]; Dick Cr. [T and S (RM 0-2.2)]; Dutchman Cr. [T and S (RM 0-4.8)]; Potlid Cr. [T and S (RM 0-5.2)]; Bull Cr. [T and S (RM 0-1.8)]; all systems [F, CS]; Clover Cr. [IP].	Productivity, abundance, spatial structure and diversity	Livestock grazing, agriculture practices, building of flood control berms, channel straightening, roads	All life stages are affected.

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F), degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), temperature (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.3 Deschutes River Westside Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the Recovery Planning Team for the Deschutes Westside steelhead population are degraded channel structure and complexity, altered sediment routing, high water temperature, low flows and lack of fish passage over Pelton-Round Butte Complex.

Degraded riparian communities and large wood recruitment
The Shitike Creek and Warm Springs River systems have experienced a slight to moderate loss of riparian vegetation and vegetative diversity due to grazing, roads and other land use practices. Habitat is primarily degraded in the lower reaches, with upper reaches in good to excellent condition (NPCC 2004b). The lower four miles of Shitike Creek have experienced substantial loss of riparian vegetation. The cottonwood gallery forest is now a fraction of its former size and contributes a smaller amount of large wood to the stream channel. Roads located in many riparian areas within the subbasin have played a major role in degrading riparian habitat in the Shitike Creek and Warm Springs River systems (NPCC 2004b). Riparian fencing in some areas of the Warm Springs River system has allowed riparian vegetation to become established that has stabilized stream banks (NPCC 2004b).

Riparian conditions along upper and lower Whychus Creek are generally good. Many sections of lower Whychus Creek have a broad riparian area comprised of floodplains, willow stands and cottonwood bottom lands. Riparian vegetation along sections of the creek's middle reach has been damaged by past grazing, channel alterations and development (NPCC 2004b).

Degraded floodplain connectivity and function
Off-channel habitats provide critical steelhead habitat. In 1995, about 68% of all steelhead spawning in the Deschutes River from the Reregulating Dam to Trout Creek occurred in side channels between islands and channel margins, despite the fact that such channels comprise less than 10% of the channel length in the reach (Zimmerman and Ratliff 2003). In tributary reaches, including the Warm Springs drainage and many small tributaries in the area, loss of connectivity with the floodplain has reduced groundwater discharge, further exacerbating problems of low flow and high water temperature. This is especially true for the lower four miles of Shitike Creek and segments of Beaver Creek where Hwy 26 has reduced floodplain connectivity.

Degraded channel structure and complexity
The results of EDT analysis identified lack of habitat diversity and complexity as major limiting factors for the Deschutes River above Trout Creek, and for several reaches on Shitike Creek and the Warm Springs River system. Habitat degradation on the stretch of the Deschutes River above the mouth of Trout Creek results primarily from recreational impacts on riparian vegetation on the east side of the river and from grazing impacts on the west side of the river. On lower Shitike Creek and the Warm Springs River, channel simplification and land use practices have accentuated flashy flows that scour the channel and reduce habitat complexity (NPCC 2004b). Some instream habitat projects have been implemented on the Warm Springs River and have increased habitat complexity (NPCC 2004b). Channelization and loss of large wood along the lower four miles of Shitike Creek have reduced channel and fish habitat heterogeneity (e.g. side channels, substrate diversity, etc.). Loss of floodplain connectivity has

resulted in increased water temperatures and the loss of off-channel juvenile rearing habitat and winter high flow refugia. EDT results identified channel instability as a major limiting factor for the Shitike and Warm Springs systems (NPCC 2004b). In the Whychus Creek drainage, channel simplification has reduced channel complexity and stability from RM 24.7 to the National Grassland Boundary (RM 5), resulting in a loss of sinuosity and stream length (NPCC 2004b).

Degraded water quality

The lower Deschutes River and several westside tributary reaches are included on the 2002 ODEQ 303(d) list of water quality limited streams (NPCC 2004b). The lower Deschutes River exceeds temperature criteria for salmonid rearing from White River to Pelton Dam. In addition, water temperatures in lower reaches of Warm Springs River and Shitike Creek can exceed 70°F from mid to late summer. EDT results identified water temperature during incubation and juvenile rearing as a major limiting factor in lower Shitike Creek, Beaver Creek, and several other reaches (NPCC 2004b). Suspended sediment further reduces water quality in smaller tributaries to the Deschutes River and in Quartz and Coyote creeks in the Warm Springs River system. Whychus Creek is also included on the 2002 ODEQ 303(d) list for exceeding water temperature criterion for salmonid spawning during summer months (NPCC 2004b).

Information regarding chemical contaminants and nutrients in streams is lacking for this area. It is likely that levels of both are above pre-settlement levels because of fertilizer and pesticide use for agriculture. Irrigation return flows to the Deschutes River and its tributaries may pose water quality problems (NPCC 2004b). Contaminants from municipal waste spill/discharge into Shitike Creek and from water lagoons and golf course at the resort on the mainstem Warm Springs River also degraded water quality.

Altered hydrologic processes

Lands in watersheds that support the Deschutes River Westside steelhead population have generally been degraded through grazing, agriculture, forest practices, and roads, and are not able to capture and slowly release precipitation as efficiently as they did historically. Headwater channel scour has reduced water storage and lowered the water table (NPCC 2004b). This is especially true for Coyote, Quartz, Tenino, Skookum, Eagle, and Nena Creeks. It is also the case on upper Beaver Creek where the creek has been channelized along Hwy 26. Flows, which are dominated by snowmelt, peak in spring and taper off through the summer to base levels in August or September. Small tributary flows are often intermittent, limiting habitat availability in the summer. EDT results identified reduced streamflows as a major limiting factor in this area.

Altered sediment routing

Fine sediment levels in spawning substrate are a concern in Shitike and Warm Springs systems and small tributaries to the Deschutes River. Several drainages, including Quartz and Coyote creeks in the Warm Springs system, contain highly erosive soils that have become more unstable due to extensive grazing, construction of logging roads, and conversion of land for tilled agriculture (NPCC 2004b). Excessive sediment loads also occur occasionally in the Warm Springs River, primarily due to runoff from lower tributaries, including Coyote and Quartz creeks in the Beaver Creek drainage, and from Charlie Canyon. Lower Whychus Creek also displays a high percentage of fine sediment associated with unstable streambanks and livestock grazing (NPCC 2004b).

The small tributaries to the Deschutes River have become incised and lost some of the steelhead spawning gravel that was historically abundant. In-channel large wood, which has decreased the ability of streams to sort and store spawning gravels, has also been reduced throughout the area (NPCC 2004b). Increased fine sediment in small tributaries results from cropland and rangeland runoff. Substrates contained less fine sediment before European settlement due to stable vegetation conditions (NPCC 2004b).

Impaired fish passage

The Pelton-Round Butte Complex on the Deschutes River at RM 100 blocks fish passage to and from historical habitats in the Metolius River, Whychus Creek and other previously accessible habitats above the complex. Fish passage facilities were constructed with the dams, but attempts to pass juveniles out of the system failed. Currently efforts are underway to restore passage as part of the FERC relicensing process (NPCC 2004b). The new downstream fish passage structure is scheduled to be functioning by 2010. Details of the proposed reintroduction are presented in the tributary hydro actions in Section 9.

Adult steelhead are also affected by structural barriers, such as culverts, irrigation diversions, roads and railroad crossings that block upstream passage. Juvenile rearing is greatly affected by all of the passage barriers.

Table 8-17 shows limiting factors and priorities identified in the EDT Diagnostic Report for the Deschutes Westside steelhead population. A summary of the major limiting factors and threats by geographic area is presented in Table 8-18.

Shitike Creek MaSA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp, pollutants); altered sediment routing	Shitike Cr. [F, CS, R (mouth to upper road crossing, City of Warm Springs, near Hwy. 26); WQ (Warm Springs mill site and sewage lagoons)]	Productivity, abundance, spatial structure and diversity	Livestock grazing, riparian degradation and confinement through Warm Springs, Hwy. 26, Warm Springs mill site and sewage lagoons, channelization	All life stages

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F), degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), high water temperatures (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.4 Crooked River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified for the Crooked River steelhead population are degraded channel structure and complexity and floodplain connectivity, degraded riparian condition, high water temperature, low flows and lack of fish passage over Pelton-Round Butte Complex (ODFW 1996).

The Crooked River and tributaries were historically inhabited by Mid Columbia summer steelhead. They were extirpated in the upper Ochoco Creek watershed in 1921 with the construction of Ochoco Dam approximately five miles east of Prineville. Steelhead use in the upper mainstem Crooked River including the North and South forks and Beaver and Bear creeks was terminated with the completion of Bowman Dam at Rm 70 in 1961. Limiting factors are similar for habitats upstream and downstream of the two dams. However, only the lower Crooked River watershed below the dams is identified by the Upper Deschutes Subbasin Plan amendment (ODFW 2003) for reintroduction of the species. Discussion of habitat limiting factors in the Crooked River watershed will focus on the reintroduction area followed by a section describing conditions in the upper watershed above Ochoco and Bowman dams.

Degraded riparian communities and large wood recruitment
Riparian vegetation condition in the lower Crooked River watershed is largely a function of geomorphology and land use practices. Two separate reaches of the mainstem flow through steep narrow basalt canyons and are managed by the Bureau of Land Management as Wild and Scenic Rivers. These reaches extend from the head of Lake Billy Chinook at Rm 6 to the Highway 97 crossing at Rm 17 and from Rm 62 upstream from Prineville to Bowman Dam at Rm 70. Riparian communities in these reaches are in excellent condition resulting in stable channel conditions and reduced sediment inputs. However, limited numbers of large riparian trees, lack of wood recruitment from portions of the watershed above Ochoco and Bowman Dams and periodic scouring high flow events result in these reaches lacking in large wood.

Riparian condition in the mainstem between the two Wild and Scenic reaches is extremely degraded. Past grazing and agricultural practices contributed to almost complete removal of native vegetation resulting in bank instability, minimal canopy cover and high sediment loads. Restoration efforts have had limited success due to the erosive soils, lack of vegetation, incised channel and altered hydrograph. Large wood is absent in this reach.

Ochoco Creek below Ochoco Dam is characterized by largely degraded riparian conditions resulting from livestock and agricultural practices as well as development in and around Prineville. Scattered remnant willows and cottonwoods are present but the riparian community is dominated by reed canary grass. Limited overstory canopy is present in the section of the creek that flows through Prineville. Large wood is absent. Riparian conditions in lower McKay Creek are similar to Ochoco Creek. The upper McKay watershed is on USDA Ochoco National Forest ownership. Riparian conditions are significantly improved from that of the lower watershed. Vegetation consists of both conifers and woody species. Full site potential is not realized due to livestock grazing and damage resulting from unauthorized off highway vehicle use.

Degraded floodplain connectivity and function
Floodplain interaction in the lower Crooked River was important for dissipating energy during high flow events, providing off channel refugia for juvenile salmonids and storing water for late season release. Floodplain connectivity and function is variable within the Crooked River steelhead reintroduction area. Generally, in the Wild and Scenic reaches of the mainstem and upper McKay Creek connectivity is intact. However, the middle section of the mainstem, Ochoco Creek and lower McKay Creek have limited connectivity to the floodplain. In particular, the reach of the Crooked River from Lone Pine to Prineville (Rm 31 to Rm 51) has a deeply incised channel and extremely poor floodplain connectivity resulting in chronic bank erosion that has hampered restoration efforts.

Degraded channel structure and complexity
Diverse habitats including pools and structures providing cover increase the production capacity of a stream through increased holding areas for migrating adults and particularly for juvenile steelhead rearing. The entire section of the Crooked River watershed in the steelhead reintroduction area was channelized following the 1964 floods excluding the two canyon reaches of the mainstem and the upper section of McKay Creek. Channelization resulted in severe reduction in channel complexity and width/depth and pool/riffle indices.

Degraded water quality
Water quality degradation in the Crooked River is largely from nonpoint pollution sources including livestock grazing, timber harvest, and agricultural and stormwater runoff. Primary water quality parameters limiting steelhead production are temperature, dissolved oxygen and turbidity. The Crooked River is on the Oregon Department of Environmental Quality's 303d list for not meeting water quality standards for temperature, turbidity and total dissolved gas. In particular, the Crooked River mainstem from the Highway 97 crossing (Rm 17) to the Feed Canal (Rm 51) suffers from chronically high summer temperatures often in excess of 80F. Partially treated wastewater discharged into the river near Prineville during the winter months also impairs water quality.

The hypolimnotic release of water from Bowman Dam results in cool water (52F) discharged into the Crooked River. This results in favorable summer conditions supporting a very robust redband trout population and popular tailrace fishery. Conversely, flows released from the dam in excess of 2000 cfs result in nitrogen supersaturation and dependent upon length of exposure can result in varying degrees of gas bubble disease.

Altered hydrologic processes
The natural hydrograph was largely driven by climactic patterns of the Blue Mountain physiographic province characterized by hot arid summers and cold winters. The majority of annual precipitation occurred as snowfall. Annual streamflow was determined largely by snowpack. This resulted in low to moderate year around base flow with annual spring runoff events.

The hydrology of the lower Crooked River steelhead reintroduction area has been significantly altered by construction of Ochoco and Bowman dams and management of water released from Prineville and Ochoco reservoirs, irrigation practices and removal of beaver. Reservoir

management has the greatest influence on flows in the mainstem Crooked River and Ochoco Creek. Releases of water for irrigation delivery result in flows (250 cfs – Crooked R., 20 cfs - Ochoco Cr.) exceeding natural levels from April through October in the reaches upstream of the major points of diversion: Rm 51 to Rm 70 on the Crooked and Rm 3 to Rm 10 on Ochoco Creek. At the close of irrigation season in October, water is stored in the two reservoirs and releases are reduced to 50-75 cfs in the Crooked River (legally protected flows in the non irrigation period are 10 cfs) and 5-10 cfs in Ochoco Creek. This pattern is occasionally punctuated by spring high flow events when the respective reservoirs fill and inflow is discharged downstream. This flow management has generally resulted in robust populations of redband trout in the tailrace reaches of both the Crooked River and Ochoco Creek Below the major points of diversion streamflows are critically low, particularly in the Crooked River from Rm 14 to Rm 51. Low summer flows and high temperatures (exceeding 80F) limit trout production in this reach. Below the Highway 97 crossing on the Crooked River groundwater from the east slope of the Cascades Mountains resurfaces as springs recharging the streamflow with cool water. Summer readings at the Opal gauge near Culver average 1250 cfs just upstream from Lake Billy Chinook. This results in favorable water quality and quantity conditions for resident redband trout and introduced steelhead, however, the reach is spawning gravel limited.

Hydrology in lower McKay Creek has been significantly altered as well downstream of the Ochoco National Forest boundary at Rm 14. Irrigation withdrawals frequently dewater the creek from this point downstream to Rm 5 during the irrigation season. At Rm 3.5 and Rm 5 Ochoco Irrigation District's main canals bisect McKay Creek at each of these points 1-10 cfs of water is diverted from the canal and the creek serves as a conduit to deliver irrigation water to downstream customers. This results in artificially favorable flows in this reach of McKay Creek that supports a healthy redband trout population despite relatively degraded habitat conditions.

Altered sediment routing
Sediment deposition and substrate composition in the lower Crooked River recovery area are altered through two pathways. The mainstem reach from Prineville to Lone Pine and most of the Ochoco and McKay Creek watersheds have degraded riparian areas, poorly functioning channels and unstable banks. These conditions result in high levels of fine sediment incorporated into available spawning gravel. Conversely, the mainstem reach below Bowman Dam receives little sediment impact from eroding banks but has chronic high turbidity levels resulting from fine sediments released from Prineville Reservoir. Bowman Dam also serves to limit gravel recruitment, which may limit steelhead production, into this reach. In general, the reaches with the highest water quantity and quality have limited amounts of spawning gravel, while the reaches with abundant gravel are water and sediment limited. The one reach in the reintroduction area currently with fair to good conditions for both spawning and rearing is the mainstem Crooked River from Prineville (Rm 51 to Rice Baldwin Dam Rm 55). The lower five miles of McKay Creek and the eight miles within the Ochoco National Forest as well as the ten miles of Ochoco Creek from the mouth to Ochoco Dam also have moderate potential to support each steelhead life history stage.

Impaired fish passage
Artificial barriers are a significant limiting factor for steelhead production in the Crooked River. However, ongoing efforts by ODFW, the Crooked River Watershed Council, U.S Fish and

Wildlife Service, Natural Resource Conservation Service and others are making progress at addressing several barriers. The Pelton-Round Butte Complex represents the paramount impediment to steelhead passage into upper Deschutes Basin including the Crooked River. Development of passage facilities is a FERC license condition to operate the hydroelectric project. Passage efforts here are discussed elsewhere in this document.

A second large barrier to upstream fish migration into the Crooked River is Opal Springs Dam at Rm 7, approximately one mile upstream from the Crooked River Arm of Lake Billy Chinook. This is a 24 foot high concrete dam owned and operated by Deschutes Valley Water District. It was constructed in 1982 as part of a FERC licensed hydroelectric project. At the time of licensing passage was not required. The license does not expire until 2032, however, numerous stakeholders are working collaboratively with the dam operator to construct passage facilities at Opal Springs with an estimated completion date in 2012.

There are four additional concrete irrigation dams on the mainstem Crooked River between Opal and Bowman Dams. The Crooked River Watershed Council and others completed construction of passage facilities at the Crooked River Central and People's Irrigation District Dams at Rms 44 and 51 respectively in January 2009. The Rice Baldwin and Stearns Dams remain partial barriers with the former passable by adult fish at all flows and the later passable to adults at high flows. Discussions are underway to improve passage at Stearns Dam in the near future.

Both Crooked River major tributaries, Ochoco and McKay Creeks had numerous seasonal and permanent barriers prior to the 1998 flood in Prineville. Ochoco Irrigation District alone had eleven permanent or seasonal barriers in the two creeks prior to the flood. The irrigation district worked collaboratively with ODFW, OWEB and others to replace each of these diversions with state of the art structures. Currently there is one seasonal barrier on Ochoco Creek and two permanent partial barriers on McKay Creek. ODFW and the Watershed Council are engaged with private landowners to provide passage at each of these sites.

Upper Crooked River Watershed Limiting Factors

The upper Crooked River watershed includes the mainstem, North Fork, South Fork, Bear Creek and Beaver Creek above Bowman Dam and Ochoco Creek and Mill Creek above Ochoco Dam. The entire upper subbasin was historically inhabited by summer steelhead with the exception of the North Fork Crooked River that had a largely impassable natural barrier (Lower Falls) nine miles upstream from the mouth. However, these historic habitats are not in the current Mid Columbia steelhead reintroduction area.

Limiting factors in the upper watershed are largely similar to the lower watershed. A notable exception is the water quality and quantity issues in the mainstem above Prineville Reservoir are more pervasive. Summer flow is routinely below 5 cfs with stream temperatures in the mid 80s. Suitable steelhead production areas are fragmented are largely disconnected from viable migration and rearing areas. Conversely, the upper Ochoco watershed has considerable steelhead production potential. The Mill Creek watershed in particular has had considerable restoration work and could be one of the most productive streams in the subbasin. Altered hydrology is the primary limiting factor in upper Ochoco as well.

A summary of the major limiting factors and threats for the Crooked River steelhead population by geographic area is presented in Table 8-19.

Table 8-19. Habitat limiting factors summary for the Crooked River steelhead population.

Population MaSA and MiSA	Major Limiting Factors	Sites Affected*	VSP Characteristics Impacted	Potential Causes/Threats	Life Stages Affected
CROOKED RIVER POPULATION					
Crooked River Population	Degraded riparian communities; degraded floodplain and channel structure (complexity, side-channel habitat, diversity); water quality (temp); altered hydrology (low flow); altered sediment routing; blocked and impaired fish passage	MaSAs and MiSAs	Abundance, productivity, spatial structure, diversity	Primarily livestock grazing, residential development and agricultural practices that simplify habitat, irrigation withdrawals, unauthorized OHV use, dams and other barriers, reservoir release flows	All life stages
Crooked confluence MISA (reintroduction)	Limited spawning habitat, passage	Crooked River (Rm 6 – Rm 7) BP	Productivity, abundance, spatial structure and diversity	Barrier at Opal Springs Dam	Spawning
Lone Pine MISA (reintroduction)	Limited spawning habitat	Crooked River (Rm 7 –Rm 20)	Productivity, abundance, spatial structure and diversity		Spawning
McKay MASA (reintroduction)	Degraded channel structure; water quality (temp), altered hydrology, degraded riparian communites, altered sediment routing, passage	McKay Cr. (Rm 0 - Rm 14) including Allen Cr. F, CS, R, H, S, T, BP; McKay Cr. (Rm 14-Rm 19) including Little McKay Cr.CS, R, S, WQ	Productivity, abundance, spatial structure and diversity	Past channelization, livestock grazing and agricultural practices, irrigation withdrawals, unauthorized OHV use, permanent and seasonal barriers, removal of riparian vegetation, loss of LWD	All life stages
Lower Ochoco MASA (reintroduction)	Degraded channel structure and reduced complexity, altered hydrology, degraded riparian communites, altered sediment routing,	Ochoco Cr (Rm 0 – Rm 10) F, CS, R, H, S, IP	Productivity, abundance, spatial structure and diversity	Urban development in reach through Prineville, flow management in releases from Ochoco Dam. Livestock grazing and agricultural practices in upper reach below Ochoco Dam	All life stages
Lower Crooked MASA (reintroduction)	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp, pollutants); altered sediment routing	Crooked River (Rm 20 – Rm 56) F, CS, R ,H, WQ, T, S; Crooked River (Rm 56 – Rm 70) H, WQ, S, BP	Productivity, abundance, spatial structure and diversity	Livestock grazing and agricultural practices, past channelization, flow management or releases from Bowman Dam, irrigation withdrawals	All life stages
Upper Ochoco MASA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp, pollutants); altered sediment routing	Mill Creek (Rm 0-Rm 15) F, CS, H, T; considerable restoration has occurred. Ochoco Cr. (Rm 14-Rm 32) F,CS,R, H, T, S; Wolf Cr. (Rm 0 – Rm 4). CS, R; Marks Cr. (Rm 0-	Productivity, abundance, spatial structure and diversity	Livestock grazing and agricultural practices, past channelization, irrigation withdrawals, roads , forest management	All life stages

Upper Crooked, South Fork Crooked, Beaver Cr MASAs, Bear Cr. MISA	Degraded floodplain and channel structure; degraded riparian communities; altered hydrology; degraded water quality (temp, pollutants); altered sediment routing	Crooked R (Rm 86 – Rm 125) and tribs. F,CS,R,H,T,S , BP (Horse Heaven Cr), IP; South Fk Crooked (Rm 0 – Rm 20) CS, R, H, T, S, IP; Beaver Cr.(Rm 0 – Rm 25) and tribs F,CS, R, H, T, S,; North Fk Crooked (Rm 0 – Rm 9) CS, R, H, T	Productivity, abundance, spatial structure and diversity	Livestock grazing and agricultural practices, past channelization, irrigation withdrawals, roads, forest management	All life stages

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F), degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), high water temperatures (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.5 Lower Mainstem John Day River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified for this population are: degraded floodplain and degraded channel structure (key habitat quantity and habitat diversity), altered sediment routing, water quality (temperature), and altered hydrology. Obstructions are high priority limiting factors in Bridge, Kahler, Muddy, Rock (lower in Gilliam County), and Thirtymile creeks.

Degraded floodplain connectivity and function
Land cover in the lower John Day River watershed is predominately rangeland and cropland (ODA 2004). Floodplains and riparian areas have been extensively altered by agriculture, livestock grazing, transportation corridors, and other development.

Degraded channel structure and complexity
The lower reaches of tributaries in many MaSAs and MiSAs for this population have had extensive channel modifications. Channelization and streambank hardening are extensive, affecting channel conditions and dynamics. Habitat diversity and LWD are also lacking, and overall habitat complexity is well below benchmark condition. Examples include lower Bridge, Mountain, Rock (Wheeler County), Cottonwood, Ferry Canyon, Pine Hollow, and Thirtymile**.** Conditions improve upstream in many of the streams that flow out of the Bridge Creek Wilderness, including Bridge, Mountain, and Rock (Wheeler County), as well as Cottonwood Creek, that flows out of a roadless area.

Kahler and Service creeks have low levels of LWD and overall habitat complexity. EDT results identified habitat diversity as a medium priority limiting factor and key habitat quantity as a high priority. Ferry Canyon has an incised channel that is generally unstable, though conditions have improved recently. Pine Hollow has a pipeline buried in the channel for 6.6 miles, which in

combination with the 1964 flood, contributes to a very unstable channel. Channel conditions in Thirtymile Creek are generally degraded, with low levels of LWD and habitat complexity. Habitat complexity in Butte Creek is generally higher, with rearing occurring throughout the system. Rock Creek (Gilliam County) channel conditions are degraded, with areas that have been channelized and have low levels of LWD.

Altered sediment routing
EDT findings indicated that sediment impacts in the Lower John Day watershed are higher than elsewhere in the subbasin (NPCC 2005). Sediment problems are often associated with changes in native plant communities due to wheat farming, grazing, and other activities that can cause severe streambank erosion and sedimentation. Forest and other roads, if not constructed and maintained with best management practices, can contribute to altered sediment routing. EDT results show sediment as a high priority limiting factor in Bridge, Butte, Grass Valley, Muddy, Scott Canyon, Lower and Upper Rock (Gilliam County), Thirtymile, Pine Hollow, and Mountain creeks, and gravel embeddedness as a significant limiting factor in the lower watershed.

Altered hydrologic processes
The USGS-maintained gage at McDonald Ferry, Oregon at RM 21, the oldest gage in the subbasin, has been in operation since December 1904. The lowest recorded discharge from the McDonald Ferry station was zero cfs for part of September 2, 1966, August 15 to September 16, 1973, and August 13, 14 and 19-25, 1977. Peak flow at the McDonald Ferry gaging station is typically more than 100 times greater than the lowest flows of the same year. From year to year, peak flows can vary as much as 300 to 700%. This portion of the watershed is prone to intense thunderstorms, which can scour channels down to bedrock, during summer months.

According to NMFS 2005, water withdrawals, riparian corridor alterations, grazing, channel alterations, and wetland loses have all contributed to lower base flows. Low flows are below benchmark in the lower reaches of Bridge, Cottonwood, and Mountain creeks. Flows are also below benchmark in Ferry Canyon, Pine Hollow, Thirtymile, Lower Rock (Wheeler County), and Butte. Water diversions contribute to reduced summer low flows in most of these areas.

EDT results rated "flow" as either a medium or low priority for restoration in 16 out of 18 reaches in the Lower John Day, though the subbasin planning technical team considered flow restoration a higher priority for several reaches. Flow is not a restoration priority for the lower John Day River McDonald Ferry reach since it is frequently inundated by backwaters from the John Day reservoir. Flow restoration would improve several other limiting factors addressed by EDT including habitat complexity and temperature.

Degraded water quality
From July to September, groundwater provides much of the base flow to the Lower John Day River (NPCC 2005). Elevated temperature is an important limiting factor for most stream segments for the Lower John Day population that are measured (ODA 2004).

BLM (1999) characterized temperature as "Not Properly Functioning" for all streams rated in the lower John Day. Other water quality constituents such as total phosphates, biological oxygen demand, and fecal coliform can also limit water quality in late summer when flows are lowest

and water temperatures are the greatest. Cottonwood, Rock (Wheeler Co) and Bridge have good quality water in their upper reaches, but water quality conditions, especially temperature, degrade in the lower reaches. Butte Creek has water quality that supports rearing throughout the stream. Table 8-20 shows 303(d) listed streams in the Lower John Day watershed.

Table 8-20. Lower John Day watershed 303(d) listed stream segments and parameters of concern (ODEQ 2002 cited in NPCC 2005). Waterbodies that are listed multiple times represent different locations and/or different life stages.

Waterbody Name	Parameter	Waterbody Name	Parameter
Bear Creek	Temperature	John Day River	Temperature
Bridge Creek	Temperature	John Day River	Temperature
Gable Creek	Temperature	John Day River	Fecal Coliform
Grass Valley Canyon	Temperature	John Day River	Dissolved Oxygen
Henry Creek	Temperature	Nelson Creek	Temperature
John Day River	Fecal Coliform	Pine Creek	Biological Criteria
John Day River	pH	Sorefoot Creek	Temperature
John Day River	Temperature	Stahl Canyon	Temperature
John Day River	Temperature	Thirtymile Creek	Temperature

Blocked or impaired fish passage
EDT results identified "obstructions" as a high priority limiting factor in Bridge, Kahler, Muddy, Lower Rock (Gilliam County), and Thirtymile creeks, and a medium priority in Rock Creek (Wheeler County). The passage barrier on Bridge Creek is near the town of Mitchell and is considered passable to adults. The passage barrier on Kahler Creek is low in the system and only a juvenile barrier. Irrigation diversions create passage barriers on Lower Rock Creek (Gilliam County). Some of these have been repaired, but others have not. A fish passage structure was installed recently on Thirtymile Creek. None of the passage barriers identified are complete barriers, except for the one on Muddy Creek. ODFW biologists also identified passage problems on Mountain Creek (Unterwegner 2005).

Many irrigation diversions occur within the John Day subbasin watershed and, in low-water years, fish may encounter passage and spawning difficulties in some tributary reaches due to these diversions. Flows necessary for migration may be unavailable during early summer months and low-flow conditions may limit the use of some potential spawning areas (NMFS 2003a).

Degraded riparian communities and large wood recruitment
Riparian conditions have been degraded by agriculture, grazing, stream channelization, and riparian roads, and other development and activities. EDT rated riparian habitat improvements as "high" to "very high" priorities for restoration in all reaches of the lower John Day watershed. Reaches of Lower Rock (Gilliam County), Kahler, Service, Pine Hollow, and Thirtymile have very poor riparian conditions. Riparian conditions are fairly good in the Bridge Creek Wilderness areas of Bridge, Mountain and Rock (Wheeler County) creeks and in the inventoried roadless area of Cottonwood Creek. Many reaches of Ferry Canyon and Pine Creek also have good riparian cover. Butte has generally fairly good riparian cover, except for isolated areas.

Table 8-21 shows limiting factors and priorities identified by EDT diagnostic reports for the Lower John Day steelhead population. A summary of major limiting factors and threats by geographic area is presented in Table 8-22.

Rock (Wheeler) MaSA	degraded floodplain and channel structure; water quality (temp); altered hydrology	Rock [F, CS (lower), H, IP]	Reduced productivity, abundance, spatial structure, diversity	Agricultural and livestock grazing practices, irrigation withdrawals	Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, one-year smolts
Kahler MaSA	Altered hydrology; degraded floodplain and channel structure; impaired fish passage; altered sediment routing; water quality (temp); degraded riparian communities	Kahler Cr. [IP (lower), F, CS, R,]	Reduced productivity, abundance, spatial structure, diversity	Agricultural and livestock grazing practices, irrigation withdrawals	Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, one-year smolts
Butte MaSA	Altered hydrology; degraded floodplain and channel structure; altered sediment routing; water quality (temp), degraded riparian communities in isolated reaches	Butte Cr. [H, S (lower)], R	Reduced productivity, abundance, spatial structure, diversity	Agricultural and livestock grazing practices, irrigation withdrawals	Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, one-year smolts
Service MaSA	degraded floodplain and channel structure; degraded riparian communities; altered hydrology; altered sediment routing; water quality (temp)	Service Cr. [F, CS, R]	Reduced productivity, abundance, spatial structure, diversity	Agricultural and livestock grazing practices	Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, one-year smolts
Cottonwood MaSA	Altered hydrology; water quality (temp)	Cottonwood Cr. [H, F, CS (lower reaches)]	Reduced productivity, abundance, spatial structure, diversity	Agricultural and livestock grazing practices, irrigation withdrawals	Juvenile rearing, egg incubation, egg-to-fry, fry-to-smolt, one-year smolts

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F), degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), temperature (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.6 North Fork John Day River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for the North Fork John Day River steelhead population are degraded floodplain connectivity and function, degraded channel structure and complexity (key habitat quantity, habitat diversity, channel stability), altered sediment routing, water quality (temperature), and altered hydrology.

Degraded floodplain connectivity and function
Floodplain connectivity in several reaches of the Granite Creek system has, until recently, been limited by dredge piles from historical mining operations. Many of these historical dredge piles sat very near the stream and prevented the stream from overflowing into the floodplain during

high flow events. During the last five years, many of the tailing piles along Granite and Clear creeks have been leveled and floodplain connectivity has been re-established. However, a high flow event is needed to reconfigure the channel and create the necessary pool frequency.

Degraded channel structure and complexity
Most indicators of channel condition within the North Fork John Day River are "functioning at risk" (NMFS 2003). The North Fork River does not meet PACFISH pool frequency management objectives (USDA and USDI 1994 cited in NPCC 2005). Key habitat quantity is identified by the EDT analysis as the most important limiting factor to address for this population. Pool frequency and quality limit production in the Granite Creek and upper North Fork systems. Degraded channel conditions also limit steelhead production in the Big Wall Creek drainage (NMFS 2003). Middle Camas and lower Owens Creek watersheds have good potential; however, stream channels are incised, LWD is low, and habitat diversity is limited. Large pools, channel habitat, wetted width/maximum depth ratio, and streambank condition are considered properly functioning in the Granite Creek subwatershed.

Altered sediment routing
Erosion caused by forest practices and other activities affects habitat conditions in several parts of the North Fork drainage. The Wallowa Whitman National Forest (WWNF) has identified sediment as "functioning at risk" in both the Granite Creek and Upper North Fork John Day subwatersheds. The Umatilla National Forest (UNF) considers sediment to be "not properly functioning" and substrate embeddedness to be functioning at risk in the Big Wall Creek subwatershed (NMFS 2003). Big Wall Creek was listed on the 303(d) list for sediment. Sediment modeling conducted for the parts of the Big Wall Creek subwatershed indicates that only prescribed fire and instream habitat improvement posed more than negligible risk of sediment increases (NMFS 2003). Wissmar et al. (1994) noted that turbidity in Cottonwood Creek, a North Fork tributary, is notoriously high after storm events. The resulting siltation of stream beds decrease aquatic insect production and degrades spawning habitat.

Altered hydrologic processes
Water yield is generally close to benchmark conditions in most of the upper reaches and tributaries to the North Fork John Day, where much of the watershed is protected as a wilderness area. Low flows are more a problem in the lower elevation tributaries to the west including the lower reaches of Big Wall, Cottonwood, and Rudio. EDT results identified flow as a medium priority restoration need in Cottonwood Creek and as a low restoration priority for Granite, upper and lower Camas, and the lower North Fork John Day River.

The Pete Mann ditch system in the Granite Creek watershed is a complex of ditches originally constructed in the late 1800s to deliver water to local mines. Currently, the ditch system delivers water to both mines and land irrigated for agriculture. The Pete Mann ditch system often completely diverts Lightning Creek, Salmon Creek, and the East Fork Clear Creek (all steelhead streams) into the Burnt River subbasin, a non-anadromous basin. Although the Forest Service did not rate change in peak/base flows, it is likely that this indicator is functioning either "at risk" or "not properly functioning" because of this ditch system.

Degraded water quality

The North Fork has the best chemical, physical, and biological water quality in the John Day subbasin as compared to ODEQ water quality standards (USDI 2000 cited in NPCC 2004). Most of the streams in this subbasin are considered in relatively good condition, with the exception of elevated late summer water temperatures that do not meet ODEQ standards (Table 8-23). Water temperature is primarily a concern in Cottonwood Creek, the lower North Fork John Day and lower reaches of Granite Creek. Because the North Fork (including its primary tributary, the Middle Fork) contributes 60% of the flow to the mainstem John Day (OWRD 1986), the influence of the North Fork on temperature is significant.

Leaching of toxic mine waste and a high degree of stream sedimentation from highly erodible, decomposing granitic soils also create water quality problems in the North Fork. Waste from abandoned mine sites may be having serious negative effects on water quality in the upper North Fork John Day and Granite Creek watersheds, where ODFW biologists have observed dead fish and adult spring Chinook with gill lesions (NMFS 2003; Wilson et al. 2005a). The cause of this mortality is not certain, but elevated iron and heavy metal concentrations may be a contributing factor. While recent surveys conducted by the UNF and U.S. Environmental Protection Agency indicate that mercury was not present in high enough concentrations known to cause these types of effects, conditions at abandoned mine sites and abatement ponds may change yearly, increasing the amount of heavy metals released (NMFS 2003). Hot geothermal springs also exist, but their effects on water quality are not fully known (NPCC 2005).

Table 8-23. North Fork John Day River subbasin 303(d) listed stream segments and water quality parameters of concern (ODEQ 2002 cited in NPCC 2005).

Blocked or impaired fish passage
Physical barriers in the Big Wall Creek and Granite Creek drainages are considered to be "functioning at risk" (NMFS 2003). Currently a number of culverts on forest land from partial passage barriers for steelhead (USFS 2001).

Degraded riparian communities and large wood recruitment
Much of the Upper North Fork watershed is designated as wilderness and is likely at or near benchmark condition. Riparian conditions are also likely near benchmark conditions in the Potamus and Stony watersheds where access and road densities are very limited. Riparian conditions are considered to be "functioning at risk" in the Big Wall and Granite watersheds. The active recent fire history has caused some changes in riparian conditions. Large fires in Desolation Creek, Upper North Fork John Day, and Granite Creek from 1986-1996 modified stream shade and sediment routing in some locations.

Table 8-24 provides information from EDT Diagnostic Report on limiting factors for each HUC5 occupied by the North Fork John Day steelhead population. A summary of limiting factors and threats by geographic area is presented in Table 8-25.

Population MaSA and MiSA	Major Limiting Factors	Sites Affected*	VSP Characteristics Impacted	Threats	Life Stages Affected
NORTH FORK JOHN DAY POPULATION					
North Fork John Day Population	degraded floodplain and channel structure (pools, connectivity, diversity); altered sediment routing; water quality (temp, toxic mine waste)	MaSAs and MiSAs	Productivity and abundance most affected; possible slightly altered spatial structure.	Riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, irrigation withdrawals, mining and dredging	Parr-to-smolt survival and egg-to-fry survival. All stages affected by toxic leaching in Granite Cr. and NF John Day R.
Lower Camas MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (temp)	Camas between Hideaway and Wilkins (T, F, CS, R, H, S	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads,	Parr-to-smolt survival and egg-to-fry survival.
Potamus MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (temp)	Potamus [T,S,F,CS]	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads,	Parr-to-smolt survival and egg-to-fry survival.
Big Wall MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (temp); altered hydrology	[H (lower), F, CS,S,T,IP,R]	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads,	Parr-to-smolt survival and egg-to-fry survival.
Upper NF John Day MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (toxic mine waste)	[WQ (mine sites), F,CS,S,]	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads, mining and dredging	Primarily parr-to-smolt and egg-to-fry survival. All stages affected by toxic leaching
Desolation MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (temp)	[F,CS,S,T]	Productivity and abundance most affected; slightly altered spatial structure	Livestock grazing, forest practices, roads,	Primarily parr-to-smolt and egg-to-fry survival.
Granite MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (toxic mine waste); altered hydrology	[H (Pete Mann ditch system), WQ (mine sties), F,CS, S,T,R]	Productivity and abundance most affected; possible slightly altered spatial structure	forest practices, roads, mining and dredging	Parr-to-smolt and egg-to-fry survival. All stages affected by toxic leaching
Cottonwood MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (temp); altered hydrology; degraded riparian communities	[H, IP (lower reaches), F,CS, S, WQ, R (biological criteria)]	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads, irrigation withdrawals	Primarily parr-to-smolt and egg-to-fry survival.
Owens MaSA	degraded floodplain and channel structure	[F, CS, S, T]	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads, irrigation withdrawals	Primarily parr-to-smolt and egg-to-fry survival.
Upper Camas MaSA	degraded floodplain and channel structure; altered sediment routing; water quality (temp)	[F, CS, S, T,]	Productivity and abundance most affected; possible slightly altered spatial structure	Livestock grazing, forest practices, roads	Primarily parr-to-smolt and egg-to-fry survival.

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F); degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), temperature (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.7 Middle Fork John Day River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for Middle Fork John Day steelhead are degraded floodplain and channel structure (key habitat quantity and habitat diversity), altered sediment routing, altered hydrology, and water quality (temperature).

Degraded floodplain connectivity and function
Channels have become disconnected from their floodplains in several areas of the Middle Fork John Day watershed (Malheur National Forest (MNF) 1999). A number of areas with very wide grassy valley bottoms historically were likely Rosgen E-channels but have been altered to type G and C channels by past overgrazing and road construction within floodplains (MNF 1999). Known areas with this condition include the mainstem Middle Fork John Day River, Squaw Meadow, Summit Creek and Squaw Creek near their mouths, and Olmstead Creek at Olmstead meadows. Floodplains along the Middle Fork and tributaries were also altered by mining operations.

Degraded channel structure and complexity
Tributaries to the Middle Fork that flow out of the Dixie Divide between the Middle Fork John Day and the Upper John Day are generally steep and incised in the lower reaches. Long, Squaw and Camp creeks flow through low-gradient meadow systems in the upper reaches. Tributaries that flow out of the Elkhorn Mountains to the north do not generally have meadow systems in their upper reaches, and the base rock is granite. Portions of Bridge, Dry Fork Clear, Crawford, Summit, and Squaw creeks have significant lengths of their channels impacted by streamside roads. EDT results identified habitat diversity and key habitat quantity as limiting factors in all major and minor spawning areas.

Mining operations have altered many of the stream channels and floodplains along the Middle Fork and its tributaries (MNF 1999). Alterations have occurred along Elk, Davis, Deep, Vinegar, Placer Gulch, Vincent, Caribou, Beaver, Granite Boulder, Big Boulder, Ragged, Butte, Ruby, and the Middle Fork mainstem. Some of the meadow areas have incised channels, including Phipps Meadow. Road construction has altered and constricted channels in many tributaries and along the Middle Fork mainstem. Log weirs, placed in lower Camp Creek, keep the channel from re-establishing its natural morphology.

Altered sediment routing
The BLM has identified sediment/turbidity and substrate embeddedness as "functioning at risk" in the Middle Fork John Day and a number of its tributaries (NMFS 2004/00383). EDT results identified sediment loading to be a significant limiting factor in the watershed. Excessive fine sediment problems are generally located in the Middle Fork mainstem (Unterwegner 2005). Poor riparian conditions, riparian roads, grazing activities, and past forestry, mining, and channel alterations all contribute sediment to streams in the watershed.

Altered hydrologic processes
The Middle Fork drainage is susceptible to rain-on-snow events capable of producing high volume, short duration run-off surges during the late winter and early spring months. Late

season base flows are sustained by slow release of water from the soil matrix, effluent groundwater, numerous wet meadows, and perennial springs (MNF 1999). Where channels have become entrenched, water tables are lowered and water storage capacity is reduced, resulting in lower base flows.

While low flows are a problem throughout the subbasin, irrigation withdrawals are not as significant as for some other populations in the John Day subbasin, or as significant as they were a few years ago. Most water rights in the upper Middle Fork subbasin are no longer being used for irrigating pastures. Four of the five largest water users above Highway 395 have converted their consumptive rights to instream rights for either the entire year or for the most critical low flow period. Three properties in the Middle Fork subbasin above Highway 395 continue to irrigate pastures with flood irrigation. One of the properties is located on Camp Creek, one is on the Middle Fork immediately above Camp Creek, and the other is near Galena.

Degraded water quality

Water quality in the Middle Fork subbasin generally exhibits satisfactory chemical, physical, and biological quality as compared to ODEQ water quality standards (USDI 2000 cited in NPCC 2005). The Middle Fork usually has worse water quality problems than its tributaries, with the most serious water quality problem being elevated summer temperatures. Season-long cattle grazing contributes to elevated fecal coliform counts during summer. However, agricultural runoff presents a low level of potential impact to water quality (NPCC 2001 cited in NPCC 2005). Flow from Bates Pond, an old mill pond on Bridge Creek less than 200 yards from its confluence with the Middle Fork, likely increases temperatures in the Middle Fork.

ODEQ has identified several streams in the Middle Fork subbasin as water quality limited for high temperatures, dissolved oxygen, or biological criteria, with the most serious water quality problem being elevated summer temperatures caused by vegetation disturbance, stream straightening/relocation, livestock grazing, forest practices, road building, irrigation water withdrawals, and historical mining and dredging (NPCC 2005). Table 8-26 provides data on listed stream segments in the Middle Fork subbasin.

Table 8-26. Middle Fork John Day River subbasin 303(d) listed stream segments and parameters of concern in 1998 and 2002 (ODEQ 2002).

Waterbody Name	River Mile	Parameter	Season	List Date
Big Creek	0 to 11.6	Temperature	Summer	1998
Camp Creek	0 to 15.6	Temperature	Summer	1998
Caribou Creek	0 to 3.6	Temperature	Summer	1998
Clear Creek	0 to 12.7	Temperature	Summer	1998
Coyote Creek	0 to 2.5	Temperature	Summer	1998
Crawford Creek	0 to 3.5	Temperature	Summer	1998
Davis Creek	0 to 6.8	Temperature	Summer	1998
Dry Fork Clear Creek	0 to 11	Temperature	Summer	1998
Granite Boulder Creek	0 to 8.1	Temperature	Summer	1998
Little Boulder Creek	0 to 2.1	Temperature	Summer	1998

Ragged Creek	0 to 4.1	Temperature	Summer	1998
Squaw Creek	0 to 9.4	Temperature	Summer	1998
Summit Creek	0 to 8.6	Temperature	Summer	1998
Summit Creek	0 to 8.6	Temperature	August 15 - July 15	2002
Unnamed Waterbody	0 to 2.4	Temperature	Summer	1998
Vinegar Creek	0 to 7.1	Temperature	Summer	1998

Poage et al. (1996) studied stream temperatures along the length of the Middle Fork John Day River and found they differed from other subbasins of the John Day River. The average stream temperature profile for the Middle Fork John Day River indicated that the pattern of water temperature was highly variable, with the highest average water temperatures observed at the upstream end of the study section. The authors hypothesized that the decrease in downstream temperature can be explained by cold-water inputs from cooler tributaries, including Clear Creek, and as the result of relatively cool groundwater seeping into the main stream channel (Poage et al. 1996).

Blocked or impaired fish passage

Currently a number of culverts on forest land form partial passage barriers for steelhead (Unterwegner 2005). In the past, numerous pushup dams and irrigation diversions in the upper Middle Fork and several of its tributaries created intermittent passage barriers; they also increased sedimentation, seasonally reduced flows, altered channels, and caused other water quality impacts. Many of these irrigation diversions have been converted to permanent, more fish passage friendly structures within the last ten years. Water diversions that are not properly screened to prevent intake of juvenile Mid-C steelhead may still exist in the system, particularly

on Long Creek and other tributaries of the lower Middle Fork (NPCC 2001 cited in NMFS 2004a).

Degraded riparian communities and large wood recruitment

Riparian corridors and levels of instream LWD have changed significantly from historical conditions. The reduction in large wood has resulted in fewer pools, increased stream velocities, reduced sediment trapping, and an overall reduction in channel diversity and key habitat (MNF 1999). Exceptions include the Clear Creek and Lunch Creek watersheds that contain high levels of woody material and good riparian conditions. Weir "hard structures" have been constructed in Camp, Lick, Squaw, Summit, Phipps, Dry Fork Clear creeks, and the lower portion of Clear Creek in an attempt to increase pool habitat and instream diversity (MNF 1999).

Table 8-27 provides information from EDT Diagnostic Report on limiting factors for each HUC5 occupied for the Middle Fork John Day River steelhead population. A summary of major limiting factors and threats by geographic area is presented in Table 8-28.

8.2.8 South Fork John Day River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for the South Fork John Day River steelhead population are altered sediment routing, degraded floodplain and channel structure (key habitat quantity and habitat diversity), altered hydrology, water quality (temperature) and blocked or impaired fish passage.

Degraded floodplain connectivity and function
While the extent of floodplain connectivity has not been measured, ODFW considers this attribute as not properly functioning in sections of Murderers Creek below Cabin Creek. New beaver dams are contributing to improving off-channel habitats.

Degraded channel structure and complexity
Loss of beavers, active LWD debris removal projects, road construction, riparian timber harvests, and poor grazing management have accelerated water runoff and instream velocities in the South Fork system and led to increased channel and bank erosion, with incised and unstable channels (MNF 1997). Current stream bank surveys on the lower 14.6 miles indicate that the banks of Murderers Creek are between 98 and 100% stable. A riparian fence protects the stream bank along this reach except for in six water gaps used by cattle. Stream surveys conducted by ODFW in 1960 and the Malheur National Forest in 1997 showed that most reaches of Murderers Creek were deficient in LWD. Lower reaches of Murderers Creek are likely still deficient in LWD, but this condition is expected to improve as riparian vegetation recovers within the fenced riparian areas. Murderers Creek currently has few braided channels and backwaters. As the water drops in the summer, braiding and backwaters are reduced and flow is restricted to the channel. During low water and periods of high stream temperatures, distribution of juvenile steelhead is limited to cool water areas. Today, pool habitat is closer to benchmark conditions in the South Fork than generally found in the tributaries (Unterwegner 2005). There is more beaver activity in the creek than in the 1960s and the riffle-pool ratio has likely improved.

Altered sediment routing
Results from properly functioning condition (PFC) assessments conducted by the Malheur National Forest in 2004 in the South Fork and tributaries showed that sediment conditions in pool and riffle habitats were generally "not properly functioning" (MNF 2004). The MNF (2004) also noted that ongoing management of the existing road network associated with Reach 1 of Deer Creek is continuing to contribute excess gravel to the channel. The Forest Service lands within Deer Creek HUC5s have road densities of 4.14 miles of road/mile^2. This high road density may contribute to elevated sediment levels and embedded substrates in the South Fork and its tributaries.

The MNF (2004) also collected substrate embeddedness data for 40 streams in the South Fork watershed that showed substantial problems with embeddedness throughout the watershed. Out of 26 summaries, 21 were found to have more than 50% of the unit embedded (MNF 2004).

Roads might be the single most important threat causing the increases in sedimentation of streams (MNF 1997) because of density, location, and maintenance. Road densities on Forest Service lands in various HUC5s of the South Fork drainage are; 2.75 miles/mile² in Murderers Creek; 4.14 miles/mile² in Deer Creek; 4.25 miles/mile² in Middle South Fork; and 3.27 miles/mile² in Upper South Fork. The most heavily roaded areas are coincident with sedimentary soils in the upper watershed (MNF 1997). Surveys from 1992 to 1997 identified a number of reaches in the Murderers Creek watershed that were contributing excessive sediment to stream channels including, Beaver and North Fork Beaver, Miner, Grapefruit, Orange, Charley Mack, South Fork Murderers, Bark Cabin, Murderers (reach between Stewart's Cabin and Murderers Creek Guard Station), Oregon Mine, and Tennessee creeks.

Altered hydrologic processes
Livestock grazing, logging, road construction, beaver removal and fire suppression have all contributed to changes in peak/base flows in the South fork drainage. Further changes in the area's hydrology resulted from intensive stream channelization, flow modifications and drainage (including some tiling of drainage ditches) projects in the South Fork between 1943 and 1951. Irrigation withdrawals also reduce summer low flows in some reaches; however, overall, irrigation withdrawals and agricultural impacts in steelhead occupied reaches of the South Fork drainage are not as significant as for Upper Mainstem John Day or Lower John Day steelhead populations.

Low-flow conditions in Murderers Creek and other South Fork tributaries may limit the use of some potential spawning areas, even in unaltered habitat, due to the lack of water in early summer months. In some years, flows fall below recommended levels for successful spawning in Murderers Creek as early as May. Water temperatures and unsuitable habitat associated with naturally occurring low water conditions in Murderers Creek likely alter or temporarily block movement of juveniles during summer months (Harcombe and Unterwegner 2005).

Tributaries such as Black Canyon remain a source of good quality, cool water to the mainstem South Fork. The loss of beaver in the John Young Meadows in the upper South Fork Murderers Creek, where beavers were very active historically, has reduced the water storage capacity and led to entrenched channels downstream of the meadows (MNF 1997). MNF (1997) describes the Murderers Creek watershed as having a higher density of springs than most of the Bear Valley Ranger District. However, many of the tributaries flow only intermittently during the summer.

Degraded water quality
Elevated water temperatures during the summer months are considered a major limiting factor in the South Fork John Day River, Deer Creek, North Fork Deer Creek and Murderers Creek. All four streams are on the ODEQ's 303(d) list (ODEQ 2000). Monitoring by the stream gage near the mouth of Murderers Creek shows that water temperatures exceed 64ºF, 54% of the time (65 days out of 122 days) between July 1 and September 30, averaged over the 5-year period (ODFW 2005a). Elevated stream temperatures are also a problem in other major tributaries. Water withdrawals and agricultural impacts above Izee Falls contribute to water quality problems in occupied reaches of the lower South Fork (Unterwegner 2005).

Blocked or impaired fish passage

Izee Falls, at RM 28.5, is a complete natural block to steelhead migration. Water diversion structures and thermal barriers restrict juvenile steelhead passage at times. Irrigation withdrawals can also hinder upstream adult migration during late spring in very low water years.

Degraded riparian communities and large wood recruitment

Riparian areas are typically managed as part of range operations, and many have been altered from their natural state by water diversions, channelization, vegetation changes and the like (NPCC 2005). Grazing activities on the forest and private lands have impacted riparian functions by reducing or eliminating native plant communities, altering soil conditions and infiltration rates (MNF 1997; Kauffman 2004). Private, state and Federal forest practices have also altered riparian vegetation. These activities have reduced instream large wood concentrations and the potential for future large wood contributions. The MNF (2004) measured LWD in the South Fork watershed. Out of 28 streams, 15 streams met NMFS criteria of >20 pieces per mile of LWD >35 feet in length.

Table 8-29 provides information from EDT Diagnostic Report on limiting factors for the South Fork John Day River steelhead population. A summary of major limiting factors and threats by geographic area is presented in Table 8-30.

8.2.9 Upper Mainstem John Day River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for the Upper Mainstem John Day River steelhead population are degraded floodplain and channel structure (key habitat quantity and habitat diversity), altered sediment routing, water quality (temperature) and altered hydrology. Impaired fish passage is also a priority limiting factor for Beech and Laycock creeks.

Degraded floodplain connectivity and function
There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows. Degraded floodplain connectivity and function has led to more extreme flows and summer water temperatures.

Degraded channel structure and complexity
EDT results rated key habitat quantity as either a high or medium priority restoration need for all areas of the Upper Mainstem John Day River population and habitat diversity ranked as either a medium or low priority restoration need in all Upper John Day reaches (NPCC 2005). In addition, the Malheur National Forest rated LWD conditions and potential recruitment as "functioning at risk" in their Environmental Baseline for the Upper John Day (MNF 2004). Levels of big LWD are well below benchmark conditions for all areas outside wilderness boundaries (Unterwegner 2005, personal communication). Beech, Laycock, Fields, and Strawberry creeks are areas where restoration needs are highest for key habitat quantity and habitat diversity. Removal of beaver and their associated dams has reduced habitat complexity, floodplain function, and the amount of stored water. Livestock grazing has contributed to increased channelization, reductions in LWD, cover and bank stability, particularly in lower reaches of tributaries.

Altered sediment routing
Canyon Creek has a large supply of spawning gravels, with most good spawning habitat in upper meadow reaches. However, surveys of substrate embeddedness for the Upper John Day watershed show that, for measured streams, more than 50% of their summaries showed >35% embeddedness. Substrate embeddedness is a problem in 5 of 8 Canyon Creek reaches measured and 10 of 32 mainstem John Day reaches measured (MNF 2004).

Altered hydrologic processes
The upper John Day River experienced intensive stream channelization, flow modifications and drainage (including some tiling of drainage ditches) projects between 1943 and 1951. These and other activities altered the routing and timing of water delivery to streams; often increasing peak flows and reducing summer low flows. Irrigation withdrawals further reduce summer low flows, especially considering that the vast majority of the irrigation is from surface waters of the John Day and its tributaries (NPCC 2005). Livestock grazing, logging, road construction, beaver removal and fire suppression have all contributed to altered flow regimes. Today, summer low streamflows are below what would have existed historically. Water withdrawals dewater the lower reaches of Pine, Strawberry, Indian, Riley, Moon, McClellan, Laycock, and Fields creeks.

Degraded water quality
Water quality is fair in the upper watershed during most of the year, as compared to ODEQ water quality standards (USDI 2000 cited in NPCC 2005). Low summer flows on the mainstem John Day River above Dayville contribute to elevated temperatures; higher streamflows during the winter/spring and streambank erosion contribute to turbidity. Problematic eutrophication in the mainstem John Day River is a partial result of irrigation return flow and possibly cattle feedlots (NPCC 2001 from NPCC 2005). Table 8-31 lists stream segments within the Upper John Day watershed included on ODEQ's 303(d) list. Elevated stream temperatures are common to almost all the streams in the Upper John Day watershed. Historical mining has added to water quality problems by removing riparian vegetation, simplifying stream channels and changing stream substrate composition, all of which contribute to increased water temperatures.

Table 8-31. Upper John Day River watershed 303(d) listed stream segments and parameters of concern (ODEQ 2002). Waterbodies that are listed multiple times represent different locations and/or different life stages.

Blocked or impaired fish passage

Strawberry Creek has numerous unscreened ditches that may strand fish. Water withdrawals dewater the lower reaches of Pine, Indian, Strawberry, Moon, Laycock, McClellan, Riley, and Field creeks and create passage problems for juvenile fish. Diversions and low flows in Strawberry Creek create passage problems for adults as well. Push-up dams and other irrigation structures throughout the Upper John Day watershed often obstruct or delay fish passage. Culverts on national forest, state, county and private lands also create passage barriers in many areas. EDT results identified obstructions as high priority restoration needs in Beech and Laycock creeks**.** Panama Ditch crosses Beech Creek approximately one mile above its convergence with the John Day River forming a juvenile passage barrier, and possibly an adult barrier, at certain flows. High water temperatures in numerous tributaries and portions of the mainstem alter or sometimes block juvenile steelhead movements in the summer months.

Degraded riparian communities and large wood recruitment

Riparian conditions are generally degraded in the Upper John Day watershed. Roads along riparian corridors have altered riparian functions; the Malheur National Forest has identified 123.8 miles of roads within RHCAs in the Upper John Day watershed (MNF 2004). Forest practices on private and public lands have altered riparian vegetation and reduced LWD recruitment potential. Grazing activities on the forest and private lands have reduced or eliminated native plant communities, altering soil conditions and infiltration rates (Kauffman 2004).

Table 8-32 shows the primary limiting factors identified in the EDT Diagnostic Report for the Upper Mainstem John Day population. A summary of major limiting factors and threats is presented in Table 8-33.

Table 8-32. Limiting factors and priorities for protection and restoration as defined by EDT for the Upper Mainstem John Day River steelhead population.

1/ "Channel stability" applies to freshwater areas only.

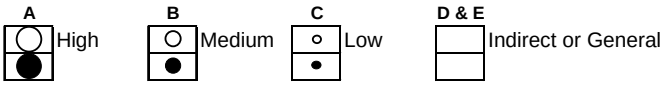

Table 8-33. Habitat limiting factors summary for the Upper Mainstem John Day River steelhead population.

Population MaSA and MiSA	Major Limiting Factors	Sites Affected*	VSP Characteristics Impacted	Threats	Life Stages Affected
UPPER MAINSTEM JOHN DAY POPULATION					
Upper Mainstem John Day Population	Degraded floodplain and channel structure (loss of cover, pools, LWD, overall habitat diversity, connectivity); water quality (temp);altered sediment routing; degraded riparian communities; altered hydrology; impaired fish passage	MaSAs and MiSAs	Productivity, abundance, spatial structure.	Agricultural practices, livestock grazing, removal of large trees from riparian corridor, wetland draining and conversion, stream channelization and diking, mining and dredging, irrigation withdrawals	Juvenile rearing, egg incubation, egg-to-parr survival, spawning
Up. John Day MaSA	Degraded floodplain and channel structure; altered hydrology; water quality (temp); altered sediment routing; degraded riparian communities; impaired passage	Mainstem and tribs [F,CS, S, H, T); Strawberry [H (lower), F,CS]; Pine [H (lower)}; Indian [H (lower)]; IP (pushup dam sites	Productivity, abundance, spatial structure.	Agricultural practices, livestock grazing, irrigation withdrawals, beaver removal, roads	Juvenile rearing, egg incubation, egg-to-parr survival, spawning
Beech MaSA	Degraded floodplain and channel structure; altered hydrology; water quality (temp); altered sediment routing; impaired passage	IP (Panama Ditch), F,CS (lower reaches, next to Hwy 395), H (lower reaches of Riley, Moon, McClellan, Laycock and Fields crs.); S,T	Productivity, abundance, spatial structure.	Hwy 395, forest roads, irrigation withdrawals, livestock grazing	Juvenile rearing, egg incubation, egg-to-parr survival, spawning
Canyon MaSA	Degraded floodplain and channel structure; altered hydrology; water quality (temp); altered sediment routing	F,CS (Hwy 395, forest roads), S,T,H	Productivity, abundance, spatial structure.	Hwy 395, forest roads, irrigation withdrawals, livestock grazing	Juvenile rearing, egg incubation, egg-to-parr survival, spawning

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F); degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), temperature (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.10 Umatilla River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for the Umatilla River steelhead population are water quality (temperature), sediment routing dysfunction, blocked and impaired fish passage, degraded floodplain and channel structure (key habitat quantity and habitat diversity) and hydrologic alterations.

Degraded floodplain connectivity and function

Intensive land uses within Umatilla subbasin flood plains and upslope habitats have led to dramatic changes in waterway characteristics since arrival of Euro-American pioneers to the area during the middle 1800's. Dikes, levies, and roads border many streams in the subbasin and limit connectivity between streams and their floodplains.

Degraded channel structure and connectivity

The mainstem Umatilla River from Wildhorse Creek to the forks and sections of 17 tributaries of the mainstem are 303(d) listed because of habitat (including substrate) problems. Habitat benchmarks developed by ODFW were used to list stream reaches based upon standardized habitat surveys (Moore et al.1999 cited in NPCC 2004c). Parameters measured in these surveys include habitat features known to be important to salmonids such as presence and amount of large woody debris, pool frequency, presence of eroding streambanks, type of riparian vegetation, stream channel form and pattern, and the proportion of the substrate composed of fine materials. Key habitat quantity and habitat diversity are also identified as medium impact limiting factors that are pervasive throughout the subbasin. Channel stability is frequently noted as a low impact limiting factor.

Overall, instream habitat has been simplified and pool habitat has decreased. Some stream reaches have been channelized in agricultural fields to prevent flooding of fields and natural channel movement into fields. Channelization greatly decreases winter habitat (e.g., braided channels, sloughs) for juvenile salmon and steelhead. This habitat is very important for overwinter survival and juvenile growth. The loss of this type of habitat in the Umatilla River and its tributaries is thought to be one of the most significant causes of the reduction in naturally surviving salmonid and steelhead (personal communication: C. Contor, CTUIR, April 2004 cited in NPCC 2004c). Other primary causes of low habitat diversity/complexity include past forest practices that removed conifers from riparian areas, and the ongoing removal of LWD from streams to prevent flooding and streambank erosion.

Altered sediment routing

The Umatilla River receives large amounts of sediment, much of which originates from weathered basalt and unconsolidated loess deposits — the dominant geology in the subbasin. Primary sources include bank and upland erosion of tributaries and tributary watersheds, which may be accelerated by land uses (ODEQ et al. 2001). Peak sedimentation usually occurs during rainstorms or snowmelts associated with freeze and thaw periods (CTUIR and ODFW 1990).

The entire Umatilla mainstem from the mouth to the forks is 303(d) listed for either sediment or turbidity. One sediment-impaired stream segment that significantly deviated from the target standard for turbidity was Wildhorse Creek (at its confluence with the Umatilla River) that had a peak turbidity value of over 5,000 nephelometric turbidity units (NTU) measured on April 23,1997. High levels were also measured in McKay Creek. Wildhorse Creek turbidity mainly results from spring runoff, while McKay's turbidity is mostly a result of bottom withdrawal of water from the reservoir for flow augmentation. Composite samples of turbidity, collected at various stations during the winter of 1997-1998, show that Tutuilla, Birch, and five sites on the Umatilla mainstem exceeded standards on numerous occasions (ODEQ et al. 2001).

Surveys conducted by ODFW and CTUIR throughout the Umatilla River subbasin found that 19 of 42 stream reaches had fine sediment as the dominant substrate (Boyd et al.1999 cited in NPCC 2004c). In the Patawa/Tutuilla watershed, fine sediment made up the dominant substrate in 9 of 19 reaches surveyed (Watershed Professionals and Duck Creek Associates 2003 cited in NPCC 2004c). Substrate sediment is less of a problem in the upper Umatilla subbasin; a survey of the upper Umatilla River and Meacham Creek by the Umatilla National Forest (2001) in

which substrate embeddedness was measured directly found that only two sub-watersheds of 18 had embeddedness levels greater than 35% (a level of embeddedness considered detrimental to salmon) (NPCC 2004c). EDT analyses also showed that sediment is a large limiting factor in many areas of the Umatilla, especially in Butter and Wildhorse creeks, in the lower reaches of the Umatilla, and in reaches of Umatilla mainstem from Mission Bridge to Meacham Creek.

Altered hydrologic processes

Flow patterns observed in the Umatilla/Willow subbasin are the result of snow melt and rain in late winter and early spring that cause peaks in flow. Water runoff peaks in April, while base flows generally occur in September. The average monthly discharge of the Umatilla River near its mouth (measured at RM 2.1) varies from 23 cfs in July to 1,095 cfs in April (low flow at the mouth occurs in July rather than September because of upstream removals for irrigation). Summer baseflows can be extremely low and many of the larger tributaries lose all surface flow during the summer through parts of their lengths. Flows in sections of Birch, McKay, Butter, Meacham, Wildhorse and Iskuulpa creeks are subsurface during low flow periods (ODEQ 1998 cited in NPCC 2004c).

Past evaluations of the Umatilla River have identified summer low flows as a primary limiting factor to salmonid natural production throughout all life stages (Boyce 1985, Contor et al. 1995, and CTUIR 1994 cited in White et al. 2004). EDT identifies flow as either a medium or low impact limiting factor in almost all reaches of the Umatilla subbasin.

Fluctuation of flows related to Umatilla Basin Project operations, for both the winter-spring storage and spring-fall release periods, is identified as a possible concern for juvenile steelhead and the food web on which they depend (BOR 2001). Significant fluctuations in flows on a weekly, daily, or even hourly basis may cause cyclic dewatering and rewatering of near shore habitats, riffles, and pools, which reduces biotic productivity and strands salmonid fry (BOR 2001), particularly in McKay Creek. Currently, there are six major irrigation diversions in the lower Umatilla River that withdraw approximately 129,000 acre-feet on an average year (Umatilla River Subbasin Local Agricultural Water Quality Advisory Committee et al. 1999). The irrigation withdrawals dewater the river below Dillon Dam, resulting in an average daily flow over a 14-day period of less than 1 cfs.

During late spring through late fall (April to November), water is released from McKay Reservoir to supply water for irrigation and instream uses. Summer discharge has more than tripled from RM 52.0 to 27.2 since the early 1900s; however, the river has been virtually de-watered from RM 27.2 to the confluence with the Columbia River (White et al. 2004). Streamflows below McKay Dam fluctuate greatly depending on flood water releases, irrigation releases, and other operations from McKay Reservoir (BOR 2001). BOR modeling results indicated that these water releases would increase Umatilla River flows. The model predicted that water releases in the late spring would aid juvenile steelhead in their out-migration, and that water releases in the summer and fall would aid juvenile summer rearing and adult upstream migration. The model also predicted that increased flows would connect pool and riffle habitat, increase the width and depth of flow, and improve velocity, water temperature, rearing space, and food production. Despite these predictions, however, actual July and August streamflows in the lower Umatilla River fall well below the recommended levels, with or without the operation

of the Umatilla Basin Project, and often dewater the lower three miles of the Umatilla River completely from July 1 to August 15. These conditions delay steelhead entry into the Umatilla Subbasin (BOR 2001; ODEQ et al. 2001).

Degraded water quality

Summer water temperatures in the lower Umatilla River frequently exceed the incipient lethal limit for salmonids of 21°C (ODEQ et al. 2001; White et al. 2004). Water temperature is a concern throughout most of the Umatilla subbasin during periods of low flow (May until early November). On the 1998 303(d) list, 287 miles of the Umatilla River and its tributaries were listed as impaired for elevated water temperatures including the entire mainstem Umatilla River (ODEQ et al. 2001 cited in NPCC 2004c) (Table 8-34). The highest water temperatures have been recorded in late July and early August when ambient air temperatures are high. During this period, the Umatilla River warms rapidly from the headwaters to the mouth, reaching sub-lethal (64-74°F, 20-23°C) and incipient lethal temperatures (70-77°F, 21-25°C) for its entire length (Boyd et al.1999; Contor and Crump 2003 cited in NPCC 2004c). White et al. (2004) noted that during 2002, mean weekly water temperature at RM 2.1 on the Umatilla River ranged from 39.2°F to 88.5°F. Daily mean water temperatures exceeded 75.2°F for 55 days in 2002, with 31 of those days at or above 82.0°F (White et al. 2004). Many of its tributaries also reach sub-lethal and incipient lethal ranges for salmonids (Boyd et al.1999; CTUIR 2004).

Water releases from McKay Reservoir during summer generally cool temperatures in reaches of the Umatilla River below the McKay Creek confluence (RM 50.5). Surveys determined that hypolimnetic releases of cool water from the reservoir during early summer months kept temperatures suitable for salmonids in areas between the McKay Creek confluence and Westland Dam (RM 27.2) (Contor et al.1997 cited in NPCC 2004c). However, releases from McKay Reservoir for fish are not made from July 1 to approximately September 15, though water is released to provide for irrigation. In addition, warmer epilimnetic waters can be discharged upon the depletion of the hypolimnion and can contribute to unsuitable habitat conditions for salmonids (Contor et al.1997 cited in NPCC 2004c).

The Umatilla subbasin's coolest mid-summer recorded temperatures are in the North Fork of the Umatilla River, where maximum summer temperatures usually do not exceed the state standard of 64°F (17.8°C). For example, in the summer of 2002, maximum water temperature in the North Fork did not exceed 60.8°F (16.0°C) (Contor and Crump 2003 cited in NPCC 2004c). The South Fork of the Umatilla River experiences higher summertime temperatures often above 64°F, though rarely above 70°F. Data indicate a significant increase (approximately 5° F) in temperature from the Umatilla River east of the Gibbon site (RM 80.0) to the Umatilla River at Cayuse Bridge (RM 69.4). This increase in temperature is attributed to Meacham Creek that enters the Umatilla Mainstem at RM 79. Summer water temperatures in Meacham Creek are frequently in the high 60s ºF. However, maximum summer temperatures drop further downstream (at RM 50) as a result of cold water releases from McKay Reservoir.

Wildhorse Creek is one of the warmest tributaries of the Umatilla River. This drainage regularly experiences excessive summertime stream temperatures throughout the entire stream length. Headwaters often exceed 70˚F for long periods in the summer, while lower Wildhorse Creek can often experience stream temperatures exceeding 85˚F.

The lower Umatilla River and the North Hermiston Drain are in violation of EPA ammonia standards, primarily because of excessive temperatures and pH during the summer months (ODEQ et al. 2001). Other problem areas include Butter Creek, where ammonia concentrations have been measured at 0.3 to greater than 0.4mg/L (ODEQ 1998).

Excessive growth of attached algae (periphyton) and attendant increases in pH are common during summer months throughout much of the mainstem Umatilla River (from Speare Canyon, RM 44, to the forks) (ODEQ et al. 2001). Large periphyton mats can be found in this section of the Umatilla River in the summer, affecting river odor, aesthetics, contact recreation, and pH. As periphyton obtains carbon dioxide for cell growth it decreases bicarbonate levels in the water. This has the effect of increasing pH levels that can be stressful to fish. Because periphyton growth is positively influenced by water temperature, patterns in summer water pH are influenced by water temperature. pH increases from the forks to RM 58, where it frequently exceeds 9.0 (the water quality standard); pH drops at RM 49 because of inputs of cold water from McKay Reservoir and then increases downstream where it routinely exceeds the water quality standard at Yoakum Bridge (RM 37.2)(ODEQ et al. 2001 cited in NPCC 2004c). Elevated summertime temperatures and excessive algal growth are also likely contributors to high pH levels recorded in Willow Creek, from the mouth upstream to Heppner.

Table 8-34. Impaired stream reaches from the 1998 303(d) list and used for development of the 2001 Umatilla Subbasin TMDL (ODEQ et al. 2001).

Blocked or impaired fish passage

In the Umatilla River subbasin, 36 barriers were identified in the Umatilla Subbasin Plan and these are listed in Table 8-35, along with their priority for removal. While it is not mentioned in the list, McKay Dam was not designed to include fish passage facilities, and blocks steelhead and salmon access to approximately 108 miles of highly productive tributary habitat in upper McKay Creek (CTUIR 2001). Historical abundance of steelhead in McKay Creek is unknown, but CTUIR tribal members report that a high number of steelhead spawned in McKay Creek before the construction of McKay Dam and Reservoir in 1927 (CTUIR 2001).

A number of significant passage barriers remain, particularly in Birch, and Butter creeks. Unscreened water diversions can also have a substantial impact on anadromous fish. All known gravity feed diversions in steelhead habitat areas of the Umatilla subbasin are screened, but it is not known to what extent pump diversions have been screened in the habitat areas.

Table 8-35. Barriers to upstream passage on streams in the Umatilla River Subbasin.

Degraded riparian communities and large wood recruitment

Riparian vegetation on the mainstem Umatilla River and many tributaries is in poor condition, with 70% of 422 miles inventoried identified as needing riparian improvements (CTUIR and ODFW 1990 cited in NPCC 2004c). Losses of riparian vegetation are particularly high in the lower subbasin; Kagan et al. (2000) estimated these losses at greater than 95% as compared to pre-settlement conditions (c. 1850).

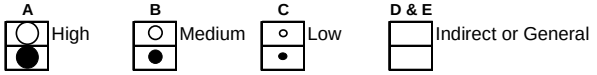

Table 8-36 shows key limiting factors for Mid-C steelhead in the Umatilla River drainage based on EDT findings. Table 8-37 summarizes major limiting factors and threats.

Table 8-36. Limiting factors and priorities for protection and restoration as defined by EDT for Umatilla River summer steelhead population.

UMATILLA RIVER POPULATION					
Upper Umatilla MaSA	Water quality (temp); degraded floodplain and channel structure (diversity/complexity); altered sediment routing; impaired fish passage		Abundance, productivity, spatial structure and diversity	Agricultural cultivation and practices, livestock grazing, water storage and diversion, Union Pacific railroad, roads, forest practices, flood control	All life stages
West Birch MaSA	Impaired fish passage; altered sediment routing; degraded floodplain and channel structure	West Birch Cr. [T and S (mouth to headwaters); IP (irrigation dams- RM 1, 3.5, 5.5, 8.5; bridge – RM 3.8)] Bridge Cr. [BP (culvert – RM 2)]	Abundance, productivity, spatial structure and diversity	Agricultural cultivation and practices, livestock grazing, water storage and diversion, forest practices	All life stages

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F); Degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), temperature (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.2.11 Walla Walla River Population, Tributary Habitat Limiting Factors

The primary tributary habitat limiting factors identified by the recovery planning team for the Walla Walla River steelhead population are water quality (temperature), altered sediment routing, blocked and impaired fish passage, degraded floodplain and channel structure (key habitat quantity and habitat diversity) and flow.

Degraded floodplain connectivity and function
Land use activities within the Walla Walla Subbasin including flood plains and upslopes have dramatically altered connectivity between the river channel and the floodplain. Dikes, levies, roads and channels exist throughout the subbasin and separate the channel from the floodplain.

Degraded channel structure and complexity
Habitat complexity is generally reduced or absent in the lower reaches of the Walla Walla River, particularly in channelized areas. Habitat complexity in headwater areas of some streams, including the South Fork, North Fork, and Mill Creek is close to or at properly functioning condition. The lower reaches of these tributaries, particularly in areas of agricultural or urban development, have poor habitat complexity due to a lack of pools and LWD.

Altered sediment routing
EDT analyses for streams occupied by this population indicate that elevated fine sediment levels in stream substrates are present, particularly in the lower reaches. Land management activities such as agriculture and road building add fine sediment to streams and reduced high flows can interrupt normal sediment flushing events.

Altered hydrologic processes
The runoff pattern in the Walla Walla River subbasin generally consists of high flows from November through May and low flows from June through October. The spring snowmelt flood period usually extends from about the first of March through the end of May, but peak discharges resulting from snowmelt runoff rarely result in damaging stages. In the past, winter flood peaks in the period of December through February have been responsible for flash-flood damage, caused by intense rainfall occurring on ground with high soil moisture content or by warm temperatures and rainfall on snow and frozen ground. (USACE 1997).

The Walla Walla River valley is extensively and intensively irrigated (NPCC 2004d). Primary water sources include the Touchet and Walla Walla rivers, East-West Canal, Gardena Canal, Lowden Canals, gravel aquifers, and the underlying basalt aquifer system (NPCC 2001, 2004d). Water diversions reduce flows in some reaches of the river and principle tributaries; lower Mill Creek and Walla Walla River near the border of Oregon and Washington have been completely dewatered in the past (NPCC 2004d). An increasing number of shallow individual domestic wells resulting from urban sprawl also pose a very real and significant deterrent to full utilization of the available water resources in the underlying aquifer (NPCC 2001, 2004d).

Degraded water quality
High water quality in the upper Walla Walla drainage generally degrades in lower elevations (NPCC 2001, 2004c). Temperature is a primary concern, with much of the lower Walla Walla remaining above 20°C (68°F) for most of the summer (NPCC 2001, 2004d). In Oregon, the Walla Walla River, North and South Forks of the Walla Walla River, and Mill Creek were all listed as 303(d) water quality limited for temperature in 2002 (ODEQ 2002). Sediment also reduces water quality as rain on frozen snow events in winter and spring often lead to high surface erosion in agricultural lands (NPCC 2001, 2004c).

Blocked or impaired fish passage
There are several total or partial fish passage barriers in the streams occupied by this population. Table 8-38 shows barriers to upstream passage in the subbasin for the Walla Walla steelhead population; however, the accuracy of the list is unknown because there has not been a comprehensive on-the-ground inventory of passage barriers in the subbasin. Obstructions are caused by low streamflow and channel spawning diversion structures and dams. Some culverts also act as fish passage barriers.

Table 8-38. Barriers to Upstream Passage on Streams in the Walla Walla Subbasin within the Area Inhabited by the Walla Walla River steelhead population. This list is based on a combination of archived records and field observation.

Degraded riparian communities and large wood recruitment

Vegetative conditions in the Walla Walla subbasin reflect land use practices. Historically, extensive riparian zones existed along streams in the Walla Walla subbasin (USACE 1997). Along the Oregon portion of the river, 70% of the existing riparian zone is in poor condition (Water Resources Commission 1988 cited in USACE 1997). Where steppe grassland vegetation communities once existed in the valley, crops and invasive plant species have largely replaced them.

Table 8-39 shows key limiting factors for Mid-C steelhead in different parts of the Walla Walla drainage based on EDT findings. A summary of major limiting factors and threats is presented in Table 8-40.

* Abbreviations for limiting factors: degraded floodplain connectivity and function (F); degraded channel structure and complexity (CS); degraded riparian communities (R); altered hydrology (H); degraded water quality (WQ), temperature (T); altered sediment routing (S); man-made block to migration (BP); impaired fish passage (IP).

8.3 Mainstem and Tributary Hydrosystems

This section describes direct and delayed effects of mainstem and tributary hydropower projects on Mid-C steelhead originating from the Fifteenmile Creek and the Deschutes, John Day, Umatilla and Walla Walla rivers. It describes how configurations and operations of the Federal Columbia River Power System affect the abundance and productivity of Mid-C steelhead juveniles and adults. This includes a discussion of how current actions under NOAA Fisheries 2004 FCRPS BiOp affect the juvenile and smolt-to-adult return of steelhead populations as well as factors related to species recovery. The section also discusses how tributary hydropower

projects in the Deschutes, Umatilla and Walla Walla rivers subbasins influence steelhead viability.

8.3.1 Mainstem Hydropower Configurations and Operations

The FCRPS consists of 19 sets of dams, powerhouses, and reservoirs, operated as a coordinated system for power production and flood control by the Federal Action Agencies (i.e., USACE, USBR, and BPA) under various Congressional authorities. The principle projects are: Dworshak, Lower Granite, Little Goose, Lower Monumental, and Ice Harbor dams, power plants, and reservoirs in the Snake River basin; Albeni Falls, Hungry Horse, Libby, Grand Coulee and Banks Lake (features of the Columbia Basin Project), and Chief Joseph dams, power plants, and reservoirs in the upper Columbia River basin; and McNary, John Day, The Dalles, and Bonneville dams, power plants, and reservoirs in the lower Columbia River basin.

Development and operation of the mainstem Columbia hydropower system dramatically alters travel conditions in the mainstem Columbia River, resulting in delayed upstream passage (adults), downstream passage (juveniles), and direct and indirect mortality for downstream migrants (juveniles). The hydropower system also changes the hydrograph; depleting historically available nutrients, increasing water temperatures, and degrading rearing and food resources for both presmolts and smolts in the Columbia River. Changes in the hydrograph leave steelhead more vulnerable to bird and pinniped predation in the mainstem and Columbia River estuary. These impacts increase somewhat for each population in direct relation to the number of dams that fish must pass during their migration to and from the Pacific Ocean. Mid-C steelhead populations pass one to four Columbia River dams: the Fifteenmile Creek population passes one dam; Deschutes River populations pass two dams; John Day River and Umatilla River populations pass three dams; and the Walla Walla River population passes four dams).

Legacy and Current Effects of Hydropower System
Hydropower development and operation in the Columbia Basin has reduced productivity, restricted salmonid migrations, altered habitats, and increased predation on and competition between juvenile salmonids. The hydropower system affects the following factors:

> **Loss of population traits and productivity:** Low adult abundance attributable to direct mortality of downstream migrant smolts at a dam, or to direct mortality or delayed passage of upstream migrant adults at a dam. Selective mortality resulting in non-normative changes in genetic and phenotypic characteristics. Reduction and possible elimination of iteroparity due to high mortality of kelts attempting to return to the ocean.
>
> **Impaired habitat access:** Impaired access to spawning and rearing areas upstream from a dam, or restriction of spawning and rearing to sub-optimal areas downstream from a dam.
>
> **Degraded habitat quality and quantity:** Modification of riverine habitat into impoundments results in changes in habitat availability, migration patterns, and feeding ecology. Downstream migration is significantly slower through impoundments. Food webs are different in the impoundments than in natural rivers.

Increased predation: Ecosystem alterations attributable to dams led to increased predation by native and introduced fish species on naturally produced juveniles. Other fishes, including northern pikeminnow, walleye, smallmouth bass, and salmonids, prey on juvenile salmonids. Modification of the Columbia River hydrosystem and estuarine habitat also led to increased predation by pinnipeds and birds on adult and juvenile salmonids.

Degraded water quality: Flow regulation and reservoir construction have increased average water temperatures beyond optimums for salmonids in the lower Columbia River. High water temperatures can cause migrating adult steelhead to stop or delay their migrations. Warm temperatures can also increase the fishes' susceptibility to disease. Flow regulation and reservoir construction also have increased water clarity that can affect salmonids through food availability and susceptibility to disease. Water can become supersaturated with atmospheric gases, primarily nitrogen, when water is spilled over high dams and this has resulted in significant salmonid mortality. Temperature changes influence physiological transition and seawater readiness of migrating smolts.

Altered hydrograph/water quantity: Changes in flow patterns affect steelhead migration and survival directly and indirectly. Juvenile and adult migration behavior and travel rates are related to river flow. Flow fluctuations stimulate or delay juvenile emigration or adult migration, thereby affecting the timing of juvenile arrival in the estuary and ocean, or adult arrival at the spawning grounds. Reduced springtime flows, for example, have delayed upstream migrations. Flow also affects the availability of habitat for mainstem spawning and rearing stocks. Rapid diurnal flow fluctuations can disrupt mainstem spawners, leave redds dewatered, or strand juveniles.

While management of the hydropower system has improved in recent years, the conditions created by current practices continue to exert negative impacts on the viability to Mid-C steelhead and other listed species today.

Current Effects of Federal Columbia River Power System Management

The FCRPS is currently operated consistent with actions identified in *NOAA Fisheries 2004 Federal Columbia River Power System Biological Opinion* (BiOp)(NOAA Fisheries 2004) and the U.S. Army Corps of Engineers *Final Updated Proposed Action for the FCRPS Biological Opinion Remand* (UPA) (USACE et al. 2004). These actions are intended to address the needs for survival and recovery of all ESA-listed salmon and steelhead ESUs and DPSs in the Columbia Basin. Operation of the FCRPS may change as a result of a remand of the NOAA Fisheries 2004 BiOp, as ordered in June 2005 by the Federal District Court. However, pending any court-ordered hydrosystem operational changes during the remand process, the FCRPS Action Agencies intend to implement the actions identified in the 2004 BiOp and UPA through 2014. Many of the actions are continuation of the 'Reasonable and Prudent Alternative' (RPA) actions contained in the 2000 Biological Opinion.

The following hydrosystem actions are currently being implemented under the 2004 BiOp and UPA.

Continue adult fish passage operations. The Action Agencies continue to complete capital construction projects at federal dams to improve adult fish passage. These fish passage improvements have resulted in meeting or exceeding the adult fish survival performance standards set out in the 2000 BiOp, however there is concern that they do not adequately address delayed mortality and reduced spawning success effects from upstream passage (delay/fallback). The effect of reduced operation of adult passage facilities during winter maintenance, which is especially critical for Fifteenmile Creek winter steelhead, is also a concern.

Improve juvenile fish passage. The Action Agencies continue to implement specific capital improvements, giving priority for funding and implementation to dams with the lowest juvenile passage survival rates. They are pursuing the use of removable spillway weirs (RSWs) or similar surface bypass devices, where feasible. RSWs are installed or planned for installation at all Snake River projects and feasibility studies are being conducted for RSWs at McNary and John Day dams and a forebay guidance device at The Dalles. These RSWs/surface bypass systems are currently designed to operate with reduced levels of conventional spill to provide similar or greater spillway passage and survival at a lower overall spill level to reduce operational costs. However, RSWs with greater training spill or multiple RSWs could be installed at projects to provide even higher spillway passage and survival.

Continue and enhance spill for juvenile fish passage. The basic spring and summer spill program from the 2004 BiOp continues to be implemented. Under the 2004 BiOp remand, court-ordered summer spill was provided in 2005 at Snake River collector projects and McNary Dam to improve survival of listed Snake River fall Chinook.

Continue reservoir operations and flow augmentation to benefit migrating fish. The Action Agencies continue to operate federal storage reservoirs to supplement streamflows and provide spill at mainstem dams to benefit juvenile fish migration consistent with current implementation of the 2000 BiOp as modified through implementation plans. The hydrosystem operations include both discretionary and nondiscretionary actions. Under these operations, the Action Agencies operate federal storage projects at or near upper (flood control) rule curve elevations during the spring to pass spring runoff downstream and to help refill the projects by July 1 for summer flow augmentation operations.

Modify fish transportation to improve juvenile survival. Collection and transport of juvenile fish at Lower Granite, Little Goose, Lower Monumental and McNary dams continues. Under the 2004 and previous Biological Opinions, spring migrants including Mid-C steelhead are not transported during the spring April 10-June 30 spill period so transportation effects (only potentially applicable to Yakima and Walla Walla steelhead) are not considered aside the effects of transportation of upriver stocks on straying in Middle Columbia tributaries.

While current actions under NOAA Fisheries 2004 BiOp are improvements over past hydropower system management, the FCRPS continues to affect Mid-C steelhead abundance and productivity by restricting migrations, altering habitats, and increasing predation on and competition between juvenile salmonids. As a result, the ICTRT ranked the Columbia hydropower system as a major limiting factor for all Oregon Mid-C steelhead populations. Effects of the FCRPS are assessed in the following four categories:

1. Smolt-to-adult returns
2. Juvenile migration and survival related to dam operations and river environment
3. Delayed mortality associated with the FCRPS
4. Adult migration and survival related to dam operations and river environment

Because of the lack of specific survival data for Mid-C steelhead, research data from juvenile steelhead marked primarily from Snake and upper Columbia River stocks, and run-at-large juvenile and adult fish were used to generalize effects of the FCRPS on Mid-C steelhead. These data gaps need to be addressed by the TRT.

1. Smolt-to-Adult Returns

Smolt-to-adult return (SAR) rates provide a measure of survival that encompasses smolt migration, estuary/ocean residence, and adult returns. Changes in SAR over a number of years provide an index of temporal variability in stock productivity and viability, and a basis to understand the relative effects of natural limiting factors in freshwater and marine environments, as well as effects of the FCRPS.

SAR data for hatchery and wild steelhead in the Umatilla and Hood rivers indicate that the effects of the FCRPS increase in relation to the number of dams the fish pass while migrating through the Columbia. Data for the Hood River, which is not part of the Mid-Columbia DPS, have been used here to represent fish passage through one mainstem dam, such as is true for Fifteenmile Creek. These data show that, although not directly comparable, survival of hatchery summer and winter steelhead released from the Hood River have about four to five-fold higher SARs (1.94 % summer and 1.65% winter for 1992-97 brood or 1994-99 migration years) than the Umatilla (0.39%). ODFW contends that that is likely due to additional mortality incurred from passage at three mainstem dams (John Day, The Dalles, and Bonneville) for Umatilla steelhead vs only one dam (Bonneville) for Hood River steelhead. Similarly, SARs of combined wild summer and winter steelhead in Hood River were about four-fold higher than SARs of wild summer steelhead in the Umatilla River.

For Umatilla River wild steelhead, SARs for 1995-2002 migration years ranged from 1.418% in 1996 to 5.316% in 1998, and averaged 2.570% for the eight-year period (Table 8-41).

Table 8-41. Smolt-to-adult return of Umatilla River wild summer steelhead at Three Mile Falls Dam for 1995-2002 migration years (White et al. 2007). Data are incomplete for 2001 and 2002 migration years.

Smolt Migration Year	No. of Smolts	No. Returns to TMFD	Smolt-to-Adult Return Rate (%)
1995	54,361	837	1.540
1996	73,361	1,040	1.418
1997	22,221	1,026	4.615
1998	59,182	3,146	5.316
1999	46,530	2,299	4.941
2000	81,759	4,045	4.948
2001	33,844	1,135	3.353
2002	77,016	1,649	2.141
2003	24,773		
2004	35,640		
2005	59,807		
Mean =	**51,681**		**2.570**

For hatchery summer steelhead released in the Umatilla River from 1987-97 broods, SARs have ranged from 0.043% for the 1988 brood to 0.752% for the 1994 brood and averaged 0.38% for the 11 years (Table 8-42).

Table 8-42. Smolt-to-adult return (hatchery release to Three Mile Falls Dam) of Umatilla Hatchery steelhead 1987-97 broods (Rowan 1998; Chess et al. 2005).

Brood Year	Rearing Location	No. CWT'ed	Total Released	Smolt-to-Adult Return Rate (%)	No. Adults Produced	No. Returns to TMFD
1987	Oak Springs Hatchery	58,067	61,306	0.437	374	268
1988	Oak Springs Hatchery	52,726	81,712	0.043	41	35
1989	Oak Springs Hatchery	56,034	89,193	0.704	838	628
1990	Oak Springs Hatchery	57,825	71,935	0.598	612	430
1991	Umatilla Hatchery	103,353	199,404	0.085	221	169
1992	Umatilla Hatchery	92,952	158,388	0.313	587	495
1993	Umatilla Hatchery	57,033	153,098	0.385	826	589
1994	Umatilla Hatchery	57,884	146,463	0.752	1372	1101
1995	Umatilla Hatchery	61,580	146,703	0.333	541	489
1996	Umatilla Hatchery	58,699	137,287	0.283	407	389
1997	Umatilla Hatchery	60,914	137,485	0.248	393	341
Mean =		**65,188**	**125,725**	**0.380**	**565**	**449**

For the Hood River, estimated SARs for combined wild summer and winter steelhead for 1994-2002 migration years ranged from 3.68% for 1997 migration year to 17.84% for 2001 and averaged 9.00% for the nine years (Table 8-43). Hatchery summer steelhead SARs for the same time period ranged from 0.98-4.52% with a mean of 2.51% (Table 8-44). Hatchery winter steelhead SARs for the same time period ranged from 0.64-2.90% with a mean of 1.78% (Table 8-45).

Table 8-43. Combined estimates of wild summer and winter steelhead subbasin smolt production, escapement to the mouth of the Hood River, and smolt-to-adult survival rate. Estimates are by year of migration. Year of migration is bold faced for those years in which estimates of adult escapements back to the mouth of the Hood River subbasin are greater than 97% complete (Olsen 2005).

Year of smolt migration	Smolts	Adult returns		Smolt-adult survival (%)
		Run years[a]	No.[b]	
1994	7,573	1994/95-1999/00	538	7.10
1995	4,656	1995/96-2000/01	438	9.41
1996	6,799	1996/97-2001/02	400	5.88
1997	13,334	1997/97-2001/02	400	3.68
1998	25,485	1998/99-2003/04	491	6.16
1999	18,842	1999/00-2004/05	1,569	8.22
2000	14,882	2000/01-2004/05	1,979	13.30
2001	5,786	2001/02-2004/05	1,032	17.84
2002	8,096	2002/03-2004/05	765	9.45

[a] Summer steelhead escapements in the 2004-2005 run year are preliminary estimates through 31 December, 2004. Winter steelhead returns are complete through the 2003-2004 run year.

[b] Hooking mortality was assumed to average approximately 10% in the sport fishery located from the mouth of the Hood River to Powerdale Dam.

Table 8-44. Estimates of Foster and Hood River stock hatchery summer steelhead subbasin smolt production releases, adult escapements to the mouth of the Hood River, smolt-to-adult survival rate, and percent difference from the wild smolt-to-adult survival rate. Estimates are by year of migration. Year of migration is bold faced for those years in which estimates of adult escapements back to the mouth of the Hood River subbasin are more than 97% complete (Olsen 2005).

[a] Production releases of Foster stock hatchery summer steelhead smolts were direct released into the West Fork of the Hood River from 1994-1997. Annual production releases were made below Powerdale Dam (RM 4.5) beginning in 1998.

[b] Number represents the estimated hatchery smolt production release. Numbers have not been adjusted for residualism.

[c] Escapements in the 2004-2005 run year are preliminary estimates through 9 March, 2005.

[d] Hood River stock hatchery summer steelhead smolts were first released into the Hood River subbasin in 1999 (1998 brood). The entire production release is acclimated for up to two weeks prior to being volitionally released into the West Fork of the Hood River.

[e] Hood River stock summer steelhead were generally not available for harvest in the sport fishery through the 2003-2004 run year; with the exception of a small number of adipose-left maxillary clipped adults returning from the 2000 brood release (i.e., 29 adults). This was because of their unique hatchery mark combination (i.e., maxillary only clip). The 2002 brood release was the first brood release in which the entire production group was marked with an adipose clip; in combination with another mark (i.e., a maxillary clip). Hooking mortality of maxillary only clipped adults was assumed to average approximately 10% in the sport fishery located from the mouth of the Hood River to Powerdale Dam.

[f] Estimates include counts at Powerdale Dam of adult steelhead with a valid (i.e., for harvest) Hood River stock summer steelhead mark combination that were classified as a Hood River stock (Unknown) winter steelhead.

Table 8-45. Estimates of Hood River stock hatchery winter steelhead subbasin smolt production releases, adult escapements to the mouth of the Hood River, smolt-to-adult survival rate, and percent difference from the wild smolt-to-adult survival rate. Estimates are by year of migration. Year of migration is bold faced for those years in which estimates of adult escapements back to the mouth of the Hood River subbasin are more than 97% complete (Olsen 2005).

		Adult returns		Smolt-adult survival

2002	8,096	2002/03-2004/05	1,220	1.94	-79.47

[a] Hood River stock hatchery winter steelhead smolts were first released into the Hood River subbasin in 1993 (1992 brood). The entire production release was first acclimated in 1996 (1995 brood). Hatchery smolts are acclimated for up to two weeks prior to being volitionally released into both the East and Middle forks of the Hood River.
[b] Number represents estimated smolt release. Numbers have not been adjusted for residualism.
[c] Number includes counts at Powerdale Dam of adult steelhead with a valid Hood River stock winter steelhead mark combination that were classified as a Hood River (Unknown) stock summer steelhead.

2. Juvenile Migration and Survival Related to Dam Operations and River Environment

Juvenile steelhead migration and survival are affected by dam operations (primarily spill), environmental parameters (primarily flow and temperature), and predation. Impacts on juvenile survival and migration timing are discussed below.

Juvenile survival

Currently, there are inadequate data to estimate juvenile survival of Mid-C steelhead because very few of these fish have been PIT-tagged, and only steelhead from the Umatilla and John Day rivers have been tagged. Consequently, data from PIT-tagged steelhead from the Snake River have been used to gain a better understanding of Mid-C steelhead survival through Mid-Columbia dams (McNary to Bonneville). While these findings cannot be directly extrapolated to Mid-C steelhead, they provide a basis for understanding probable environmental and dam operational conditions that might be influencing survival and viability of Mid-C steelhead. Additional tagging of specific Mid-C stocks is needed to corroborate results.

Data collected by the Fish Passage Center (FPC 2005) from 1999 to 2005 show statistically significant relationships between survival of PIT tagged steelhead from McNary to Bonneville dams and spill (Figure 8-3), water transit time (related to flow) (Figure 8-4), and temperature (Figure 8-5). Pearson's correlation matrix for these analyses is provided in Table 8-46. Although these relationships were highly influenced by a single low flow year (2001), they still suggest that survival of steelhead is influenced by the amount of spill, flow, and temperature at Mid-Columbia dams, with higher survival at higher spill and flow and lower water temperatures. These results are similar to those found for yearling Chinook between McNary to Bonneville (FPC 2005), and for yearling Chinook and steelhead between Lower Granite to McNary dams.

(FPC 2005) where greater sample sizes and observations over a wider range of dam operations and environmental conditions allow greater statistical rigor and strength of relationships.

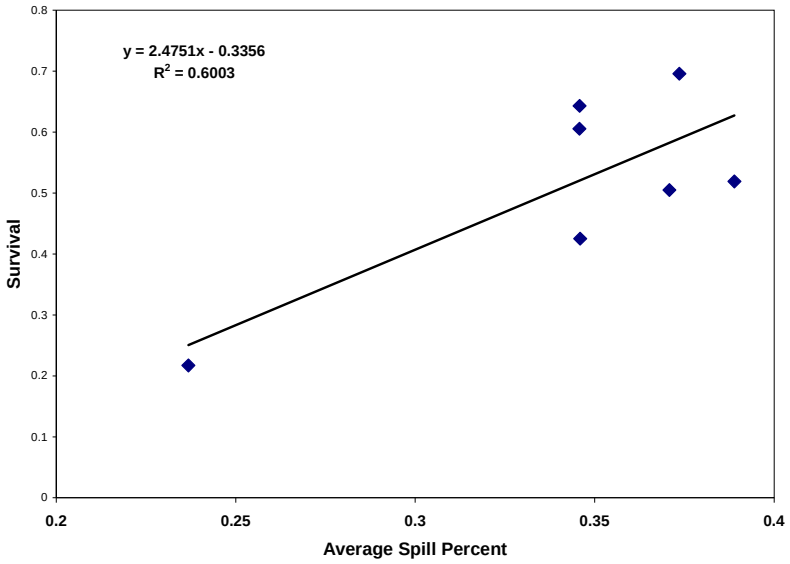

Figure 8-3. Reach survival from McNary Dam to Bonneville Dam for PIT-tagged steelhead detected at McNary Dam between May 11 and June 8 for years 1999 to 2005 plotted with average spill percent at John Day, The Dalles and Bonneville dams.

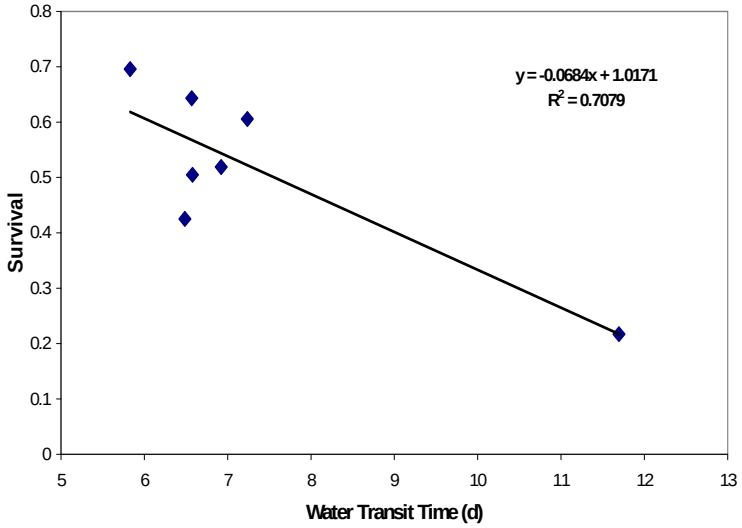

Figure 8-4. Reach survival from McNary Dam to Bonneville Dam for PIT-tagged steelhead detected at McNary Dam between May 11 and June 8 for years 1999 to 2005 plotted with average water transit time for the reach McNary Dam to Bonneville Dam.

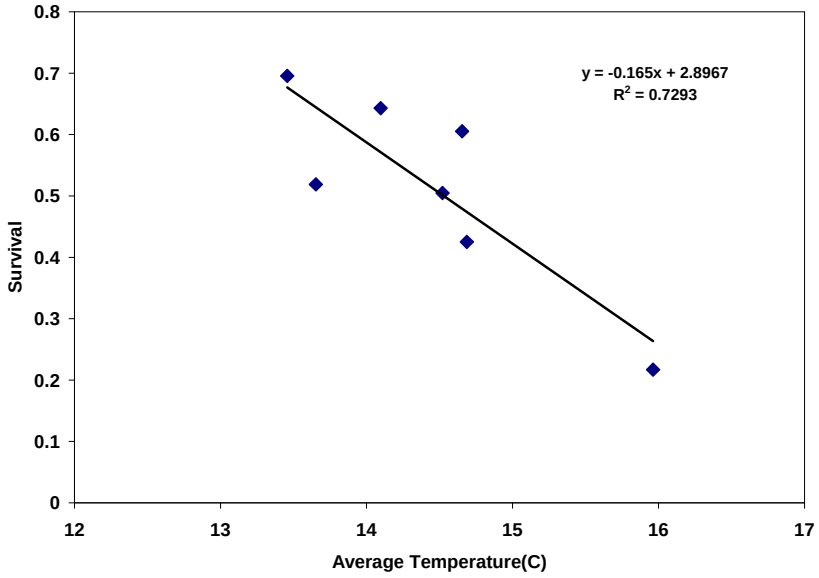

Figure 8-5. Reach survival from McNary Dam to Bonneville Dam for PIT-tagged steelhead detected at McNary Dam between May 11 and June 8 for years 1999 to 2005 plotted with average water temperature(C) measured at tailwater TDGS monitors for the reach McNary Dam to Bonneville Dam.

Table 8-46. Pearson correlation matrix for Snake River steelhead survival relationships.

	SURVIVAL	TRAVTIME	WTT	AVGSPILL	AVTEMP
SURVIVAL	1.00000				
TRAVTIME	-0.76894	1.00000			
WTT	-0.84138	0.96015	1.00000		
AVGSPILL	0.77482	-0.92923	-0.93281	1.00000	
AVTEMP	-0.85401	0.87935	0.85638	-0.90103	1.00000

Data from PIT-tagged steelhead from the Snake River have been used to estimate survival through Mid-Columbia dams. These data were not sufficient to estimate juvenile steelhead survival from McNary to Bonneville until 1997, and then only for pooled wild and hatchery steelhead (Table 8-47). Annual estimates ranged from 0.250 in 2001 to 0.770 in 1998, and averaged 0.540 for the seven years. These survival estimates include only direct effects of passage through the Mid-Columbia dams and reservoirs; delayed, or latent, mortality from hydrosystem passage for these fish is discussed later in this section.

Data from 1997 to 2003 indicate that steelhead survival from McNary Dam to Bonneville Dam is influenced by dam operations (spill); as well as migration rate (as influenced by flow), temperature, and predation. Survival in 2001 was only about one-third of 1998, due to extremely

low flows, high temperatures, and limited spill at each dam because of a declared power emergency by BPA (Williams et al. 2005).

Table 8-47. Estimated survival from McNary Dam tailrace to Bonneville Dam tailrace for hatchery and wild steelhead (pooled) PIT tagged from the Snake River (from Williams et al. 2005).

Year	Survival	Standard Error
1997	0.651	0.082
1998	0.770	0.081
1999	0.640	0.024
2000	0.580	0.047
2001	0.250	0.016
2002	0.488	0.090
2003	0.510	0.015
Average	0.540	0.071

Survival data from 1999 to 2005 for wild summer steelhead from release in the Umatilla River to John Day Dam echo these findings. Results from these data — which examine effects in the Umatilla River and also passage through John Day Reservoir — show that survival probabilities were lowest in 2001 and 2004, two below normal flow years in both the Umatilla and Columbia rivers (Table 8-48).

Table 8-48. SURPH generated survival and capture probabilities for natural summer steelhead tagged and released into the Umatilla River, 1999 – 2005 (White et al. 2007). S*P = Survival Probability.

	Survival probabilities			Capture probabilities		Final S*P		
Year	TMFD	TMFD to JDD	JDD	TMFD	JDD	TMFD	JDD	Number tagged
				All fish tagged and released in Upper Basin[a]				
1999	0.26	0.75	0.19	0.32	0.42	0.40	0.19	2010
2000	0.34	0.52	0.18	0.34	0.34	0.25	0.22	1652
2001	0.39	0.38	0.15	0.15	0.53	0.27	0.36	2622
				Fish tagged and released from January - June in Upper Basin[ab]				
2000	0.37	0.57	0.21	0.36	0.29	0.24	0.18	1281
2001	0.40	0.37	0.15	0.15	0.53	0.26	0.36	2480
				Fish tagged at TMFD for Trap Efficiency tests[c]				
1999	0.97	0.69	0.67	0.21	0.37		0.20	1845
2000	--	--	--	--	--	--	--	24
2001	0.75	0.53	0.40	0.35	0.25		0.21	281
2002	1.04	0.61	0.64	0.17	0.30		0.14	468
2003	0.80	0.64	0.51	0.18	0.40		0.32	498
2004	0.84	0.44	0.37	0.43	0.39		0.13	309
2005	0.91	0.54	0.49	0.29	0.41		0.10	704

[a] These fish were tagged at various times and released at various upriver sites (RM 48 – RM 80) but were grouped for species survival. Natural fish were only tagged from 1999 to 2001.

[b] Fish tagged from January to June were assumed to be actively migrating smolts. These fish were separated because of the potential for overwintering mortality associated with fish tagged from July to December.

[c] These fish were released about 1.5 miles upstream of TMFD at various times.

Predation by Piscivorous Fish. Survival rates also reflect predation that has increased due to dam development and operations. Slower river flows and warmer water temperatures in the lower Columbia River caused by hydropower development and operations create hospitable environments for northern pikeminnow, walleye, smallmouth bass and other fishes that prey on outmigrating juvenile steelhead. The dams can stress and disorient migrating smolts, making them vulnerable to predators. Dams may also delay migration, thereby increasing travel time and exposure to predators. Northern pikeminnow are considered the major piscivore responsible for predation on juvenile salmonids, with mortality potentially similar to that caused by dam passage (Rieman et al. 1991). Predation impacts are further discussed in Sections 8.7.

Juvenile migration timing

Data on the migration timing for wild Mid-C steelhead in the mainstem Columbia River, as determined by detection of PIT tagged fish, are limited to wild and hatchery steelhead PIT tagged in the Umatilla River, where adequate numbers have been PIT tagged since 2001. PIT tagging of wild steelhead has also been initiated in the John Day, Wind and Hood rivers, but inadequate numbers have been detected at mainstem dams to determine migration timing.

Summarized migration timing data for Umatilla River wild and hatchery PIT tagged steelhead from 2001 to 2005 show that Umatilla steelhead generally passed John Day Dam during April and May, typical of migration timing of steelhead PIT tagged in the Snake and upper Columbia rivers (Figures 8-6--8-10). However, in 2001, Umatilla steelhead migrations extended into August because of drought and power emergency (limited spill) conditions (Figure 8-6).

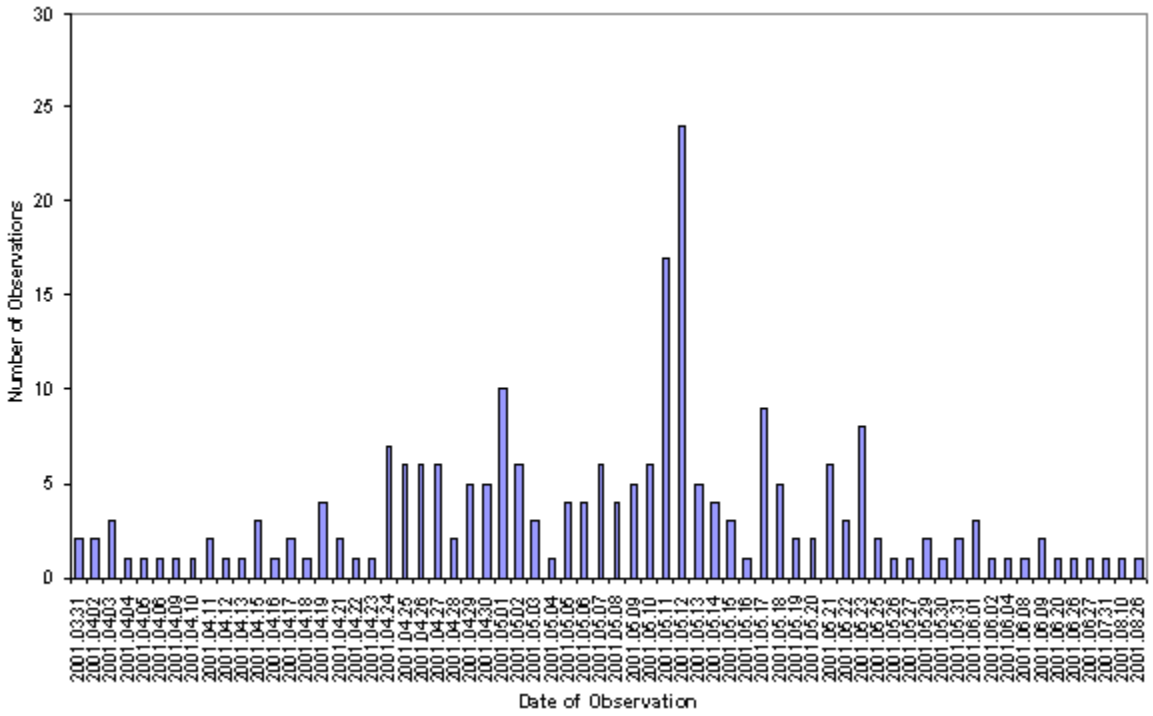

Figure 8-6. Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2001.

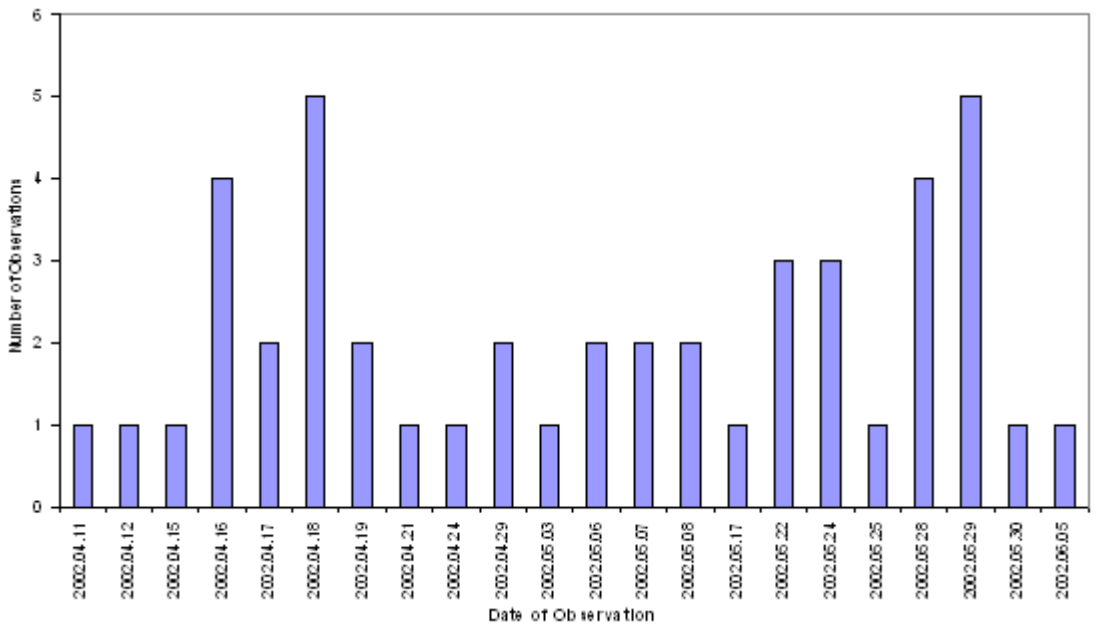

Figure 8-7. Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2002.

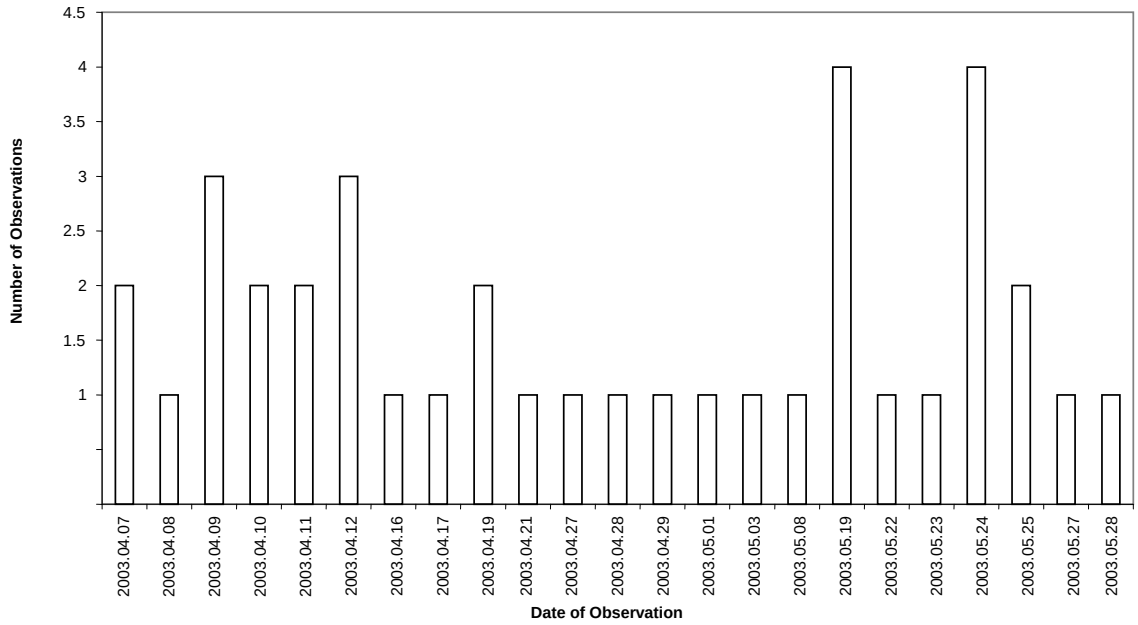

Figure 8-8. Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2003.

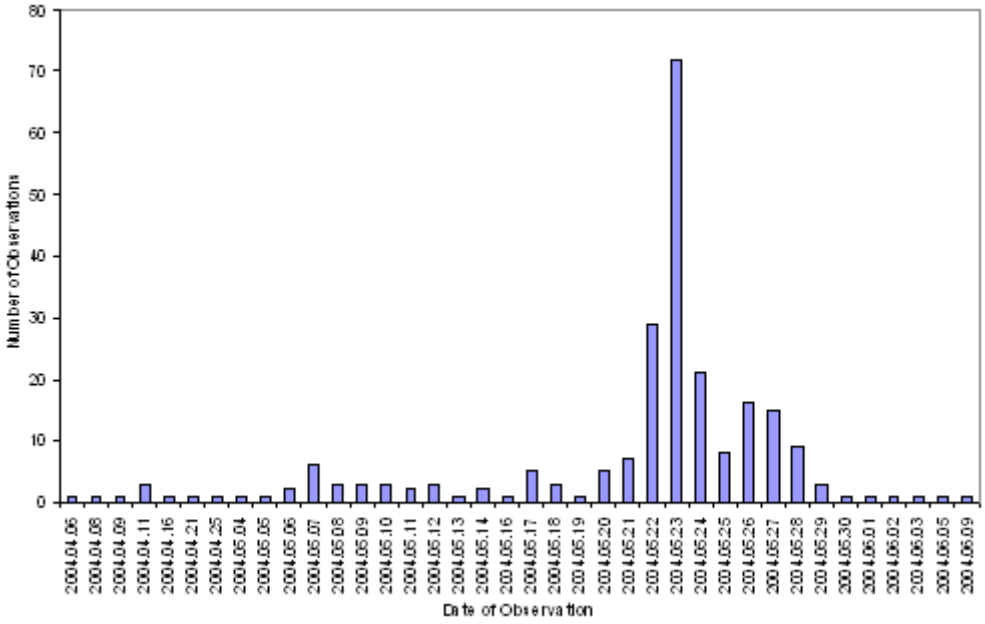

Figure 8-9. Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2004.

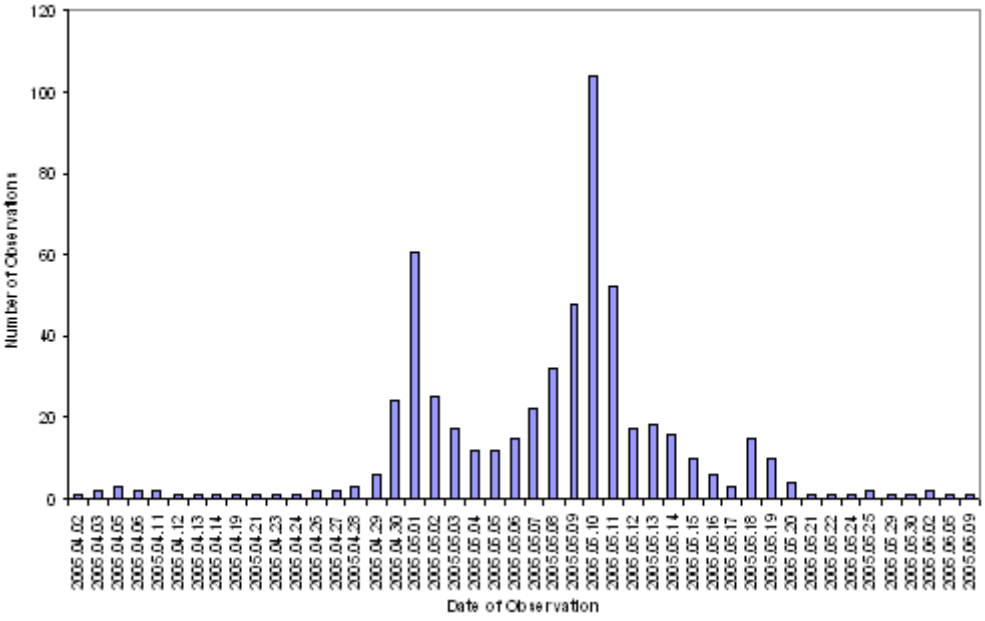

Figure 8-10. Migration timing of wild PIT-tagged Umatilla River steelhead at John Day Dam in 2005.

3. Delayed Mortality Associated with the FCRPS

While there currently is not enough data to determine what level of latent mortality for Mid-C steelhead can be attributed to passage through the hydropower system, studies and analyses conducted on Snake River spring/summer Chinook and steelhead indicate that latent mortality can be high. Comparisons of SARs for Snake River spring/summer Chinook and steelhead with survival estimates through the FCRPS (both juvenile downstream and adult upstream direct survival estimates) indicate that most mortality of both in-river and transported fish occurs outside the hydrosystem, manifested as "delayed" mortality (Marmorek et al. 2004). Studies and analyses have been conducted over the last 10 years to identify causative mechanisms including changes in migration timing (from delay of in-river smolts and acceleration of transported smolts), disease transmission or stress resulting from concentration of fish in bypass/transportation facilities, depletion of energy reserves due to prolonged migrations, altered estuary/plume characteristics, and disruption of homing instincts.

The Comparative Survival Study (CSS) Workshop (Marmorek et al. 2004) found that results from updated modeling (Delta model used by Deriso et al. 2001) indicate that delayed mortality for Snake River spring/summer Chinook has remained high in recent years (long-term average=0.81) despite improvements in ocean conditions. The CSS Workshop evaluated evidence of several mechanisms of delayed mortality, including several that are directly applicable to Mid-C steelhead:

The hydrosystem indirectly affects SARs by delaying in-river arrival of smolts in the estuary- Snake River steelhead arrive in the estuary 2-3 weeks later than historically (travel times greatly extended due to reduced water particle time from dam construction) that influence availability of prey that might be key in estuary/early ocean survival. Although delay of Mid-C steelhead may not be as great as Snake River stocks, any delay may affect survival.

The hydrosystem indirectly affects SARs by delaying the smolt development process through altered entry timing and stress- Similar to Snake River stocks, Mid-C steelhead may be stressed from hydrosystem passage and reverse in smolt development decreasing overall survival.

The hydrosystem indirectly affects SARs through size selectivity and annual variation in bypass survival- Although thought to be a key hypothesis (Williams et al. 2005), a re-analysis of data by Marmorek et al. (2004) for Snake River wild Chinook showed a weak trend in size selectivity and only at Little Goose Dam. Bypass passage for Mid-C steelhead is probably less of a factor than for upriver stocks due to less bypass systems encountered (most stocks are affected by only two dams, John Day and Bonneville, as there is no bypass at The Dalles).

Smolt passage through the hydrosystem increases stress, reduces growth rate and fish condition that increases vulnerability to mortality factors including predation and horizontal transmission of pathogens- This hypothesis is likely but uncertain as evidence is mainly from laboratory studies and lack of empirical data confirming results.

4. Adult Migration and Survival Related to Dam Operations and River Environment

Research by the University of Idaho and NMFS since 1996 (provided by Dr. Chris Peery, University of Idaho) indicates that adult steelhead migration and survival is also affected by the FCRPS. The research focused primarily on passage of adult Snake River salmon and steelhead, but the findings are also applicable, though to a lesser degree, to Mid-C steelhead.

From 1996 to 2003, more than 18,000 adult Snake River salmon and steelhead, were radio-tagged and monitored, and the fates of individual fish were assessed. Monitored groups included spring, summer, and fall Chinook salmon, steelhead, and sockeye salmon. Samples from later years included adults that were PIT-tagged as juveniles at known locations, allowing researchers to assess behavior and survival for individuals with known homing destinations. The tagging program has included several ESA-listed stocks including limited Mid-C steelhead (primarily Umatilla and John Day steelhead). Additional information related to research results described here can be found at, http://www.cnr.uidaho.edu/uiferl/.

Survival and pre-spawn mortality

Survival. Survival through the Columbia River hydrosystem (Bonneville Dam to Lower Granite or Priest Rapids dams) averaged 73% for spring–summer Chinook salmon, 61% for fall Chinook salmon, and 63% for steelhead; survival varied significantly among years (Figure 8-11). Fish that did not reach spawning areas were presumed lost to harvest and other causes. Survival of Mid-C steelhead is likely to be higher due to less dams encountered.

Non-Harvest Mortality. After accounting for fishing mortality, an average of 12–17% of Columbia River and Snake River salmon and steelhead adults had unknown fates before reaching spawning tributaries or exiting the monitored hydrosystem. Causes for these mortalities are unknown, but likely include extended migrations, stress from elevated water temperatures, energetic exhaustion, disease, unreported harvest, delayed mortality due to injuries sustained during fallback or from encounters with fisheries, or other factors. An important finding applicable to Mid-C steelhead is that survival for all runs has tended to be lowest in the lower Columbia River (Bonneville to McNary) and higher through lower Snake River reaches.

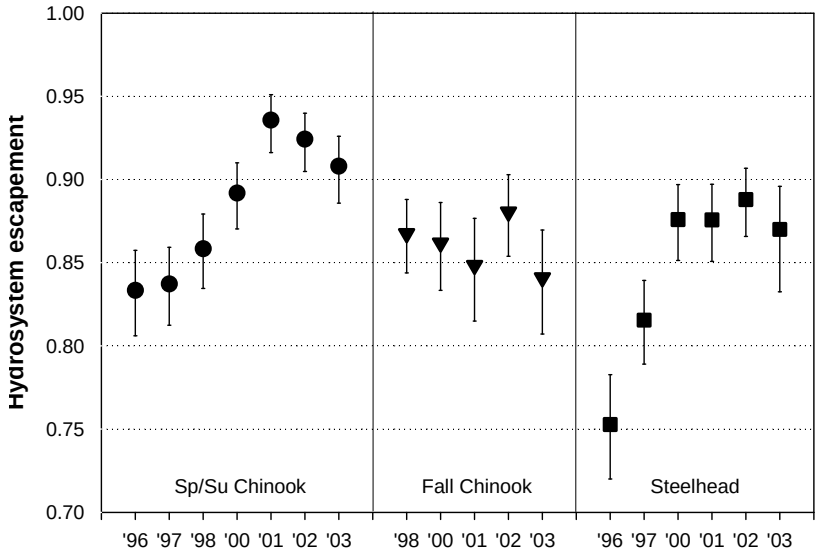

Figure 8-11. Average escapement for adult spring/summer Chinook salmon, fall Chinook salmon, and steelhead through the Federal Columbia River Power System, adjusted for known commercial and sport harvests. Error bars are 95% CIs.

Pinniped Predation. Predation by Pacific harbor seals, Steller sea lions and California sea lions on salmon and steelhead in the lower Columbia River has increased in recent years. More and more seal lions have been traveling as far as Bonneville Dam to prey on adult salmon and steelhead that congregate below the dam before attempting to climb the fish ladders. They also consume large numbers of salmon and steelhead in the 145 miles of the Columbia River below the dam. Section 8.7 discusses the effects of pinniped predation on Mid-C steelhead.

Pre-Spawn Mortality. Additional mortality occurs upstream from the hydrosystem and before spawning, but quantitative summaries of these components of adult survival are limited. Intensive surveys of spawning areas in the South Fork Salmon River, Idaho, reveal 25 to 60% of successful Chinook salmon migrants die before spawning each year compared to numbers observed at Lower Granite. A study is underway to determine how migration history, water temperatures in and upstream from the hydrosystem, and fish energetics are related to pre-spawn mortality for this population. Similar studies are needed for Mid-C steelhead.

Straying. Permanent inter-basin straying is a challenging component of assessing adult survival because they could be considered either successful migrants (they reached a spawning area) or unsuccessful migrants (they did not home to their natal site). On average, 2–4% of known-origin spring–summer and fall Chinook salmon and 7% of steelhead in the radiotelemetry study strayed into non-natal basins where they may have spawned with native stocks. Hatchery fish and fish transported (barged) from the Snake River as juveniles were more likely than other groups to stray. Many stray steelhead from the Snake River entered the Deschutes and John Day rivers and possibly spawn with native populations.

Wandering. In warm years and during warm periods within years, large proportions of summer and fall Chinook salmon and steelhead runs encounter temperatures considered stressful for salmonids. In response, many fish seek cool thermal refuges—and particularly cool non-natal tributary streams particularly the Deschutes River. During the warmest times, majorities of the fall Chinook and steelhead runs concentrate in these refugia, where they may be highly vulnerable to harvest. While the behavior likely has immediate energetic benefits, delays and elevated harvest risks during warm water periods may lead to overall decreases in system productivity. There is some evidence that survival consequences of high temperature exposure may be greater for obligatory migrants like Chinook salmon than for steelhead which migrate many months in advance of spawning.

Effects of dams and operations

Passage Rates. Most adult salmon and steelhead pass individual dams in 1 to 2 days, and pass quickly through reservoirs. However, a proportion of each run (typically between 2–12%) takes several days to weeks to pass individual dams. Research found that fish that took a relatively long time to pass individual dams were less likely to migrate successfully to spawning tributaries. Similarly, relatively slow passage through the lower Columbia hydrosystem (multiple dams and reservoirs) from McNary to Bonneville was associated with unsuccessful migration. Though the cause is unknown, the association described above may have resulted from inadequate dam passage facilities 'delaying' some individuals, the expenditure of large amounts of energetic stores, and resulting in premature death. Alternatively, individuals in poor condition at river-entry may have been both slow and less likely to reach spawning grounds, regardless of passage conditions at dams. Studies are on-going to determine the relative roles of these two mechanisms. Improving passage efficiency has been a management goal, and incremental improvements to fishways (transition pools, count windows, entrance and exit conditions) and operations (spill, fishway temperatures) are being studied and implemented.

Fallback. Some fish from all runs pass dams and then fall back downstream. Approximately 22% of spring/summer Chinook salmon, 15% of fall Chinook salmon, and 21% of steelhead fell back at one or more dams during migration. Fallback is associated with both direct and delayed mortality, slowed migration rates, and increased likelihood of straying. Fallback rates have been highest in years with high river flow and high spill at dams, at least in part because most fish fall back via dam spillways. Fish also appear to fall back as a result of orientation errors, including failure to locate natal tributaries and imprinting problems associated with juvenile barging. Providing benign downstream passage routes for these individuals could lessen the survival costs of fallback. Operational changes may help reduce fallback and therefore increase overall survival, but it is unclear how large a reduction is possible given the management constraints.

Juvenile Barging. Currently, about 70% of juvenile migrating seaward in the Snake River are collected and transported by barge below Bonneville Dam. Returning adults that had been barged as juveniles were ~10% less likely to migrate to spawning grounds, exhibited less direct migrations, and strayed to non-natal tributaries (ex: Deschutes River) at rates that were approximately twice that of adults that had migrated in the river as juveniles. Barging probably interrupts the 'sequential imprinting' process whereby adults use olfactory memories from the juvenile seaward migration during homing. It should be noted that fish used in this study are captured at the Washington shore fish trap which may have influenced results.

Spill. Results three years when spill levels were manipulated at Bonneville Dam suggest that high spill volumes (>100 to kcfs at Bonneville) increase adult passage times slightly compared to moderate spill volumes of ~75 kcfs. Higher spill was also associated with higher fallback rates in spring Chinook salmon and in steelhead. As already noted, longer passage times and fallback events have been associated with lower survival for individual fish.

Summer Spill. Preliminary results from the adult radiotelemetry project suggest that moderate spill during summer would likely have only a limited impact on adult passage. Summer Chinook salmon also exhibited slight increases in passage time and fallback rate at high spill levels at Bonneville dam. However, these effects should be weighted against the potential benefits of limited spill for those adults that volitionally fallback (i.e., those that overshot natal tributaries) because fallback via spillways is more benign than through turbines.

Fishway Temperatures. Elevated water temperatures and large temperature differentials (between the top and bottom of ladders) in dam fishways can deter passage. Mean passage times for spring-summer Chinook at Lower Granite Dam increased from 6.6 hours when temperatures at the ladder exit were similar to those at the base of the ladder, to 19.1 hours when exit temperatures were ≥ 2˚C warmer than at the base. Similarly, the proportion of fish requiring more than one day to pass the dam increased from 32.7% with no temperature barrier to 71.4% when temperatures differed by ≥ 2˚C. Greater numbers of fish reject fishways at John Day Dam when water temperatures exceed 18ºC. Temporary temperature barriers contribute to adult passage delay that may result in permanent straying to downstream sites or migration failure.

Dissolved Gas. High spill at dams can create supersaturated dissolved gas condition in tailraces and downstream areas, and there is concern that fish that encounter these conditions may develop gas bubble disease. Results from an archival tag study that monitored fish swimming depths suggest that adults do not avoid plumes of high dissolved gas and frequently experience high dissolved gas conditions. However, most adults remained at depths that provided adequate "hydrostatic compensation" and consequently prevented expression of gas bubble disease. Little is known about the effects of the observed frequent, but short, exposures to supersaturated conditions. Addition of flow deflectors and increased use of surface flow weirs at spillways should moderate dissolved gas conditions in the system. Additional study of this issue may be warranted given the incidence of gas bubble disease symptoms in adults in some years.

River and ocean environment

Flow and Survival. Adult Chinook salmon appear to have lower hydrosystem survival in years with high flow (discharge). This pattern is probably the result of higher fallback and slower migration rates in high-flow years, two energetically demanding aspects of migration. Survival for runs that migrate during typical low-flow times (most fall Chinook salmon and steelhead) has not been correlated with river flow.

Temperature and Survival. Water temperatures in the Columbia and Snake Rivers have been increasing since dam construction began due to development and management of the hydrosystem as well as from regional climate and water use patterns, resulting in longer summers and higher summer temperatures. Adults returning in the late spring, during summer, and in the early fall frequently choose the coolest water available to them to migrate in, but still

frequently encounter stressful temperatures. Higher temperatures were associated with altered migration behavior and lower migration success. Predictions for continued warming will probably adversely affect migrating adults because migration through stressful temperature conditions requires more energy and may contribute to higher rates of prespawn mortality. A study is underway to evaluate effects of temperature exposure on gamete quality and spawning success.

8.3.2 Tributary Hydropower Configurations and Operations

Several hydroelectric dams on Columbia River tributaries pose significant threats to the viability of specific Mid-C steelhead populations, including the Deschutes Westside, Crooked, Umatilla, and Walla Walla populations.

Deschutes River Populations
The Pelton-Round Butte Complex on the Deschutes River at RM 100 significantly impacts abundance, productivity, and spatial structure of the Deschutes Westside steelhead population and to a lesser extent the Deschutes Eastside Population. The complex blocks passage to historical upstream habitats in the Deschutes watershed, including the Crooked River, Metolius River, the Deschutes River upstream to Big Falls, and Whychus Creek. On the Deschutes River, Big Falls (RM 132) is considered to have been the upstream limit of anadromous fish migration (Nehlsen 1995). Summer steelhead were historically present throughout much of the Crooked River subbasin, with the exception of the North Fork Crooked River above Upper and Lower Falls.

Construction of the complex, a system of three dams and reservoirs, began in the late 1950s and was completed in 1964. The complex spans 20 miles on the Deschutes River and also extends into two tributaries, the lower seven miles of the Crooked River and the lower 13 miles of the Metolius River. The complex was constructed with upstream and downstream fish passage facilities, however, by 1966 it appeared that downstream passage through Lake Billy Chinook, the reservoir behind Round Butte Dam, could not be maintained due to poor guidance of out-migrating smolts. The last fish were passed in 1968, and production shifted to state hatchery facilities. In 1974 Round Butte Hatchery was completed at Round Butte Dam, and production shifted to this facility.

With the new federal license issued in June 2005, the joint owners of the project (PGE and CTWSRO) have developed plans to reinitiate fish passage through the complex and reintroduce Chinook and steelhead above the complex. A comprehensive fish passage plan includes development of effective downstream collection and passage for parr and smolt life history stages. The facility is scheduled for completion in 2009.

Potential to Introduce Disease
The reintroduction of steelhead to historical habitats upstream of Round Butte Dam in the Deschutes River subbasin may expose existing resident populations to diseases. Resident trout upstream of the dam have been isolated from the rest of the Columbia Basin for over 30 years. As such, they have not been subject to newly introduced or more virulent disease found downstream. Primary diseases of concern that may affect upstream fish populations include

Infectious Hematopoietic Necrosis Virus (IHNV) and *Myxobolus cerebralis* the parasite that causes whirling disease.

Umatilla River Population

The Boyd Hydro Project has been in operation since the early 1980's and is located at approximately RM 9-10 on the Umatilla River. Water is diverted from the Umatilla River at approximately RM 10 into a mile long canal that routes water to the generating facility where the water is returned to the river. The hydraulic capacity of the facility is 500 cubic feet per second with an average head of 30 feet. Flows for operation of the facility are generally only available during the winter and spring months. The Oregon Water Resources Department and Federal Energy Regulatory Commission have established minimum flows for the Bypass reach of 150 cfs from September through November and 100 cfs from December through August. These flows are well below the instream water right for this reach with priority date of November 3, 1983. The instream water right flows are 300 cfs October through November 15, 250 cfs November 15 – June, 120 cfs in July, 85 cfs August – September 15, and 250 cfs September 15 to October 1.

A low head dam exists at the point of diversion and fish screens are installed across the intake canals. Malfunction of the fish screens led to entrainment of fish and an associated fish kill in 1993. Problems with the screens were corrected and no further problems with the screens have been identified. A fishway exists at the dam structure, but this facility does not meet current fish passage standards for anadromous adult salmonids.

Walla Walla River Population

The Twin Reservoirs Hydro Project, owned and operated by the city of Walla Walla, is located on Mill Creek along a six-mile reach that dips into Oregon (most of this creek is within the state of Washington). The City diverts water from Mill Creek for municipal uses and to generate electricity that is sold on the power market to offset costs of the City's water supply system. Water for both uses is diverted at the same point of diversion and routed to Walla Walla through a pipeline. The current hydraulic capacity of the facility is 38 cfs when the hydro plant is in operation. The City's original 1866 municipal water right has no instream flow requirements. However, when the city operates its hydropower project the following bypass flows are required:

Immediately below project intake:	
Aug-Nov	13 cfs
December	15 cfs
January	20 cfs
February	25 cfs
Mar- Apr	30 cfs
May	25 cfs
June	15 cfs
July	14 cfs

At Kooskooskie	
October	32 cfs
November	35 cfs
December	37 cfs
January	44 cfs
February	53 cfs
March	63 cfs
April	86 cfs
May	64 cfs
June	39 cfs
July	32 cfs
Aug-Sept	31 cfs

The City's hydroelectric license is conditioned to require gauging equipment as necessary to provide full-time, continuous records of project diversions and of streamflow below the project intake. A dam with fishway exists at the point of diversion and fish screens are installed on the intake. The current fish screens were installed in 1999 to replace old screens that were found to result in fish mortality. The screens meet current ODFW and NMFS standards. Recovery team members are unsure of the fishway's compliance with current passage standards.

8.4 Estuarine and Plume Habitat

Changes in estuarine and plume habitat at the mouth of the Columbia River impact Mid-C steelhead juveniles and adults as they undergo the vast physiological changes needed to transition to and from saltwater production. This section summarizes relevant information presented in the Columbia River Estuary Recovery Plan Module (LCREP 2006). The module provides detailed descriptions of limiting factors and proposes recovery actions to improve salmon and steelhead habitat conditions in the estuary.

The Columbia River estuary and plume are considerably degraded compared to only 200 years ago. In terms of absolute size, the estuary tidal prism is about 20% smaller than it was when Lewis and Clark camped along the Columbia's shore (NPCC 2004). This reduction in estuary size is due mostly to dike and filling practices used to convert the floodplain to agricultural, industrial, commercial, and residential uses. Instream flows entering the estuary also have changed dramatically—there has been a 44% decrease in spring freshets or floods, and the annual timing, magnitude, and duration of flows no longer resemble those of the historical hydrograph in the Columbia River (Jay and Kukulka 2002). Changes to the hydrograph are attributed to flow regulation by the hydrosystem, water withdrawal for irrigation and water supplies, and climate fluctuations.

While much remains to be learned about how Mid-C steelhead and other stream-type juveniles use estuarine and plume habitats, scientists generally believe that stream-type salmonids are particularly affected by changes in plume habitat conditions and by predation in the estuary and plume (LCREP 2006). Changes in estuarine habitats affect ocean-type juveniles more because they reside in the estuary longer than stream-type juveniles and tend to use shallow-water

habitats, thus they are more affected by flow alterations that structure habitat and/or restrict access to wetland or floodplain areas than are stream-type juveniles. Mid-C steelhead and other stream-type juveniles have relatively short estuary residence times and use the plume much more extensively than ocean types do. Thus they are more affected by plume habitat conditions. They are also threatened by predation in the estuary and plume (LCREP 2006).

8.4.1 Changes in Plume Habitat

Mid-C steelhead and other stream-type salmonids are affected by the size, shape, behavior, and composition of the plume. The plume is believed to function as habitat, as a transitional saltwater area, and as refugia for juvenile salmonids as they prepare for ocean life (LCREP 2006; Fresh et al. 2005).

Evidence suggests that the plume supports ocean productivity by increasing primary plant production during the spring freshet period, distributing juvenile salmonids in the coastal environment, concentrating food sources such as zooplankton, and providing refugia from predators in the more turbid, low-salinity plume waters (Fresh et al. 2005). Changes in the Columbia River hydrograph alter both the size and structure of the plume during the spring and summer months (NPCC 2000). Changes in the hydrograph also affect plume habitat by reducing fine-sediment inputs leaving the estuary.

8.4.2 Predation

Predation is a primary concern for juvenile and adult Mid-C steelhead during their stay in the Columbia River estuary and plume. Effects of predation are discussed below and in Section 8.7.

Estuary habitat modifications have increased the number and/or predation effectiveness of Caspian terns, double-crested cormorants, and a variety of gull species (Fresh et al. 2005). Stream-type juvenile salmonids, including Mid-C steelhead, are most vulnerable to avian predation by Caspian terns because they use deep-water habitat channels that have relatively low turbidity and are close to island tern habitats.

Native pinnipeds, including harbor seal, Stellar sea lions and California sea lions, also prey on steelhead in the estuary (NPCC 2004). Native pinniped abundance has steadily increased since passage of the Marine Mammal Protection Act in 1972. Diet studies indicate that pinnipeds consume both juvenile and adult salmonids. Mortality of adult salmonids at Bonneville Dam because of sea lions was estimated at 4.1% in 2007 (USACE 2005), however the estimate does not reflect pinniped mortality occurring in the 145 river miles downstream of the dam. There are also no official estimates of downstream mortality on adult spring Chinook and winter steelhead (both of which are stream-type salmonids); however, unsubstantiated estimates are as high as 10%, which would equate to about 29,000 adult fish (LCREP 2006).

The northern pikeminnow and other native piscivorous fish likely pose a lesser concern for Mid-C steelhead in the estuary. The fish prey on ocean-type juveniles more than stream-type juveniles because of their longer estuary residency times and use of shallow-water habitats;

however, it is believed that stream-type juveniles leave faster, deeper water to forage for food in the shallows and also experience mortality from pikeminnow predation.

8.5 Harvest

This section explains the different types of harvest impacts, the types of fisheries and areas that Mid-C steelhead fisheries occur, and the multitude of jurisdictions and processes that influence harvest. The section also provides perspective on historical and current harvest impacts.

Harvest may affect population viability by affecting abundance, productivity, spatial structure and/or diversity. Harvest decreases survival rates relative to an un-harvested population by direct and incidental mortality. Steelhead may be removed at several life stages, ranging from pre-smolts taken in trout fisheries to adults taken after they have returned to natal tributaries to spawn. Harvest, therefore, directly decreases adult abundance (viewed either as the number of spawners or as the number of adult recruits) and productivity, measured as the number of adult recruits per spawner returning to the spawning ground. The extent of this decrease in abundance is usually reported as a harvest rate. Harvest also may be selective and influence diversity and spatial structure viability criteria. Harvest may selectively remove fish based on size, age, distribution or run timing, depending on the gear, timing and location of the fishery. Selectivity impacts have rarely been measured or reported.

The ICTRT identified harvest-related adverse effects as a secondary level limiting factor and the Mid-C Expert Panel did not identify harvest as a primary or secondary threat (Mid-C Expert Panel 2006). Given the current management regulations for mainstem and tributary fisheries we consider harvest to be a threat that does limit viability; however, the combined affect of all fisheries only raises the threat to a secondary level.

8.5.1 Fisheries Management — Historically to Present

Steelhead may be caught in ocean, mainstem Columbia River, or tributary fisheries depending on their distribution, run timing relative to fishery openings and vulnerability to gear. Because of their exposure to fisheries across large geographic regions of the West Coast, Pacific salmon and steelhead management is governed by a number of regional organizations. Fisheries of the Columbia River are established within the guidelines and constraints of the Pacific Salmon Treaty, the Columbia River Fish Management Plan, the Endangered Species Act administered by NOAA Fisheries, The Pacific Fishery Management Council, the states of Oregon and Washington, the Columbia River Compact, and management agreements negotiated between the parties to US v. Oregon.

Fisheries management through these various organizations has resulted in the decline of total exploitation rates for Columbia River salmon and steelhead, especially since the 1970s. Because of these changes, the ICTRT and Expert Panel currently consider harvest a secondary limiting factor for Oregon Mid-C steelhead populations. There has been no direct freshwater non-tribal harvest on wild steelhead from the Mid-Columbia DPS since 1992 when the last wild fish catch-and release regulations on these populations became effective. It is also assumed that steelhead are rarely caught in ocean fisheries. Therefore, all current non-tribal harvest impacts on Mid-

Columbia DPS steelhead are due to incidental by-catch in commercial or recreational fisheries that target hatchery steelhead or other species. Tribal fishers in Zone 6 of the Columbia mainstem (between Bonneville Dam and McNary Dam) continue to retain wild steelhead for commercial sale or for personal use. The impact of these various fisheries is discussed below.

Ocean Fisheries

Columbia River steelhead have been captured in high-seas sampling in the far North Pacific and along the coast of SE Alaska and British Columbia (Burgner et al. 1992). According to Rich (1942), Columbia River steelhead were historically taken along with Chinook and coho in ocean fisheries off the mouth of the Columbia River, but accounted for less than 0.1% of the catch and numbered only in the few hundreds of fish. More recent ocean commercial fisheries have not been monitored for incidental steelhead by-catch, and it is assumed that by-catch is very low. Recreational fisheries in the ocean catch small numbers of steelhead.

Mainstem Commercial Fisheries

Steelhead catch in Columbia River mainstem commercial fisheries was reported starting in 1889, although it is thought that some steelhead were processed along with Chinook (and counted as Chinook) in previous years. The available information is mostly about summer steelhead catch since early reporting focused on the fall fishery, but earlier spring fisheries probably caught some winter steelhead. The maximum annual catch reported was about 492,000 fish (Figure 8-12) (Craig and Hacker 1940). Annual catches were averaging about 189,000 fish by the 1930s. Escapements were not estimated before the late 1930s so the harvest rates due to these early fisheries were not known. All early catch was of wild steelhead.

The Bonneville Dam fish ladder opened in 1938 and allowed escapement estimates to be made on populations that passed above that location. Rich (1942) estimated that the 1938 harvest rate on up-river steelhead was 67%, with 80% of the catch occurring below Bonneville Dam. Subsequent harvest records indicate that commercial harvest rates on up-river steelhead were about 66% between 1938 and 1950 (Figure 8-15) (WDFW and ODFW 2002). Most of the harvest was probably of summer steelhead. Winter steelhead were not identified as a separate race until 1953. From 1939 through 1950, about 8% of the steelhead passing the dam were probably winter steelhead based on run timing.

Total mainstem commercial harvest rates on steelhead (tribal and non-tribal combined) began to decline in the 1950s, and also began to include a mix of hatchery and wild fish. Mainstem harvest rates on up-river summer steelhead declined from about 50% to about 20% from the early 1950s to the early 1970s, while winter steelhead harvest rates declined from about 30% to about 5% over the same period. Non-tribal mainstem commercial fisheries on steelhead were discontinued in 1975. Subsequent impacts in the non-tribal commercial fishery were due to by-catch during fisheries on other species. All steelhead were released in these fisheries, although some release mortality occurred. Tribal commercial harvests in Zone 6 since 1975 ranged from about 30% to less than 10% (Figure 8-13).

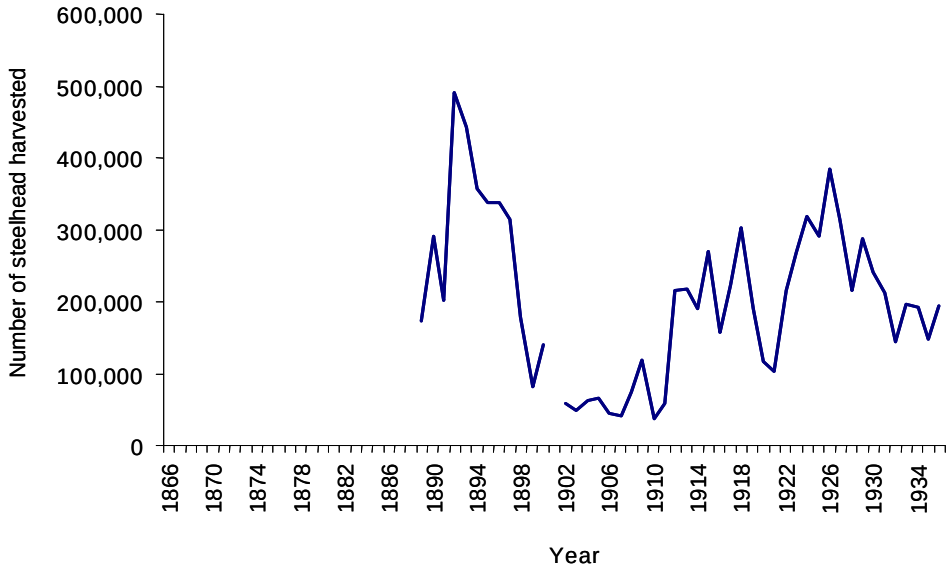

Figure 8-12. Number of steelhead harvested each year in mainstem Columbia River fisheries (1866-1936) (Craig and Hacker 1940).

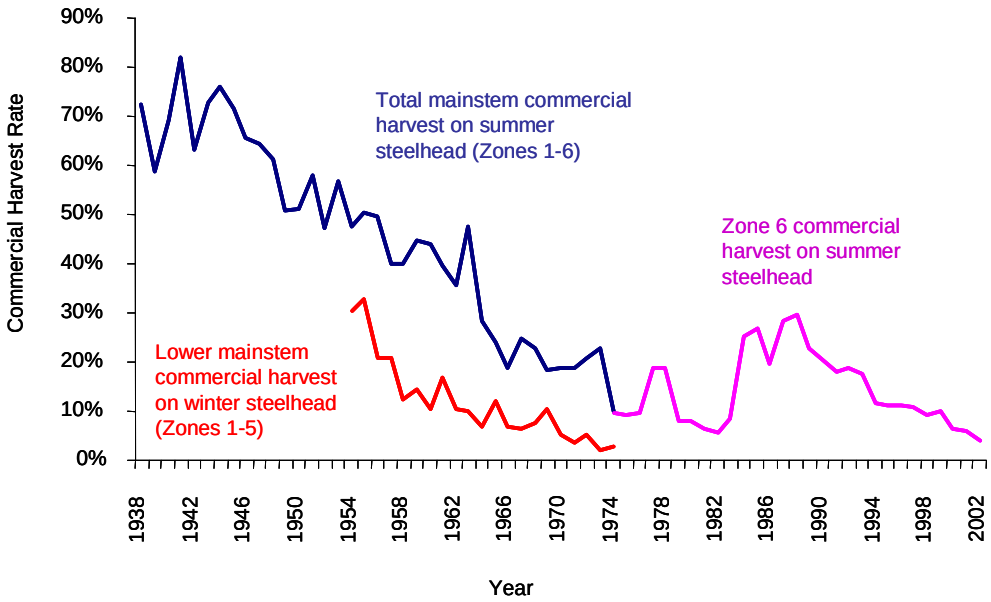

Figure 8-13. Commercial harvest rates on steelhead, 1938 – 2002 (WDFW and ODFW 2002). Non-tribal commercial harvest was discontinued in 1975.

Mainstem Recreational Fisheries

Mainstem recreational fisheries below Bonneville Dam have been monitored by creels since 1964. The harvest rate on summer steelhead ranged from over 16% to less than 1% until 1992

when all fisheries became catch-and-release for wild fish (Figure 8-14). The harvest rate on winter steelhead over the same period ranged from 2% to less than 1%. Current recreational harvest impacts for both life histories are estimated to be less than 1% and are due entirely to hooking mortality.

Recreational fisheries in the mainstem above Bonneville Dam are not monitored, except by punch card estimates. Bubble fisheries at the mouths of some tributaries can be seasonally intense, but the impact rates are unknown except for a bubble fishery at the mouth of the Deschutes. These fisheries have also been catch-and-release since 1992 and impacts to wild fish are thought to be less than 1%.

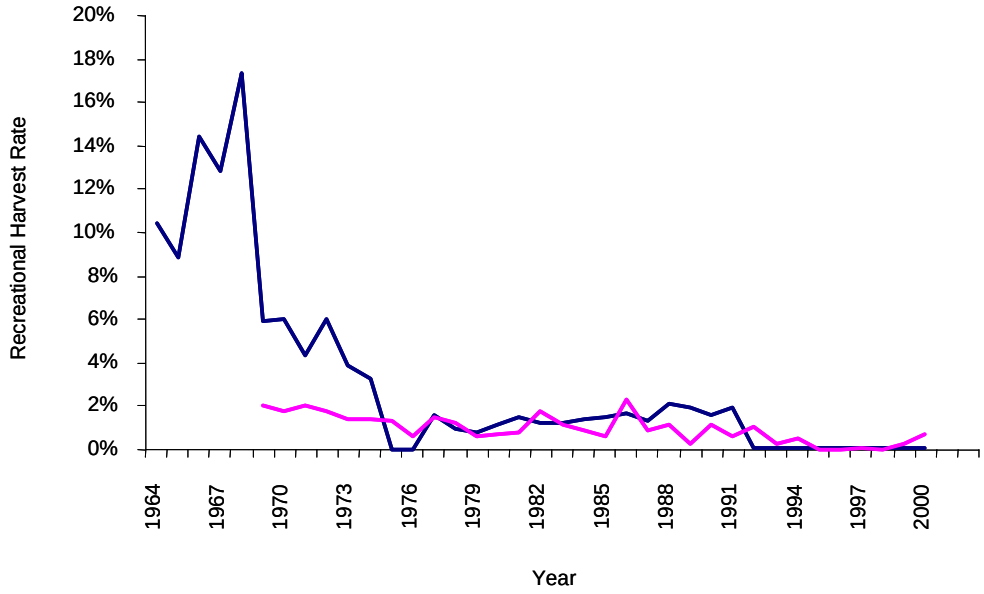

Figure 8-14. Recreational harvest rates on steelhead in the mainstem below Bonneville Dam, 1964 – 2002 (WDFW and ODFW 2002). Blue is summer steelhead while pink is winter steelhead. All mainstem fisheries became catch-and-release in 1992 and the impacts since that year were calculated by the encounter rate and an estimated release mortality.

8.5.2 Allowed Harvest Impacts under NOAA Biological Opinions

Harvest of ESA-listed fish, including the Mid-C steelhead DPS, is controlled by NOAA Fisheries to protect weak stocks. The Oregon Fish and Wildlife Commission also sets limits on certain fisheries to protect the listed stocks. Impacts from harvest regulations to protect Mid-C steelhead are discussed below.

Mid-C Winter Steelhead
The NOAA Biological Opinion for 2008 set a mainstem Columbia River non-tribal impact limit on winter steelhead of 2% (including both sport and commercial impacts), and an average tribal impact of 2.3%. Oregon has FMEPs in place that set tributary impact limits between 0% and 2.5%.

Mid-C Summer Steelhead
The NOAA Biological Opinion for 2008 set a mainstem Columbia River non-tribal impact limit on summer steelhead of 4%, including both sport and commercial impacts. This limit is split across two seasons, with 2% applied to spring and summer fisheries and 2% applied to fall fisheries. An average annual tribal impact of 9.3% (1.9% summer season and 7.4% fall season) is set for Zone 6. Oregon has FMEPs in place or proposed that set tributary impact limits between 0% and 5%.

8.5.3 Actual Recent Harvest Impacts

Monitoring of harvest impacts on Mid-C steelhead is complex because there is no direct non-tribal harvest on wild steelhead from the DPS and all catch is indirect. Indirect effects include incidental mortality of fish that are caught and released, encounter fishing gear but are not landed, or are harvested incidentally to the target species or stock. Monitored and unmonitored fisheries, and impacts due to fishing gear and environmental conditions are discussed below.

Monitored Fisheries
Actual harvest impacts on Mid-C DPS steelhead over the last several years have been incompletely monitored. Monitoring of incidental harvest impacts is complex for two reasons. First, since all caught fish are released, encounter rates and characteristics of encountered fish are difficult for monitors to observe. Second, released fish experience a mortality rate, possibly delayed and difficult to measure, that is highly variable and depends upon what gear is used, how the fish is caught by the gear, how the fish are handled during capture and release, and on environmental conditions.

Ocean commercial and recreational harvest of salmon has generally declined in recent years because of international treaties, fisheries conservation acts, regional conservation goals, the Endangered Species Act, and state and tribal management agreements. Creels on recreational ocean fisheries recorded less than 100 steelhead caught each year in 2003 – 2005. Of these, less than 10 were estimated to be released wild fish mortalities.

The only effort to regularly monitor steelhead by-catch in non-tribal commercial fisheries occurs in the spring Chinook commercial fishery, which impacts primarily winter steelhead, in the mainstem Columbia below Bonneville Dam. This monitoring effort, which began in 2003, employs observers on board fishing boats to measure steelhead encounter rates and uses information from recent literature to set a release mortality rate from gill nets according to mesh size. The estimated impact rate on wild winter steelhead from 2003 to 2005 ranged from 0.5% to 1%. The measurements have an unknown error around these numbers due to the use of point estimates for encounter rates, mortality rates and escapements, all of which actually contain some variance and/or measurement error.

Recreational creel surveys in the lower Columbia mainstem below Bonneville Dam and in the lower Deschutes and Umatilla include questions about wild steelhead releases to estimate encounter rates, and use recent literature to set a hooking mortality rate. Estimated recent impact rates in these recreational fisheries ranged from 0.1% to 1.5% in each fishery. The fish in any particular population may be exposed to several of the fisheries as they move through the

mainstem and into tributaries, but the total recreational impact is probably less than 2.5% in most cases. Again, there is an unknown error around these numbers.

Catch of steelhead in the Zone 6 tribal fishery is easier to monitor since steelhead sold to commercial buyers are counted and measured. However, some tribal steelhead catch, and possibly much of it, may not be reported if they are sold over the bank by individuals or if they are retained for personal use. Tribal biologists make some effort to account for unreported catch, especially in fall fisheries. Reported steelhead catch in Zone 6 winter and spring fisheries for 2003 to 2005 ranged from 0.7% to 7.9% of the winter steelhead run over Bonneville Dam (Table 8-49). Reported steelhead catch in Zone 6 summer and fall fisheries in 2003 and 2004 was 2.6% and 2.7% of the summer steelhead run over Bonneville Dam (Table 8-50). In 2004, the estimated non-reported catch increased the impact to 4.8% of the run at Bonneville. Again, there is an unknown error around these numbers.

Potential impacts due to harvest selectivity are only taken into account in the Zone 6 tribal fishery that is thought to select for larger steelhead because of the use of gill nets with unrestricted mesh sizes. Mesh size in these fisheries is generally selected to optimize the catch of Chinook, the target species. Smaller and younger steelhead are able to escape many nets. The Zone 6 fishery monitors the catch of large steelhead as a separate stock. The 2004 estimated impact on large verses small fish is presented in Table 8-51. Each of the four "stocks" also has a distinct run timing which may account for hatchery/wild differences within size category.

Table 8-49. Estimated impacts (percent of run) on winter steelhead in winter and spring mainstem fisheries (2003–2005).

	Non-tribal Commercial		Tribal	
Year	Number of wild steelhead	Impact rate (of Columbia River mouth escapement)	Total number of steelhead (wild + hatchery)	Impact rate (of Bonneville Dam escapement)
2003	229	1.0%	807	7.9%
2004	238	0.8%	81	0.7%
2005	69	0.5%	208	3.6%

Table 8-50. Estimated impacts (percent of run) on summer steelhead in summer and fall Zone 6 fisheries. Fish numbers include hatchery and wild steelhead, and impact rates are calculated based on the Bonneville Dam escapement.

				Fall							
		Summer		Bonneville Pool		The Dalles Pool		John Day Pool		Total summer/fall	
Year		Fish	Impact rate	Fish	Impact rate	Fish	Impact rate	Fish	Impact rate	Fish	Impact rate
2003	Ticketed	96	<0.1%	4,484	1.3%	2,478	0.7%	2,251	0.6%	9,309	2.6%
2004	Ticketed	714	0.2%	4,611	1.5%	1,792	0.6%	1,219	0.4%	8,336	2.7%
	Est. Total Landed in 2004 (Ticketed, non-ticketed, and C&S)									14,757	4.8%

Table 8-51. Estimated size selectivity of the 2004 Zone 6 fishery. The size breakout is that "Small" fish are less than 78 cm, while "Large" fish are equal to or greater than 78 cm. Estimated impact rates are based on the abundance of each group at Bonneville Dam.

Characteristic	Number of Fish	Estimated Impact Rate
Small hatchery	6,791	3.2%
Small wild	1,963	3.4%
Large hatchery	4,963	17.2%
Large wild	1,040	10.6%

Unmonitored Fisheries

All other fisheries that could encounter steelhead have been unmonitored or irregularly monitored in the past few years. All of these other fisheries must release caught steelhead, but mortality can still occur. The Mid-Columbia steelhead DPS is a diverse DPS that includes winter and summer-run steelhead. Winter steelhead move through the Columbia River between November and May; summer steelhead move through the Columbia River primarily between April and October, although some may be present at other times. Therefore, steelhead from the DPS are present in the mainstem Columbia River nearly year-round, making them potentially vulnerable to a variety of lower mainstem fisheries (Figure 8-15). Some information about potential impacts caused by these fisheries can be inferred by the season and gear, which determine steelhead vulnerability to the fisheries.

The primary fisheries targeting steelhead occur in the Columbia River mainstem and tributaries. These fisheries harvest primarily hatchery fish, and wild fish mortality is incidental. Unmonitored recreational fisheries currently occur in the mainstem Columbia above Bonneville Dam, Fifteenmile Creek (winter steelhead), Deschutes River above Sherars Falls, and in the John Day and Walla Walla rivers.

Unmonitored mainstem non-tribal commercial fisheries target sturgeon, summer and fall Chinook, sockeye, shad and coho. These fisheries all use gill nets of various sizes and occur

between the mouth of the Columbia River and Bonneville Dam, although particular fisheries may target specific zones (Table 8-52). All steelhead taken in commercial nets must be released, but are subjected to encounter rates and release mortalities that vary by gear and season.

Ocean fisheries generally target Chinook and coho salmon, and interception of steelhead is believed to be rare. Currently, however, all ocean commercial fisheries are unmonitored for steelhead by-catch.

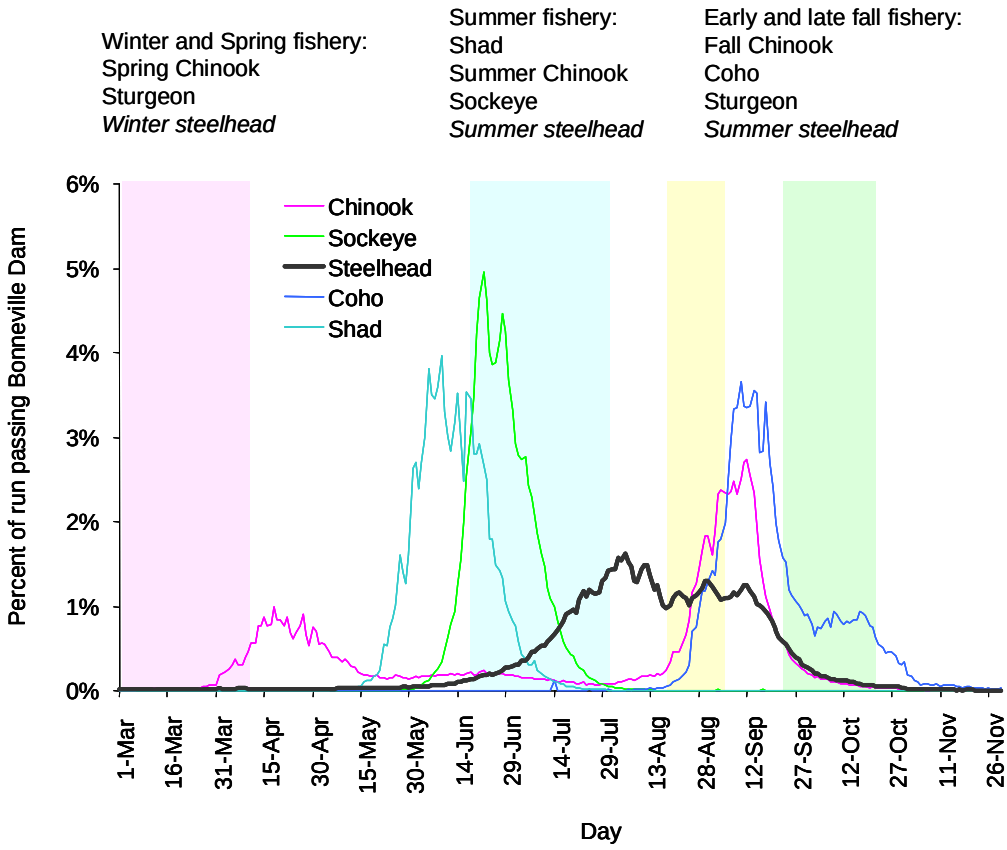

Figure 8-15. Run timing at Bonneville Dam of steelhead and other species that are targeted in mainstem commercial fisheries.

Table 8-52. Characteristics of commercial fisheries in the Columbia River below Bonneville Dam.

Fishery	Non-tribal Season	Non-tribal Gear	Tribal Season	Tribal Gear	Water temperature	Steelhead life history present
Sturgeon	Variable	9 inch min.	Variable		variable	Winter and summer
Spring Chinook	Late Feb. to early April	9 inch min. or 4 ¼ inch max.	February through April	Dip nets, set lines and gill nets with no	low	winter steelhead
Shad	May and June	5 $^{3}/_{8}$ to 6 ¼ inch 10 lb break	no specific fishery	mesh size restrictions	high	Summer steelhead
Sockeye	June and July	4 ¼ inch max.	June and July		high	Summer steelhead
Summer Chinook	June and July	8 inch min.	June and July		high	Summer steelhead
Fall Chinook	August, late Sept.	8 inch min. or 9 inch min.	August through October		high	Summer steelhead
Coho	Late Sept. and October	No min. 5 - 6 inch nets used	September and October		high	Summer steelhead

Encounter Rates and Mesh Size

Encounter rates for Mid-C steelhead increase with smaller mesh nets. Figure 8-16 shows the number of steelhead caught and released per Chinook landed, by mesh size, as observed in the spring Chinook fishery, 2003 to 2005 (test fisheries, research, and observer data combined).

Generally, few steelhead are caught in nets that are 9-inch mesh or larger because most fish are able to swim through them, although steelhead catch has been observed to be as high as one steelhead per four Chinook landed, and the steelhead that are caught are the large fish. Some fisheries use 8-inch minimum mesh size, which has a slightly higher encounter of steelhead, and is also selective for large fish. Mid-size mesh nets (5 to 6 inches) gill or body-wedge steelhead, and have high encounter rates and a high mortality rates. Small mesh "tangle" nets (4¼-inch) tangle most steelhead, causing high encounter rates but lower mortality rates compared to nets that gill fish. Some fisheries that are designed to catch small species (like shad) use nets with low break poundage that allow larger salmonids to break loose from the nets.

Release Mortality Rates, Mesh Size and Environmental Conditions

Release mortality rates in mainstem commercial fisheries vary by mesh size. The highest mortality rates occur when fish are gilled or body-wedged by the nets. In spring fisheries, when the river is relatively cool, release mortalities from nets that gill fish are 40% or higher. Steelhead are gilled or wedged in nets that are 5.5 inches are larger, until the mesh is large enough for the fish to swim through them. Nets that tangle fish, (4¼-inch for steelhead) have mortalities near 20% during the cool spring fisheries. Some fishing practices, particularly long soak times, increase mortality rates. Mortality rates increase dramatically during warm water conditions that occur in the summer and fall.

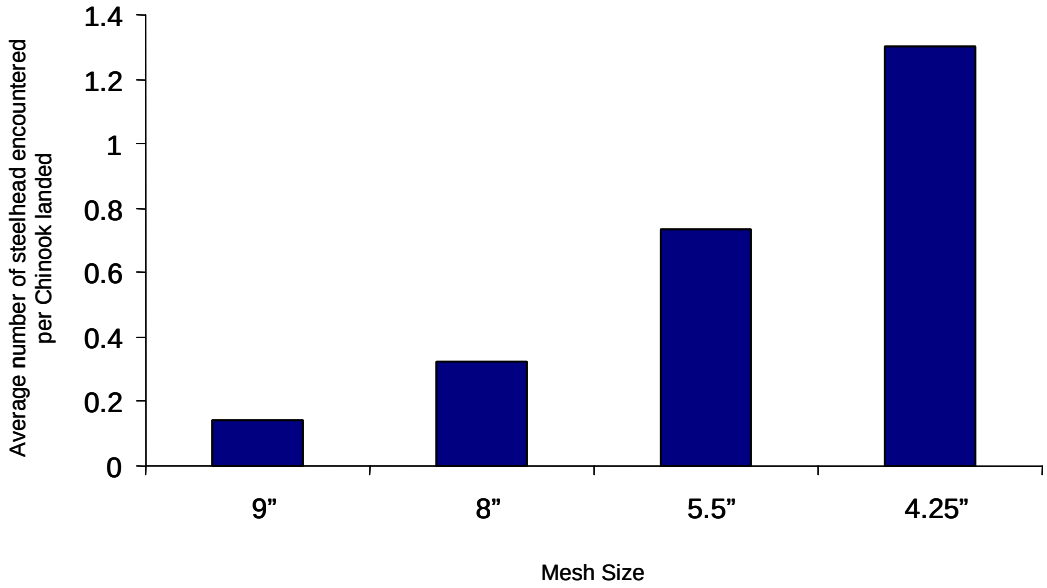

Figure 8-16. Number of steelhead released per number of Chinook landed by mesh size, as observed during monitoring and test fishing in 2003 – 2005 spring Chinook fisheries.

8.5.4 Tributary Fishery Impacts

Fishery Management and Evaluation Plans (FMEPs) have been developed for Oregon Mid-C steelhead populations to address the take of listed fish in recreational fisheries. The primary goal of a FMEP is to devise biologically based fishery management strategies that are consistent with the conservation and recovery of listed populations. FMEPs focus primarily on limiting impacts to abundance and productivity, the two key viability parameters most directly affected by sport fisheries.

Overview

Harvest regulations for Fifteenmile Creek and the Deschutes, John Day, Umatilla rivers and the Oregon portion of the Walla Walla River all reflect strategies that provide protection for natural-origin fish while allowing maximum levels of harvest on hatchery fish. We did not identify tributary harvest as a threat to viability of any of the Mid-C populations. In the review of past and present tributary fisheries, the Mid-C Expert Panel (2006) found that while legacy harvest practices had affected population traits of Mid-C steelhead the impacts of contemporary harvest management on populations in the DPS were much less significant than threats from current land use practices, hatchery programs, and hydropower projects.

Steelhead Sport Harvest Management

In part, ODFW bases steelhead sport fishery harvest rates on the results of model runs that examine the extinction probability risks at different fisheries mortality rates. Chilcote (2001) estimated extinction probabilities for 27 Oregon steelhead populations with respect to a variety of fishery mortality rates. These model runs were then used to assess the impact of fisheries mortality on the status and recovery of steelhead in Oregon (Chilcote 2001). The model looked

at a range of fisheries mortalities from 0% to 75%. The results were stated in terms of the probability of population extinction in 50 years at each mortality rate. For most populations, the modeling suggested that the probability of extinction was essentially zero as long as fisheries mortality rates remained less than 30%. However there was significant variation between populations. The probability of extinction increased dramatically as mortality rates became greater than 40%. Furthermore, once the probability of extinction increased beyond 0.05, the transition to an extinction probability of 1.00 was very rapid. In other words, once mortality rates increase sufficiently to cause the probability of extinction to exceed 0.05, any additional mortality would cause a rapid increase in the likelihood of extinction. Because the transition from low to high risk happens rapidly, there is little room for error (in the model or the measurements of mortality rates). To address this concern, ODFW generally manages steelhead fisheries not to exceed a maximum fisheries mortality rate of to 20%, but it is more conservative when warranted.

Trout Harvest Management

Fisheries managers reduce juvenile steelhead mortality during trout fisheries by requiring catch and release fisheries and by prohibiting the use of natural and synthetic baits. They also restrict fisheries to areas, times and size limits that protect steelhead. Such steps are necessary because steelhead occupy many waters that are also occupied by resident trout species, and it is not possible to visually separate juvenile steelhead from similarly sized stream-resident rainbow trout.

Juvenile steelhead and resident rainbow trout are the same species, are similar in size, and have the same food habits and habitat preferences; so, assumably, catch-and-release mortality studies on stream-resident trout would also apply to juvenile steelhead. Many studies have shown trout mortality to be higher when using bait than when angling with artificial lures and flies (Mongillo 1984; Taylor and White 1992; Schisler and Bergersen 1996; Schill and Scarpella 1997; Wydoski 1997). As a result, the prohibition of natural and artificial bait is believed to reduce juvenile steelhead mortality more than any other angling regulatory change. Hook-and-release mortality of juvenile steelhead is expected to be less than 10% and approaches 0% when anglers are restricted to use of artificial flies and lures with barbless hooks.

Studies show that catch and release mortalities tend to increase for juvenile steelhead as water temperatures increase, with over 80% of the observed mortalities in one study occurring above 21° C (Taylor and Barnhart 1997). Consequently, fisheries are restricted in some areas during times of the year when stream temperatures are high.

Fifteenmile Creek

Under current fisheries regulations, adult steelhead cannot be legally retained in any of the minor Columbia River tributaries (Fifteenmile, Mill or Chenoweth creeks). Steelhead are rare in Mosier, Rock and Threemile creeks; though they have been observed in each of the streams. Conservative trout angling regulations are currently in effect on Rock, Mosier, Chenoweth, Mill, Threemile and Fifteenmile creeks and provide a high level of protection for steelhead juveniles.

Chenoweth, Mill, Rock, Mosier, Threemile and Fifteenmile creeks open to trout angling the fourth Saturday in May and remain open through October. It is believed that most steelhead

smolts emigrate for their natal streams before the opening date. Further, Chenoweth, Mill, and Fifteenmile Creeks are restricted to catch and release angling with artificial lures only.

Rock, Mosier and Threemile creeks have very limited areas that are accessible to steelhead. Rock Creek has a porous alluvial fan at its mouth and fish passage across this fan is possible only at high winter and spring flows, and natural barriers that are not passable to steelhead are present a short distance upstream. Anadromous fish are blocked from accessing all but the lower 400 meters of Mosier Creek by an impassable falls. Steelhead access in Threemile Creek is severely restricted by improperly functioning culverts under Interstate 84, and culverts under Highway 197 block access approximately 300 meters above that point. Trout fishing in these streams does not open until the fourth Saturday in May, but is not restricted to catch and release or artificial lures. Five trout can be harvested per day with an 8-inch minimum length limit. Managers are not aware of any trout angling effort in the portions of these streams that are accessible to steelhead.

In Fifteenmile Creek, juvenile steelhead receive significant protection from angling mortality. As noted above, anglers are restricted to artificial flies and lures for all angling. The incidental mortality associated with these fisheries is due to impacts from the catch and release of juvenile steelhead. ODFW has estimated that the mortality rate from the trout fisheries is less than 1% of the juvenile steelhead in Fifteenmile Creek, based on the low effort observed, and the low catch and release mortality. ODFW (2005) has submitted to NMFS a FMEP for fisheries affecting Mid-C steelhead in Fifteenmile Creek and the other mainstem Columbia River tributaries downstream of the Deschutes River (as part of the Deschutes River Basin FMEP), for review and concurrence under Limit 5 of the 4(d) rule for Mid-C steelhead (71 FR 834).

Deschutes River

The Deschutes River FMEP (ODFW 2005c) submitted to NMFS, specifies that the management objective is to provide consumptive recreational fisheries on adult hatchery summer steelhead, non-listed salmon, and resident redband trout in the Deschutes River while allowing for the recovery of ESA listed steelhead. Only adipose fin-clipped adult steelhead may be retained in the fisheries. The source of mortality in these selective fisheries is from the hook-and-release of listed fish.

Steelhead Sport Harvest Management

Specific exploitation rate goals for hatchery summer steelhead in the Deschutes River have not been identified, but fisheries managers recognize that maximizing removal of hatchery origin summer steelhead through angling is important to maintain the genetic health of the wild population. Removing hatchery steelhead utilizing harvest reduces the number of hatchery fish available to spawn in the wild. Continuing sport angler removal of hatchery steelhead from the Deschutes River is an important tool to meet management objectives.

The importance of sport angler removal of hatchery steelhead in the Deschutes River is underscored by extinction probabilities estimated by Chilcote (2001). The current long-term average percentage of hatchery steelhead in the Westside population is estimated to be 18% and 34.4 % for the Eastside population. Chilcote (2001) concluded that hatchery-origin fish spawning naturally in the Deschutes River subbasin posed significant risk to persistence of

natural populations. Reduction in the proportion of natural spawners that are hatchery origin would significantly reduce the risk of extinction. It is crucial that subbasin fish managers continue to use sport anglers as a tool to maintain and even increase removal of hatchery fish from the spawning population.

The best available information suggests that the fishing mortality rate for summer steelhead in the Deschutes River is expected to be 1% (section 1.4.1 of the FMEP; ODFW 2005c). This estimate was derived using a 10% encounter rate and a 10% catch-and-release mortality rate (Hooton 1987). Also, as discussed earlier, catch and release mortalities tend to increase as water temperatures increase, with over 80% of the observed mortalities in one study occurring above 21° C (Taylor and Barnhart 1997); and water temperatures in the Deschutes can approach 21° C during parts of the summer. As a result, a 10% hooking mortality was used to estimate fishing impacts on natural summer steelhead. The average recreational catch rate of Round Butte Hatchery origin steelhead from the mouth to RM 43 has been estimated to be 9.3% for the last 5 years. Assuming that natural steelhead are also caught at this rate and that they suffer a 10% hook-and-release mortality, fishery impacts of less than 1% are expected for natural-origin steelhead.

The steelhead fishery will continue as proposed as long as the average natural spawning summer steelhead escapement is above 1,479 at Sherars Falls. The trend in natural steelhead escapement will be monitored annually. If there is a downward trend or if escapement is expected to fall below 1,479 in the foreseeable future, fishery restrictions will be imposed.

The current harvest rate on steelhead is believed to be well below that seen in the past. Cramer et al. (1997) reviewed harvest rates of adult steelhead in sport fisheries in Oregon and Washington before wild (unmarked) steelhead release regulations and concluded that harvest rates on natural summer steelhead were in the neighborhood of 50%. While past harvest impacts to adult steelhead in the Deschutes River before the start of mandatory unmarked fish release regulations in 1979 are unknown, harvest rates in the Deschutes River could have been of this magnitude during some years. It is estimated that the annual harvest impacts for fisheries covered in this FMEP will remain at less than 1.5%, which is well below the 50% observed in the past.

ODFW sport harvest regulations for the Deschutes are also designed to protect holding and spawning steelhead. ODFW believes that the vast majority of mainstem steelhead spawning occurs in that portion of the Deschutes River bordering the Warm Springs Reservation (RM 71 to 100). This river reach is closed to all angling from January 1 to the fourth Saturday in April each year. This closure minimizes disturbance to holding and spawning steelhead and outmigrating smolts.

Steelhead Tribal Harvest

The Warm Springs Tribal steelhead fisheries typically occur from September through December. The majority of fish are harvested at Sherars Falls and creel surveys are conducted to estimate harvest. Typically steelhead are not the target species but are caught incidentally during the Fall Chinook salmon fishery. Tribal members fish from scaffolds and with hook and line. Scaffold fishing is the more common method. Targeted hook and line steelhead fisheries occur on the Reservation lands but are minimal in scope and impact. In response to the listing of Mid-C

steelhead, the Warm Springs Tribal Council has annually approved Tribal Resolutions requiring the release of wild steelhead. Compliance with the resolution is generally good; however a few wild fish are retained. Table 8-53 shows harvest of wild and hatchery fish from 1980-2005. Prior to 1999 natural-origin fish were retained; after 1999 the majority of the natural-origin fish were released back into the Deschutes River. Since 1992, the estimated harvest of natural-origin fish has been well below previous years and has generally been low.

Table 8-53. Deschutes River expanded summer steelhead tribal harvest estimates for Sherars Falls, by run year (June 16 – October 31). Harvest estimates are for the dip net and hook and line fisheries combined (ODFW/CTWSRO Creel Data).

Year	Anglers/ Fishers	Hours	Tribal*	
			Wild	Hatchery
1980	944	7,357	981	1,309
1981	605	5,025	688	772
1982	516	4,628	549	1,066
1983	954	5,131	903	3,286
1984	576	5,553	1,600	2,730
1985	710	6,126	1,463	2,728
1986	523	5,848	1,225	3,729
1987	724	4,736	972	1,800
1988	744	5,978	339	939
1989	973	6,347	529	1,294
1990	602	4,232	301	1,300

2004	478	1,919	69	546
2005	671	3,031	23	505

Every year, the Tribal Council sanctions a sport fishery that occurs in select areas on and bordering the Warm Springs Reservation. These fisheries are for non-tribal anglers and require the purchase and possession of a permit. The regulations that are adopted by the Tribal Council are very similar to the ODFW regulations, where the fishing areas overlap. In 1999 the fishing area in the Warm Springs River near the Kah-Nee-Tah Resort was closed to reduce the impact of hook and line angling on steelhead. Also, the area along the Deschutes River from Dry Creek to Trout Creek is closed from November 1st until the third Saturday in April. Camping, fishing, or landing on all islands west of the middle of the main channel (Reservation Islands) is prohibited, and critical spawning areas for steelhead and fall Chinook are posted and the regulations require that no fishing is to occur within 100 feet of the signs. These regulations greatly reduce the amount of fishing pressure and harassment on the west bank of Deschutes River along the Reservation boundary during the steelhead run. Given the low exploitation and restrictive current regulations, no additional Tribal management regulations are proposed.

Salmon Harvest Management

Spring Chinook are reared at the Round Butte Hatchery and at the Warm Springs National Fish Hatchery. Spring Chinook are harvested principally from April 15 through June 15, and virtually all sport and tribal spring Chinook harvest takes place in the one-mile reach immediately downstream from Sherars Falls. This reach is characterized by very deep, high velocity areas where the river is constrained between bedrock cliffs; conditions that restrict use by significant numbers of juvenile steelhead. In addition, while natural bait is legal in the three-mile stretch of river downstream from Sherars Falls, anglers tend to use large hooks and bait when angling for Chinook salmon. Very few adult steelhead are caught in this fishery because very few steelhead are in this area at this time of year. The mortality on steelhead (adults and juveniles) caught and released in the fishery is estimated to be very low.

Fall Chinook salmon return to the Deschutes River starting in late June and early July. The sport harvest scenario for fall Chinook is very similar to that for spring Chinook, with the majority of the sport harvest taking place in the one-mile stretch immediately downstream of Sherars Falls. Greater numbers of natural summer steelhead are caught and released during this fishery, given the greater number of natural steelhead present at the time of this fishery. The increased hooking mortality to natural summer steelhead due to the use of bait is unknown, but is likely small given the spatial and temporal constraints on the fishery.

For all of the tributary fisheries described in the FMEP, the impacts are estimated to be less than 1.5% of the natural-origin summer steelhead.

Trout Harvest Management

Trout fisheries for native redband trout are ongoing in the Deschutes River. Trout angling is closed from the northern boundary of Warm Springs Reservation upstream to Pelton Regulating Dam from November 1 through the fourth Saturday in April. This closure minimizes disturbance to rearing juvenile steelhead before spring migration. Redband trout are very abundant in the lower Deschutes River, where estimated population densities of more than 2,000 trout (greater than or equal to eight inches) per mile have been observed. The total abundance of redband trout in the lower 100 miles of the Deschutes River likely exceeds 100,000 individuals,

and the magnitude of that population provides an effective buffer against juvenile steelhead mortality in the redband trout fishery.

Juvenile steelhead are protected through the current fisheries regulations. There is a two fish bag limit for redband trout, and only fish between 10 and 13 inches in length can be retained. Other trout must be released unharmed. Most natural steelhead smolts are less than eight inches in length. Effort and harvest information collected from redband trout anglers in the lower Deschutes River for many years shows that the current trout slot length limit and bait ban combine to nearly eliminate consumptive trout angling. Data from harvest samples in the lower 43 miles of the Deschutes consistently show that anglers harvest approximately 3% of their total redband trout catch. This harvest rate translates into an actual harvest of less than 1% of the redband trout population in the river each year. This very low harvest rate also protects juvenile steelhead caught incidentally by redband trout anglers. Further protection was provided in 1978 with the end of stocking of legal-sized rainbow trout, which limited impacts to natural juvenile steelhead that are harvested incidentally to the catchable trout fishery. Protection is also provided by restricting anglers to artificial flies and lures for all angling on 97 of the 100 miles open to fishing in the lower Deschutes River.

John Day River

Fishery impacts on adult and juvenile steelhead in the John Day River have been minimized under the fishing regulations established in the FMEP, with impacts from all tributary fisheries estimated to be less than 2% of the natural-origin fish. The John Day River FMEP (ODFW 2005a) submitted to NMFS, specifies that the management objective for the plan is to conduct consumptive fisheries for marked adult hatchery steelhead, resident rainbow trout, and warmwater species. Fisheries for spring Chinook salmon have not been open in the John Day River subbasin since 1976.

While specific exploitation rate goals for hatchery summer steelhead in the John Day River have not been identified, managers stress that maximizing removal of hatchery origin summer steelhead through angling is important to maintain the genetic health of natural populations. Removing hatchery steelhead utilizing harvest reduces the number of hatchery fish available to spawn in nature. Continuing sport angler removal of hatchery steelhead from the John Day River is an important tool to meet management objectives. To help increase harvest of hatchery steelhead from the John Day River, managers have adopted a 3 fish per day, no annual limit regulation for adipose fin-clipped steelhead.

Steelhead Sport Harvest Management

Adult steelhead fishery impacts are minimized by season and areas closures. Listed below are the areas and times that are open to adult steelhead fisheries.

- Mouth of the John Day to Cottonwood Bridge RM 38: Year round.
- RM 38 Cottonwood Bridge to RM 185 at Kimberly: Year round.
- RM 185 at Kimberly to RM 257, the mouth of Indian Creek: Sept.1 to April 15.
- Mouth of the North Fork to RM 60 at Hwy 395 Bridge: Sept.1 to April 15.
- Mouth of the Middle Fork to RM 24.2 at Hwy 395 Bridge: Sept.1 to April 15.
- South Fork: Closed to adult steelhead angling.

- All other tributaries and portions of the Middle Fork, North Fork and Mainstem not listed: Closed to adult steelhead angling.

In addition, ODFW has implemented restrictive regulations permitting only the retention of marked adult hatchery steelhead and requiring the release of natural-origin adult steelhead in the John Day subbasin. Punchcard estimates during years when retention of wild steelhead was permitted indicate that wild fish harvest rates in the John Day River subbasin averaged approximately 12% of the annual return (ODFW 2005a). This estimate includes years when bag limits allowed retention of 2 fish per day and up to 20 fish per year, and also includes a significant component of hatchery fish in some years. For 1996 (the only year in which statistical creel data are available), the proportion of hatchery fish in the harvest below Cottonwood Bridge (where most fish are caught) was approximately 48% (ODFW 2005a); so the estimated 12% harvest rate on natural-origin fish is likely higher than actual. Based on these data, ODFW estimates the potential encounter rate of natural-origin steelhead in the John Day River fishery to be in the range of 6 to 12% of wild steelhead present in the subbasin. A fishery requiring release of wild fish has been in effect since 1995, so in-subbasin fishery related mortality rates (likely less than 1% [12% encounter rate x 5% hooking mortality rate = 0.6%]) and angler effort have dropped substantially since the hatchery only harvest regulation was implemented.

The 5% catch and release mortality rate is conservative for steelhead based on the mortality estimate for steelhead of 3.4% developed by Hooton (1987). Studies show that catch and release mortalities tend to increase as water temperatures increase, with more than 80% of the observed mortalities in one study occurring above 21° C (Taylor and Barnhart 1997). While the adult steelhead fisheries in the John Day River do not begin until September when the water temperatures are slightly elevated, steelhead returns and fishing effort do not increase until mid-October when flows increase and water temperatures drop below 21° C.

ODFW estimates that the annual harvest impacts on natural-origin fish under the FMEP will remain at less than 1.5% annually. Harvest impacts on adult steelhead in the John Day River before the start of mandatory unmarked fish release regulations in 1996 are unknown, but were clearly greater than the current level

Trout Harvest Management

While the John Day River is not highly regarded by most anglers for its trout angling opportunities, redband trout occur throughout the subbasin and westslope cutthroat trout occur in the upper John Day River system and a few North Fork tributaries. Presently, angling effort for trout is targeted to standing water bodies where ODFW routinely stocks hatchery fingerling or legal sized rainbow trout. Past harvest impacts on juvenile steelhead during trout fisheries in the John Day River are unknown.

Historically, most trout angling effort in streams was associated with areas where legal or fingerling rainbow were released. An evaluation of ODFW's fingerling rainbow stocking program in the South and Middle forks was completed in 1995. The evaluation concluded that the stocked fingerling were not being caught by the few anglers interviewed, and that there were

adequate numbers of wild, legal-sized rainbow trout in both streams to support the modest fishery.

Since 1998, there have been no releases of hatchery rainbow trout into any streams within the subbasin. The trout-angling season for streams does not open until the fourth Saturday in May and the minimum legal size is 8 inches. Monitoring of smolt migration at irrigation diversion bypass traps and out-migrant traps (screw traps located on the South Fork John Day River, Middle Fork John Day River and mainstem John Day River) indicates that most steelhead smolts emigrate before the second week in May. Juvenile *O. mykiss* length frequency data from selected steelhead spawning and rearing streams indicate that 98% of them are less than six inches long. The combination of a late opener and the eight-inch minimum size limit provides significant protection for juvenile steelhead and smolts. In addition, the following streams are closed to all angling: the Granite Creek system (North Fork John Day tributary), and the Middle Fork John Day River from Highway 7 to Summit Creek.

It is difficult to quantify the impacts to juvenile steelhead from sportfishing because of the lack of information specific to the John Day River. However, given the current regulations that are in place to protect juvenile steelhead, the dispersed nature of the fishery and cessation of trout stocking after 1997, it is estimated that <1% of rearing juvenile steelhead in the John Day River subbasin are caught and released in the trout fishery.

Warmwater Fisheries Harvest Management

Warmwater fisheries in the subbasin are believed to have little, if any impact on the steelhead population because they occur primarily at a time and location where juvenile and adult steelhead are not present. These fisheries are open only during trout, salmon, or steelhead seasons, and the angling is largely dependent upon water temperatures and water clarity. Significant angler effort does not begin until mid- to late-May in most years. The bulk of the warmwater fishery takes place in the lower mainstem from RM 40 to RM 185 where steelhead do not rear. There is virtually no warmwater fishery in the John Day River above Kimberly or above Wall Creek on the North Fork John Day River because the abundance of smallmouth bass is relatively low. The probability of encountering juvenile steelhead increases as one progresses upstream due to improved rearing conditions. Additionally, most warmwater anglers use terminal angling gear that reduces the probability of catching steelhead, and if hooked, it facilitates easy release.

Umatilla River

The Umatilla River system supports steelhead sport and tribal harvests. Steelhead are also captured in fisheries targeting resident trout, warmwater fish and Chinook salmon.

Steelhead Sport Harvest Management

The Umatilla River steelhead sport fishery is directed at the harvest of hatchery steelhead produced by the Umatilla Hatchery and stray hatchery fish. Current angling regulations require the release of natural-origin (unmarked) steelhead in the Umatilla River. The general steelhead season for the Umatilla River (September 1 – April 15) and open area (mouth to west reservation boundary) seek to maximize harvest opportunity of hatchery steelhead while minimizing impacts to wild fish. The open season encompasses the period of adult migration into and through the

Umatilla River. The open area includes approximately 56 miles of the mainstem Umatilla River and does not include spawning areas of natural-origin summer steelhead. The bag limit of 3 hatchery steelhead per day with no annual limits seeks to balance maximization of harvest and equally distribute the harvest among the angling constituents. When necessary, the Oregon Commission can adopt and implement emergency regulations that further restrict fisheries for conservation purposes.

The abundance threshold for triggering harvest management regulation changes is the 6-year average natural-origin adult steelhead escapement of at least 650 unmarked steelhead; approximately two times the critical fishery conservation threshold recommended by Chilcote (2001).

The draft FMEP for the Umatilla (ODFW 2005b) focuses primarily on the potential impacts of harvest on abundance and productivity, the two key viability parameters most directly affected by harvest. Although fisheries with high harvest rates and fisheries that are selective on phenotypic traits can influence spatial structure and diversity, the tributary fisheries in the Umatilla River are not selective and have little or no influence on spatial structure and diversity.

Chilcote (2001) estimated extinction probabilities with respect to a variety of fishery mortality rates and demonstrated that for the Umatilla population there is substantial increase in risk of extinction for harvest greater than 10% (Table 8-54). Within the Umatilla, it is estimated that fisheries will result in a mortality rate of approximately 1.5% on the natural-origin fish. This estimate is based on an assumed post-catch and release mortality rate of 5% and a maximum fishery interception rate of 30% for the natural-origin fish. The interception rate for wild fish in the most recent years has been less than 25% and averaged 17%. The net mortality impact on natural-origin fish is between 1-2%. This is considerably less than the within subbasin maximum mortality objective of 5% (ODFW 2005b) natural-origin fish.

Table 8-54. Results of Population Viability Analysis (PVA) simulations of estimated probability of extinction in 50 years for Umatilla steelhead under 16 different adult mortality rates.

CTUIR Tribal Steelhead Harvest

Tribal fisheries are conducted within the Umatilla subbasin and both natural- and hatchery-origin fish are allowed to be harvested. CTUIR estimated that 50-100 fish are harvested annually, of which about 33% are natural-origin fish (Gary James, personal communication, 2006). Tribal harvest is not considered a significant threat.

Trout Harvest Management

Significant protection for juvenile steelhead is provided under current trout fisheries regulations. Redband trout fisheries in the Umatilla subbasin have been adapted to protect wild *O. mykiss* in natural production areas. The upper Umatilla and tributaries upstream from the eastern boundary of the Umatilla Indian Reservation have been catch and release only, and flies and lures only for

redband trout since 1995. Streams within the boundaries of the Umatilla Indian Reservation are under jurisdiction of the CTUIR. Other steelhead production streams, including Meacham Creek and Birch Creek, have a bag limit of five trout per day with an eight-inch minimum length. Both of these streams have limited public access. The lower 20+ miles of Meacham Creek are only accessible via the Union Pacific Railroad right-of-way that is managed to exclude public entry. Upper parts of the Meacham drainage are lands under private ownership. The lands adjacent to Birch Creek are all private with limited public access available. Mortality due to harvest on these streams, while not quantified, is estimated to be low.

The redband trout fishery is open from the fourth Saturday in May to October 31, with an eight-inch minimum length to minimize angling impacts on adult steelhead spawners and outmigrating smolts. Thus, the fishery through the summer and fall likely focuses on resident trout (eight-inch minimum length) rather than younger fish, which could be either resident or anadromous juveniles.

All stocking of hatchery rainbow trout was ceased in 1999 in streams within the Umatilla subbasin to protect wild stocks of *O. mykiss*. Legal-sized rainbow trout have been historically stocked in many streams throughout the Umatilla subbasin. However, stocking over the past decade has only occurred in the Umatilla River (downstream of steelhead production areas) and lower McKay Creek. From 1990 through 1993, approximately 8,000 legal sized Cape Cod stock rainbow trout were stocked in the forks area of the upper Umatilla River. In 1994, stocking of legal sized rainbow trout was moved downstream to the Pendleton area to reduce interaction with wild O. *mykiss* in the upper Umatilla River.

Fishing effort is currently much lower than in previous years because of the elimination of hatchery catchable trout stocking in the Umatilla River and the conservative, selective fishing regulations currently in place. It is difficult to quantify the impacts to juvenile steelhead from sportfishing because of the lack of information specific to the Umatilla River. However, given the current regulations that are in place for juvenile steelhead, the dispersed nature of the fishery and cessation of trout stocking, it is estimated that <1% of rearing juvenile steelhead in the Umatilla River subbasin are caught and released in the trout fishery.

Warmwater Fishery Harvest Management

The warmwater game fish fishery is focused in the lower Umatilla River downstream from Echo; isolating the fishery from areas where anglers would likely encounter significant numbers of steelhead parr. Smolts and adults are the only life history forms that would be expected in the lower Umatilla River. Adult wild steelhead are required to be released unharmed. The warmwater gamefish fishery is closed from April 16 through the third Saturday in May, the peak of the steelhead smolt out-migration. During creel census of the fall and spring salmon fisheries and the steelhead fishery, personnel also census warmwater anglers to gather baseline data on this fishery. Data from 1998 through 2000 show that warmwater anglers catch very few smolts. The potential impact is not of concern.

Spring Chinook Harvest Management

Mortality on steelhead (adults and smolts) caught and released by spring Chinook salmon anglers is low and does not warrant further restrictions. The Umatilla River spring Chinook fishery

occurs in two sections of the Umatilla River: section 1 from Hwy 730 Bridge upstream to Threemile Dam during April 16 – May 21 and section 2 from Threemile Dam upstream to the western boundary of the Umatilla Indian Reservation (RM 55) from April 16 through June 30. The fishery begins after most steelhead adults have migrated above the fishery area to spawning areas. Although this fishery occurs through the peak of the steelhead smolt out-migration, the fishing tackle is not conducive to catching of smolts (large hook sizes and large lures).

Walla Walla River

Steelhead in the Walla Walla River system are captured in the tributary steelhead fishery and in resident trout fisheries.

Steelhead Harvest Management

The Walla Walla River steelhead fishery is directed at catch and release of natural-origin fish and harvest of stray hatchery steelhead. The season occurs from December 1 through April 15 and the area open to angling is from the Oregon-Washington state line upstream to the confluence of the North and South forks. The entire upper subbasin has been set aside as an adult steelhead sanctuary area and will remain closed to steelhead angling. The daily bag limit (three fish/day) is restricted to adipose fin-clipped steelhead only. Natural-origin steelhead are required to be released unharmed. Harvest of natural-origin steelhead or further restrictions on this fishery are not anticipated in the foreseeable future.

This fishery is managed based on the six-year rolling average of returns to Nursery Bridge Dam. As long as the rolling average natural-origin spawner escapement is above the critical fishery conservation threshold of 220 adults, the current fishery regime will be maintained (draft FMEP, revised September 2005). However, the abundance of natural-origin steelhead is monitored and evaluated annually. If there is a downward trend of wild adult steelhead below the objective of 220, the fishery will be modified to reduce impacts. Possible adjustments could be gear restrictions, restriction of the open area and/or season length.

There is also a process to make in-year adjustments to fisheries when returns approach the critical fishery conservation threshold. To make reasonable predictions for steelhead returns to the Walla Walla River, ODFW has developed a regression of Bonneville wild Group A summer steelhead counts and wild steelhead counts at Nursery Bridge Dam (Figure 8-17). This regression is used to develop a steelhead return estimate for the Walla Walla Annual Operation Plan to provide managers with a forecast model. As discussed above, the fishery will be managed based on a rolling six-year average. However, the Bonneville predictive tool will also be used to adjust fishery management within-year if escapements are expected to approach and/or go below the critical fishery conservation threshold.

As seen in Figure 8-17, the data show two time series trends that are quite distinct; the years 1993 through 1995 plot higher and result in a steeper trend line than do data from 1996 to 2000. While the apparent shift in population productivity in relation to the total wild Group A summer steelhead run is not fully understood, it is distinct enough for use in developing run predictions. The data and trend line from 1996 to 2000 are used to develop in-year run forecasts based on wild Group A returns to Bonneville. This conservative run estimate seems a prudent approach since this is the most current trend.

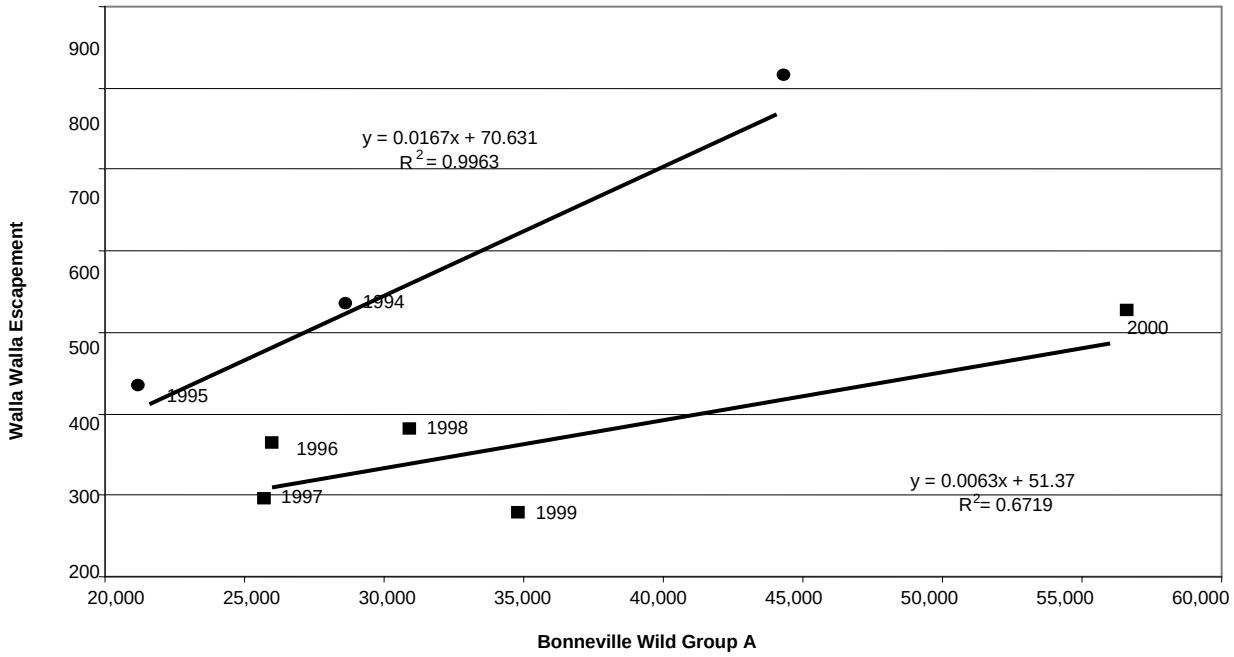

Figure 8-17. Relationship of Bonneville Dam wild Group A steelhead counts to estimated escapement above Nursery Bridge Dam, Oregon for run years 1993-1994 through 1996-2000.

Based upon Population Viability Analysis simulations of estimated extinction probability for 27 steelhead populations in Oregon, Chilcote (2001) recommended a maximum fishery mortality rate for most wild steelhead populations of 20%. The fisheries that currently occur do not exceed this exploitation rate.

Within the Walla Walla, it is estimated the current and proposed future fisheries will result in a mortality rate of approximately 1.5% on the natural-origin fish. This estimate is based on an assumed post-catch and release mortality rate of 5% (from Hooton 1987) and a maximum fishery interception rate for natural-origin fish of 30%.

Creel surveys conducted by the WDFW from 1997 to 2000 indicate that approximately 27% of the steelhead caught during the Washington Walla Walla subbasin recreational steelhead fisheries are natural origin. Because there are currently no estimates of total wild steelhead escapement to the entire Walla Walla subbasin, these creel data cannot be used to determine the catch rate of natural-origin fish in the Walla Walla population. However it does indicate that significant numbers of wild fish are caught. The WDFW (2001) estimates that an average of 438 natural-origin adults are caught and released in their steelhead fishery, resulting in an estimated mortality of 22 natural-origin adults. Natural-origin adults from both the Touchet and Walla Walla populations are caught and released in the fishery. This level of mortality results in 1-2% annual impact given the recent 10-year geomean abundance of 1,000 adults in the Walla Walla population.

Trout Harvest Management

To minimize angling impacts on adult steelhead spawners and outmigrating smolts, redband trout angling in the Walla Walla subbasin where anadromous fish are present is open from the fourth Saturday in May through October 31, with an eight-inch minimum length. The fishery through the summer and fall is focused on resident trout (eight-inch minimum length) rather than younger fish, which could be either resident or anadromous juveniles. All waterways in the subbasin are open to fishing for redband trout during the appropriate season. There are no closed areas.

Significant protection for juvenile steelhead and bull trout is also being provided under the current fisheries regulations. Fisheries for redband trout in the Walla Walla subbasin have been adapted to protect wild *O. mykiss* in natural production areas. Anglers have been restricted to the use of flies and lures in the South Fork since 1996 and in Walla Walla River and tributaries since 1999. The daily bag limit is five fish over eight inches in length.

Legal-sized hatchery rainbow trout have been historically stocked in many streams throughout the Walla Walla subbasin in Oregon. In 1994, all stocking of hatchery rainbow trout was discontinued in streams within the Oregon portion of the Walla Walla subbasin to protect wild stocks of *O. mykiss* and bull trout.

Fishing effort is currently much lower than in previous years because of the elimination of hatchery catchable trout stocking in the Walla Walla River and the conservative, selective fishing regulations currently in place. It is difficult to quantify the impacts to juvenile steelhead from sportfishing because of the lack of information specific to the Walla Walla River. However, given the current regulations that are in place for juvenile steelhead, the dispersed nature of the fishery and cessation of trout stocking, it is estimated that <1% or rearing juvenile steelhead in the Walla Walla River subbasin are caught and released in the trout fishery.

8.6 Hatchery Practices and Releases

This section describes potential hatchery-related limiting factors for Mid-C steelhead populations in the Fifteenmile, Deschutes, John Day, Umatilla and Walla Walla rivers systems.

8.6.1 Overview

Two hatchery programs are operated within the Mid-C DPS in Oregon, the Round Butte Hatchery program in the Deschutes River and the Umatilla Hatchery program in the Umatilla River. In addition WDFW releases hatchery smolts into the Walla Walla population as part of the Lower Snake River Compensation Plan program. The Mid-C Expert Panel expressed particular concern regarding the continuing detrimental impact of stray out-of-DPS hatchery fish in natural spawning areas on the genetic traits and productivity of naturally produced Mid-C steelhead. They also concluded that the spawning of hatchery produced adult steelhead from programs in the Umatilla and Walla Walla subbasins with naturally produced fish in these and other drainages adversely affects the population traits (productivity, genetic traits, and adult abundance) of the steelhead populations. Round Butte Hatchery in the Deschutes subbasin also

produces steelhead; however, the risks from this hatchery program to naturally spawning populations are considerably less than those from the other programs.

8.6.2 Fifteenmile Creek Steelhead

ODFW stocked rainbow trout in Fifteenmile Creek at the Taylorville Bridge until 1974 and at the downtown Dufur Bridge until 1991; and in Mosier Creek from 1952-1963 and 1968-1971. Today, hatchery fish are only stocked in Hanel Lake that has been stocked annually since 1994 with approximately 500 catchable coastal rainbow trout from a private hatchery/trout farm near Sandy, Oregon or Oak Springs Fish Hatchery. A screen in the Wolf Run Ditch prevents the stocked fish from migrating out of the reservoir.

Interbreeding between hatchery rainbow trout and steelhead in Fifteenmile Creek is believed to have been minimal. The particular stock of rainbows used for these introductions is not believed to have survived the summer due to susceptibility to a naturally occurring disease (*Ceratomyosis*), to which native rainbow are resistant.

Currently, there are no plans to use artificial propagation to augment fisheries or enhance natural production in the Fifteenmile Creek subbasin any time in the future. Consequently, the main hatchery-related threat to the Fifteenmile steelhead population is from out-of-subbasin strays. There have been very few stray hatchery steelhead observed in Fifteenmile Creek and there are few likely sources of winter steelhead strays in the Mid-Columbia DPS. Stray hatchery fish were not identified as a risk in the viability assessment.

8.6.3. Deschutes River Steelhead

Round Butte Hatchery
Round Butte Hatchery (RBH) currently produces and releases steelhead in the Deschutes as mitigation for loss of habitat and harvest opportunities due to the construction of the Round Butte Complex of hydroelectric dams. The goal of the program is to produce 1,800 adults returning to the project. The RBH summer steelhead program is limited to known RBH stock to prevent the propagation of out-of-subbasin fish and associated disease concerns. Natural-origin fish were incorporated into the broodstock during the 1990–1998 brood years, but the practice was discontinued due to concerns about introducing or propagating diseases borne by unmarked fish of unknown origin from outside the subbasin. All RBH steelhead not used for broodstock and all out-of-subbasin hatchery fish are removed from the river at Pelton Trap and Warm Springs National Fish Hatchery (WSNFH).

The RBH program minimizes impacts to naturally produced summer steelhead by releasing juveniles as age 1+ smolts, and at sizes and times that support rapid migration from the subbasin. This limits the potential for competitive interactions. RBH steelhead are acclimated at the hatchery before release to improve homing back to the hatchery. As a result, competitive interactions with wild juvenile steelhead in overwintering or rearing habitat are believed to be low. Resident *O. mykiss* naturally exist at multiple ages and at relatively great densities in parts of the Deschutes River and co-exist with other native salmonids including natural steelhead. This acclimation and homing of the RBH steelhead has been effective; in recent years less than 1% of

the steelhead observed at the WSNFH have been of RBH origin. RBH summer steelhead are uniquely marked to allow for their harvest and removal in selective recreational fisheries and to allow for identification during broodstock collection activities.

Out-of-Subbasin Strays

The large number of out-of-subbasin hatchery steelhead straying into the Deschutes River each year presents a major risk to the population. In recent years, out-of-subbasin hatchery steelhead collected and removed at WSNFH and the Pelton Trap averaged over 30% of the returns. The Mid-C Expert Panel considered strays a primary threat to Deschutes steelhead populations.

The number of out-of-subbasin hatchery-origin steelhead observed in the Deschutes River began to increase as mitigation programs developed in other Columbia Basin watersheds (Figure 8-18 and Table 8-55). A majority of these fish were produced in the Snake River Basin under the Lower Snake River Compensation Program, with a relatively large proportion of the out-of-subbasin stray steelhead originating from the Wallowa Hatchery program (Carmichael and Hoffnagle 2006; Olson and Spateholz, no date). At WSNFH, where all steelhead known to be artificially produced are removed from the natural-origin population that is allowed to pass upstream, RBH steelhead make up a small proportion of the fish collected at the trap (Table 8-56).

Hatchery-origin steelhead have been observed spawning with unmarked steelhead in Deschutes River tributaries, and both live and dead hatchery-origin steelhead have been observed during spawning ground surveys in Bakeoven and Buck Hollow creeks (Table 8-57). However, the fish are not handled and stock composition of hatchery-origin steelhead is unknown. Stock composition of hatchery-origin fish that ascend Sherars Falls (the trapping facility nearest Bakeoven and Buck Hollow creeks) is monitored in terms of the proportion of Round Butte Hatchery steelhead relative to hatchery fish that originate from outside the subbasin, but the rate at which out-of-subbasin fish that ascend the falls remain within the Deschutes and spawn among the native populations is not well known. The trend in abundance of hatchery-origin fish within Bakeoven and Buck Hollow creeks has appeared to follow that at Sherars Falls, but at an overall lower rate. Most hatchery fish observed on the spawning grounds are out-of-subbasin strays.

Out-of-DPS hatchery strays comprised an average of 29% of the Westside population and 15.2% of the Eastside population over the past three generations. This high fraction resulted in high risk ratings for spawner composition for both populations as described in the viability assessment.

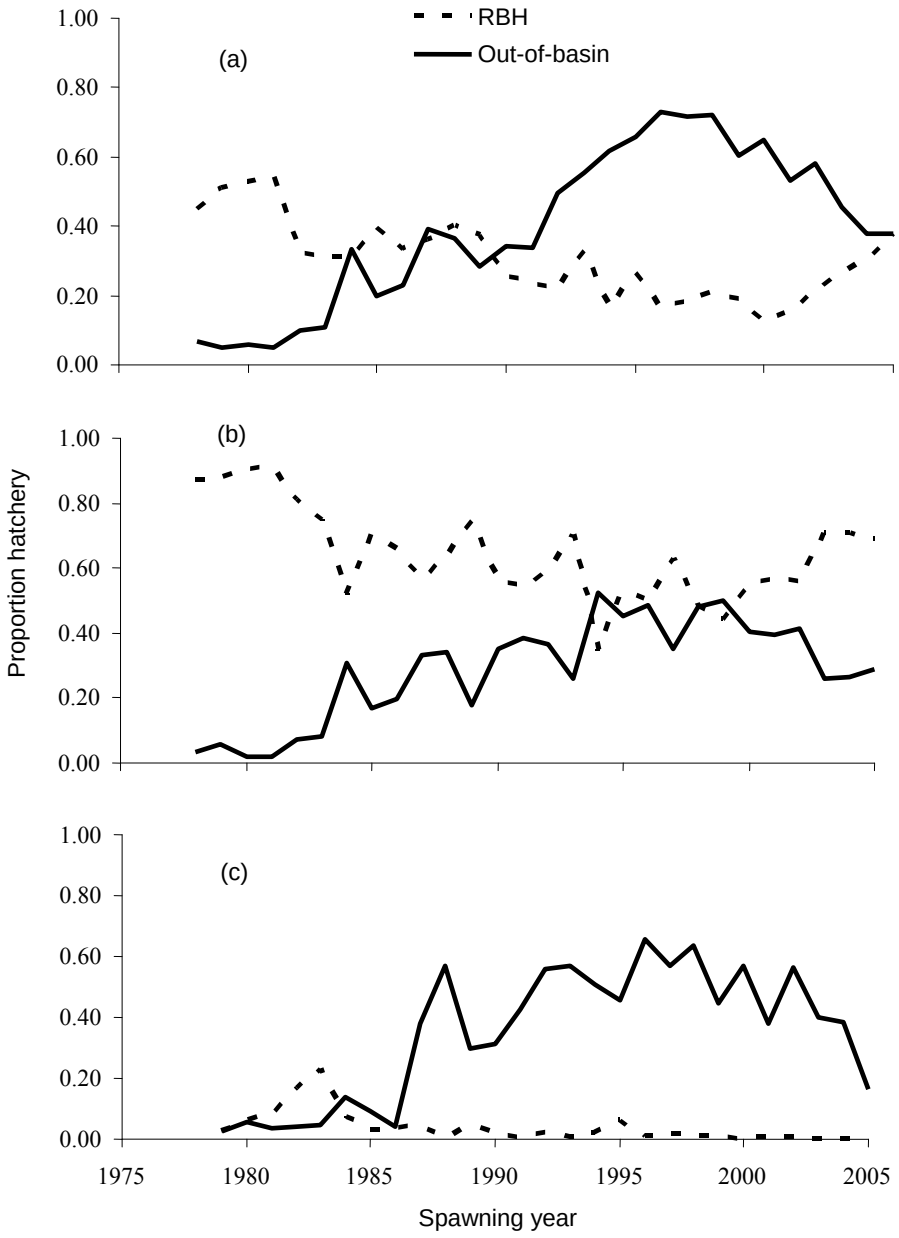

Figure 8-18. Proportion of steelhead that are Round Butte Hatchery and out-of-subbasin hatchery origin by trapping facility: (a) Sherars Falls, (b) Pelton Trap, (c) WSNFH.

Potential Inter-Specific Hatchery Interactions

Two spring Chinook salmon hatchery programs exist in the Deschutes River subbasin, one at Warm Springs NFH and one at Round Butte Hatchery, to mitigate for lost habitat and harvest opportunities due to construction and operation of the Pelton-Round Butte Complex. Spring Chinook salmon occur naturally in the Warm Springs River and Shitike Creek. Spring Chinook salmon are reared as juveniles to age 1+ smolts. Smolts actively migrate downstream after release, thus the duration of time that negative interactions could occur with native steelhead juveniles is relatively short. Interactions in overwintering and other rearing habitat are thought to be minimal. Bacterial Kidney Disease occurs within the Round Butte Hatchery broodstock. The influence of the Chinook hatchery programs is minimal and of little concern.

8.6.4 John Day River Steelhead

The John Day River steelhead populations are currently managed entirely as wild populations. No hatchery production or supplementation occurs within the John Day River subbasin. Hatchery releases of summer and winter run steelhead occurred historically in the John Day River subbasin between 1925 and 1969 (Table 8-58). Hatchery steelhead were last released into the John Day River subbasin in 1969. Hatchery steelhead released between 1966 and 1969 were for experimental use only and were not meant for production purposes (ODFW 1990, Olsen et al. 1994).

Table 8-58. Year, run (W-winter, S-summer, U-unknown), number, tributary, and subbasin of release for all known hatchery steelhead released into the John Day River subbasin from 1925 - 1969.

Year	Run	Number	Tributary	Subbasin
1925	U	16,080	Canyon Creek	Upper Mainstem
1941	U	8,760	Canyon Creek	Upper Mainstem
1947	U	7,600	Rock Creek	Lower Mainstem

1969	S	22,375	Bridge Creek	Middle Fork

Rainbow trout make up the majority of all hatchery fish species released into the John Day River subbasin (Table 8-59). The mean annual stocking rate of hatchery *O. mykiss* in the John Day River subbasin between 1925 and 1997 was 71,402 fish and ranged between 5,000 and 612,668 fish. Concern over competition for resources with wild fish and potential hybridization with natural-origin fish resulted in termination of all hatchery stocking of *O. mykiss* in the John Day River subbasin in 1997.

Table 8-59. Summary of all known stocking records for hatchery salmonids released into the John Day River subbasin from 1925-1997. Species include rainbow trout (RbT), steelhead of unknown run (Sthd), winter steelhead (StW), summer steelhead (StS), brook trout (BkT), and west slope cutthroat trout (WcT).

Out-of-Subbasin Strays

Out-of-subbasin hatchery steelhead strays pose a significant and primary threat to John Day steelhead populations. The Mid-C Expert Panel identified out-of-DPS hatchery strays as a threat to population traits for the Lower Mainstem population. Most hatchery stray recoveries occur in the Lower Mainstem below the North Fork (Table 8-60); however, strays have been observed in all populations. Carmichael et al. (2006) reports that the proportion of hatchery spawners in the Lower Mainstem population ranged from 0.01 in the early 1990's to 0.18 in 2004, with a mean of 0.07. The ICTRT considers this to be a high risk for the metric of spawner composition because of the increasing trend since the 1990's, fraction of strays and origin of the strays (Carmichael et al. 2006). Carmichael et al. (2006) concluded that all five of the John Day steelhead populations were at high risk for the John Day spawner composition viability metric. Data from coded-wire tagged hatchery steelhead recovered between 1986 and 2003 indicate that a large portion of the hatchery fish were from Wallowa stock releases into the Grande Ronde Rivers; however, most hatchery fish from upper Columbia River tributaries are not coded-wire tagged.

Hatchery steelhead coded-wire tag (CWT) recoveries in the John Day subbasin from 1986 to 2003 (378 recoveries) identify 18 separate hatcheries as the sources of strays. The majority of CWT recoveries were located downstream of Tumwater Falls in the John Day Arm (316

recoveries) and may not accurately represent fish that stayed and spawned within the John Day subbasin. The recoveries indicate that Dworshak National Hatchery is the predominate source of hatchery steelhead strays in the lower portion of the subbasin (97 CWT recoveries; 31%). Between Tumwater Falls and Cottonwood Bridge (RM 40) 55 hatchery CWT recoveries have been reported with many recoveries (26 CWT recoveries; 47%) in this area identifying Irrigon Hatchery (fish primarily released in the Grande Ronde Subbasin) as the source of strays (Table 8-61). Limited information is available upstream of Cottonwood Bridge with only seven hatchery CWT recoveries reported. Irrigon Hatchery was the source of two hatchery steelhead strays in this area. It should be noted that the probability of observation of strays in the John Day River from any particular hatchery stock is dependent on the survival, stray rate of that stock, and the number of individuals tagged from the stock. There is substantial difference in numbers of fish tagged between stocks, and in some cases no hatchery fish are marked with CWTs.

Table 8-60. Hatchery source, stock, number recovered, recovery period, and release agency for hatchery steelhead with coded wire tags in the John Day River arm. (Tumwater Falls upstream to Cottonwood Bridge) from 1996-2003. Data were compiled from the Pacific States Marine Fishery Commission Regional Mark Information System.

Hatchery Source	Stock	Number Recovered	Recovery Period	Release Agency

Upper Columbia	Unknown	Cottonwood Bridge to Little Ferry Canyon	1	1988
Wallowa	Unknown	Lower North Fork	1	1992

Distribution of Hatchery and Natural Adults
Most observations of hatchery adults in the John Day have occurred in the Lower Mainstem, below the confluence with the North Fork (Wiley et al. 2004). However, several reports have noted observations of fin-clipped fish in the North Fork and South Fork drainages. These observations come from both spawning ground surveys and creel programs.

Claire and Gray (1992a) reported 17 (23%) adipose fin clipped steelhead of 75 caught upstream of Kimberly (RM 185) during the 1992 steelhead fishery. Within the 1992 Zone 3 summer steelhead fishery (Kimberly to Indian Creek), 16% (6 of 37) of the fish reported by anglers were of hatchery origin (Claire and Gray 1992a). Within the 1992 lower North Fork summer steelhead fishery, 29% (11 of 37 reported) of steelhead reported by anglers were of hatchery origin. Claire and Gray (1992a) did not provide an explanation for the high stray rates observed during the 1992 fishery. Wilson et al. (2001) reported observing thirteen adipose fin-clipped adult summer steelhead (46%, both live and as carcasses) of twenty-eight steelhead observed while seining for smolts in the Mainstem John Day River between Kimberly (RM 185) and Spray (RM 170).

Wiley et al. (2004) observed 50, live adult steelhead and sampled five carcasses on spawner surveys conducted during 2004. Of the ten sites where live fish were observed they were able to identify 34 fish as hatchery or wild at six of those sites based upon the presence (hatchery) or absence (wild) of an adipose fin clip (fin mark). Hatchery steelhead (13 fish) comprised 38% of live fish observations and were found at two of the six sites where identifications could be made. The majority of live hatchery steelhead observed (12 fish; 92%) and hatchery carcasses sampled (3 fish; 100%) during spawner surveys came from one stream (Service Creek) located in the Lower Mainstem at RM 157. An additional live hatchery steelhead was also observed in the Lower Mainstem in Rock Creek. They estimated 3,726 wild and 2,284 hatchery steelhead were present during the spawning season based upon the wild:hatchery ratio of live fish observed during spawner surveys.

Wiley et al. (2004) observed fin-clipped adults paired with wild adults on redds during 2004. Others have also observed hatchery origin fish paired with wild fish during spawning (Wilson et al. 2004). Observations of pairings between hatchery and wild fish on the spawning grounds indicate introgression. No evidence is available for any negative impacts resulting from interactions between hatchery and natural steelhead in the John Day River subbasin.

8.6.5 Umatilla River Steelhead

The Umatilla River summer steelhead program was designed to enhance the natural production through supplementation and to provide sustainable harvest in the Umatilla River subbasin. The annual production goal is for a release of 150,000 smolts. Smolts are adipose fin-clipped to allow for selective fisheries and to monitor returns to TMFD. The program is funded by BPA through the NPCC Fish and Wildlife Program.

Several ongoing management actions were implemented to limit potential negative impacts on wild steelhead from the hatchery program. These actions all have positive benefits, and include 1) marking hatchery produced steelhead to limit fishing mortality on wild steelhead, 2) reading

coded-wire tags before spawning broodstock to prevent using out-of-subbasin strays, and 3) acclimating and releasing a portion of hatchery smolts near areas targeted for supplementation and a portion lower in the subbasin to increase fishing opportunities in the lower river. Releasing a portion of the adults in the lower river also has the potential to limit spawning interactions between hatchery and wild adults. Nevertheless, the existing hatchery programs for steelhead and coho in the subbasin continue to pose potential risks to the wild steelhead population. However, the Mid-C Expert Panel did not identify hatchery fish as a primary threat to the population.

Hatchery Program History

The first attempt to supplement the natural population of summer steelhead in the Umatilla River and tributaries was in 1967 when hatchery-produced, non-endemic steelhead from Skamania and Idaho (Oxbow) stocks were released in the Umatilla River (ODFW 1987). From 1968 through 1970, only non-endemic Skamania stock steelhead were released into the Umatilla River. No hatchery-produced steelhead were released in the Umatilla River from 1971 through 1974. The early release numbers and size-at-release varied considerably (Table 8-62). The first release of smolts from endemic Umatilla stock occurred in 1975. There were no releases of hatchery-produced steelhead from 1976 through 1980. Annual releases of smolts from endemic Umatilla stock ensued from 1981 to the present.

Broodstock are currently collected from returns to the Three Mile Falls Dam (TMFD) trap on the Umatilla River (RM 3.7). The broodstock goal is 120 adults, including 10 pairs of coded-wire tagged program fish. Steelhead are transferred to the Minthorn acclimation site for holding and spawning. The coded-wire tags are read prior to spawning to insure out-of-subbasin hatchery fish are not used for broodstock. Spawning is performed using a 3x3 matrix, selecting for natural x natural crosses whenever possible, and no hatchery x hatchery crosses are used. Hatchery fish are used when there are not enough natural-origin fish to meet egg-take objectives.

Run Composition

Steelhead returns to TMFD have averaged 956 hatchery, and 1,668 natural fish from the 1992-93 through 2003-04 run years (Table 8-63). Over the same time period, Umatilla hatchery steelhead comprised 23.9-52.0% of the run (mean 32.0%), while out-of-subbasin hatchery steelhead comprised 2.1-10.1% of the run (mean 3.1%; Table 8-63). Some steelhead are removed at TMFD for broodstock while others are harvested upstream in tribal and non-tribal recreational fisheries. Umatilla hatchery steelhead have comprised 19.0-57.1% of steelhead available to spawn in nature (mean 29.4%), and out-of-subbasin hatchery steelhead have comprised 1.8-9.7% of potential spawners (mean 4.8%; Table 8-64). Carmichael (2000) concluded that the Umatilla River population was at high risk for the spawner composition viability metric. This high risk rating was the result of a moderate risk rating for proportion of out-of-DPS strays and a moderate risk rating for within-population hatchery spawners.

Table 8-62. Releases of summer steelhead in the Umatilla River subbasin prior to the current program at Umatilla Fish Hatchery (Chess et al. 2003a).

Release Year	Hatchery	No. Released	Fish/lb.	Strategy	Stock	Acclimation Facility	Direct-release

Distribution of Hatchery and Natural Adults

In 2003, 70.0% of the summer steelhead available to spawn (fish released above TMFD minus all harvest components) were natural origin, and during spawning surveys 68.9% of the spawning steelhead identified were natural-origin (Schwartz et al. 2005; Table 8-66).

Adult steelhead were trapped and counted at Birch Creek by ODFW from 1995 to 1999 (DeBano et el. 2004; Table 8-65). The fish were collected in a fish ladder trap on a diversion dam located approximately 1/4 mile downstream of the confluence of the East and West forks of Birch Creek. An estimated 60% of the adult steelhead that pass this location jump over the diversion dam and are not counted in the trap. In 1995-1996, ODFW biologists conducted a mark/recapture study that led to a total escapement estimate above the trap location of 358 natural-origin and 15 hatchery-origin fish for a total of 373. For that year, this accounted for approximately 30% of the natural-origin fish that were counted at TMFD on the Umatilla. Mark/recapture data in other years were insufficient to make an accurate escapement estimate. A significant proportion of spawners observed on spawning ground surveys from 2001-2004 were hatchery origin in some locations within the population (Schwartz et al. 2005; Table 8-66).

Similarity between Hatchery-Origin and Natural-Origin Fish

Hatchery summer steelhead are produced primarily from unmarked summer steelhead returning to the subbasin. All hatchery juveniles are released as one-year smolts, compared to natural-origin summer steelhead that emigrate primarily as two-year smolts, with some three- and four-year-old smolts. The adult return timing and relative monthly percent of hatchery and natural

steelhead returning overlap closely. No large-scale seasonal separation exists between natural and hatchery steelhead, however Chi-Square and Kolmolgorov-Smirnov tests reveal significant differences between natural and hatchery frequencies on a monthly scale for most years (Chess et al. 2003a). The female-to-male ratio of natural summer steelhead is higher than hatchery steelhead. Female summer steelhead comprised 69.3 ± 1.3% (mean ± SE) of the natural return for return years 1992-93 through 2001-02, whereas females comprised 57.3 ± 2.3% (mean ± SE) of the hatchery return for the same period (Chess et al. 2003a). Age structure of hatchery and natural steelhead is similar. For run years 1992-93 through 2001-02, natural female summer steelhead were 58.8 ± 4.8% (mean ± SE) one-salt, compared to 57.2 ± 5.1% (mean ± SE) one-salt for hatchery female steelhead (not significantly different: ANOVA, P = 0.82; Chess et al. 2003a). For the same years, natural male steelhead were 68.5 ± 5.1% (mean ± SE) one-salt compared to 74.6 ± 4.4% (mean ± SE) of the hatchery male returns (not significantly different: ANOVA, P = 0.37; Chess et al. 2003a).

Smolt Releases and Acclimation Sites

Umatilla hatchery steelhead have always been released as one-year-old smolts, and are currently released at approximately 4.5 fish per pound (FPP). From the mid 1980s to the present, Bonifer Springs Pond and the Minthorn Springs site have been consistently used for acclimating Umatilla River summer steelhead. Large-grade summer steelhead and small-grade steelhead were acclimated at Bonifer Springs from brood years 1992 to 1998, excluding 1995 when the small-grade steelhead were acclimated at the Thornhollow site (RM 73.5). Bonifer Springs Pond is located at the confluence of Boston Canyon and Meacham creeks, two miles above the confluence with the Umatilla River at RM 80. Bonifer Springs Pond was used to acclimate steelhead because it is a tributary of Meacham Creek, which was identified as a major component of the available summer steelhead habitat in the Umatilla River subbasin (CTUIR and ODFW 1990) and was targeted for steelhead supplementation. Large-grade steelhead were acclimated at the Minthorn Springs site from brood year 1992 to 1998. The Minthorn Springs site is located at RM 64.5 of the mainstem Umatilla River. Minthorn Springs is a large spring system connected to the Umatilla River and floodplain. For brood years 1999 to 2001, small-grade (pass A) steelhead were no longer acclimated at Bonifer Springs, instead smalls were acclimated at Minthorn Springs following acclimation and release of the large-grade steelhead. The second group of large-grade steelhead was acclimated at Bonifer Springs Pond. In an effort to increase smolt survival, co-managers decided to release some steelhead from Pendleton (RM 56), the most downstream acclimation site in the subbasin. From 2002 to present, ungraded steelhead were released in approximately equal numbers (approx. 30,000-50,000 ea.) from the Pendleton and Minthorn acclimation facilities, and direct stream released in Boston Canyon Creek near Bonifer Springs. Acclimated fish are held in ponds for 2-3 weeks, allowed to volitionally migrate for one week, and then forced out of the ponds.

Juvenile Migration Timing

Natural and hatchery steelhead show similar trends in out-migration timing, except for the earlier migration of natural fish (Chess et al. 2003a; Figure 8-19). Hatchery steelhead were released from acclimation sites in early and late April. Small-grade steelhead were reared an extra month in the hatchery, acclimated and released a month later than the large-grade steelhead. If the hatchery steelhead migrated out of the Umatilla River subbasin soon after release, then a distinct, bimodal distribution of hatchery out-migrants would be produced. This was the case for three of

four years. The 1999 out-migrant year was skewed, but unimodal for hatchery steelhead. Natural steelhead started migration earlier than the earliest release hatchery steelhead release date in all four years. A small percentage of natural and hatchery steelhead arrive in late May and early June. Natural and hatchery out-migrants are being detected at Three Mile Falls Dam during rising and falling limbs of the hydrograph.

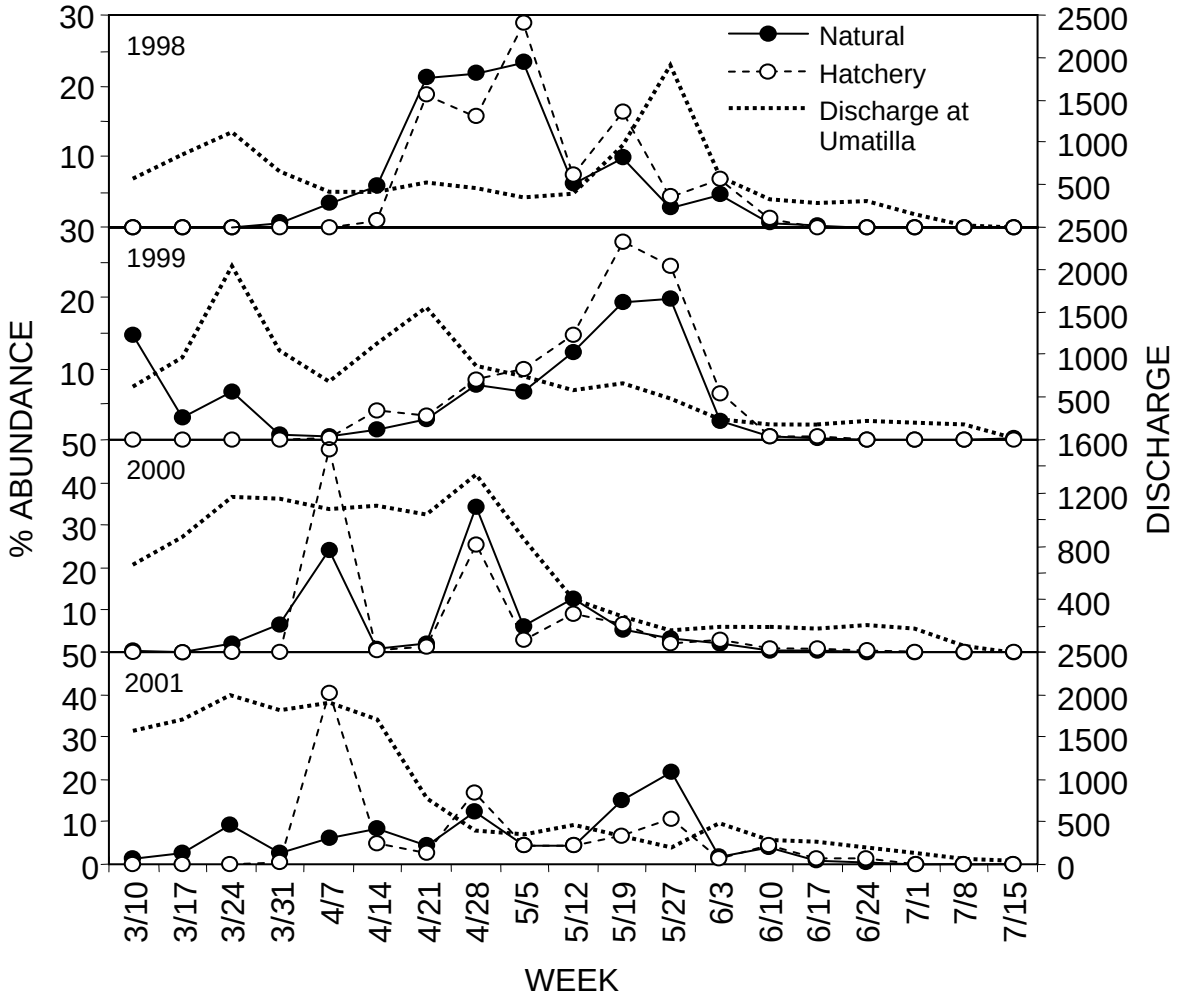

Figure 8-19. Migration timing of natural and hatchery summer steelhead smolts counted at Three Mile Falls Dam. The percentages were from weekly totals of fish divided by the respective total for the out-migration period. Daily Flow data at the lower Umatilla River gauge (RM 2.1) were averaged on a weekly interval (from Chess et al. 2003a).

Residualism

Steelhead, which were the smallest in the fall and were separated by grading for release in the spring, exhibited lower PIT tag detections at TMFD and lower smolt-to-adult survival, suggesting they either had lower out-migration survival or they were residualizing in the Umatilla River (Chess et al. 2003b). There was evidence that small-grade steelhead residualized and did not migrate until the second or third year following acclimation. Only 3 of 20 radio-tagged, small-grade steelhead migrated out of the subbasin after release from the outlet of Bonifer Springs (Stonecypher et al. 2001). Several detections of small-grade steelhead, PIT-tagged two years earlier have occurred at TMFD (White et al. 2003), confirming delayed out-migration of the small-grade production. Contor et al. (1995) estimated that 1,100 hatchery steelhead residualized in Boston Canyon Creek, with evidence of displacement of natural steelhead found in the stream. Approximately 4,000 hatchery steelhead residualize each year in Boston Canyon, Meacham, Minthorn Springs creeks, and in the mainstem Umatilla River (Contor et al. 1995). This estimate was 2.5% to 3.3% of the total steelhead released per year in the Umatilla River. There is evidence that many residual steelhead move into the lower Umatilla River. In recent years, anglers reported catching adipose and ventral fin clipped "trout" in the Stanfield area (RM 32). Summer steelhead are no longer size graded, all are released at approximately 4.5 FPP.

Other Salmonid Releases in the Umatilla Subbasin

Besides summer steelhead, coho salmon and spring and fall Chinook salmon are also released in the Umatilla River annually. Approximately 810,000 spring Chinook salmon are released annually, 600,000 from Umatilla hatchery and an additional 210,000 from Little White Salmon Hatchery (LWSH). All spring Chinook salmon are acclimated at the Imeques acclimation facility (RM 80). Fish raised at Umatilla Hatchery are transferred in fall or winter and released in mid-March at 12 FPP, whereas steelhead raised at LWSH are transferred to the acclimation site in mid-March and released in mid-April at 15 FPP. Approximately 1.5 million coho salmon are released in the Umatilla River annually. All coho salmon are acclimated at the Pendleton acclimation facility and released at 15 FPP. Half (~750,000) are transferred to the acclimation site in mid-February and released in mid-March and the other half are transferred in Mid-March and released in mid-April. Approximately 1.08 million fall Chinook salmon are released in the Umatilla River annually, of which 600,000 are subyearlings and 480,000 are yearlings. Half of the subyearlings (~300,000) are transferred to the Thornhollow acclimation site (RM 73.5) in early May and released in late May at 50 FPP, whereas the other half are direct stream released at Umatilla RM 49 in late May at 35 FPP. All yearling fall Chinook salmon are acclimated and released from the Thornhollow acclimation facility at 10 FPP. One half (240,000) are transferred in mid-February and released in mid-March, while the second half is transferred in mid-March and released mid-April.

Program Performance

The stray rate for hatchery summer steelhead has not been estimated. The mean smolt-to-adult survival rate for brood years 1991-97 was 0.42% (small grade range: 0.03-0.21; large grade range: 0.02-1.52; Chess et al. 2003a). The annual return of summer steelhead to TMFD averaged 819 for the 1992-93 through 2003-04 run years (Table 8-63). Natural-origin summer steelhead returns for the same period averaged 1,668 annually. Harvest has not met expectations, with fewer than 100 steelhead caught annually from 1994 to 1999 (Chess et al. 2003a). However, an

estimated 114 steelhead were caught in 2000-01 and an estimated 278 were caught in 2001-02 (Chess et al. 2003b).

Potential Limiting Factors Influencing Viability
The net effect of the Umatilla hatchery program is unknown, but recent natural-origin escapements have been high (Table 8-63). Almost 30% of steelhead available to spawn naturally originates from the Umatilla Hatchery. The use of natural-origin steelhead for broodstock reduces the potential for divergence of the hatchery-origin steelhead from the natural-origin fish. Smolt releases occur during the normal migration period of natural steelhead, and it appears that most fish emigrate soon after release. However, there is evidence that some smolts residualize and remain in the Umatilla River another year. These fish may compete with naturally produced fish for habitat and prey resources.

Out-of-DPS strays pose several risks to the wild Umatilla steelhead population. A primary risk is spawner composition because out-of-DPS strays account for a mean of 4.8% of fish that return to TMFD, and because average hatchery fraction on the spawning grounds is 29.4%.

8.6.6 Walla Walla River Steelhead

There is one summer steelhead hatchery program in the Walla Walla River, operated by the Washington Department of Fish and Wildlife (Glen Mendel, WDFW, personal communication).

Lyons Ferry Hatchery
The Lyons Ferry Hatchery (LFH) segregated program involves the release of non-endemic LFH steelhead stock in the Walla Walla subbasin. Approximately 100,000 smolts are direct stream released annually in the lower Walla Walla River just downstream of the Mill Creek confluence. Smolts released into the Walla Walla have been targeted at 4.5 fish per pound to reduce residualism, insure rapid emigration, reduce interactions between wild and hatchery steelhead, and increase survival (WDFW 2005).

The LFH stock program utilizes a non-endemic steelhead hatchery stock originally developed from Wells Hatchery (Wells Stock) on the upper Columbia River. Other steelhead stocks were also used in the past to fulfill production needs (Wallowa, Pahsimeroi, Oxbow, and Ringold stocks). Hatchery origin adults (mainly Wells and Wallowa stocks) were later trapped on site at LFH to build LFH stock summer steelhead.

Broodstock Source, Collection and Spawning
Broodstock collection, spawning, incubation, and juvenile rearing for the program are conducted at LFH. Well water (52^{o}F) is the source for all facets of the hatchery production. The hatchery is operated in compliance with all applicable fish health guidelines and facility operation standards and protocols. Fish collected for broodstock are taken throughout the return or spawning period in proportions approximating the timing and age distribution of the population from which broodstock is taken. Annual broodstock collections goals for all LFH stock summer steelhead production programs are 360 adult hatchery returns. Additional fish may be collected to account for pre-spawning loss and incidence of IHNV in egg lots that are destroyed. Adults are spawned two males per female. Eggs are incubated without temperature regulation. Average eggs/female

is about 4,750 eggs. Fry are ponded in indoor rearing tanks and then moved to standard outdoor raceways.

Survival and Distribution

Survival data collected to date indicate 89% survival from green egg to fry, and 68% survival from fry to smolt. Currently, about 100,000 smolts of the 345,000 total LFH Stock fish produced annually are released into the lower Walla Walla River from LFH. Releases were greater in the past (Table 8-67), but have been reduced because of ESA concerns. Currently, smolts are direct stream released at a size of 4-5 fish/lb at RM 35 between April 15 and 25.

Table 8-67. Release of LFH, Wallowa, Wells and Ringold stock steelhead smolts into the Walla Walla River, 1983-2005 release years.

Release Year	Stock	River Mile	Number of smolts

		35	

The Walla Walla watershed above Nursery Bridge Dam (NBD) has been designated a wild, endemic steelhead production area. Until 1999, stray hatchery adult steelhead were trapped and removed at NBD, preventing them from entering the natural production area and spawning with wild fish. This trapping was discontinued after 1999.

The termination of trapping at NBD causes a potential threat to the diversity of the endemic steelhead population. For all brood years on record (1993-2005) the proportion of hatchery fish passing NBD and allowed to escape with natural-origin fish to the spawning grounds has remained below 5% (Table 8-68). Nevertheless, the proportion of hatchery adults escaping above NBD has been increasing since adult trapping and removal of strays ceased in 1999. Further increases in the future will increase the risk for the natural steelhead population. There is considerable evidence of genetic introgression of LFH stock into the Walla Walla natural population (Narum et al. 2004). In addition, results of telemetry studies conducted by CTUIR

demonstrated spatial and temporal overlap in LFH and natural-origin fish. Carmichael (2006) concluded that the Walla Walla steelhead population was at moderate risk for the spawner composition viability metric. However, since out-of-DPS strays are no longer removed at NBD this risk level will rise to high in the future. Overall we consider the out-of-DPS spawners to be a key threat to the Walla Walla population.

Table 8-68. Estimated numbers of adult hatchery- and natural-origin summer steelhead passing upstream of Nursery Bridge Dam from brood years 1993-2005.

Brood Year	Hatchery Steelhead	Natural Steelhead	Percent Hatchery
1993	4	1695	0.2%
1994	2	1113	0.2%
1995	10	894	1.1%
1996	15	745	2.0%
1997	10	607	1.6%
1998	6	786	0.8%
1999	2	580	0.3%
2000	27	1069	2.5%
2001	75	1548	4.6%
2002	89	2417	3.6%
2003	46	1252	3.5%
2004	NA	NA	NA
2005	15	374	3.9%
Mean	25	1,090	2.2%

In 2001, WDFW reduced the number of non-endemic smolts released into the lower Walla Walla River to reduce genetic risks to the endemic steelhead population. The reduction was justified because the adult returns were exceeding compensation goals set by the Lower Snake River Compensation Program (Glen Mendel, WDFW, personal communication). Releases in the lower Walla Walla River were reduced from approximately 170,000 smolts annually to 100,000 smolts annually in 2001. It is unknown at this time whether these reduced stocking rates will reduce genetic risks to endemic steelhead in the Walla Walla River.

WDFW is currently developing an endemic steelhead program for the Touchet River population. The Touchet is a tributary to the Walla Walla River located entirely in Washington State. The success of this program will determine whether the Lyons Ferry Hatchery stock used in the Walla Walla and Touchet rivers will continue to be propagated. Evaluation results, available in 1-2 years, will also be used to determine whether to expand the endemic program (Glen Mendel, WDFW, personal communication). If the Touchet River endemic program is successful, it is possible that the endemic stock could be used to produce smolts for release in the lower Walla Walla River.

8.7 Predation and Competition

Oregon Mid-C steelhead are also affected by threats from predation and competition.

8.7.1 Predation by Pinnipeds, Birds and Piscivorous Fish

Predation by pinnipeds, birds, and piscivorous fish in the mainstem Columbia River has become a contributing factor affecting the viability of the Mid-Columbia River steelhead DPS. Anthropogenic changes in the Columbia River have altered the relationships between salmonids and other fish, bird, and pinniped species. Some species' abundance levels have increased dramatically, particularly in localized areas, with associated changes in predation of steelhead juveniles and adults (LCREP 2006).

Predation by Pinnipeds
The abundance of native pinnipeds has steadily increased since passage of the Marine Mammal Protection Act (MMPA) in 1972. Pacific harbor seals, Steller sea lions, and California sea lions all prey on salmon and steelhead in the lower Columbia River (NPCC 2004). Before 1980, few California sea lions were observed in the Columbia River. However, in recent years, more and more sea lions have been traveling as far upstream as Bonneville Dam to prey on returning salmon and steelhead congregating below the dam. The fish often spend several days in the river below the dam before climbing the fish ladders. The minimum daily occurrence of pinnipeds at Bonneville Dam increased from 14 animals in 2002 to 54 in 2007. Some marked individuals have been repeatedly observed at Bonneville since 2002. Estimates of spring-run adult salmonid mortality due to sea lions at Bonneville Dam ranged from 0.4% in 2002 to 3.4% in 2006 and to 4.1% in 2007 (USACE 2007; USACE unpublished data). These estimates do not account for pinniped mortality occurring in the 145 miles of the Columbia River downstream of Bonneville Dam.

A pinniped hazing program has been implemented at Bonneville Dam since 2005, but the efforts have largely been ineffective. Recently, the states of Oregon, Washington, and Idaho have applied to NOAA Fisheries for authorization under Section 120 of the MMPA to lethally remove problem California sea lions. NOAA Fisheries Northwest Regional Office in Seattle has appointed an 18-person panel of experts to review the request.

Predation by Avian Predators
Alteration of the estuary environment has lead to a significant increase in the number of native bird species, such as Caspian terns and double-crested cormorants, in the area, with measurable impacts on stream-type salmonids (BPA, BOR, and USACE 2004). These increases in population in the Columbia River estuary are attributed to the deposition of dredge spoils that represent high-quality habitat for the birds (Bottom et al. 2005). The loss of habitat elsewhere has contributed to terns and cormorants effectively relocating to the Columbia River estuary, with the populations there now representing the largest nesting colonies in North America.

In 1997 it was estimated that avian predators consumed 10 to 30% of the total estuarine salmonid smolt production in that year (NPCC 2004). The draft 2005 season summary of Research, Monitoring, and Evaluation of Avian Predation on Salmonid Smolts in the Lower and Mid-Columbia River (Collis and Roby 2006) estimates that 3.6 million juvenile salmonids were consumed by terns in 2005. Double-crested cormorants consume a similar number of juvenile salmonids (approximately 3.6 million juveniles) from their East Sand Island nesting grounds (LCREP 2006; Collis and Roby 2006). Caspian terns on Crescent Island, an island in the mid-

Columbia that was also created by dredge spoils, consumed an estimated 679,000 juvenile salmonids during the 2001 breeding season (Antolos et al. 2005).

Predation by Piscivorous Fishes

The northern pikeminnow is a native piscivore that preys on juvenile salmon and steelhead in the Columbia River. Although northern pikeminnow have always been a significant source of mortality for juvenile salmonids in the mainstem Columbia, changes in physical habitats may have created more favorable conditions for predation (NPCC 2004). Dams can stress and disorient migrating smolts, making them vulnerable to predators. Dams may also delay migration, thereby increasing travel time and exposure to predators. Northern pikeminnow were found to be the major piscivore responsible for predation on juvenile salmonids, with mortality potentially similar to that caused by dam passage (Rieman et al.1991). Since 1990, the Northern Pikeminnow Management Program (NPMP) has implemented fisheries targeting northern pikeminnow at an exploitation rate of 10-20%. This level of exploitation is expected to reduce predation on juvenile salmonids by 25-50% (Rieman and Beamesderfer 1990).

A wide variety of fish species have been introduced into the mainstem Columbia River. Among these introduced species, walleye, smallmouth bass, and channel catfish are considered to be the most successful as predators of juvenile salmonids (Gray and Rondorf 1986; Poe et al.1991). Densities of non-indigenous predators have been found to be higher in impoundments created by mainstem dams compared to the unimpounded Columbia River below Bonneville Dam (Zimmerman and Parker 1995). Sampling suggests that smallmouth bass abundance in The Dalles and John Day reservoirs, as well as walleye abundance in parts of John Day Reservoir, has increased in recent years (Takata et al. 2007). Although non-indigenous species do not prey on juvenile salmonids to the extent that northern pikeminnow do, they can be an important predator at certain times and locations (Poe et al.1991).

8.7.2 Intra-Species Interactions

Unique to the Deschutes River Westside population is the presence of a highly abundant population of large resident rainbow trout throughout the population. Nowhere in any of the other Oregon Mid-C steelhead populations, except in the mainstem Deschutes River reaches of the Deschutes River Eastside population, are abundant large rainbow trout found. Cramer and Beamsderfer (2006) concluded that habitat conditions (perennial steady flows and cool temperatures) in many areas in the upper Deschutes subbasin favor production of resident rainbow trout over steelhead. Similar habitat conditions are also found in much of the currently available habitat of the Deschutes River Westside population.

Current abundance for steelhead in the Westside population is low relative to the quantity and quality of habitat available. With the exception of the South Fork John Day River population, the Deschutes River Westside population has the lowest current abundance of all other Oregon Mid-C steelhead populations.

Although we cannot quantify the effects of resident rainbow trout on the capacity of steelhead in the Westside population, we hypothesize that the capacity may be significantly reduced by competition with resident rainbow. This hypothesis is supported by the conclusion of Cramer

and Beamesderfer (2006) regarding steelhead production capacity in the upper Deschutes subbasin. Although there may be reduced steelhead capacity resulting from the abundance of resident rainbow trout, this should be viewed as a natural outcome. Thus, no management actions are proposed to address this potential natural interaction effect. If, in the future, additional studies confirm this reduction in capacity in waters with abundant larger rainbow trout, then the abundance criteria for the Deschutes River Westside steelhead should be reevaluated.

8.8 Climate Change

This section describes the potential environment changes that will accompany climate change in the future and some likely life stage specific responses for Oregon's Mid-C steelhead. In addition, we have developed a potential climate change vulnerability risk index based on projected future stream temperatures, projected future springtime water availability, and historical variation in precipitation.

8.8.1 Steelhead Habitat Impacts

Climate change will alter environmental conditions across the entire life cycle for all life stages of Oregon's Mid-Columbia River steelhead. There remains considerable uncertainty regarding the magnitude of loss and degradation of salmonid habitat in the Columbia Basin that will result from climate change. The magnitude of environmental change will vary considerable across ecoregions and thus will have different impacts on viability of steelhead populations within the Mid-C DPS. In general, habitats at lower elevations east of the Cascade Mountains in the southern portion of the Columbia River basin will experience the greatest level of change (ISAB 2007a).

Many of the environmental attributes that will be influenced by climate change (temperature and hydrograph) are those that have already been influenced significantly by past land use and are currently considered key limiting factors. The degree to which climate change will impact a given population is partially dependent on the degree to which natural processes have already been altered. A number of reviews have recently been completed that characterize potential climate change impacts in the Pacific Northwest (O'Neal 2002; Mote et al. 2003; ISAB 2007a; Michael and O'Brien 2008). The environmental changes most often described as significant threats to salmonid viability include:

- Increased air and stream temperatures
- Reduced snow pack and a shift in precipitation from snow to rain
- Altered hydrographs with earlier and higher peak flows, and lower summer-fall flows
- More frequent extreme storm events
- Increased periods of drought
- Changing ocean temperatures and current patterns
- More frequent and severe fire events

8.8.2 Potential Life Stage Specific Impacts

The ISAB (2007) generally characterized potential impacts of climate change to salmonids in the Columbia River basin. Expanding on their conclusions with a specific focus on Oregon's Mid-Columbia River steelhead, we developed the following summary of potential life stage specific impacts of climate change. Again, we emphasize that the life stage specific impacts will vary considerably between populations based on many factors, and our summary attempts to capture the range of potential impacts across all populations.

Egg incubation: The potential for increased mortality exists due to increased flood events in early spring resulting in greater redd scouring and dewatering of redds due to low spring flows (Jager et al. 1997). Increased temperatures will result in accelerated embryo development and earlier fry emergence.

Fry emergence and colonization: Warmer spring temperatures will likely result in earlier fry emergence. Fry emergence timing is critical for successful colonization, thus altered emergence timing may reduce success in colonizing quality habitat and increase mortality.

Summer rearing: Most Mid-C steelhead spend a minimum of two summers srearing prior to smolt seasonal migration. Reduced summer flows and increased temperatures will impact both the quality and quantity of summer rearing habitat. Summer temperatures currently limit habitat quality and quantity in most Oregon Mid-C populations. Lower flows and warmer temperatures have the potential to influence steelhead in many ways. The potential effects include the following:

- Reduced rearing capacity due to loss of habitat that reaches lethal temperatures
- Reduced growth rates due to metabolic stress of high temperatures
- Increased growth rates in some locations that are currently below growth optimum temperatures
- Reduced ability to compete with non-native and native competitors due to elevated temperatures
- Increased predation mortality resulting from more active, abundant, and effective predators at high temperatures

Overwinter Rearing
Environmental changes have the potential to influence growth and survival including:

- Reduced growth rates resulting from higher metabolic demands and low available food resources
- Increased growth rates resulting from increased temperatures
- Increased overwinter mortality resulting from more frequent and intense winter flood events
- Reduced or improved overwinter survival resulting from changes in body size at the onset of winter

Smolt Migration
Environmental changes have the potential to influence migration timing and survival including:

- Alteration of smolt seaward migration timing as a result of hydrographic changes, prior life stage growth patterns, and size-at-age
- Alteration of the proportion of steelhead offspring that express anadromous and resident life history strategies as a result of changes in prior life stage growth rates and size-at-age
- Increased smolt mortality in tributary and mainstem migratory corridor due to elevated temperatures and increased predation
- Increased smolt mortality resulting from prolonged migration timing resulting from reduced flows

Smolt to Adult Ocean Rearing
Environmental changes have the potential to influence survival, growth, and age-at-maturation including:

- Increased mortality at time of ocean entrance due to mismatch in smolt physiology and ocean entrance timing
- Reduced early ocean survival due to changes in temperature, plume dynamics, and predator-prey relationships
- Altered ocean growth patterns due to elevated temperatures and altered current patterns resulting in reduced survival and changes in adult age at return

Adult Migration and Holding
Environmental changes have the potential to influence migration timing, survival, and straying including:

- Reduced migration success and increased mortality due to increased mainstem temperatures during the summer migration period. Increased temperatures can influence migration success and survival in a variety of ways including increased energetic demands, delayed passage, and direct mortality due to lethal temperature encounters
- Potential for increased straying, for some populations, into summer coldwater refugia like the Deschutes River
- Increased pre-spawn mortality due to high late summer and fall temperatures in adult holding habitat

Adult Spawning
Environmental changes have the potential to influence spawn timing and spawner distribution including:

- Shifts in adult spawn timing resulting from increased temperature and associated changes in sexual maturation rates during adult migration and holding periods (some Mid-C adult steelhead spend up to 11 months in freshwater prior to spawning)
- Shifts in adult spawner distribution due to flow and temperature changes in tributary spawning areas.

8.8.3 Potential Vulnerability Risk to Climate Change

Introduction

There is a considerable amount of new information available regarding the potential impacts of climate change on air temperature, precipitation, and rain/snowfall patterns. Although some work is underway to assess the impacts of environmental change on salmon in the Pacific Northwest, there is no spatially explicit information available for Oregon's Mid-C steelhead populations that links climate change to potential vulnerability.

We have taken the first step in linking climate change to potential vulnerability risk by developing an integrated risk analysis. One key objective of this effort is to produce maps that will serve as the basis for comparing the high priority tributary habitat actions and targeted limiting factors with geographic areas that are most vulnerable to climate change impacts. We want to emphasize that this effort is only a first step and that this should serve as a stepping stone for others to build from and improve on.

As discussed earlier, climate change will pose significant challenges to steelhead ecology throughout the entire life cycle. The magnitude of environmental change will vary considerably from one geographic area to another, even within the boundaries of an individual population. Ideally, we would like to assess the potential effects of climate change on abundance, productivity, spatial structure, and diversity of all Oregon Mid-C populations and determine the effectiveness of our management strategies in addressing climate impacts. However, the state of knowledge is not yet advanced to the point to allow this level of quantitative assessment.

To characterize spatially explicit, potential vulnerability risk we utilized available environmental information to develop three risk metrics and a combined overall risk metric that integrates the three individual metrics. We chose key environmental parameters that should change significantly under all climate change scenarios and that should provide adaptive challenges to multiple life stages of Mid-C steelhead. We selected changes in springtime available water (Graves 2008) to index potential future risk for spawning and changes in peak summer temperature (Cooney and Holzer, *in prep*) to index potential future risk for summer rearing capacity and growth, incubation, and emergence/colonization. We also utilized past variation in precipitation (Brown 2009) as an index of adaptive capacity.

Approach

Springtime Water Availability Change (SWAC)

Graves (2008) compiled contemporary climate conditions (1971-2000) from PRISM data (Daly et al. 1994) in a GIS format for Columbia Basin watersheds. He then conducted an analysis to assess monthly water balances from precipitation and snowmelt for three future climate timeframes (2020s, 2040s, and 2080s) using future projections of monthly temperatures and precipitation changes generated by the University of Washington Climate Impact Group (UWCIG 2007). This UWCIG (2007) data included monthly expected change in temperature and precipitation from the baseline period including 2010-2029 (2020s), 2030-2059 (2040s) and 2070-2099 (2080s). These projections of change were applied to the spatial grid of contemporary climate, producing a scalable result. Graves (2008) assessed changes in water availability for seven subbasins that are of importance to Columbia River Basin tribes.

We conducted our analyses in a five step sequence:

1. We obtained percent change in water availability from contemporary climate conditions (1971-2000) to the 2040s future climate scenario (Graves 2008).

2. We aggregated the data for each 6th field hydrologic unit (HUC6) for all Mid-C populations.

3. We calculated the percent springtime water availability change (SWAC) for each month and each HUC6. We selected the months of March, April, and May for our analyses because these months represent the period of time for spawning, incubation, fry emergence and fry colonization for most Oregon Mid-C steelhead. Therefore, hydrograph changes during this critical time period will pose significant adaptive challenges to multiple life stages.

We calculated the mean percent directionless change in springtime water availability for each HUC6 as:

$$\overline{SWAC} = \frac{|SWAC_1| + |SWAC_2| + |SWAC_3|}{N_{SWAC}}$$

where

$SWAC_1$ = March absolute value of percent change in water availability

$SWAC_2$ = April absolute value of percent change in water availability

$SWAC_3$ = May absolute value of percent change in water availability

N_{SWAC} = number of months

4. We developed risk rating criteria to categorize values into four risk levels. Criteria were based on expert opinion, manually selected categories:

Very Low Risk: $\overline{SWAC} = 1.2\%\text{-}5.0\%$
Low Risk: $\overline{SWAC} = 5.1\%\text{-}15.0\%$
Moderate Risk: $\overline{SWAC} = 15.1\%\text{-}35.0\%$
High Risk: $\overline{SWAC} = 35.1\%\text{-}203.1\%$

5. We mapped the $\overline{SWAC}$ and risk rating for each HUC6 for all populations. These results were used in the development of the integrated risk assessment.

Summer Temperature Change (STC)

Interior Columbia basin naturally produced steelhead populations rely on tributary habitats for juvenile rearing. Interior steelhead typically emerge from spawning gravels in the early summer of their natal year, spending two or more summer growth seasons in freshwater prior to

emigrating to the ocean. Smolt outmigration sampling indicates that emigration may be triggered by reaching a size threshold (e.g., Mullan et al. 1992). As with other salmonids, stream temperatures are extremely influential on juvenile growth and mortality rates (McCullough 1999).

Climate modeling projections for the Interior Columbia indicate a warming trend in air temperatures over the next 20 to 80 years (e.g., Mote and Salathe 2009). Mantua et al. (2009) developed statistical models relating patterns in available historical stream temperature records to associated air temperature estimates from throughout Washington State. The stream sites used in that analysis were largely associated with major mainstems or lower sections of river systems, very few of the sample series in their study were from upper tributary habitats used by juvenile steelhead. Cooney and Holzer (*in prep*) used recent historical stream temperature series from upper tributary habitats, exhibiting the physical characteristics associated with juvenile steelhead rearing, to model the potential impacts of increased temperatures on juvenile steelhead growth potential. This analysis had two major objectives: to highlight high intrinsic potential steelhead production areas across populations within the Columbia River basin that are particularly vulnerable to projected temperature increases and to identify representative drainages in which to carry out more detailed temperature assessments that would include groundwater interactions, etc.

Recent historical stream temperature data: Stream temperature data sets were collected from various agencies, including federal (USGS, NOAA), state (Oregon Department of Environmental Quality, Washington State Department of Ecology), and tribal (Nez Perce) sources. The candidate data sets were limited to those that: 1) included at least two summers after 2000, and 2) were located within Interior Columbia basin stream reaches identified as historic or current natural steelhead spawning/rearing areas. In a few cases, locations on streams blocked to anadromous migration were included in order to incorporate data series from underrepresented ecotypes. The Yakima River mainstem sites were excluded due to the influence of the highly modified flow regimes in that system. In addition, locations elsewhere throughout the Interior Columbia basin that are located directly downstream from reservoirs were excluded. Cooney and Holzer (*in prep*) also discarded temperature series in very small tributaries directly associated with springs. After screening, a total of 167 sites were available for the analysis.

Stream temperature models: Stream temperatures in a given tributary reach can be influenced by a number of factors in addition to local air temperatures (e.g., Isaak and Hurbert 2001). Reach specific factors that could influence stream temperatures include air temperature, topography, flow, geology (e.g., potential for groundwater influence), and shading. Stream temperatures in a tributary reach can also be influenced by upstream conditions such as basin area, mean precipitation, ice or snow contribution (such as from glaciers) and geology. A set of candidate variables representing these potential factors was selected from available Interior Columbia basin GIS data sets.

A forward stepwise multiple regression analysis (Statgraphics REGRESS routine) was used to generate statistical models of mean summer stream temperatures (defined as the maximum two week average stream temperature during July or August). A cross-validation approach was used for the analysis, each of the 167 site-series was randomly assigned to one of three groups. The

stepwise multiple regression analysis was repeated three times, leaving out one of the random groups for each repeat. Residuals were calculated for the out-of-sample set for each of the three runs and tabulated. Three variables were identified among the three runs as having the most significant influence: mean maximum air temperature, elevation range (ln) and percent forest cover. A fourth variable, basin alluvial geology, was included in the analyses for two of the three subsets. Given the high degree of consistency among results from the subset analyses, the data sets were combined in an aggregate analysis.

Projected stream temperatures: The resulting aggregated stream temperature model was applied to estimate two-week mean average stream temperatures for current steelhead rearing habitats in accessible stream reaches and potential habitat within extinct population reaches. Estimates were expressed at the reach level for rearing habitats associated with each Interior Columbia steelhead population. The current distribution of steelhead production within stream networks was adapted from ICTRT data and generally reflects the distribution extent developed by state agencies (WDFW, ODFW, and IDFG). Historically occupied areas that are targeted for reintroductions were incorporated using an intrinsic potential habitat analysis (ICTRT 2007) as a proxy for current distribution. Temperature estimates were calculated for current conditions as well as for climate change projections. The potential increases in stream temperatures corresponding to future climate scenarios were generated by increasing the estimated current air temperature input values at the reach level by the average incremental change projected by the climate models (1.1, 1.3 and 3.1 °C by 2020, 2040 and 2080 after Mantua et al. 2009). The resulting point estimates of mean temperature by stream reach were summarized by HUC6 subbasins. Aggregate values were then assigned to potential growth categories. The growth categories were assigned based on information summarized in McCullough (1999) and are presented below:

Stream Temperature	Growth Impact Assumption
<4.5 °C	Zero Growth
4.5 to 10 °C	Cold Growth
10 to 15 °C	Optimum Growth
15 to 19 °C	Warm Growth
19 to 20 °C	Zero Growth
> 20 °C	Negative Growth/Lethality

We mapped the temperatures and growth categories for current conditions and a 2080 temperature scenario.

Risk assessment: The statistical models used to estimate stream temperatures had a relatively high degree of uncertainty. An estimate of the relative uncertainty in predicting stream temperatures based on a residuals analysis was directly incorporated in calculating a relative risk index at the reach level summarized by HUC6. The risk index was expressed relative to the

lower threshold of zero growth temperature zone (19 °C). Using either the aggregate or composite model, approximately 80% of observed temperature values fell above the model predicted value +2 °C. If the point estimate of stream temperature for a HUC6 was between 19 and 21 °C the risk was classified as High. If the point estimate exceeded the 19 °C threshold by 2 °C or more, the risk rating was set at Very High. If the point estimate was more than 2 °C below the threshold (<17 °C), the HUC6 was rated at Low risk. Relative risk levels were assigned based on the following thresholds:

Predicted Temperature	Assigned Risk
< 17 °C	Low
17 to 19 °C	Moderate
19 to 21 °C	High
> 21 °C	Very High

The relative risk levels for the 2080 scenario were mapped and incorporated into the integrated risk analyses.

Historical Precipitation Variation (HPV)

We used historical precipitation variation as a metric to index adaptive capacity. As discussed earlier adult spawn timing, egg incubation, and fry emergence are key Mid-C steelhead life stages that are likely to be impacted by climate change, specifically hydrograph and temperature changes.

A variety of salmon life history traits have been shown to vary with environment characteristics including flow, elevation, and temperature (Waples et al. 2004; Quinn 2005). Characteristic life history strategies, that are often geographically unique, represent adaptation to local environmental conditions (Lichatowich 1999). Many authors have concluded that life history strategies are an adaptive response to environmental conditions and when climate or habitat changes occur some life history strategies will perform better than others (Lichatowich 1999). McClure et al. (2008) concluded that some key adult and early life-stage traits are closely linked with environmental conditions and have moderate to high levels of heritability. Particularly relevant to Mid-C steelhead vulnerability to hydrograph and temperature changes, phenotypic traits such as adult migration timing, spawn timing, developmental rate, and emergence timing are known to be heritable and vary between populations.

Life history diversity and degree of local adaptation are key elements influencing population capacity to deal with variable and changing environments. The ability of populations to adapt to changing environments depends, in part, on the rate and magnitude of environmental change as well as the inherent life history variation. Those populations that persist in highly variable environments and that exhibit diverse life history patterns will likely have greater capacity to

adapt to changing environments. Brown (2009) hypothesized that the capacity of basins to adapt to water availability changes will likely be dependent on the level of historic precipitation. We hypothesize that populations which persist in areas with highly variable precipitation patterns will have greater resilience to future climate change than populations which reside in low precipation variability areas.

To link environmental variation to adaptive capacity risk, we conducted the HPV analyses in a four step sequence:

1. We obtained precipitation coefficient of variation data from Brown (2009) with the original data source of PRISM.

2. We aggregated the data for each HUC6 for all Mid-C steelhead populations.

3. We developed risk rating criteria to categorize values into four risk levels. Categories were based on natural break (Jenks 1967) methodology:

Very low risk:	CV = 0.688 – 0.865
Low risk:	CV = 0.596 – 0.687
Moderate risk:	CV = 0.513 – 0.595
High risk:	CV = 0.413 – 0.512

4. We mapped HPV and risk ratings for each HUC6 for all populations. We then used the HPV results in the integrated risk assessment.

Integrated Potential Vulnerability Risk

We combined the three individual risk metrics to develop an integrated potential vulnerability risk index. The integrated risk index was developed to identify the geographic areas where climate change is projected to influence multiple environmental factors and life stages. We weighted the influence of STC risk greater than $\overline{SWAC}$ risk, and $\overline{SWAC}$ risk greater than HPV risk. We placed the greatest weight on STC because of the potential impacts to capacity, survival, and life history that are associated with the magnitude of temperature changes that are projected to occur.

We developed rating criteria to categorize risk into four levels. Table 8-69 shows the combinations of $\overline{SWAC}$, STC and HPV which were designated as very low, low, moderate and high risk.

Very low risk: assigned when the metric combinations were low risk and very low risk.

Low risk: assigned when the metric combinations included one metric at moderate risk with two metrics at low or very low risk, or, all three metrics with low risk.

High risk: assigned when STC was very high risk regardless of the other metric ratings, when there were two high risks with any other risk rating, and if $\overline{SWAC}$ or STC were high and the other two metrics were moderate.

Moderate risk: assigned to all other risk combinations.

We mapped the integrated risk index for each currently occupied HUC6 for all populations and HUC6s in the Deschutes Basin where steelhead reintroductions are planned.

Table 8-69. Criteria for considering springtime water availability change ($\overline{SWAC}$), summer temperature change (STC), and historical precipitation variation (HPV) climate change risk metrics into an integrated potential climate change vulnerability index. The order of individual metric risk ratings is $\overline{SWAC}$, STC, HPV. (VH=Very High; H=High, M=Moderate, L=Low, VL=Very Low)

Results and Discussion

Springtime Water Availability Change

The percent change in springtime water availability and the associated risk levels are shown for each HUC6 in Figure 8-20. We observed a similar pattern in springtime water availability as described in Graves (2008) and Mantua et al. (2009). Mantua et al. (2009) concluded that many of the Washington State Mid-Columbia River steelhead basins will transition from rain and snow basins to rainfall dominant basins resulting in significant hydrograph shifts. In our analysis, moderate to higher elevation areas showed the greatest $\overline{SWAC}$, and thus the highest risk levels. There were only a few populations with substantial areas that were rated as high risk, including the North Fork, Middle Fork, and Upper Mainstem John Day populations. The geographic areas with the highest risk levels were those areas with significant at-risk snow (Nolin and Daly 2006; Brown 2009) that are projected to shift from snow-dominated to rain-dominated precipitation patterns by mid-century (Graves 2008). Much of the currently occupied spawning habitat within all populations, except the Deschutes River Eastside and Lower John Day River, was classified at moderate risk.

The water availability at HUC6 scale serves as a reasonable index of potential hydrograph changes for headwater and lower order streams. However, flow in larger mainstem, higher order streams is not influenced significantly by local area water availability, rather by upstream tributary flow inputs. Therefore, the $\overline{SWAC}$ analysis does not effectively index potential hydrograph changes for mainstem higher order stream reaches. The effect of this bias on our analysis is somewhat minimized because steelhead spawning distribution is concentrated in lower order tributary streams. The development of hydrologic models (see Mantua et al. 2009) to characterize future hydrograph changes would significantly improve the ability to characterize geographic specific risk to Mid-C steelhead in Oregon. In addition, inclusion of ground water inputs as well as water withdrawals would increase the value and applicability of the analysis.

Summer Temperature Change

Modeled, mean stream temperatures and the associated steelhead growth zones for current conditions and the 2080 climate scenarios are shown in Figures 8-21 and 8-22 respectively (Cooney and Holzer, in prep). Significant proportions of the Deschutes River Eastside, Lower Mainstem John Day River, Umatilla River, and Walla Walla River populations currently exhibit mean summer temperatures residing in the zero net growth and negative growth zones (Figure 8-21). Many of the streams and rivers within the Mid-Columbia Oregon population boundaries exhibited mean summer temperatures in the negative growth zone in the 2080 climate scenario (Figure 8-22). A majority of the streams and rivers within the boundaries of the Deschutes River Eastside, Lower Mainstem John Day River, Umatilla River, and Walla Walla River populations show predicted mean summer temperatures exceeding 20 °C in the 2080 climate scenario (Figure 8-22).

Maximum mean summer stream temperature risk levels are shown in Figure 8-23. All populations showed areas with Very High and/or High risk. Populations that showed the greatest vulnerability with large proportions of the streams and rivers in Very High and High risk included the Deschutes River Eastside, Lower Mainstem John Day River, Umatilla River and Walla Walla River. All populations exhibited Low and Moderate risk categories at the higher elevation headwater reaches (Figure 8-23).

Historical Precipitation Variation

The historical coefficient of variation and associated risk levels are presented in Figure 8-24. A pattern emerged that showed low precipitation variation and high risk ratings in currently occupied areas within populations in the eastside of the DPS (SF, Upper Mainstem, MF, NF John Day River, Umatilla River, and Walla Walla River) whose headwaters originate in the Blue Mountains. In contrast, currently occupied areas within populations in the westside of the DPS (Fifteenmile Creek and Deschutes River Westside) whose headwaters originate from the eastslope of the Cascades Mountains showed moderate to high precipitation variation and moderate to low risk ratings (Figure 8-24).

Integrated Potential Vulnerability Risk

Extensive geographic areas within all populations, except Fifteenmile Creek and Deschutes River Eastside, exhibit high vulnerability risk (Figure 8-25). In addition, all populations have a substantial proportion of the geographic area rated at moderate risk.

Two patterns emerged that are characteristic of the areas rated at high risk. High risk levels for higher elevation areas within the John Day River populations were attributable to the combination of high risk for $\overline{SWAC}$ and HPV. In contrast, the high risk ratings for lower elevation areas in many of the populations, particularly evident in the Lower Mainstem John Day, Umatilla and Walla Walla populations, resulted primarily from the STC risk.

Results that are of particular concern for Oregon's Mid-C steelhead populations include:

1. The very small number of HUC6s that were at low or very low risk.

2. Many populations, including the South Fork John Day, Upper Mainstem John Day, Middle Fork John Day, North Fork John Day, Umatilla and Walla Walla, have the entire geographic area within the population boundaries rated at moderate or high risk.

3. The combination of environmental characteristics that are projected to change under future climate scenarios will threaten capacity, productivity, diversity and spatial distribution from both lower elevations upward and higher elevations downward. The life stages, capacity, and productivity impacts will vary depending on the specific environmental factors that are altered and the adaptive capacity.

As discussed earlier, we recognize this is a first step in development of a climate change vulnerability index for Oregon's Mid-C steelhead. Significant improvements to the approach can be made with use of hydrologic models that project reach scale flow changes, use of historical flow variation instead of precipitation variation, and incorporation of other environmental factors and life stages in the analysis. In addition, it would be beneficial to examine the relationship between current life stage specific habitat use and potential vulnerability risk for each population.

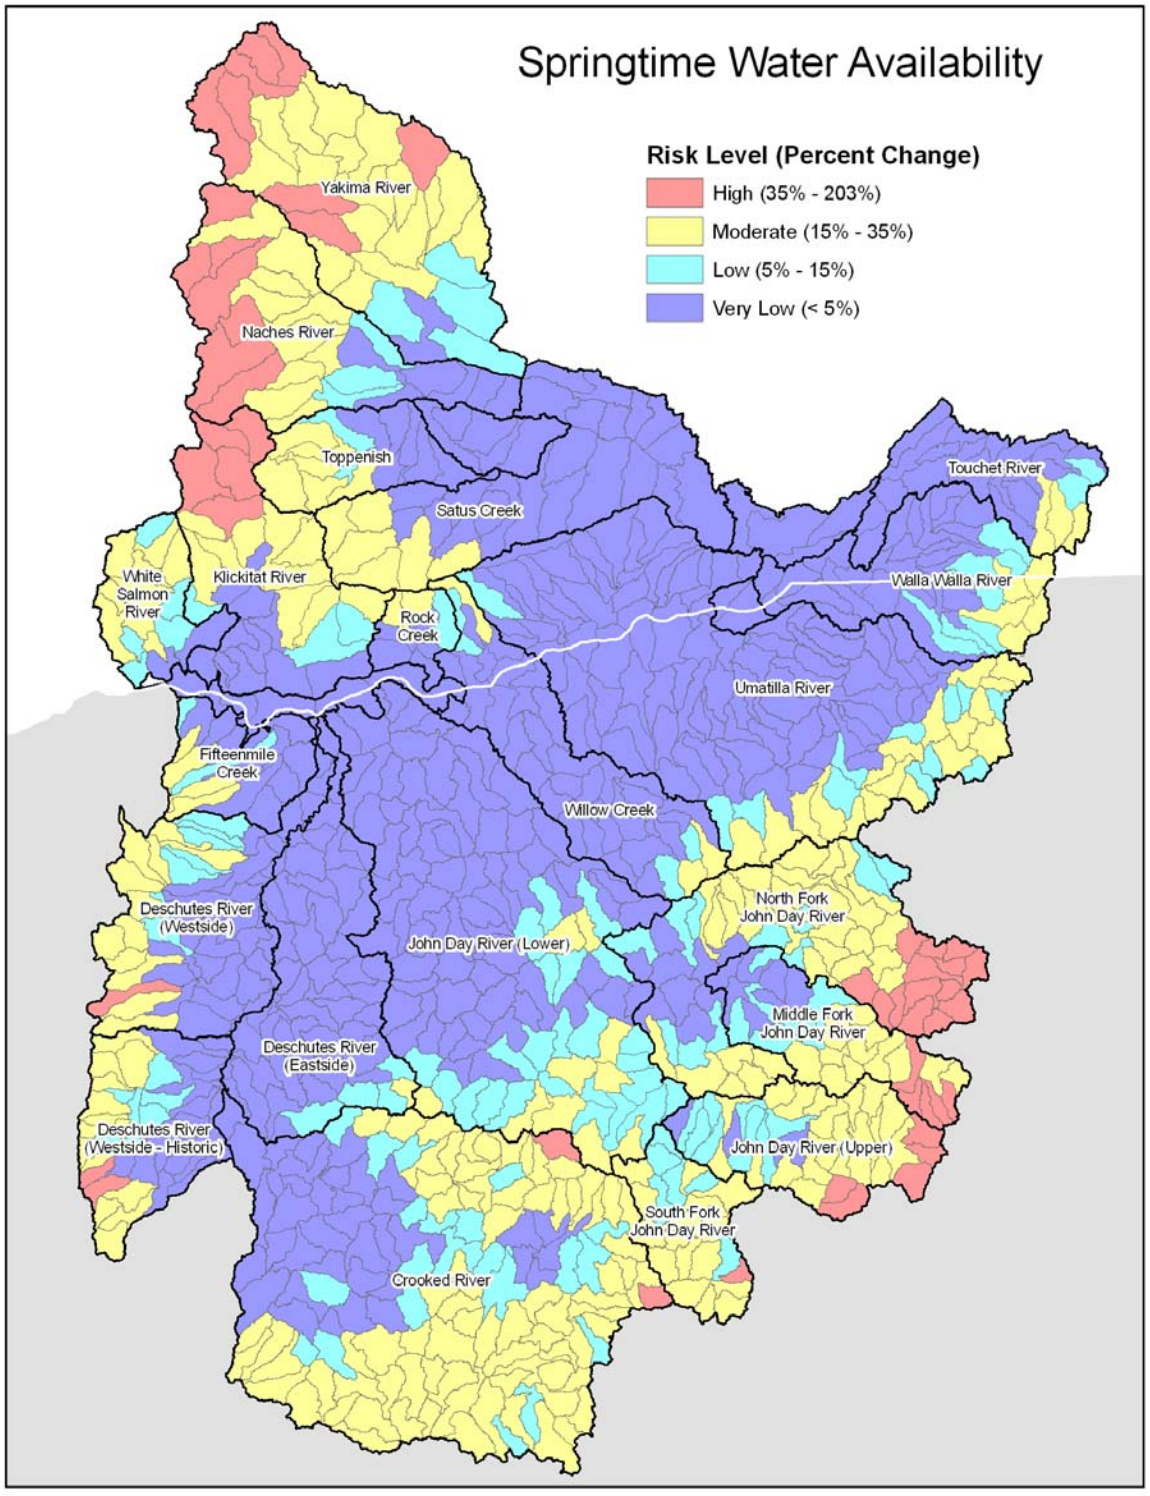

Figure 8-20. Percent change in springtime water availability (March-May) from baseline conditions (1971-2000) to future conditions (2040s) and projected future relative risk to Mid-Columbia River steelhead (6th field hydrologic units). Data sources include Graves (2008) and UWCIG (2007).

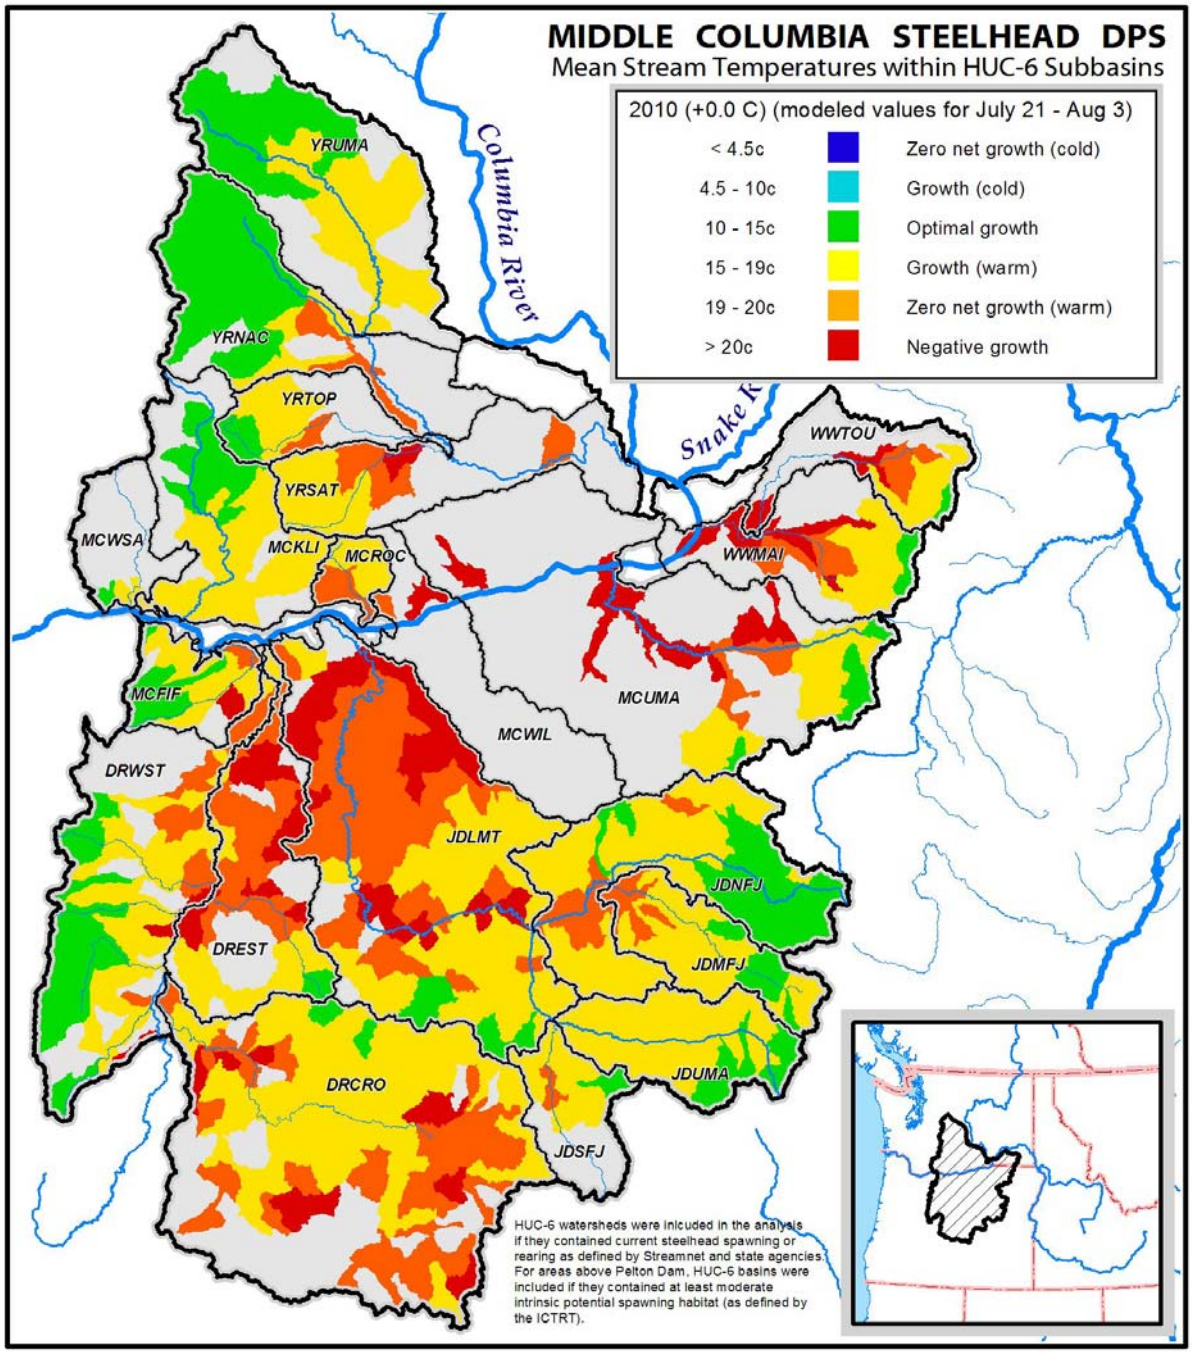

Figure 8-21. Modeled current summer (July 21-August 3) stream temperatures and growth zone characterization for Mid-Columbia River steelhead (6th field hydrologic units). From Cooney and Holzer, *in prep*. All areas shown in the Crooked River and Deschutes River Westside-Historic are currently unoccupied; however, reintroduction efforts are currently underway in some areas.

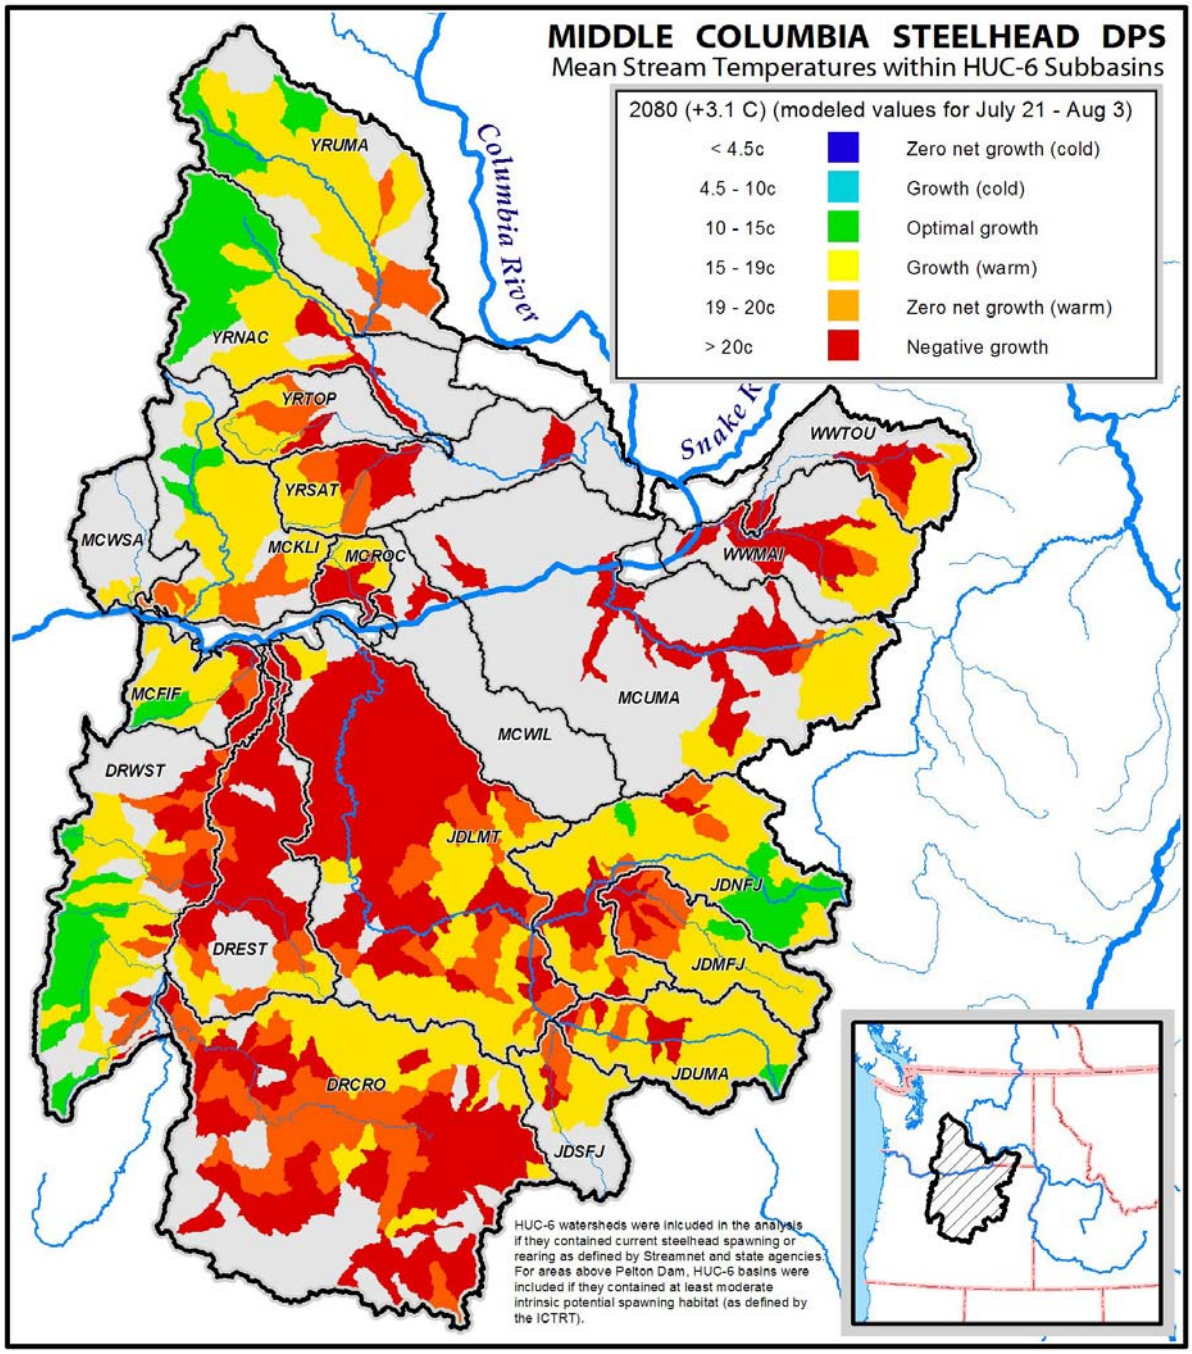

Figure 8-22. Modeled future (2080) summer (July 21-August 3) stream temperatures and growth zone characterization for Mid-Columbia River steelhead (6th field hydrologic units). From Cooney and Holzer, *in prep*. All areas shown in the Crooked River and Deschutes River Westside-Historic are currently unoccupied; however, reintroduction efforts are currently underway in some areas.

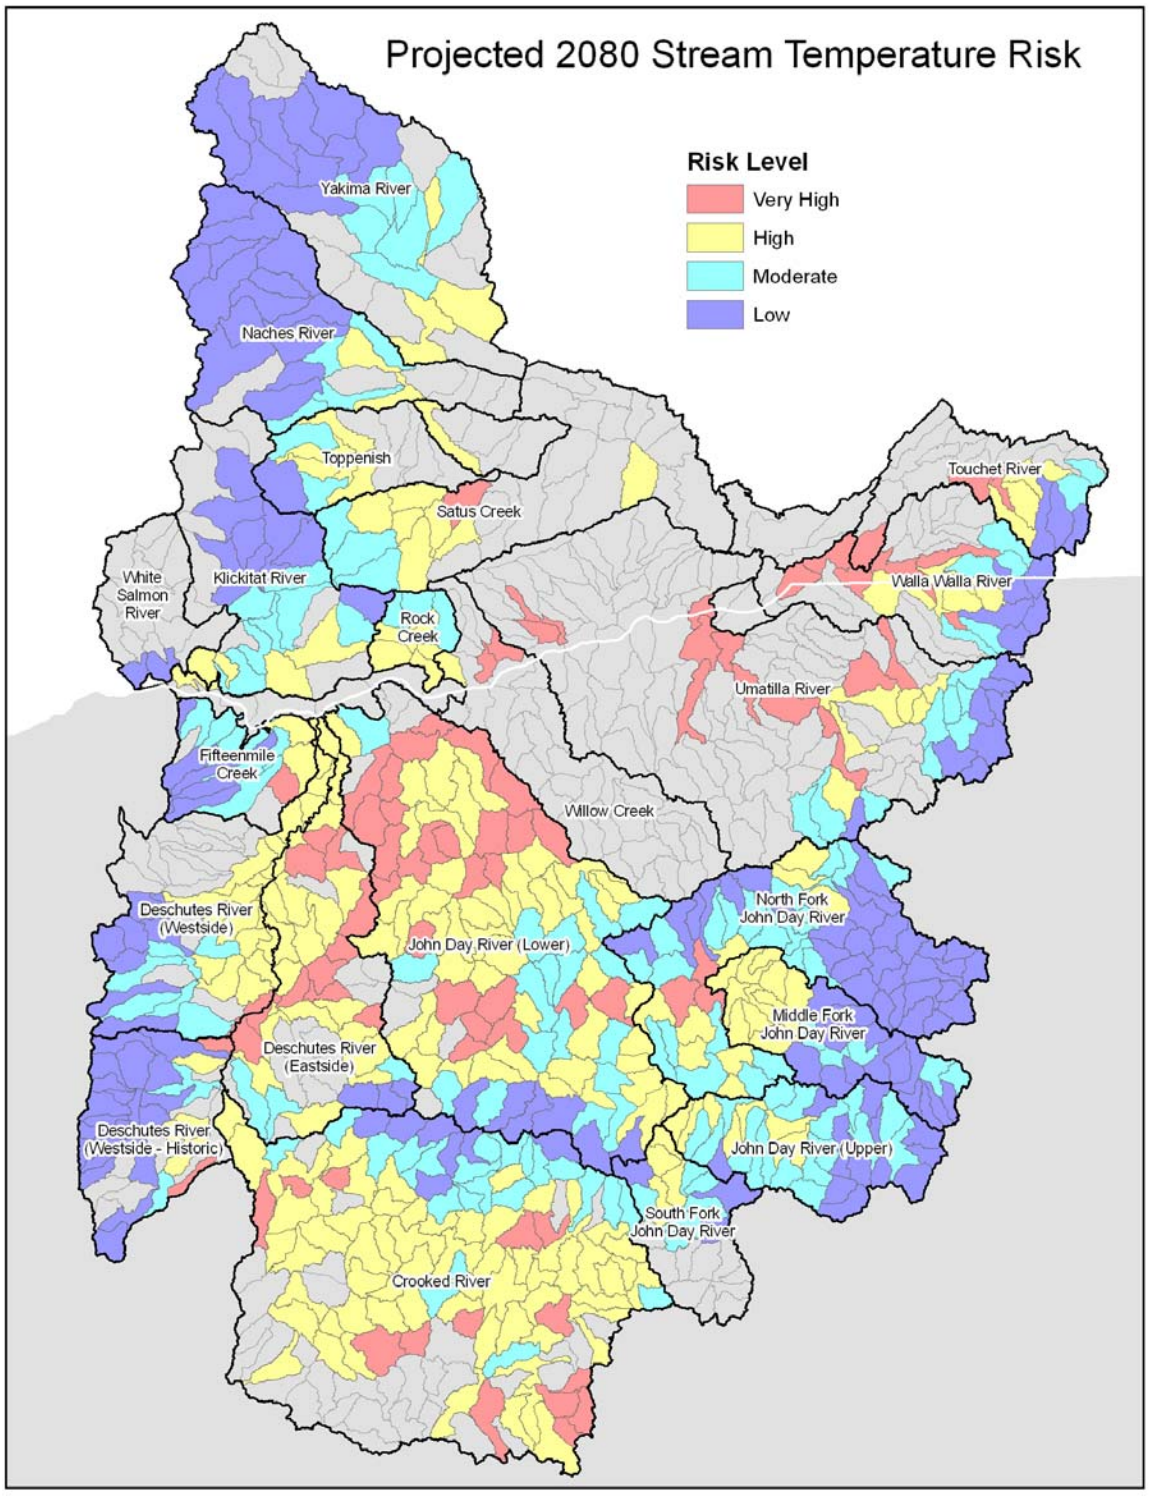

Figure 8-23. Projected future relative risk to Mid-Columbia River steelhead habitat (6th field hydrologic units) due to changes in summer (July 21-August 3) stream temperatures from current (2010) to future (2080) conditions. Data source is Cooney and Holzer, *in pre*p. All areas shown in the Crooked River and Deschutes River Westside-Historic are currently unoccupied; however, reintroduction efforts are currently underway in some areas.

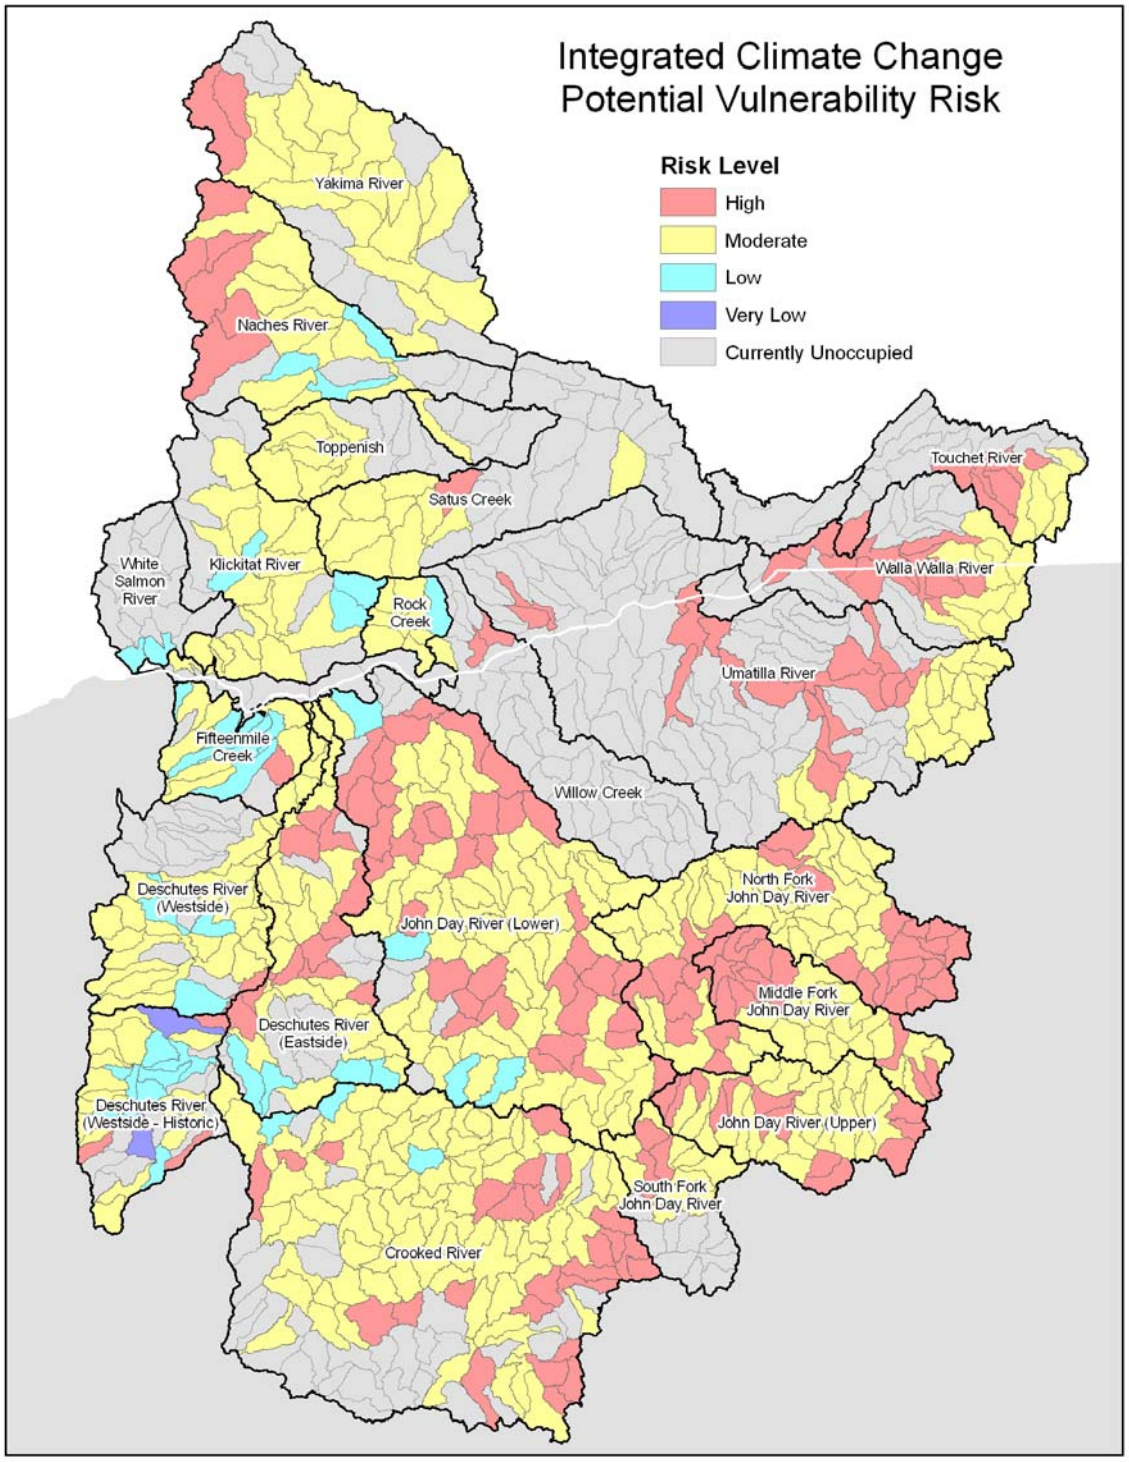

Figure 8-25. Integrated climate change potential vulnerability risk for Mid-Columbia River steelhead (6th field hydrologic units). Integrated risk index was developed from springtime water availability change risk, summer temperature change risk, and historical variation in precipitation.

Section 9 Recovery Strategies and Management Actions

This section describes strategic guidance, strategies and specific management actions proposed for achieving recovery of Oregon populations in the Mid-Columbia River steelhead DPS. The strategic guidance supplies the framework for developing strategies and prioritizing actions at all scales. The management strategies and actions provide an integrated approach to address threats across the entire life cycle. These are identified in sections 9.3 (Tributary Habitat), 9.4 (Hydrosystem), 9.5 (Estuarine and Plume Habitat), 9.6 (Harvest), 9.7 (Hatcheries) and 9.8 (Predation and Competition). Together the strategies and actions provide broad guidance for recovery efforts at the local and regional level, consistent with both regional and local visions, as well as detailed management actions.

While fundamentally intended to produce biological results, strategies and actions included in this plan also reflect economic, political, social, and cultural considerations. In particular, they are framed to regain DPS viability as well as make progress beyond delisting criteria to broad sense recovery goals. These considerations are critical to the prospects for developing and implementing an effective and equitable plan. It is expected that additional actions will be incorporated over time as part of the ongoing adaptive management process.

9.1 Strategic Guidance for Management Actions

Achieving recovery for the Mid-Columbia River steelhead DPS will depend on restoring the viability of extant populations in major population groups to levels that support the proper functioning of the DPS. This will require intensive effort by individuals at the regional, watershed and local levels. It is clear that not all of the management actions that should be implemented can be done in the near-term due to various constraints.

The purpose of this strategic framework is to provide guidance for developing and prioritizing management actions to recover Mid-C steelhead populations. Prioritized actions will lead to more timely and effective results. Our strategic vision recognizes that reversing the decline of key populations, life histories, and habitats requires use of well-formulated scientifically sound approaches. Since multiple causes are responsible for impaired population viability and disrupted ecosystem function, limiting factors and threats throughout the entire life cycle will need to be addressed in concert. Efforts must also be focused to protect and enhance populations that are critical to achieving DPS recovery.

As part of this and other planning processes, management actions and strategies were developed at multiple scales including tributaries, watersheds, and the Columbia River mainstem and estuary to achieve recovery of local populations. This strategic framework is used as strategic guidance for where, when, and how actions identified in this plan are implemented to address factors and threats limiting viability of extant and extirpated Mid-C steelhead populations.

Managing for past, current and future adverse impacts of human activities throughout the life cycle is critical to achieving recovery goals. Development and implementation of management actions that lead to recovery will require a sound understanding of conservation biology

principles and ecosystem management as well as integration of leadership, planning, funding, monitoring, policy and science such that each contributes synergistically in a timely and effective manner. The approaches to ecosystem restoration and management actions needed to achieve recovery goals will necessarily vary by ecosystem type, management objectives of the various lands and ownerships within the ecosystem, and social and economic capacity to support the effort. Actions that balance achievement of sustainable environmental, social, cultural and economic processes have the best chance of success for the long term.

The primary goals of the recovery plan are to:

1) Sustain the ecosystem processes that currently, and will in the future, support high quality habitats and their productive capacity.
2) Enhance ecosystem processes that are impaired but are currently important to productive capacity.
3) Restore habitat and ecosystem processes that were historically important but do not currently contribute to productive capacity.

We identified some key principles (adapted from Meffe and Carrol 2002) that form the basis for sound salmon recovery efforts, including:

1) Set aside or protect the highest quality habitat
2) Prevent any further habitat degradation
3) Maintain and restore critical ecological processes
4) Develop goals and objectives based on thorough understanding of ecological processes and properties of the systems
5) Conserve and restore evolutionary processes
6) Manage in an adaptive manner that is minimally intrusive

Conservation of the existing quality habitat that supports core production and primary life history types — as well as quality migration habitats within populations and across the DPS — is the critical first step toward recovery. This needs to include a shared vision of desired ecosystem conditions that integrates ecological, socioeconomic, and institutional perspectives and identifies ways in which all parties can contribute to and benefit from achieving the desired ecosystem conditions. Protecting and restoring the normative natural ecological processes throughout the entire life cycle is essential for conserving the productive capacity of the habitat.

These principles provide general guidance but are difficult to apply specifically for prioritizing a broad list of actions at the population, major population group, and DPS levels. Because we have the need for criteria that deal with setting priorities across broad geographic and ecological scales, we propose more detailed prioritization considerations that are formulated from the broader conservation principles. In simplistic terms, the order of priority is first to protect and conserve high quality habitats and natural processes that currently support productive capacity and implement actions that provide immediate abundance and productivity benefits through reduction of key limiting factors and threats; second to enhance habitat and restore natural processes that are impaired but are currently important to productive capacity; and last to restore

habitat and natural processes that were historically important but do not currently contribute to productive capacity.

9.1.1 Prioritization Considerations

Setting priorities for management actions is difficult because of the scientific complexity and diverse policy issues and economic implications. Although priorities must be science based, they are ultimately policy choices. The following considerations are used as guidance and criteria for the development, prioritization, and implementation of management strategies and actions for recovery of Mid-C steelhead populations in Oregon.

We consider actions that achieve the following to be highest priority:

- Actions that provide long-term protection of habitat conditions and conservation of natural ecological processes that support the viability of priority extant populations and their primary life history strategies throughout their entire life cycle. A population is considered a priority if it is critical for MPG or DPS viability.
- Actions that protect or enhance viability of multiple steelhead populations.
- Actions that support conservation of unique and rare functioning habitats, habitat diversity, life histories and genetic attributes.
- Actions that target the key limiting factors and that contribute the most to closing the gap between current status and desired future status of priority populations.
- Actions that provide immediate benefits to enhancing the viability of priority populations.
- Actions that provide critical information needed for assessing success and making adaptive management decisions.

We consider the following types of actions to be high priority but less than highest:

- Actions that enhance the habitat conditions and restore natural ecological processes of priority extant populations and their primary life history strategies throughout the entire life cycle.
- Actions that enhance the viability across the entire life cycle of priority extant populations.
- Actions that are required to protect and enhance habitats for populations that are not critical for MPG or ESU viability but must be maintained.

Other things being equal, actions that demonstrate the following have enhanced priority:

- Actions where opportunity for success is high (rather than those of limited feasibility).
- Actions that likely produce a large (rather than small) improvement in viability attributes.
- Actions that support restoration of normative ecological processes rather than short-term substitutions for normative processes.
- Actions that are complementary to other land management, water quality, environmental management and recreational objectives as specified in fish management, conservation, recovery or other plans developed with and supported by regional and subbasin stakeholders (rather than those that are isolated, stand-alone efforts).

- Actions that have regional and local support and generate increased participation.
- Actions that demonstrate cost effectiveness relative to alternative means of achieving the same objectives.
- Actions that have high degree of certainty in effectiveness and outcome.

9.2 An Integrated Approach

In previous sections of this plan we identified delisting goals, broad sense recovery goals, current status and viability gaps, as well as limiting factors and threats across the entire life cycle. These elements serve as essential building blocks for identifying the strategies and actions needed to close viability gaps, reach delisting status, and progress toward our broad sense recovery goals.

The strategies and actions are developed to address the viability gaps and primary threats and factors currently limiting recovery of Oregon's Mid-C steelhead populations. Our integrated approach is designed to ensure that recovery efforts are developed and implemented in a scientifically sound and systematic manner. We strive to ensure that all recovery actions effectively complement and support each other in achieving the broad sense recovery goals.

Recovery strategies are designed to address the twelve types of factors discussed in Section 8, Limiting Factors and Threats, that affect steelhead viability throughout their entire life cycle. These factors fall into six different categories: tributary habitat; estuary/mainstem habitat; mainstem hydropower configurations and operations; in-subbasin and out-of-subbasin harvest; hatcheries; and predation and competition. Similarly, strategies and actions described in this section address threats and limiting factors in each of these categories. Table 9-1 illustrates the kinds of connections that exist between limiting factors, strategies, and actions.

The integrated approach is also intended to ensure that costs and consequences of achieving recovery are equitable across the affected constituencies. Recovery can be achieved with different combinations of actions implemented at different intensities among and on varying timelines. Thus, the plan defines expectations and direction for the various parties who will implement elements of the plan in a broader context of scientific, technical, economic, political, social, and cultural considerations. The plan also includes a strategic prioritization framework to provide flexibility for implementing parties to select, scale, and adapt regional and local strategies and actions to optimize effectiveness and efficiency in plan implementation, while also ensuring that steps toward recovery are consistent with regional goals and objectives.

Recovery of the Mid-C steelhead DPS is predicated on assumptions that: 1) remaining populations still retain the inherent characteristics needed to sustain healthy, harvestable levels when suitable conditions are provided; 2) declining trends can be reversed with appropriate actions; and 3) society is willing and able to implement appropriate strategies and their associated actions in a suitable timeframe. Guidance from the ICTRT recognizes that it may not be feasible, nor required, to protect and restore all existing populations to viable status. ICTRT criteria allow some populations to maintain status below viability standards. The plan assumes that a focused and broadly based effort will protect and restore a sufficient number of populations to ensure long-term viability and opportunities for harvest. This effort will require concerted and substantive action by people throughout the region.

Table 9-1. Integrated approach to address threats and factors limiting recovery of Oregon's Mid-Columbia River steelhead populations.

Strategies	Types of Actions	Limiting Factors and Threats Addressed
Tributary Habitat		
Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.	Protect highest quality habitats through acquisition and conservation. Adopt and manage Cooperative Agreements. Conserve rare and unique functioning habitats. Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	Degradation of tributary habitat-forming processes and functions (loss of channel structure, floodplain connectivity, riparian vegetation, and LWD recruitment)
Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.	Provide passage at Pelton-Round Butte Complex. Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures. Provide screening at 100% of irrigation diversions. Replace screens that do not meet criteria.	Loss of historical habitat because of blocked or impaired fish passage (dams, culverts, unscreened diversions)
Maintain and restore floodplain connectivity and function.	Reconnect side channels and off-channel habitats to stream channels. Restore wet meadows. Reconnect floodplain to channel.	Degraded floodplain connectivity and function (loss of off-channel habitat, side channels, connected hypotheic zone)
Restore degraded and maintain properly functioning channel structure and complexity.	Place stable wood and other large organic debris in streambeds. Stabilize streambanks. Restore natural channel form.	Degraded channel structure and complexity (loss of spawning and rearing habitat, LWD, pools)
Restore riparian condition and LWD recruitment and maintain properly functioning conditions.	Restore natural riparian vegetative communities. Develop grazing strategies that promote riparian recovery.	Degraded riparian condition (native riparian vegetative communities, LWD recruitment)
Restore natural hydrograph to provide sufficient flow during critical periods.	Implement agricultural water conservation measures. Improve irrigation conveyance and efficiency. Lease or acquire water rights and convert to instream.	Altered hydrology (low flow, scouring peak flows due to degraded watershed conditions, streamflow alterations and/or withdrawals for irrigation and other uses)
Improve degraded water quality and maintain unimpaired water quality.	Reduce chemical pollution inputs. Apply BMPs to animal feeding operations. Restore natural functions and processes through remediation actions.	Degraded water quality (high temperatures, nutrients, pesticides and other chemicals)
Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.	Achieve 95% conversion to no till farming. Upgrade or remove problem forest roads. Restore native upland plant communities. Employ BMPs to forest practices, livestock grazing, road management and agricultural practices.	Altered sediment routing and runoff patterns due to upland management activities.
Estuarine and Plume Habitat		
Restore degraded estuarine and plume habitats and associated ecological processes	Protect/restore riparian areas Remove pile dikes Protect remaining high-quality off-channel habitat Breach or lower dikes and levees Identify and reduce sources of pollutants Monitor and restore contaminated sites	Degraded estuarine and nearshore marine habitat reduces refugia available to juvenile steelhead in Columbia River estuary and plume as they prepare for ocean life.
Hydropower Systems		
Operate the FCRPS to more closely approximate the shape of the natural hydrograph to enhance flows and water quality to improve juvenile and adult fish survival.	Draft storage reservoirs (Libby, Hungry Horse, Grand Coulee, and Dworshak) in attempt to meet seasonal and weekly flow objectives in the lower Columbia River during July and August. Pursue negotiations with Canada to provide 1 million acre feet of storage to augment summer flows. Meet Non-Treaty storage refill responsibilities and pursue a new long-term agreement on use of non-treaty space in Canadian reservoirs. Implement drafts and other measures to improve flows	Altered steelhead migration conditions and delayed passage due to hydrosystem development and operations in mainstem Columbia River.

Strategies	Types of Actions	Limiting Factors and Threats Addressed
	during the lowest 20th percentile years. Implement Water Quality Plan for Total Dissolved Gas and Water Temperature in the Mainstem Columbia and Snake rivers.	
Modify Columbia and Snake River dams to maximize juvenile and adult survival.	Implement project specific configurations and operations at the eight mainstem dams on the lower Snake and Columbia rivers.	Altered juvenile and adult steelhead migration conditions due to mainstem Columbia River hydrosystem.
Implement spill and juvenile transportation improvements at Columbia and Snake River dams.	Provide spill to improve juvenile fish passage. Implement interim transportation program to improve survival of transported fish.	Altered juvenile and adult steelhead migration conditions due to mainstem Columbia River hydrosystem.
Operate and maintain juvenile and adult fish passage facilities at Corps mainstem projects to maintain biological performance.	Corps will operate juvenile and adult passage facilities year around with the regionally coordinate Fish Passage Plan.	Altered juvenile and adult steelhead migration conditions due to mainstem Columbia River hydrosystem.
Restore sustainable natural steelhead production to blocked habitats in the Deschutes River Westside, Deschutes River Eastside and extinct Crooked River populations.	Develop downstream collection and passage through Pelton-Round Butte Complex. Improve flow patterns through reservoir for juvenile migration. Modify hydro operations to restore water quality.	Tributary hydrosystem operations and configurations block access to historical habitats and alter habitat conditions in Deschutes River system.
Improve hydrosystem operations and facilities to enhance steelhead survival and viability in the Umatilla and Walla Walla river systems.	Modify bypass flows at Boyd Project as needed to mimic instream water right. Modify fish passage facilities at Boyd Project to meet current standards. Remove weir panels from diversion dam at Boyd Project during non-operation. Maintain trash racks at Boyd Project. Modify fishway at Twin Reservoirs Project to meet juvenile fish passage standards.	Tributary hydrosystem operations and configurations impair passage and alter habitat conditions in the Umatilla and Walla Walla river systems.
Harvest		
Manage to maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	Maintain current low impact fisheries and reduce harvest-related adverse effects in those fisheries that have significant impacts.	Commercial, recreational and tribal fisheries in ocean, mainstem Columbia River and tributaries
Utilize tributary harvest to reduce abundance and proportion of stray hatchery spawners in Deschutes and John Day subbasins.	Develop educational outreach program to promote use of selective recreational fisheries to reduce the number of out-of-subbasin hatchery strays.	Straying of out-of-DPS hatchery spawners into tributary spawning grounds.
Reduce catch and release mortality on natural-origin fish in John Day subbasin.	Promote voluntary curtailment of fishing at higher water temperatures (above 21°C) to reduce hook-and-release mortality	Adverse effects of tributary harvest on natural steelhead in John Day subbasin.
Improve quality of harvest and natural-origin fish in John Day subbasin.	Expand the creel surveys to monitor fisheries effort and catch.	Adverse effects of tributary harvest on natural steelhead in John Day subbasin.
Hatcheries		
Reduce uncertainty of origin of hatchery strays and increase ability to recognize hatchery-origin fish.	Implement representative coded-wire-tagging program so all hatchery stocks have adequate CWT groups released annually. Recommend development of alternative broodstocks to reduce stray rates for programs that contribute significantly to stray problem.	Straying of out-of-DPS hatchery fish into natural spawning grounds.
Reduce uncertainty in abundance and proportion of hatchery strays spawning naturally with Fifteenmile, Deschutes Eastside and Lower John Day populations.	Increase efforts to monitor incidence of hatchery fish on spawning grounds through additional stream surveys and other methods.	Straying of out-of-DPS hatchery fish into natural spawning areas of Fifteenmile, Deschutes Eastside and Lower Mainstem John Day populations.
Reduce abundance and proportion of stray hatchery fish that spawn naturally with Deschutes Westside, Deschutes Eastside, Umatilla and	Construct, improve trapping facilities and expand operations. Eliminate adult hatchery strays above Nursery Bridge Dam.	Straying of out-of-DPS hatchery fish into natural spawning areas.

Strategies	Types of Actions	Limiting Factors and Threats Addressed
Walla Walla populations.		
Reduce genetic risks to Deschutes Westside population from Round Butte Hatchery Program.	Investigate opportunities and risks associated with incorporating naturally produced Deschutes River summer steelhead into RBH broodstock.	Inside-DPS hatchery genetic risks
Restore natural production into historically utilized habitats in the Deschutes Westside and Umatilla populations.	Develop plan for steelhead reintroduction into historical habitat above Pelton-Round Butte Complex when passage is restored. Re-establish natural production in Little Butter and Butter creeks and some minor spawning areas.	Risks related to steelhead reintroductions to historical habitat using inside-DPS hatchery fish.
Reduce genetic influence of hatchery fish in hatchery broodstock in the Umatilla subbasin.	Eliminate use of hatchery produced adults in the broodstock	Potential divergence in genetic and phenotypic traits between hatchery and natural-origin steelhead.
Reduce interactions between residual hatchery steelhead and natural steelhead in the Umatilla subbasin.	No consensus actions.	Risk of hatchery fish competing with and preying on natural steelhead juveniles
Reduce potential negative ecological interactions between coho salmon and natural steelhead in the Umatilla subbasin.	Reduce number of hatchery coho released in Umatilla River and relocate releases downstream to areas not currently important to steelhead production	Potential for coho smolts to compete with juvenile steelhead for prey resources and space
Predation and Competition		
Reduce predation and competition in the Columbia River mainstem, estuary and plume.	Reduce predation by pinnipeds Redistribute Caspian terns Redistribute cormorants	Increased predation on steelhead due to degraded estuarine and plume habitats, and to hydrosystem development and operations in mainstem Columbia River.

9.2.1 Building on Current Efforts

We recognize that many steps have already been taken or are currently underway that will improve the status of different Oregon Mid-C steelhead populations. In tributary watersheds state and federal natural resource managers, tribes, local governments, watershed councils, soil and water conservation districts, non-profit organizations, local land owners and others continue to improve stream conditions to support viable steelhead populations throughout their freshwater life stages. They are also improving land use practices on uplands and floodplains that are allowing natural ecosystem functions and processes to recover. State of Oregon Forest Practices Rules were adopted in 2002 and provide improved protection through a variety of guidelines. The rules address roads built in critical locations, and in addition, private landowners implement voluntary actions to address conditions on roads built prior to 2002. Private forest landowners have experienced disincentives to active placement of large wood in the past. A recent decision has led to the ability of private landowners to place large wood under the authority of the Oregon Forest Practices Act without additional permits. This streamlined process has renewed landowner enthusiasm to place large wood. Federal lands are managed under PACFISH and Northwest Forest Plan guidelines. These guidelines provide significantly improved protection and restoration standards on federal lands.

Oregon Water Resources Department has made progress in enhancement of streamflows. Live surface flow is closed to new appropriations in 99% of the Mid-C area during the low flow period in the month of August. To date, 1,760 stream miles are protected by in-stream water rights, and in 2006, 85 cfs was restored to Mid-C streams. Interest in voluntary flow restoration is gradually increasing.

To illustrate the magnitude of effort that is underway and the types of projects completed, we compiled a list of habitat projects that have been implemented in each population on all types of lands over the past 11 years (Appendix C). Similar efforts are underway in the Columbia River estuary that will improve estuarine and plume habitats and reduce predation (Appendix D). In the mainstem Columbia River, hydrosystem managers and fish resource mangers continue to refine hydropower system operations to address the needs for survival and recovery of the Mid-C steelhead DPS and other ESA-listed salmon and steelhead. Many hydropower configuration and operational improvements have been implemented in recent years that have provided survival benefits for Mid-C steelhead (Appendix D). In the Hydro BiOp remand process, new hydropower configuration and operational improvements are proposed.

Hatchery programs operated within the DPS have been modified substantially over the past 10 years to reduce threats and improve contribution to recovery. Programs have been reduced in scope, release locations have been modified, and considerable emphasis has been placed on assessing the source and potential impacts of strays. As described earlier, extensive harvest management changes in both the mainstem and tributaries have been implemented to reduce the impacts of fisheries.

This plan is designed to build upon past and current efforts that are already improving population viability and habitat conditions. Many of these efforts are described in the plan along with their sufficiency and gaps so that future actions expand from and improve the effectiveness of the efforts. Spreading the responsibility among a range of parties lessens the cost to any one group, increases the certainty of success, and compounds the benefits of moderate improvements in each factor.

Together, the strategies and actions identified in the following subsections outline an integrated approach that will support the viability of Oregon's Mid-C steelhead populations and their primary life history strategies throughout their life cycle. These strategies and actions are designed to address threats to population viability from tributary habitat degradation, estuarine and nearshore marine habitat degradation, the Columbia River hydropower system, harvest management, hatchery management, and predation.

9.3 Tributary Habitat Strategies and Actions

The suites of strategies and actions proposed in this section will protect and improve ecosystem functions and restore normative ecological processes to levels that support recovery of Oregon's Mid-C steelhead populations. The strategies and actions were developed by planning teams comprised of natural resource specialists for the Fifteenmile, Deschutes, John Day, Umatilla and Walla Walla watersheds. The actions reflect direction identified in related regional and local plans, recent modeling and research findings, and local expert input provided by the planning team members. Together, these strategies and actions call for maintaining high quality habitats and their productive capacity, improving ecosystem processes and habitats that are impaired but are currently important to productive capacity, and habitat restoration through passive and active measures. The strategies and actions represent a complete list of needs, somewhat unconstrained by logistic and financial concerns.

- Protection of existing high quality habitats is a broad economical approach of ensuring no net loss in habitat quality and maintenance of normative ecological processes. Many objectives are likely to be met through habitat protection and the associated natural recovery of upland and riparian areas. Land acquisitions, easements, cooperative agreements, and protective land designations facilitate the accomplishment of high quality habitat protection.

- Maintaining improved habitats and halting further degradation in habitats that are not at desired condition but are still important to productive capacity is an important element of habitat management. Changes resulting from improved land use practices can be an important element to improve habitat management and ecosystem function. Education, comprehensive land use planning, and regulations can provide habitat protection and support ecosystem functions by managing growth and land use so that critical habitats and watershed functions are preserved. Those that are integrated with social and economic goals while providing desired protection are most sustainable.

- Broad opportunities exist to improve habitat conditions for Mid-C steelhead populations through restoration. The success of these strategies is enhanced when actions build from existing restoration efforts, incorporate a range of project types that address the many interrelated habitat impairments, and take into account socioeconomic and institutional perspectives. Generally, our strategies and actions stress passive approaches to restoration (such as changes in grazing management that promote riparian recovery) over active restoration (manual placement of structures) as the preferred approaches to overall habitat restoration. In some areas, regulations are expected to provide passive restoration; however, we recognize that riparian function may take a long time to fully recover. Active restoration can provide improvements in some cases while natural processes are being restored through passive approaches.

We defined eight tributary habitat strategies that are directly linked to the limiting factors. We organized the habitat actions and associated information for each population by the habitat strategies:

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

For each strategy, we examined key programs that currently contribute to actions that serve to achieve the strategy, as well as the sufficiency of the existing programs. We identified specific actions needed to fill the gaps between what is currently being implemented and what is needed in the long term to fully achieve the strategy. Actions differ from strategies in that they address specific needs for a specified geographic area, program deficiencies, as well as biophysical habitat impairments and threats.

We also identified priority areas and actions for each population based on relative importance in meeting local and regional recovery objectives for Mid-C steelhead (Figure 9-1). Priority 1 reaches represent the habitats where management actions will yield the greatest benefits towards improving the viability. The strategic guidance provided earlier in this section served as the basis for identifying priority areas and actions within each population. We realize that the result of our process is a long list of priority 1 and priority 2 habitat actions for each population. We view the population specific implementation plans as the vehicles for developing the specific time and place roadmap for implementation of priority actions. We recognize there is repetition in the actions between populations. We envision local groups using the individual population action tables for development of specific implementation plans.

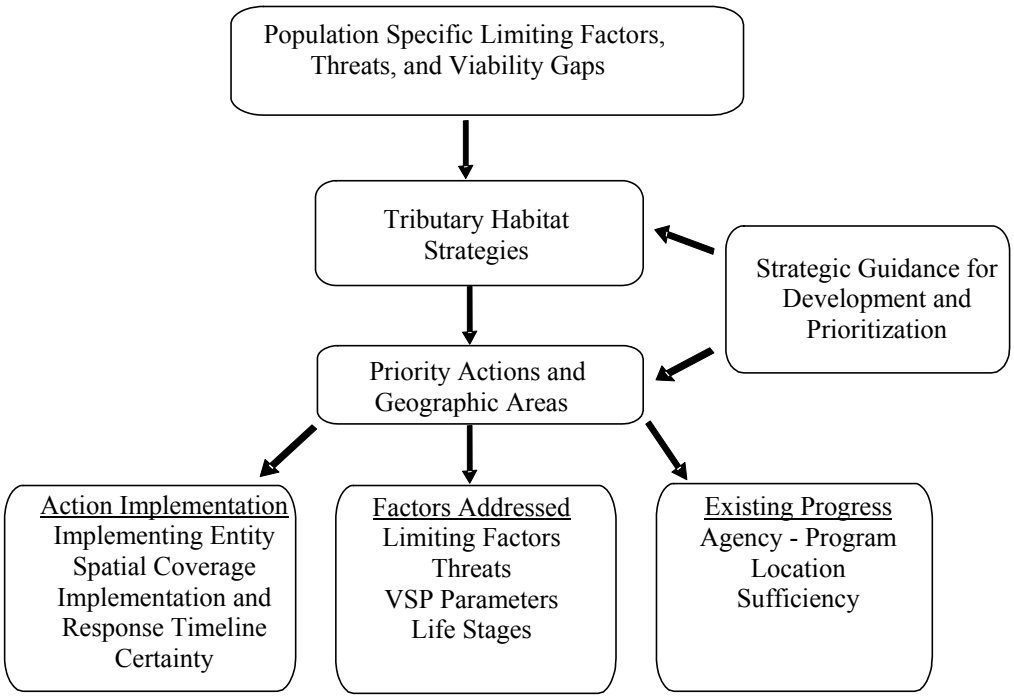

Figure 9-1. Flow chart illustrating the process for development of tributary habitat strategies, actions, and programs and their characteristics.

The following tables show strategies and actions needed to address tributary habitat limiting factors and threats for Oregon Mid-C steelhead populations. The tributary habitat strategies are not presented in priority order. Strategy tables for each population identify specific actions, limiting factors and threats addressed, and viability parameters and life stages that are most affected. Individual actions are described in terms of the status of current efforts, implementing entities, strategies addressed, spatial coverage, implementation timeframe, expected biophysical response timeframe and certainty of outcome. Priority locations are stream reaches or areas where actions should be implemented first to achieve the greatest benefit. Education and outreach actions are discussed in the first strategy only; however, they need to be applied to the implementation of all eight of the habitat strategies for all populations.

The tables also identify key programs that are currently implementing actions and discuss program sufficiency and gaps. Program sufficiency, sufficiency rationale, and program improvement needs for State of Oregon programs and most Federal programs were assessed through a formal process conducted by the State of Oregon and the Federal entities. These reviews resulted in independent reports that were then used to compile the sufficiency information in the action tables. The Oregon State Agencies program sufficiency report is not finalized; therefore, the actual sufficiency ratings were not available for use in this document. However, rationale related to the strengths and weaknesses of the State Agency programs is available and appended to this plan. For the non-state and non-federal programs, as well as federal programs that were not reviewed in the USFS/BLM Program Sufficiency Assessment, program sufficiency was assessed by the management action teams in cooperation with the implementing entities. Program sufficiency assessments are difficult to conduct. In many cases the legal mandates of a specific program were not necessarily developed for the purposes of recovering steelhead. The conclusions of an assessment can be biased when the assessment is conducted by the managers of the program for a variety of reasons. Unbiased outside reviews are probably the best approach, but can be very costly and take considerable time. We caution readers not to place too much emphasis on the sufficiency ratings themselves. We view the value of the sufficiency assessments primarily in characterizing the constraints, types of improvements, and modifications that would result in improved effectiveness of programs contributing to recovery of Mid-C steelhead.

9.3.1 Habitat Strategies and Actions for Fifteenmile Creek Steelhead Population

Primary limiting factors: low flows, high water temperatures, sedimentation, channel confinement, impaired riparian ecosystems, and reduced habitat quality.

Primary threats: roads, residential development, agricultural practices and forest uses.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect the highest quality habitats through acquisition or conservation measures	1-Fifteenmile Cr. (Hwy 197 upstream to FS boundary) 1-Eightmile Cr. (Hwy 197 upstream to FS boundary) 1-Ramsey Cr. (mouth to FS boundary) 2-Fivemile Creek from Hwy 197 upstream to headwaters.	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	All	All	Protecting high quality habitats is the most cost effective way to ensure fish have good quality habitat. It is much less expensive over the long term to protect high quality habitat than it is to degrade the habitat and then try to restore it. Protection of existing high quality habitat areas is a broad strategy capable of contributing to meeting all of biological habitat objectives. Land acquisitions, easements, and cooperative agreements will facilitate the implementation of protection and conservation.
Protect and conserve rare and unique functioning habitats	Considering the unique winter life history form present for the MaSA, and no other winter steelhead in DPS, they are all unique. Entire MaSA 1-South Fork Mill Cr. (Water treatment to falls)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	All	All	Protecting high quality unique habitats is the most cost effective way to ensure fish have good quality habitat. South Fk. Mill Creek from water treatment plant to falls is in pristine condition. One of few areas in the MiSA that remains pristine.
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	1-Fifteenmile Creek MaSA and MiSA	All factors	All	All	All	To prevent habitat degradation BMPs and existing laws that protect habitat should be applied throughout the population.
Conduct outreach to resource users and managers	1-Entire population	All factors	All	All	All	Program efficiencies will be improved through increased knowledge and understanding of the importance of habitat conditions and land use practices.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation measures.	CTWSRO, ODFW, SWCD, USDA FSA, land trusts, NGOs	Ongoing	Population-wide	Existing conservation agreements are complete. Full implementation of conservation measures will take 25 years or more	Conservation benefits are immediate	High
Protect and conserve rare and unique functioning habitats.	Land trusts, CTWSRO, ODFW, SWCD, NGOs, USFS	Ongoing	Population-wide	Immediate	Immediate	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	SWCD, USFS, private landowners, ODA, CTWSRO	Ongoing	Population-wide	Long term	Degradation prevention immediate, improved conditions 15-25 years	High
Conduct outreach to resource users and managers.	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS	Fifteenmile Riverkeeper	USFS lands and non-forest lands under Wyden Amendment Authority	Likely	Positive results where the program has been implemented, but it could be expand to more forest lands in the population, and become more available off forest lands. Contingent on year to year funding appropriations
ODFW	Fifteenmile Creek Fish Habitat Restoration Project	Private lands throughout population	No	Positive results where the program has been implemented, but funding and landowner cooperation limits the amount of available projects. In addition, limited legal guarantees that landowners remain in program.
USFS	Northwest Forest Plan	All Mt. Hood National Forest lands	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
Wasco County SWCD/USDA FSA	CREP, CRP	Private riparian areas and qualified uplands throughout population	Uncertain	Both programs are effective at protecting riparian areas and uplands, however additional lands need to be enrolled. CRP program is near capacity for Wasco County. Some landowners reluctant to enter the federal programs. See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust or other entity	Lease or purchase instream water rights	Fifteenmile, Eightmile, Fivemile MaSA	No	Program has been effective at obtaining water rights, but maintaining water instream to the mouth of the river is difficult. Many landowners reluctant to enter into program. It is important to secure water rights to guarantee instream flow.
Wasco County SWCD	No-till Conversion	Uplands throughout population		An effective program at reducing erosion, but needs to be expanded to additional properties.
OWEB	Watershed Councils	Fifteenmile and The Dalles		See State of Oregon programmatic review -- Appendix F.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
		watershed council		
ODA	Agricultural Water Quality Management Program	Fifteenmile population unit		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Tribal lands on Fifteenmile Creek	No	Various programs designed to improve riparian, stream, and upland conditions along tribal lands. Additional restoration and protection efforts are needed.
ODF	Oregon Forest Practices Act	Private and state forestlands in Fifteenmile, Eightmile, Ramsey , and Fivemile creeks		See State of Oregon programmatic review – Appendix F.
Local Government, irrigation districts	City and County Planning and Zoning	Private lands throughout the entire population	Yes	Compliance with zoning requirements is high
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Many programs already in place in the subbasin are designed to restore physical habitat. These programs have proven effective, but it will take years to return the stream to a more natural condition. Existing forest plans include special management designations for riparian reserves. Adding additional wilderness areas and wild and scenic river segments would require designation by Congress. The forest plans and BLM plans have been amended by the Northwest Forest Plan that requires riparian reserve boundaries of two site potential tree heights on both sides of any fish bearing stream and contains very restrictive standards and guidelines to ensure protection of aquatic and riparian resources. Compliance with riparian reserve standards and guidelines for a variety of land use activities including forest practices operations, cattle grazing, and others has been very good. Farm Service Agency (FSA) programs that protect riparian areas and upland watersheds include the Conservation Reserve Program (CRP) and the Conservation Reserve Enhancement Program (CREP). The CRP program pays landowners not to farm highly erodible soils and the CREP program pays landowners for setting riparian corridors aside from grazing and farming. The long term effectiveness of both programs is limited by the relatively short duration of the contracts which ranges from 10 to 15 years. ODA's Agricultural Water Quality Management Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements.				

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Replace barriers blocking passage including dams, road culverts and irrigation structures	1-Barriers that limit adult access: Ramsey Creek (culvert FS 4450 Rd), Ramsey Creek (Olsen Irrigation Diversion RM 3.5), Fifteenmile Tenold Diversion (RM 2.0), Culvert at FS Rd. 44, Dam at Boys Scout Camp Baldwin on Ramsey Creek (RM 11.0) 2-Barriers that limit juvenile access: Fifteenmile same as adults Threemile Creek (Hwys. I-84 & 197) Chenowith Creek Bridge at Hwy. 30 Fixed Long, Douglas, Standard Hollows Mays Canyon	Impaired fish passage	Dams, culverts, instream structures	Spatial structure, productivity	Primarily adults and 0+juveniles	Spatial structure of the Fifteenmile winter steelhead population has been modified and restricted by culvert barriers and hostile environmental conditions in the middle and lower elevations (NPCC 2004).
Provide screening at 100% of irrigation diversions	1-Additonal survey needed to identify unscreened diversions	Impaired fish passage	Irrigation diversions	Spatial structure,	Primarily adults and	Known diversions are screened to criteria.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
	2-All known diversions are screened in the Fifteenmile MaSA.			productivity	0+juveniles	
Replace screens that do not meet criteria	1-Additional survey needed 2-Fifteenmile all known screens meet criteria.	Impaired fish passage	Irrigation diversions	Spatial structure, productivity	Primarily adults and 0+juveniles	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Replace barriers blocking passage including dams, road culverts and irrigation structures	USFS, SWCD, ODFW	Ongoing	At barriers	Ongoing	Immediate	High
Provide screening at 100% of irrigation diversions	ODFW, BPA, NOAA Fish	Ongoing	At point of diversion	All legal diversions screened in Fifteenmile. Need further survey work to determine number of screens in other areas	Immediate	High
Replace screens that do not meet criteria	ODFW, BPA, NOAA Fish	Ongoing	At point of diversion	Legal diversion meets criteria. Need further survey work in MiSA to determine number of screens	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	Fish Passage/Screening—State and Federal funded programs	Unscreened or poorly screened diversions throughout population	Uncertain	Continued funding of federal program is uncertain. New and replaced screens are sufficient. See Appendix F for State program review.
ODOT	Culvert replacement or retrofit	Threemile Creek culvert at Hwy. I-84 and Hwy. 197; Chenowith Creek Bridge at Hwy. 30		See State of Oregon programmatic review -- Appendix F.
USFS	Culvert replacement	USFS lands	Likely	Funding and priority of programs is uncertain. Timeframe for completing work uncertain.
Wasco County Road Department, OWEB, Wasco County SWCD	Culvert replacement	North Fk Mill Creek (RM 6.0)		Funding and priority of programs is uncertain. See State of Oregon programmatic review -- Appendix F.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
The technology to provide sufficient passage conditions with screens and culverts is available and in use. Programs implementing these improvements are generally underfunded thus resulting in uncertain sufficiency ratings. The Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) provides guidance that will help prioritize culvert replacements for this population.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary)	Degraded floodplain, altered hydrology, altered	Removal of wetlands, side channels, off-stream	Abundance, productivity,	Primarily fry, summer parr,	Floodplains and channels that are in balance are essential for proper

Strategy 3. Maintain and restore floodplain connectivity and function.						
	1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters) 2-Mill Cr.(Mouth to North Fork) 2-North Fk. Mill Cr. (mouth to FS boundary)	sediment routing, degraded water quality	habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	spatial structure	winter parr	stream function.
Reconnect side channels and off-channel habitats to stream channels	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters) 2-Mill Cr.(Mouth to North Fork) 2-North Fk. Mill Cr. (mouth to FS boundary)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity, spatial structure	Primarily fry, summer parr, winter parr	Side channels provide habitat for spawning and rearing and refugia from high flows.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	Population-wide	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity, spatial structure	Primarily fry, summer parr, winter parr	Beaver have started to recolonize many areas in the watershed.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain habitats	ODFW, watershed council, SWCD, USFS Riverkeeper	Ongoing	Improved connectivity with channel will be localized; improved water table will increase streamflow and lower water temperatures downstream.	Long term	5-15 years	Moderate
Reconnect side channels and off-channel habitats to stream channels	ODFW, watershed council, SWCD, USFS Riverkeeper	Ongoing	Improved connectivity with channel will be localized; improved water table will increase streamflow and lower water temperatures downstream.	Long term	5-15 years	Moderate
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	ODFW, USFS	Ongoing		Long Term	5-15 years	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS	Fifteenmile Riverkeeper	USFS lands and non-forest lands under Wyden Amendment Authority	Likely	Positive results where the program has been implemented, but it could be expanded to more forest lands in the population, and become more available off forest lands. Contingent on year to year funding appropriations.
ODFW	Fifteenmile Creek Habitat Restoration Project	Private lands in MaSAs from forest service boundary downstream to mouth.	No	Additional projects may be available. Funding may be an issue.
ODF	Oregon Forest Practices Act	Private and state forestlands in Fifteenmile, Eightmile, Ramsey , and Fivemile Creeks		See State of Oregon programmatic review -- Appendix F.
Wasco SWCD	Watershed restoration	Areas from forest service boundary		Conservation protection and outreach measures needed

Strategy 3. Maintain and restore floodplain connectivity and function.				
		downstream		on private lands. See State of Oregon programmatic review -- Appendix F.
ODA	Agricultural Water Quality Management Program	Fifteenmile population unit		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Reservation lands	No	Various programs designed to improve riparian, stream, and upland conditions along tribal lands. Additional restoration and protection efforts are needed.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters) 2-Mill Cr.(Mouth to North Fork) 2-North Fk. Mill Cr. (mouth to FS boundary)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature, flows	Stream channelization, berming, bank armoring, large wood removal, beaver removal, overgrazing in riparian areas	Abundance, productivity	Primarily egg, alevins, fry, summer parr, winter parr	Fifteenmile has been extensively channelized and straightened and has subsequently downcut. Historical aerial photos indicate that the stream is shorter and steeper now than before the 1970s (NPCC 2004).
Increase role and abundance of wood and large organic debris in streambeds	1- Fifteenmile Cr.(Mouth to City of Dufur intake) 1-Eightmile Cr. (Hwy 197 to Walston Grade (RM19.0)) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal	Abundance, productivity	Primarily egg, alevins, fry, summer parr, winter parr	Many legacy effects of past land use practices continue to affect channel form and instream habitat. Current practices have less effect.
Increase instream habitat through manual placement of structures	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters) 2-Mill Cr.(Mouth to North Fork) 2-North Fk. Mill Cr. (mouth to FS boundary)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal	Abundance, productivity	Primarily egg, alevins, fry, summer parr, winter parr	Considered an active form of restoration while habitat conditions are restored through more passive efforts. Limited opportunities exist in reaches identified.
Stabilize streambanks	Limited areas throughout population	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily egg, alevins, fry, summer parr, winter parr	Most actively eroding banks have been protected.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCD, USFS, BPA, OWEB, CTWSRO	Expansion of existing efforts	Local to treatment area	Ongoing	Increased habitat diversity (0-10 years)	High
Increase role and abundance of wood and large organic debris in streambeds	ODFW, USFS	Expansion of existing efforts	Local to treatment area	Ongoing	Increased habitat diversity (0-10 years)	High
Increase instream habitat through manual placement of structures	ODFW, USFS	Expansion of existing efforts	Local to treatment area	Ongoing	Increased habitat diversity (0-10 years)	High
Stabilize streambanks	ODFW, SWCD, USFS	Expansion of existing efforts	Local to treatment area	Ongoing	Increased habitat diversity (0-10 years)	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS	Fifteenmile Riverkeeper	USFS lands and non-forest lands under Wyden Amendment Authority	Likely	Positive results where the program has been implemented, but it could be expanded to more forest lands in the population, and become more available off forest lands. Contingent on year to year funding appropriations.
USFS	Northwest Forest Plan	All Mt. Hood National Forest lands	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
ODFW	Fifteenmile Creek Habitat Restoration Project	Private lands in population from forest service boundary downstream to mouth	Uncertain	Additional projects may be available. Funding may be an issue.
ODF	Oregon Forest Practices Act	Private and state forestlands in Fifteenmile, Eightmile, Ramsey , and Fivemile creeks		See State of Oregon programmatic review -- Appendix F.
Wasco SWCD	Watershed restoration	Private agricultural lands		Additional opportunities exist for projects, outreach, and education. See State of Oregon programmatic review -- Appendix F.
ODA	Agricultural Water Quality Management Program	Private agricultural lands		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Reservation lands	No	Various programs designed to improve riparian, stream, and upland conditions along tribal lands. Additional restoration and protection efforts are needed.
OWEB	Watershed Councils	Private lands population-wide		See State of Oregon programmatic review -- Appendix F.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The Forest Service Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funds where it is most needed.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian communities including vegetative planting	1-Eightmile Cr (RM 7 upstream RM 17 mostly complete, some opportunities exist) 1-Fivemile Cr. Hwy 197 to RM 5, RM 7 upstream to FS boundary) 2-Fifteenmile Cr. (Mostly fenced or protected from livestock in recovering condition.) 2-Mill Cr. (mouth to forks)	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Livestock grazing, agricultural conversion, roads, urban development, loss of beaver dams	Abundance, productivity	All	Riparian areas have been altered throughout the subbasin. Many areas are recovering through newly implemented conservation practices. Approximately 126 miles of stream are currently protected through some form of riparian buffer. Additional opportunities for conservation easements exist. Primary methods of riparian enhancement include riparian corridor fences to exclude livestock while controlling weeds, changes in grazing management that promote riparian recovery, and planting of native shrubs.
Develop grazing strategies that promote riparian recovery	1-Eightmile RM 8.5 2-USFS grazing allotments	Bank degradation, degraded riparian communities, flow, sediment routing	Livestock grazing	Abundance, productivity	All	Area of heavy grazing by horses. The USFS has several grazing allotments in headwater areas of several streams.
Eradicate invasive plant species from riparian areas	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Dry Cr.(Mouth to headwaters) 1-Ramsey Cr. (Mouth to FS boundary) 1-Eightmile Cr (Mouth to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary)	Degraded riparian communities	Conversion of natural riparian vegetative communities	Abundance, productivity	All	Riparian lease agreements with ODFW and CREP programs require control of noxious weeds.
Install fencing to exclude livestock from riparian areas	1-Eightmile Cr (RM 7 upstream RM 17 mostly complete, some opportunities exist) 1-Fivemile Cr. Hwy 197 to RM 5, RM 7 upstream to FS boundary) 2-Fifteenmile Cr. (Mostly fenced or protected from livestock in recovering condition.) 2-Mill Cr. (mouth to forks)	Bank degradation, degraded riparian communities, flow, sediment routing	Livestock grazing	Abundance, productivity	All	A considerable amount of riparian fencing has been completed in the population unit, however, some opportunities remain. Long term maintenance of riparian fence is needed.
Install off-stream livestock watering	1-Fifteenmile Cr. (4 sites in Dufur Valley, multiple sites mouth to Hwy 197) 1-Eightmile Cr. Multiple sites needed 1-Fivemile Cr. Multiple sites needed 2-Ramsey Cr. Multiple sites needed 2-Dry Cr. Some sites available	Degraded riparian communities, sediment routing	Livestock grazing	Abundance, productivity	All	Off-stream watering sites reduce livestock impacts on stream banks. Many solar and other innovative techniques are currently being deployed.
Plant riparian vegetation where appropriate		Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Livestock grazing, agricultural conversion,	Abundance, productivity	All	Natural vegetation restoration generally occurs without planting, some planting occurs along with fencing projects and CREP projects.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
			roads, urban development			

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian communities including vegetative planting	ODFW,SWCD, NRCS, FSA, ODF	Expansion of existing efforts	Within treated area and downstream	Ongoing	Riparian restoration (10-25 years)	High
Develop grazing strategies that promote riparian recovery	ODA, SWCD, NRCS, USFS	Unknown	Within treated area	Ongoing	Riparian restoration (10-25 years)	Moderate
Eradicate invasive plant species from riparian areas	ODFW, SWCD, Wasco County, USFS	Expansion of existing effort	Within treated area	Ongoing	Immediate	High
Install fencing to exclude livestock from riparian areas	ODFW, SWCD, CTWSRO, NRCS, FSA	Expansion of existing effort	Within treated area and downstream	Ongoing	Riparian restoration (10-25 years)	High
Install off-stream livestock watering	ODFW, SWCD, NRCS, FSA	Expansion of existing effort	Within treated area and downstream	Ongoing	Riparian restoration (10-25 years)	High
Plant riparian vegetation where appropriate	ODFW, SWCD, FSA	Expansion of existing effort	Within treated area and downstream	Ongoing	Riparian restoration (10-25 years)	Moderate

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Wasco SWCD	Watershed restoration including all actions	Private agricultural lands		Additional opportunities exist for projects, outreach, and education. See State of Oregon programmatic review -- Appendix F.
USDA FSA, SWCD, NRCS	CREP	Qualified private riparian areas throughout population	No	Effective at protecting riparian areas, however additional lands need to be enrolled. Some landowners reluctant to enter the federal programs.
ODFW	Fifteenmile Creek Fish Habitat Restoration Project	Private lands throughout population	No	Positive results where the program has been implemented, but funding and landowner cooperation limits the amount of available projects. In addit ion, limited legal guarantees that landowners remain in program.
USFS	Fifteenmile River keeper	USFS lands and non-forest lands under Wyden Amendment Authority	Likely	Positive results where the program has been implemented, but it could expand to more forest lands in the population, and become more available off forest lands. Contingent on year to year funding appropriations.
USFS	Northwest Forest Plan	All Mt. Hood National Forest lands	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
ODA	Agricultural Water Quality Management Program	Private agricultural lands		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Reservation lands	No	Various programs designed to improve riparian, stream, and upland conditions along tribal lands. Additional restoration and protection efforts are needed with additional funds.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.				
ODF	Oregon Forest Practices Act	Private and state forestlands in Fifteenmile, Eightmile, Ramsey , and Fivemile Creek		See State of Oregon programmatic review -- Appendix F.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Constant maintenance of the fence lines must be conducted to keep livestock out and protect the riparian vegetation. Construction of more off channel watering sites or water gaps would help to address part of the issue. The Forest Service Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funds where it is most needed.				

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary)	Altered hydrology, low flows, high temperatures	water withdrawals, land conversion on uplands, road network	Abundance, productivity	Primarily fry and summer parr	EDT results indicate that high and low flows reduce steelhead populations in every reach (NPCC 2004).
Improve irrigation conveyance and efficiency	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary)	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Primarily fry and summer parr	Considerable water savings may be possible by utilizing new technology irrigation.
Finish piping Orchard Ridge and Wolf Run diversions	1- Fifteenmile Cr (Orchard Ridge) 1- Eightmile Cr (Wolf Run)	Impaired flows	Irrigation diversions	Spatial structure, productivity	primarily adults and 0+juveniles	Open ditches lose considerable water through evaporation and leakage.
Implement urban conservation measures	1-Mill Creek (City of The Dalles) 2-Fifteenmile Cr. (City of Dufur)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	All	Much of the flow of Mill Creek is utilized for domestic drinking water.
Lease or purchase water rights and convert to instream	Population-wide.	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	Program has been effective when rights have become available. Senior rights generally not available. Many landowners reluctant to sell water rights.
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	Annual fluctuations in flow levels are intensified by irrigation withdrawals
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

strategies to meet long-term needs						

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD	Expands existing program, proposes new projects	Point of diversion downstream	Ongoing	Immediate increase in streamflow	High
Improve irrigation conveyance and efficiency	SWCD, USFS, OWRD, OWEB landowners	Expands existing program, proposes new projects	Agricultural lands throughout subbasin	Ongoing	Increased streamflow (0-5 years)	High
Finish piping Orchard Ridge and Wolf Run diversions	SWCD, USFS	Expansion of existing project	Upper Fifteenmile and Eightmile	Unknown	Potentially less water diverted as a result of water savings.	High
Implement urban conservation measures	SWCD, City of The Dalles	Expands existing program, proposes new projects	Mill Cr. MaSA	Ongoing	Immediate increase in instream flow, however, increases may be moderated by urban growth and increased demand.	High
Lease or purchase water rights and convert to instream	OWRD, Oregon Water Trust, others	Ongoing	Population-wide	Unknown	Immediate increase in instream flow	High
Monitor/regulate water withdrawals	OWRD	Ongoing	Population-wide	Ongoing		High
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS	Fifteenmile Riverkeeper	USFS lands and non-forest lands under Wyden Amendment authority	Likely	Positive results where the program has been implemented, but it could be expanded to more forest lands in the population, and become more available off forest lands. Contingent on year to year funding appropriations.
USFS	Northwest Forest Plan	All Mt. Hood National Forest lands	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODFW	Fifteenmile Creek Fish Habitat Restoration Project	Private lands throughout Fifteenmile population	No	Positive results where the program has been implemented, but funding and landowner cooperation limits the amount of available projects. In addition, limited legal guarantees that landowners remain in program.
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Population-wide		See State of Oregon programmatic review -- Appendix F.

Oregon Water Trust or other entity	Lease or purchase instream water rights	Fifteenmile, Eightmile, Fivemile MaSAs	No	Program has been effective at obtaining water rights, but continually to maintain water instream to the mouth of the river is difficult. Many landowners have been reluctant to enter into program in past, but recently program is increasingly popular. Yes, important to secure water rights to guarantee instream flow.
USFS, Wasco Co. SWCD, NRCS, OWEB	Irrigation conveyance efficiency	Population-wide	USFS likely	Piping open ditches and other efficiency projects will decrease irrigation demand on streams. Program could be expanded to many additional irrigators. See State of Oregon programmatic review -- Appendix F for SWCD and OWEB.
Wasco Co. SWCD	No-till conversion, watershed restoration	Uplands population-wide		Program has proven effective at reducing erosion, but additional lands could be enrolled. See State of Oregon programmatic review -- Appendix F.
Wasco County SWCD/USDA FSA	CREP, CRP	Private riparian areas and qualified uplands throughout population	Uncertain	Both programs are effective at protecting riparian areas and uplands, however additional lands need to be enrolled. CRP program is near capacity for Wasco County. Some landowners reluctant to enter the federal programs.
CTWSRO	Watershed Restoration	Tribal lands	No	Various programs designed to improve riparian, stream, and upland conditions along tribal lands. Additional restoration and protection efforts are needed.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Peak flows are mitigated via upland vegetation, channel and riparian complexity, and closure of excess roads, particularly those with insufficient drainage. Highly successful programs now address upland and riparian conditions. Programs addressing channel complexity and road closure have, to date, only addressed a small portion of the watershed. Low summer flows are affected by the same factors that affect peak flows, but are more directly affected by irrigation withdrawals from the stream and associated aquifers. Programs have addressed irrigation efficiency on some but not all farms. They have addressed conveyance efficiency on the Wolf Run Ditch, but not the Orchard Ridge Ditch. Few if any efficiency programs have resulted in conversion to instream water rights. Fifteenmile Creek has 124 miles of stream protected by instream water rights. Voluntary restoration projects restored approximately 8.6 cfs in 2006.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Manage irrigation return flow to reduce extreme stream temperatures	1-Fifteenmile(Underhill return diversion)	Altered stream temperatures, degraded water quality	Water withdrawals	Abundance, productivity	Fry dispersal and rearing	Excessive summer temperatures have been identified as a major limiting factor for Fifteenmile Creek. Temperatures often approach or exceed lethal levels for salmonids in some of the subbasin.
Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary)	Depleted oxygen		Abundance, productivity	Fry dispersal and rearing	Warm temperatures reduce the dissolved oxygen capacity of the water.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
	2-Dry Cr.(Mouth to headwaters) 2-Mill Cr.(Mouth to North Fork) 2-North Fk. Mill Cr. (mouth to FS boundary)					
Reduce chemical pollution inputs	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Mouth to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters) 2-Mill Cr.(Mouth to North Fork)	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity		Amounts of chemical pollution reaching streams are unknown and need to be determined. Widespread use of chemicals is common in agricultural practices near streams. Reduced streamflow may accentuate pollution.
Implement Agricultural Water Quality Management Plan	1-Fifteenmile Cr. (Mouth to FS boundary) 1-Ramsey Cr. (Mouth to new FS boundary) 1-Eightmile Cr. (Hwy 197 to FS boundary) 1-Fivemile Cr. (Mouth to FS boundary) 2-Dry Cr.(Mouth to headwaters)	Degraded upland processes, altered hydrology, water quality, altered sediment routing	Land conversion and agricultural practices	Abundance, productivity	Fry dispersal and rearing	Recent conservation measures have greatly reduced sediment inputs; however, sedimentation remains elevated beyond historical conditions. Fifteenmile and Ramsey creeks are on the 303(d) list for sedimentation and EDT modeling identified sedimentation as a key factor limiting steelhead production.
Continue TMDL monitoring	Population-wide	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	All	
Acquire conservation easements or agreements, and important habitats when available.	Significant properties when they become available.	All	All	Abundance, productivity	All	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Manage irrigation return flow to reduce extreme stream temperatures	ODEQ, OWR, SWCD	Ongoing	Subbasin-wide	Ongoing	0-5 years	High
Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	ODEQ, SWCD, FSA, NRCS, ODFW	Ongoing		Ongoing	0-5 years	Moderate
Reduce chemical pollution inputs	ODEQ, WyEast RC&D, others	Ongoing		Ongoing	0-5 years	Moderate
Implement Agricultural Water Quality Management Plan	ODA, SWCD	Ongoing	Subbasin-wide	Ongoing	variable	High
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Subbasin-wide	Ongoing	Immediate	High
Acquire conservation easements or agreements, and important habitats when available.	NGO's	New	Subbasin-wide		Variable	High

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Wasco Co. SWCD, OWEB, Irrigators	Irrigation conveyance efficiency	Population-wide		Piping open ditches and other efficiency projects will decrease irrigation demand on streams. Program could be expanded to many additional irrigators. See State of Oregon programmatic review -- Appendix F.
ODEQ	TMDL Development	Population-wide		See State of Oregon programmatic review -- Appendix F.
ODEQ, Wasco Co. SWCD, ODFW, USFS	Temperature TMDL Implementation Monitoring	Fifteenmile Creek	USFS likely	Continuation of existing level of monitoring efforts could be expanded. Funding may not be sufficient. See State of Oregon programmatic review -- Appendix F.
ODEQ, ODA, Wasco SWCD, USFS	Sedimentation Monitoring (TMDL Development and Implementation)	Fifteenmile Creek	USFS likely	See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODEQ, WyEast RC&D	Toxics monitoring program doesn't actually exist yet	Population-wide		See State of Oregon programmatic review -- Appendix F.
ODA	Agricultural Water Quality Management Program	Private agricultural lands		See State of Oregon programmatic review -- Appendix F.
WyEast RC&D	IFPnet	Fifteenmile and Mill Creek	No	Program needs expansion to assist agriculture with reducing chemical demand.
Wasco Co. SWCD	No-till conversion, watershed restoration	Uplands population-wide		Program has proven effective at reducing erosion, but additional lands could be enrolled. See State of Oregon programmatic review -- Appendix F.
Wasco County SWCD/USDA FSA	CREP, CRP	Private riparian areas and qualified uplands throughout population		Both programs are effective at protecting riparian areas and uplands, however additional lands need to be enrolled. CRP program is near capacity for Wasco county. See State of Oregon programmatic review -- Appendix F. Some landowners reluctant to enter the federal programs.
CTWSRO	Watershed Restoration	Reservation lands	No	Various programs designed to improve riparian, stream, and upland conditions along tribal lands. Additional restoration and protection efforts are needed.
ODF	Oregon Forest Practices Act	Private and state forestlands in Fifteenmile, Eightmile, Ramsey , and Fivemile creeks		See State of Oregon programmatic review -- Appendix F.
ODFW	Fifteenmile Creek Fish Habitat Restoration Project	Private lands throughout population	No	Positive results where the program has been implemented, but funding and landowner cooperation limits the amount of available projects. In addit ion, limited legal guarantees that landowners remain in program.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
ODA's Agricultural Water Quality Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements.				

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and . unimpaired natural upland processes.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Continue to promote no-till and other seeding techniques that reduce erosion where site conditions are suitable	Fifteenmile Creek subbasin uplands	Altered hydrology, sediment routing	Upland land use practices, loss of water storage capacity	Abundance, productivity	All	Over half of the agricultural land in the watershed has been converted to direct seed/no till, leaving 50,000-60,000 acres that could be converted (NPCC 2004).
Convert to perennial crops/vegetation		Altered hydrology, sediment routing	Upland land use practices, loss of water storage capacity	Abundance, productivity	All	
Develop Integrated Fruit Production (IFPnet) plans	Orchard lands throughout subbasin	Water quality, hydrology, sediment	Pollution	Abundance, productivity	All	
Upgrade or remove problem forest roads	Forest lands	Altered hydrology, sediment routing	Road network	Abundance, productivity	All	
Promote fuels management	Private and federal forest lands	Altered hydrology, sediment	Conversion of vegetative communities	Abundance, productivity	All	
Initiate upland improvement demonstration projects	Subbasin-wide	Altered hydrology, sediment routing	Upland land use practices	Abundance, productivity	All	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to minimize unnatural rates of erosion	Population-wide	Altered hydrology, sediment routing, water quality	Upland land use practices, erosion, loss of water storage capacity	Abundance, productivity	all	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Continue to promote no-till and other seeding techniques that reduce erosion where site conditions are suitable	SWCD	Existing program	Croplands, MaSAs	Ongoing (completed by 2012)	Reduce runoff, sediment supply, immediate increase in base flow	High
Convert to perennial crops/vegetation	SWCD	Develop new program	uplands	Ongoing	Reduce runoff, sediment supply immediately	High
Develop Integrated Fruit Production (IFPnet) plans	WyEast RC&D	Existing effort	Orchard lands throughout subbasin	Ongoing	Reduce chemical pollution immediately	High
Upgrade or remove problem forest roads	USFS, ODF, private forestland owners	Expansion of existing project	USFS lands	Long term	Variable depending on individual treatment (5-20 yrs)	Moderate

Promote fuels management	USFS, ODF, private forestland owners	Expansion of existing project	USFS lands and private forest lands	Long term	Variable depending on individual treatment (5-20 yrs)	Moderate
Initiate upland improvement demonstration projects	SWCD, ODA, OSU extension	Ongoing	Subbasin-wide	Ongoing	Variable lag time depending on action taken	Unknown
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to minimize unnatural rates of erosion	SWCD, USFS, ODA, CTWSRO, private landowners	Ongoing	High dispersal downstream	Intermediate	Up to 15 years	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Wasco County SWCD/USDA FSA	CREP, CRP	Private riparian areas and qualified uplands throughout population		Both programs are effective at protecting riparian areas and uplands, however additional lands need to be enrolled. CRP program is near capacity for Wasco County. Some landowners reluctant to enter the federal programs. See State of Oregon programmatic review -- Appendix F.
Wasco County SWCD	No-till conversion, watershed restoration	Uplands population-wide		Program has proven effective at reducing erosion, but additional lands could be enrolled. See State of Oregon programmatic review -- Appendix F.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands in Fifteenmile, Eightmile, Ramsey , and Fivemile Creek		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
USFS	Fifteenmile River keeper	USFS lands and non-forest lands under Wyden Amendment Authority	Likely	Positive results where the program has been implemented, but it could be expanded to more forest lands in the population, and become more available off forest lands. Contingent on year to year funding appropriations.
USFS	Northwest Forest Plan	All Mt. Hood National Forest lands	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
ODA	Agricultural Water Quality Management Program	Private agricultural lands		See State of Oregon programmatic review -- Appendix F.
OSU extension	Various	Private agricultural lands	Uncertain	Provide education and outreach information. Program could be expanded to be more effective.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize active watershed restoration for this population, and helps deploy limited active watershed restoration funding where it is most needed.

9.3.2 Habitat Strategies and Actions for Deschutes River Eastside Steelhead Population

Primary limiting factors: riparian condition, low flow, temperature, habitat diversity, and lack of fish passage.

Primary threats: grazing, roads, residences, and agriculture practices that simplify habitat; irrigation withdrawals; soil tilling, forest practices, dams and roads.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect the highest quality habitats through acquisition or conservation easements.	1-Bakeoven Cr. (mouth to Deep Cr) 1-Buck Hollow Cr (mouth to Macken Canyon) 1-Trout Cr. (Little Trout Cr. to headwaters) 2-Trout Cr. (Degner Cyn to Little Trout Cr.) 2-Deschutes R. (Harris Cr. to Buck Hollow Cr.) 2-Ward Cr. (mouth to Pole Cr.) 2-Deep Cr. (mouth to Cottonwood Cr)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	Overgrazing, channelization, stream bank armoring, agricultural practices, fire suppression,	Abundance, productivity	All	Protecting functioning floodplains and channels that are in balance with their ability to transport water and sediment is identified as one of the highest priorities in the Subbasin Plan. Wild and scenic protection for Deschutes in place.
Protect and conserve rare and unique functioning habitats	1-Seasonal tributaries 2-Trout Cr. (mouth to Willowdale)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	Abundance, productivity	All	Seasonal spawning tributaries provide habitat for unique life history trait that utilize seasonal habitats with age 0 migration into Deschutes.
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	1-Entire population	All factors	All	Abundance, productivity	All	To prevent habitat degradation BMPs and existing laws that protect habitat should be applied throughout the population.
Develop new and manage existing habitat Cooperative Agreements	Trout Cr. (mouth to headwaters)	Degraded floodplain, channel structure, riparian areas	All	Abundance, productivity	All	
Conduct outreach to resource users and managers	1-Entire population	All factors	All	All	All	Program efficiencies will be improved through increased knowledge and understanding of the importance of habitat conditions and land management practices.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Protect the highest quality habitats through acquisition or conservation easements.	CTWSRO, PGE, DRC, DBLT, NGOs, ODFW, SWCD, USDA FSA	Ongoing	High dispersal downstream	Immediate	Variable depending on habitat condition	High
Protect and conserve rare and unique functioning habitats	Land trusts, CTWSRO, ODFW, SWCD, NGOs, USFS, PGE, BLM	Ongoing		Immediate	Immediate halt to degradation	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	SWCD, USFS, private landowners, ODA, NRCS, CTWSRO, watershed councils, BLM, counties		All MaSAs	Long term	Degradation stop immediately habitat recovery 15-25 years depending on status	High
Adopt and manage Cooperative Agreements	ODFW	Ongoing	High dispersal downstream	Agreements are for 10-15 years	Immediate	High, although not in perpetuity
Conduct outreach to resource users and managers	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	**Program Name**	**Geographic Locations**	**Sufficient* (yes, likely, uncertain, no)**	**Sufficiency Rationale**
USFS and BLM	Wilderness Areas, Wilderness Study Areas, Wild and Scenic River corridors, Special Management Area designations PACFISH	USFS and BLM lands throughout population	Yes	Continual implementation of programs. See USFS/BLM Program Sufficiency Assessment -- Appendix E. Currently no additional opportunities to expand programs on BLM lands.
ODFW/BPA	Trout Creek Fish Habitat Restoration Project	Private lands in the Trout Creek subbasin	No	Additional lands can be enrolled into the program. Conservation agreements are for only 10-15 years length.
USDA FSA/SWCDs	CREP/CRP	Private agricultural lands throughout population	Likely	Additional lands can be enrolled, and programs are not permanent in duration. See State of Oregon programmatic review -- Appendix F.
CTWSRO	Integrated Resources Management Plan	Reservation lands	Yes	Adaptive 10-year management plans to guide future.
CTWSRO	Watershed Maintenance/ Riparian Fence Program	Reservation lands	No	Need to expand riparian fence network and maintenance of those fence lines.
ODA/SWCDs	Agricultural Water Quality Management Program	Private agricultural lands throughout population		See State of Oregon programmatic review -- Appendix F.
Local Government	County Planning and Zoning	Private lands throughout population	Uncertain	
PGE	Pelton Habitat Mitigation Fund	Upper population	Uncertain	Newly implemented program, results not yet available.
NGOs (Deschutes Basin Land Trust, Nature Conservancy, Deschutes River Conservancy, Oregon Water Trust etc.)	Lease or purchase of land or instream water rights	Private lands throughout population	No	Limited opportunities arise, but programs can be expanded when opportunities become available.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
Watershed Councils	Various Watershed Councils	Population-wide	No	Programs can be expanded to included additional interested parties in watershed restoration and protection.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Existing forest plans include special management designations for riparian habitat conservation areas (RHCAs). Adding additional wilderness areas and wild and scenic river segments would require designation by Congress. The forest plans and BLM plans have been amended by PACFISH which generally requires 300-foot buffers on any fish bearing stream for tree removal with limited exceptions when conditions are met, as well as specific guidelines for livestock grazing and riparian vegetation use. See guidelines for Timber Management for specific rules governing the RHCA. Compliance with the 300-foot buffer for timber harvest operations has been very good.

FSA programs that protect riparian areas and upland watersheds include the CRP, which pays landowners not to farm highly erodible soils, and the CREP program, which pays landowners for setting riparian corridors side from grazing and farming. The long term effectiveness of both programs is limited by the relatively short duration of the contracts which ranges from 10 to 15 years.

ODA's Agricultural Water Quality Management Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Replace or remove barriers blocking passage including dams, road culverts, irrigation structures, infiltration galleries	1-Mud Springs Cr. (at RR culvert in section 15, above Gateway)--Jefferson County 1-Hay Creek (new channel near mouth)--private 2-Antelope Cr. (mouth to headwaters)--not culverts 2-Trout Cr. (mouth to Clover)--not culverts	Impaired fish passage	Dams, culverts, instream structures	Abundance, spatial structure, productivity	Primarily adults and 0+juveniles	Adult passage is the first priority, juvenile passage is secondary. Cumulative effects of anthropogenic factors, increase temperatures and reduce streamflow impair juvenile passage on Trout Creek downstream from Forest boundary.
Maintain irrigation diversions and screens	1-Where diversions exist throughout population	Impaired fish passage	Irrigation diversions	Abundance, spatial structure, productivity	Primarily juveniles, but also adults at facilities with ladders.	All known diversion are maintained and generally meet screening criteria.
Provide screening at 100% of irrigation diversions	1-unscreened diversions (all known diversions screened, need comprehensive survey to identify additional needs)	Impaired fish passage	Irrigation diversions	Abundance, spatial structure, productivity	Juveniles	All known legal diversions screened. More surveys are needed in Trout Creek subbasin to identify add'l diversions.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove/replace barriers blocking passage including dams, road culverts and irrigation structures	CTWSRO, USFS, SWCDs, watershed councils, NRCS	Ongoing	Access between upstream and downstream habitats	Immediate	Immediate	High
Maintain irrigation diversions and screens	ODFW	Ongoing	Diversions subbasin-wide	Based on funding	Immediate	High
Provide screening at 100% of irrigation diversions	ODFW Fish Passage and Screening	Ongoing	Access between upstream and	Immediate as need is identified	Immediate	High

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.					
			downstream habitats		
Status of Existing Programs through which Actions are Implemented					
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale	
ODFW	Trout Creek Fish Habitat Restoration Project (BPA)	Trout Creek MaSA	No	Project has made significant improvement in overall fish habitat, needs to be expanded to other properties in subbasin. Recent large scale stream rehabilitation projects conducted on properties on Trout Creek have been successful at removing berms, restoring stream function, and creating additional habitat. Needs to be expanded in scope.	
Jefferson SWCD	Trout Creek Fish Habitat Restoration Project (BPA)	Trout Creek MaSA	No	This companion project to the ODFW Habitat Project has made significant improvement is overall fish habitat, needs to be expanded to other properties in subbasin. Project has assisted in several infiltration gallery projects and other passage issues.	
ODFW	Fish Passage/Screening, State program and federal funded	Population-wide	Uncertain	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding. See State of Oregon programmatic review -- Appendix F.	
PGE/CTWSRO	Pelton Fish Passage Plan	Pelton complex	Uncertain	Program is currently being implemented; uncertain of success of downstream passage.	
CTWSRO/ODFW	Salmon and Steelhead Reintroduction Plan	Areas above Pelton complex	No	Adaptive plan over life of FERC license.	
ODOT	Culvert replacement or retrofit	Population-wide		See State of Oregon programmatic review -- Appendix F.	
CTWSRO	IRMP	Reservation Lands	Yes	Adaptive management plan guides implementation.	
CTWSRO/USFS	Culvert replacement	Population-wide	USFS likely with current program.	Needs expansion.	
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)					
A comprehensive fish screen inventory needs to be completed throughout the population. The Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) provides guidance that will help prioritize culvert replacements for this population.					

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	1-Trout Cr. (Little Trout Cr. To Clover Creek) 1-Trout Cr. (sections from mouth to Antelope Creek) 1-Antelope Cr. (mouth to headwaters)	Degraded floodplain, degraded riparian area, channel structure	Removal of interaction between river and floodplain, grazing, agricultural use, loss of	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Floodplains and channels that are in balance are essential for proper stream function. Bakeoven and Buck Hollow Creeks affected primarily from

Strategy 3. Maintain and restore floodplain connectivity and function.						
	1-Hay Cr. (mouth to headwaters) 2-Bakeoven Cr. (mouth to headwaters) 2-Buck Hollow Cr (mouth to headwaters)		beaver dams			livestock grazing.
Reconnect side channels and off-channel habitats to stream channels	1-Trout Cr. (Little Trout Cr. To Clover Creek) 1-Trout Cr. (sections from mouth to Antelope Creek) 1-Antelope Cr. (mouth to headwaters) 1-Hay Cr. (mouth to headwaters) 2-Bakeoven Cr. (mouth to headwaters) 2-Buck Hollow Cr (mouth to headwaters)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Off channel habitat important juvenile rearing habitat. Bakeoven and Buck Hollow Creeks effected primarily from livestock grazing.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	1-Throughout population	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity	All	As riparian areas recovery beaver recolonization occurs naturally.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain habitats.	CTWSRO, ODFW, watershed council, BLM, SWCDs, USFS, PGE, counties	Ongoing	High dispersal downstream from site	Long term	5-15 years	High
Reconnect side channels and off-channel habitats to stream channels.	CTWSRO, ODFW, watershed council, SWCD, USFS, BLM, PGE	Ongoing	High dispersal downstream from site	Long term	5-15 years	High
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	CTWSRO, ODFW, USFS, BLM	Ongoing	Subbasin-wide	Long term	Within 15 years	Moderate, high

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Sherman and Wasco SWCD, Landowners, Oregon State agencies.	Bakeoven and Buck Hollow Watershed Restoration Projects.	Bakeoven and Buck Hollow Creek	Likely	Project is underway in Bakeoven watershed and is planned over a 10-year period. Project is transitioning to effectiveness monitoring. See State of Oregon programmatic review -- Appendix F.
NRCS,SWCD, USDA FSA, Private Landowners	CREP/CRP	Private lands throughout population	SWCD likely Others uncertain	An effective program that could be expanded to more landowners. See State of Oregon programmatic review -- Appendix F.
BLM Prineville District	Various range and upland restoration projects.	BLM lands throughout population	Likely	Most lands currently meeting BLM Standards and Guidelines, continued monitoring is needed to ensure long-term compliance. Program implementation may need to expand in scope. See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODFW	Trout Creek Fish Habitat Restoration Project (BPA)	Trout Creek MaSA	No	Project has made significant improvement is overall fish habitat, needs to be expanded to other properties in subbasin.

Strategy 3. Maintain and restore floodplain connectivity and function.				
Jefferson SWCD	Trout Creek Fish Habitat Restoration Project (BPA)	Trout Creek MaSA	No	This companion project to the ODFW Habitat Project has made significant improvement is overall fish habitat, needs to be expanded to other properties in subbasin.
PGE/CTWSRO	Relicensing of Pelton-Round Butte Complex	Throughout population	No	Habitat restoration and protection projects to mitigate effects of hydro projects. Addit ional opportunities exist.
CTWSRO	Various projects	Reservation lands	No	Improving riparian conditions, grazing remains problematic in some areas. Program needs expansion.
BLM, Oregon State Parks, CTWSRO	Wild and Scenic Rivers	Deschutes from mouth to Trout Creek		See State of Oregon and Federal agencies' programmatic reviews.
ODA/SWCD	Agricultural Water Quality Management Program	Private lands		See State of Oregon programmatic review -- Appendix F.
USFS	Stream Restoration Program (PACFISH)	Forest lands only when specifically identified that passive restoration is not working	Likely	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. Program implementation needs to expand in scope. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
CRP in uplands and riparian protection in the Buckhollow watershed have and will provide short term benefits, but instream physical habitat improvements may not accrue until the longer term. The future status of habitat benefits accruing from CRP enrollments could be unknown, since economic decisions by the landowners and government entities involved will influence the area under agreements. Planning and implementation of restoration and protection measures for Bakeoven Creek are similar to the Buck Hollow project, but began more recently. A draft watershed assessment has been completed and includes an action plan with a 10-year time frame (Clark and Lamson, 2005). The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form, includes berm and levee removal	1-Trout Cr. (Little Trout Cr. To Clover Creek) 1-Trout Cr. (sections from mouth to Antelope Cr.) 1-Antelope Cr. (mouth to headwaters) 1-Hay Cr. (mouth to headwaters) 2-Bakeoven Cr. (mouth to headwaters) 2-Buck Hollow Cr. (mouth to headwaters)	Degraded channel structure and complexity, floodplain, degraded riparian area, altered hydrology, degraded water quality, sediment routing	Grazing, agricultural practices, channelization, berms, roads, railroad bank armoring, floodplain, loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Channelization, berm construction, and bank armoring, following floods has isolated the stream from the floodplain in many areas. Large wood and other instream habitat complexity is lacking in the Buck Hollow watershed.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Increase role and abundance of wood and large organic debris in streambeds	1-Trout Cr. (Mouth to Board Hollow Cr.) 1-Antelope Cr. (mouth to headwaters)	Degraded channel structure and complexity, floodplain, degraded riparian area , altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Large woody debris in Deschutes River mainstem consists mostly from white alder trees downstream of hydro projects, currently little or no recruitment from upstream sources. Most problematic upstream of Warm Springs River.
Increase instream habitat through manual placement of structures		Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Considered an active form of restoration while habitat conditions are restored through more passive efforts
Stabilize streambanks with passive restoration processes	1-Trout Cr. (Little Trout Cr. To Clover Creek) 1-Trout Cr. (sections from mouth to Antelope Creek) 1-Antelope Cr. (mouth to headwaters) 1-Hay Cr. (mouth to headwaters) 2-Bakeoven Cr. (mouth to headwaters) 2-Buck Hollow Cr. (mouth to headwaters)	Degraded channel structure and complexity, floodplain connectivity, degraded riparian areas, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form, includes berm and levee removal	CTWSRO, ODFW, SWCD, USFS, BLM, watershed councils	Ongoing	High dispersal downstream	Long term	5-15 years	High
Increase role and abundance of wood and large organic debris in streambeds	ODFW, USFS, PGE, CTWSRO, watershed councils	Ongoing	Localized to treatment area	Long term	Immediate	High
Increase instream habitat through manual placement of structures	ODFW, USFS, CTWSRO	Ongoing	Limited application throughout population	Long term	Immediate	High
Stabilize streambanks	CTWSRO, ODFW, SWCD, watershed councils, USFS, BLM, ODA	Ongoing	High dispersal downstream	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Sherman and Wasco SWCD, Landowners, Oregon State agencies, BPA	Bakeoven and Buck Hollow Watershed Restoration Projects	Bakeoven and Buck Hollow Creeks		Effective project, but could be developed onto more private lands. See State of Oregon programmatic review -- Appendix F.
NRCS,SWCD, USDA FSA, Private Landowners	CREP/CRP	Riparian and upland areas throughout population	Uncertain	An effective program for both upland and riparian protection, but could be expanded to additional private lands. See State of Oregon programmatic review -- Appendix F.
BLM Prineville District	Various range and upland restoration projects.	BLM lands	Likely	Most lands currently meeting BLM Standards and

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.				
				Guidelines, continued monitoring is needed to unsure long-term compliance.
ODFW	Trout Creek Fish Habitat Restoration Project (BPA)	Trout Creek MaSA	No	Project has made significant improvement is overall fish habitat, needs to be expanded to other properties in subbasin.
Jefferson SWCD	Trout Creek Fish Habitat Restoration Project (BPA)	Trout Creek MaSA	No	This companion project to the ODFW Habitat Project has made significant improvement is overall fish habitat, needs to be expanded to other properties in subbasin.
PGE/CTWSRO	Relicensing of Pelton-Round Butte Complex	Throughout population	No	Habitat restoration and protection projects to mitigate effects of hydro projects. Addit ional opportunities exist.
CTWSRO	Various projects	Reservation lands	No	Improving riparian conditions, grazing remains problematic in some areas, needs expansion.
BLM, Oregon State Parks, CTWSRO	Wild and Scenic Rivers	Deschutes from mouth to Trout Creek	Likely	See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODA/SWCD	Agricultural Water Quality Management Program	Throughout population		See State of Oregon programmatic review -- Appendix F.
USFS	Stream Restoration Program (PACFISH)	Forest lands only when specifically identified that passive restoration is not working	Likely	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. Needs to be expanded to more streams in Trout Creek Subbasin. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (UDSA-FS, 2005).
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
CRP in uplands and riparian protection have and will provide short term benefits, but instream physical habitat improvements may not accrue until the longer term. The upper third of Buck Hollow remains a restoration priority. The future status of habitat benefits accruing from CRP enrollments are unknown, since economic decisions by the landowners and government entities involved will influence the area under agreements. Planning and implementation of restoration and protection measures for Bakeoven Creek are similar to the Buck Hollow project but began more recently. Some riparian areas are still unbuffered through fences or grazing management plans. Where riparian buffers do exist, habitat complexity will develop over the longer term if buffers are maintained. Some benefits from trees will be slow to accrue because their size is relatively small, and only when larger age-classes are present, will the biological and physical results of large wood recruitment be realized. Recent large scale stream rehabilitation projects in the Trout Creek watershed have been successful at removing berms, restoring stream function, and creating additional habitat, however long-term monitoring is needed. Several landowners with sensitive key spawning and rearing habitats in the Upper Trout Creek may be willing to participate in conservation efforts. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Bakeoven Project is beginning and is planned over a 10-year period. Some riparian areas are still unbuffered through fences or grazing management plans. Habitat complexity will develop over the longer term if existing buffers are maintained. Some benefits from trees will be slow because the trees are small. Only when larger age-classes exist will biological and physical results of large wood recruitment be realized.

Riparian improvements in Trout Creek watershed have improved water quality, but additional protection is needed throughout the subbasin.

Public land managers have implemented PACFISH standards for protection and restoration of USFS and BLM lands. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funding where it is most needed.

The USFS requires fence maintenance for all grazing allotments. New fencing may be part of adjustments to existing grazing strategies by the USFS/BLM to promote riparian recovery.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	1-Trout Cr. (mouth to Clover Cr.) 1-Antelope Cr. (mouth to headwaters) 2-Hay Cr. (mouth to headwaters)	Altered hydrology, low flows, high temperatures	Water withdrawals, land conversion on uplands, road network	Abundance, productivity	Primarily fry and summer parr	Consumptive use of flows in Trout Creek exceeds the natural streamflow. Streamflow below Amity Creek averages < 1cfs during the summer (WPN 2002). Flows in Trout Cr. below diversions in the Ashwood and Willowdale areas frequently become intermittent from mid-summer to late fall. Trout Cr. from Hay Creek to Little Trout Creek is listed as priority in EDT.
Improve irrigation conveyance and efficiency	1-Trout Cr. Forest boundary downstream	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Primarily fry and summer parr	Conversion of flood to sprinkler irrigation, irrigation efficiency improvement, and piping would increase flows.
Lease or purchase water rights and convert to instream	1-Trout Cr. subbasin (where available) 2-Buck Hollow Creek	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	One surface water right exists (0.57 cfs) in a lower reach of Buck Hollow.
Monitor/regulate water withdrawals	1-Trout Cr. MaSA	low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	Most water withdrawals are not monitored for compliance.
Water retention structures	1-Uplands in Bakeoven and Buck Hollow Creeks	Altered hydrology, low flows	Degradation on uplands	Abundance, productivity	Primarily fry and summer parr	
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Altered hydrology, low flows, high temperatures, impaired natural functions and processes on uplands, floodplains, riparian areas	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Primarily fry and summer parr	Flow fluctuations are now larger than they were historically. High flows have scoured out channels reducing habitat diversity. Reduct ion of native upland vegetation has reduced its ability to retain and slowly release runoff. Lack of water in the lower reaches and Bakeoven and Deep creeks impedes upstream and downstream fish passage.
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Implement agricultural water conservation measures	SWCD, CTWSRO, USBOR, irrigation districts, landowners	Expands existing program, new projects	Croplands, MaSAs	Based on funding	Immediate increase in Streamflow; habitat diversity, floodplain connection (0-5 yrs)	High
Improve irrigation conveyance and efficiency	SWCD, USFS, OWRD, CTWSRO, OWEB, landowners	Expands existing program, proposes new projects	High dispersal downstream	Ongoing	Increased streamflow (0-5 years)	High
Lease or purchase water rights and convert to instream	OWRD, Oregon Water Trust, PGE, DRC, others	Ongoing	Point of diversion to mouth of Deschutes	Long term	Immediate increase in instream flow	High
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion to mouth of Deschutes	Long term		High
Water retention structures	SWCDs	Ongoing	Uplands	Intermediate	0-10 years	Moderate
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD, USFS, OWRD, OWEB, ODFW, CTWSRO, landowners	Ongoing	Subbasin-wide	Intermediate	Up to 15 years	High
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

FSA, OWEB	Lease instream water rights	Specific locations determined by opportunities		Both OWEB and FSA have partnered with landowners to return water instream. Additional opportunities should be pursued.
OWRD	Stream Flow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Specific locations determined by opportunities		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust	Lease water rights and return instream	Specific locations determined by opportunities	Uncertain	Program works well, could be expanded with more willing landowners. Need assurance that instream leases remain instream.
Jefferson SWCD, NRCS	Various irrigation efficiency improvements, CRP, CREP	Specific locations determined by opportunities	Uncertain	Needs expansion.
ODA/SWCD	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The Deschutes subbasin plan's (NPCC 2004) inventory notes that Buck Hollow "runs clean", intermittent tributaries have become perennial. Opportunities may exist to increase summer flows, reduce temperature, and decrease sedimentation through water development (Lower Deschutes River Management Plan). In 2001, 1 to 1.5 cfs from a headwater well in Buck Hollow Cr. was used to supplement flow to protect fish from the drought (BPA #200105400). The Deschutes River subbasin has 578 miles of stream protected by instream water rights. Voluntary flow restoration restored 13.4 cfs in 2006, of which 3.2 cfs was permanent.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Manage irrigation return flow to reduce extreme stream temperatures	1-Trout Cr. (mouth to Clover Cr.) 1-Antelope Cr. (mouth to headwaters) 2-Hay Cr. (mouth to headwaters)	Altered stream temperatures, degraded water quality	Water withdrawals	Abundance, productivity	Fry dispersal and rearing	Reaches of Buck Hollow, Bakeoven and Trout creeks are included on the 303(d) list for exceeding temperature and sediment limits. Temperatures in the systems typically exceed criteria for salmonid rearing during summer months. Several reaches are also listed

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
						because of sediment concerns.
Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	1-Trout Cr. (mouth to sagebrush)	Depleted oxygen		Abundance, productivity	Fry dispersal and rearing	Warm temperatures and potential pollutants reduce the dissolved oxygen capacity of the water.
Implement Agricultural Water Quality Management Program	Agricultural lands throughout population	Degraded upland processes, altered hydrology, water quality, altered sediment routing	Land conversion and agricultural practices	Abundance, productivity	Fry dispersal and rearing	
Continue TMDL monitoring	Population-wide	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	All	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Manage irrigation return flow to reduce extreme stream temperatures	SWCDs	Ongoing	High dispersal downstream	Less than 5 years	Immediate	High
Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	ODA, SWCD, ODEQ	Ongoing	Localized and downstream	Long term	Long term	Moderate
Implement Agricultural Water Quality Management Plan	ODA, SWCD		Subbasin-wide	Ongoing	Variable	High

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.				
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Many benefits to steelhead have accrued through changes in upland and riparian management plans since the 1987 Farm Bill. CRP in uplands and riparian protection have and will provide short term benefits, but instream physical habitat improvements may not accrue until the longer term. The upper third of Bakeoven and Buck Hollow creeks remain restoration priorities. The future status of habitat benefits accruing from CRP and CREP enrollments could be unknown, since economic decisions by the landowners and government entities involved will influence the area under agreements. No areas within the Bakeoven or Buck Hollow watersheds are in a "protected" status. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize active watershed restoration for this population, and helps deploy limited active watershed restoration funding where it is most needed.				

9.3.3 Habitat Strategies and Actions for Deschutes River Westside Steelhead Population

Primary limiting factors: degraded floodplain connectivity and function, altered sediment routing, water temperatures, degraded channel structure and complexity, degraded riparian area, altered hydrology, and degraded fish passage – particularly lack of passage over Pelton-Round Butte Complex.

Primary threats: road networks (including Hwy 26 Beaver Creek, USFS roads, Tribal road networks), logging practices, grazing practices, removal of overstory trees and bank vegetation from the riparian corridor, stream channelization, water withdrawal (Whychus Creek).

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect the highest quality habitats through acquisition or conservation easements	Spawning areas in mainstem Deschutes River below Pelton-Round Butte Complex	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	All	All	Protecting high quality habitats is the most cost effective way to ensure fish have good quality habitat. Land acquisitions, easements, and cooperative agreements may facilitate the implementation of active restoration projects.
Protect and conserve rare and unique functioning habitats	Throughout population	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	All	All	
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	MaSAs in Warm Springs River subbasin, MaSA in Shitike Creek, potential MaSAs in Whychus Creek and Metolius River	All	All	All	All	
Adopt and manage Cooperative Agreements	Private and public lands	Degraded floodplain, channel structure, riparian areas	All	All	All	
Special management designations on public lands	Public lands	All	All	All	All	
Conduct outreach to resource users and managers	1-Entire population	All	All	All	All	Program efficiencies will be improved through increased knowledge and understanding of the importance of habitat practices.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements.	CTWSRO, PGE, DRC, DBLT, NGOs, ODFW, SWCD, USDA FSA	Ongoing	High dispersal downstream	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	Immediate halt to degradation--recovery long term	High
Protect and conserve rare and unique functioning habitats.	Land trusts, CTWSRO, ODFW, SWCD, NGOs, USFS	Ongoing	Population-wide	Immediate	Immediate halt to degradation--recovery long term	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	SWCD, USFS, private landowners, ODA, CTWSRO	Ongoing	Population-wide	Long term	5-15 years	High
Adopt and manage Cooperative Agreements.	CTWSRO	Ongoing	High dispersal downstream	Agreements are for 10-15 years	Immediate	High, although not in perpetuity
Special management designations on public lands.	USFS, BLM	Ongoing	High dispersal downstream	Complete; potentially subject to change in Forest Plan revisions	Immediate in some cases, long term for recovery of habitat	High, although subject to change from Forest Plan or management plan revision
Conduct outreach to resource users and managers.	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Varies depending on location and issues	Unknown, depends upon action taken as a result of being more informed

		Beaver Creek RM 14-18 Bager Creek RM 0.5-2.5 Skookum Creek RM 0-1.0 Mill Cr. (RM 5.5 to RM 6)		
ODA	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.
Local Government	City and County Planning and Zoning	Whychus Creek floodplain zoning - In Progress	Yes	Could be expanded.
NGOs	Deschutes Basin Land Trust, Nature Conservancy, Deschutes River Conservancy, etc.	Land purchase on Lake Creek Land purchase on Whychus Creek	Uncertain	Need to increase minimum flows by another 10 cfs through the city of Sisters.
SWCD	CREP	Population-wide		Agreements are for only 10-15 years and should be extended.
Watershed Councils	Upper Deschutes River Watershed Council	Upper Deschutes		
Deschutes River Conservancy or other entity	Lease or purchase instream water rights	Whychus Creek 20cfs secured instream flow	Yes	Important to secure water rights to guarantee instream flow, could be expanded.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The majoriy of the Deschutes Westside steelhead spawning areas occurs within the CTWSRO boundaries. The CTWSRO has developed and implemented the Integrated Resources Management Plan on Reservation lands. Adding additional wilderness areas and wild and scenic river segments would require designation by Congress. Exist ing forest plans include special management designations for RHCAs. The forest plans and BLM plans have been amended by PACFISH, which requires 300-foot buffers on any fish bearing stream for tree removal, as well as specific guidelines for livestock grazing and riparian vegetation use. Compliance with the 300-foot buffer for timber harvest operations has been very goods. FSA programs that protect riparian areas and upland watersheds include the CRP, which pays landowners not to farm highly erodible soils, and the CREP program, which pays landowners for setting riparian corridors aside from grazing and farming. The long-term effectiveness of both programs is limited by the relatively short duration of the contracts which ranges from 10 to 15 years. ODA's Agricultural Water Quality Management Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements.				

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore passage at Pelton-Round Butte Complex	1- Deschutes R. (RM 100, Pelton-Round Butte)	Blocked fish passage, altered flows, sediment routing, degraded channel structure and complexity	Dam	Spatial structure, productivity, abundance	All	Dam construction in 1964 and failure of downstream fish passage led to extirpated steelhead populations above the complex. Currently efforts underway to restore passage as part of FERC process.
Replace barriers blocking passage including dams, road culverts and irrigation structures	1- Warm Springs R. 1- Beaver Cr. 1- Shitike Cr. There are six culverts that need replacement on CTWSRO lands.	Impaired fish passage	Dams, culverts, instream structures	Spatial structure, productivity	Primarily adults and 0+juveniles	Irrigation diversions occur primarily above the project. There has been a culvert inventory conducted on the CTWS Reservation identifying problem areas.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Provide screening at 100% of irrigation diversions	1-Whychus Cr. – Three Sisters irrigation diversion	Impaired fish passage	Irrigation diversions	Spatial structure, productivity	Primarily smolts and 0+juveniles	
Replace screens that do not meet criteria	1-Whychus Cr.	Impaired fish passage	Irrigation diversions	Spatial structure, productivity	Primarily smolts and 0+juveniles	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore passage at Pelton-Round Butte Complex	PGE, CTWSRO, ODFW,	Expansion of existing project	Historical steelhead range	Unknown	Immediate increase in instream flow	High
Replace barriers blocking passage including dams, road culverts and irrigation structures	CTWSRO, USFS, SWCDs, watershed councils	Ongoing	Provide access to upstream habitat	Ongoing, replacing all culverts expected to take 20 years	Immediate	High
Provide screening at 100% of irrigation diversions	ODFW	Ongoing	At point of diversion	Number of screens needs to be determined	Immediate	High
Replace screens that do not meet criteria	ODFW	Ongoing	At point of diversion	Number of screens needs to be determined	Immediate	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name		Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	Fish Passage/Screening	Whychus Creek – Three Sisters irrigation diversion Whychus Creek – Sokol Diversion Whychus Creek – Baker Ranch Irrigation Pond	No	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding. Rating of no given because adequate funds to quickly complete screening not available.
PGE, CTWSRO	Pelton Fish Passage Plan	Whychus Creek Deschutes River Metolius River	Uncertain	Program not implemented. 50-year timeframe. Considerable uncertainty regarding smolt passage survival.
CTWSRO, ODFW	Salmon and Steelhead Reintroduction Plan	Whychus Creek Metolius River	Uncertain	Adaptive plan over life of FERC license, considerable uncertainty regarding future success.
ODOT	Culvert replacement or retrofit		Uncertain	See State of Oregon programmatic review -- Appendix F.
CTWSRO	IRMP	Warm Springs River	Yes	Adaptive management plan could use expansion.
CTWSRO, USFS	Culvert replacement	Metolius River 5th field HUC Oak Creek Rm 0.01	USFS Yes	Timeframe to complete installation uncertain and program could use expansion. Only two major culverts left to be replaced in the Metolius—USFS has replaced 8 culverts in last 4 years.
Upper Deschutes Watershed Council	Various passage projects	Lake Creek Whychus Creek	Yes	Projects currently on Whychus Creek and Lake Creek could be expanded to other areas.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The major issue for this strategy is passage above the Pelton-Round Butte Complex. A new FERC license was issued in June of 2005. A main component of the license is the reintroduction of salmon and steelhead above the PRB. New facilities, evaluation, modifications will need to be implemented. Juvenile out plants, downstream fish passage efficiencies and timelines have been defined in the Salmon and Steelhead Reintroduction and Conservation Plan in draft written by ODFW and CTWS.

The Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) provides guidance that will help prioritize culvert replacements for this population.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	1- Deschutes R. (Eagle Cr to Shitike Cr) 1- Deschutes R. (Trout Cr. to PRB) 1- Warm Springs R. (mouth to RM 31) 1- Shitike Cr. (mouth to RM 5) 1- Beaver Cr. (mouth to RM 26) 1- Mill Cr. (RM 5 to RM 6.5) 2- Quartz Cr. (Mouth to RM 5) 2- Coyote Cr. (Mouth to RM 11) 1- Potential MaSAs in Whychus Cr. 2- Potential MaSAs in Metolius	Degraded floodplain, degraded riparian area, channel structure	Removal of interaction between river and floodplain, grazing, agricultural use, loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Floodplains and channels that are in balance are essential for proper stream function.
Reconnect side channels and off-channel habitats to stream channels	1- Deschutes R. (Eagle Cr to Shitike Cr) 1- Deschutes R. (Trout Cr. to PRB) 1- Warm Springs R. (mouth to RM 31) 1- Shitike Cr. (mouth to RM 5) 1- Beaver Cr. (mouth to RM 26) 2- Quartz Cr. (Mouth to RM 5) 2 - Coyote Cr. (Mouth to RM 11) 1- MaSAs in Whychus Cr. 2- Potential MaSAs in Metolius	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	In 1995, about 68% of all steelhead spawning in the mainstem Deschutes River from the Reregulating Dam to Trout Creek occurred in side channels between islands and channel margins, despite the fact that such channels comprise less than 10% of the channel length in the reach (Zimmerman and Ratliff 2003).
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	1- Beaver Cr. (RM 11 to RM 22)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity	All	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain habitats	CTWSRO, ODFW, watershed council, SWCD, USFS	Ongoing	Improved connectivity with channel will be localized; improved water table will increase streamflow and lower water temperatures downstream.	Long term	5-15 years	Moderate
Reconnect side channels and off-channel habitats to stream channels	CTWSRO, ODFW, watershed council, SWCD, USFS	Ongoing	Improved connectivity with channel will be localized; improved water table will increase streamflow and lower water temperatures downstream.	Long term	5-15 years	Moderate
Promote the maintenance and creation of beaver dams to restore the role in natural	CTWSRO, ODFW, USFS	Ongoing	Subbasin-wide	Long term	Within 5 years	Moderate

Strategy 3. Maintain and restore floodplain connectivity and function.						
ecological processes.						
Status of Existing Programs through which Actions are Implemented						
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale		
USFS, BLM, Grasslands	Stream enhancement program (PACFISH/NWFP)	Metolius River 5th field HUCs Whychus Creek 5th Field HUCs. Only when specifically identified that passive restoration is not working.	Yes	The USFS/BLM preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. Additional opportunities are limited, projects may arise. See USFS/BLM Sufficiency Assessment—Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).		
Watershed Councils	Watershed restoration	Whychus Creek RM 16.5	Uncertain	Only if specific needs cannot be addressed by passive restoration techniques.		
Soil and Water Conservation Districts	Watershed restoration	Population-wide		Only if specific needs cannot be addressed by passive restoration techniques.		
CTWSRO	IRMP	Warm Springs 5th field HUCs (8) Shitike Creek 5th Field HUC	Yes	Adaptive management plan, program could be expanded. See State of Oregon programmatic review -- Appendix F.		
ODA	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.		
NRCS, SWCD, private landowners	CREP	Beaver Creek (RM 0.25 to RM 3.5 and RM 14 to RM 18) Warm Springs River (RM 0 to RM 3.5 and RM 27.5 to RM 30)	Yes	Could be expanded.		
Upper Deschutes Watershed Council	Various restoration projects	Upper Deschutes subbasin	Uncertain	Program needs additional resources to expand.		
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)						
The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.						

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	1- Deschutes R. (Eagle Cr to Shitike Cr) 1- Deschutes R. ((Trout Cr. to PBR) 1- Warm Springs R. (mouth to RM 31) 1- Shitike Cr. (mouth to RM 5) 1- Beaver Cr. (RM 0.25 to RM 4, RM 14 to RM 15, and RM 18 to RM 26) 2 - Quartz Cr. (Mouth to RM 5)	Degraded channel structure and complexity, floodplain, degraded riparian area	Removal of interaction between river and floodplain, grazing, agricultural use, loss of beaver	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Habitat complexity has been reduced in Shitike Creek and Warm Springs River by channel simplification and land use practices, resulting in flashy flows that have scoured the channel.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
	2 - Coyote Cr. (Mouth to RM 11) 1- MaSAs in Whychus Cr. 2- MaSAs in Metolius 2- Mill Cr. (RM 5 to RM 7.5)		dams			
Increase role and abundance of wood and large organic debris in streambeds	1- Deschutes R. (Eagle Cr to Shitike Cr) 1- Deschutes R. (Trout Cr. to PBR) 1- Metolius R. 1- Warm Springs R. (mouth to RM 37 and RM 41 to RM 42) 1- Shitike Cr. (mouth to RM 5) 1- Beaver Cr. (RM 14 to RM 15 and RM 18 to RM 26) 2- Quartz Cr. 2- Coyote Cr. 1- MaSA in Shitike Cr. 1- MaSAs in Whychus Cr.	Degraded channel structure and complexity, floodplain, degraded riparian area , altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Removal of large wood (Metolius River) and channelizing streams have increased water velocities and reduced the ability of the stream to hold water for gradual release.
Increase instream habitat through manual placement of structures	2- Metolius R. 1- Shitike Cr. RM 0-5 1- Quartz Cr. RM 1-RM 2 1- Whychus Cr. RM 0.0-RM 32	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	large wood removal	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Considered an active form of restoration while habitat conditions are restored through more passive efforts.
Stabilize streambanks	1- Deschutes R. (Eagle Cr to Shitike Cr) 1- Deschutes R. (spawning areas below PRB) 1- Warm Springs R. (mouth to RM 31) 1- Shitike Cr. (mouth to RM 5) 1- Beaver Cr. (mouth to RM 26) 2- Quartz Cr. (mouth to headwaters) 2- Coyote Cr. (mouth to headwaters) 1- Potential MaSAs in Whychus Cr. 2- Potential MaSAs in Metolius	Degraded channel structure and complexity, floodplain connectivity, degraded riparian areas, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	CTWSRO, ODFW, SWCD, USFS, watershed councils	Ongoing	High dispersal downstream	Long term	5-15 years	High
Increase role and abundance of wood and large organic debris in streambeds	ODFW, USFS, PGE, CTWSRO, watershed councils	Ongoing	Treated area	Long term	Immediate	Moderate
Increase instream habitat through manual placement of structures	ODFW, USFS, CTWSRO	Ongoing	Treated area	Long term	Immediate	Moderate
Stabilize streambanks	CTWSRO, ODFW, SWCD, watershed councils, USFS, ODA	Ongoing	High dispersal downstream	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
PGE, CTWSRO	Lower Deschutes Gravel Study	Lower Deschutes	Yes	Possibly, based upon study results.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.				
PGE, CTWSRO	Large Wood Management Plan	Lower Deschutes	Yes	Adapt as program is implemented, program needs expansion.
USFS	Stream enhancement program (PACFISH)	Population-wide, only when specifically identified that passive restoration is not working	Yes	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. Programs generally effective. See USFS/BLM Sufficiency Assessment—Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
Watershed Councils	Watershed restoration	Population-wide	Uncertain	Only if specific needs cannot be addressed by passive restoration techniques.
SWCDs	Watershed restoration	Population-wide		Only if specific needs cannot be addressed by passive restoration techniques. See State of Oregon programmatic review -- Appendix F.
CTWSRO	IRMP	Reservation	Yes	Adaptive management plan, program could be expanded.
ODA	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.
NRCS, SWCD, private landowners	CREP	Population-wide	Likely	Could be expanded
Upper Deschutes Watershed Council	Various restoration projects	Upper Deschutes subbasin	Uncertain	Could be expanded.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Large wood placement in the lower Deschutes, gravel augmentation studies and evaluation will be conducted by PRBC licensees. The area of study and implementation will occur between the Reregulating Dam and Shitike Creek. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian communities	1- Deschutes R. (Eagle Cr. to Shitike Cr.) 1- Deschutes R. (Trout Cr. to PBR) 2 - Metolius R. 1- Warm Springs R. (mouth to RM 31., Ka-Nee-Ta resort area) 1- Shitike Cr. (mouth to RM 5, Community of Warm Springs, near Hwy 26) 1 - Beaver Cr. (mouth to RM 26) 2- Quartz Cr. (mouth to RM 5) 2 - Coyote Cr. (mouth to RM 11) 1- Potential MaSAs in Whychus Cr. 2- Mill Cr. (RM 5 to RM 6.5)	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing, noxious Weeds	Livestock grazing, agricultural conversion, roads, bank armoring, residential development, loss of beaver dams, noxious weeds	Abundance, productivity	All	Many stream systems have experienced a loss of riparian vegetation. Roads are located in many riparian areas within the subbasin (NPCC 2004b).

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Develop grazing strategies that promote riparian recovery	1- Whychus Cr.- RM 4 to RM16 2- Seekseequa Cr. 5th field HUC 1- Warm Springs R. 5th field HUCs 1- Shitike Creek 5th field HUC 2- Lower Deschutes River RM 74 to RM 100	Bank degradation, degraded riparian communities, flow, sediment routing	Overgrazing	Abundance, productivity	All	Significant opportunity to improve grazing strategies.
Eradicate invasive plant species from riparian areas	Lower Warm Springs River 5th field HUC Mill Creek 6th Field HUC Shitike Creek 5th field HUC Deschutes River RM 87 to Rm 100 Beaver Creek 5th field HUC	Degraded riparian communities	Conversion of natural riparian vegetative communities	Abundance, productivity	All	
Install fencing to exclude livestock from riparian areas	Warm Springs River RM 0.0 – 3.5 Warm Springs River RM 27.5 - 30 Lower Deschutes River RM 73-84 Beaver Creek RM 0.25-3.5 Beaver Creek RM 14-18 Badger Creek RM 0.5-2.5 Skookum Creek RM 0-1.0	Bank degradation, degraded riparian communities, flow, sediment routing	Overgrazing	Abundance, productivity	All	Specific locations will benefit significantly from livestock exclusion.
Install off-stream livestock watering	Badger Creek (RM 2.2) Warm Springs River (RM 28)	Degraded riparian communities, sediment routing	Overgrazing	Abundance, productivity	All	Off-channel water will reduce impacts in channel.
Plant riparian vegetation where appropriate	Beaver Creek Warm Springs River (mouth to Schoolie Creek, Ka-Nee-Ta resort area) Shitike Creek (mouth to RM 5, City of Warm Springs, near Hwy 26) Deschutes River (Eagle Creek to Shitike Creek) Deschutes River (Trout Creek to PBR)	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Overgrazing, agricultural conversion, confinement in Ka-Nee-Ta area, roads, development	Abundance, productivity	All	Riparian planting can accelerate the rate of recovery.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian communities	CTWSRO, USFS, ODA, SWCDs, ODFW, watershed councils	Ongoing	High dispersal downstream	Long term	5-15 years	High
Develop grazing strategies that promote riparian recovery	CTWSRO, USFS, ODA, SWCDs, BLM	Ongoing	High dispersal downstream	Long term	5-15 years	High
Eradicate invasive plant species from riparian areas	CTWSRO, USFS, ODA, SWCDs, watershed councils, BLM	Ongoing	Localized	Long term	After multiple years of treatment	Moderate
Install fencing to exclude livestock from riparian areas	CTWSRO, ODA, SWCDs, ODFW	Ongoing	High dispersal downstream	Long term	Riparian restoration (0-5 years)	High
Install off-stream livestock watering	ODFW, CTWSRO, USFS, ODA, SWCD	Expansion of existing effort	Private lands	Ongoing	Riparian restoration (0-5 years)	High
Plant riparian vegetation where appropriate	CTWSRO, USFS, ODA, SWCDs, ODFW, watershed councils	Ongoing	High dispersal downstream	Long term	5-15 years	Moderate

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTWSRO	Watershed maintenance	Warm Springs River RM 0.0 – 3.5	Likely	Needs to be continued.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.				
		Warm Springs River RM 27.5 - 30 Lower Deschutes River RM 73-84 Beaver Creek RM 0.25-3.5 Beaver Creek RM 14-18 Badger Creek RM 0.5-2.5 Skookum Creek RM 0-1.0		
CTWSRO	IRMP	Warm Springs 5th field HUCs Shitike Creek 5th field HUC	Yes	Adaptive management plan in place, program could be expanded.
SWCDs	Upland improvements, riparian improvements	Private land		Program could be expanded. See State of Oregon programmatic review -- Appendix F.
ODFW	ODFW COID mitigation and enhancement program	Upper Deschutes River, Whychus Creek	No	Limited to small geographical scale. More downstream effects need to be addressed need to be addressed.
USFS	Allotment Management Plan, Forest Management Plans	Metolius 5th field HUCs Whychus 5th field HUCs	Yes	See USFS/BLM Sufficiency Assessment—Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
NRCS	EQUIP, CRP, CREP	Upper Deschutes 4th field HUC	Yes	Programs for property owners to enroll riparian and upland.
ODA	Agricultural Water Quality Management Program	Private land		See State of Oregon programmatic review -- Appendix F.
Upper Deschutes Watershed Council	Various restoration projects	Whychus Creek	Yes	Could be expanded.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The CTWSRO has erected and maintains nearly 70 miles of riparian exclusion fences, constructed water gaps, and off channel watering station for livestock. Constant maintenance of the fence lines must be conducted to keep livestock out and protect the riparian vegetation. Construction of more off channel watering sites or water gaps would help to address part of the issue. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. The USFS requires fence maintenance for all grazing allotments. New fencing may be part of adjustments to existing grazing strategies by the USFS/BLM to promote riparian recovery.				

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	1-Whychus Creek 1-Upper Deschutes River	Altered hydrology, low flows, high temperatures	Water withdrawals, land conversion on uplands, road network	Abundance, productivity	Primarily fry and summer parr	
Improve irrigation conveyance and efficiency	1-Whychus Creek 1-Upper Deschutes River	Low flows, high temperatures	Water withdrawals,	Abundance, productivity	Primarily fry and	Irrigation withdrawals in Whychus Creek dewater sections of the creek

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
			loss during conveyance		summer parr	during summer baseflows.
Lease or purchase water rights and convert to instream	1-Whychus Creek 1-Upper Deschutes River	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	Small tributary flows are often intermittent limiting habitat availability in summer. EDT identified streamflows as a major limiting factor in this area.
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD, CTWSRO, landowners	Ongoing	Point of diversion downstream	Long term	Immediate increase in streamflow	High
Improve irrigation conveyance and efficiency	SWCD, USFS, OWRD, CTWSRO, OWEB, landowners	Expands existing program, proposes new projects	High dispersal downstream	Ongoing – Long term	Increased streamflow (0-5 years)	High
Lease or purchase water rights and convert to instream	OWRD, Oregon Water Trust, PGE, DRC, DBLT, others	Ongoing	Point of diversion to mouth of Deschutes	Long term	Immediate increase in instream flow	High
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion to mouth of Deschutes	Long term	Immediate	High
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CTWSRO	IRMP, water quality standards	Warm Springs 5th Field HUCS Shitike Creek 5th field HUC Seekseequa Creek 5th field HUC	Yes in some areas, no in others	Program could be expanded to improve effectiveness.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.				
ODFW	Habitat Program, riparian improvements	Upper Deschutes 4th field HUC	Uncertain	Needs expansion.
OWRD	Stream Flow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Upper Deshcutes 4th field HUC		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust and BOR	Leasing and Purchase of Water Rights	Upper Deschutes 4th field HUC	Uncertain	Program needs expansion.
SWCDs	Improve irrigation efficiency, upland improvements, riparian improvements	Population-wide		See State of Oregon programmatic review -- Appendix F.
ODEQ	Water quality management plans	Upper Deschutes 4th field HUC		See State of Oregon programmatic review -- Appendix F.
USFS, BLM	Water quality restoration plans (WQRP), PACFISH	Upper Deschutes 4th field HUC	Uncertain	WQR Plans identify projects but don't direct implementation of projects. See USFS/BLM Program Sufficiency Assessment -- Appendix E. and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
Watershed Councils	Upland improvements, riparian improvements	Whychus Creek, Lake Creek	No	Program needs additional resources.
NRCS	Upland improvements, riparian improvements	Population-wide	Uncertain	Program could be expanded.
DRC	Flow restoration projects	Upper Deschutes River Whychus Creek	No	Currently have projects in Whychus Creek. Needs to be expanded.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The CTWSRO, ODFW, Watershed Councils, NRCS and Soil and Water Districts have implemented riparian improvements on federal, tribal, state, and private lands to improve base streamflows and other habitat parameters, primarily through construction of riparian corridor fences that exclude livestock grazing and development of off channel watering devices. Public land managers have implemented PACFISH standards for protection and restoration of USFS and BLM lands. Primary constraints on more riparian improvements are personnel and funding. The Deschutes River subbasin has 578 miles of stream protected by instream water rights. Voluntary flow restoration restored 13.4 cfs in 2006, of which 3.2 cfs was permanent. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Manage irrigation return flow to reduce elevated stream temperatures	2- Warm Springs R. 2- Mill Cr. 1- Whychus Cr. 1-Deschutes R.	Altered stream temperatures, degraded water quality	Water withdrawals	Abundance, productivity	Fry dispersal and rearing	
Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	1- Warm Springs R. (RM 7) 1- Shitike Cr. (RM1.5)	Depleted oxygen Nutrient enrichment Bacteria increase	Point source inputs	Abundance, productivity	Fry dispersal and rearing	Warm temperatures reduce the dissolved oxygen capacity of the water.
Reduce chemical pollution inputs	Agricultural lands throughout population	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity		

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
			point source inputs			
Implement Agricultural Water Quality Management Program	Agricultural lands throughout population	Degraded upland processes, altered hydrology, water quality, altered sediment routing	Land conversion and agricultural practices	Abundance, productivity	Fry dispersal and rearing	Recent conservation measures have greatly reduced sediment inputs.
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	1- Deschutes R. Pelton Dam to Trout Cr. 1- Warm Springs MaSAs and MiSAs 1- Shitike Cr. MaSAs and MiSAs 2- Potential MaSAs in Metolius 1- Potential MaSAs in Whychus	Degraded upland processes, floodplains, riparian areas, altered hydrology, altered sediment routing	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Spawning, incubation, fry dispersal, rearing, over-wintering	The Deschutes River and several westside tributary reaches are included on the 2002 ODEQ 303(d) list of water quality limited streams. The lower Deschutes River exceeds temperature criteria for salmonid rearing from White River to Pelton Dam. Water temperatures in lower reaches of Warm Springs River and Shitike Creek can exceed 70°F from mid to late summer. EDT identified water temperature during incubation as a major limiting factor in lower Shitike Creek, Beaver Creek, and several other stream reaches (NPCC 2004b). Reduced streamflows negatively affect water quality. Excessive sediment loads can also reduce water quality in the Warm Springs River, primarily from runoff in lower tributaries including Quartz and Coyote creeks.
Continue TMDL monitoring	Population-wide	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	All	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Manage irrigation return flow to reduce extreme stream temperatures	SWCDs	Ongoing	High dispersal downstream	Less than 5 years	Immediate	High
Minimize unnatural factors that lead to fluctuations in dissolved oxygen levels	ODEQ, municipalities	Ongoing	Dispersal downstream	Ongoing – Long term	Variable	Moderate
Reduce chemical pollution inputs	ODEQ, WyEast RC&D, others Municipal sewage treatment plants		Dispersal downstream	Ongoing – Long term	Reduce chemical pollution immediately	High
Implement Agricultural Water Quality Management Program	ODA, SWCD		Subbasin-wide	Ongoing – Long term	Long term	High
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD	Ongoing	Subbasin-wide, high dispersal downstream	Long term	Up to 15 years	High
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Subbasin-wide	Ongoing	Immediate	High

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.					
Status of Existing Programs through which Actions are Implemented					
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale	
ODEQ	CWA Section 401	Upper Deschutes 4th field HUC		See State of Oregon programmatic review -- Appendix F.	
CTWSRO	CWA Section 401, Water Quality Standards, Integrated Resource Management Plan	Warm Springs 5th field HUCs Shitike Creek 5th field HUC	Likely	Needs expansion.	
ODA	Agricultural Water Quality Management Program	Middle Deschutes River Whychus Creek		See State of Oregon programmatic review -- Appendix F.	
USFS, BLM	Stream Restoration Program (PacFish/NWFP)	Metolius River/5th field HUCs Whychus Creek5th field HUCs Middle Deschutes River 5th field HUCs	Yes	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).	
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)					
ODA's Agricultural Water Quality Management Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.					

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Continue to promote no-till and other seeding techniques that reduce erosion where site conditions are suitable	Subbasin-wide	Altered hydrology, sediment routing	Upland land use practices, loss of water storage capacity	Abundance, productivity	All	
Restore native upland plants	Subbasin-wide	Altered hydrology, sediment routing	Upland land use practices, loss of water storage capacity	Abundance, productivity	All	
Upgrade or remove problem forest roads	Forest lands	Altered hydrology, sediment routing	Road network	Abundance, productivity	All	
Utilize appropriate fire suppression techniques, implement mitigation measures	Subbasin-wide	Altered hydrology, sediment	Conversion of vegetative communities	Abundance, productivity	All	Appropriate mitigation methods minimize suppression impacts on habitat.
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Employ BMPs to minimize unnatural rates of erosion	Subbasin-wide	Altered hydrology, sediment routing, water quality	Upland land use practices, erosion, loss of water storage capacity	Abundance, productivity	All	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Continue to promote no-till and other seeding techniques that reduce erosion where site conditions are suitable	SWCD	Existing program	Croplands, MaSAs	Ongoing	Reduce runoff, sediment supply, immediate increase in base flow	High
Restore native upland plants	USFS, BLM, NRCS, SWCDs, watershed councils, CTWSRO, BIA	Ongoing	High dispersal downstream	Juniper control can be quick, other actions such as control of invasive plants may take 20 years or more	0-20 years	High
Upgrade or remove problem forest roads	CTWSRO, USFS, ODOT, ODF	Ongoing	High dispersal downstream	Long term	Immediate for sediment, other parameters 5-15 yrs	High
Utilize appropriate fire suppression techniques, implement mitigation measures	CTWSRO, USFS, BLM	Ongoing	Areas where fires have occurred	Long term	5-15 yrs	High
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to minimize unnatural rates of erosion	SWCD, USFS, ODA, ODF, BLM, CTWSRO, watershed councils, NRCS, private landowners	Ongoing	High dispersal downstream	Intermediate	5-15 years	High

Status of Existing Programs through which Actions are Implemented

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

9.3.4 Habitat Strategies and Actions for Crooked River Steelhead Population

Primary limiting factors: degraded channel structure and complexity and floodplain connectivity, degraded riparian condition, high water temperature, low flows, altered hydrology sediment routing and lack of fish passage.

Primary threats: grazing and agricultural practices, urban development, off highway vehicle use, irrigation withdrawal, dams, lack of floodplain connectivity.

Geographic area designations: Allen Cr-1 (Rm 0 – Rm 4); Crooked MS-1 (Rm 6 – Rm 7); Crooked MS-2 (Rm 7 – Rm 14); Crooked MS-3 (Rm 14 – Rm 30); Crooked MS-4 (Rm 31 – Rm 45); Crooked MS-5 (Rm 45 – Rm 46); Crooked MS-6 (Rm 46 – Rm 51); Crooked MS-7 (Rm 51 – Rm 55); Crooked MS-8 (Rm 55 – Rm 62); Crooked MS-9 (Rm 62 – Rm 70); Crooked R. above Bowman Dam; Little McKay Cr-1 (Rm 0 – Rm 3); McKay Cr-1 (Rm 0 – Rm 5); McKay Cr-2 (Rm 5 – Rm 10); McKay Cr-3 (Rm 10 – Rm 14); McKay Cr-4 (Rm 14 – Rm 16); McKay Cr-5 (Rm 16 – Rm 19); Ochoco Cr-1 (Rm 0 – Rm 5); Ochoco Cr-2 (Rm 5 – Rm 10); Ochoco Cr. above Ochoco Dam.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority, 3-third priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect the highest quality habitats through acquisition or conservation easements	1- Crooked MS-1,8,9 1- McKay Cr-1,3 1- Ochoco Cr-2 2- Crooked MS-3,4,5,6 2- McKay Cr-2 2- Ochoco Cr-1 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	Abundance, productivity	All	Additional riparian fencing on McKay and Ochoco creeks would greatly improve riparian conditions and recruitment of woody vegetation.
Adopt and manage Cooperative Agreements	Private and public lands	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	Abundance, productivity	All	Continue stream channel restoration on City of Prineville property and expand up and downstream.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Conserve rare and unique functioning habitats	1- Crooked MS-1,2,9 2- McKay Cr-4,5 2- Little McKay Cr-1 2- Crooked MS-7	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	All	Abundance, productivity	All	
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	1- Entire population	All factors	All	Abundance, productivity	All	Apply BMP's and other existing habitat protection laws to the entire population to prevent habitat degradation.
Conduct outreach to resource users and managers	1- Entire population	All factors	All	All	All	Program outputs will be improved as knowledge of ecological processes, hydrological processes, and land use management is expanded.
Special management designated on public lands	1- Crooked MS-1,2,9	All factors	All	All	All	Management of Wild and Scenic River

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements	BLM, USFS, Crooked River Watershed Council (CRWC), City of Prineville, Deschutes Basin Land Trust	Ongoing	McKay MASA, Lower Crooked MASA, Lower Ochoco MASA	Immediate	Variable depending on habitat condition	High
Adopt and manage Cooperative Agreements	CRWC, City of Prineville, private landowners, ODFW, Ochoco lumber,	Ongoing	Ent ire subbasin	Long term	Variable depending on habitat condition	Likely
Conserve rare and unique functioning habitats	BLM, USFS, ODFW	Ongoing	1- Crooked MS-1,2,9 2- McKay Cr-4,5 2- Little McKay Cr-1 2- Crooked MS-7	Immediate	Variable depending on habitat condition	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	SWCD, USFS, ODA, NRCS, CRWC, BLM, counties, private landowners	Ongoing	Entire subbasin	Long term	Degradation stop immediately, habitat recovery 15-25 years depending on status	Unknown, depends upon action taken as a result of being more informed
Conduct outreach to resource users and managers	ODFW, CRWC, BLM, USFS, NOAA Fisheries, SWCD's, OSU extension, CTWSRO, PGE	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS and BLM	Special Management Area designations PACFISH, Wild and Scenic River Corridors	Crooked MS-1,2,-9 McKay Cr-4, Cr-5 Little McKay Cr-1	Likely	Continual implementation of programs. See USFS/BLM Program Sufficiency Assessment -- Appendix E. Currently no additional opportunities to expand programs

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
				on BLM lands.
USDA FSA/SWCD's	CREP/CRP	Agricultural lands throughout population	Likely	Additional programs can be enrolled, and programs are not permanent in duration. See State of Oregon Programmatic review -- Appendix F.
ODA/SWCD's	Agricultural Water Quality Management Program	Agricultural lands throughout population	Uncertain	See State of Oregon Programmatic review -- Appendix F.
Local Government	County planning and zoning, City of Prineville Comprehensive Plan	Private lands throughout population	Uncertain	Riparian protection not adequate. Discharge of partially treated wastewater from city facility into Crooked River.
PGE	Lower Crooke MASA, Lower Ochoco MASA	Upper Population	Uncertain	Newly implemented program, results not yet available.
NGOs	Lease or purchase of land or instream water rights	Private lands throughout population	No	Limited opportunities arise, but programs can be expanded when opportunities become available.
Watershed Councils	CRWC	Population-wide	Uncertain	Water council currently active and successful, however success and future is dependent on ability to continue procuring funds.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guidelines for FS and BLM grazing management remains challenging in some locations. FSA programs that protect riparian areas and upland watersheds include CRP, which pays landowners not to farm highly erodible soils, and the CREP program that pays landowners for setting riparian corridors side from grazing and farming. The long-term effectiveness of both programs is limited by the relatively short duration of the contracts, which ranges from 10-15 years. ODA's Agricultural Water Quality Management Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements.				

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Replace or remove barriers blocking passage including dams, road culverts, irrigation structures, infiltration galleries	1- Rice Baldwin Dam 1- Stearns Dam 1- Seamus Dam 1- Parga Dam 2- Ochoco Creek (Prineville Country Club) 2- Bowman Dam 2- Ochoco Dam 2- Opal Springs Dam	Impaired fish passage	Dams, culverts, instream structures	Abundance, spatial structure, productivity	Primarily adults and 0+juveniles	Passage has been provided at the Crooked River Central and Peoples Irrigation diversions. It is likely that passage will be provided at Seamus and Parga Dams by 2011. Passage at other dams and diversions will be a greater challenge.
Maintain irrigation diversions and screens	1-Where diversions exist throughout population	Impaired fish passage	Irrigation diversions	Abundance, spatial structure, productivity	Primarily juveniles, but also adults at facilities with ladders.	All known diversions are maintained and generally meet screening criteria.
Provide screening at 100% of irrigation diversions	1-Peoples Irrigation 2-private irrigation diversions	Entrainment in canals	Irrigation diversions	Abundance, spatial structure, productivity	Juveniles	Screening of Peoples irrigation is planned. Significant progress in screening in

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
						recent years, including each of Ochoco Irrigation District's diversions. Most remaining screening issues in McKay Cr.
Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Remove/replace barriers blocking passage including dams, road culverts and irrigation structures	CRWC, BLM, USFS, ODFW, private landowners	Ongoing	Access between upstream and downstream habitats	Immediate	Immediate	High
Maintain irrigation diversions and screens	ODFW, private landowners, irrigation districts	Ongoing	Diversions subbasin-wide	Based on funding	Immediate	High
Provide screening at 100% of irrigation diversions	ODFW Fish Passage and Screening	Ongoing	Access between upstream and downstream habitats	Immediate as need is identified	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	**Program Name**	**Geographic Locations**	**Sufficient* (yes, likely, uncertain, no)**	**Sufficiency Rationale**
CRWC, BLM, ODFW, BOR, NRCS, Ochoco Irrigation, private landowners	Fish passage and screening, state funding and federal funding	Rice Baldwin Dam, Stearns Dam, Seamus Dam, Parga Dams, Ochoco Creek, Bowman Dam, Ochoco Dam, Opal Springs Dam.	Likely	Passage has been provided at the Crooked River Central and Peoples Irrigation diversions. It is likely that passage will be provided at Seamus and Parga Dams by 2011. Passage at other dams and diversions will be a greater challenge.
ODFW	Fish Passage/Screening, State program and federal funded	Population-wide	Uncertain	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding. See State of Oregon programmatic review -- Appendix F.
CTWSRO/ODFW	Salmon and Steelhead Reintroduction Plan	Areas above Pelton complex	No	Adaptive plan over life of FERC license.
ODOT	Culvert replacement or retrofit	Population-wide		See State of Oregon programmatic review -- Appendix F.
USFS and BLM	Culvert replacement	Population-wide	USFS likely with current program.	Needs expansion.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
A comprehensive fish screen inventory needs to be completed throughout the population. The Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) provides guidance that will help prioritize culvert replacements for this population. Fish will not be able to pass beyond Crooked MS-1 without passage at Opal Springs Dam, successful construction of a fish ladder is crucial.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	**Geographic Locations (1-first priority, 2-second priority)**	**Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Reconnect floodplains to	1- Crooked MS-4,5,6	Degraded floodplain,	Removal of interaction	Abundance,	Primarily 0 to	Floodplains and channels that are in

Strategy 3. Maintain and restore floodplain connectivity and function.						
channels	1- McKay Cr-1,2,3,4 2- Little McKay Cr-1 2- Crooked MS-3,7,8 2- McKay Cr-5,6 2- Allen Cr-1 2-Ochoco Cr-1,2 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	degraded riparian area, channel structure	between river and floodplain, grazing, agricultural use, loss of beaver dams	productivity	2-age rearing and 2-age migrants	balance are essential for proper stream function. Improved livestock grazing and agricultural practices necessary for successful restoration. Floodplain connection in Crooked MS-8 is highly desirable, but landowner cooperation is necessary.
Reconnect side channels and off-channel habitats to stream channels	1- Crooked MS-4,5,6 1- McKay Cr-1,2,3,4 2- Little McKay Cr-1 2- Crooked MS-3,7,8 2- McKay Cr-5,6 2- Allen Cr-1 2-Ochoco Cr-1,2 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Off channel habitat important juvenile rearing habitat. Improved livestock grazing and agricultural practices necessary for successful restoration. Floodplain connection in Crooked MS-8 is highly desirable, but landowner cooperation is necessary.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	1-McKay Cr 1,2,3,4,5 1-Little McKay Cr 1 1-Ochoco Cr 1,2 2-Allen Cr 1 3-Crooked above Bowman 3-Ochoco Cr above Ochoco Dam	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity	All	As riparian areas recovery, beaver recolonization occurs naturally.
Restore wet meadows and wetlands	1- Crooked MS-4,5,6 1- McKay Cr-1,2,3,4 2- Little McKay Cr-1 2- Crooked MS-3,7,8 2- McKay Cr-1,4 2- Allen Cr-1 2-Ochoco Cr-1,2 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands and wet meadows	Abundance, productivity	Primarily fry and age 0+	Restoration of wet meadows and wetlands will be by-product of floodplain and side channel restoration; however, specific projects may be required to reach acceptable status.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain habitats.	CTWSRO, ODFW, CRWC, BLM, SWCD's, USFS, PGE, ODOT, City of Prineville	Ongoing	High dispersal downstream from site	Long term	5-15 years	Likely, dependent on further landowner cooperation
Reconnect side channels and off-channel habitats to stream	CTWSRO, ODFW, CRWC, SWCD, USFS, BLM, PGE,	Ongoing	High dispersal downstream from site	Long term	5-15 years	Likely, dependent on

Strategy 3. Maintain and restore floodplain connectivity and function.						
channels.	ODOT					further landowner cooperation
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	CTWSRO, ODFW, USFS, BLM	Ongoing	Subbasin-wide	Long term	Within 15 years	Likely
Restore wet meadows and wetlands	CTWSRO, ODFW, CRWC, BLM, SWCD's, USFS, PGE, ODOT, City of Prineville	Ongoing	Subbasin-wide	Long term	Within 15 years	Likely

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
CRWC, City of Prineville	Crooked River stream channel restoration	Crooked MS-5	No	Engineering for project complete, implementation expected summer 2010. Project only restores one stream segment, more restoration necessary in this reach and others. Efforts to re-establish floodplain connectivity in other reaches of the Crooked River were not successful due to channel degraded channel condition, altered hydrology and project design.
CRWC, Ochoco Lumber, ODFW	Ochoco Creek Enhancement, Ochoco Mill Site	Ochoco CR-1	No	Although this project will improve fish habitat within the project boundaries, similar strides are necessary in Ochoco CR-1 and Ochoco CR-2
CRWC, private landowners, ODFW	Middle McKay passage protection, stream restoration	McKay Cr-2,3 Allen Creek Cr-1	Uncertain	Projects will create fish passage and restore natural stream channels. However, landowner cooperation is necessary for project completion and restoration needs to be expanded throughout entire stream and some tributaries.
NRCS,SWCD, USDA FSA, Private Landowners	CREP/CRP	Private lands throughout population	Uncertain	An effective program that could be expanded to more landowners. See State of Oregon programmatic review -- Appendix F.
BLM, Oregon State Parks,	Wild and Scenic Rivers	Crooked MS-1,2,3 (RM 6-17) Crooked MS-9	Yes	See State of Oregon and Federal agencies' programmatic reviews.
ODA/SWCD	Agricultural Water Quality Management Program	Private lands	No	See State of Oregon programmatic review -- Appendix F.
USFS	Stream Restoration Program (PACFISH)	Forest lands only when specifically identified that passive restoration is not working	Likely	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. Program implementation needs to expand in scope. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
CRP in uplands and riparian protection provide short-term benefits, however longer periods are required to restore stream channel and habitat. Habitat benefits of CRP enrollments are dependent upon agreements between participating agencies and landowners. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 3. Maintain and restore floodplain connectivity and function.
The success of all stream channel and riparian restoration is dependent on cooperation between landowners and government agencies. Proper land management practices must be adopted by landowners and natural resource managers to assure that further habitat degradation does not occur. Channel and floodplain restoration projects in the recovery area will require long-term monitoring agreements between the CRWC and landowners.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority, 3-third priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form, includes berm and levee removal	1- Crooked MS-4,5,6 1- McKay Cr-1,2,3,4, 1- Ochoco Cr 2 2- Little McKay Cr-1 2- Crooked MS-3,7,8 2- McKay Cr-5,6 2- Allen Cr-1 2-Ochoco Cr-1, 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Degraded channel structure and complexity, floodplain, degraded riparian area, altered hydrology, degraded water quality, sediment routing	Grazing, agricultural practices, channelization, berms, roads, railroad bank armoring, floodplain, loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Channelization, berm construction, and bank armoring, following floods has isolated the stream from the floodplain in many areas. Large wood and other instream habitat complexity is lacking. Efforts to re-establish floodplain connectivity in other reaches of the Crooked River were not successful due to channel degraded channel condition, altered hydrology and project design.
Increase role and abundance of wood and large organic debris in streambeds	1- McKay CR-1,2,3,4,5 1- Little McKay Cr-1 1- Ochoco CR-1,2 2- Crooked MS- 3,4,5,6,7,8,9 2- Allen Cr-1 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Degraded channel structure and complexity, floodplain, degraded riparian area , altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Limited opportunity to recruit and maintanin large woody debris in mainstem Crooked River. Agricultural practices have nearly eliminate woody vegetation from riparian areas and woody vegetation rehabilitation is necessary for entire Crooked River, McKay CR-1,2,3,4 and Ochoco CR-1 and 2. Bowman and Ochoco Dams prevents LWD recruitment from above the dam.
Increase instream habitat through manual placement of structures	1- McKay Cr-1,2,3,4,5 1- Little McKay Cr-1 1- Ochoco Cr 1,2 2- Allen Cr-1 2- Crooked MS- 3,4,5,6,7,8	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Considered an active form of restoration while habitat conditions are restored through more passive efforts
Stabilize streambanks with passive restoration processes	1- Crooked MS-4,5,6 1- McKay Cr-1,2,,4.5 1- Little McKay Cr-1 2- Crooked MS-3,7,8 2- McKay Cr-3 2- Allen Cr-1	Degraded channel structure and complexity, floodplain connectivity, degraded riparian areas, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily 0 to 2-age rearing and 2-age migrants	Passive restoration will not be adequate in lower Crooked River valley. Passive restoration should be considered above Bowman and Ochoco Dams to prepare for steelhead recovery in coming decades.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
	2-Ochoco Cr-1,2 3- Ochoco Cr. (above Ochoco Dam) 3- Crooked R. (above Bowman Dam)					

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form, includes berm and levee removal	CTWSRO, ODFW, SWCD, USFS, BLM, CRWC, City of Prineville	Ongoing	High dispersal downstream	Long term	5-15 years	Likely
Increase role and abundance of wood and large organic debris in streambeds	ODFW, USFS, BLM, PGE, CTWSRO, CRWC	Ongoing	Localized to treatment area	Long term	Immediate	High
Increase instream habitat through manual placement of structures	ODFW, USFS, BLM, CTWSRO, CRWC, private landowners	Ongoing	Limited application throughout population	Long term	Immediate	High
Stabilize streambanks	CTWSRO, ODFW, SWCD, CRWC, USFS, BLM, ODA, City of Prineville	Ongoing	High dispersal downstream	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
NRCS,SWCD, USDA FSA, Private Landowners	CREP/CRP	Riparian and upland areas throughout population	Uncertain	An effective program for both upland and riparian protection, but could be expanded to additional private lands. See State of Oregon programmatic review -- Appendix F.
BLM Prineville District	Various range and upland restoration projects.	BLM lands	Likely	Most lands currently meeting BLM Standards and Guidelines continued monitoring is needed to unsure long-term compliance.
BLM, Oregon State Parks, CTWSRO	Wild and Scenic Rivers	Crooked MS-1,2,3, 9 (RM 6-17, 62-70) Crooked MS-9	Likely	See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODA/SWCD	Agricultural Water Quality Management Program	Throughout population	No	See State of Oregon programmatic review -- Appendix F.
USFS	Stream Restoration Program (PACFISH)	Forest lands only when specifically identified that passive restoration is not working	Likely	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. Needs to be expanded to more streams in Trout Creek Subbasin. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (UDSA-FS, 2005).
CRWC	Various restoration projects	Entire Crooked River Subbasin	Uncertain	Project capacity currently at a maximum, expansion of council personnel could improve recovery effort.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

CRP in uplands and riparian protection provide short-term benefits, however longer periods are required to restore stream channel and habitat. Habitat benefits of CRP enrollments are dependent upon agreements between participating agencies and landowners. Riparian fencing must be maintained to assure that the riparian vegetation can re-establish and eventually provide a source of LWD.

The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.
Channel and floodplain restoration projects in the recovery area will require long-term monitoring agreements between the CRWC and landowners.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority, 3-third priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian communities including vegetative planting	1- Crooked MS-3,4,5,6,7,8 1- McKay Cr-1,2,3,4,5 1- Ochoco Cr-1,2 1- Allen Cr-1 2- Crooked MS-1,2,9 2- Little McKay Cr-1 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Livestock grazing, agricultural conversion, roads, bank armoring, residential development, loss of beaver dams	Abundance, productivity	All	Past grazing practices throughout the subbasin have caused riparian degradation. Current practices, though improved, continue to limit recovery. Heavy off road vehilcle use has lead to severe riparian degradation in McKay Cr-5. Riparian vegetation contributes little to LWD recruitment and canopy cover. Streambank erosion and loss of riparian vegetation has led to undesirable width-to-depth ratios throughout the watershed
Develop grazing strategies that promote riparian recovery	1- Crooked MS-3,4,5,6,7,8 1- McKay Cr-1,2,3,4,5 1- Ochoco Cr-1,2 1- Allen Cr-1 2- Little McKay Cr-1 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Overgrazing	Abundance, productivity	All	Significant opportunity to improve grazing strategies.
Eradicate invasive plant species from riparian areas	Where opportunities exist throughout the subbasin	Degraded riparian communities	Conversion of natural riparian vegetative communities	Abundance, productivity	All	
Install/maintain fencing to exclude livestock from riparian areas	1- Crooked MS-3,4,5,6,7,8 1- McKay Cr-1,2,3,4,5 1- Ochoco Cr -2 2- Allen Cr-1 2- Little McKay Cr-1 2- Ochoco Cr-2 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Overgrazing	Abundance, productivity	All	Several locations will benefit from livestock exclusion.
Install off-stream livestock watering	Throughout entire subbasin	Degraded riparian communities, sediment routing	Overgrazing	Abundance, productivity	All	
Plant riparian vegetation where appropriate	1- Crooked MS-3,4,5,6,7,8 1- McKay Cr-1,2,3,4,5 1- Ochoco Cr-1,2	Bank degradation, degraded riparian communities, LWD recruitment, temperatures, flow, sediment routing	Overgrazing, agricultural conversion, roads,	Abundance, productivity	All	Natural vegetation restoration generally occurs without planting, some planting occurs along with

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
	1- Allen Cr-1 2- Crooked MS-1,2,9 2- Little McKay Cr-1 3- Crooked R. (above Bowman Dam) 3- Ochoco Cr. (above Ochoco Dam)		urban development			fencing projects and CREP projects.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian communities including vegetative planting	USFS, SWCD's, ODFW, CRWC, BLM, OWEB, private landowners	Ongoing	High dispersal downstream	Long term	Riparian restoration (10-25 years)	Likely
Develop grazing strategies that promote riparian recovery	USFS, ODA, SWCD's, BLM, CRWC, private landowners	Ongoing	High dispersal downstream	Long term	Riparian restoration (10-25 years)	Likely
Eradicate invasive plant species from riparian areas	CTWSRO, USFS, ODA, SWCD's, CRWC, BLM, private landowners	Ongoing		Immediate	Riparian restoration (10-25 years)	Uncertain
Install/maintain fencing to exclude livestock from riparian areas	NRCS, , ODA, SWCD's, ODFW, USFS, BLM, private landowners	Ongoing	High dispersal downstream	Immediate	Riparian restoration (10-25 years)	Likely
Install off-stream livestock watering	USFS, ODA, SWCD, CRWC, private landowners	Expansion of existing effort	Private lands	Ongoing	Riparian restoration (10-25 years)	Likely
Plant riparian vegetation where appropriate	USFS, SWCD's, ODFW, CRWC, BLM, OWEB, private landowners	Ongoing	High dispersal downstream	Long term	Riparian restoration (10-25 years)	Likely

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
BLM, Oregon State Parks, CTWSRO	Wild and Scenic Rivers	Crooked MS-1,2,3 (RM 6-17) Crooked MS-9	Likely	See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E.
USFS	Stream Restoration Program (PACFISH)	Forest lands	Likely	Needs to be expanded to more streams in Trout Creek Subbasin. See USFS/BLM Program Sufficiency Assessment -- Appendix E and Regional Aquatic Restoration Strategy. See discussion in Gaps commentary below.
NRCS,SWCD, USDA FSA, Private Landowners	CREP	Throughout population	Uncertain	An effective program for both riparian protection and restoration, but could be expanded to additional private lands.
ODA	Agricultural Water Quality Management Program	Throughout population		See State of Oregon programmatic review -- Appendix F.
CRWC/OWEB	Various restoration projects	Throughout population	Uncertain	Effective program for developing restoration/protection projects and supplying outreach information on resource management. Participation could be expanded.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The Forest Service Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funds where it is most needed.

Public land managers have implemented PACFISH standards for protection and restoration of USFS and BLM lands. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS,

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.
2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funding where it is most needed. The USFS/BLM requires fence maintenance for all grazing allotments. New fencing may be part of adjustments to existing grazing strategies by the USFS/BLM to promote riparian recovery.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	1- Crooked MS-3,4,5,6,7 1- McKay Cr-1,2,3 1- Allen Cr-1 1- Ochoco Cr-1,2 2- Crooked R. (above Bowman Dam) 2- Ochoco Cr. (above Ochoco Dam)	Altered hydrology, low flows, high temperatures	Water withdrawals, land conversion on uplands, road network	Abundance, productivity	Primarily fry and summer parr	Major flows of Crooked River and its tributaries diverted for irrigation purposes. Conserved flows from the Crooked River above Bowman Dam and Ochoco Creek above Ochoco Dam would benefit downstream fish populations. Flow gauges at diversions could be used to regulate irrigation allocations.
Improve irrigation conveyance and efficiency	1- Crooked MS-3,4,5,6,7 1- McKay Cr-1,2,3 1- Allen Cr-1 1- Ochoco Cr-1,2 2- Crooked R. (above Bowman Dam) 2- Ochoco Cr. (above Ochoco Dam)	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Primarily fry and summer parr	Conversion of flood to sprinkler irrigation, piping, irrigation efficiency improvement, and diversion gauging would increase flows.
Lease or purchase water rights and convert to instream	1- Reallocation of Prineville Reservoir 1- Where available	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Primarily fry and summer parr	Most water withdrawals are not monitored for compliance.
Water retention structures	Population-wide	Altered hydrology, low flows	Degradation on uplands	Abundance, productivity	Primarily fry and summer parr	Many water retention structures would not be necessary if riparian areas were left intact and uplands were properly managed thereby increasing the water retention abilities of the soil.
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Altered hydrology, low flows, high temperatures, impaired natural functions and processes on uplands, floodplains, riparian areas	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Primarily fry and summer parr	Juniper encroachment and consequential reduction of native grasses, shrubs, and forbs has reduced retention of precipitation in uplands. Flow fluctuations are now larger than they were historically. High flows have scoured channels reducing habitat diversity.
Assess existing and future water needs, complete statewide inventory of above	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial	All stages	New programs in development

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs				structure, diversity		

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD, , BOR, irrigation districts, landowners, OWRD	Expands existing program, new projects	Croplands throughout subbasin	Based on funding	Immediate increase in streamflow; habitat diversity, floodplain connection (0-5 yrs)	Likely
Improve irrigation conveyance and efficiency	SWCD, USFS, OWRD, OWEB, landowners, CRWC	Expands existing program, proposes new projects	High dispersal downstream	Ongoing	Increased streamflow (0-15 years)	Likely
Lease or purchase water rights and convert to instream	OWRD, Oregon Water Trust, PGE, DRC, BOR	Ongoing	Point of diversions to mouth of Crooked	Long term	Immediate increase in instream flow	Uncertain
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversions to mouth of Crooked	Long term		Likely
Water retention structures	SWCD's	Ongoing	Uplands	Intermediate	0-15 years	Uncertain
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD, USFS, OWRD, OWEB, ODFW, CTWSRO, landowners	Ongoing	Subbasin-wide	Intermediate	Up to 15 years	Uncertain
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Likely

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
BLM	Various projects related to rangeland improvements in uplands	BLM lands	Uncertain	Effective programs. Long-term monitoring of effectiveness is needed. See USFS/BLM Program Sufficiency Assessment--Appendix E.
NRCS,SWCD, FSA, Private Landowners	CRP, CREP	Riparian and upland areas within population	No	An effective program for both upland and riparian protection, but could be expanded to additional private lands.
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use	Specific locations determined by opportunities		See State of Oregon programmatic review -- Appendix F.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.				
	Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment			
Oregon Water Trust	Lease water rights and return instream	Specific locations determined by opportunities	Uncertain	Program works well, could be expanded with more willing landowners. Need assurance that instream leases remain instream.
SWCD, NRCS	Various irrigation efficiency improvements, CRP, CREP	Specific locations determined by opportunities	Uncertain	Needs expansion.
ODA/SWCD	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Many landowners have adopted modern irrigation techniques; however downstream irrigators generally take unused water. Monitoring of irrigation withdrawals with flow gauges is essential before the benefits of conservative water management are realized. However, irrigation waters should not be returned to streams if they will compromise the water quality of essential habitats. The BOR, as required in the Columbia River Biological Opinion, is required to identify and assist with passage improvement design and flow restoration.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Manage irrigation return flow and wastewater effluent to improve water quality	1- Crooked MS-1,2,3,4,5,6,7 1- McKay Cr-1,2,3 1- Ochoco Cr-1,2 2- Allen Cr-1 2- Crooked R. (above Bowman Dam) 2- Ochoco Cr. (above Ochoco Dam)	Altered stream temperatures, degraded water quality	Land use practices, water withdrawals, pesticides, fertilizers, herbicides, raw sewage	Abundance, productivity	Fry dispersal and rearing	Returns contain multiple pollutants, excessive nutrients, and have increased temperatures leading poor downstream water quality and reduced dissolved oxygen capacity,
Implement Agricultural Water Quality Management Program	Agricultural lands throughout population	Degraded upland processes, altered hydrology, water quality, altered sediment routing	Land conversion and agricultural practices	Abundance, productivity	Fry dispersal and rearing	
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Degraded upland processes, floodplains, riparian areas, altered hydrology, altered sediment routing	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Eggs, fry, juveniles, adults	There are opportunities to improve irrigation methods and reduce runoff from agricultural fields reducing nutrient loading and pollution of streams.
Continue TMDL monitoring	Population-wide	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	All	
Permit and enforce actions that could affect water quality	Population-wide	Water quality	Land use practices	Abundance, productivity, diversity	All	Directed actions at known sources of pollution should be addressed through BMP's and restoration projects.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Manage irrigation return flow to reduce extreme stream temperatures	SWCD's, Irrigation Districts	Ongoing	High dispersal downstream	Less than 5 years	Immediate	Likely
Implement Agricultural Water Quality Management Plan	ODA, SWCD		Subbasin-wide	Ongoing	Variable	Likely
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD	Ongoing	Subbasin-wide, high dispersal downstream	Intermediate	Up to 15 years	Uncertain
Continue TMDL monitoring	USFS, SWCD, ODEQ, CRWC	Ongoing	Subbasin-wide	Ongoing	Immediate	High
Permit and enforce actions that could affect water quality	ODA, SWCD, Municipalities, CDs, USFS, BLM, Irrigation Districts, private landowners, ODEQ	Ongoing	High dispersal downstream	Ongoing	Immediate	Uncertain, degree of implementation is unknown

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
BLM	Various projects related to rangeland improvements in uplands	BLM lands	Uncertain	Effective programs. See USFS/BLM Program Sufficiency Assessment -- Appendix E.
FSA, NRCS,SWCD, Private Landowners	CRP, CREP	Riparian and upland areas throughout population	Uncertain	An effective program for both upland and riparian protection, but could be expanded to additional private lands. See State of Oregon programmatic review -- Appendix F for SWCD.
ODA/SWCD	Agricultural Water Quality Management Program	Throughout population	Uncertain	See State of Oregon programmatic review -- Appendix F.
USFS	Stream Restoration Program (PACFISH)	USFS lands	Uncertain	Needs expansion. See USFS/BLM Program Sufficiency Assessment -- Appendix E and Regional Aquatic Restoration Strategy.
ODEQ	Water Quality	Subbasin-wide	Likely	See State of Oregon programmatic review – Appendix F
ODEQ/EPA	Pesticides/Toxics	Subbasin-wide	Likely	See State of Oregon programmatic review – Appendix F, for ODEQ
Municipalities	Public Works	Crooked MS- 3,4,5,6	No	Treatments of sewage returns unacceptable

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funding for riparian planting where it is most needed.

Implementation of PACFISH standards and guides for Forest and BLM programs, in conjunction with Forest Plan Management Area allocations, has been highly successful for passive upland restoration over most of this population's area.

The TMDLs set loading capacity to achieve water quality standards. To address high summer water temperatures, near stream vegetation disturbance, channel widening and low flows are the existing sources of increased solar radiation loading. Achievement of the TMDL targets is dependent of determination of system potential vegetation. During TMDL development, the best professional judgment of the team described the potential streamside shade-producing vegetation broadly, as continuous tree-belts on each side of the river.

While permit processes implemented by the US Army Corps of Engineers are thorough and actions authorized are protective of aquatic resources, the program lacks personnel resources to insure that terms and conditions of permitted actions are followed. In addition, this agency lacks resources to adequately monitor waterways for non-permitted actions or act upon non-permitted situations reported by other agencies or private parties. See State of Oregon programmatic review -- Appendix F for ODSL.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority, 3- third priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Remove junipers	1-Crooked MS-3,4,5,6,7,8 1-McKay Cr-3,4,5 1-Allen Cr-1 1- Ochoco Cr-2 2- Crooked above (Bowman Dam) 2- Ochoco (above Ochoco dam)	Altered hydrology	Loss of water storage capacity	Abundance, productivity	All	
Restore native upland plants and remove noxious weeds	1-Crooked MS-3,4,5,6,7,8,9 1-McKay Cr-1,2,3,4,5 1-Allen Cr-1 1- Ochoco Cr-2 2- Ochoco Cr-1 3- Crooked above (Bowman Dam) 3- Ochoco (above Ochoco dam)	Altered hydrology, sediment routing	Upland land use practices, loss of water storage capacity	Abundance, productivity	All	
Upgrade or remove problem forest roads	1- McKay Cr-4,5 1- Little McKay Cr-1	Altered hydrology, sediment routing	Road network	Abundance, productivity	All	
Promote reforestation and fuels management	1- McKay Cr-4,5 1- Little McKay Cr-1	Altered hydrology, sediment	Conversion of vegetative communities	Abundance, productivity	All	
Demonstration projects to restore forest health and resilience to wildfire	Private forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to minimize unnatural rates of erosion	Subbasin-wide	Altered hydrology, sediment routing, water quality	Upland land use practices, erosion, loss of water storage capacity	Abundance, productivity	All	
Apply BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Subbasin-wide	Altered hydrology, sediment routing	Forestry, roads, overgrazing, Agricultural practices, noxious weeds	Abundance, productivity	All	Upland management practices affect the hydrologic function of the watershed by causing rapid runoff rather than infiltration. BMP's should be implemented to insure that the watershed functions to its potential, given the anthropogenic influence in the watershed.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove junipers	SWCD's, NRCS	Ongoing	Uplands	Immediate	0-20 years	Uncertain, control must be followed by appropriate

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
						management strategies
Restore native upland plants	USFS, BLM, NRCS, SWCD's, watershed councils, CTWSRO, BIA	Ongoing	High dispersal downstream	Juniper control can be quick, other actions such as control of invasive plants may take 20 years or more	0-20 years	Uncertain
Upgrade or remove problem forest roads	CTWSRO, USFS, ODOT, ODF	Ongoing	High dispersal downstream	Long term	Immediate for sediment, other parameters 5-15 yrs	Likely
Promote reforestation and fuels management	CTWSRO, USFS, watershed councils, SWCD's, counties	Ongoing	Forestlands	Long term	0-10 yrs	Likely
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to minimize unnatural rates of erosion	SWCD, USFS, ODA, ODF, BLM, CTWSRO, watershed councils, NRCS, private landowners	Ongoing	High dispersal downstream	Intermediate	5-15 years	Likely
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	SWCD, USFS, ODA, CTUIR, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of water quality management plans and other plans.	0-20 years, depending on treatments applied	Uncertain, dependent on voluntary landowner participation

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
NRCS,SWCD, Private Landowners	CRP, CREP, Environmental Quality Incentive Program (EQUIP)	Private upland and riparian lands	Uncertain	An effective program for both upland and riparian protection, but could be expanded to additional private lands. Continued implementation of program dependent on funding. See State of Oregon programmatic review -- Appendix F for SWCD.
SWCD's	Voluntary Watershed Restoration	Private agricultural lands		Dependent on funding, and landowner interest. See State of Oregon programmatic review -- Appendix F.
BLM	Various projects related to rangeland improvements in uplands.	BLM lands	Uncertain	Effective programs that could be expanded to additional lands.
CTWSRO	IRMP	Reservation Lands	Likely	Adaptive plan could be expanded.
USFS	Stream Restoration Program (PACFISH), Vegetation Management Programs, Range Management Programs	USFS forest lands	Uncertain	Effectiveness of program unproven. May need expanded monitoring. See USFS/BLM Program Sufficiency Assessment -- Appendix E and Regional Aquatic Restoration Strategy. See discussion in Gaps commentary below.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
Many benefits to steelhead have been seen in upland and riparian management plans since the 1987 Farm Bill. CRP in uplands and riparian protection provide short-term benefits, however longer periods are required to restore stream channel and habitat. Habitat benefits of CRP enrollments are dependent upon agreements between participating agencies and landowners. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize active watershed restoration for this population, and helps deploy limited active watershed restoration funding where it is most needed. Implementation of PACFISH standards and guides for Forest and BLM programs, in conjunction with Forest Plan Management Area allocations, has been highly successful for passive upland restoration over most of this population's area.

9.3.5 Habitat Strategies and Actions for Lower Mainstem John Day River Steelhead Population

Primary limiting factors: degraded channel structure and complexity (habitat quantity and diversity), altered sediment routing, water temperature, and altered hydrology. Impaired fish passage is also a high priority limiting factor in Bridge, Butte, Kahler, Muddy, Rock, and Thirtymile creeks.

Primary threats: agricultural and grazing practices, removal of overstory trees and bank vegetation from the riparian corridor, water withdrawals, wetland draining and conversion, and stream channelization and diking.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition or conservation easements	Mountain Cr. (2); Pine Cr. (1); Cottonwood Cr. (1); Bridge Cr (1). Reaches are either designated roadless areas, Wilderness Study Areas, or designated Wilderness Areas within the watershed. John Day River, Parrish Cr to Tumwater Falls (a Wild and Scenic River) (2); Butte Cr, lower 8 miles (2)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	Many threats including livestock overgrazing of riparian area, channelization, stream bank armoring, agricultural practices (fertilizers, herbicides, sediments, changes in plant communities), water withdrawals, loss of beaver dams	Abundance, productivity	All	Protection of high quality habitats is the most cost effective way of ensuring fish have good quality habitat. It is much less expensive over the long term to protect high quality habitat than it is to degrade the habitat and then try to restore it. Many objectives are likely to be met just by habitat protection and the associated natural recovery of upland and/or riparian areas. Land acquisitions, easements, and cooperative agreements may also facilitate the implementation of active restoration projects.
Adopt and manage Cooperative Agreements	For those stream reaches already under either CREP or ODFW cooperative agreements on Alder (2), Pine Hollow (1), Rock (Gilliam Co) (2), Mountain (1), Cottonwood (1), Squaw (2) and Butte (1) crs	Same as above	Same as above	Abundance, productivity	All	
Designate additional wilderness and wild and scenic status	Convert Wilderness Study Areas on public lands to Wilderness at Spring Basin (1), Pat's Cabin (1), Sutton Mountain (2), North Pole Ridge (2), Thirtymile (1), and Lower John Day mainstem (2)	Same as above	Land use practices	Abundance, productivity	All	
Special management designations in forest and BLM	Bridge Cr, adjacent to the Sutton Mt. WSA (1), and on Ochoco National Forest (2)	Same as above	Livestock grazing of riparian area, changes in	Abundance, productivity	All	These special designations include Riparian Habitat Conservation

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
plans			plant communities			Areas and Anadromous Fish Emphasis
Protect access to key habitats	None identified at this time, although ODFW periodically reviews proposals that could block passage into spawning and rearing habitat.	Passage barriers, altered hydrology, channel structure		Abundance, productivity, distribution	All	Thoroughly review projects that may block fish passage. Current ODFW policy is to grant exemptions from fish passage requirements only if mitigation meets or exceeds the loss of habitat. Exemptions must be approved by the Fish and Wildlife Commission
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	Population-wide	All	Same as above	Abundance, productivity	All	
Conduct outreach to resource users and managers	Population-wide	All				

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements	CTUIR, TNC, RMEF, John Day Basin Trust, SWCDs	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5-15 years with passive restoration approaches	High, based on previous cooperative agreements
Adopt and manage Cooperative Agreements	ODFW, SWCDs, FSA	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Agreements are for 10-15 years	Immediate	High, although not in perpetuity
Designate additional wilderness and wild and scenic status	USFS, Oregon State Parks	Ongoing as identified	Water quality and flow improvements would have high dispersal downstream, stream corridor and function improvements confined to the specific site	unknown	5-15 years	Unknown, subject to availability of areas that meet criteria
Special management designations in forest and BLM plans	USFS, BLM	Ongoing as identified	Same as above	Many complete, potentially subject to change in Forest Plan revisions	Immediate	High, although subject to change from Forest Plan or mgmt plan revision
Protect access to key habitats	None identified at this time, although ODFW periodically reviews proposals that could block passage into spawning and rearing habitat.					

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	NRCS, SWCDs, USFS, ODFW, ODF, DSL, BLM, ODOT, CTWSRO, ODA, FSA, private landowners	ongoing	Population-wide	Long term	5-15 years	High
Conduct outreach to resource users and managers	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	ongoing	Population-wide	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS and BLM	Wilderness Areas, Wilderness Study Areas, Wild and Scenic River corridors, Special Management Area designations, PACFISH	Bridge Cr, Cottonwood Cr, Pat's Cabin, North Pole Ridge, Lower John Day, Spring Basin, Thirtymile, and Sutton Mountain for Wilderness, all streams within National Forest and BLM lands for PACFISH	Yes	See USFS/BLM Program Sufficiency Assessment—Appendix E. Additional areas may be considered for addition to special management area protected status on FS lands. BLM has no opportunities to expand any of these programs.
ODFW	Cooperative Agreements	Alder, Cottonwood, Squaw and Mountain crs	Uncertain	The agreements are for only 10-15 years and need extended.
FSA	CREP	Rock, Pinehollow, and Butte crs	Uncertain	The agreements are for only 10 or 15 years and need extended.
NGOs	Lease or purchase of lands or instream water rights		Yes	Important to secure critical habitat and/or water rights.
ODA	Agricultural Water Quality Management Program	The entire lower subbasin		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Pine Cr	Likely	Could expand program.
ODF	Oregon Forest Practices Act	All private and state owned lands		See State of Oregon programmatic review -- Appendix F.
Local Government	City and County Planning and Zoning	Private land and population-wide	Varies by county, Grant County currently has 100' riparian setbacks.	Although large scale development is not presently occurring throughout the John Day subbasin, it will likely occur within the next 30 years.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The John Day River has 248.6 miles designated as Federal Wild and Scenic River and 317 miles designated as State Wild and Scenic, including the John Day River from Tumwater Falls (RM 10) to Service Cr (RM 157). State designated reaches include the John Day mainstem from Tumwater Falls (RM 10) to Parrish Cr (RM 170). Although wild and scenic designation does not preclude development, it requires development to be consistent with protecting the Outstandingly Remarkable Values (ORV's) for which the river was designated, requires review of any activity that may affect ORV's within the ¼ mile river corridor, and protects the free flowing condition of the river. Designation as W&S essentially precludes construction of any major dam. A Management Plan adopted by BLM and Oregon State Parks Department in 2001 for the designated rivers segments identifies specific management actions including development of livestock grazing management plans for each allotment. Grazing management plans for most of the allotments within the corridor are complete; all BLM grazing plans are complete.

Existing forest plans include special management designations for RHCAs. Adding additional wilderness areas and wild and scenic river segments would require designation by Congress. The forest plans and BLM plans have been amended by PACFISH, which requires 300-foot buffers on any fish bearing stream for tree removal, as well as specific guidelines for livestock grazing and riparian vegetation use. Compliance with the 300-foot buffer for timber harvest operations has been very good. In areas where trees were harvested before the rules went into effect, it will take decades for them to grow big enough to function as large wood and contribute to LWD. Forest practices rules for private and state owned forest lands have guidelines for protection of riparian function, although they are not nearly as restrictive as those on federal lands.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.
Designating additional RMAs or adding to the current restrictions within RHCAs will be revisited during the Forest Plan Revision process that is currently underway. Cooperative and conservation agreements on private land are tools for protecting high quality habitats. ODFW has used cooperative agreements over the last 21 years to protect riparian corridors that have been fenced to exclude livestock grazing. Unfortunately those agreements are for only 15 years and there have not been funds or personnel needed to extend them for longer time periods. CTWSRO owns mitigation property near Clarno on the mainstem John Day River. It encompasses 33,557-acres and includes approximately 20 miles of steelhead spawning and rearing habitat. All CTWSRO properties will be in conservation status perpetually. FSA programs that protect riparian areas and upland watersheds include the CRP, which pays landowners not to farm highly erodible soils, and the CREP program, which pays landowners for setting riparian corridors aside from grazing and farming. The long term effectiveness of both programs is limited by the relatively short duration of the contracts which ranges from 10 to 15 years. NRCS programs that protect riparian areas and upland watersheds include the Conservation Reserve Program (CRP) and the Conservation Reserve Enhancement Program (CREP). The CRP program pays landowners not to farm highly erodible soils and the CREP program pays landowners for setting riparian corridors aside from grazing and farming. The long term effectiveness of both programs is limited by the relatively short duration of the contracts which ranges from 10 to 15 years.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Remove or minimize use of push up dams	Rock (1); Upper Rock (1), Middle Rock (1), Lone Rock (1), Thirtymile (1), Butte (1), Big Muddy (2), and Rock/Mountain crs (2)	Impaired fish passage	Push up dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Push up irrigation dams are located throughout the entire subbasin and are common in the Rock/Mountain Cr drainages. Annual maintenance and construction of push up dams contributes to onsite and downstream channel stability, loss of pools and other structure, and increased sediment loads.
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	Rock (1), Upper Rock (1), Middle Rock (1), Lone Rock (1), Thirtymile (1), Butte (1), Kahler (1), Big Muddy (2), and Rock/Mountain crs (2)	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Concrete diversions, in-channel stock ponds, and road culverts are located throughout the entire subbasin. Concrete structures are located primarily in the Rock Cr (Lower John Day) drainage although there are a number of structures scattered throughout other parts of the subbasin, including Cherry Cr. Passage problems at culverts are widespread throughout all subbasins.
Provide screening at 100% of irrigation diversions	Rock Cr (Gilliam Co.) (1), Keeton Cr. (Wheeler Co.) (2), Bridge Cr. (Wheeler Co.) (1), Lower John Day mainstem pumping sites (2)	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry	Adequately screened diversions provide immediate benefits.
Replace screens that do not meet criteria	Rock Cr (Gilliam Co.) (1), Keeton Cr. (Wheeler Co.) (2), Bridge Cr. (Wheeler Co.) (1), Lower John Day mainstem pumping sites (2)	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry	Screening of irrigation diversions began in 1950s and most were screened by mid-1970s. Many screens now need to be replaced to address new criteria to reduce entrainment of emergent fry and bull trout.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove or minimize use of push up dams	SWCD	Ongoing	Provide access to upstream habitat	Ongoing, but all push up dams not expected to be corrected for at least 15 years	Immediate	High, if comply with fish passage design criteria
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	USFS, watershed councils, SWCDs, ODOT	Ongoing	Access to upstream habitat	Ongoing, replacing all culverts blocking fish passage expected to take 50 years	Immediate	High, if comply with fish passage design criteria. BLM has no culvert barriers to adult fish. Monitoring needed to determine if upstream passage for juveniles is an issue.
Provide screening at 100% of irrigation diversions	ODFW, SWCDs	Ongoing	At point of diversion	Approximately 16 diversions need to be screened, should take 5-10 years	Immediate	High if comply with fish passage design criteria
Replace screens that do not meet criteria	ODFW	Ongoing	At point of diversion	Approximately 10 screens need to be replaced, should take 5-10 years	Immediate	High if comply with fish passage design criteria

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Soil and Water Conservation Districts	Irrigation dam improvements, culvert replacement or retrofits	Unscreened or poorly screened diversions throughout population		The Soil and Water Districts are constrained by the construction window of opportunity. The counties could expand the program but are constrained by funding and personnel. See State of Oregon programmatic review -- Appendix F.
ODFW	Fish Passage/Screening state program and federally funded	Unscreened or poorly screened diversions throughout population	No	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding.
USFS	Culvert replacement	Throughout population on Federal land	Uncertain	Program progressing slowly, culverts replaced are sufficient. BLM has no culvert barriers to adult fish. Monitoring needed to determine if upstream passage for juveniles is an issue.
Watershed Councils	Road Crossing Passage improvements, passage improvements	Throughout population	Uncertain	Programs need additional resources.
ODOT	Culvert replacement or retrofit	Throughout population		See State of Oregon programmatic review -- Appendix F.
BOR	John Day Basin Program		Yes	
CTWSRO	John Day Basin Program		No	The tribe contracts with Soil and Water Districts to assist with consultation, permits, and monitoring program.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The mainstem passage problems for the Lower Mainstem John Day population have been addressed, but there are many tributaries where adult passage is blocked and more areas where juvenile passage problems occur. Irrigation dams, stock ponds, and road culverts are the primary causes of passage issues. Soil and Water Districts are correcting passage at irrigation diversions and improperly installed culverts, but are constrained by funding and by personnel needed for construction oversight. An inventory of road crossings on state and county roads in 1999 indicated 23 culverts on state owned roads and 43 culverts on county owned roads did not meet fish passage criteria in the Lower Mainstem John Day River population. Appendix G presents an inventory of known passage problems associated with culverts on state, county, or Federal roads. Some of those culverts have been replaced with structures that do meet the fish passage criteria, but much work remains. Watershed councils and ODOT, who are the principal entities working on culverts

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.
are constrained primarily by funding. An inventory of road crossings on federal lands indicates juvenile passage problems are pervasive, particularly on National Forests, with approximately 22 culverts not meeting passage criteria on National Forest land. The US Forest Service and BLM are constrained primarily by funding and the personnel needed for NEPA analysis. At the current rate of culvert replacements, it will take over 50 years to correct all passage problems on National Forests in all five John Day populations. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Another constraint is that existing state laws do not require passage improvements at existing barriers unless there is a major change in the structure, such as reconstruction or significant modifications, so landowner cooperation is critical for improving passage throughout the subbasin.
US Bureau of Reclamation is required in the Columbia River Biological Opinion to identify and assist with passage improvement design and flow restoration.
Currently, the ODFW Fish Passage and Screening program replaces about 20 irrigation diversion screens per year in the John Day subbasin. With over 120 diversions in the John Day subbasin that either do not meet current screening criteria or are unscreened, it would take at least 6 years to replace them all. Of the 120 diversions, 26 need screens or screens replaced in this population. Currently, highest priority is given to diversions that are unscreened with lower priority given to diversions that have screens, but do not meet the criteria. The program is constrained primarily by funding and personnel. Current law does not require water users to screen diversions less than 30 cubic feet per second and virtually all diversions in the John Day are less than 30 cfs, so landowner cooperation is essential to success of the program.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Rock (2), Upper Rock (1), Middle Rock (2), Lone Rock (1), Thirtymile (1), Butte (1), Bridge (1) Kahler (1), Mountain (1), Pinehollow (1), Grass Valley (2), and Hay (2) crs	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily eggs, fry and 0+	
Restore wet meadows	Thirtymile (1), Butte (1), Bridge (1), Kahler (1), Mountain (1), Rock (2), Upper Rock (2), Middle Rock (2), Lone Rock (2), Pinehollow (2), Grass Valley (2), and Hay (2) crs	Degraded floodplain, altered hydrology	Removal of wetlands	Abundance, productivity	Primarily eggs, fry and 0+	
Reconnect side channels and off-channel habitats to stream channels	Upper Rock (1), Rock (2), Middle Rock (2), Lone Rock (2), Thirtymile (2), Butte (1), Bridge (1), Kahler (2), Mountain (1), Pinehollow (2), Grass Valley (2), and Hay (2) crs	Degraded floodplain, altered hydrology	Removal of side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily eggs, fry and 0+	There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	Rock (2), Upper Rock (1), Middle Rock (2), Lone Rock (1), Thirtymile (2), Butte (1), Bridge (1), Kahler (1), Mountain (1), Pinehollow (1), Grass Valley (2), and Hay (2) crs	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity	Primarily eggs, fry and 0+	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain habitats	ODFW, watershed council, SWCD, USFS, BLM	Ongoing	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Restore wet meadows	TNC, USFS, CTWSRO	Ongoing and	Benefits of improved channel	Intermediate	5-15 years	Moderate

Strategy 3. Maintain and restore floodplain connectivity and function.						
		planned	morphology localized, improved water table and resulting increased streamflow and lower water temperatures have high dispersal downstream			
Reconnect side channels and off-channel habitats to stream channels	ODFW, watershed council, SWCD, USFS, BLM, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, because of widespread need	5-15 years, depending upon frequency and duration of channel altering flows	Moderate, depending upon how extensive the project is and frequency and duration of channel altering flows
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	ODFW, CTWSRO, USFS, BLM	ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, due to acceptance by landowners and widespread need	Within 5 years once the dams are built	Moderate-high, dependent upon acceptance by landowners

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	None completed to date	No	If specific needs cannot be addressed by passive restoration techniques, program underfunded
USFS, BLM	Stream enhancement program	Population-wide on Federal land, only when specifically identified that passive restoration is not working	Likely	The USFS/BLM preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
Watershed Councils	Watershed restoration	Population-wide	Dependent upon need and funding	Only if specific needs cannot be addressed by passive restoration techniques
Soil and Water Conservation Districts	Watershed restoration	Population-wide		See State of Oregon programmatic review -- Appendix F.
Nature Conservancy and other NGOs	Restoration projects	Population-wide	Uncertain	Yes
ODA	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.
CTWSRO, CTUIR	Watershed restoration	Pine Cr	Uncertain	Program could be expanded.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Rock (1), Upper Rock (2), Middle Rock (1),	Degraded channel	Stream channelization,	Abundance,	Primarily	Passive restoration techniques, such as

	Lone Rock (2), Thirtymile (2), Butte (2), Bridge (2), Kahler (2), Mountain (2), Pinehollow (1), Grass Valley (2), and Hay (2) crs	structure and complexity, habitat diversity, sediment routing, water temperature, flows	bank armoring, large wood removal, beaver removal, removal of riparian vegetation, livestock overgrazing in riparian areas	productivity	eggs, fry and 0+	riparian fencing, are the preferred method for improving channel structure and stability. More active restoration techniques may be appropriate in these reaches.
Place stable wood and other large organic debris in streambeds and in floodplains	Rock (2), Upper Rock (1), Middle Rock (2), Lone Rock (2), Thirtymile (1), Butte (1), Bridge (1), Kahler (1), Mountain (1), Pinehollow (2), Grass Valley (2), and Hay (2) crs	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal channelization	Abundance, productivity	Primarily eggs, fry and 0+	More active restoration techniques, such as rootwad placement or channel reconfiguration, may be appropriate in these reaches.
Stabilize streambanks	Rock (1), Upper Rock (2), Middle Rock (1), Lone Rock (2), Thirtymile (1), Butte (2), Bridge (2), Kahler (2), Mountain (2), Pinehollow (1), Grass Valley (2), and Hay (1) crs	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily eggs, fry and 0+	Some bank erosion is inevitable and beneficial. However, where erosion is actively taking place due to unnatural processes, stabilization may be needed to reduce fine sediments

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, USFS, BLM, watershed councils	Ongoing and planned	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Place stable wood and other large organic debris in streambeds and in floodplains	ODFW, USFS, watershed councils, BLM, SWCDs	As needed	For the immediate stream reach	Once identified, short term	Immediate	High
Stabilize streambanks	ODFW, USFS, watershed councils, BLM, SWCDs	Ongoing	For the treated stream reach, physical benefits dispersed downstream	Passive stabilization techniques are referred and take longer to implement	With passive restoration the response may take 15 years	Moderate to high, depending upon the extent of the treatments

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Only used where passive restoration has not been successful. To date, no structural work has been identified	Uncertain	If specific needs cannot be addressed by passive restoration techniques then program needs expansion.
USFS, BLM	Stream enhancement program	Only used where passive restoration has not been successful. To date, no structural work has been identified	Uncertain	The USFS/BLM preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. May need expansion in some areas. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
Watershed Councils	Watershed restoration	Only used where passive restoration has not been successful. To date, no structural work has been identified	Dependent upon need and funding	If specific needs cannot be addressed by passive restoration techniques needs expansion.
Soil and Water Conservation Districts	Watershed restoration	Only used where passive restoration has not been successful. To date, no structural work has been identified		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Only used where passive restoration has not been successful. To date, no structural work has been identified	Dependent upon need and funding	If specific needs cannot be addressed by passive restoration techniques needs expansion.

NGOs	Watershed restoration	Only used where passive restoration has not been successful. To date, no structural work has been identified	Dependent upon need and funding	If specific needs cannot be addressed by passive restoration techniques needs expansion.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Instream activities have not been identified as a high priority by the recovery planning team or the management action planning team except when identified as a need for specific sites. The planning team prefers that more passive approaches, such as riparian and upland improvements be emphasized. Typically, instream activities that would improve floodplain function and channel migration processes would include placement of rootwads, whole trees, or boulder clusters to improved habitat complexity and habitat diversity where those parameters are deficient and not expected to improve with passive restoration. Another structural activity would be to construct boulder or log weirs to raise the water table, but only where a passive approach has not worked. Currently little instream structure placement has been identified for this population. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	Lower John Day River mainstem below Cottonwood Bridge and above Service Cr (2); Rock Cr (2); Upper Rock (2); Middle Rock (2); Lone Rock (1); MaSAs (Gilliam Co) (2); Grass Valley Canyon (2); some reaches of Mountain Cr (Wheeler Co) (1); portions of Parrish Cr (1), Cherry Cr (1); some reaches of Kahler Cr (1), Ferry Cr (2), upper Hay Cr (2); portions of Bridge Cr (1), Thirtymile Cr (1), Horseshoe Cr (2), Johnson Cr(2), Butte Cr (1), Franks Cr (2), and upper reaches of Pine Hollow Canyon Cr (1)	Degraded riparian area, channel structure and complexity, floodplain degradation, altered hydrology, sediment, water quality	Livestock overgrazing of riparian area, channelization, stream bank armoring, cutting of trees in riparian areas, changes in plant communities (including invasive plants), loss of beaver dams	Abundance, productivity	Primarily fry and 0+	Primary methods of riparian enhancement include riparian corridor fences to exclude livestock, changes in grazing management that promote riparian recovery, and planting of native shrubs.
Develop grazing strategies that promote riparian recovery	Lower John Day River mainstem below Cottonwood Bridge and above Service Cr (2); Rock Cr (2), Upper Rock (1), Middle Rock (2), Lone Rock (1); MaSAs (Gilliam Co) (2), Grass Valley Canyon (2); some reaches of Mountain Cr (Wheeler Co) (1); portions of Parrish Cr (1), Cherry Cr (1); some reaches of Kahler Cr (1), Ferry Cr (2), upper Hay Cr (2); portions of Bridge Cr (1), Thirtymile Cr (1), Horseshoe Cr (2), Johnson Cr (2), portions of Butte Cr (1), Franks Cr (2), and upper reaches of Pine Hollow Canyon Cr (1)	Degraded riparian area, channel structure and complexity, floodplain degradation, altered hydrology, sediment, water quality	Livestock overgrazing of riparian area	Abundance, productivity	Primarily fry and 0+	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities including vegetative planting	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high	Long term because of widespread need	5-15 years, (see above)	High, based upon experience with existing grazing management

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
			dispersal downstream from site			and riparian recovery projects
Develop grazing strategies that promote riparian recovery	NRCS, AFS, USFS, BLM, SWCDs, ODFW, Watershed Councils, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, depending upon grazing plan adopted. Riparian corridor fencing and removal of riparian grazing has the fastest recovery rate.	High, based upon experience with existing grazing management and riparian recovery projects

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Alder, Squaw, Cottonwood, and Mountain crs	No	Program could be expanded.
SWCDs	Upland improvements, riparian improvements	Service, lower Rock, Lone Rock, Pinehollow, Grass Valley, Hay, Alder, Butte	Yes in some areas, no in others	Expansion would approve effectiveness.
Watershed Councils	Upland improvements, riparian improvements	Service, lower Rock, Lone Rock, Pinehollow, Grass Valley, Hay, Alder, Butte	No	Expansion in scope needed.
USFS, BLM	Upland improvements, riparian improvements	Lower John Day mainstem from Kimberly to Tumwater Falls, Cottonwood, Bridge, Thirtymile, Ferry, Hay, Squaw	Likely	Expansion in scope needed. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
NRCS	Upland improvements, riparian improvements	Pinehollow, Grass Valley, Ferry, Hay, Thirtymile, Butte	Yes	Program currently meeting objectives.
ODA	Agricultural Water Quality Management Program	All		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Pine Cr	Uncertain	Needs expansion.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

In the last 20+ years ODFW, Watershed Councils, NRCS and Soil and Water Districts have implemented hundreds of miles of riparian improvements on private lands, primarily through construction of riparian corridor fences that exclude livestock grazing and development of off channel watering devices. Public land managers have implemented PACFISH standards for protection and restoration of USFS and BLM lands. Even though hundreds of miles of riparian improvements have been completed there are many more miles of stream occupied by steelhead within the Lower Mainstem John Day population that need improvement. At the current rate of implementation it could take 50 years to complete restoration actions. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Bank stabilization using some rock is still infrequently occurring after high water events in the lower John Day River, primarily along irrigated pastures and on Rock Cr (Gilliam County). These bank stabilization projects have historically relied on riprap and large rock, however in recent years the high economic and ecological cost of bank armoring with riprap and of channelization has been recognized, so the emphasis has shifted toward a more passive approach for stabilization, primarily through riparian vegetation improvements. Overgrazing of riparian areas by livestock continues in some reaches; however it is not as widespread as historically. Interest by private landowners and public land managers in riparian improvement remains high.

Other projects that have been well accepted and will improve riparian condition are restoring historical cover types by removing juniper, reintroducing fire, enrollment into CREP, and control of invasive/noxious plants. Primary constraints on implementing additional projects for more riparian improvements are funding and personnel needed for planning, promotion, education of landowners, and implementation.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters	Life Stages	Discussion

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
				Addressed	Affected	
Implement agricultural water conservation measures	Rock (1), Bridge (1), Butte (2), Cherry (2), Big Muddy (2), Cottonwood (2), Rock/Mountain (1), Alder (2), lower Parrish (1), and Kahler (1)crs	Altered hydrology, low flows, high temperatures	Water withdrawals, land conversion on uplands, road network	Abundance, productivity	Eggs, fry and 0+	Rock, Bridge, Butte, Cherry, Big Muddy, Cottonwood, Rock/Mountain, Alder, lower Parrish, and Kahler crs are all affected by irrigation withdrawals.
Improve irrigation conveyance and efficiency	Rock (1), Bridge (1), Butte (2), Cherry (2), Big Muddy (2), Cottonwood (2), Rock/Mountain (1), Alder (2), lower Parrish (1), and Kahler (1) crs.	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Eggs, fry and 0+	Rock Cr is intermittent for the lower 29 miles due to extensive pumping for irrigation and several of its tributaries are dry during summer months in lower reaches.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	Grass Valley Canyon (2), Pinehollow Canyon (1), Rock (1), Bridge (1), Butte (1), Cherry (1), Big Muddy (2), Cottonwood (1), Rock/Mountain (1), Alder (2), Johnson (2), Horseshoe (2), Ferry (2), Hay (1), Thirtymile (1), Service (2), Parrish (1), and Kahler (1) crs	Low flows, high temperatures	Channel incision, loss of water table	Abundance, productivity	Fry and 0+	
Lease or acquire water rights and convert to instream water rights	Rock (1), Bridge (2), Butte (2), Cherry (2), Big Muddy (2), Cottonwood (2), Rock/Mountain (1), Alder (2), lower Parrish (1), and Kahler (1)crs	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Eggs, fry and 0+	
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Eggs, fry and 0+	Annual fluctuations in flow levels are intensified by irrigation withdrawals.
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Altered hydrology, low flows, high temperatures, impaired natural functions and processes on uplands, floodplains, riparian areas	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Eggs, fry and 0+	Changes in the upland plant community due to fire suppression, invasive plants, and conversion of bunch grass prairies to wheat fields have resulted in lower precipitation infiltration rates, which results in higher peak flows and lower low flows. Some tributaries are now dry where they join the John Day River. Removal of large wood and channelizing streams also increases water velocities and reduces the ability of the stream to hold water for gradual release. Restoring watershed function in Pinehollow Canyon will likely result in longer duration of surface flows.
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Implement agricultural water conservation measures.	SWCD, OWRD, watershed councils, NRCS	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights.
Improve irrigation conveyance and efficiency.	SWCD, OWEB, OWRD, watershed councils, NRCS, landowners	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights.
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	SWCD, ODFW, CTWSRO, USFS	Ongoing	High dispersal downstream	Long term	Immediate increase in instream flow, 5-15 years for full functional role	High
Lease or acquire water rights and convert to instream water rights.	OWRD, FSA, OWEB, Oregon Water Trust, others	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and highly dependent upon landowner willingness to lease.	Immediate	High, if the leased water is protected from being appropriated to a downstream user in areas with instream water rights. FSA pays higher rates for CREP enrollment when water rights are leased for instream use.
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion downstream to mouth of John Day River	Long term, dependent upon OWRD enforcing the requirement to measure water usage	Immediate	High if water user reporting requirement and installation of measuring devices on diversions is implemented.
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD, USFS, OWRD, OWEB, ODFW, CTWSRO, landowners	Ongoing	Population-wide	Intermediate	Up to 15 years	High
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate
Status of Existing Programs through which Actions are Implemented						
Agency/Organization	**Program Name**		**Geographic Locations**	**Sufficient* (yes, likely, uncertain, no)**	**Sufficiency Rationale**	
ODFW	BPA Habitat Program, riparian improvements		Alder, Cottonwood, Squaw, Rock/Mountain	No	Yes	

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.				
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Population-wide		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust, BOR	Leasing and Purchase of Water Rights	Lower John Day River near Twickenham, Pine Cr	Uncertain	Dependent on availability and funding.
Soil and Water Conservation Districts	Improve irrigation efficiency, upland improvements, riparian improvements	Butte, Pinehollow, Lower Mainstem John Day River below Service Cr		Could be expanded in some areas. See State of Oregon programmatic review -- Appendix F.
Watershed Councils	Upland improvements, riparian improvements	Most of Gilliam, Sherman, and parts of Wasco counties in dryland wheat country, juniper treatments in Wheeler County	No	Wheat field terracing, conversion to no-till, construction of sediment retention basins—could all be expanded in rate of implementation.
NRCS	Upland improvements, riparian improvements	Most of Gilliam, Sherman, and parts of Wasco counties in dryland wheat country, juniper treatments in Wheeler County	No	Wheat field terracing, conversion to no-till, construction of sediment retention basins, could all be expanded in rate of implementation.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Many landowners have converted from flood to sprinkler or gated pipe irrigation, which makes more efficient use of the water and grows more palatable forage, but there has not been an effective mechanism to protect saved water from being used by another irrigator downstream. Water measuring devices are just beginning to be required on irrigation withdrawals and while progress is being made there is considerable resistance from irrigators. Extensive work by Watershed Councils and NRCS in the Lower John Day has concentrated on preventing erosion of valuable topsoil by terracing wheat fields, building small sediment retention basins, enrollment of highly erodible soils into the CRP program, and using no-till planting techniques, all of which increases precipitation infiltration rates and reduces the rate of runoff. Other projects that will improve flow are restoring historical cover types by removing juniper, reintroducing fire, enrollment into CRP, and control of invasive/noxious plants. Primary constraints on implementing additional projects are funding, instream water rights that are junior to most irrigation rights, and water laws that sometimes conflict with conservation practices. Approximately 76 miles of stream in the lower John Day River are protected with either existing or pending instream water rights. The instream water rights do not preclude further appropriation of water until flows in the affected reach drop down to the instream water rights as adopted by OWRD. Voluntary efforts restored 25.5 cfs instream in 2006. US Bureau of Reclamation, as required in the Columbia River Biological Opinion, is required to identify and assist with passage improvement design and flow restoration. They have partnered with Oregon Water Trust on several water leases with one recent permanent acquisition of 10 cfs in the Middle Fork that will be left instream after July 20.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Increase riparian shading	Thirtymile (1), Rock (2), Butte (1), Service (2), Kahler (1), Parrish (1), Upper Rock (1), and Lone Rock (1) crs; upper Butte (1), Cottonwood (1), Squaw (2), Horseshoe (2), Johnson (2), Bridge (2), Ferry (2), Pinehollow (1), Grass Valley (2), Mountain (1), Kahler (1), Parrish (1), Cherry (1), Hay (1), Alder(1), and Shoefly (2)crs	High water temperatures	Degraded riparian forests	Abundance, productivity	Eggs, fry, 0+, adults	Elevated water temperature is the most pervasive water quality problem for the Lower John Day River population, with 13 stream reaches listed as water quality limited. Additional reaches would probably be listed if water temperature data were available.
Reduce chemical pollution inputs	None currently identified	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity	Eggs, fry, 0+, adults	

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Apply BMPs to animal feeding operations	Lower Rock Cr (1)	Degraded water quality	Animal feed operations	Abundance, productivity	Eggs, fry, 0+, adults	
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Degraded upland processes, floodplains, riparian areas, altered hydrology, altered sediment routing	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Eggs, fry, 0+, adults	Using efficient irrigation methods reduces the amount of surface water returning to the stream, and should result in fewer nutrients from pastures reaching the John Day River. Reducing nutrient loads will contribute to increased water quality by reducing biological oxygen demand and algae blooms.
Continue TMDL monitoring	Population-wide	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	Eggs, fry, 0+, adults	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Increase riparian shading	ODFW, Watershed Councils, SWCDs, USFS, BLM	Ongoing	water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years	High
Reduce chemical pollution inputs	ODEQ, others	Ongoing		Ongoing	Reduce chemical pollution immediately	High
Apply BMPs to animal feeding operations	ODA	Ongoing	Water quality improvement would have high dispersal downstream	Some treatments could be done immediately. There are few animal feeding operations within the subbasin, only one of which has been identified as a problem	5-15 years	High, once a treatment has been agreed upon
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD	Ongoing	Subbasin-wide, high dispersal downstream	Intermediate	Up to 15 years	High
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Subbasin-wide	Ongoing	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA	CREP, CRP	Gilliam, Sherman and portions of Wasco counties for CRP, Butte, lower Rock, Pinehollow, and Grass Valley tributaries for CREP	No	Program needs expansion, effective where applied.
ODA	Confined animal feeding operations (CAFO), Agricultural Water Quality Management Program	Rock Cr		See State of Oregon programmatic review -- Appendix F.
ODEQ, ODA, SWCD, USFS	Sedimentation Monitoring (TMDL Development and Implementation)	Population-wide		See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment—Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
Extensive grain fields in the Lower John Day River area have contributed to relatively high sediment loads in the lower river and tributaries. NRCS and FSA programs in this area (primarily CRP and terracing)) have been used extensively by landowners on the most erodible soils, but the removal of perennial grasses to plant annual crops still contributes unnatural levels of sediment. Other sources of sediment include relatively high road densities on forested lands. Low streamflows during the hottest part of the year exacerbate the already warm water temperatures. Opportunities for increasing streamflow through leasing of water rights, which often results in cooler water over a longer stream reach, are being pursued by Oregon Water Trust and US Bureau of Reclamation. Constraints for future projects include acceptance by landowners and a secure, long term funding source. ODA's Agricultural Water Quality Management Program is designed to prevent and control water pollution from agricultural activities and soil erosion on non-Federal and non-Tribal Trust or Reservation lands. ODA relies on voluntary measures to protect water quality, but also enforces pollution and streamside vegetation requirements. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Reducing water temperatures through the use of improved riparian vegetation and more efficient methods of irrigation may take several years to provide measurable results. Many projects that improve water quality by reducing irrigation return water have been completed.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Continue to promote no-till farming and other seeding techniques that reduce erosion where site conditions are suitable	Rock (1), Grass Valley (1), Ferry(1), Thirtymile (2), Pinehollow (2), Jackknife (2) crs,	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices, loss of water storage capacity	Productivity	Eggs, fry, and 0+	No till seeding has been used in much of Sherman and Gilliam counties, however, other economically viable alternatives that reduce erosion are desirable.
Restore native upland plant communities	Thirtymile (1), Rock (2), Butte (1), Service (2) , Kahler (2), Parrish (2), Upper Rock (2), and Lone Rock (1) crs, Pinehollow (1), Ferry(1), Horseshoe (2), Service (2), Squaw (2), Bridge (1),	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices, loss of water storage capacity	Productivity	Eggs, fry, and 0+	Upland improvements such as restoring native plant communities and controlling invasive weed species will improve precipitation infiltration rates and ultimately improve watershed health, including the hydrograph.
Upgrade or remove problem forest roads	Thirtymile (1), Upper Rock (2), Alder (2), Parrish (2)	Altered hydrology, sediment routing	Road network	Productivity	Eggs, fry, and 0+	
Initiate upland improvement demonstration projects	Thirtymile (2), Rock (2), Butte (2), Service (1), Kahler (1), Parrish (1), Upper Rock (1), and Lone Rock (2) crs	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Productivity	Eggs, fry, and 0+	
Manage vegetation, including juniper removal	Thirtymile (2), Rock (2), Butte (1), Service (2), Kahler (1), Parrish (1), Upper Rock (2), and Lone Rock (2) crs	Altered hydrology, sediment routing	Invasive plants	Productivity	Eggs, fry, and 0+	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Thirtymile (1), Rock (2), Butte (1), Service (2), Kahler (2), Parrish (1), Upper Rock (1), and Lone Rock (2) crs	Altered hydrology, sediment routing	Upland land use practices	Productivity	Eggs, fry, and 0+	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Continue to promote no-till farming and other seeding techniques that reduce erosion where site conditions are suitable	SWCD, NRCS	Ongoing	High dispersal downstream	Long Term	5-15 years	Moderate to high depending upon the rate of participation by landowners
Restore native upland plant communities	SWCD, USFS, BLM	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term	5-30 years	Moderate to high depending upon how severely impacted the sites are and how successful prescribed treatments are
Upgrade or remove problem forest roads	USFS, ODF	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff. Decommissioning may take many years	5-15 years	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Initiate upland improvement demonstration projects	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed
Manage vegetation, including juniper removal	USFS, BLM, NRCS, SWCDs, Watershed Councils	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Juniper control can be done relatively quickly, other strategies such as control of invasive plants may take more than 20 years	5-30 years	Moderate
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	SWCD, VSFS, ODA, CTWSRO, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of Agricultural Water Quality Management Plans	0-20 years, depending upon treatments applied	Moderate, dependent upon voluntary landowner participation

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
NRCS, Farm Service Agency	CRP	Lower and Middle Rock, Thirtymile, Grass Valley, Pinehollow, Ferry, and Butte crs	No	Program needs expansion, effective where applied.
SWCDs	Juniper control	Butte, Service, Bridge crs	Uncertain	More effective if expanded.
ODFW	Green Forage		Uncertain	Very small program, could be expanded.
USFS, BLM	Individual Forest or Area Management Plans, PACFISH	Bridge, Cottonwood, Lower John Day, Butte, Hay, Rock/Mountain, Upper Rock, and Kahler crs	Yes, but dependent on consistent implementation	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005).
ODA	Agricultural Water Quality Management Program	Population-wide		See State of Oregon programmatic review -- Appendix F.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Pine Cr	Yes, where implemented	More acreage needs to be treated.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Programs initiated by the NRCS, SWCDs and ODFW are relatively small, with the CRP program the largest and best funded. CRP has been in existence for 20 years and has been one of the better farm subsidy programs for watershed restoration. The CRP program has focused on the Lower John Day River (primarily below Thirtymile Cr) where dry land grain crops are grown and where significant acres of highly erodible soil exist. Juniper control programs have focused on areas where extensive juniper encroachment has occurred. Juniper control can be completed using several different methods, including controlled burns, cutting with chainsaws, or by removing with bulldozers or trackhoes. Although controlled burns are probably the most effective at controlling the spread of juniper, they are the most difficult to implement because of the threat of the fire getting out of control and costs. Another drawback to controlled burns is that livestock grazing should be excluded from burned areas for at least two growing seasons after the burn to ensure full recovery of desirable perennial grasses. There are opportunities to expand the juniper control program but the lack of a pasture to put livestock into for two years after burning has limited its acceptance. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize FS restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. The ODFW Green Forage program provides a wildlife seed mixture of native grasses and desirable forage to landowners who have recently completed juniper clearing projects, logging projects or other ground disturbing activities. The primary purposes are to provide additional forage for deer and elk and to reduce deer and elk damage complaints; however it also has benefits to watershed health by providing grasses that provide perennial ground cover. The limitations to all the programs are funding and, to a lesser extent, acceptance by landowners.				

9.3.6 Habitat Strategies and Actions for North Fork John Day River Steelhead Population

Primary limiting factors: Degraded channel structure and complexity (habitat quantity, diversity and channel stability), altered sediment routing, water temperature, altered hydrology, degraded floodplain function and connectivity.

Primary threats: riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, irrigation withdrawals, mining, and dredging.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition or conservation easements	Tributaries of the North Fork John Day River within the NF John Day Wilderness (1); North Fork John Day River, from Big Cr upstream to headwaters (1); Granite Cr (2); South Fork Desolation Cr (1); upper Clear Cr (1); upper Hidaway Cr. (2)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing	Many threats including livestock overgrazing of riparian area, mining, channelization, stream bank armoring, agricultural practices (fertilizers, herbicides, sediments, changes in plant communities), water withdrawals, loss of beaver dams	Abundance, productivity	All	Protection of high quality habitats is the most cost effective way of ensuring high quality habitat. It is much less expensive over the long term to protect high quality habitat than it is to degrade the habitat and then try to restore it. Land acquisitions, easements, and cooperative agreements facilitate protection.
Adopt and manage Cooperative Agreements	Cottonwood (1); Deer (1), and Rudio crs (2); North Fork John Day River, below Wall Cr (2)	Same as above	Same as above	Abundance, productivity	All	
Special management designations in forest and BLM plans	Recently acquired BLM parcels on the North Fork John Day River, between Monument and Camas Cr (1); areas identified in existing Forest Plans (2)	Same as above	Livestock overgrazing of some riparian areas, changes in plant communities	Abundance, productivity	All	
Designate additional wilderness and wild and scenic status	Those areas identified in the Umatilla National Forest Plan Revision and in the BLM Management Plan currently being developed (2)	Same as above	Livestock overgrazing of riparian area, changes in plant communities	Abundance, productivity	All	
Protect access to key habitats	The lower reaches of Hideaway (1), Cable (1), Desolation (1), Owens (2), Camas (2), Meadowbrook (2), Rudio (2), and Cottonwood (1) crs	Passage barriers, altered hydrology, channel structure		Abundance, productivity, distribution		Current state law requires ODFW to review any new or substantially modified structure with regard to fish passage. Potential still exists for access to be blocked by warm water temperatures and flow alterations. Channel structure may be severely modified by higher than natural flows.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	Population-wide	All	Same as above	Abundance, productivity	All	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements	CTUIR, TNC, RMEF, John Day Basin Trust, SWCDs	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5-15 years with passive restoration approaches	High, based on previous cooperative agreements
Adopt and manage Cooperative Agreements	ODFW, SWCDs, FSA	Ongoing	Same as above	Agreements are for 10-15 years	Long term	High, although not in perpetuity
Special management designations in forest and BLM plans	USFS, BLM	Ongoing as identified	Same as above	Many complete, potentially subject to change in Forest Plan revisions	Immediate and long term	High, although subject to change from Forest Plan or management plan revision
Designate additional wilderness and wild and scenic status	UDFS, BLM Oregon State Parks	Ongoing as identified	Water quality and flow improvements would have high dispersal downstream, stream corridor and function improvements confined to the specific site	Unknown	5-15 years	Unknown, subject to availability of areas that meet criteria
Protect access to key habitats	SWCDs, Watershed Councils, BLM, USFS	Ongoing	Immediate area only	Long term	5-15 years	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	NRCS, SWCDs, USFS, ODFW, ODF, DSL, BLM, ODOT, CTWSRO, ODA, FSA, private landowners	Ongoing	Population-wide	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS, BLM	Wilderness Areas, Wilderness Study Areas, Wild and Scenic River corridors, Special Management Area designations, PACFISH	FS and BLM lands for PACFISH, North Fork Wilderness, North Fork Wild and Scenic Corridor	Yes, PACFISH standards are good, but implementation is inconsistent between forests. See discussion below.	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODFW	Cooperative Agreements	Privately owned lands, Camas, Cottonwood/Fox, Granite creeks	No	The agreements are for only 10-15 years and need to be for longer timeframes.
FSA	CREP	Privately owned lands, primarily on Cottonwood/Fox Creek	No	The agreements are for only 10-15 years and need to be for longer timeframes.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
NGOs	Lease or purchase of lands	Cottonwood Creek conservation easement	Yes	Important to secure critical habitat and/or water rights.
ODA	Agricultural Water Quality Management Program	Private lands throughout the North Fork watershed		See State of Oregon programmatic review -- Appendix F.
CTUIR	Watershed Restoration	Camas and Desolation creeks	Uncertain	Needs expansion.
ODF	Oregon Forest Practices Act	Private and state owned lands		See State of Oregon programmatic review -- Appendix F.
Local Government	City and County Planning and Zoning	Private lands	Uncertain	Needs expansion.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The North Fork John Day River from Camas Cr (RM 57) to the headwaters (RM 112) is designated as a Federal Wild and Scenic River. The North Fork John Day from near Monument (RM 20) to the North Fork wilderness boundary (RM 76.5) is designated a State Wild and Scenic River. A wild and scenic designation requires development to be consistent with protecting the ORVs for which the river was designated, requires review of any activity that may affect ORVs within the ¼ mile river corridor, and protects the free flowing condition of the river. Designation as W&S essentially precludes construction of any major dam. A Management Plan was adopted by BLM and Oregon State Parks Department in 2001 for the designated rivers segments. Implementation of all the actions identified in the plan will likely take many years, however grazing management plans for most of the allotments within corridor are complete. All BLM allotments have grazing plans, except recently acquired lands. Wilderness areas within the boundaries of the North Fork population include the North Fork John Day Wilderness (85,000 acres). The primary rationale for designating the North Fork Wilderness was for protection of anadromous fish habitat. Adding additional wilderness areas and wild and scenic river segments would require designation by Congress. Implementation of PACFISH standards and guides for Forest and BLM programs, including grazing management, has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management programs remains challenging in a few locations. Cooperative and conservation agreements on private land are tools for protecting high quality habitats. ODFW has used cooperative agreements over the last 21 years to protect riparian corridors that have been fenced to exclude livestock grazing. Unfortunately those agreements are for only 15 years and there have not been funds or personnel needed to extend them for longer time periods. In the North Fork subbasin, a perpetual conservation agreement to prevent subdividing a 10,000 acre parcel is in place on Gilmore and Straight crs and includes approximately 3.3 miles of steelhead spawning and rearing habitat. See discussion for Strategy 1, Lower Mainstem John Day River population.				

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Remove or minimize use of push up dams	Cottonwood Cr/Fox drainage (1)	Impaired fish passage	Push up dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Push up dams are common in the Cottonwood Cr drainage. Passage problems at culverts are widespread throughout all subbasins. Annual maintenance and construction of push up dams contributes to onsite and downstream channel stability, loss of pools and other structure, and increased sediment loads.
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	For irrigation related passage issues: Cottonwood Cr/Fox drainage (1) For culverts: SF Trail, Meadowbrook (1), Upper Granite (2) crs	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Push up irrigation dams, concrete diversions, in-channel stock ponds, and road culverts are located throughout the entire subbasin.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Construct ladders over existing permanent concrete or earth fill dams, or remove the barrier	None currently identified	Impaired fish passage	Dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	A comprehensive barrier assessment has not been completed for all private lands, so there may be a few barriers that are not currently identified
Provide screening at 100% of irrigation diversions	Cottonwood/Fox Cr (1).	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry, juveniles, and smolts	All unknown existing screens meet criteria

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove or minimize use of push up dams	SWCD	Ongoing	Provide access to upstream habitat	Ongoing, but all push up dams not expected to be corrected for at least 15 years. A comprehensive barrier assessment has not bee completed.	Immediate	High, if comply with fish passage design criteria
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	USFS, watershed councils, SWCDs, ODOT	Ongoing	Access to upstream habitat	Ongoing, replacing all culverts blocking fish passage expected to take 50 years (see Appendix G)	Immediate	High, if comply with fish passage design criteria
Construct ladders over existing permanent concrete or earth fill dams	ODFW, SWCDs	Ongoing	Provide access to upstream habitat	Ongoing, providing passage at all diversion and pond barriers will take many years. A comprehensive barrier assessment has not bee completed.	Immediate	High if comply with fish passage design criteria
Provide screening at 100% of irrigation diversions	ODFW, SWCDs	Ongoing	At point of diversion	Approximately 3 diversions need to be screened	Immediate	High if comply with fish screening design criteria

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Soil and Water Conservation Districts	Irrigation dam improvements, culvert replacement or retrofits	Unscreened or poorly screened diversions throughout populations	Likely	The Grant Soil and Water District is constrained by the construction window of opportunity. Other counties could expand the program but are constrained by funding and personnel. See State of Oregon programmatic review – Appendix F.
ODFW	Fish Passage/Screening	Unscreened or poorly screened diversions throughout populations	No	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding. Rate of implementation needs accelerated.
USFS	Culvert replacement	Federally owned lands, Meadowbrook Creek	Uncertain	Based on total number of identified problem culverts on federal lands, will take about 50 years at current rate to complete culvert replacements. See comments below in Gaps section.
Watershed Councils	Road Crossing Passage improvements, passage improvements	Privately owned lands, primarily in North Fork John Day and tributaries below and including Wall Creek	No	Rate of implementation slow, technology sufficient to deal with threats.
ODOT	Culvert replacement or retrofit	State and Federal highway systems	Uncertain	See State of Oregon programmatic review – Appendix F.
BOR	John Day Basin Program	Privately owned lands as identified by SWCDs and Watershed Councils	Yes	Program rate sufficient.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.				
CTWSRO, CTUIR	John Day Basin Program	Privately owned lands, primarily in Camas, Desolation, and lower NF tributaries	No	The tribes contract with Soil and Water Districts to assist with consultation, permits, and monitoring; additional efforts needed to address problems in a timely manner.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Most of the mainstem passage problems have been addressed, but there are many tributaries where adult passage is blocked and more areas where juvenile passage problems occur. Irrigation dams, stock ponds, and road culverts are the primary causes of passage issues. Soil and Water Districts are correcting passage at irrigation diversions and improperly installed culverts, but are constrained by funding and by personnel needed for construction oversight. Watershed councils and ODOT, who are the principal entities working on culverts are constrained primarily by funding. An inventory of road crossings on federal lands indicates juvenile passage problems are pervasive, particularly on National Forests, with approximately 200 culverts not meeting passage criteria in this population. The BLM has no adult barriers at culverts. Monitoring is needed to determine if upstream passage for juveniles is an issue. The US Forest Service and BLM are constrained primarily by funding and the personnel needed for NEPA analysis. At the current rate of culvert replacements, it will take over 50 years to correct all passage problems on National Forests. Another constraint is that existing state laws do not require passage improvements at existing barriers unless there is a major change in the structure, such as reconstruction or significant modifications, so landowner cooperation is critical for improving passage throughout the subbasin.

The Malheur, Wallowa Whitman, Umatilla and Ochoco National Forests have culvert inventories for their lands. The Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005), provides guidance that will help prioritize culvert replacements for this population. ODFW has an inventory of culverts on state and county-owned roads. Appendix G presents an inventory of culverts with known passage problems on state, county, and USFS owned roads. The inventory shows there are three culverts on state owned roads and one culvert on county owned roads that do not meet fish passage criteria within the North Fork population boundary. There has not been an inventory of road culverts on private lands.

US Bureau of Reclamation, as required in the Columbia River Biological Opinion, is required to identify and assist with passage improvement design and flow restoration.

See discussion for ODFW Fish Passage and Screening program in Strategy 2, Lower Mainstem John Day River population.

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Camas Cr, from Wilkins Cr to Cable Cr (2), Owens Cr (1), Clear Cr below Ruby Cr (2), Beaver Cr below Olive Cr (1), Bull Run Cr (1), Crane Cr above Forest Rd 73 (2), lower Boulder Cr (Granite Cr trib) (2), Cottonwood Cr below EF Cottonwood (1)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily fry and 0+	
Reconnect side channels and off-channel habitats to stream channels and reconnect surface flow/restore fish passage in tributaries.	Camas Cr from Wilkins Cr to Cable Cr (2), Owens Cr (1), Clear Cr below Ruby Cr (1), Beaver Cr below Olive Cr (2), Bull Run Cr (1), Crane Cr above Forest Rd 73 (2), lower Boulder Cr (Granite Cr trib) (2), Cottonwood Cr below EF Cottonwood (1)	Degraded floodplain, altered hydrology	Removal of side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity, spatial structure	Primarily fry and 0+	There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows.
Restore wet meadows	Cottonwood/Fox, Granite (1), Owens (2), Camas from Wilkins Cr to Cable Cr (2), Upper Wilson Cr (1)	Degraded floodplain, altered hydrology	Removal of wetlands	Abundance, productivity	Primarily fry and 0+	
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	Camas Cr from Wilkins Cr to Cable Cr (1), Owens Cr (1), Clear Cr below Ruby Cr (2), Rudio (1), Wall (1), Wilson (2), Beaver Cr below Olive Cr (2), Bull Run Cr (2), Boulder Cr (2), Crane Cr above Forest Rd 73 (2), lower Boulder Cr (Granite Cr trib) (2), Cottonwood (1), Fox Cr (1)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity, spatial structure	Primarily fry and 0+	

Strategy 3. Maintain and restore floodplain connectivity and function.						
Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Reconnect floodplain to channel	ODFW, watershed council, SWCD, USFS, BLM	Ongoing	For the treated stream reach	Short term, once identified	Physical response will be immediate; biological response up to 5-10 years	High
Reconnect side channels and off-channel habitats to stream channels	ODFW, watershed council, SWCD, USFS, BLM, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, because of widespread need	5-15 years, depending upon frequency and duration of channel altering flows	Moderate, depending upon how extensive project is and frequency/duration of channel altering flows
Restore wet meadows	TNC, USFS, CTWSRO	Ongoing and planned	Benefits of improved channel morphology localized, improved water table and resulting increased streamflow and lower water temperatures have high dispersal downstream	Intermediate	5-15 years	Moderate
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	ODFW, CTWSRO, USFS, BLM	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, due to acceptance by landowners and widespread need	Within 15 years once the beavers are well established	Moderate-high, dependent upon acceptance by landowners

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	**Program Name**	**Geographic Locations**	**Sufficient* (yes, likely, uncertain, no)**	**Sufficiency Rationale**
ODFW	BPA Habitat Program	Cottonwood/Fox Creek, other privately owned lands when specifically identified	No	If specific needs cannot be addressed by passive restoration techniques then active measures taken. Program has limited resources.
USFS, BLM	Stream enhancement program	Granite Creek, NF John Day between Big and Desolation creeks for USFS and blocks of BLM on NF and tributaries between Camas Creek and Monument, but only when specifically identified that passive restoration is not working	Yes in some areas, no in others due to limited funding	The USFS/BLM preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	Private lands between Camas Creek and Kimberly	Uncertain	Dependent on future funding.
Soil and Water Conservation Districts	Watershed restoration	Private lands between Camas Creek and Kimberly		See State of Oregon programmatic review – Appendix F.
Nature Conservancy and other NGOs	Restoration projects	None currently identified, but may be opportunities in the future	Yes	Sufficiency yes when opportunities arise.
CTUIR	Watershed restoration	Camas Creek, Desolation Creek, and other privately owned lands	Uncertain	Program could be expanded.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Camas Cr, from Wilkins Cr to Cable Cr (1), Owens Cr (2), Clear Cr below Ruby Cr (1), Beaver Cr below Olive Cr (1), Bull Run Cr (1), Crane Cr above Forest Rd 73 (2), lower Boulder Cr (Granite Cr trib) (2), Cottonwood Cr below EF Cottonwood (1).	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature, flows	Stream channelization, bank armoring, large wood removal, beaver removal, removal of riparian vegetation, livestock overgrazing in riparian areas	Abundance, productivity	Primarily fry and 0+	Passive restoration techniques, such as riparian fencing, are the preferred method for improving channel structure and stability. More active restoration techniques may be appropriate in these reaches.
Place stable wood and other large organic debris in streambeds and in floodplains	Camas Cr (2), Owens Cr (2), Clear Cr (1) below Ruby Cr, Beaver Cr (1) below Olive Cr, Bull Run Cr (1), Crane Cr (2) above Forest Rd 73, lower Boulder Cr (1) (Granite Cr trib), Cottonwood/Fox Cr (1), Desolation Cr (2), Rudio (2)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	Large wood removal, channelization	Abundance, productivity	Primarily fry and 0+	More active restoration techniques, such as rootwad placement or channel reconfiguration, may be appropriate in these reaches when passive restoration techniques have not been successful
Stabilize streambanks	Camas Cr (1) from Wilkins Cr to Cable Cr, Owens Cr (2), Cottonwood Cr below EF Cottonwood (1).	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily eggs, fry and 0+	Some bank erosion is inevitable and beneficial. However, where erosion is actively taking place due to unnatural processes, stabilization may be needed to reduce fine sediments

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, USFS, BLM, watershed councils	Ongoing and planned	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Place stable wood and other large organic debris in streambeds and in floodplains	ODFW, USFS, watershed councils, BLM, SWCDs	As needed	For the immediate stream reach	Short term, once identified	Immediate	High
Stabilize streambanks	ODFW, USFS, watershed councils, BLM, SWCDs	Ongoing	For the treated stream reach, physical benefits dispersed downstream	Passive stabilization techniques are preferred and take longer to implement	With passive restoration the response may take 15 years	Medium to high, depending upon the extent of the treatments

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Cottonwood/Fox, Granite, Rudio, and Deer creeks, NF below Monument, but only when specifically identified that passive restoration is not working	No	Program has limited resources.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.				
USFS, BLM	Stream enhancement program	NF between Camas and Big Creek for USFS and BLM blocks between Kimberly and Camas Creek, but only when specifically identified that passive restoration is not working	Yes in some areas, no in others due to limited funding.	The USFS/BLM preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	NF between Wall Creek and Kimberly, Rudio, Cottonwood/Fox, and Deer creeks. Only when specifically identified that passive restoration is not working	Uncertain	Depends on availability of funds.
Soil and Water Conservation Districts	Watershed restoration	Granite Creek, NF John Day between Wall Creek and Kimberly. Only when specifically identified that passive restoration is not working		See State of Oregon programmatic review – Appendix F.
CTWSRO, CTUIR	Watershed restoration	Granite, Camas, and Desolation, Creeks. Only when specifically identified that passive restoration is not working	Uncertain	Funding future uncertain.
NGOs	Watershed restoration	None currently identified. Only when specifically identified that passive restoration is not working	Uncertain	No current activities.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Instream activities have not been identified as a high priority by the recovery planning team or the subbasin plan team except when identified as a need for specific sites. The planning team prefers that more passive approaches, such as riparian and upland improvements be emphasized. Typically, instream activities that would improve floodplain function and channel migration processes would include placement of rootwads, whole trees, or boulder clusters to improved habitat complexity and habitat diversity where those parameters are deficient and not expected to improve with passive restoration. Another structural activity would be to construct boulder or log weirs to raise the water table, but only where a passive approach has not worked. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	Rudio (2), Cottonwood below Fox Cr (1), Deerhorn (2), Jericho (2), Camas above Wilkins Cr (1), and Desolation from the mouth to Park Cr (2)	Degraded riparian area, channel structure and complexity, floodplain degradation, altered hydrology, sediment, water quality	Overgrazing of riparian area, channelization, stream bank armoring, tree harvest in riparian areas, changes in plant communities (including invasive plants), loss of beaver dams	Abundance, productivity	Primarily fry and 0+	Primary methods of riparian enhancement include riparian corridor fences to exclude livestock, changes in grazing management that promote riparian recovery, and planting of native shrubs.
Develop grazing strategies that promote riparian recovery	Rudio (2), Cottonwood below Fox Cr (1), Deerhorn (2), Jericho (2), Camas above Wilkins Cr (1), and Desolation from the mouth to Park Cr. (2), recently acquired BLM parcels on the North Fork John Day River, between Monument and Camas Cr (1)	Same as above	Livestock overgrazing of riparian area	Abundance, productivity	Primarily fry and 0+	

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities including vegetative planting	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years (see above)	High, based upon experience with existing grazing management and riparian recovery projects
Develop grazing strategies that promote riparian recovery	NRCS, AFS, USFS, BLM, SWCDs, ODFW, Watershed Councils, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, depending upon grazing plan adopted. Riparian corridor fencing and removal of riparian grazing has the fastest recovery rate.	High, based upon experience with existing grazing management and riparian recovery projects

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Cottonwood/Fox, Camas, and Granite creeks	No	Insufficient resources.
SWCDs	Upland improvements, riparian improvements	Private lands on Rudio, and Cottonwood creeks, NF John Day between Monument and Kimberly		May need additional resources. See State of Oregon programmatic review – Appendix F.
Watershed Councils	Upland improvements, riparian improvements	Private lands on Rudio, and Cottonwood creeks, NF John Day between Monument and Kimberly	No	Need additional resources.
USFS and BLM	Upland improvements, riparian improvements	NF John Day between Wall and Camas Creek for BLM and NF John Day and tributaries above and including Camas Creek for USFS	Uncertain	See USFS/BLM Program Sufficiency Assessment -- Appendix E and Regional Aquatic Restoration Strategy. See discussion in Gaps commentary below.
NRCS	Upland improvements, riparian improvements	Private lands on NF John Day below Wall Creek	Yes	Deemed sufficient.
ODA	Agricultural Water Quality Management Program	Private lands within the NF watershed		See State of Oregon programmatic review -- Appendix F.
CTUIR	Watershed restoration	Camas, Desolation, and Deer creeks on private land.	Uncertain	Limited by resources.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

See discussion for Strategy 5, Lower Mainstem John Day River population. Implementation of PACFISH standards and guides has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management programs remains challenging in a few locations. Forest Services's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	Cottonwood/Fox (1), lower Rudio Cr (1), Mainstem North Fork below Wall Cr (2)	Altered hydrology, low flows, high temperatures	Water withdrawals, land conversion on uplands, road network	Abundance, productivity	Fry and 0+	Cottonwood/Fox and lower Rudio Crs are the tributaries most affected by irrigation withdrawals. The mainstem North Fork below Wall Cr has numerous irrigation withdrawals, but warm water temperatures preclude steelhead from using for year long rearing.
Improve irrigation conveyance and efficiency	Cottonwood/Fox (1), lower Rudio Cr (1), Mainstem North Fork below Wall Cr (2)	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Fry and 0+	
Increase pool habitat (beaver ponds)	Cottonwood/Fox (1), Rudio (1), Granite (2), Olive (2), Clear (2), Owens (1), Desolation (2), Wilson (1), and Wall(1) crs, Camas Cr above Wilkins Cr (1)	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Fry and 0+	
Floodplain aquifer recharge	Camas Cr above Wilkins Cr (1)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	
Lease or acquire water rights and convert to instream	Cottonwood/Fox (1), lower Rudio Cr (2), Mainstem North Fork below Wall Cr (2)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	Annual fluctuations in flow levels are intensified by irrigation withdrawals
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Altered hydrology, low flows, high temperatures, impaired natural functions and processes on uplands, floodplains, riparian areas	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Fry and 0+	Changes in the upland plant community due to fire suppression, invasive plants, and conversion of bunch grass prairies to wheat fields have resulted in lower precipitation infiltration rates, which results in higher peak flows and lower low flows. Some tributaries are now dry where they join the John Day River. Removal of large wood and channelizing streams also increases water velocities and reduces the ability of the stream to hold water for gradual release.
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
incentive funding to develop strategies to meet long-term needs						
Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD, watershed councils, NRCS	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights
Improve irrigation conveyance and efficiency	SWCD, OWEB, watershed councils, NRCS, landowners	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights
Increase pool habitat (beaver ponds)	SWCD, ODFW, CTWSRO, USFS	Ongoing	High dispersal downstream	unknown	Immediate increase in instream flow	High
Floodplain aquifer recharge	CTWSRO, SWCDs	Planned, some ongoing	Potentially high dispersal from recharge project site downstream for many miles	Long term, although opportunities for pilot projects is dependent upon willing landowner	Immediate	High, if the additional water is protected from being appropriated to a downstream user in areas with instream water rights
Lease or acquire water rights and convert to instream	OWRD, FSA, OWEB, Oregon Water Trust, others	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and highly dependent upon landowner willingness to lease.	Immediate	High, if the leased water is protected from being appropriated to a downstream user in areas with instream water rights. FSA pays higher rates for CREP enrollment when water rights are leased for instream use.
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion downstream to mouth of John Day River	Long term, dependent upon OWRD enforcing the requirement to measure water usage	Immediate	High if water user reporting requirement and installation of measuring devices on diversions is implemented
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD, USFS, BLM, OWRD, OWEB, ODFW, CTWSRO, landowners	Ongoing	MaSAs	Intermediate	Up to 15 years	High
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program, riparian improvements	Private lands on Cottonwood/Fox, Rudio, Camas, and Granite creeks	No	Program has limited resources.
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Cottonwood/Fox, Rudio, NF John Day below Wall Creek and other streams with water withdrawals		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust and BOR	Leasing and Purchase of Water Rights	No existing sites identified	Uncertain	Depends on opportunities and funding.
Soil and Water Conservation Districts	Improve irrigation efficiency, upland improvements, riparian improvements	Cottonwood/Fox, Rudio, Deer and Granite creeks, and NF John Day below Wall Creek		See State of Oregon programmatic review – Appendix F.
Watershed Councils	Upland improvements, riparian improvements	Cottonwood/Fox, Rudio, Deer and Granite creeks, and NF John Day below Wall Creek	No	Program has limited resources and needs expansion.
NRCS	Upland improvements, riparian improvements	Cottonwood/Fox, Rudio, Deer and Granite creeks, and NF John Day below Wall Creek	No	Program needs expansion.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Approximately 170 miles of stream in the North Fork are protected with either existing or pending instream water rights. The instream water rights do not preclude further appropriation of water until flows in the affected reach drop down to the instream water rights as adopted by OWRD. Voluntary efforts restored 1.2 cfs instream in 2006. See discussion for Strategy 6, Lower Mainstem John Day River population.				

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Increase riparian shading	North Fork John Day River below Camas Cr (2), Camas Cr. (1), Lower Cottonwood Cr. (1), Rudio Cr. (1), Owens Cr. (1), lower reaches of Wall (2), Desolation(2), and Wilson (2) Crks.	High water temperatures	Degraded riparian forests	Abundance, productivity	Eggs, fry, juveniles, adults	Elevated water temperature is a pervasive water quality problem for the North Fork John Day River population, with 39 stream reaches listed as water quality limited. Additional reaches would probably be listed if water temperature data were available. Camas, Owens and Cottonwood crs and lower reaches of Wall, Desolation, and Wilson crs are relatively good producers of steelhead that are listed as water quality limited due to elevated water temperatures.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Manage return flow to reduce extreme stream temperatures	lower North Fork John Day River (2) Camas Cr. (1), Cottonwood Cr. (1), Rudio Cr. (1), Owens Cr. (2)	High water temperatures	Water withdrawals	Abundance, productivity	Eggs, fry, juveniles, adults	
Address contamination from mine related discharge	Granite Cr and tributaries (1)	Chemical contaminants	Heavy metal and mine waste pollution	Abundance, productivity	Eggs, fry, juveniles, adults	
Reduce chemical pollution inputs	None currently identified	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity	Eggs, fry, juveniles, adults	
Apply BMPs to animal feeding operations	None currently identified	Degraded water quality	Animal feed operations	Abundance, productivity	Eggs, fry, juveniles, adults	
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	Population-wide	Degraded upland processes, floodplains, riparian areas, altered hydrology, altered sediment routing	Degradation and conversion of uplands, floodplains, riparian areas	Abundance, productivity	Eggs, fry, juveniles, adults	While irrigation is not common in the North Fork, there are some opportunities to use more efficient irrigation methods, which reduces the amount of surface water returning to the stream, and result in fewer nutrients from pastures reaching the North Fork John Day River and its tributaries. Reducing nutrient loads will contribute to increased water quality by reducing biological oxygen demand and algae blooms.
Continue TMDL monitoring	Population-wide	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	Eggs, fry, juveniles, adults	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Increase riparian shading	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years	High
Manage return flow to reduce extreme stream temperatures	SWCDs, watershed councils	Ongoing	Water quality improvement would have high dispersal downstream	Less than 5 years, once the project has been identified	Immediate	High, reduced temperatures has been well documented
Address contamination from mine related discharge	ODEQ, USFS	Ongoing	Primarily in contaminated reaches, with intermediate dispersal downstream	Long term, although actual treatment may take only a matter of days.	Immediate in the specific stream reach.	High, although contingent upon adequate maintenance
Reduce chemical pollution inputs	ODEQ, others	Ongoing		Ongoing	Reduce chemical pollution immediately	High
Apply BMPs to animal feeding operations	ODA	Ongoing	Water quality improvement would have high dispersal downstream	Some treatments could be done immediately. There are few animal feeding operations within the subbasin, only one of which has been identified as a problem	5-15 years	High, once a treatment has been agreed upon

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Restore natural functions and processes through actions identified in strategies 1,3,4,5,8	SWCD, USFS, BLM	Ongoing	Subbasin-wide, high dispersal downstream	Intermediate	Up to 15 years	High
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Subbasin-wide	Ongoing	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA	CREP, CRP	Cottonwood/Fox, Rudio, and Camas creeks, NF John Day below Wall Creek	No	Program needs expanded.
ODFW	Riparian Enhancement Program	Cottonwood/Fox, Rudio, and Camas creeks.	No	Constrained by funding and personnel.
ODEQ	Mine Waste Program	Granite Creek		See State of Oregon programmatic review -- Appendix F.
ODA	Confined animal feeding operations (CAFO), AgWQM	None currently identified	Likely	See State of Oregon programmatic review -- Appendix F.
ODEQ, ODA, SWCD, USFS	Sedimentation Monitoring (TMDL Development and Implementation)	Watershed-wide		See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E and Regional Aquatic Restoration Strategy. See discussion in Gaps commentary below.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Heavy metal and other contaminants coming from historical and ongoing mining activity in the Granite Cr drainage has resulted in elevated levels of these contaminants found in sediments. ODFW biologists have observed dead fish and adult fish with gill lesions in the streams of this watershed. Although the cause of this mortality is not certain, elevated iron and heavy metal concentrations may be a contributing factor. Although recent surveys conducted by the UNF and U.S. Environmental Protection Agency (EPA) indicated that mercury was not present in high enough concentrations known to cause these types of effects, conditions at abandoned mine sites and abatement ponds may change yearly, increasing the amount of heavy metals released (NMFS 2004/0008). Low stream flows during the hottest part of the year exacerbate the already warm water temperatures. Opportunities for increasing streamflow through leasing of water rights, which often results in cooler water over a longer stream reach, are being pursued by Oregon Water Trust and US Bureau of Reclamation. Constraints for future projects include acceptance by landowners and a secure, long term funding source. Forest Services's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize stream enhancement actions for this population, and helps deploy limited active restoration funding for riparian planting where it is most needed.

Reducing water temperatures through the use of improved riparian vegetation and more efficient methods of irrigation may take several years to provide measurable results. Many projects that improve water quality by reducing irrigation return water have been completed.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore native upland plant communities	Cottonwood/Fox Cr (1), upper Rudio Cr (1), Deer Cr (1), Wilson Cr (2), Wall Cr (2).	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices, loss of water storage capacity	Abundance, productivity	Eggs, fry, and 0+	Upland improvements such as restoring native plant communities and controlling invasive weed species will improve precipitation infiltration rates and ultimately improve watershed health, including the hydrograph.
Upgrade or remove problem forest roads	Upper North Fork John Day River and tributaries above and including Trail Cr (1), Wilson Cr (2),	Same as above	Road network	Abundance, productivity	Eggs, fry, and 0+	

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
	Upper Camas Cr tributaries (2), Clear Cr and tributaries (1), Granite Cr (2)					
Initiate upland improvement demonstration projects	Population-wide	Same as above	Upland land use practices	Abundance, productivity	Eggs, fry, and 0+	
Manage vegetation, including juniper removal	Cottonwood/Fox Cr (1), upper Rudio Cr (2), Deer Cr (2), Wall Cr (1), Wilson Cr (2)	Altered hydrology, sediment routing	Invasive plants	Abundance, productivity	Eggs, fry, and 0+	
Demonstration projects to restore forest health and resilience to wildfire	Private and state forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road management and agricultural practices	Population-wide	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	Eggs, fry, and 0+	Suppression of fires over the last 80 years has contributed to higher than normal tree densities and increased threat of high intensity fires. High intensity fires have greater potential for damaging watershed function than lower intensity fires. There are areas on National Forest lands that have degraded conditions due to fire suppression, but they are difficult to quantify.

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore native upland plant communities	SWCD, USFS, BLM	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term		
Upgrade or remove problem forest roads	USFS, ODF, ODOT	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff. Decommissioning may take many years	5-15 years	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Initiate upland improvement demonstration projects	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	unknown, depends upon action taken as a result of being more informed
Manage vegetation, including juniper removal	USFS, BLM, NRCS, SWCDs, Watershed Councils	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Juniper control can be done quickly, other strategies such as control of invasive plants may take more than 20 years	5-30 years	Moderate
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to forest practices including fuels management and fire suppression mitigation, livestock grazing, road	SWCD, USFS, BLM, ODA, CTWSRO, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of Agricultural Water Quality Management Plans	0-20,years, depending upon treatments applied	Moderate, dependent upon voluntary landowner participation

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
management and agricultural practices						
Status of Existing Programs through which Actions are Implemented						
Agency/Organization	**Program Name**	**Geographic Locations**	**Sufficient* (yes, likely, uncertain, no)**	**Sufficiency Rationale**		
NRCS, Farm Service Agency	CRP	Rudio, Lower Cottonwood, NF John Day below Wall Creek	No	Needs expansion.		
SWCDs	Juniper control	Rudio and Cottonwood creeks	No	Needs expansion.		
ODFW	Green Forage	Rudio and Cottonwood creeks	No	Very small program.		
USFS, BLM	Forest Plan, Resource Management Plan, PACFISH	All FS/BLM lands throughout watershed	Likely	See USFS/BLM Program Sufficiency Assessment -- Appendix E and Regional Aquatic Restoration Strategy. See discussion in Gaps commentary below.		
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review -- Appendix F.		
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.		
ODA	Agricultural Water Quality Management Program	Private lands throughout the watershed		See State of Oregon programmatic review -- Appendix F.		
CTUIR	Watershed Restoration	Camas and Desolation creeks on private lands	Uncertain	Limited resources.		
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)						
See discussion for Strategy 8, Lower Mainstem John Day River population. Implementation of PACFISH standards and guides (BMPs) to Forest and BLM programs, has been highly successful for passive upland restoration over most of this population's area. Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize active watershed restoration for this population, and helps deploy limited active watershed restoration funding where it is most needed.						

9.3.7 Habitat Strategies and Actions for Middle Fork John Day River Steelhead Population

Primary limiting factors: degraded channel structure and complexity (habitat quantity and diversity), degraded floodplain function and connectivity, altered sediment routing, altered hydrology, and water temperature.

Primary threats: riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, passage barriers, irrigation withdrawals, mining, and dredging.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition or conservation easements	Upper reaches of Big, Big Boulder, and Granite Boulder crs that originate in the Vinegar Hill-Indian Rock Scenic Area (1); Other areas with high potential for protection once they are restored include the Middle Fork mainstem from Ragged Cr to the upper end of Phipps Meadow (2), and streams that drain the north side of Dixie Butte -- Davis (2), Butte (2), Placer Gulch (2), and Greenhorn (2) crs.	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing,	Many threats including livestock overgrazing of riparian area, channelization, stream bank armoring, agricultural practices (fertilizers, herbicides, sediments, changes in plant communities), water withdrawals, loss of beaver dams	Abundance, productivity	All	Protecting base streamflows from further appropriations is a very important function of protecting existing high quality habitats. Protection of high quality habitats is the most cost effective way of ensuring fish have good quality habitat. Land acquisitions, easements, and cooperative agreements may also facilitate the implementation of active restoration projects.
Adopt and manage Cooperative Agreements	Middle Fork between Placer Gulch and Caribou Cr (1); through Phipps Meadow (1), from Ragged to Tincup Cr (1), from Paradise Canyon to below Lick Cr.(2), Granite Cr (2)	Same as above	Same as above	Abundance, productivity	All	
Special management designations in forest and BLM plans	Riparian Habitat Conservation Areas identified in existing Forest Plans	Same as above	Same as above	Abundance, productivity	All	
Designate additional wilderness and wild and scenic status	Public lands identified in the Forest Plan Revision process	Same as above	Same as above	Abundance, productivity	All	
Protect and conserve rare and unique functioning habitats	Phipps Meadow (1)	Same as above	Same as above	Abundance, productivity	All	It is much less expensive over the long term to protect high quality habitat than it is to degrade the habitat and then try to restore it.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Protect access to key habitats	None identified at this time, although ODFW periodically reviews proposals that could block passage into spawning and rearing habitat.	Passage barriers, altered hydrology, channel structure	High water temperatures, low flow, channelization	Abundance, productivity, distribution	All	Thoroughly review projects that may block fish passage. Current ODFW policy is to grant exemptions from fish passage requirements only if mitigation meets or exceeds the loss of habitat. Exemptions must be approved by the Fish and Wildlife Commission.
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	Population-wide	All	Same as in first cell above	Abundance, productivity	All	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements	CTUIR, TNC, RMEF, John Day Basin Trust, SWCDs	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5-15 years with passive restoration approaches	High, based on previous cooperative agreements
Protect and conserve rare and unique functioning habitats	Land trusts, CTWSRO, ODFW, SWCD, NGOs, USFS	Ongoing	Same as above	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5-15 years with passive restoration approaches	High, based on previous cooperative agreements
Adopt and manage Cooperative Agreements	ODFW, SWCDs, FSA	Ongoing	Same as above	Agreements are for 10 to 15 years	Immediate	High, although not in perpetuity
Special management designations in forest and BLM plans	USFS, BLM	Ongoing as identified	Same as above	Subject to Forest Plan Revision timeframe for designation	Immediate	High, although subject to change from Forest Plan or mgmt plan revision
Designate additional wilderness and wild and scenic status	Public lands identified in the Forest Plan Revision process	Same as above	Same as above	Intermediate, depending on socio-political acceptance	5-15 years	High if designated
Protect access to key habitats	ODFW, USFS, BLM, Watershed Councils, SWCDs	Ongoing	Same as above	Immediate	Immediate	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	NRCS, SWCDs, USFS, ODFW,ODF, DSL, BLM, ODOT, CTWSRO, ODA, FSA, private landowners	Ongoing	Population-wide	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS/ BLM	Wilderness Areas, Wilderness Study Areas, Wild and Scenic River corridors, Special Management designations, PACFISH	Indian Rock/Vinegar Hill Scenic Area and buffers on FS and BLM lands	Yes, PACFISH standards are good, but implementation is inconsistent between forests. See discussion below.	See USFS/BLM Program Sufficiency Assessment -- Appendix E.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
ODFW	Cooperative Agreements	Middle Fork private lands with cooperative agreements, Camp Creek and Phipps Meadows	No	The agreements are for only 10-15 years and need to be longer.
FSA	CREP	Middle Fork on Oxbow and Forrest Ranch properties owned by CTWRSO	No	The agreements are for only 10 or 15 years and need to be longer.
NGOs	Lease or purchase of lands or instream water rights	Conservation easement on Middle Fork John Day RPB property and The Nature Conservancy Middle Fork Preserve	Yes	Important to secure critical habitat and/or water rights as additional opportunities arise.
ODA	Agricultural Water Quality Management Program	Private lands		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Oxbow and Forrest Ranch properties and other private lands	Likely	Could be expanded to include other areas.
ODF	Oregon Forest Practices Act	Private and state owned timber lands		See State of Oregon programmatic review -- Appendix F.
Local Government	City and County Planning and Zoning	Private lands	Uncertain	

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

The John Day River has 317 miles designated as State Wild and Scenic. State designated reaches include the Middle Fork John Day River from its mouth to Crawford Cr Bridge (RM 71). The Indian Rock Vinegar Hill Scenic Area in the Malheur and Umatilla National Forests is managed primarily for its scenic value, which offers good protection for watershed and fish habitat parameters. Adding addit ional wilderness areas and wild and scenic river segments would require designation by Congress.

Cooperative and conservation agreements on private land are tools for protecting high quality habitats. ODFW has used cooperative agreements over the last 21 years to protect riparian corridors that have been fenced to exclude livestock grazing. Unfortunately those agreements are for only 15 years and there have not been funds or personnel needed to extend them for longer time periods. Over 120 miles of stream throughout the subbasin have been protected under this program. Additional opportunities will be limited by availability of funds and by willingness of landowners to sign conservation easements and/or agreements.

Conservation agreements and acquisitions by conservation organizations are another recently used tool that can protect high quality habitat. The Middle Fork John Day River has five parcels with conservation easements or conservation organizations as the owners. A perpetual riparian conservation agreement restricting development and grazing is currently in place on a 310 acre private parcel in the Middle Fork near river mile 40. Another conservation property is the Nature Conservancy Dunstan Preserve (approx. 1,200 acres) near RM 50. It is managed primarily for fish benefits. The Oxbow Conservation Area (1,022 acres) and the Forrest Conservation Area (approx 867 acres) both owned by the Confederated Tribes of the Warm Springs Reservation of Oregon are managed as mitigation for the loss of fish and wildlife habitat associated with hydroelectric development on the Columbia River. Another privately owned parcel has a perpetual water lease agreement to prevent water withdrawals after July 20, which will result in approximately 10 cfs being left in the stream, primarily for the benefit of salmon and steelhead.

Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management programs remains challenging in some locations.

See discussion for Strategy 1, Lower Mainstem John Day River population.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	**Geographic Locations (1-first priority, 2-second priority)**	**Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Remove or minimize use of push up dams	Long Cr and tributaries (1)	Impaired fish passage	Push up dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Annual maintenance and construction of push up dams contributes to onsite and downstream channel stability, loss of pools and other structure, and increased sediment loads.
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	Irrigation or water storage related issues: Long Cr and tributaries (1) Culverts: Camp (2), Long (1), Vinegar (2), Butte (1), Crawford (2), Granite Boulder (1), and Little Boulder (1) crs	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Push up irrigation dams, concrete diversions, in-channel stock ponds, and road culverts are located throughout the entire subbasin. Passage problems at culverts are widespread throughout all subbasins.
Construct ladders over existing permanent concrete or earth fill dams (complete barrier inventory)	None identified	Impaired fish passage	Dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	A comprehensive survey of all barriers has not been completed, BOR has completed an aerial survey, but has not field verified the potential barriers identified in the aerial survey.
Replace screens that do not meet criteria	Beaver (2), Big, Butte (2), Granite Boulder (2), Long (1), MF John Day (1)	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry	All known diversions in the Middle Fork are currently screened. Most screens within the Middle Fork population boundaries have been replaced to address new criteria to reduce entrainment of emergent fry and bull trout. Priority areas identified where additional upgrades needed.

Action Implementation						
Actions	**Implementing Entity**		**Spatial Coverage**	**Implementation Timeframe**	**Expected Biophysical Response Timeframe**	**Certainty of Outcome**
Remove or minimize use of push up dams (complete comprehensive survey)	SWCD	Ongoing	Provide access to upstream habitat	Ongoing, but all push up dams not expected to be corrected for at least 15 years. A comprehensive survey has not been completed.	Immediate	High, if comply with fish passage design criteria
Remove or replace barriers blocking passage -- dams, road culverts and irrigation structures	USFS, BLM, watershed councils, SWCDs, ODOT	Ongoing	Access to upstream habitat	Ongoing, replacing all culverts blocking fish passage expected to take 50 years. See Appendix G.	Immediate	High, if comply with fish passage design criteria
Construct ladders over existing permanent concrete or earth fill dams	ODFW, SWCDs	Ongoing	Provide access to upstream habitat	Ongoing, providing passage at all diversion and pond barriers will take many years.	Immediate	High if comply with fish passage design criteria
Replace screens that do not meet criteria	ODFW	Ongoing	At point of diversion	Approximately 14 diversions need to be replaced, should take - years	Immediate	High if comply with fish passage design criteria

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.				
Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Soil and Water Conservation Districts	Irrigation dam improvements, culvert replacement or retrofits	Middle Fork John Day, Big Boulder Creek, and other private lands		The Grant Soil and Water District is constrained by the construction window of opportunity. Other counties could expand the program but are constrained by funding and personnel. See State of Oregon programmatic review -- Appendix F.
ODFW	Fish Passage/Screening	Private lands throughout the MF watershed, Bridge Creek	No	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding.
USFS	Culvert replacement	Federal lands, and specifically Granite Boulder and Beaver creeks. See Appendix G for list of the 223 culverts needing replacement.	No	Limited resources result in slow progress and long timeline for completion.
Watershed Councils	Road Crossing Passage improvements, passage improvements	Butte and Bridge creeks, others as identified in Appendix G.	No	Needs additional resources.
ODOT	Culvert replacement or retrofit	Bridge Creek, Summit Creek, Clear Creek		See State of Oregon programmatic review -- Appendix F.
BOR	John Day Basin Program	Private lands throughout the MF watershed as identified by SWCD or Watershed Council.	Yes	Program sufficient.
CTWSRO	John Day Basin Program	Oxbow and Forrest Ranch properties and other private lands as later identified.	No	The tribe contracts with Soil and Water Districts to assist with consultation, permits, and monitoring. Additional resources needed.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Most of the mainstem passage problems have been addressed, but there are many tributaries where adult passage is blocked and more areas where juvenile passage problems occur. Irrigation dams, stock ponds, and road culverts are the primary causes of passage issues. Soil and Water Districts are correcting passage at irrigation diversions and improperly installed culverts, but are constrained by funding and by personnel needed for construction oversight. An inventory of road crossings on state and county roads in 1999 indicated 14 culverts on state owned roads and 4 culverts on county owned roads did not meet fish passage criteria within the Middle Fork population boundary. Appendix G presents an inventory of culverts with known passage problems on state, county, and USFS owned roads. Some culverts have been replaced with structures that do meet the fish passage criteria, but much work remains. Watershed councils and ODOT, who are the principal entities working on culverts are constrained primarily by funding. An inventory of road crossings on federal lands indicates juvenile passage problems are pervasive, particularly on National Forests, with approximately 223 culverts not meeting passage criteria in this population. The US Forest Service and BLM are constrained primarily by funding and the personnel needed for NEPA analysis. At the current rate of culvert replacements, it will take over 50 years to correct all passage problems on National Forests, however, the Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005), provides guidance that will help prioritize culvert replacements for this population. The BLM has no adult barriers at culverts. Monitoring is needed to determine if upstream passage for juveniles is an issue. Another constraint is that existing state laws do not require passage improvements at existing barriers unless there is a major change in the structure, such as reconstruction or significant modifications, so landowner cooperation is critical for improving passage throughout the subbasin. See discussion for Strategy 2, Lower Mainstem John Day River population.				

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Upper mainstem Middle Fork from Big Cr upstream to Idaho Cr (1), Lower Vinegar (2), Vincent (2), and	Degraded floodplain, altered hydrology,	Removal of wetlands, side channels, off-stream	Abundance, productivity	Primarily, fry and 0+	

Strategy 3. Maintain and restore floodplain connectivity and function.						
	Long (1) crs	altered sediment routing, degraded water quality	habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams			
Reconnect side channels and off-channel habitats to stream channels	Upper mainstem Middle Fork from Big Cr upstream to Idaho Cr (1), Lower Vinegar (2), Vincent (2), and Long (1) crs	Degraded floodplain, altered hydrology	Removal of side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity, spatial structure	Primarily, fry and 0+	There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows.
Restore wet meadows	Long Cr (2), Phipps Meadow (1), Middle Fork between Ragged Cr and Phipps Meadow (1), Flood Meadow (2), Keeney Meadow (2), Camp Cr (1) Coxie Meadow (2)	Degraded floodplain, altered hydrology	Removal of wetlands	Abundance, productivity	Primarily, fry and 0+	
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	Upper mainstem Middle Fork from Big Cr upstream to Idaho Cr (2), Lower Vinegar (2), Vincent (2), and Long crs (1), Camp Cr (1), Placer Gulch (1), Davis Cr (1), Indian Cr (2)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity, spatial structure	Primarily, fry and 0+	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain to channel	ODFW, watershed council, SWCD, USFS, BLM	Ongoing	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Reconnect side channels and off-channel habitats to stream channels	ODFW, watershed council, SWCD, USFS, BLM, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, because of widespread need	5-15 years, depending upon frequency and duration of channel altering flows	Moderate, depending upon how extensive the project is and frequency and duration of channel altering flows
Restore wet meadows	TNC, USFS, CTWSRO	Ongoing and planned	Benefits of improved channel morphology localized, improved water table and resulting increased stream flow and lower water temperatures have high dispersal downstream	Intermediate	5-15 years	Moderate
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	ODFW, CTWSRO, USFS, BLM	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, due to acceptance by landowners and widespread need	Within 5 years once the dams are built	Moderate-high, dependent upon acceptance by landowners

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Private lands throughout the MF watershed, Phipps Meadow, Rush Creek, and Eightmile Creek	No	Program limited primarily by funding.

Strategy 3. Maintain and restore floodplain connectivity and function.				
USFS/BLM	Stream enhancement program	Federal lands, Middle Fork John Day, Summit Creek. Only when specifically identified that passive restoration is not working.	Yes in some areas, no in others due to limited funding	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	Private lands throughout the MF Watershed, Rush Creek has been specifically identified	Uncertain	Active restoration only if specific needs cannot be addressed by passive restoration techniques, need additional resources.
Soil and Water Conservation Districts	Watershed restoration	Private lands throughout the MF Watershed		See State of Oregon programmatic review -- Appendix F.
Nature Conservancy and other NGOs	Restoration projects	TNC Middle Fork Preserve and conservation easement on RPB property	Yes where applied	Program could expand to other priority areas.
CTWRSO	Watershed restoration	Oxbow and Forrest Ranch properties	Likely	Program could expand.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Instream activities have not been identified as a high priority by the recovery planning team or the subbasin plan team except when identified as a need for specific sites. The planning team prefers that more passive approaches, such as riparian and upland improvements be emphasized. Typically, instream activities would include placement of rootwads, whole trees, or boulder clusters to improved habitat complexity and habitat diversity where those parameters are deficient and not expected to improve with passive restoration. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Upper mainstem Middle Fork from Big Cr upstream to Idaho Cr (1), Lower Vinegar (2), Vincent (2), and Long (2) crs Channel reconfiguration work needed: mouth of Granite Boulder Cr to Ragged Cr (1), between Big Boulder Cr and Camp Cr (1), between Elk Cr and Bear Cr (2), and near the mouth of Mosquito Cr (1); Rush Cr (2)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature, flows	Stream channelization, bank armoring, large wood removal, beaver removal, removal of riparian vegetation, livestock overgrazing in riparian areas	Abundance, productivity	Primarily, fry and 0+	Passive restoration techniques, such as riparian fencing, are the preferred method for improving channel structure and stability. More active restoration techniques may be appropriate in these reaches. Historical dredge mining in several reaches of the mainstem Middle Fork between Caribou Cr and Mosquito Cr has simplified the stream channel. The North Fork Watershed Council is working with a landowner to restore channel sinuosity on Rush Cr.
Place stable wood and other large organic debris in	Upper mainstem Middle Fork from Big Cr upstream to Idaho Cr (1), Lower Vinegar (2),	Degraded channel structure and complexity,	large wood removal channelization	Abundance, productivity	Primarily, fry and 0+	More active restoration techniques, such as rootwad placement or channel

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.						
streambeds and in floodplains	Vincent (2), and Long (2) crs; Big Boulder Cr (1), Rush Cr (2)	habitat diversity, sediment routing, water temperature				reconfiguration, may be appropriate in these reaches.
Stabilize streambanks	Upper mainstem Middle Fork from Big Cr upstream to Idaho Cr (1),Lower Vinegar (2), Vincent (2), and Long (2) crs	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily eggs, fry and 0+	Some bank erosion is inevitable and beneficial. However, where erosion is actively taking place due to unnatural processes, stabilization may be needed to reduce fine sediments

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, USFS, BLM, watershed councils	Ongoing and planned	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Place stable wood and other large organic debris in streambeds and in floodplains	ODFW, USFS, watershed councils, BLM, SWCDs	As needed	For the immediate stream reach	Once identified, short term	Immediate	High
Stabilize streambanks	ODFW, USFS, watershed councils, BLM, SWCDs	Ongoing	For the treated stream reach, physical benefits dispersed downstream	Passive stabilization techniques are preferred and take longer to implement	With passive restoration the response may take 15 years	Medium to high, depending upon the extent of the treatments

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Big Boulder Creek and those specifically identified as deficient in habitat diversity	No	Program could expand, approach sufficient.
USFS, BLM	Stream enhancement program	Those streams specifically identified as deficient in habitat diversity	Yes in some areas, no in others due to limited funding	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	Those streams specifically identified as deficient in habitat diversity	Uncertain	Restricted by resources, approach sufficient.
Soil and Water Conservation Districts	Watershed restoration	Those streams specifically identified as deficient in habitat diversity		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	Big Boulder Creek and those specifically identified as deficient in habitat diversity	Uncertain	Scope of program limits success, approach sufficient.
NGOs	Watershed restoration	TNC Middle Fork Preserve and RPB conservation easement property	Uncertain	

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Instream activities have not been identified as a high priority by the recovery planning team or the subbasin plan team except when identified as a need for specific sites. The planning team prefers that more passive approaches, such as riparian and upland improvements be emphasized. Typically, instream activities that would improve floodplain function and channel migration processes would include placement of rootwads, whole trees, or boulder clusters to improved habitat complexity and habitat diversity where those parameters are deficient and not expected to improve with passive restoration. Another structural activity would be to construct boulder or log weirs to raise the water table, but only where a passive approach has not worked.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.
The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	Mainstem Middle Fork John Day between Crawford and Bridge crs (1), between Horse and Camp crs (1), below Highway 395 (2); and Long (1), Slide (2), Eightmile (2), Sixmile (2), Twelvemile (2), Granite (2), Camp (!), and Crawford (2) crs	Degraded riparian area, channel structure and complexity, floodplain degradation, altered hydrology, sediment, water quality	Overgrazing of riparian area, channelization, stream bank armoring, tree harvest in riparian areas, changes in plant communities (including invasive plants), loss of beaver dams	Abundance, productivity	Primarily fry and 0+	Primary methods of riparian enhancement include riparian corridor fences to exclude livestock, changes in grazing management that promote riparian recovery, and planting of native shrubs.
Develop grazing strategies that promote riparian recovery	Mainstem Middle Fork John Day between Crawford and Bridge crs (1), between Horse and Camp crs (1), below Highway 395 (2); and Long (1), Slide (2), Eightmile (2), Sixmile (2), Twelvemile (2), Granite (2), Camp (!), and Crawford (2) crs	Same as above	Livestock overgrazing of riparian area	Abundance, productivity	Primarily fry and 0+	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities including vegetative planting	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, (see above)	High, based upon experience with existing grazing management and riparian recovery projects
Develop grazing strategies that promote riparian recovery	NRCS, AFS, USFS, BLM, SWCDs, ODFW, Watershed Councils, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years, depending upon grazing plan adopted. Riparian corridor fencing and removal of riparian grazing has the fastest recovery rate.	High, based upon experience with existing grazing management and riparian recovery projects

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Big Boulder Creek, MF John Day,	No	Program limited by funding.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.				
		Phipps Meadow		
SWCDs	Upland improvements, riparian improvements	Private lands throughout the watershed		Could be expanded.
Watershed Councils	Upland improvements, riparian improvements	Eightmile and Rush Creek, and others as later identified	No	Limited by resources, approach sufficient.
USFS/BLM	Upland improvements, riparian improvements	Federal lands, Long Creek specifically identified	Uncertain	Funding is limited. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
NRCS	Upland improvements, riparian improvements	Private lands as identified by SWCD and Watershed Council	Yes	Program sufficient.
ODA	Agricultural Water Quality Management Program	Private lands, specifically Granite Creek		See State of Oregon programmatic review -- Appendix F.
CTWRSO	Watershed restoration	Oxbow and Forrest Ranch properties	Likely where implemented	Program could be implemented on broader scale.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
See discussion for Strategy 5, Lower Mainstem John Day River population. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management program remains challenging in some locations.				

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Implement agricultural water conservation measures	Long Cr and its tributaries (1); Mainstem Middle Fork, Coyote Cr. to Camp Cr. (2)	Altered hydrology, low flows, high temperatures	Water withdrawals, land conversion on uplands, road network	Abundance, productivity	Fry and 0+	Most other sections of the Middle Fork with consumptive water rights are now under conservation agreements.
Improve irrigation conveyance and efficiency	Long Cr and its tributaries (1); Mainstem Middle Fork, Coyote Cr. to Camp Cr. (2)	Low flows, high temperatures	Water withdrawals, loss during conveyance	Abundance, productivity	Fry and 0+	
Increase pool habitat (beaver ponds)	Long Cr and its tributaries (1), Camp (1), Crawford (1), Deerhorn (2), Davis (2), Placer Gulch (2), Granite (1), Rush (2), Twelvemile (2), Slide (1), Sixmile(2), Squaw (1), Idaho (1), Lick (2), Mainstem Middle Fork, Coyote Cr. to Camp Cr. (2)	Altered hydrology, low flows, high temperatures	Loss of wet meadows	Abundance, productivity	All freshwater life stages	
Floodplain aquifer recharge	Granite Boulder Cr (1)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	Pilot project with CTWSRO.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Lease or acquire water rights and convert to instream	Long Cr. and its tributaries (2); Mainstem Middle Fork, Coyote Cr. to Camp Cr. (1)	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	
Monitor/regulate water withdrawals	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	Annual fluctuations in flow levels are intensified by irrigation withdrawals.
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	Population-wide	Low flows, high temperatures	Water withdrawals	Abundance, productivity, spatial structure, diversity	All stages	New programs in development

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Implement agricultural water conservation measures	SWCD, watershed councils, NRCS	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights.
Improve irrigation conveyance and efficiency	SWCD, OWEB, watershed councils, NRCS, landowners	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and dependent upon landowner willingness to participate and availability of projects	Immediate	High, if the saved water is protected from being appropriated to a downstream user in areas with instream water rights.
Increase pool habitat (beaver ponds)	SWCD, ODFW, CTWSRO, USFS	Ongoing	High dispersal downstream	Unknown	Immediate increase in instream flow	High
Floodplain aquifer recharge	CTWSRO, SWCDs	Planned, some ongoing	Potentially high dispersal from recharge project site downstream for many miles	Long term, although opportunities for pilot projects is dependent upon willing landowner	Immediate	High, if the additional water is protected from being appropriated to a downstream user in areas with instream water rights.
Lease or acquire water rights and convert to instream	OWRD, FSA, OWEB, Oregon Water Trust, others	Ongoing	Point of diversion downstream to mouth of John Day River	Long term and highly dependent upon landowner willingness to lease.	Immediate	High, if the leased water is protected from being appropriated to a downstream user in areas with instream water rights. FSA pays higher rates for CREP enrollment when water rights are leased for instream use.

Strategy 6. Restore natural hydrograph to provide sufficient flow during critical periods.						
Monitor/regulate water withdrawals	OWRD	Ongoing	Point of diversion downstream to mouth of John Day River	Long term, dependent upon OWRD enforcing the requirement to measure water usage	Immediate	High if water user reporting requirement and installation of measuring devices on diversions is implemented.
Assess existing and future water needs, complete statewide inventory of above and below ground potential storage, complete assessment of conservation opportunities, provide incentive funding to develop strategies to meet long-term needs	OWRD	Ongoing	Population-wide	2007-2009 except incentive funding ongoing	Long term	Moderate

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program, riparian improvements	Camp Creek, Phipps Meadow, Oxbow property	No	Limited by funding, approach sufficient.
OWRD	Streamflow Monitoring and Restoration, Flow Restoration, Lease/Transfer Water Rights, Administration of Water Rights, Water Use Measurement, Water Needs Assessment, Storage Assessment, Conservation Assessment	Where irrigation withdrawals occur throughout the MF John Day watershed		See State of Oregon programmatic review -- Appendix F.
Oregon Water Trust and BOR	Leasing and Purchase of Water Rights	Middle Fork John Day, Vinegar and Clear creeks	No	Program limited by funding.
Soil and Water Conservation Districts	Improve irrigation efficiency, upland improvements, riparian improvements	Middle Fork John Day, Vinegar and Clear creeks		See State of Oregon programmatic review -- Appendix F.
Watershed Councils	Upland improvements, riparian improvements	Rush and Eightmile creeks	No	Limited resources.
NRCS	Upland improvements, riparian improvements	Those identified by SWCD and Watershed Council	No	Limited resources.
CTWSRO	Watershed restoration	Oxbow and Forrest Ranch properties	Likely in areas of implementation	Program could expand.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Approximately 66 miles of stream in the Middle Fork are protected with either existing or pending instream water rights. The instream water rights do not preclude further appropriation of water until flows in the affected reach drop down to the instream water rights as adopted by OWRD. Voluntary efforts restored 5.7 cfs instream in 2006.

The Oregon Water Trust has made good progress at restoring flows in the Middle Fork with a total of over 20 cfs of water being converted to instream flow and water leases for another approximately 11 cfs on various streams throughout the subbasin.

See Strategy 6, Lower Mainstem John Day River population for further discussion.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Increase riparian shading	Mainstem: between Crawford and Caribou crs (1), between Tincup and Ragged crs (1), between Balance and Camp crs (1), below Highway 395 (2); Long Cr and tributaries (1); Indian Cr (2), Twelvemile (2), Sixmile (2) and Slide (2) crs	High water temperatures	Degraded riparian forests	Abundance, productivity	Fry and 0+	Elevated water temperatures are the result of reduced riparian vegetation and loss of floodplain function (wet meadow storage). Elevated water temperature is a pervasive water quality problem for the Middle Fork John Day River population, with 21 stream reaches listed as water quality limited. Additional reaches would probably be listed is water temperature data were available.
Manage return flow to reduce extreme stream temperatures	Mainstem: between Highway 7 and Caribou Cr (1), and between Horse and Camp crs (2); Long Cr (1)	High water temperatures	Water withdrawals	Abundance, productivity	Fry and 0+	
Reduce chemical pollution and nutrient inputs	None identified at this time	Chemical pollution	Pesticides, fertilizers, herbicides, vehicle hydrocarbons, etc.	Abundance, productivity	Fry and 0+	Using more efficient irrigation methods should result in fewer nutrients from pastures reaching the John Day River. Although the Middle Fork has been extensively impacted by historical mining activity, there are no known contamination issues.
Apply BMPs to animal feeding operations	Granite Cr (1)	Degraded water quality	Animal feed operations	Abundance, productivity	Fry and 0+	
Continue TMDL monitoring	For sediment: Mainstem Middle Fork above Camp Cr (2), Long Cr and tributaries (1), Butte Cr (2), Indian Cr (2), and Slide Cr (2). For temperature: Mainstem: between Highway 7 and Caribou Cr (1), below Camp Cr (2); Long Cr (1); Indian Cr (2)	Degraded water quality, sediment routing	Land use practices, water withdrawals, pesticides, fertilizers, herbicides	Abundance, productivity	Eggs, fry, juveniles, adults	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Increase riparian shading	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	water quality benefits will have high dispersal downstream from site	Long term because of widespread need	5-15 years	High
Manage return flow to reduce extreme stream temperatures	SWCDs, watershed councils	Ongoing	Water quality improvement would have high dispersal downstream	Less than 5 years, once the project has been identified	Immediate	High, reduced temperatures has been well documented

Strategy 7. Improve degraded water quality and maintain unimpaired water quality.						
Reduce chemical pollution and nutrient inputs	ODEQ, others	Ongoing	High dispersal downstream	Ongoing	Reduce chemical pollution immediately	High
Apply BMPs to animal feeding operations	ODA	Ongoing	Water quality improvement would have high dispersal downstream	Some treatments could be done immediately. There are few animal feeding operations within the subbasin, only one of which has been identified as a problem	5-15 years	High, once a treatment has been agreed upon
Continue TMDL monitoring	USFS, ODFW, SWCD, ODEQ	Ongoing	Subbasin-wide	Ongoing	Immediate	High

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
FSA	CREP, CRP	Middle Fork John Day, Granite Creek	No	Yes
ODEQ	Mine Waste Program	None currently identified, although extensive mining activity occurred on Middle Fork and tributaries		See State of Oregon programmatic review -- Appendix F.
ODA	Confined animal feeding operations (CAFO), AgWQM	Granite Creek, others as later identified		See State of Oregon programmatic review -- Appendix F.
ODEQ, ODA, SWCD, USFS	Sedimentation Monitoring (TMDL Development and Implementation)	Throughout the Middle Fork watershed		See State of Oregon programmatic review -- Appendix F. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Low streamflows during the hottest part of the year exacerbate the already warm water temperatures. Opportunities for increasing streamflow through leasing of water rights, which often results in cooler water over a longer stream reach, are being pursued by Oregon Water Trust and US Bureau of Reclamation. Constraints for future projects include acceptance by landowners and a secure, long term funding source.

The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Reducing water temperatures through the use of improved riparian vegetation and more efficient methods of irrigation may take several years to provide measurable results. Many projects that improve water quality by reducing irrigation return water have been completed.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore native upland plant communities	MaSAs; Middle Fork and north side tributaries below Highway 395 (1), Long Cr (1), Slide Cr (2)	Altered hydrology, sediment routing, channel stability, floodplain and riparian area	Upland land use practices, loss of water storage	Abundance, productivity	Fry and 0+	Upland improvements such as restoring native plant communities and controlling invasive weed species will improve

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
		degradation, water quality	capacity			precipitation infiltration rates and ultimately improve watershed health, including the hydrograph.
Upgrade or remove problem forest roads	Forest lands, 46 miles on Camp Cr and five miles on the Upper MF have been identified for treatment	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Road network	Abundance, productivity	Fry and 0+	
Initiate upland improvement demonstration projects	None identified	Same as above	Upland land use practices	Abundance, productivity	Fry and 0+	
Manage vegetation, including juniper removal	Middle Fork and north side tributaries below Highway 395 (1), Long Cr (1), Slide Cr (2)	Altered hydrology, sediment routing	Invasive plants	Abundance, productivity	Fry and 0+	
Demonstration projects to restore forest health and resilience to wildfire	Private and forest lands	Altered hydrology, sediment, water quality, riparian functions, LWD recruitment	Conversion of vegetative communities	Abundance, productivity	All	Suppression of fires has altered fire regimes and increased threat of high intensity fires.
Employ BMPs to forest practices including fuels management and fire suppression mitigation; livestock grazing; roads; and agricultural practices	Middle Fork and north side tributaries below Highway 395 (1), Long Cr (1), Slide Cr (2)	Altered hydrology, sediment routing, channel stability, floodplain and riparian area degradation, water quality	Upland land use practices	Abundance, productivity	Fry and 0+	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore native upland plant communities	SWCD, USFS, BLM	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Long term	5-15 years	Moderate, depending upon which treatments are used to restore native plant communities, and whether appropriate short term restrictions on grazing are adopted
Upgrade or remove problem forest roads	USFS, ODF, ODOT	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, many forest roads have legacy issues with regard to sediment transport and routing of runoff. Decommissioning may take many years	15 years	Moderate, although funding on public lands and landowner cooperation on private lands will determine rate of treatment
Initiate upland improvement demonstration projects	ODFW, NOAA Fisheries, USFWS, USFS, BLM, CTWSRO, Watershed Councils, SWCDs	Ongoing	Entire subbasin	Long term	Variable lag time	Unknown, depends upon action taken as a result of being more informed
Manage vegetation, including juniper removal	USFS, BLM, NRCS, SWCDs, Watershed Councils	Ongoing	Effects of higher precipitation infiltration rates will have high dispersal downstream	Juniper control can be done quickly, other strategies such as control of invasive plants may take more than 20 years	5-30 years	Moderate

Strategy 8. Restore degraded and maintain properly functioning upland processes to minimize unnatural rates of erosion and runoff.						
Demonstration projects to restore forest health and resilience to wildfire	ODF	Ongoing	Private and state forest lands	Long term	Variable 5-20 years	Moderate
Employ BMPs to forest practices including fuels management and fire suppression mitigation; livestock grazing; roads; and agricultural practices	SWCD, USFS, ODA, CTWSRO, BLM, private landowners	Ongoing	Reduced sediment and improved hydrologic function will have high dispersal downstream	Long term, dependent on implementation of Agricultural Water Quality Management Plans	0-20,years, depending upon treatments applied	Moderate, dependent upon voluntary landowner participation

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
NRCS/Farm Service Agency	CRP	Long Creek, Basin Creek	No	Program needs expansion.
SWCDs	Juniper control	Long Creek, Basin Creek	No	More areas need treatment, rate of treatment restrictive.
ODFW	Green Forage	Long Creek, Basin Creek	No	Very small program.
USFS/BLM	Forest Plan, PACFISH, Resource Management Plan	Federal lands within the Middle Fork watershed	Uncertain	See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
ODF	Private land protection from fire, Private Forest Program	Private and state forestlands throughout population		See State of Oregon programmatic review -- Appendix F.
ODF	Oregon Forest Practices Act	Private and state forest lands		See State of Oregon programmatic review -- Appendix F.
ODA	Agricultural Water Quality Management Program	Private lands within the Middle Fork watershed		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed Restoration	Oxbow and Forrest Ranch properties	Likely where implemented	Could be expanded.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

See Strategy 8, Lower Mainstem John Day River population for further discussion.

The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed. Implementation of PACFISH standards and guides for Forest and BLM programs, has been highly successful for passive upland restoration over most of this population's area.

9.3.8 Habitat Strategies and Actions for South Fork John Day River Steelhead Population

Primary limiting factors: altered sediment routing, degraded channel structure and complexity (habitat quantity and diversity), altered hydrology and low flow, water temperature, and impaired fish passage.

Primary threats: riparian disturbance, stream channelization and relocation, grazing, forest practices, road building, fish passage barriers (culverts, and other seasonal barriers), and irrigation withdrawals.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Protect high quality habitats through acquisition or conservation easements	Lower Murderers Cr tributaries draining the south side of Aldrich Mountain: Todd (1), Cabin (1), Dry Cabin (1), Duncan (1) and Dry Duncan (1); Black Canyon Cr (1); mainstem South Fork, north boundary of PW Schneider WMA to Izee Falls (2)	Degraded floodplain connectivity and function, degraded channel structure and complexity, degraded riparian area, altered hydrology, degraded water quality, altered sediment routing,	Many threats including livestock overgrazing of riparian area, channelization, stream bank armoring, agricultural practices (fertilizers, herbicides, sediments, changes in plant communities), water withdrawals, loss of beaver dams	Productivity, abundance	Primarily fry and 0+	Protecting base streamflows from further appropriations is a very important function of protecting existing high quality habitats. Protection of high quality habitats is the most cost effective way of ensuring fish have good quality habitat. Land acquisitions, easements, and cooperative agreements may also facilitate the implementation of active restoration projects.
Adopt and manage Cooperative Agreements	South Fork, north boundary of PW Schneider WMA to Dayville (1); South Fork above Izee Falls (2)	Same as above	Same as above	Productivity, abundance	Primarily fry and 0+	
Special management designations in forest and BLM plans	Public lands as identified in Forest Plan Revision	Same as above	livestock overgrazing of riparian area, changes in plant communities	Productivity, abundance	Primarily fry and 0+	
Designate additional wilderness and wild and scenic status	Public lands identified as meeting the criteria during the Forest Plan Revision process	Same as above	livestock overgrazing of riparian area, changes in plant communities	Productivity, abundance	Primarily fry and 0+	
Protect access to key habitats	Black Canyon Cr (1)	Passage barriers, altered hydrology, channel structure		ivity, abundance, distribution	Primarily fry and 0+	Thoroughly review projects that may block fish passage. Current ODFW policy is to grant exemptions from fish passage requirements only if mitigation meets or exceeds the loss of habitat. Exemptions must be approved by the Fish and Wildlife Commission

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.						
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes	Population-wide	All	Same as above	Productivity, abundance	Primarily fry and 0+	

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Protect the highest quality habitats through acquisition or conservation easements	CTUIR, TNC, RMEF, John Day Basin Trust, SWCDs, CTWSRO, USFS, ODFW	Ongoing	Water quality improvement have high dispersal downstream, stream corridor and function improvements would be confined to the specific site	Existing conservation agreements are complete. Full implementation of conservation measures will take 5-15 years or more	5-15 years with passive restoration approaches	High, based on previous cooperative agreements
Adopt and manage Cooperative Agreements	ODFW, SWCDs, FSA	Ongoing	Same as above	Agreements are for 10 to 15 years	Immediate	High, although not in perpetuity
Special management designations in forest and BLM plans	USFS, BLM	Ongoing as identified	Same as above	Many complete, potentially subject to change in Forest Plan revisions	Immediate	High, although subject to change from Forest Plan or mgmt plan revision
Designate additional wilderness and wild and scenic status	Public lands identified as meeting the criteria in the Forest Plan Revision process and BLM Resource Management Plan revision.	Same as above	livestock overgrazing of riparian area, changes in plant communities	Immediate depending on socio-political acceptance	5-15 years	High
Consistently apply Best Management Practices and existing laws to protect and conserve natural ecological processes.	NRCS, SWCDs, USFS, ODFW, ODF, DSL, BLM, ODOT, CTWSRO, ODA, FSA, private landowners	Ongoing	Population-wide	Long term	5-15 years	High

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
USFS, BLM	Wilderness Areas, Wilderness Study Areas, Wild and Scenic River corridors, Special Management designations, PACFISH	Black Canyon, SF Wild and Scenic Corridor, and other FS and BLM lands	Yes, PACFISH standards are good, but implementation is inconsistent between forests. See discussion below.	See USFS/BLM Program Sufficiency Assessment -- Appendix E.
ODFW	Cooperative Agreements and PW Schneider Wildlife Management Area	Murderers Creek, SF John Day between Murderers Cr and Dayville, Upper SF on private lands	No	The agreements are for only 10-15 years and need to be for longer time periods.
FSA	CREP	Upper SF John Day	No	The agreements are for only 10-15 years and need to be for longer time periods.
NGOs	Lease or purchase of lands or instream water rights	None currently identified	Yes, although limited by acceptance from landowners	Important to secure critical habitat and/or water rights when opportunities arise.
ODA	Agricultural Water Quality Management Program	Private lands, primarily in upper SF (above Izee Falls)		See State of Oregon programmatic review -- Appendix F.

Strategy 1. Protect and conserve natural ecological processes that support the viability of populations and their primary life history strategies throughout their life cycle.				
CTWSRO	Watershed Restoration	Upper SF in cooperation with SWCD	Yes	Funding uncertain.
ODF	Oregon Forest Practices Act	Private and state owned timberlands	Likely	See State of Oregon programmatic review -- Appendix F.
Local Government	City and County Planning and Zoning	Private lands	Likely, riparian setbacks are sufficient when enforced	Monitoring of compliance needs to be increased.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)

Federally designated Wild and Scenic River reaches include the South Fork John Day River from Smokey Cr (RM 6.5) to the Malheur National Forest boundary (RM 52.5). State designated reaches include the South Fork from the PW Schneider Wildlife Management Area Boundary (RM 5.5) to County Road 63 (RM 35). Although wild and scenic designation does not preclude development, it requires development to be consistent with protecting the ORVs for which the river was designated, requires review of any activity that may affect ORVs within the ¼ mile river corridor, and protects the free flowing condition of the river. Designation as W&S essentially precludes construction of any major dam. A Management Plan was adopted by BLM and Oregon State Parks Department in 2001 for the designated rivers segments. Implementation of all the actions identified in the plan will likely take many years; however, grazing management plans for most of the allotments within corridor are complete. BLM allotment plans are complete.

One of the reasons for purchase of ODFW's Philip W. Schneider Wildlife Management Area in the South Fork John Day River subbasin was for its value as a steelhead spawning and rearing area. The mixture of BLM and ODFW owned lands, along with the adjoining Malheur National Forest lands are under a Coordinated Resource Management Plan (CRMP). The mainstem South Fork John Day River, which runs through the CRMP lands, has shown remarkable riparian recovery in the last 30 years, with 100% canopy closure on some reaches. Unfortunately several of the tributaries have not benefited as much from the same management strategy.

Wilderness designation essentially prevents any development and offers the greatest opportunity for protection of high quality habitat. Wilderness areas within the South Fork population boundary include, Black Canyon Wilderness (13,400 acres). Other special designated areas include the Utley Butte and Dry Cabin wildlife emphasis areas.

Implementation of PACFISH standards and guides for most Forest and BLM programs has been highly successful over most of this population's area, but implementation of PACFISH Standards and Guides for FS grazing management programs remains challenging in some locations.

See Strategy 1, Lower Mainstem John Day River population for further discussion.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	**Geographic Locations (1-first priority, 2-second priority)**	**Factors Addressed**	**Threats Addressed**	**VSP Parameters Addressed**	**Life Stages Affected**	**Discussion**
Remove or minimize use of push up dams	South Fork John Day River mainstem (1); Wind Cr (2)	Impaired fish passage	Push up dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	Push up dams in the South Fork mainstem are scheduled for replacement within the next year. Annual maintenance and construction of push up dams contributes to onsite and downstream channel stability, loss of pools and other structure, and increased sediment loads.
Remove or replace barriers blocking passage such as dams, road culverts and irrigation structures	Culverts on Deer, Murderers (1), SF Murderers (2), Tex (1) and Thorn (2) crs; head cut on SF Murderers Cr (1) A total of 74 culverts need replacement (see Appendix G).	Impaired fish passage	Dams, culverts, instream structures	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	
Construct ladders over existing permanent concrete or earth fill dams	None identified below Izee Falls	Impaired fish passage	Dams	Abundance, productivity, spatial structure	Primarily adults and 0+juveniles	

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.						
Provide screening at 100% of irrigation diversions	South Fork below PW Schneider boundary (1)	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry	All known diversions in the drainage area currently screened.
Replace screens that do not meet criteria	South Fork John Day River (1)	Impaired fish passage	Irrigation diversions	Abundance, productivity, spatial structure	Emergent fry	Most irrigation diversions are in the Upper John Day drainage and it has been the major emphasis for replacement of screens not meeting criteria.

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Remove or minimize use of push up dams	SWCD	Ongoing	Provide access to upstream habitat	Ongoing, but all push up dams not expected to be corrected for at least 15 years	Immediate	High, if comply with fish passage design criteria
Remove or replace barriers blocking passage -- dams, road culverts and irrigation structures	USFS, BLM, watershed councils, SWCDs, ODOT	Ongoing	Access to upstream habitat	Ongoing, replacing all culverts blocking fish passage expected to take 50 years (see Appendix G)	Immediate	High, if comply with fish passage design criteria
Construct ladders over existing permanent concrete or earth fill dams	ODFW, SWCDs	Ongoing	Provide access to upstream habitat	Ongoing, providing passage at all diversion and pond barriers will take many years (none below Izee falls)	Immediate	High if comply with fish passage design criteria
Provide screening at 100% of irrigation diversions	ODFW, SWCDs	Ongoing	At point of diversion	No screening currently needed	Immediate	High if comply with fish passage design criteria
Replace screens that do not meet criteria	ODFW	Ongoing	At point of diversion	Approximately four screens need to be replaced	Immediate	High if comply with fish passage design criteria

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
Soil and Water Conservation Districts	Irrigation dam improvements, culvert replacement or retrofits	Private land on SF John Day and tributaries below Izee Falls		The Grant Soil and Water District is constrained by the construction window of opportunity. See State of Oregon programmatic review -- Appendix F.
ODFW	Fish Passage/Screening	Private and state owned lands on SF John Day and tributaries below Izee Falls	Likely	The program completes a minimum of one project per year, but is dependent upon landowner cooperation and limited funding. No screen upgrades currently identified.
USFS, BLM	Culvert replacement	Federal lands, BLM previously corrected the Smokey Creek culvert. The BLM has no adult barriers at culverts. Monitoring is needed to determine if upstream passage for juveniles is an issue.	Uncertain	Slow pace will take 50 years to complete. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Road Crossing Passage improvements, passage improvements	Private land on SF John Day and tributaries below Izee Falls	No	Program needs expansion.
BOR	John Day Basin Program	Private land on SF John Day and tributaries below Izee Falls	Yes	No

Strategy 2. Restore passage and connectivity to habitats blocked or impaired by artificial barriers and maintain properly functioning passage and connectivity.				
CTWSRO	John Day Basin Program	Private land on SF John Day and tributaries below Izee Falls in cooperation with SWCD	No	The tribe contracts with Soil and Water Districts to assist with consultation, permits, and monitoring, program needs additional resources.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
See discussion in Strategy 2, Lower Mainstem John Day River population. Most of the mainstem passage problems have been addressed, but there are many tributaries where adult passage is blocked and more areas where juvenile passage problems occur. Soil and Water Districts are correcting passage at irrigation diversions and improperly installed culverts, but are constrained by funding and by personnel needed for construction oversight. An inventory of road crossings on state and county roads in 1999 indicated no culverts on state owned roads and 10 culverts on county owned roads did not meet fish passage criteria within the South Fork population boundary. Appendix G presents an inventory of culverts with known passage problems on state or county owned roads. The US Forest Service and BLM are constrained primarily by funding and the personnel needed for NEPA analysis. At the current rate of culvert replacements it will take over 50 years to correct all passage problems on National Forests, however the Forest Service Pacific Northwest Region's Aquatic Restoration Strategy (USDA-FS, 2005) provides guidance that will help prioritize culvert replacements for this population. The BLM has no adult barriers at culverts. Monitoring is needed to determine if upstream passage for juveniles is an issue.				

Strategy 3. Maintain and restore floodplain connectivity and function.

Strategy 3. Maintain and restore floodplain connectivity and function.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Reconnect floodplains to channels	Murderers Cr, Chickenhouse Gulch to Todd Cr (2); South Fork mainstem, Izee Falls upstream to Malheur NF boundary (1)	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity	Primarily, fry and 0+.	The upper South Fork from Indian Cr upstream to the Malheur NF boundary is no longer connected to its floodplain and is deeply incised. Although this is above steelhead distribution, it would have substantial benefits to steelhead rearing in the SF below Izee Falls.
Reconnect side channels and off-channel habitats to stream channels	Murderers Cr, Chickenhouse Gulch to Todd Cr (2); South Fork mainstem, Izee Falls upstream to Malheur NF boundary (1)	Degraded floodplain, altered hydrology	Removal of side channels, off-stream habitat; conversion of floodplain for agricultural use; roads; loss of beaver dams	Abundance, productivity, spatial structure	Primarily, fry and 0+.	There has been a loss of off-channel and side-channel habitats that once provided habitat for spawning and rearing, and refugia from high flows.
Restore wet meadows	SF Murderers (1); Murderers (2); Upper Deer Cr. (1)	Degraded floodplain, altered hydrology	Removal of wetlands	Abundance, productivity	Primarily, fry and 0+.	
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes	Murderers Cr, Chickenhouse Gulch to Todd Cr (2); South Fork mainstem, Izee Falls upstream to Malheur NF boundary (1); SF Murderers (1); Wind (2); and Deer (1) crs	Degraded floodplain, altered hydrology, altered sediment routing, degraded water quality	Removal of wetlands, side channels, off-stream habitat	Abundance, productivity, spatial structure	Primarily, fry and 0+.	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Reconnect floodplain to channel	ODFW, watershed council, SWCD, USFS, BLM	Ongoing	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High

Strategy 3. Maintain and restore floodplain connectivity and function.						
Reconnect side channels and off-channel habitats to stream channels	ODFW, watershed council, SWCD, USFS, BLM, CTUIR	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, because of widespread need	5-15 years, depending upon frequency and duration of channel altering flows	Moderate, depends on how extensive the project is and frequency and duration of channel altering flows
Restore wet meadows	TNC, USFS, CTWSRO	Ongoing and planned	Benefits of improved channel morphology localized, improved water table and resulting increased streamflow and lower water temperatures have high dispersal downstream	Intermediate	5-15 years	Moderate
Promote the maintenance and creation of beaver dams to restore the role in natural ecological processes.	ODFW, CTWSRO, USFS, BLM	Ongoing	Effect on physical habitat features will be localized, but effects on water quality will have high dispersal downstream	Long term, due to acceptance by landowners and widespread need	Within 5 years once the dams are built	Moderate-high, depends upon acceptance by landowners

Status of Existing Programs through which Actions are Implemented				
Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	Private and state owned lands on SF John Day above Izee Falls, SF John Day below Izee Falls, Murderers Cr	No	Sufficient approach, resource limited.
USFS, BLM	Stream enhancement program	SF John Day and tributaries above and below Izee Falls on Federal land. Only when specifically identified that passive restoration is not working.	Yes in some areas, no in others	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming processes. May need expansion. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	Private lands on SF John Day and tributaries above Izee Falls	Uncertain	Active approaches only if specific needs cannot be addressed by passive restoration techniques.
Soil and Water Conservation Districts	Watershed restoration	Private lands on SF John Day and tributaries above and below Izee Falls		Active approaches only if specific needs cannot be addressed by passive restoration techniques.
Nature Conservancy and other NGOs	Restoration projects	None currently identified	Uncertain	Needs expansion.
CTWSRO	Watershed restoration	Private lands in SF John Day and tributaries above and below Izee Falls in cooperation with SWCD and Watershed Council	Likely	Could be expanded to other areas.

Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)
The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.

Strategic Actions and Impacts on Limiting Factors, Threats, and Population

Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural channel form	Murderers Cr, Chickenhouse Gulch to Todd Cr (2); South Fork mainstem, Izee Falls upstream to Malheur NF boundary (1)	Degraded channel structure and complexity, habitat diversity, riparian area degradation, connectivity with floodplain, sediment routing, water temperature, flows	Stream channelization, bank armoring, large wood removal, beaver removal, removal of riparian vegetation, livestock overgrazing in riparian areas	Abundance, productivity	Primarily eggs, fry and 0+.	The upper South Fork from Indian Cr upstream to the Malheur NF boundary is no longer connected to its floodplain and is deeply incised.
Place stable wood and other large organic debris in streambeds and in floodplains	Murderers Cr, Chickenhouse Gulch to Todd Cr (1); South Fork mainstem, Izee Falls upstream to Malheur NF boundary 92); Deer (1); SF Murderers (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, water temperature	large wood removal channelization	Abundance, productivity	Primarily eggs, fry and 0+.	More active restoration techniques, such as rootwad placement or channel reconfiguration, may be appropriate in these reaches. Typical structures include rootwads, boulder clusters, whole trees, and rock weirs where appropriate.
Stabilize streambanks	South Fork mainstem from Izee Falls upstream to Malheur NF boundary (1)	Degraded channel structure and complexity, habitat diversity, sediment routing, flows	Stream channelization, berming, bank armoring, overgrazing in riparian areas	Abundance, productivity	Primarily eggs, fry and 0+.	Some bank erosion is inevitable and beneficial. However, where erosion is actively taking place due to unnatural processes, stabilization may be needed to reduce fine sediments

Action Implementation

Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural channel form	ODFW, SWCDs, USFS, BLM, watershed councils	Ongoing and planned	For the treated stream reach	Short term, once identified	Physical response will be immediate, biological response may take 5-10 years	High
Place stable wood and other large organic debris in streambeds and in floodplains	ODFW, USFS, watershed councils, BLM, SWCDs	As needed	For the immediate stream reach	Once identified, short term	Immediate	High
Stabilize streambanks	ODFW, USFS, watershed councils, BLM, SWCDs	Ongoing	For the treated stream reach, physical benefits dispersed downstream	Passive stabilization techniques are preferred and take longer to implement	With passive restoration the response may take 15 years	Medium to high, depending upon the extent of the treatments

Status of Existing Programs through which Actions are Implemented

Agency/Organization	Program Name	Geographic Locations	Sufficient* (yes, likely, uncertain, no)	Sufficiency Rationale
ODFW	BPA Habitat Program	None currently identified.	No	When specific needs cannot be addressed by passive restoration techniques.
USFS, BLM	Stream enhancement program	Deer, Wind and Murderers creeks on Federal lands, but only	Yes in some areas, no in others	The USFS preferred strategy is passive restoration; managing riparian areas to protect channel-forming

Strategy 4. Restore degraded and maintain properly functioning channel structure and complexity.				
		when specifically identified as deficient in habitat diversity and that passive restoration is not working		processes. See USFS/BLM Program Sufficiency Assessment -- Appendix E and USFS Region's Aquatic Restoration Strategy (USDA-FS, 2005). See discussion in Gaps commentary below.
Watershed Councils	Watershed restoration	None currently identified.	Uncertain	Only if specific needs cannot be addressed by passive restoration techniques.
Soil and Water Conservation Districts	Watershed restoration	None currently identified.		See State of Oregon programmatic review -- Appendix F.
CTWSRO	Watershed restoration	None currently identified.	Uncertain	No opportunities currently identified.
NGOs	Watershed restoration	None currently identified.	Uncertain	No opportunities currently identified.
Program Sufficiency and Gaps (including current and near-term efforts, and additional efforts needed, constraints)				
Instream activities have not been identified as a high priority by the recovery planning team or the subbasin plan team except when identified as a need for specific sites. The planning team prefers that more passive approaches, such as riparian and upland improvements be emphasized. Typically, instream activities that would improve floodplain function and channel migration processes would include placement of rootwads, whole trees, or boulder clusters to improved habitat complexity and habitat diversity where those parameters are deficient and not expected to improve with passive restoration. Another structural activity would be to construct boulder or log weirs to raise the water table, but only where a passive approach has not worked. The Forest Service's Aquatic Restoration Strategy for the Pacific Northwest Region (USDA-FS, 2005) helps prioritize restoration actions for this population, and helps deploy limited active restoration funding where it is most needed.				

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
Strategic Actions and Impacts on Limiting Factors, Threats, and Population						
Actions	Geographic Locations (1-first priority, 2-second priority)	Factors Addressed	Threats Addressed	VSP Parameters Addressed	Life Stages Affected	Discussion
Restore natural riparian vegetative communities including vegetative planting	mainstem South Fork John Day above Izee Falls (1); Murderers Cr between the lower USFS boundary up to Tex Cr (2); SF Murderers (1); Deer Cr, mouth to headwaters (1)	Degraded riparian area, channel structure and complexity, floodplain degradation, altered hydrology, sediment, water quality	Overgrazing of riparian area, channelization, stream bank armoring, tree harvest in riparian areas, changes in plant communities (including invasive plants), loss of beaver dams	Abundance, productivity	Primarily fry and 0+	Primary methods of riparian enhancement include riparian corridor fences to exclude livestock, changes in grazing management that promote riparian recovery, and planting of native shrubs.
Develop grazing strategies that promote riparian recovery	mainstem South Fork John Day above Izee Falls (1); Murderers Cr between the lower USFS boundary up to Tex Cr (2); SF Murderers (1); Deer Cr, mouth to headwaters (1)	Same as above	Livestock overgrazing of riparian area	Abundance, productivity	Primarily fry and 0+	

Action Implementation						
Actions	Implementing Entity		Spatial Coverage	Implementation Timeframe	Expected Biophysical Response Timeframe	Certainty of Outcome
Restore natural riparian vegetative communities	ODFW, Watershed Councils, SWCDs, USFS, BLM, CTUIR	Ongoing	Riparian function will be limited to specific reach; water quality	Long term because of widespread need	5-15 years	High, based upon experience with existing grazing

Strategy 5. Restore riparian condition and LWD recruitment and maintain properly functioning conditions.						
			benefits will have high dispersal downstream from site			management and riparian recovery projects
