ABSTRACT

The domestic groundfish fishery off Alaska is an important segment of the U.S. fishing industry. This report contains figures and tables which summarize various aspects of the economic performance of the fishery. Generally, data are presented for the domestic groundfish fishery for 1998 through 2002. Limited catch and ex-vessel value data are reported for earlier years in order to depict the rapid development of the domestic groundfish fishery in the 1980s and to provide a more complete historical perspective on catch. Pacific halibut (*Hippoglossus stenolepis*) is not included in data for the groundfish fishery in this report because for management purposes halibut is not part of the groundfish complex.

The report provides estimates of total groundfish catch, groundfish discards and discard rates, prohibited species bycatch and bycatch rates, the ex-vessel value of the groundfish catch, the ex-vessel value of the catch in other Alaska fisheries, the gross product value (F.O.B. Alaska) of the resulting groundfish seafood products, the number and sizes of vessels that participated in the Alaska groundfish fisheries, vessel activity, and employment on at-sea processors.

In addition, this report contains data on some of the external factors which, in part, determine the economic status of the fisheries. Such factors include foreign exchange rates, the prices and price indexes of products that compete with products from these fisheries, cold storage holdings, domestic per capita consumption of seafood products, and fishery imports.

An attachment to this report contains some regional economic information. That information will be expanded and integrated into the main report in the final version of this report.

The estimates in this report are intended both to provide information that can be used to describe the Alaska groundfish fisheries and to provide industry and others an opportunity to comment on the validity of these estimates.

The final version of this report will also include a summary of recent estimates of capacity, capacity utilization, and fishery utilization for the vessels that participated in federally managed commercial fisheries off Alaska in 2002 (Felthoven et al. 2003).

12. Prohibited species bycatch by species, area and gear, 1999-2002.
13. Prohibited species bycatch in the Gulf of Alaska by species, gear, and groundfish target fishery, 2001-02.
14. Prohibited species bycatch in the Bering Sea and Aleutian Islands by species, gear, and groundfish target fishery, 2001-02.
15. Prohibited species bycatch rates in the Gulf of Alaska by species, gear, and groundfish target fishery, 2001-02.
16. Prohibited species bycatch rates in the Bering Sea and Aleutian Islands by species, gear, and groundfish target fishery, 2001-02.
17. Groundfish catch off Alaska by area, residency, and species, 1998-2002.
18. Ex-vessel prices in the groundfish fisheries off Alaska by area, gear, and species, 1998-2002.
19. Ex-vessel value of the groundfish catch off Alaska by area, catcher category, gear, and species, 1998-2002.
20. Ex-vessel value of Alaska groundfish delivered to shoreside processors by area, gear and catcher vessel length, 1996-2002.
 - 20.1 Ex-vessel value per catcher vessel for Alaska groundfish delivered to shoreside processors by area, gear, and catcher-vessel length, 1996-2002.
21. Ex-vessel value of the groundfish catch off Alaska by area, residency, and species, 1998-2002.
22. Ex-vessel value of groundfish delivered to shoreside processors by processor group, 1996-2002.
- 22.1 Ex-vessel value of groundfish as a percentage of the ex-vessel value of all species delivered to shoreside processors by processor group, 1996-2002.
23. Gross product value of Alaska groundfish by area and processing mode, 1997-2002.

24. Gross product value of Alaska groundfish by catcher/processor category, vessel length, and area, 1997-2002.
- 24.1 Gross product value per vessel of Alaska groundfish by catcher/processor category, vessel length, and area 1997-2002.
25. Gross product value of groundfish processed by shoreside processors by processor group, 1996-2002.
- 25.1 Groundfish gross product value as a percentage of all-species gross product value by shoreside processor group, 1996-2002.
26. Number and total registered net tons of vessels that caught groundfish off Alaska by area and gear, 1996-2002.
 - 26.1. Number of vessels that caught or caught and processed more than \$3.5 million ex-vessel value or gross product value of groundfish by area, vessel type and gear, 1998-2002.
 - 26.2. Number of vessels that caught or caught and processed less than \$3.5 million ex-vessel value or gross product value of groundfish by area, vessel type and gear, 1998-2002.
 - 26.3. Average revenue of vessels that caught or caught and processed more than \$3.5 million ex-vessel value or gross product value of groundfish by area, vessel type and gear, 1998-2002.
 - 26.4. Average revenue of vessels that caught or caught and processed less than \$3.5 million ex-vessel value or gross product value of groundfish by area, vessel type and gear, 1998-2002.
27. Number of vessels that caught groundfish off Alaska by area, catcher category, target, and gear, 1998-2002.
28. Number of vessels, mean length and mean net tonnage for vessels that caught groundfish off Alaska by area, vessel-length class, and gear, 1998-2002 (excluding catcher/processors).
 - 28.1 Number of smaller hook-and-line vessels that caught groundfish off Alaska, by area and vessel-length class, 1998-2002 (excluding catcher-processors).
 29. Number of vessels, mean length and mean net tonnage for vessels that caught and processed groundfish off Alaska by area, vessel-length class, and gear, 1998-2002.
30. Number of vessels that caught groundfish off Alaska by area, tonnage caught, and gear, 1996-2002.

31. Number of vessels that caught groundfish off Alaska by area, residency, target, and gear, 1998-2002.
32. Number of vessels that caught groundfish off Alaska by month, area, vessel type, and gear, 1998-2002.
33. Catcher vessel (excluding catcher/processors) weeks of fishing groundfish off Alaska by area, vessel-length class, gear, and target, 1998-2002.
34. Catcher/processor vessel weeks of fishing groundfish off Alaska by area, vessel-length class, gear, and target, 1998-2002.
35. Total at-sea processor crew weeks in the groundfish fisheries off Alaska by month and area, 1998-2002.
36. Production and gross value of groundfish products in the fisheries off Alaska by species, 1998-2002.
 - 36.1 Price per pound of groundfish products in the fisheries off Alaska by species and processing mode, 1998-2002.
37. Production of groundfish products in the fisheries off Alaska by species, product and area, 1998-2002.
38. Production of groundfish products in the fisheries off Alaska by species, product and processing mode, 1998-2002.
39. Monthly Japanese landing market price of selected groundfish by species, 1989-2002.
40. Monthly Tokyo wholesale prices of selected products, 1989-2002.
41. U.S. imports of groundfish fillets, steaks, and blocks, 1976-2002.
42. U.S. population and per capita consumption of fish and shellfish, 1970-2002.
43. U.S. consumption of all fillets and steaks, and fish sticks and portions, 1980-2002.
44. Annual U.S. economic indicators: Selected producer and consumer price indexes and gross domestic product implicit price deflator, 1976-2002.
45. Monthly U.S. economic indicators: Selected producer and consumer price indexes, 2000-02.
46. Annual foreign exchange rates for selected countries, 1976-2002.

47. Monthly foreign exchange rates for selected countries, 2000-02.
48. Monthly U.S. cold storage holdings of selected groundfish blocks, 2000-02.
49. Monthly U.S. cold storage holdings of selected groundfish fillets, 2000-02.

INTRODUCTION

The domestic groundfish fishery off Alaska is an important segment of the U.S. fishing industry. With a total catch of 2.1 million metric tons (t), a retained catch of 2.0 million t, and an ex-vessel value of \$566 million in 2002, it accounted for 49% of the weight and 18% of the ex-vessel value of total U.S. domestic landings as reported in Fisheries of the United States, 2002. The value of the 2002 catch after primary processing was approximately \$1.5 billion (F.O.B. Alaska).

All but a small part of the commercial groundfish catch off Alaska occurs in the groundfish fisheries managed under the Fishery Management Plans (FMP) for the Gulf of Alaska (GOA) and the Bering Sea/Aleutian Islands area (BSAI) groundfish fisheries. In 2002, other fisheries accounted for only 3,000 t of the catch reported above. The footnotes for each table indicate if the estimates provided in that table are only for the fisheries with catch that is counted against federal TACs or if they also include other Alaska groundfish fisheries.

The fishery management and development policies for the BSAI and GOA groundfish fisheries have resulted in high levels of catch, ex-vessel value (i.e., revenue), processed product value (i.e., revenue), exports, employment, and other measures of economic activity. The cost data required to estimate the success of these policies with respect to net benefits to either the participants in these fisheries or the Nation are not available. However, the use of the race for fish as a principal mechanism for allocating the groundfish quotas and prohibited species catch (PSC) limits among competing fishing operations has adversely affected at least some aspects of the economic performance of the fisheries. The individual fishing quota (IFQ) program for the fixed gear sablefish fishery, the Western Alaska Community Development Quota (CDQ) program for BSAI groundfish, and the American Fisheries Act (AFA) cooperatives for the BSAI pollock fishery have demonstrated that eliminating the race for fish as the allocation mechanism and replacing it with a market-based allocation mechanism can decrease harvesting and processing costs, increase the value of the groundfish catch, and, in some cases, decrease the cost of providing more protection for target species, non-target species, marine mammals, and seabirds. However, the distribution of net benefits and the magnitude of net benefits to the Nation resulting from such programs are difficult to measure. As with most any management program, there are winners and losers.

This report presents the economic status of groundfish fisheries off Alaska in terms of economic activity and outputs using estimates of catch, bycatch, ex-vessel prices and value (i.e., revenue), the size and level of activity of the groundfish fleet, and the weight and gross value of (i.e., F.O.B. Alaska revenue from) processed products. The catch, ex-vessel value, and fleet size and activity data are for the fishing industry activities that are reflected in Weekly Production Reports, Observer Reports, fish tickets, and the Commercial Operators' Annual Reports. All catch data reported for 1991-2002 are based on the blend estimates of total catch which are used by the National Marine Fisheries Service (NMFS) to monitor groundfish and PSC quotas during

each fishing year.

A variety of external factors influence the economic status of the fisheries. Information concerning the following external factors are included in this report: foreign exchange rates, the prices and price indexes of products that compete with products from these fisheries, gross domestic product implicit price deflators, U.S. cold storage holdings, and fishery imports. This report updates last year's report (Hiatt et al. 2002) and is intended to serve as a reference document for those involved in making decisions with respect to conservation, management, and use of these fishery resources.

The qualifications made in both the overview of the fisheries and the footnotes to the tables are critical to understanding the information contained in this report.

An attachment to this report contains some regional economic information. Such information can be used to measure the regional economic importance of the fisheries and to estimate how changes in the fisheries would impact regional economic activity. That information will be expanded and integrated into the main report in the final version of this report.

The final version of this report will also include a summary of recent estimates of capacity, capacity utilization, and fishery utilization for the vessels that participated in federally managed commercial fisheries off Alaska in 2002 (Felthoven et al. 2003).

The estimates in this report are intended both to provide information that can be used to describe the Alaska groundfish fisheries and to provide the industry and others an opportunity to comment on the validity of these estimates. It is hoped that the industry and others will identify estimates in this report that can be improved and provide the information and methods necessary to improve them for both past and future years. There are two reasons why it is important that such improvements be made. First, with better estimates, the report will be more successful in monitoring the economic performance of the fisheries and in identifying changes in economic performance that should be addressed through regulatory actions. Second, the estimates in this report often will be used as the basis for estimating the effects of proposed fishery management actions. Therefore, improved estimates in this report will allow more informed decisions by those involved in managing and conducting the Alaska groundfish fisheries. The industry and other stakeholders in these fisheries can further improve the usefulness of this report by suggesting other measures of economic performance that should be included in the report or other ways of summarizing the data that are the basis for this report.

OVERVIEW

The commercial groundfish catch off Alaska totaled 2.1 million t in 2002, compared to 2.0 million t in 2001 (Fig. 1 and Table 1). The real ex-vessel value of the catch, excluding the value added by at-sea processing, increased from \$547 million in 2001 to \$566 million in 2002 (Fig. 3

and Table 2.1). The gross value of the 2002 catch after primary processing was approximately \$1.5 billion (F.O.B. Alaska). The groundfish fisheries accounted for the largest share (58%) of the ex-vessel value of all commercial fisheries off Alaska in 2002 (Fig. 4, Tables 2.1 and 2.2), while the shellfish fishery, with an ex-vessel value of \$149 million, displaced salmon for the second largest share (15%) of the total Alaska ex-vessel value. The value of the Pacific salmon (*Oncorhynchus spp.*) catch amounted to \$130 million or 13% of the total for Alaska. The decline in the ex-vessel value of the salmon catch from previous years is the result of low prices paid to salmon fishers due largely to competition from farmed salmon.

During the last 15 years, estimated total catch in the commercial groundfish fisheries off Alaska (including foreign and joint venture fisheries as well as the domestic fishery) varied between 1.7 and 2.4 million t (Fig. 1 and Table 1). The rapid displacement of the foreign and joint-venture fisheries by the domestic fishery between 1984 and 1991 can be seen by comparing Figures 1 and 2; by 1991, the domestic fishery accounted for all of the commercial groundfish catch off Alaska.

The peak catch occurred in 1991, in part, because blend estimates of catch and bycatch were not yet used to monitor most quotas. If they had been, several fisheries would have been closed earlier in the year. There are three reasons why the catch estimates for 1988 through 1990 have a significant downward bias compared to the estimates for the other years. First, the domestic fishery accounted for a large part of total catch in 1988 through 1990. Second, discards were not included in the reported estimates of domestic catch prior to 1991, but they were included in the catch estimates for the foreign and joint venture fisheries. Based on estimates of the discard rates for 1992 through 1995, discards would have been about 16% of total catch. Finally, the blend estimates of catch, excluding at-sea discards, tend to exceed the estimates based solely on industry reports and prior to 1991 only industry reports were used to estimate retained catch in the domestic fishery. Variations in the catch estimates also reflect changes in the total allowable catch (TAC), area closures or restrictions, and bycatch restrictions.

The information provided by the Observer Program has had a key role in the success of the groundfish management regime. For example, it would not be possible to monitor total allowable catches (TACs) in terms of total catch without Observer Program data. Similarly, the PSC limits, which have been a key factor in controlling the bycatch of prohibited species, could not be used without the Observer Program. In recent years, the reliance on observer data for individual vessel accounting is of particular importance in the management of the CDQ program and AFA fisheries. In addition, much of the information that is used to assess the status of groundfish stocks, to monitor the interactions between the groundfish fishery and marine mammals and sea birds, and to analyze fishery management actions is provided by the Observer Program. Estimates of the numbers of vessels and plants with observers, observer-deployment days, and estimated observer costs by year and type of operation for 2001-2002 are presented in Table 3.

Walleye (Alaska) pollock (*Theragra chalcogramma*) has been the dominant species in the commercial groundfish catch off Alaska. The 2002 pollock catch of 1.53 million t accounted for

73% of the total groundfish catch of 2.10 million t (Table 1). The pollock catch was up approximately 5% from 2001. The next major species, Pacific cod (*Gadus macrocephalus*), accounted for 239,100 t or 11.4% of the total 2002 groundfish catch. The Pacific cod catch was up about 9.5% from a year earlier. The 2002 catch of flatfish, which includes yellowfin sole (*Pleuronectes asper*), rock sole (*Pleuronectes bilineatus*), and arrowtooth flounder (*Atheresthes stomias*) was 196,500 t, up about 14% from 2001. Pollock, Pacific cod, and flatfish comprised almost 94% of the total 2002 catch. Other important species are sablefish (*Anoplopoma fimbria*), rockfish (*Sebastodes* and *Sebastolobus spp.*), and Atka mackerel (*Pleurogrammus monopterygius*). The contributions of the major groundfish species or species groups to the total catch in the domestic groundfish fisheries off Alaska are depicted in Fig. 2.

Trawl, hook and line (including longline and jigs), and pot gear account for virtually all the catch in the BSAI and GOA groundfish fisheries. There are catcher vessels and catcher/processor vessels for each of these three gear groups. Table 4 presents catch data by area, gear, vessel type, and species. The catch data in Table 4 and the catch, ex-vessel value, and vessel information in the tables of the rest of this report are for the BSAI and GOA FMP fisheries, unless otherwise indicated.

In the last five years, the trawl catch averaged about 90% of the total catch, while the catch with hook and line gear accounted for 8.2%. Most species are harvested predominately by one type of gear, which typically accounts for 90% or more of the catch. The one exception is Pacific cod, where in 2002, 41% (98,000 t) was taken by trawls, 49% (118,000 t) by hook and line gear, and 10% (23,000 t) by pots. In the last five years for the BSAI and GOA as a whole, catcher vessels took 46% of the catch and catcher/processor vessels took the other 54%. In each of the years 2001 and 2002, catcher vessels took about 47% of the total. That increase from earlier years is explained in part by the AFA, which among other things increased the share of the BSAI pollock TAC allocated to catcher vessels delivering to shoreside processors. The distribution of catch between catcher vessels and catcher/processor vessels differed substantially by species and area.

The discards of groundfish in the groundfish fishery have received increased attention in recent years by NMFS, the Council, Congress, and the public at large. Table 5 presents the blend estimates of the discarded groundfish catch and discard rates by gear, area, and species. The discard rate is the percent of total catch that is discarded.

Although these are the best available estimates of discards and are used for several management purposes, these estimates are not necessarily accurate. The groundfish TACs are established and monitored in terms of total catch, not retained catch; this means that both retained catch and discarded catch are counted against the TACs. Therefore, the estimation methods used by at-sea observers focus on providing good estimates of total catch by species, not on the disposition of that catch. Observers on vessels sample randomly chosen catches for species composition. For each sampled haul, they also make a rough visual approximation of the weight of the non-prohibited species in their samples that are being retained by the vessel. This is expressed as the percent of that species that is retained. Approximating this percentage is difficult because

discards occur in a variety of places on fishing vessels. Discards include fish falling off of processing conveyor belts, dumping of large portions of nets before bringing them on-board the vessel, dumping fish from the decks, size sorting by crewmen, quality control discard, etc. Because observers can only be in one place at a time, they can provide only this rough approximation based on their visual observations rather than data from direct sampling. The discard estimate derived by expanding these approximations from sampled hauls to the remainder of the catch may be inaccurate because the approximation may be inaccurate. The numbers derived from the observer discard approximation can provide users with some information as to the disposition of the catch, but the discard numbers should not be treated as sound estimates. At best, they should be considered a rough gauge of the quantity of discard occurring.

For the BSAI and GOA fisheries as a whole, the annual discard rate for groundfish decreased from 8.2% in 1998 to 6.8% in 2002 after a small increase in 1999, decreases in both 2000 and 2001, and a slight increase in 2002. The overall discard rate in 1998 represents a 43% reduction from the 1997 rate (not shown in Table 5), a result of prohibiting pollock and Pacific cod discards in all BSAI and GOA groundfish fisheries beginning in 1998. Total discards decreased by almost 49% in 1998 due to the reduction in the discard rate and the 9.4% reduction in total catch. The prohibition was so effective in decreasing the overall discard rate because the discards of these two species had accounted for 43% of the overall discards in 1997. The benefits and costs of the reduction in discards since 1997 have not been determined. In 2002, the overall discard rates were, 13.9% and 6.1%, respectively, for the GOA and the BSAI compared to 16.2% and 14.3% in 1997.

Although the fixed gear fisheries accounted for a small part of either total catch or total discards, in 1998 and later years, the overall discard rates were substantially higher for fixed gear (11.6% in 2002) than for trawl gear (6.3% in 2002). Prior to 1998, the overall discard rates had been similar for these two gear groups. This change occurred because the prohibition on pollock and Pacific cod discards had a much larger effect on trawl discards than on fixed gear discards. In the BSAI, the 2002 discard rates were 12.7% and 5.6% for fixed and trawl gear, respectively. However, in the GOA, the corresponding discard rates were 7.4% and 15.8%. One explanation for the relatively low discard rates for the BSAI trawl fishery is the dominance of the pollock fishery with very low discard rates. The mortality rates of groundfish that are discarded are thought to differ by gear or species; however, estimates of groundfish discard mortality are not available.

Target fisheries are defined by area, gear and target species. The target designations are used to estimate prohibited species catch (PSC), to apportion PSC limits by fishery (i.e., establish PSC allowances by fishery) and to monitor those PSC allowances. The target fishery designations can also be used to provide estimates of catch and bycatch data by fishery. The blend catch data are assigned to a target fishery by processor, week, area, and gear. CDQ fishing activity is targeted separately from non-CDQ fishing. Generally, the species or species group that accounts for the largest proportion of the retained catch of the TAC species is considered the target species. One

exception to the dominant retained catch rule is that the target for the pelagic pollock fishery is assigned if 95 percent or more of the total catch is pollock.

Tables 6 and 7, 8 and 9, and 10 and 11, respectively, provide estimates of total catch, discarded catch, and discard rates by species, area, gear, and target fishery. Within each area or gear type, there are substantial differences in discard rates among target fisheries. Similarly, within a target fishery, there are often substantial differences in discard rates by species. Typically, in each target fishery the discard rates are very high except for the target species. The regulatory exceptions to the prohibition on pollock and Pacific cod discards explain, in part, why there are still high discard rates for these two species in some fisheries.

The bycatch of Pacific halibut, crab, Pacific salmon, and Pacific herring (*Clupea pallasi*) has been an important management issue for more than twenty years. The retention of these species was prohibited first in the foreign groundfish fisheries. This was done to ensure that groundfish fishermen had no incentive to target these species. Estimates of the bycatch of these prohibited species for 1999-2002 are summarized by area and gear in Table 12. More detailed estimates of prohibited species bycatch and of bycatch rates for 2001 and 2002 are in Tables 13 - 16. The estimates for halibut are in terms of bycatch mortality because the bycatch limits for halibut are set and monitored using estimated discard mortality rates. The estimates for the other prohibited species are of total bycatch, this is in part due to the lack of well established discard mortality rates for these species. The discard mortality rates probably approach 100% for salmon and herring in the groundfish fishery as a whole; however, the discard mortality rates for crab may be substantially lower.

An extensive at-sea observer program was developed for the foreign fleets and then extended to the domestic fishery once it had all but replaced participation by foreign fishing and processing vessels. The observer program resulted in fundamental changes in the nature of the bycatch problem. First, by providing good estimates of total groundfish catch and non-groundfish bycatch by species, it eliminated much of the concern that total fishing mortality was being underestimated due to fish that were discarded at sea. Second, it made it possible to establish, monitor and enforce the groundfish quotas in terms of total catch as opposed to only retained catch. For the groundfish fisheries, this means that both retained catch and discarded catch are counted against the TACs. Third, it made it possible to implement and enforce bycatch quotas for the non-groundfish species that by regulation had to be discarded at sea. Finally, it provided extensive information that managers and the industry could use to assess methods to reduce bycatch and bycatch mortality. In summary, the observer program provided fishery managers with the information and tools necessary to prevent bycatch from adversely affecting the stocks of the bycatch species. Therefore, the bycatch in the groundfish fishery is principally not a conservation problem but it can be an allocation problem. Although this does not make it less controversial, it does help identify the types of information and management measures that are required to reduce bycatch to the extent practicable, as is required by the Magnuson-Stevens Fishery Conservation and Management Act (MSA).

Residents of Alaska and of other states, particularly Washington and Oregon, are active participants in the BSAI and GOA groundfish fisheries. Catch data by residency of vessel owners are presented in Table 17. These data were extracted from the NMFS blend catch database and from the State of Alaska groundfish fish ticket database and vessel registration file which includes the stated residency of each vessel owner. For the domestic groundfish fishery as a whole, 95% of the 2002 catch was made by vessels with owners who indicated that they were not residents of Alaska. The catches of the two vessel-residence groups were much closer to being equal in the Gulf where Alaskan vessels accounted for the majority of the Pacific cod catch.

Table 18 contains the estimated ex-vessel prices that were used with estimates of retained catch to calculate ex-vessel values. The estimates of ex-vessel value by area, gear, type of vessel, and species are in Table 19. The ex-vessel value of the domestic landings in the FMP fisheries, excluding the value added by at-sea processing, increased from \$384 million in 1998 to \$461 million in 1999, increased again in 2000 to \$593 million, decreased to \$543 million in 2001, and increased to \$566 in 2002. The distribution of ex-vessel value by type of vessel differed by area, gear and species. In 2002, catcher vessels accounted for 57% of the ex-vessel value of the groundfish landings compared to 47% of the total catch because catcher vessels take larger percentages of higher-priced species such as sablefish, which was \$2.11 per pound in 2002. Similarly, trawl gear accounted for only 73% of the total ex-vessel value compared to 91% of the catch because much of the trawl catch is of low-priced species such as pollock, which was about \$0.12 per pound in 2002.

Tables 20 and 20.1 summarize the ex-vessel value of catch delivered to shoreside processors by vessel-size class, gear, and area. Table 20 gives the total ex-vessel value in each category and Table 20.1 gives the ex-vessel value per vessel. The relative dominance of each of the three vessel size classes differs by area and by gear.

Table 21 provides estimates of ex-vessel value by residency of vessel owners, area, and species. For the BSAI and GOA combined, 84.6% of the 2002 ex-vessel value was accounted for by vessels with owners who indicated that they were not residents of Alaska. Vessels with owners who indicated that they were residents of Alaska accounted for 15.3% of the total and the remaining 0.2% was taken by vessels for which the residence of the owner was not known. The vessels owned by residents of Alaska accounted for a much larger share of the ex-vessel value than of catch (15.3% compared to 5.3%) because these vessels accounted for relatively large shares of the higher-priced species such as sablefish.

Table 22 presents estimates of ex-vessel value of catch delivered to shoreside processors, and Table 22.1 gives the ex-vessel value of groundfish as a percentage of the ex-vessel value of all species delivered to shoreside processors. The data in both tables, which include both state and federal managed groundfish, are reported by processor group, which is a classification of shoreside processors based primarily on their geographical locations. The processor groups are described in the footnote to the tables.

Gross product value (F.O.B. Alaska) data, through primary processing, are summarized by category of processor and by area in Table 23, and by catcher/processor size class, gear, and area in Table 24. Table 24.1 reports gross product value per vessel, categorized in the same way as Table 24. Tables 25 and 25.1 present gross product value of groundfish processed by shoreside processors and the groundfish gross product value as a percentage of all-species gross product value, both tables are broken down by processor group. The processor groups are the same as in Tables 22 and 22.1 and no distinction is made between groundfish catch from the state and federal managed groundfish fisheries.

Although at-sea processors were required to complete the Alaska Department of Fish and Game (ADF&G) Commercial Operators' Annual Report (COAR) this year, the estimates of gross product value (i.e., revenue) for at-sea processors in 2002 are calculated the same as in previous years in order to provide a comparison of the estimates from year to year. These estimates are based on COAR product price data (submitted voluntarily by at-sea processors for activity through 2001) and on product quantity data in the NMFS Weekly Production Reports (WPR). Beginning with the 2001 report (Hiatt et al. 2001), the estimates of gross product value for shoreside processors were based on COAR product price and quantity data. Prior to that, the estimates for all processors were based on COAR price data and WPR product quantity data.

Estimates of the numbers and net registered tonnage of vessels in the groundfish fisheries are presented by area and gear in Table 26 and estimates of the numbers of vessels that landed groundfish are depicted in Fig. 6 by gear type. More detailed information on the BSAI and GOA groundfish vessels by type of vessel, vessel size class, catch amount classes, and residency of vessel owners is in Tables 27 - 31. In particular, Table 28.1 gives detailed estimates of the numbers of smaller (less than 60 feet) hook-and-line catcher vessels. Estimates of the number of vessels by month, gear, and area are in Table 32. Table 33 provides estimates of the number of catcher vessel weeks by size class, area, gear, and target fishery. Table 34 contains similar information for catcher/processor vessels. For this year's report, we have improved our estimates of the numbers of vessels participating in federally-managed groundfish fisheries by excluding those vessels that fished only under either sablefish permits in the inside waters of southeast Alaska or non-groundfish gear operator permits. This change affects Tables 26-33 and results in significant reductions in the numbers of vessels counted compared to the numbers published in last year's report (Hiatt et al. 2002).

For the purposes of Regulatory Flexibility Act analyses, a business involved in fish harvesting is a small business if it is independently owned and operated and not dominant in its field of operation (including its affiliates) and if it has combined annual receipts not in excess of \$3.5 million for all its affiliated operations worldwide. The information necessary to determine if a vessel is independently owned and operated and had gross earnings of less than \$3.5 million, is not available. However, by using estimates of Alaska groundfish revenue by vessel, it is possible to identify vessels that clearly are not small entities. Estimates of both the numbers of fishing vessels that clearly are not small entities and the numbers of fishing vessels that could be small entities are presented in Tables 26.1 and 26.2, respectively. With more complete revenue,

ownership, and affiliation information, some of the vessels included in Table 26.2 would be determined to be large entities. Estimates of the average revenue per vessel for the vessels in Tables 26.1 and 26.2, respectively, are presented in Tables 26.3 and 26.4.

The Weekly Production Reports include employment data for at-sea processors but not inshore processors. Those data are summarized in Table 35 by month and area. The data indicate that in 2002, the crew weeks totaled 102,727 with the majority of them (97,440) occurring in the BSAI groundfish fishery. In 2002, the maximum monthly employment (17,095) occurred in March. Much of this was accounted for by the BSAI pollock fishery.

Estimates of weight and value of the processed products made with BSAI and GOA groundfish catch are presented by species, product form, area, and type of processor in Tables 36, 37 and 38. Product price-per-pound estimates are presented in Table 36.1.

There are a variety of at least partially external factors that affect the economic performance of the BSAI and GOA groundfish fisheries. They include landing market prices in Japan, wholesale prices in Japan, U.S. imports of groundfish products, U.S. per capita consumption of seafood, U.S. consumer and producer price indexes, foreign exchange rates, and U.S. cold storage holdings of groundfish. Such data are included in Tables 39 - 49.

Exchange rates and world supplies of fishery products play a major role in international trade. Exchange rates change rapidly and can significantly affect the economic status of the groundfish fisheries. There is also considerable uncertainty concerning the future conditions of stocks, the resulting quotas, and future changes to the fishery management regimes for the BSAI and GOA groundfish fisheries. The management actions taken to allocate the catch between various user groups can significantly affect the economic health of either the domestic fishery as a whole or segments of the fishery. Changes in fishery management measures are expected as the result of continued concerns with: 1) the bycatch of prohibited species; 2) the discard and utilization of groundfish catch; 3) the effects of the groundfish fisheries on marine mammals and sea birds; 4) other effects of the groundfish fisheries on the ecosystem and habitat; 5) excess harvesting and processing capacity; and 6) the allocations of groundfish quotas among user groups.

Notes: All groundfish and all gear may include additional categories. These estimates include only catch counted against federal TACs. Although these are the best available estimates of discards and are used for several management purposes, these estimates are not necessarily accurate. The reasons for this are as follows: 1) they are wholly or partially derived from observer estimates; 2) discards occur at many different places on vessels; 3) observers record only a rough approximation of what they see; 4) the estimation methods used by at-sea observers focus on providing good estimates of total catch by species, not on the disposition of that catch.

Source: Blend estimates, National Marine Fisheries Service, P.O. Box 15700, Seattle, WA 98115-0700.

Notes: Totals may include additional categories. The target, determined by AFSC staff, is based on processor, week, processing mode, NMFS area, and gear. These estimates include only catch counted against federal TACs. Although these are the best available estimates of discards and are used for several management purposes, these estimates are not necessarily accurate. The reasons for this are as follows: 1) they are wholly or partially derived from observer estimates; 2) discards occur at many different places on vessels; 3) observers record only a rough approximation of what they see; and 4) the estimation methods used by at-sea observers focus on providing good estimates of total catch by species, not on the disposition of that catch.

Notes: Totals may include additional categories. The target, determined by AFSC staff, is based on processor, week, processing mode, NMFS area, and gear. These estimates include only catch counted against federal TACs. Although these are the best available estimates of discards and are used for several management purposes, these estimates are not necessarily accurate. The reasons for this are as follows: 1) they are wholly or partially derived from observer estimates; 2) discards occur at many different places on vessels; 3) observers record only a rough approximation of what they see; and 4) the estimation methods used by at-sea observers focus on providing good estimates of total catch by species, not on the disposition of that catch.

Notes: These estimates include only catches counted against federal TACs. Totals may include additional categories. The estimates of halibut bycatch mortality are based on the International Pacific Halibut Commission discard mortality rates that were used for in-season management. The halibut Individual Fishing Quota program allows retention of halibut in the hook-and-line groundfish fisheries, making true halibut bycatch numbers unavailable. This is particularly a problem in the Gulf of Alaska for all hook-and-line fisheries and in the Bering Sea and Aleutian Islands for the sablefish hook-and-line fishery. Therefore, estimates of halibut bycatch mortality are not included in this table for those fisheries.

Notes: These estimates include only catches counted against federal TACs. Totals may include additional categories. The estimates of halibut bycatch mortality are based on the International Pacific Halibut Commission discard mortality rates that were used for in-season management. The halibut Individual Fishing Quota program allows retention of halibut in the hook-and-line groundfish fisheries, making true halibut bycatch numbers unavailable. This is particularly a problem in the Bering Sea and Aleutian Islands sablefish hook-and-line fishery. Therefore, estimates of halibut bycatch mortality are not included in this table for that fishery.

Source: Blend estimates, National Marine Fisheries Service, P.O. Box 15700, Seattle, WA 98115-0070.

Notes: Totals may include additional categories. The target, determined by AFSC staff, is based on processor, week, processing mode, NMFS area and gear. These estimates include only catch counted against federal TACs. International Pacific Halibut Commission discard mortality rates are used to estimate halibut mortality. The halibut Individual Fishing Quota program allows retention of halibut in the hook-and-line groundfish fisheries making true halibut bycatch numbers unavailable. No prohibited species bycatch numbers were available for the sablefish fishery.

Source: Blend estimates, National Marine Fisheries Service, P.O. Box 15700, Seattle, WA 98115-0070.

* Prices do not include the value added by at-sea processing; therefore they reflect prices prior to processing. Prices do reflect the value added by dressing fish at sea, where the fish have not been frozen. Except where noted unfrozen landings price is calculated as landed value divided by estimated or actual round weight.

** Since this category is not well represented by on-shore landings, a price was calculated from product-report prices. The price in this case is the value of the product divided by the calculated round weight and multiplied by a constant .4 to correct for value added by processing.

*** This column is the weighted average of the other columns.

Note: These estimates include only catches counted against federal TACs. Ex-vessel value is calculated using prices on Table 18. Please refer to Table 18 for a description of the price derivation. Catch delivered to motherships is classified by the residence of the owner of the mothership. All other catch is classified by the residence of the owner of the fishing vessel. All groundfish include additional species categories.

Table 22.1 Ex-vessel value of groundfish as a percentage of the ex-vessel value of all species delivered to shoreside processors by processor group, 1996-2002. (percent)

	1996	1997	1998	1999	2000	2001	2002
Processor group:							
Alaska Peninsula/Aleutians	12.3%	16.1%	10.8%	9.8%	16.0%	22.1%	23.1%
Bering Sea Pollock Processors	66.4%	73.5%	56.6%	56.2%	77.1%	81.5%	77.9%
Kodiak	32.6%	43.5%	39.8%	40.1%	48.0%	45.3%	55.8%
South Central	22.7%	20.7%	18.8%	15.2%	23.1%	19.6%	18.8%
Southeastern	21.7%	26.8%	22.4%	18.6%	23.3%	18.9%	22.5%
TOTAL	28.1%	34.0%	27.6%	25.5%	38.3%	40.8%	44.6%

Note: This table includes the value of groundfish purchases reported by processing plants, as well as by other entities, such as markets and restaurants, that normally would not report sales of groundfish products. Keep this in mind when comparing ex-vessel values in this table to gross processed-product values in Table 25. The data are for catch from the EEZ and State waters. The processor groups are defined as follows:

"Bering Sea Pollock Processors" are the AFA inshore pollock processors including the two AFA floating processors.

"Alaska Peninsula/Aleutian" are other processors on the Alaska Peninsula or in the Aleutian Islands.

"Kodiak" are processors on Kodiak Island.

"South Central" are processors west of Yakutat and on the Kenai Peninsula.

"Southeastern" are processors located from Yakutat south.

Table 23. Gross product value of Alaska groundfish by area and processing mode, 1997-2002 (\$ millions).

	Gulf of Alaska		Bering Sea and Aleutian		All Alaska	
	At-sea	Shoreside	Motherships	Catcher/ processors	Shoreside	Total
1997	30.2	212.6	79.6	626.7	280.0	1,229.0
1998	28.3	237.2	58.8	539.8	160.7	1,024.8
1999	43.0	207.6	58.1	579.9	289.4	1,178.1
2000	41.8	199.1	81.5	624.1	399.4	1,345.8
2001	26.9	176.9	90.5	663.9	432.6	1,390.8
2002	36.5	170.0	99.0	710.7	466.5	1,482.8

Note: For shoreside processors, these estimates include production resulting from catch from federal and state of Alaska fisheries. For at-sea processors, they include production only from catch counted against federal TACs. Catcher/processors that at times during a year act like motherships are classified as catcher/processors for the entire year. For shoreside processors the area represents the location of the plant, not necessarily the area of the catch.

Notes: A vessel that fished more than one category in a week is apportioned a partial week based on catch weight. A target is determined based on vessel, week, processing mode, NMFS area, and gear. All groundfish include additional target categories.

Source: Blend estimates, fish tickets, Norpac data, federal permit file, CFEC vessel data, National Marine Fisheries Service, P.O. Box 15700, Seattle, WA 98115-0070.

Notes: A vessel that fished more than one category in a week is apportioned a partial week based on catch weight. A target is determined based on vessel, week, processing mode, NMFS area, and gear. All groundfish include additional target categories.

Note: Crew weeks are calculated by summing weekly reported crew size over vessels and time period. These estimates include only vessels targeting groundfish counted toward federal TACs. Catcher processors accounted for the following proportions of the total crew weeks in all areas: 1998 - 93%, 1999 - 97%, 2000 - 90%, 2001 - 90%, 2002 - 89%.

2002	287.1	11.0	4.3	.3	15.6

Note: Per capita consumption represents pounds of edible meat consumed from domestically caught and imported fish and shellfish adjusted for beginning and ending inventories, and exports, divided by the civilian population of the United States as of 1 July of each year. Population estimates for 1980-91 were revised to reflect changes from the 1990 decennial population enumeration. Changes did not significantly alter pounds per capita.

Regional Economic Information

This section provides information concerning the importance of seafood processing in Alaska to regional economic activity in Alaska. Subsequent analyses will address the importance of other sectors of the fishing industry to regional economic activity in Alaska and in other states.

Processing Sector Analysis

Seafood processing is an important part of the basic sector in many coastal regions in Alaska. In this section, the importance of seafood processing sector for the coastal regions is measured in terms of the following: (1) the percentage of total employment in a region accounted for by seafood processing employment, (2) labor earnings in seafood processing as a percentage of total regional labor earnings, (3) multipliers for an example Alaska region, Kodiak Island Borough, and (4) economic base analysis for eleven selected fishery-dependent areas using employment and labor income multipliers. Since different data will be used for the analysis in this section, a comparative discussion of the different data is provided before the results of the analysis are presented.

1. Data

Four different sources of employment/earnings data by borough/census area are used for analysis in this section. They are the U.S. Census, the Bureau of Economic Analysis (BEA)/Regional Economic Information System (REIS), IMPLAN (IMpact analysis for PLANning), and the Alaska Department of Labor (ADOL). The following descriptions of the data from each source explain why the employment/earnings estimates differ by source.

Census Data

The Census Bureau collects primary data on population, housing, and economic characteristics (income and employment by industry) every ten years. The employment in the Census data is defined as the number of employed civilian population 16 years or over, and includes self employment. The Census definition of employment is different from the definitions used by other data sources such as BEA, IMPLAN, and ADOL below, in which employment is defined as the number of full- and part-time jobs. Since a worker can have more than one job, it is possible that the employment in an industry reported in Census data is smaller than that reported by the other data sources. The Census data also reports the employment in armed forces. The strength of the Census data is that it is gathered by primary research rather than by other secondary sources. However, it does not provide annual information. In addition, seafood processing employment is not separated from total manufacturing employment in the Census data. Also, information on labor earnings by industry is not available.

BEA/REIS Data

In the BEA data, the nation's disparate economic data are reconciled into a single set of balanced accounts. Thus, the BEA data provides a comprehensive view of the nation's economic activity. BEA relies almost entirely on secondary data provided by many federal government agencies including the Census Bureau, Bureau of Labor Statistics (BLS), and Internal Revenue Service (IRS). For wage and salary employment, BEA takes the information from BLS employment data, which comes from state report ("Alaska Quarterly Contribution Report" for Alaska). For information on self-employment, BEA relies on IRS data. One of the major BEA products is the REIS. The REIS data has information on both labor income by industry and other sources of income such as transfer payment and investment income. In producing REIS, BEA uses the data generated via various federal and state programs, including unemployment insurance (UI), social security, and military payroll. The BEA/REIS employment data is generated every year. The employment in BEA/REIS data is defined as the total number of full- and part-time jobs. The employment data includes self-employment and military employment as well as wage and salary jobs; however, as with other data sources, fisherman employment is underestimated. BEA/REIS data do not separate seafood processing employment from total manufacturing employment. Much of the information on employment and earnings for industries are confidential.

IMPLAN Data

IMPLAN data is generated by Minnesota IMPLAN Group, Inc. IMPLAN has two components – the database and the software. IMPLAN database includes data on 21 economic and demographic variables for 528 sectors for any county (borough) or state in the U.S. The economic variables include employment, value-added, government purchases, and household purchases. The database also includes use matrix and make matrix. The use matrix details the dollar values of intermediate inputs used in each industry to produce output in the industry – i.e., the goods and services purchased by each industry and used in its production process. The make matrix gives the value of each commodity or service produced by each industry. It is possible for a single industry to produce more than one commodity. The software is an algorithm to solve an input-output (IO) model. IMPLAN was originally developed by the USDA Forest Service to assist the agency in land and resource management planning. In 1993, Minnesota IMPLAN Group (MIG), Inc. took over the development of IMPLAN data and software. IMPLAN data are available for years 1990 through 2000. The currently available version of IMPLAN software is version 2.0. The new version (version 3.0), which will be released soon, will use new industry classification scheme called North American Industrial Classification System (NAICS), and will have the capability to develop multiregional input-output (MRIO) models, in which interregional flows of intermediate inputs are specified.

Three different employment data sets comprise the IMPLAN employment data since no one data set provides enough information to make a complete database. These data sets are the BLS ES 202 data, the REIS data, and the County Business Patterns (CBP) data. ES 202 data (“covered employment and wages” data) contains quarterly job and wage data from all employers participating in state UI program. Since states collect the data as part of the UI program, only establishments that pay UI are captured. This means that the data misses self-employed workers or any other establishments that do not pay into the UI program. IMPLAN uses CBP data to derive those employment numbers which are missing in ES 202 data and in REIS data due to confidentiality. The REIS data is expanded to separate wage and salary employment and self-employment. The REIS data is then used as final control totals. Employment in IMPLAN is defined as the number of full- and part-time jobs. There are three fishery-related sectors in the IMPLAN data. They are Commercial Fishing (Sector 25), Canned and Cured Seafood (Sector 97), and Prepared Fresh or Frozen Fish or Seafood (Sector 98). In IMPLAN, both self employment and military employment are included in the total regional employment; however, as with other data sources, fisherman employment is underestimated. Like BEA/REIS data discussed above and ADOL data discussed below, IMPLAN data is available for every year.

ADOL Data

ADOL collects data on employment and earnings from employers through the UI program. Under this program, each employer is required to file in each quarter the Alaska Quarterly Contribution Report (Form 1004) to the state. This report includes information on the number of workers who worked during or received pay for the payroll period, which includes the 12th of the month, for each of the three months in a quarter. Also, the report has information on, among other things, (1) number of workers employed at some time during the quarter and (2) names, social security numbers, and reportable wages of the workers. This information would only be available for workers employed at any time during a calendar quarter, not monthly, since employers file quarterly and do not indicate which of their workers were employed in which month of the quarter. The data by worker are confidential, as are the data by sector and area if there are not a sufficient number of employers for a sector in an area. These confidential data are not available to NMFS. Currently, the ADOL monthly employment data is available for years 1997 through 2001 at borough or census area level. However, ADOL has historical employment data available back to 1990 for six larger economic regions (Table 1). The employment in the ADOL data is defined as total number of full- and part-time jobs. The employment on Alaska Quarterly Contribution Report is the number of employees (jobs), not the number of different individuals, because workers holding more than one job or who change jobs during the week of the 12th may be reported by more than one employer. The annual average monthly employment in the ADOL employment data is derived by dividing the summation of monthly employments over 12 months by number of months (12 months). Self-employment is not included in the data. Fishers are self-employed, and therefore, are not included in

the ADOL employment data. Most of agricultural workers are excluded from ADOL employment data (Personal communication with Dan Robinson, ADOL). The wage and salary employment not covered by UI is estimated and included in the employment data. The total regional employment reported in the data includes civilian military workers (personal communications with Jeff Hadland, ADOL). The ADOL employment data has several advantages over Census data, BEA/REIS data, and IMPLAN data. First, ADOL data provides monthly employment numbers and annual average employment numbers. Second, the employment numbers for all industries are disclosed – i.e., not confidential. Third, the ADOL data separates seafood processing employment (i.e., employment in “Food and Kindred Products”) from total regional manufacturing employment. However, the ADOL data has a limitation, self employment is not included. In addition, uniformed military employment is not reported in ADOL data set. Overall, however, ADOL data is judged to be the best data for the analysis in this section because no other data provides more frequent and detailed information on seafood processing employment than the ADOL data. Table 2 shows which categories of employment (e.g., wage and salary employment and self-employment) are included in each of the four data sources.

2. Processing Employment as Percentage of Total Regional Employment

Table 3 presents the percentages of employment accounted for by seafood processing employment for selected boroughs and census areas in Alaska and for the state. Different data sources are used to calculate the numbers in the table. The average percentages from the different data sources are also estimated. Only those boroughs and census areas whose average percentage for processing employment is five percent or higher are listed in the table. To calculate the percentages in the second column in Table 3, 1998 IMPLAN data are used. Percentages are calculated by dividing employment (full- and part-time jobs) in seafood processing sector (IMPLAN sectors 97 and 98) by the total regional employment given by IMPLAN. Since many of the fishermen/crew members in commercial harvesting sector are not captured in the IMPLAN data, the total regional employment could be underestimated. This implies that the percentages for processing employment in the second column in this table could be overestimated.

To calculate the percentage in the third column, 2000 ADOL data are used. Percentages are calculated by dividing annual average monthly employment (full- and part-time jobs) in Food and Kindred Products sector by the total regional employment. However, since self-employment (fishermen and most agricultural workers) is not included in the total regional employment in ADOL data, it is possible that the percentages presented in third column are overestimated. The percentages reported in the fourth column are computed using 2000 BEA/REIS data. Since BEA/REIS data do not separate seafood processing employment from total regional manufacturing employment, it was necessary to adjust the BEA/REIS information in the following manner. First, the percentage of processing employment (Food and Kindred Products) to the total manufacturing employment is

calculated for each region using ADOL data. Then, this percentage is multiplied by the percentage of total manufacturing employment to total regional employment derived from BEA/REIS data, to compute the percentages reported in this column.

For the numbers in the fifth column, 2000 U.S. Census data are used. Like BEA/REIS data, Census data do not separate seafood processing employment from total manufacturing employment. Therefore, to calculate the percentages reported in this column, first, the percentage of processing employment (Food and Kindred Products) to the total manufacturing employment is calculated for each region using ADOL data. This percentage is then multiplied by the percentage of total manufacturing employment to total regional employment derived from U.S. Census data, to calculate the percentages reported in this column. Although Census data has information on employment in armed forces, the total regional employment used to compute the percentages of processing employment in the fifth column does not include any military employment. As a result, it is possible that the percentages reported in this column are overestimated. The last column in the table presents the average percentages computed using the four different sources. According to the last column, the four regions with the highest average percentage are Aleutians East Borough (59.6%), Aleutians West Census Area (40.6%), Kodiak Island Borough (21.6%), and Bristol Bay Borough (20.0%). The average percentage for the state is 2.5%.

Figures 1 through 4 are based on ADOL data. Figure 1 presents the processing employment as percentage of total regional employment from 1997 to 2001 for three larger Alaska regions which are heavily dependent on fisheries – Southwest, Gulf Coast, and Southeast regions. Table 1 lists the boroughs and census areas which belong to each of these and other larger Alaska regions. Figure 1 shows that the percentages of employment accounted for by seafood processing employment in Southwest region are the highest for all years, followed by Gulf Coast and Southeast regions. Figures 2, 3, and 4 present the processing employment as percentages of total regional employment from 1997 to 2001 for selected boroughs and census areas in Southwest, Gulf Coast, and Southeast regions, respectively. As shown in Figure 2, the percentages for Aleutian East Borough are the highest for all years, followed by Aleutian Island West Census Area and other areas.

Table 4 presents monthly distribution of processing employment for the same boroughs and census areas as in Table 3, i.e., those boroughs and census areas whose average percentage of processing employment is five percent or higher, and for state of Alaska. 2001 ADOL employment data are used to calculate the numbers in Table 4. Percentages are computed by dividing monthly employment in Food and Kindred Products sector by total annual employment in the sector.

3. Labor Earnings in the Seafood Processing Sector as Percentage of Total Regional Labor Earnings

Table 5 presents labor income in the seafood processing sector as a percentage of total regional labor income for selected areas. Only three different data sources – IMPLAN, ADOL, and BEA/REIS – are used to calculate the numbers in the table since Census data do not provide labor earnings data by industry. The average percentages from the different data sources are also presented in the last column. Table 6 presents the dollar amount of labor earnings from 1998 IMPLAN data for selected areas. In the second column of the table, labor earnings in the seafood processing sectors (IMPLAN sectors 97 and 98) are presented. The third column shows the labor earnings in Food and Kindred Products (IMPLAN sectors 58-103). The fourth column presents similar information for the whole manufacturing sector (IMPLAN sectors 58-432). In the fifth column, the ratios of labor earnings in the seafood processing sector to labor earnings in the Food and Kindred Products sector are presented. In the sixth column, the ratios of labor earnings in seafood processing sector to labor earnings in the whole manufacturing sector are shown. The ratios in the sixth column in Table 6 could be used to adjust some of the percentages in the fourth column in Table 5. For example, in Table 5, the labor income in the whole manufacturing sector is about 7.1 percent of the total regional labor income for Valdez-Cordova Census Area. This percentage (7.1 %) can be multiplied by the ratio (0.74) of seafood processing earnings to the labor earnings in the whole manufacturing sector for the same area in the sixth column in Table 5, to derive the labor earnings in the seafood processing sector as a percentage of total regional labor income.

Table 7 presents the annual labor earnings in the seafood processing sector for years 1992 through 2001, for selected areas. Table 8 presents the annual labor earnings as a percentage of total regional labor earnings for the same years and for the same selected areas. The information presented in Table 9 and Figure 5 is based on data obtained from an economist (Dan Robinson) at ADOL. Table 9 presents annual labor earnings in the seafood processing sector (not “Food and Kindred Products” sector) for 13 years (1990-2002) for Southwest, Gulf Coast, and Southeast regions. Figure 5 shows labor earnings in the seafood processing sector as percentage of total regional labor earnings for years 1997 through 2001 for the same regions. In calculating the percentages in Figure 5, data for total regional labor earnings is from *Employment and Earnings Summary Report* (ADOL, various years) and the data for labor earnings in the seafood processing sector (not “Food and Kindred Products” sector) is obtained from the ADOL economist. Since the total regional labor earnings data in the *Employment and Earnings Summary Report* is available for only five years (1997-2001), Figure 5 shows the annual percentages for the five years only.

In Table 10, seafood processing labor income as percentage of *total personal income* for each of the selected areas is shown. The total personal income used to calculate the percentages in the table is derived as earnings by place of work (i.e., total regional labor earnings) minus personal contribution for social insurance plus adjustment for residence plus transfer payments and investment income (dividends,

interest, and rent). Transfer payments, an important source of personal income in Alaska, are presented for years 1992 through 2001 in Table 11.

4. Multiplier Analysis for Kodiak Island Borough

When there is an exogenous change in final demand for the goods and services of a region, there are direct, indirect, and induced effects on a regional economy. Input-output (IO) models are used to estimate these effects. Direct effects are the changes in the industries (e.g., changes in output, employment, or labor income) to which a final demand change was made. Indirect effects are changes in inter-industry purchases as they respond to the new demands of the directly affected industries. Induced effects reflect changes in household spending as income changes due to the changes in production. The total effects are the sum of direct, indirect, and induced effects. In an IO model, a multiplier is defined as the total effects (direct, indirect, and induced effects) divided by the direct effects. There are three types of multipliers used in this analysis – output multiplier, employment multiplier, and labor income multiplier. An output multiplier measures the effects on outputs of the sectors in a regional economy. Thus, the output multiplier is defined as the increase (decrease) in total regional output (total effects) due to an increase (decrease) in final demand for an industry's output by \$1 (direct effects). An employment multiplier measures the effects on employment (in physical terms) due to an increase (decrease) in final demand for an industry's output by \$1 million. A labor income multiplier measures the effects on labor income generated due to an increase (decrease) in final demand for an industry's output by \$1. Labor income in this section is defined as employee compensation plus proprietors' income. Multiplier values depend on, among other things, the size of the economy, the relationships between industries, and the leakage of expenditures and income. For detailed definitions of these and other terms used in IO analysis, see Miller and Blair (1985).

In this section, an inter-industry, multiplier analysis is conducted using an IO model for Kodiak Island Borough as an example fishery-dependent region. The Kodiak Island IO model is implemented by 1998 IMPLAN data and software. The 528 IMPLAN sectors are aggregated into 16 sectors – 13 private sectors and 3 government sectors. Table 12 shows how the sectors are aggregated. For the multiplier analysis in this section, the two IMPLAN seafood processing sectors (Sectors 97 and 98) are aggregated into one sector labeled Fish Processing Sector in this analysis.

Tables 13, 14, and 15 present output, employment, and labor income multipliers, respectively, for the 16 aggregated sectors for the Kodiak Island Borough. The estimated multipliers in Table 13 indicate that if the landings of raw fish (ex-vessel value) caught by catcher vessels owned by residents of the borough increase by \$1 million, then the total output in the borough will increase by about \$1.25 million. This includes only downstream effects; therefore, it does not include any of the effects of the associated increase in seafood production. The estimates in that table also indicate that if there is an increase in final demand for processing output (e.g.,

exports of processed products) by \$1million, then the total output in the regional economy will increase by \$1.37 million, which is the sum of \$1 million (direct effects), \$0.23 million (indirect effects), and \$0.14 million (induced effects). The multipliers given in the table show by how much a change in final demand for the output of an industry (or landings for commercial fishing industry) contributes to the regional economy. For example, the indirect effects of \$0.23 million, due to a \$1 million increase in seafood processing output, include increased demand of fish processing sector for raw fish from commercial fishing sector (i.e., catcher vessels owned by residents of the region) and goods and services from other regional economic sectors.

Although not reported in Table 13, the increased demand for fish processing sector will result in increase in imports of raw fish (i.e., raw fish landed by catcher vessels owned by non-residents). The increased imports of raw fish to the borough (i.e., the increased exports of raw fish from the rest of the world (ROW) to the borough) will require the ROW commercial fishing sector to increase its output (harvest of raw fish) to meet the increased exports to the borough. To produce more output, the ROW commercial fishing sector will need to use more of each intermediate input (fuel and other goods and services). Some of these intermediate inputs used for harvesting activity on ROW-owned vessels are purchased from the borough. Conceptually, those intermediate inputs purchased from the borough are exports from the borough to the ROW. The increase in exports of these intermediate inputs from the borough to the ROW will have another round of positive effects on the borough's economy although most of those inputs (goods and services) purchased by ROW-owned vessels from the borough are imported from the ROW. But, this round of effects from the increased exports by the borough is not captured by the Kodiak Island Borough IO model. The reasons are that export is an exogenous variable in the IO model, and that the IO model is a single-region model in which the interregional feedback effects are not addressed. However, the base-year IMPLAN data for exports includes the borough's exports of these inputs to ROW-owned vessels (Personal communication with Doug Olson, IMPLAN).

As was mentioned above, the values of multipliers depend on the relationships between industries. If more reliable data, such as Fish Ticket data, on the purchases of raw fish by the fish processing sector from resident-owned catcher vessels and nonresident-owned catcher vessels is available, the multiplier values reported in Table 13 and those in Tables 14 and 15 below can be improved.

Table 14 presents employment multipliers for the region. The table says, for example, that if the landings of raw fish by locally owned vessels increase by \$1 million, then about 16 new jobs (full- and part-time jobs) will be created in the commercial fishing industry (direct effects) and about 3 additional jobs (indirect and induced effects) will be created in the economy. In total, about 19 new jobs will be created in the region (total effects). Looking at the processing industry, \$1 million

increase in final demand for processing output will result in about 7 new jobs in processing industry (direct effects) and about 5 additional jobs (indirect and induced effects) in the borough. The additional 5 jobs include those local jobs in commercial fishing sector and other sectors, which are created due to increased purchases by the fish processing sector of goods and services from these sectors (indirect effects) and those jobs in the sectors, which are created due to increased household spending (induced effects). There will be a total of about 12 new local jobs created in the borough (total effects).

Table 15 presents labor income multipliers for the borough. The table shows, for example, that if landings of raw fish increase by \$1 million (i.e., if the landings of raw fish (ex-vessel revenue) by catcher vessels owned by residents of Kodiak Island Borough increase by \$1 million), then the labor income from the commercial fishing industry will increase by about \$311,000 (direct effects) and the total labor income in the region will increase by about \$402,000 (total effects). The directly generated labor income of \$311,000, or about 31.1 % of total ex-vessel value, is paid to resident and nonresident fishermen on the resident-owned catcher vessels. The labor income share of 31.1 % is compared to a crew share of 40 %, which was estimated initially by Fisheries Economic Assessment Model (FEAM) and later used by Northern Economics in their Supplemental Environmental Impact Statement (DPSEIS; Northern Economics, November 2001). Table 15 also shows that if final demand for processing output increases by \$1 million, then the labor income from the processing industry will increase by about \$212,000 and the total labor income in the region will increase by about \$339,000. The direct effect of about \$212,000 is about 21.2 % total value of output in fish processing sector. This labor income share of 21.2 % is compared to a labor income share used in DPSEIS. DPSEIS assumed that processing labor accounts for 20 to 30 percent of total wholesale production value for the various processor classes.

5. Economic Base Analysis

In this section, the contribution of the seafood processing sector to overall regional economic activity is measured by conducting an economic base analysis for 11 selected fishery-dependent areas. According to economic base theory, a region's economic base determines the level of total economic activity of the region. In economic base analysis, the sectors that export a large share of their production are called basic sectors. These sectors bring in the money from outside, which is spent and respend on other sectors (non-basic sectors) within the economy, generating multiplier effects. The seafood processing sector is an important basic sector for fishery-dependent areas in Alaska since much of its output is exported. A preferred method for conducting an economic base analysis is an IO model such as IMPLAN model. Therefore, the IMPLAN IO model with its 1998 data is used for the economic base analysis in this section. As in the multiplier analysis for Kodiak Island Borough above, the two IMPLAN seafood processing sectors (sectors 97 and 98) are aggregated into one sector to conduct the analysis.

Table 16 presents processing employment, total regional employment, and employment that is dependent on processing activity for each of the selected areas. The total processing-dependent employment is the sum of direct, indirect, and induced effects. For example, the total processing-dependent employment in Aleutian East Borough of 1,244.2 jobs is the sum of 1,123.7 jobs (direct effects), 54.8 jobs (indirect effects), and 65.7 jobs (induced effects). Direct effects in this analysis are the jobs that produce exported products in processing sector. These jobs are directly dependent on the exports of processed products. For example, in Kodiak Island Borough, about 98.2% (1,966.5 jobs) out of the total labor in the sector (2,002 jobs) is used to produce processed products for exports. The rest of the labor (35.5 jobs = 2,002 jobs – 1,966.5 jobs) in the processing sector in Kodiak Island Borough produces processed products to satisfy local demand from restaurants, grocery stores, etc. Indirect effects are the jobs in non-processing industries that produce commodities and services used as intermediate inputs in production of exported products in the seafood processing sector. Induced effects are the jobs created in the economy when households spend income earned from both direct and indirect effects.

Table 16 shows that the processing-dependent employment (column (7)) in all the areas is larger than the processing employment (column (1)). For example, processing employment in Aleutian East Borough (second row in the table) is 1,146 jobs or about 66.3 percent of total regional employment (column (3)). The total processing-dependent employment in the borough is about 1,244.2 jobs (column (7)), which accounts for about 72.0 percent of total regional employment (column (9)). In column (8), employment multipliers for the selected areas are shown. For example, the employment multiplier for Aleutians East Borough is 1.11. This means that the total regional employment will increase by 1.11 jobs if employment in seafood processing sector increases by one job, which results from an increase in sales of processed products. Table 16 also presents the ratios of total processing-dependent employment to processing employment (column (10)). The region with the highest ratio is Haines Borough. The ratio for this borough is 1.62. This means that for every job created in seafood processing sector as a result of, say, an increase in landings, additional 0.62 jobs are created in non-processing industries in the borough. Although the processing employment in Aleutians East Borough is relatively large (1,146 jobs), the ratio of processing-dependent to processing employment is relatively small probably due to a large leakage of expenditures and income from the borough. The ratio for the borough is only 1.09, which means that, for every job created in processing industry, only 0.09 additional jobs are created in the rest of the borough economy. The table also shows that, for state of Alaska as a whole, a new job in processing sector results in additional 0.6 jobs in the rest of the state economy. Table 17 presents similar information for processing labor income for each of the selected areas.

The IMPLAN model employed for the economic base analysis and multiplier analysis for Kodiak Island Borough above is useful, but has some limitations. First,

the model uses a national-level production function for regional industries including seafood industries. This could be a problem for Alaska seafood industries because the production functions of the industries in Alaska could be different from the national average production functions. Second, much of labor employed in commercial fishing industry is excluded in the IMPLAN data. Third, IMPLAN does not have good information on leakages of expenditures and income. For example, there are some discrepancies in information about leakage of labor income between IMPLAN data and published data (e.g., ADOL data). For these reasons, it is necessary to obtain primary or survey data to fix these problems in IMPLAN.

Some of these limitations can be overcome relatively easily by revising the IMPLAN data with information in other studies/reports without collecting primary or survey data. For example, Northern Economics estimated payments to labor on catcher vessels owned by residents of Kodiak Island region as 40 % of ex-vessel values, which are obtained from Commercial Fisheries Entry Commission (CFEC) Fish Tickets data and Alaska state vessel-registration files. Using the Northern Economics' estimate of the labor earnings, the IMPLAN labor earnings data can be revised. On the other hand, it is not an easy task to revise the production function for commercial fishing sector because one needs to collect, via survey, the data on the expenditures of catcher vessels, and revise all the numbers in the IMPLAN production function. Because of these limitations of IMPLAN data, it is possible that the indirect and induced effects and related results presented in Tables 16 and 17 are over or underestimated.

A: The percentages can not be estimated because no information is available for labor earnings for Food and Kindred Products sector and the whole manufacturing sector.

B: Since the labor earnings information for Food and Kindred Products is not available, the percentages are calculated as labor earnings in the whole manufacturing sector divided by total regional personal income.

Note: The total personal income used to calculate the percentages in the table is derived as earnings by place of work (i.e., total regional labor earnings) minus personal contribution for social insurance plus adjustment for residence plus transfer payments and investment income (dividends, interest, and rent).

Table 12 Sector Aggregation for Multiplier Analysis for Kodiak Island Borough

IMPLAN SECTORS	NAMES OF AGGREGATED SECTORS
Sectors 1-24 and 26-27	Agriculture
Sector 25	Commercial Fishing
Sectors 28-47	Mining
Sectors 48-57	Construction
Sectors 97 and 98	Fish Processing
Sectors 58-89, 90-96, and 99-432	Other Manufacturing
Sectors 433-440	Transportation
Sectors 441-442	Communications
Sectors 443-446	Public Utilities
Sector 447	Wholesale Trade
Sectors 448-455	Retail Trade
Sectors 456-462	FIRE
Sector 519	Federal Gov't – military
Sector 520	Federal Gov't – non-military
Sectors 522-523	State and Local Gov't
Sectors 463-518, 521, 524-528	Services

Note: FIRE is Finance, Insurance, and Real Estate

Table 13 Output Multipliers for Kodiak Island Borough

Industry	Direct effects	Indirect effects	Induced effects	Total effects	Multiplier

State and Local	21.0	0.0	5.2	26.2	1.25

Source: 1998 IMPLAN data

Note: The direct, indirect, and induced effects are defined per million dollars of output. Employment is in number of full- and part-time jobs. In addition to wage and salary employment, IMPLAN employment reported in this table includes self-employment and military employment. Many of the crew members/fishermen in the commercial fishing sector are excluded from the IMPLAN data.

Table 15 Labor Income Multipliers for Kodiak Island Borough

Industry	Direct effects	Indirect effects	Induced effects	Total effects	Multiplier
Agriculture	495,893	52,571	106,818	655,282	1.32
