1 Introduction

The North Pacific Fishery Management Council (Council) developed its groundfish management policy in 2004, following a comprehensive review of the Bering Sea and Aleutian Islands (BSAI) and Gulf of Alaska (GOA) groundfish fisheries. The *Alaska Groundfish Fisheries Programmatic Supplemental Environmental Impact Statement* (2004 PSEIS; NMFS 2004) evaluated the cumulative changes in the management of the groundfish fisheries since the implementation of the Fishery Management Plan for the Groundfish of the Bering Sea and Aleutian Islands Management Area (BSAI FMP) and the Fishery Management Plan for the Groundfish of the Gulf of Alaska (GOA FMP) and considered a broad array of policy-level programmatic alternatives. On the basis of the analysis, the Council adopted a management approach statement, and nine policy goal statements with 45 accompanying objectives. The management policy is included in full in Appendix 1.

Periodically, the Council conducts a review of the nine policy goal statements and accompanying objectives to assess how they are being implemented, and see whether changes are warranted.[1] In February 2012, in conjunction with this review, the Council also reviewed a discussion paper identifying factors that may influence the timing for supplementing or updating the 2004 PSEIS. An expanded discussion paper was later reviewed in June 2012. To determine if a revision or supplement to the 2004 PSEIS was necessary, the Council and NMFS decided first to conduct a "non-NEPA" evaluation of the 2004 PSEIS using a supplemental information report (SIR).

A SIR is a tool to evaluate the need to prepare a new environmental impact statement (EIS) to supplement a previous EIS. The National Environmental Policy Act (NEPA) requires agencies to prepare a supplemental EIS (SEIS) to either draft or final EISs if the agency (1) makes substantial changes in the proposed action that are relevant to environmental concerns; or (2) there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts (40 CFR 1502.9(c)). An SEIS is required if the new information is sufficient to show a proposed or remaining action will affect the quality of the human environment in a significant manner or to a significant extent not already considered. If a subsequent related Federal action occurs, and new information indicates that the subsequent action will affect the quality of the human environment in a significant manner or to a significant extent not already considered, an SEIS must be prepared. Courts have upheld the use of SIRs, and similar non-NEPA evaluation procedures, for the purpose of determining whether new information or changed circumstances require the preparation of a supplemental EIS.

With this SIR analysis, the Council and NMFS have been able to determine whether the triggers for supplementing the PSEIS have been met. In April 2014, the Council evaluated the information in the draft SIR, and concluded both that a supplemental EIS was not required, and also that they did not choose to reinitiate programmatic changes to the groundfish fisheries that would necessitate an SEIS. NMFS has since finalized the SIR and reached a determination affirming that the 2004 PSEIS continues to provide NEPA compliance for the groundfish FMPs.

---

[1] Changes to the management approach statement, the nine policy goal statements, or the 45 objectives would require an FMP amendment.

2 Considerations for Supplementing the 2004 PSEIS

2.1 What triggers the need to prepare an EIS?

NEPA requires that an EIS be prepared on proposals for legislation and other major Federal actions significantly affecting the quality of the human environment (40 CFR 1502.3). EISs are also prepared (1) when the proposed action is novel, (2) when there is controversy in the underlying science used to understand the impacts of the alternatives, or (3) when the potential impacts are unknown. Courts have also found that significant scientific differences of opinion, controversy, and uncertainty require preparation of an EIS.[2]

2.2 What is a programmatic EIS?

A "major Federal action" includes adoption of official policy, formal plans, programs, and specific projects (40 CFR 1508.18). When the EIS addresses a policy, plan, or program, it is called a programmatic EIS or PEIS. PEISs should focus on broad Federal proposals and be timed to coincide with meaningful points in planning and decision making. Preparing a PEIS presents an opportunity to evaluate cumulative impacts of past, present, and reasonably foreseeable future actions under the program or within a geographical area. NEPA's legal requirements for a PEIS are the same as those for an EIS.

2.3 What triggers the need to prepare a supplemental EIS?

NEPA requires agencies to prepare an SEIS to either draft or final EISs if the agency (1) makes substantial changes in the proposed action that are relevant to environmental concerns, or (2) there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts (40 CFR 1502.9(c)). An agency need not supplement an EIS every time new information comes to light. Not every change requires the preparation of an SEIS; only those changes that cause effects that are significantly different from those already studied require supplementary consideration.[3] The Supreme Court explained that "an agency need not supplement an EIS every time new information comes to light after the EIS is finalized. To require otherwise would render agency decision-making intractable."[4]

An SEIS is required if the new information is sufficient to show a proposed or remaining action will affect the quality of the human environment in a significant manner or to a significant extent not already considered.[5] If a subsequent related Federal action occurs, and new information indicates that the subsequent action will affect the quality of the human environment in a significant manner or to a significant extent not already considered, an SEIS must be prepared.[6]

2.4 What is the history leading to the 2004 PSEIS?

The Council and NMFS prepared EISs for the original BSAI FMP and GOA FMP, finalized in 1981 and 1979, respectively. In March 1997, NMFS issued a Notice of Intent to prepare an SEIS on "the Federal action by which total allowable catch specifications and prohibited species catch limits in the groundfish fisheries that are conducted in the Bering Sea and Aleutian Islands Area and the Gulf of Alaska are annually established and apportioned." (62 FR 15151, March 31, 1997). NMFS explained why the SEIS was needed:

> The fisheries have evolved … through the Council process including FMP amendments, regulations, and continued compliance with other Federal laws and executive orders. The frequencies of marine mammal, marine bird, and fish species in the biological assemblage present now are different from frequencies that existed and were displayed in [the EISs prepared for the original FMPs]. Several marine species have been listed under the Endangered Species Act, some of which may be affected by fishery management actions. New information about the ecosystem, impacts of the fisheries, and management tools has become available since the EISs were prepared (62 FR 15152, March 31, 1997).

Given these changes and new information, NMFS stated that the SEIS would incorporate the following:

> … the amendments to the FMPs; the annual process for determining the [total allowable catch] TAC specifications; and the public processes for in place for implementing new regulations, revising existing ones, and incorporating new information. … The SEIS will analyze the process by which annual TAC specifications and prohibited species catch limits are determined, together with the procedures for implementing changes to those processes. The processes encompass decisions about location and timing of each fishery, harvestable amounts, exploitation rates, exploited species, groupings of exploited species, gear types and groupings, allocations, product quality, organic waste and secondary utilization, at-sea and on-land organic discard, species at higher and lower trophic levels, habitat alterations, and relative impacts to coastal communities, society, the economy, and the domestic and foreign groundfish markets. Effects of these decisions are manifested over many years in multifaceted social and biological arenas. Inherent in implementing groundfish fisheries management regime are commitments to provide in-season management, enforcement, monitoring, stock assessment, and summary analyses. In addition to evaluating the no Action Alternative, the SEIS will include a full range of alternatives and discussions of their potential impacts on the biological and socioeconomic environments. (62 FR 15152, March 31, 1997).

Other than the general description alternatives quoted above, no specific alternatives were identified in the Notice of Intent.

NMFS issued a Final SEIS in December 1998 (1998 SEIS; NMFS 1998). The 1998 SEIS stated that the attainment of Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) goals and NEPA regulations require a periodic evaluation of the impacts of the BSAI and GOA groundfish fisheries on (1) the stocks of fish taken as catch and bycatch in the groundfish fisheries, (2) protected species including marine mammals and seabirds, (3) other components of the BSAI and GOA ecosystems, (4) habitat, and (5) those who benefit from consumptive and non-consumptive uses of the living marine resources of the BSAI and GOA.[7] The 1998 SEIS updated the scientific information known about the North Pacific ecosystem, and analyzed this information by considering a range of

[7] 1998 SEIS, at 2.

alternative total allowable catch (TAC) levels: (1) the status quo method of setting TAC levels annually, for each species complex, within the optimum yield (OY) range based on the biological status of the species and "other ecological and socio-economic aspects of the fisheries"; (2) setting TAC levels at the lower end of the OY range; (3) setting TAC levels at the upper end of the OY range; and (4) no directed groundfish fishing. The SEIS did not consider how new information about the affected environment related to other aspects of the fisheries that the FMPs regulate, such as time and area closures, gear restrictions, bycatch limits of prohibited species, and allocations of TACs among vessels delivering to different types of processors groups, gear types, and qualifying communities.

2.5 Why did the court determine a programmatic SEIS was needed?

The adequacy of the 1998 SEIS was challenged in U.S. district court.[8] The plaintiffs argued that NEPA required NMFS to prepare an SEIS that included alternatives commensurate with the broad scope of the FMPs.[9] Because the 1998 SEIS analyzed the new information under a range of alternatives dealing with only one particular aspect of the FMPs – TAC levels – the plaintiffs argued that the scope of the 1998 SEIS was impermissibly narrow.[10] By narrowing the range of alternatives to those specifically dealing with TAC levels rather than the FMPs as a whole, the plaintiffs argued that NMFS failed to take the requisite "hard look" at the environmental consequences of the agency action, the FMPs.[11] NMFS argued that the agency properly defined the scope of the SEIS and considered an adequate range of alternatives.[12]

In July 1999, the court ruled that the 1998 SEIS was impermissibly narrow and thus legally inadequate under NEPA, and remanded the document back to NMFS for additional analysis, directing the agency to produce a "programmatic" SEIS.[13] Briefly stated, the court determined a broad programmatic SEIS that fairly evaluated the dramatic and significant changes that occurred in the groundfish fisheries in North Pacific ecosystem was required by NEPA "[i]n light of the significant changes to the FMPs and the new information about the broad range of issues" covered by the regulations managing the fisheries.[14] Because the 1998 SEIS narrowly focused its analysis on TAC levels, the court determined that it was not sufficiently broad.[15]

In reaching this conclusion, the court first determined that the action under review in the 1998 SEIS should have been the FMPs and the numerous regulations managing the groundfish fisheries. The court noted that the FMPs constituted major Federal actions requiring an EIS,[16] that NMFS seemed to acknowledge that an SEIS to the original EISs was necessary under both the "substantial changes to the action" and the "significant new information" prongs of 40 CFR 1502.9(c),[17] and that the level of detail necessary in an SEIS is directly related to scope of Federal action under NEPA review.[18] Because the FMPs as a whole were the proposed action about which there were significant new circumstances and to which substantial changes had been made, an SEIS that examined only one aspect of the FMPs, TAC

levels, was insufficient to satisfy the requirements at 40 CFR 1502.9(c). The court also found that the SEIS lacked any explanation of why and how analysis of TAC levels "results in a practical analysis" of the impact of the fisheries, as governed by a myriad of regulations.[19] The court's determination that the SEIS must be treated as a broad, programmatic analysis of the FMPs as a whole lead directly to its conclusion that the range of alternatives considered in the 1998 SEIS was inadequate.[20]

The court also determined that NEPA regulations at 40 CFR 1508.7 and 1508.27(b)(7) required NMFS to prepare an analysis that thoroughly examined the cumulative effects of the changes that had occurred to the FMPs.[21] The court concluded that the "vast changes to the FMPs have reached the threshold of 'cumulatively significant impact on the human environment,' thereby requiring preparation of an SEIS addressing these vast changes."[22]

In summary, the court stated that NEPA requires NMFS to analyze the ways in which the groundfish fisheries affect the North Pacific ecosystem, and to provide decision-makers and the public with a document that will help further informed decision-making as to the consequences of the FMPs.[23] The 1998 SEIS, by focusing its analysis only on TAC levels, did not fulfill this mandate.[24]

2.6 Will the Council and NMFS have to prepare a new PSEIS at some point?

As stated in numerous court decisions, Federal agencies have a continuing duty to gather and evaluate new information relevant to the environmental impacts of its actions and to review the continuing vitality of an EIS in light of changing conditions.[25] As stated in Friends of the Clearwater v. Dombeck:

> "…[A]n agency that has prepared an EIS cannot simply rest on the original document. The agency must be alert to new information that may alter the results of its original environmental analysis, and continue to take a "hard look at the environmental effects of [its] planned action, even after a proposal has received initial approval. It must "ma[ke] a reasoned decision based on … the significance or lack of significance – of the new information," and prepare a supplemental EIS when there are "significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts." "If there remains major Federal action to occur, and the new information is sufficient to show that the remaining action will affect

25 See Warm Springs Dam Task Force v. Gribble, 621 F.2d 1017, 1023-1024 (9th Cir. 1980); Monarch Chemical Works v. Exon, 452 F.Supp 493, 500 (D.C. Neb. 1978). See also Southern Oregon Citizens v. Clark, 720 F.2d 1475, 1480 (9th Cir. 1983). This continuing duty is especially relevant where the original EIS covers a series of actions continuing over a decade. … In general, an EIS concerning an ongoing action more than five years old should be carefully examined to determine whether a supplement is needed); Senville v. Peters, 327 F.Supp.2d 335, 355-56 (D. Vt. 2004) – An agency's duty to take a hard look at the environmental consequences of its proposed action does not end with publication of an EIS. NEPA imposes an ongoing obligation to supplement EISs if there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts. The decision whether to prepare an SEIS is similar to the decision whether to prepare an EIS in the first place. Major Federal action, plus new information that shows "that the remaining action will affect the quality of the human environment in a significant manner or to a significant extent not already considered," dictates the preparation of an SEIS. Marsh 490, 360-61. The parties do not dispute that the proposed action is major, nor that there is new information. At issue is whether the new information results in impacts that are significantly different in degree or in kind from the impacts previously considered.

> the quality of the human environment in a significant manner or to a significant extent not already considered, a supplemental EIS must be prepared."[26]

The court in Friends of the Clearwater v. Dombeck also stated: "As we have admonished, Compliance with NEPA is a primary duty of every Federal agency; fulfillment of this vital responsibility should not depend on the vigilance and limited resources of environmental plaintiffs."[27] It is the agency, not an environmental plaintiff, that has a "continuing duty to gather and evaluate new information relevant to the environmental impact of its actions," even after release of an EIS.

The Supreme Court has held that supplementation of an EIS is necessary only if there remains major Federal action to occur.[28] As the court in Defenders of Wildlife v. Bureau of Ocean Energy Management, Regulation, and Enforcement stated that:[29]

> Although the case law is not uniform, a reasonable, helpful formulation of the "major Federal action" test provides that if "the actions remaining to the [agencies] ... are purely ministerial, or if the agencies have no discretion that might usefully be informed by further environmental review, then there is no major federal action and no SEIS must be prepared." Hammond v. Norton, 370 F.Supp.2d 226, 255 (D.D.C.2005) (citing Citizens Against Rails–to–Trails v. Surface Transp. Bd.,267 F.3d 1144, 1151 (D.C.Cir.2001)); see also Southern Utah Wilderness Alliance v. Office of Surface Min. Reclamation and Enforcement, 2008 WL 4912058, *12 (D.Utah Nov. 14, 2008) (no "major federal action" requiring supplemental EIS where agency "retained no discretion to decide whether the projects should go forward or to determine the terms and conditions of the projects' approval").

Because fisheries management is dynamic – the FMPs are regularly amended to adjust fisheries management based on new circumstances, and new information on the environment and the impacts of fishing on the environment is continually being developed – and because the Council and the agency have broad discretion to manage fisheries consistent with the requirements of the MSA, the Council and the agency have a continuing duty to gather and evaluate new information relevant to the environmental impacts of its actions and to review the continuing vitality of its PSEIS in light of changing conditions.[30] When the changes and the information is significantly different in degree or in kind from the impacts previously considered, the Council and the agency must prepare a supplement to the PSEIS.

2.7 How do the Council and NMFS decide when it is time to initiate a new PSEIS?

The passage of time alone does not trigger the need for a supplement. However, the Council of Environmental Quality (CEQ) advises in its Forty Most Asked Questions (46 FR 18026, March 23, 1981) that an EIS over five years old should be carefully scrutinized to determine whether there are changes in the action or the affected environment:

[29] 791 F.Supp.2d 1158 (S.D.Ala. May 23, 2011)

[30] NEPA requires an agency to continue evaluating a project's environmental effects, even after preparation of an initial EIS. From Greenpeace Decision at 1259; see also Chemical Weapons v. U.S. Department of Army 935 F. Supp. 1206, 1217-19 (D. Utah 1996) (preliminary injunction denied on allegations of new information with respect to EIS on chemical weapons disposal facility; in this case, the daily operation will itself constitute major Federal action that would require a supplemental EIS if new information is sufficient to show that the remaining action will affect the quality of the human environment in a significant manner or to a significant extent not already considered).

Question No. 32: Supplements to Old EISs. Under what circumstances do old EISs have to be supplemented before taking action on a proposal?

A. As a rule of thumb, if the proposal has not yet been implemented, or if the EIS concerns an ongoing program, EISs that are more than 5 years old should be carefully reexamined to determine if the criteria in Section 1502.9 compel preparation of an EIS supplement.

If an agency has made a substantial change in a proposed action that is relevant to environmental concerns, or if there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts, an SEIS must be prepared for an existing EIS so that the agency has the best possible information to make any necessary substantive changes in its decisions regarding the proposal (40 CFR 1502.9(c)).

To determine if an SEIS is necessary at this time, the Council and NMFS conducted a "non-NEPA" evaluation of the 2004 PSEIS resulting in this SIR. A SIR is a tool to evaluate the need to prepare a new EIS to supplement a previous EIS. Courts have upheld the use SIRs and similar non-NEPA evaluation procedures for the purpose of determining whether new information or changed circumstances require the preparation of a supplemental EIS.[31] This SIR discusses each of the considerations for an SEIS: changes to the action, new information, and new circumstances, and whether these changes are significant and relevant to environmental concerns and the impacts of the proposed action. Depending on the results of this analysis, the Council and NMFS may determine that the triggers for supplementing the PSEIS have not been met and therefore a new PSEIS is not necessary at this time. On the other hand, the SIR may provide detailed information demonstrating that the triggers have been met and that a new PSEIS should be prepared. Note that if the Council and NMFS determine new information or circumstances are significant, the Council or NMFS must prepare a supplemental EIS; a SIR cannot serve as a substitute.[32]

The Council also considered whether to initiate an environmental assessment or a supplemental EIS. The Council considered the following factors in its decision to do a SIR:

- A SIR is not a NEPA document; therefore the Council would retain some flexibility in defining the public participation process as well as general timing issues.
- A SIR could help inform the Council if it chooses to consider whether to revise the objectives, policy statements, or overall management approach for the groundfish fisheries found in the current FMP and NEPA analysis.
- A SIR could also inform the public and serve as a useful focal point for further discussions with the Council.
- Since a SIR cannot serve as a substitute for a proper NEPA document, an environmental assessment (EA) or supplemental EIS, once final, would ensure NEPA compliance.
- An EA or an SEIS would require a proposed action, purpose and need, and a reasonable range of alternatives and the related NEPA requirements for these documents.

The Council chose to move forward with a SIR, to:

United States Dep't of Transp., 42 F.3d 517, 529-30 (9th Cir 1994), Price Rd. Neighborhood Ass'n v. United States Dep't or Transp., 113 F.3d 1505, 1510 (9th Cir. 1997)

[32] Idaho Sporting Congress, Inc. v. Alexander, 222 f.3d 562, 566 (9th Cir. 2000)

- Evaluate the changes to the action, Federal groundfish fisheries management, since the 2004 PSEIS using readily available information synthesized into a complete picture of today's fishery management so that it could be compared to the fishery management regime described under the preferred alternative in the 2004 PSEIS.
- Identify the new information available and new circumstances since 2004 by summarizing the new information in the stock assessment and fishery evaluation (SAFE) reports, recent analytical documents (EAs, EISs, and biological opinions), and any other sources.
- Evaluate whether the changes in the action, new information, and the new circumstances are significant and relevant to environmental concerns and the impacts of the proposed action by assessing whether the impacts predicted in the 2004 PSEIS for the preferred alternative are still valid given these changes since 2004.

This SIR enables the Council and NMFS to evaluate new information and make a reasoned determination whether it is sufficiently significant to require formal supplementation under NEPA. Courts have upheld an agency's decision not to supplement if it is reasonable. The reasonableness of an agency's decision not to supplement depends on such factors as the environmental significance of the new information, the probably accuracy of the information, the degree of care with which the agency considered the information and evaluated its impact, and the degree to which the agency supported its decision not to supplement with a statement of explanation or additional data.[33] The court plays the limited role of determining, under the foregoing standards, whether the new information is so significant that it would be irresponsible, arbitrary, and capricious for the agency not to act on it. However, the court would determine whether the new information presents a seriously different picture of the likely environmental consequences of the proposed action than the picture already considered. Resolution of this dispute involves primarily issues of fact requiring deference to the informed discretion of the responsible agency.[34]

2.8 What efficiencies are gained by doing an EIS?

EISs are major undertakings, and the process to determine whether or not to supplement an existing EIS also requires substantial effort and analysis. However, as explained above, NEPA analysis is required for major Federal actions and once an EIS is completed, there is a continuing duty to make sure the analysis is relevant in light of new information, circumstances, or changes in the proposed action. Once an EIS is completed for a proposed action and that action is implemented, the EIS is useful for subsequent related actions and for understanding the impacts of specific actions in the larger context. Having an EIS can greatly streamline future NEPA analyses using tools described in the CEQ regulations. A comprehensive programmatic EIS can also allow other efficiencies for future NEPA analyses, such as tiering, incorporation by reference, or in applicable instances, allowing for categorical exclusions (see short summaries of these actions below).

The 2004 PSEIS implemented a change to the groundfish management policy. Each subsequent action to implement the policy has been evaluated in a separate NEPA document. The 2004 PSEIS provides the baseline for conducting NEPA analysis for groundfish management actions. NMFS and Council staff incorporate by reference the information in the 2004 PSEIS, and update as necessary in the NEPA analysis for a specific action. This allows the subsequent NEPA document to focus on recent information and information relevant to the action, without a large amount of background information, or a re-analysis

[33] Oregon Natural Resources Council v. Marsh, 845 F.Supp. 758, 766-69 (D. Ore. 1994)
[34] Oregon Natural Resources Council v. Marsh, 845 F.Supp. 758, 766-69 (D. Ore. 1994)

of the status quo. Also, the 2004 PSEIS provided a comprehensive analysis of the cumulative effects and past actions that are relied on for groundfish action EAs.

Tiering

Tiering means the coverage of general information in a PEIS with subsequent narrower EISs or EAs incorporating by reference the general discussions from the PEIS and concentrating solely on the issues specific to the subsequent project-specific action (40 CFR 1508.28, 40 CFR 1500.4(i), 1502.4(d), and 1502.20). The CEQ regulations encourage agencies preparing NEPA documents to "tier their environmental impact statements to eliminate repetitive discussions of the same issues and to focus on the actual issues ripe for decision at each level of environmental review." Specifically, 40 CFR 1502.20 states the following:

> Whenever a broad environmental impact statement has been prepared (such as a program or policy statement) and a subsequent statement or environmental assessment is then prepared on an action included within the entire program or policy (such as a site specific action) the subsequent statement or environmental assessment need only summarize the issues discussed in the broader statement and incorporate discussions from the broader statement by reference and shall concentrate on the issues specific to the subsequent action.

In 40 CFR 1508.28, the CEQ regulations further define tiering as "the coverage of general matters in broader environmental impact statements … with subsequent narrower statements or environmental analyses incorporating by reference the general discussions and concentrating solely on the issues specific to the statement subsequently prepared." This section of the CEQ regulations further notes that tiering is appropriate "when the sequence of statements or analyses is … from a program, plan, or policy environmental impact statement to a program, plan, or policy statement or analysis of lesser scope or to a site-specific statement or analysis."

Incorporation by reference

An EIS can incorporate by reference material from other sources (40 CFR 1502.21). Incorporated material must be cited and summarized in the EIS and must be publicly available. Information that is not publically available may not be incorporated by reference into an EA or EIS.

Categorical Exclusion

NOAA Administrative Order 216-6 (NAO 216-6) sets forth requirements for implementing and documenting Categorical Exclusions (CEs). Section 5.05 provides information on the general requirements for CEs. Section 6.03 provides specific guidance on the use of CEs for various types of actions undertaken by NOAA. For example, Section 6.03a.3 provides guidance regarding CEs for management plan amendments (i.e., FMP amendments).

As defined in section 6.03a.3(b)(1) of NAO 216-6, a proposed action would be categorically excluded from the need to prepare an EA or an EIS if the proposed action is a minor change to a previously analyzed and approved action and the proposed change has no effect individually or cumulatively on the human environment.

2.9 What risks might be present if a NEPA-compliant programmatic SEIS is not in place?

It is a statutory requirement to comply with NEPA. The primary means of enforcing NEPA is through lawsuits brought by concerned private citizens, interest groups, and state and local agencies (Bass et al., 2001). Plaintiffs typically ask for declaratory judgments establishing the government's NEPA obligations or a writ of mandamus ordering specific agency action to comply with NEPA (Bass et al., 2001). Plaintiffs may also seek preliminary injunction:

> If a preliminary injunction is granted, courts will enjoin some or all project activities pending NEPA compliance, and may order appropriate NEPA documents to be prepared. … Most courts decide to grant a preliminary injunction by balancing … the plaintiff's probability of success on the merits of the claim, the harm to the plaintiff if the injunction is denied versus the harm to the defendant if it is granted, and whether the public interest would be served by granting the injunction. Courts may also be asked to issue a permanent injunction …. In some cases, a court may find a NEPA violation but deny an injunction based on equitable principles.

It should be noted that if a court does order a new NEPA document be prepared, the court will set the schedule, likely with input from both parties, but that such a schedule might not be favorable for the Council or NMFS.

3 Approach

The primary purpose of this SIR is to evaluate comprehensively whether either of the two requirements for supplementing an EIS has been met with respect to the 2004 PSEIS:

1. if NMFS and the Council have made a substantial change in the proposed action (i.e., the management of the Federal groundfish fisheries) that is relevant to environmental concerns, or
2. if there are significant new circumstances or information relevant to environmental concerns and bearing on the management of the groundfish fisheries or their impacts.

With respect to the first requirement, there have been changes to the management program since the 2004 PSEIS, as documented in the May 2012 discussion paper (NPFMC 2012). All management changes since 2004 have been subject to NEPA analysis. The Council's Scientific and Statistical Committee (SSC) discussed the management changes at their March 2012 meeting in Anchorage, Alaska, and determined that the changes are all consistent with the preferred alternative evaluated in the 2004 PSEIS. The management changes synthesized in this SIR are not identified as substantial changes relevant to environmental concerns.

As a result, this SIR focuses more on the second requirement, to allow NMFS and the Council to make a reasoned determination of whether, since the 2004 PSEIS was completed, there exist new circumstances or information that are sufficiently significant to require supplementation under NEPA. The goal is to evaluate whether information since 2004 indicates that the groundfish fisheries affect the quality of the human environment in a significant manner or to a significant extent that was not considered in the 2004 PSEIS.

This SIR evaluates whether there are significant new circumstances or information relevant to the groundfish fisheries by reevaluating the conclusions from the 2004 PSEIS in light of new information, to see whether there are likely to be changes to the impacts. This SIR provides information to answer two overarching questions:

- Are the impacts predicted in the 2004 PSEIS for the preferred alternative still valid, given any changes since 2004?
- Does the new information present a seriously different picture of the likely impacts of the groundfish fisheries on a particular resource, compared to what was considered in the 2004 PSEIS?

This has been addressed by analysts revisiting each of the 2004 PSEIS conclusions, and considering the following questions in light of new information:

- Has the way that the resource is managed under the groundfish FMPs changed?
- Has the status of the resource changed?
- Is there new information regarding the impacts of the groundfish fisheries on the resource?
- Are there new methods of analysis or protocols for evaluating impacts?
- Based on information that is available imminently or now, would a new analysis using the latest methods and information reach a seriously different conclusion?

Additionally, this SIR builds on the SSC's review of environmental impacts from the March 2012 meeting. The SSC considered whether, on the basis of existing analyses, the Council understands the environmental impacts of the groundfish management program today, by evaluating (1) whether environmental conditions affecting the fisheries have changed, (2) whether the status of fish stocks and other marine life has changed, and (3) the availability of new information. The SSC identified many continuing trends and variability in environmental conditions and status of stocks that were accounted for in the 2004 PSEIS. There were, however, a few distinct areas that merit further investigation. These include the following:

- changes in the spatial and temporal distribution of the groundfish fisheries in response to fishery management changes, together with technical innovations, may have altered the environmental impact of fishing
- changes in species abundance affecting interactions with groundfish fisheries, particularly those species that are listed under the Endangered Species Act (ESA)
    - increase in the abundance of whale populations may be altering lower trophic level energy pathways in the region
    - the continued decline of the western portion of the western distinct population segment of Steller sea lions
    - the declining trend of Northern fur seal populations on the Pribilof Islands
    - increase in short-tailed albatross populations and potential for increased incidental take by fisheries
    - listing of certain crab stocks as overfished and consequent Council action restricting groundfish fisheries
    - increase in arrowtooth flounder and Pacific halibut populations in the GOA and Bering Sea (BS), and changes in the size at age of halibut
- changes in the ice extent and season in the BS and Arctic impacting the distribution and behavior of cetaceans and pinnipeds, as well as lower trophic levels and patterns of productivity. Resulting direct and indirect impacts of fishing activity are not well understood.

The advantage of focusing the SIR more comprehensively on the conclusions of the PSEIS, rather than limiting it specifically to the issues identified by the SSC, is that it provides updated information on the entire management program. By providing a more comprehensive evaluation of the current fisheries baseline, the final SIR can be incorporated by reference with the 2004 PSEIS when analyzing proposed groundfish management actions in future EAs. Even though a SIR is not a NEPA document, it can be referenced in NEPA analyses, especially if the overall conclusion of the SIR is that the PSEIS remains valid. In this way, the SIR will better meet the Council and NMFS' intent to develop a document that also improves efficiency for other management actions.

The approach used in this SIR is similar to that used for the 2010 Essential Fish Habitat (EFH) 5-year review. In that evaluation, stock assessment authors, and other experts, were asked to review EFH information contained in the Council's FMPs (and the 2005 EFH EIS, NMFS 2005) in the context of any new information. The authors were each asked to consider a series of questions about whether new information is available and relevant for identifying EFH for their species, whether changes in fishing activities over the time period were likely to have affected the fishing impacts analysis, and whether, based on these considerations, they concurred with the description of EFH and habitat associations that is included in the FMPs. In the case of the EFH 5-year review, the authors' responses were vetted through the Council's Groundfish Plan Teams, and then compiled into a summary report that was presented to the Council, upon which basis the Council subsequently initiated amendments to the FMPs.

For this SIR, a similar approach has been employed. Scientific experts have been identified for each of the resource components analyzed in the 2004 PSEIS, primarily Alaska Fisheries Science Center (AFSC) staff. In many cases, these are the lead authors that prepared those sections for the 2004 PSEIS, or who prepare annual stock assessments. These experts were asked to review the 2004 PSEIS analysis and conclusions, consider them in light of new information, and determine whether the 2004 conclusions are still valid. In order to provide everyone with a similar understanding of what is required in the review, staff facilitated a kickoff workshop to discuss the project, and prepared a template identifying the questions to be addressed (Appendix 2). The experts completed their review, and their contributions were synthesized by Council and Alaska Region staff into a draft SIR. The draft SIR was presented to the Council's SSC and the Council in April 2014 for review, and a 60-day public comment period was offered at the request of stakeholders who wished to submit written comments. Minor revisions were made to the draft SIR, to address issues raised in public and Council comments. When revisions addressed information in the resource reviews, these were made in collaboration with the expert reviewers. Finally, the SIR was finalized with the agency's determination.

4 Description of the 2004 PSEIS

4.1 History of the 2004 PSEIS

In late1990s, NMFS and the Council realized that they needed to take a broader view of the cumulative effects of their management decisions. Typically, the Council addresses a management problem by developing specific solutions. Staff analyzes alternatives to determine their direct effects in a variety of contexts, and the Council shares that analysis with the public prior to making a decision and forwarding that recommendation to the agency and the Secretary of Commerce for final review and approval.

Beginning in 2000, the Council and NMFS conducted a comprehensive, programmatic environmental review of the BSAI FMP and GOA FMP. The analysis evaluated the management of Alaska's groundfish fisheries from a policy-level perspective, with alternatives ranging from a more aggressive harvest management policy to a highly precautionary one. Each management policy was illustrated and framed with a range of management measures within which the Council would intend to implement the alternative. The 2004 PSEIS, published in June 2004, serves the Council and NMFS as the overarching EIS in support of Federal authorization of the groundfish fisheries off Alaska. It also described the physical, biological, and human environment; every fishery and gear type; and scientific data gaps and research needs.

In April 2004, the Council used this PSEIS as the basis for amending its FMPs to incorporate a new policy statement that communicates its intent to take a more precautionary approach to fishery management decision-making when faced with scientific uncertainty. The Council now routinely reviews its policy goals and objectives when making decisions and when developing its annual workplan.

One aspect of the 2004 PSEIS that made its preparation particularly challenging was that approximately 25 years of management decisions had to be evaluated as a cumulative whole. Both FMPs had over 80 plan amendments that had to be reviewed and analyzed, and the management program had changed substantially during the time period, from a fishery with a large foreign participation, to an exclusively domestic one. The next time it is appropriate to revisit the Council's management policy, and supplement the 2004 PSEIS, it should be more straightforward, as an environmental baseline has been established, and the new analysis will focus on the actions taken by the Council and NMFS since then.

4.2 What did the 2004 PSEIS analysis address?

The Federal action that was analyzed in the 2004 PSEIS was the authorization of the groundfish fisheries under the existing management program. There were four policy-level alternatives included in the PSEIS, from which the Council crafted a fifth, preferred alternative (Table 1). For each alternative, a management approach statement was developed, with accompanying objectives. Example FMPs were included to illustrate how the Council might implement each policy alternative with specific management measures. For all alternatives except the status quo, the policy alternative was illustrated with two example FMPs, which were intended to indicate the range of management measures that might fall within the implementation of that alternative. Although the example FMPs were important to illustrate how a management policy might operate in practice, the adoption of the policy itself was the immediate outcome of the 2004 PSEIS. It was intended that the Council would undertake subsequent amendments to fully implement the new management policy, as illustrated in the example FMPs, over the next five to ten years.

4.3 Data used in the 2004 PSEIS analysis

The data used in the analysis of biological impacts for groundfish stocks was largely based on 2002 stock assessments, using data from the 2001 and 2002 surveys. For some other seabird and marine mammal species, the most recent assessment data may have been from 2000. For the economic analysis, the most recent year included in the detailed fishery analysis was 2001. This was the basis on which the draft PSEIS was prepared, and issued for public comment in 2003. Some adjustments were subsequently made during the preparation of the 2004 PSEIS, to take into account more recent information. For example, the results from the new model for assessing impacts of fishing on essential fish habitat were incorporated in the analysis. In general, however, the most recent information in the document dates from 2000 to 2002.

4.4 Impacts of the Preferred Alternative

The following subsections summarize conclusions for each resource component analyzed in the 2004 PSEIS. The impact analyses started with the baseline status of each resource category, and then evaluated how specific characteristics of each component would respond directly and indirectly to management actions under the preferred alternative (PA) FMP bookends, PA.1 and PA.2. The expected cumulative effects on that stock were also evaluated and discussed, building on the direct and indirect effects evaluations as a starting point, and then bringing in persistent past effects as well as reasonably foreseeable future natural events and human activities external to fisheries management.

Possible evaluations were significant and beneficial (S+), insignificant (I), significant and adverse (S-), and unknown (U). In addition, effects were classified as conditionally significant (CS+ or CS-), if significant effects could be expected under a plausible set of conditions. The intent of the conditional label was to imply uncertainty about whether an alternative FMP would actually result in conditions that led to a significant impact. When the conditional label was applied, a plausible mechanism for the impact and the conditions under which a significant impact would be realized was stated. In cases where data were lacking to rank an effect according to the significance criteria, the effect was determined to be unknown.

Table 1 Alternatives analyzed in the 2004 PSEIS

Alternative	Example FMP bookend(s)
Alternative 1 ***Continue Under the Current Risk Averse Management Policy***	<u>FMP 1</u> • 2002 BSAI and GOA Groundfish FMPs
Alternative 2 ***Adopt a More Aggressive Harvest Management Policy***	<u>Example FMP 2.1</u> • remove constraints (remove buffer between acceptable biological catch (ABC) and overfishing level (OFL) • no OY cap • repeal all closures except Steller sea lion (SSL) measures • no prohibited species catch (PSC) limits or gear restrictions • repeal all catch share programs except American Fisheries Act (AFA) and Community Development Quota (CDQ) • repeal Observer Program and vessel monitoring system (VMS) <u>Example FMP 2.2</u> • remove OY cap • repeal any bycatch reduction incentives and restrictions except for PSC limits or improved retention/improved utilization (IRIU), including seabird avoidance requirements
Alternative 3 ***Adopt a More Precautionary***	<u>Example FMP 3.1</u> • formalize ABC greater than or equal to TAC in FMP

Alternative	Example FMP bookend(s)
Management Policy	• move sharks and skates into target category and develop criteria for all species in “other species” category • accelerate efforts to develop ecosystem indicators for use in TAC-setting • develop marine protected area (MPA) methodology and evaluate efficacy of existing closures • formal procedures to increase Alaska Native participation in management • 0-10% reduction in existing PSC limits • establish PSC limits for GOA salmon and crab • improve Observer Program Example FMP 3.2 • incorporate uncertainty correction into ABC estimation • specify OY separately for each stock rather than for groundfish complex, • incorporate stock-specific reference points (e.g. $F_{60\%}$ rather than $F_{40\%}$ for rockfish) • move stocks from ‘other species’ category • close 0-20% of exclusive economic zone (EEZ) as an MPA to protect full range of habitats • no bottom trawl for pollock in GOA • comprehensive rationalization of all fisheries • reduce existing PSC limits by 10-30% • established PSC limits GOA salmon and crab • 100% observer coverage on vessels greater than 60 ft length overall.
Alternative 4 ***Adopt a Highly Precautionary Management Policy***	Example FMP 4.1 • increase buffer between OFL and ABC ($F_{75\%}$ for Steller sea lion prey species and for rockfish) • reduce *max* F_{ABC} for stocks based on the lower bound of a confidence interval surrounding the survey biomass estimate) • set OY for each stock rather than for the groundfish complex • designate 20-50% of EEZ as no-take marine reserve covering full range of habitats (including Aleutian Islands special management area for coral, and spawning reserves) • reduce PSC limits and bycatch by 30-50% • 100% observer coverage on vessels greater than 60 ft LOA and 30% coverage on all other vessels • mandatory VMS Example FMP 4.2 • no fishing until target fisheries can be shown to have no adverse effect on the resource and its environment

Alternative	Example FMP bookend(s)
Preferred Alternative ***Adopt a conservative, precautionary approach to ecosystem-based fisheries management***	<u>Example FMP PA.1</u> • formalize ABC greater than or equal to TAC in FMP • use harvest control rules to maintain spawning stock biomass • accelerate efforts to develop ecosystem indicators for use in TAC-setting • develop MPA methodology • consider 0-10% reduction of BSAI PSC limits • establish PSC limits or other measures in GOA for salmon, crab, and herring • continue rights-based management as needed • formal procedures to increase Alaska Native participation in management <u>Example FMP PA.2</u> • incorporate uncertainty correction into ABC estimation • periodically review OY caps to determine their relevancy • develop and implement criteria for use of ecosystem indicators in TAC-setting • develop appropriate harvest strategies for rockfish • develop criteria to manage target and non-target species consistently • re-examine existing area closures • consider adopting MPAs (0-20% of EEZ to protect full range of habitats, including as Aleutian Islands management area for coral) • no bottom trawl for pollock in GOA • reduce existing PSC limits 0-20% • establish PSC limits in GOA for salmon, crab, and herring • comprehensive rationalization of all fisheries • increase consultation with and representation of Alaska Natives in fishery management • improve observer coverage on all vessels • establish mandatory economic data collection

4.4.1 Target species direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

The 2004 PSEIS examined the potential direct, indirect, and cumulative effects that the implementation of the PA was expected to have on target species, prohibited species, forage fish species, other species, and non-specified species. The significance of these effects was evaluated as to whether the impacts, within the PA fishery management regime, might be reasonably expected to jeopardize the sustainability of each target species or species group. The effects are described below:

Direct Effects

<u>Fishing Mortality</u>: This is the rate at which the stock is depleted by direct mortality imposed by removing the fish from the sea.

<u>Change in Biomass Level</u>: This is the change over time in the biomass of the stock, as measured in metric tons (mt). Two measures are used: total biomass, which is the estimated biomass of the entire stock, and spawning biomass, which is the estimated biomass of all of the spawning females in the stock.

<u>Spatial/Temporal Concentration of Catch</u>: This is the degree to which the fishery will concentrate in a particular geographic area during a particular period of time each season. This pattern in space and time can affect fishing mortality and can also influence habitat suitability for spawning, rearing, and feeding.

Direct and/or Indirect Effects

> Habitat Suitability: This is the degree to which habitat has the right characteristics to support the stock at one or more life-history stages (spawning, rearing of juveniles, availability of food at all stages, availability of refuge areas to allow escape from predators at all stages). Habitat suitability can be affected directly, for example by mechanical damage from bottom trawling, or influenced indirectly, for example by the gradual depletion of corals that provide hard substrate.
>
> Prey Availability: This is the extent to which prey species are present in the environment and available as food to the stock. Like habitat suitability, this measure can be affected directly, for example by the direct removal of prey species by the fishery, or indirectly, for example by a change in the structure of the food web.

The baseline status of the BSAI and GOA stocks was their status in 2002, and the analysis then used a computer-based analytic model to project how specific characteristics of the these stocks would respond directly and indirectly to management actions under the preferred alternative FMP bookends. Relevant data were not always available for all stocks.

Target species were unique, in that thresholds for overfishing and stock size had been developed that relate to sustainability of the stock. As such, these thresholds were used to evaluate the significance of the effects of the example FMPs relative to their impacts on the sustainability of the target species. Fishing mortality rates that exceeded the overfishing mortality rate were considered to jeopardize the capacity of the stock to produce maximum sustainable yield (MSY) on a continuing basis and adversely impact the sustainability of the stock. A related measure of this potential was indicated by change in biomass levels. The significance of effects of the current spatial/temporal concentration of the catch, and the level of prey availability and habitat suitability for target species were evaluated with respect to each stock's current size relative to its maximum stock size threshold (MSST). An action that jeopardized the stock's ability to sustain itself at or above its MSST was considered to adversely affect the sustainability of the stock.

Species or species complexes that fall within Tiers 1 through 5 have estimates of fishing mortality rates, and were evaluated with respect to exceeding the overfishing mortality rate (fishing mortality effect). Species or species complexes that fall within Tiers 1, 2, or 3 have reliable estimates of MSST, and were evaluated for the effects on spatial/temporal concentration of the catch, prey availability, and habitat suitability. Species or species complexes that fall within Tiers 4, 5, or 6 do not have reliable estimates of MSST, and therefore could not be evaluated for the significance of these effects. Since several species or species complexes did not have estimates of abundances-at-age, in the 2004 PSEIS version of the model their abundance levels simply reflected the most recent estimate. This inability to evaluate the significance of the effects also occurs for the forage, prohibited, and non-specified species. For these groups, analysis of the effects of the preferred alternative was limited to catch projections and likely consequences given patterns in related fauna.

For the non-specified species FMP category, grenadiers were the major catch, and were chosen to illustrate potential effects to non-specified species. Non-specified species was a huge and diverse category encompassing every species not listed in the current FMP as a target, prohibited, forage, or other species. Considering a single species group from this category, such as grenadier, cannot possibly represent the diverse effects to all species in the category. However, because information is lacking for nearly all non-specified species, and due to the small or unknown amounts of bycatch (due to a lack of reporting requirements in this category), only potential effects to grenadier were discussed.

Formal stock assessments had not been conducted for grenadier. Thus, changes in total biomass, reproductive success, genetic structure of population, habitat, or mortality rates under the preferred alternative could be determined due to the lack of information needed to establish the baseline condition.

Changes in bycatch of grenadier were predicted based on modeled changes in target species catches and population trajectories (sablefish target fisheries accounted for the highest grenadier bycatch). While changes in bycatch mortality relative to the comparative baseline were reported, the 2004 PSEIS emphasized that determinations could not be made as to how these changes actually impacted grenadier populations, or whether these impacts might be adverse, beneficial, or insignificant.

Table 2 Target groundfish species significance ratings in the 2004 PSEIS

Effect		Pollock, Pacific Cod, Sablefish	BSAI Atka Mackerel	GOA Atka Mackerel	BSAI Flatfish*	BSAI Other Flatfish	GOA Flatfish*	GOA Arrowtooth Flounder
Mortality	direct/ indirect	I	I	U	I	I	I	I

4.4.2 Prohibited species direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

The 2004 PSEIS examined the potential direct, indirect, and cumulative effects that the implementation of the preferred alternative was expected to have on the prohibited species. As described above, the significance of the impacts for prohibited species were evaluated with respect to five effects: (1) fishing mortality, (2) change in biomass level, (3) spatial/temporal concentration of the catch, (4) prey availability, and (5) habitat suitability. The significance of these effects was evaluated as to whether the impacts, within the preferred alternative fishery management regime, might be reasonably expected to jeopardize the sustainability of the species. Because relevant data were not always available for all stocks, for these groups, analysis of the effects of the preferred alternative was limited to catch projections and likely consequences given patterns in related fauna. When data gaps prevented application of the model to a specific stock, the projected direct or indirect effect was evaluated as unknown (U).

Table 4 Prohibited species significance ratings in the 2004 PSEIS

Effect		Pacific halibut	BSAI salmon *	GOA Chinook salmon	GOA other salmon	Pacific herring	BSAI crab*	GOA crab*	GOA red king crab	BSAI and GOA golden king crab
Mortality	direct/ indirect	I	I	I	I	I	I	U	I	U

*BSAI salmon includes Chinook salmon and other salmon
*BSAI crab includes BSAI bairdi Tanner, BSAI opilio Tanner, BSAI red king and BSAI blue king
*GOA crab includes GOA bairdi Tanner and GOA blue king

4.4.3 Marine mammals direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

The standard for determining significance for effects on marine mammals in the 2004 PSEIS was whether the impact would be expected to be detectable at the population level. Individual effects categories did not have to cause a measurable population decline or increase to be labeled significant, but data and/or plausible arguments must exist to determine that the action would have more than a negligible impact on the reproduction and/or survival of a species group in a way that could affect the population. The expected effects of each alternative were compared to the baseline conditions to determine the relative significance of the impacts of the alternatives on marine mammals.

Table 5 Marine mammal species significance ratings in the 2004 PSEIS

Effect		W Steller sea lion	E Steller sea lion	Northern fur seal	Harbor seal	Killer whale (transients)	Other pinnipeds *	Other toothed whales*	Baleen whales *	Sea otters
Mortality (incidental take, entanglement)	direct/ indirect	I	I	I	I	I	I	I	I	I
	cumulative	S-	I	I	I	I / S-[1]	I	I	CS-[2] / I[3]	CS- / I[5]
Prey availability	direct/ indirect	I	I	I	I	I	I / U[4]	I	I	I
	cumulative	CS-	I	CS-	CS-	I	I	I	I	I
Spatial/temporal concentration of fisheries	direct/ indirect	I	I	I	I	I	I	I	I	I
	cumulative	CS-	I	CS-	CS-	I	I	I	I	I
Disturbance	direct/ indirect	I	I	I	I	I	I	I	I	I
	cumulative	I	I	I	I	I	I	I	I	I

*Baleen whales include blue whale, fin whale, sei whale, minke whale, humpback whale, gray whale, northern right whale, bowhead.
*Other pinnipeds include Pacific walrus, spotted seal, bearded seal, ringed seal, ribbon seal, elephant seal
*Other toothed whales include sperm whales, beaked whales, white sided dolphin, beluga whale, harbor porpoise, Dall's porpoise.
[1] -The exception to this finding is the AT1 transient group in Prince William Sound.
[2] -Fin, humpback and northern right whales;
[3] -Minke, gray, bowhead, sei, and blue whales
[4] -Northern elephant seals
[5] -Southcentral and southeast stocks of sea otters.

4.4.4 Seabirds direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

In the 2004 PSEIS, significance criteria for seabirds were based on whether the proposed action would have been likely to result in population level effects, defined as changes in the population trend outside the range of natural fluctuations. The projection model was used for predictions of fishing effort under the different FMP bookends, especially with respect to different gear types. The analysis also included other factors such as spatial/temporal restrictions and potential gear modifications for seabird avoidance. However, because there are a large number of unpredictable variables and gaps in our knowledge about particular species and ecosystem effects, it was impossible to ascertain significance on a strictly quantitative basis. Species were generally grouped according to the similarity of their response to the groundfish fishery and/or similarity in their management status. Conclusions are based on professional judgment of pertinent data and literature review.

Except for the supplemental food provided by the fisheries in the form of offal, the effects of the fisheries are all considered adverse to individual birds. Low levels of incidental take of seabirds are better for conservation purposes than high levels of take, but no amount of incidental take can be considered beneficial to a seabird population. The significance ratings for incidental take are, therefore, either insignificant or adverse. The same type of situation applies to fishery induced changes in benthic habitat important to benthic-feeding seabirds, so there is no beneficial rating for this effect. Effects of the fishery on food availability could be adverse, insignificant, or beneficial. If there is a plausible mechanism and a reasonable set of conditions under which an effect may occur under a given FMP, the significance rating was labeled conditional. If there is a plausible mechanism for an effect, but not enough data to assess whether it occurs or whether the FMP would create the conditions under which it would occur, the significance rating was unknown.

Table 6 Seabird species significance ratings in the 2004 PSEIS

Effect		Short-tailed albatross	Other albatross*	Shearwaters*	Northern fulmar	Red-legged kittiwakes[1]	Murrelets[1]

*Other planktivorous species - auklets and stormpetrels

4.4.5 Habitat direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

The 2004 PSEIS considered adverse effects of fishing on benthic marine habitat from the perspective of ecosystem structure and function, as well as managed fish species. The potential effects of the groundfish fisheries on habitat that were used to compare the alternatives included mortality of, and damage to, living habitat, changes to benthic community diversity, and changes to the geographic diversity of impacts and protection. Specific impacts of groundfish fisheries on habitat are very difficult to predict. Evaluation of effects requires detailed information on the distribution and abundance of habitat types, the life history of living habitat, habitat recovery rates, and the natural disturbance regime. This information is generally incomplete.

Table 7 Habitat significance ratings in the 2004 PSEIS

Effect		Bering Sea		Aleutian Islands		Gulf of Alaska

4.4.6 Socioeconomics direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

In the socioeconomic impact analysis in the 2004 PSEIS, the term "significant" for an expected change in a quantitative indicator meant a 20 percent or more change (either plus or minus), relative to the comparative baseline. If the expected change was less than 20 percent, the change is not considered to be significant. The same threshold was used to roughly assess changes in qualitative indicators (e.g., fishing vessel safety). However, whereas changes in quantitative indicators were based on model projections, predicted changes in qualitative indicators were based on the judgment of the socioeconomic analysts.

Table 8 Socioeconomic significance ratings in the 2004 PSEIS

4.4.7 Ecosystem direct/indirect and cumulative effects significance ratings under Preferred Alternative PA.1 and PA.2

Significance thresholds for determining the ecosystem-level impacts of fishing in the 2004 PSEIS involved both population-level thresholds that had already been established for species in the system (MSST for fish species; fishing-induced population impacts sufficient to lead to listing under the ESA, and fishing-induced impacts that prevent recovery of a species already listed under the ESA, for other species) and community- or ecosystem-level attributes that were outside of the range of natural variability for the system. These community or ecosystem-level attributes were more difficult to measure directly, and the range of natural variability of those attributes was not well known. We also lacked sufficient data on population status of some target or non-target species to determine whether they were above or below MSST or ESA-related thresholds. Thus, indicators of the strength of fishing impacts on the system were also used to evaluate the degree to which the preferred alternative might have a significant ecosystem impact.

For the preferred alternative FMP bookends, the possible impacts on (1) predator/prey relationships, including introduction of non-native species; (2) energy flow and redirection (through fishing removals and return of discards to the sea); and (3) diversity were addressed.

5 Synthesis of Changes Since 2004

5.1 Changes in the Management of Fisheries

Since the adoption of the groundfish management policy in 2004, the Council has continued to make changes to its groundfish management program. The changes that have occurred to date can be witnessed in the FMP and regulatory amendments that have been implemented over this time period. Additionally, there have also been national changes affecting the groundfish management program. The Magnuson-Stevens Act was reauthorized in 2006, and contained provisions that have affected the groundfish management program to some extent (for example, annual catch limits and provisions governing the development of limited access privilege programs).

Table 10 lists the groundfish FMP amendments that have been implemented from 2004 to 2015, as well as those for which the Council has taken final action, but regulations are still being developed. The Council has recommended over 20 amendments to the BSAI FMP and GOA FMP since the adoption of its groundfish management policy in April 2004. Additionally, four BSAI and four GOA amendments had been adopted by the Council prior to April 2004, but had not yet been implemented when the PSEIS was written. Table 11 provides a synthesis of the major regulatory amendments that have been implemented during the same period. Between the two lists, the major changes in groundfish management are captured.

In addition, since the 2004 PSEIS, NMFS and the Council have prepared four comprehensive EISs that analyzed changes in the management of the fisheries. The Final Environmental Impact Statement for Essential Fish Habitat in Alaska (EFH EIS, NMFS 2005) evaluates alternatives and environmental consequences for three actions: (1) describing and identifying EFH for fisheries managed by the Council; (2) adopting an approach for the Council to identify Habitat Areas of Particular Concern within EFH, and (3) minimizing to the extent practicable the adverse effects of Council-managed fishing on EFH. In 2010 NMFS and the Council conducted an EFH 5-Year Review that examined information within the 2005 EFH EIS and determined (1) new and more recent information exists to refine EFH for a small subset of managed species; (2) certain fishing effects may be impacting sensitive habitats of Bristol Bay red king crab, however additional analysis is needed; and (3) the non-fishing impacts analysis, including advisory EFH Conservation Recommendations, should be updated with the most current level of information.

The Alaska Groundfish Harvest Specifications Final Environmental Impact Statement (Harvest Specifications EIS, NMFS 2007a) evaluated the environmental, social, and economic effects of alternative harvest strategies for the federally managed groundfish fisheries in the GOA and BSAI management areas. The Harvest Specifications EIS evaluates the effects of different alternatives on target species, non-specified species, forage species, prohibited species, marine mammals, seabirds, essential fish habitat, ecosystem relationships, and economic aspects of the groundfish fisheries. Each year, NMFS prepares a SIR for that EIS to evaluate the need to prepare a supplemental EIS for the groundfish harvest specifications.

The Bering Sea Chinook Salmon Bycatch Management Final Environmental Impact Statement (Chinook EIS, NMFS 2009a) evaluated the Bering Sea pollock fishery and the effects of alternatives to minimize Chinook salmon bycatch to the extent practicable in that fishery.

The Steller Sea Lion Protection Measures Final Supplemental Environmental Impact Statement (SSL EIS, NMFS 2014b) evaluates the environmental, social, and economic effects of alternatives to the Steller sea lion protection measures for the BSAI groundfish fisheries, in particular the Atka mackerel, Pacific cod, and pollock fisheries in the Aleutian Islands.

Finally, the Council also adopted, as Council policy, an ecosystem vision statement that applies to its fishery management as a whole, including the groundfish fisheries, in February 2014. The Council explicitly considered the relationship of the vision statement with the groundfish management policy, and found no inconsistency. The vision statement is included below:

Ecosystem Approach for the North Pacific Fishery Management Council

Value Statement

The Gulf of Alaska, Bering Sea, and Aleutian Islands are some of the most biologically productive and unique marine ecosystems in the world, supporting globally significant populations of marine mammals, seabirds, fish, and shellfish. This region produces over half the nation's seafood and supports robust fishing communities, recreational fisheries, and a subsistence way of life. The Arctic ecosystem is a dynamic environment that is experiencing an unprecedented rate of loss of sea ice and other effects of climate change, resulting in elevated levels of risk and uncertainty. The North Pacific Fishery Management Council has an important stewardship responsibility for these resources, their productivity, and their sustainability for future generations.

Vision Statement

The Council envisions sustainable fisheries that provide benefits for harvesters, processors, recreational and subsistence users, and fishing communities, which (1) are maintained by healthy, productive, biodiverse, resilient marine ecosystems that support a range of services; (2) support robust populations of marine species at all trophic levels, including marine mammals and seabirds; and (3) are managed using a precautionary, transparent, and inclusive process that allows for analyses of tradeoffs, accounts for changing conditions, and mitigates threats.

Implementation Strategy

The Council intends that fishery management explicitly take into account environmental variability and uncertainty, changes and trends in climate and oceanographic conditions, fluctuations in productivity for managed species and associated ecosystem components, such as habitats and non-managed species, and relationships between marine species. Implementation will be responsive to changes in the ecosystem and our understanding of those dynamics, incorporate the best available science (including local and traditional knowledge), and engage scientists, managers, and the public.

The vision statement shall be given effect through all of the Council's work, including long-term planning initiatives, fishery management actions, and science planning to support ecosystem-based fishery management.

Table 10 BSAI and GOA Groundfish FMP amendments since 2004

BSAI amd	GOA amd	Action	Date of Council action	Year of Implementation
48	48	Revisions to the annual harvest specification process for groundfish	2003	2004
62	62	Single geographic location	2002	2009
	63	Move skates to the target species category	2003	2004
65	65	Identify habitat areas of particular concern, and harvest control measures	2005	2006
	67	Individual Fishing Quota (IFQ) – allow category B quota share to be fished on a vessel of any length, in any area	2005	2007
	68	Rockfish pilot program	2005	2006

BSAI amd	GOA amd	Action	Date of Council action	Year of Implementation
	69	Change total allowable catch specification for the 'other species' category	2005	2006
71		CDQ – allow limited non-fishing investments, CDQ oversight, and 3-year allocation cycle *(superseded by provisions of the revised Magnuson-Stevens Act)*	2002	N/A
73	77	Remove dark rockfish from the FMP	2007	2009
	72	Rescind retention requirements in shallow water flatfish fishery	2003	2008
78	73	Revise essential fish habitat descriptions, harvest control measures	2005	2006
79		Groundfish retention standard (suspended as of 2011)	2003	2008
80		Sector allocation and cooperative for head and gut groundfish catcher processors	2007	2007
81	74	Revised management policy	2004	2004
82		Allocation of Aleutian Islands pollock total allowable catch to the Aleut Corporation	2004	2005
83	75	Housekeeping updates to the FMP	2004	2005
84		Exempt certain vessels from salmon bycatch savings area closures	2005	2007
85		Pacific cod sector allocations	2006	2008
86	76	Observer program restructuring	2010	2012
87		CDQ eligibility *(superseded by provisions of the revised Magnuson-Stevens Act)*	2006	N/A
88		Aleutian Islands Habitat Conservation Area boundary adjustment	2007	2008
89		Bering Sea habitat conservation measures	2007	2008
90	78	Allow post-delivery transfers for Amendment 80 cooperatives (BSAI 90) and rockfish program (GOA 78)	2007	2009
91		Revise PSC limit for salmon bycatch, rescind savings areas	2009	2010
	79	Set allowable biological catch and overfishing level specifications for the "other species" category	2008	2008
92	82	Rescind latent trawl gear licenses	2008	2009
93		Modify rules for Amendment 80 cooperative formation	2010	2011
94		Require gear modification to trawl sweeps for nonpelagic trawl vessels targeting flatfish	2009	2010
	83	Pacific cod sector allocations	2009	2012
	85	Remove BSAI stand down provision for catcher processors participating in rockfish pilot program	2008	2009
	86	Add a Pacific cod fixed gear endorsement to GOA licenses	2009	2011
95		Move skates from the other species to the target species category	2010	2010
96	87	Revise FMP species to fit either in target or ecosystem component categories, describe current practice for setting annual catch limits and using accountability measures	2010	2010
97		Allow vessel replacement for Amendment 80 vessels	2010	2012
	88	Central GOA Rockfish Program: allocate exclusive harvest privileges to trawl vessels for Pacific ocean perch, pelagic shelf rockfish, and northern rockfish	2010	2011
	89	Establish area closures around Kodiak for GOA Tanner crab protection, require trawl sweep modification for GOA flatfish	2010	2014

BSAI amd	GOA amd	Action	Date of Council action	Year of Implementation
		fisheries		
98	90	Update EFH descriptions and associated information, and impacts of non-fishing activities on EFH, and extend timing of HAPC process to correlate with the EFH 5-year review	2011	2012
99		Change the freezer longline maximum length overall on License Limitation Program (LLP) licenses	2012	2014
100	91	Add an ecosystem component category for grenadiers to the FMP	2014	2014
	93	Establish PSC limits for Chinook salmon in the Central/Western GOA pollock fisheries, and require full retention of salmon	2011	2012
	94	Revise the vessel use caps applicable to sablefish quota share held by GOA Community Quota Entities (CQE) and add three eligible communities to the CQE Program	2011	2013
	95	Establish PSC limits for Pacific halibut in the Gulf of Alaska	2012	2014
102		CQE program in Area 4B and Area 4B “fish up”	2012	2014
103		Prohibit Pacific cod fishing in Pribilof Islands Habitat Conservation Zone	2010	2014
	96	Provide ability for CQE to buy small blocks of halibut QS	2013	2014
	97	Chinook PSC management measures for non-pollock trawl fisheries	2013	2014
104		Establish habitat areas of particular concern (HAPC) skate sites	2013	2015
105		Provide flexibility for flatfish specifications	2013	2014
106		Allow replacement of AFA vessels	2013	2014
107		Establish transit areas through walrus protection areas at Round Island and Cape Peirce	2014	2015
108	100	Correction on vessel length restriction for small vessel LLP license	2014	2015
109		Allow for small boat CDQ Pacific cod fishery	2015	
110		Chinook and chum salmon PSC limit measures	2015	
	101	Allow use of longline pots for sablefish	2015	
111		Halibut PSC limit reductions	2015	
112	102	Observer coverage for small catcher processors	2015	
113		Aleutian Islands Pacific cod catcher vessel fishery and shoreplant delivery requirement	2015	

Table 11 Major regulatory amendments for the BSAI and GOA groundfish fisheries since 2004
Note: does not include regulations that implement FMP amendments, or are temporary, interim, corrections or clarifications

Subject	Action	Year of Implementation
Harvest specifications	2004 BSAI and GOA harvest specifications	2004
	2005-2006 BSAI and GOA harvest specifications	2005
	2006-2007 BSAI and GOA harvest specifications	2006
	2007-2008 BSAI and GOA harvest specifications	2007
	2008-2009 BSAI and GOA harvest specifications	2008
	2009-2010 BSAI and GOA harvest specifications	2009
	2010-2011 BSAI and GOA harvest specifications	2010
	2011-2012 BSAI and GOA harvest specifications	2011
	2012-2013 BSAI and GOA harvest specifications	2012
	2013-2014 BSAI and GOA harvest specifications	2013
	2014-2015 BSAI and GOA harvest specifications	2014
	2015-2016 BSAI and GOA harvest specifications	2015
Catch restrictions	remove a harvest restriction on the HLA Atka mackerel fishery in the Aleutian Islands	2004
	full retention of demersal shelf rockfish and donation rules	2004
	allow processors to use the offal from halibut and salmon intended for the prohibited species donation program for commercial products (fish meal)	2004
	adjust the maximum retainable allowance (MRA) enforcement period for BSAI pollock from enforcement at any time during a fishing trip, to enforcement at the time of offload	2004
	revise the MRAs for groundfish in the GOA arrowtooth flounder fishery	2009
	repeal groundfish vessel incentive program	2008
	GOA pollock trip limits	2009
	revise the MRAs for groundfish in the BSAI arrowtooth and Kamchatka flounder fishery	2013
	remove groundfish retention standard requirements	2013
	BSAI fixed gear parallel fishery management measures	2012
Bering Sea AFA pollock fishery	remove the expiration date of regulations implementing the AFA	2004
CDQ	simplify the processes for making quota transfers, for authorizing vessels as eligible to participate in the CDQ fisheries, and for obtaining approval of alternative fishing plans	2005
	Revise CDQ regulations for recordkeeping, vessel licensing, catch retention requirements, and fisheries observer requirements to ensure that they are no more restrictive than regulations in effect for comparable non-CDQ fisheries managed under individual fishing quotas or cooperative allocations	2012

Subject	Action	Year of Implementation
BSAI and GOA IFQ sablefish fishery	allow quota shareholders in 4C to fish in either 4C or 4D	2005
	IFQ cost recovery fee reform	2006
	exclude tagged halibut and sablefish catches from IFQ account deduction	2006
	allow transfers of quota share for medical reasons; require VMS for vessels harvesting sablefish in the BSAI; allow category B catcher vessel quota share for Southeast Outside District sablefish to be fished on catcher vessels of any length	2007
	allow processing of non-IFQ species on a vessel with B, C, or D shares onboard	2008
	allow longline pot gear in Bering Sea during June, allow mobilized military personnel to make temporary IFQ transfers	2008
	IFQ online access to IFQ account information	2008
	Allow longline pot gear in Southeast GOA	2015
GOA rockfish program	revise central GOA rockfish fisheries program monitoring and enforcement provisions	2007
	extension of central GOA rockfish program under MSA	2008
seabirds	revise seabird avoidance measures in the hook-and-line fisheries off Alaska to reduce incidental catch of the short-tailed albatross and other seabird species	2004
	revise seabird avoidance measures to strengthen gear standards for small vessels and eliminate certain unnecessary requirements	2008
	eliminate seabird avoidance requirements for vessels less than or equal to 55 ft LOA in 4E	2009
Marine mammals	revise SSL protection measures for the GOA pollock and Pacific cod fishing closure areas near four SSL haul outs and modify the seasonal management of pollock harvest in the GOA	2005
	Revise SSL protection measures for the Aleutian Islands Atka mackerel and Pacific cod fisheries	2010
	Designate critical habitat for the Cook Inlet beluga whale	2011
	Revise SSL protection measures for the Aleutian Islands Atka mackerel, Pacific cod, and pollock fisheries	2014
Research areas	reopen the Cape Sarichef Research Restriction Area in the BSAI to directed fishing for groundfish	2006
	close Chiniak Gully Research Area to all commercial trawl fishing from August 1 to September 20, 2006-2010	2006
Observer program	provide flexibility in the deployment of observers	2004
	electronic reporting for vessels – ATLAS (at-sea observer communication system requirements)	2004
	technical amendment extending the North Pacific observer program beyond 2002	2004
	revise requirements facilitating observer data transmission and improve support for observers (ATLAS 2)	2006
	observer sunset date removal	2007
	Improve operational efficiency of the Observer Program and collected data	2010

Subject	Action	Year of Implementation
reporting requirements	make effective the collection of information under the AFA amendments	2004
	exempt groundfish catcher processors and motherships with operational VMS from check-in check-out requirements	2008
	implement new electronic groundfish catch reporting system, the Interagency Electronic Reporting System (IERS), and its data entry component, eLandings	2009
	exempt vessels using dinglebar gear from the requirement to use VMS	2009
	Miscellaneous recordkeeping and reporting revisions, incl to e-Landings	2008
	BS Chinook salmon bycatch economic data collection for the Bering Sea pollock fishery	2012
	Modify equipment and operational requirements for freezer longliners named on License Limitation Program licenses endorsed to catch and process Pacific cod at sea with hook-and-line gear in the BSAI	2012
	GOA trawl economic data collection	2014
	Revise the at-sea scales program for catcher/processors and motherships that are required to weigh catch at sea.	2014
	Codify type-approval standards, requirements, procedures, and responsibilities applicable to VMS products and services.	2015

5.2 Management changes as they pertain to the Council's policy goals

The following section evaluates the Council's management actions since the completion of the 2004 PSEIS in 2004. The Council's groundfish policy (the approved, preferred alternative from the 2004 PSEIS) is structured with nine goal statements, each supported by specific objectives, see Appendix 1. For each goal statement and set of objectives, we identify the relevant FMP and regulatory amendments implemented over the last ten years, as well as other management steps that the Council has taken with respect to these goals. The discussion in this section is not necessarily comprehensive, as each amendment may satisfy many of the Council's goals and objectives. Rather, it is intended to provide an overview of the major management changes of the last eleven years, and how they compare to the management objectives that the Council set for itself in 2004.

Additionally, we have also looked back to the example FMPs that illustrated the preferred alternative analyzed in the 2004 PSEIS. Given the Council's actions of the last ten years, the current groundfish management program does now fall within the range of example FMPs that were analyzed in the PSEIS.

Each of the sections below identifies one of the Council's policy goals. The specific objectives, sometimes abbreviated, linking to that policy goal are listed after each policy goal. If the objectives are also linked to a specific item on the Council's workplan,[35] that is noted also. After each policy goal and objectives are listed the FMP amendments related to this goal statement, the regulatory amendments related to this goal statement, and other management actions related to this goal statement.

[35] The Council developed a workplan to track the implementation of the various management objectives over time and prioritize issues for consideration. The workplan was developed in June 2004 revised in February 2007. The Council is updated on the status of this workplan at each meeting.

Prevent Overfishing

1. Adopt conservative harvest levels
2. Use existing OY caps
3. Specify OY as a range
4. Periodic reviews of $F_{40\%}$ and adopt improvements
5. Improve management through species categories (on workplan)

FMP amendments related to this goal statement

- revisions to the harvest specifications process (B48/G48)
- moved skates to target category (G63)
- biologically-based specifications for GOA “other species” category (G69, G79)
- amendments to bring FMPs in line with annual catch limit requirements, including moving other species into target category, and creating an ecosystem component category (B95, G87)
- amendment to include grenadiers in the ecosystem component of the FMPs (B100, G91)
- Restructured observer program reduces bias in catch accounting (B86, G76)
- Provide flexibility for flatfish specifications (B105)

Regulatory amendments related to this goal statement

- Annual specifications for setting harvest levels

Other management actions related to this goal statement

- Regular Center for International Experts reviews for stock assessments and harvest strategies
- Ongoing work on accounting for uncertainty in control rules
- Council policy and ongoing discussion of spatial management for stocks

Promote Sustainable Fisheries and Communities

6. Promote conservation while providing for OY
7. Promote management measures that avoid social and economic disruption
8. Promote fair and equitable allocation
9. Promote safety

These considerations are applied to all management actions.

Preserve Food Web

10. Develop indices of ecosystem health (on workplan)
11. Improve ABC calculations to account for uncertainty and ecosystem
12. Limit harvest on forage species
13. Incorporate ecosystem considerations in fishery management

Other management actions related to this goal statement

- Uncertainty and ecosystem considerations taken into account during stock assessment and harvest specifications
- Ecosystem indices reported and assessed in annual ecosystem SAFE report
- Adoption of the Aleutian Islands Fishery Ecosystem Plan, and development of a Bering Sea Fishery Ecosystem Plan
- Development of ecosystem synthesis reports for the Bering Sea and the Aleutian Islands ecosystem areas, and ongoing development of report for the Gulf of Alaska
- Adoption, as Council policy, of an ecosystem vision statement

Manage Incidental Catch and Reduce Bycatch and Waste

14. Continue and improve current incidental catch and bycatch program (on workplan)
15. Develop incentive programs for bycatch reduction (on workplan)
16. Encourage research for non-target species population estimates (on workplan)
17. Develop management measures that encourage techniques to reduce bycatch (on workplan)
18. Continue to manage incidental catch and bycatch through seasons and areas
19. Account for bycatch mortality in TAC accounting (on workplan)
20. Control prohibited species bycatch through PSC limits (on workplan)
21. Reduce waste to biologically and socially acceptable levels

<u>FMP amendments related to this goal statement</u>

- Groundfish retention standard (B79, subsequently removed)
- Bering Sea Chinook salmon bycatch restrictions (B84, B91)
- Trawl sweep elevation requirement in the flatfish fisheries (B94, G89)
- GOA area closures to reduce bairdi crab bycatch (G89)
- Establishment of PSC limits for Chinook salmon in the GOA trawl pollock and non-pollock fisheries (G93, G97)
- Reduce PSC limits for GOA halibut (G95)
- Restructured observer program reduces bias in bycatch accounting (B86, G76)
- Prohibit Pacific cod fishing in Pribilof Islands Habitat Conservation Zone (B103)
- BSAI Chinook and chum salmon PSC avoidance measures (B110 *approved by Council, not yet implemented*)
- Reduce PSC limits for BSAI halibut (B111 *approved by Council, not yet implemented*)

<u>Regulatory amendments related to this goal statement</u>

- Annual specifications for setting prohibited species limits
- Revisions to MRAs
- Revision to regulations for prohibited species donation program and fishmeal

<u>Other management actions related to this goal statement</u>

- Upcoming discussion paper on BSAI crab bycatch
- Council encourages research through annual research priorities
- NMFS and observer program work on improving statistical methods for bycatch accounting (as part of National Bycatch Report initiative)
- Development of a halibut management framework

Avoid Impacts to Seabirds and Marine Mammals

22. Continue to protect ESA-listed and other seabirds
23. Maintain or adjust SSL protection measures (on workplan)
24. Encourage review of marine mammal and fishery interactions
25. Continue to protect ESA-listed and other marine mammals (on workplan)

FMP amendments related to this goal statement

- Walrus protection areas around Round Island and Cape Pierce, including transit corridors for Federal fishing vessels (B107)

Regulatory amendments related to this goal statement

- Revisions to seabird avoidance measures, including in Area 4E
- Revisions to Steller sea lion closures for pollock and cod fisheries in the GOA
- Revisions to Steller sea lion protection measures for Atka mackerel, Pacific cod, and pollock fisheries in the Aleutian Islands
- Designation of critical habitat for Cook Inlet beluga whale

Other management actions related to this goal statement

- ESA consultations on fishery impacts on listed seabirds and marine mammals
- Council receives protected species report at each meeting, monitoring issues with seabirds and marine mammals
- Reconsideration of Steller sea lion closures in 2014 biological opinion and 2014 EIS

Reduce and Avoid Impacts to Habitat

26. Review and evaluate efficacy of habitat protection measures for managed species (on workplan)
27. Identify EFH and HAPC, and mitigate fishery impacts as necessary (on workplan)
28. Develop MPA policy
29. Encourage research on baseline habitat mapping (on workplan)
30. Develop goals and criteria for MPAs; implement as appropriate (on workplan)

FMP amendments related to this goal statement

- HAPC (B65/G65) and EFH (B78/G73) amendments, and associated fishery area closures in the GOA and Aleutian Islands (AI)
- Bering Sea Habitat Conservation (B89) with area closures for non-pelagic trawling
- Trawl sweep elevation requirement in the flatfish fisheries (B94, G89)
- Update to EFH information with findings from the 2010 EFH 5-year review (B98/G90)
- Designation of skate nurseries in Bering Sea as HAPC (B104)

Other management actions related to this goal statement

- Discussion of protected areas for Bering Sea canyons
- Discussion paper resulting from EFH 5-year review to look at groundfish impacts on crab EFH (especially red king crab in southwestern Bristol Bay)
- Ongoing 2015 EFH 5-year review, including updates to fishing effects model and EFH descriptions
- Discussion of a Northern Bering Sea Research Area Research Plan (subsequently tabled)
- Council discussion regarding nominating Alaska MPAs to national MPA center register (tabled)
- Council encourages research through annual research priorities

Promote Equitable and Efficient Use of Fishery Resources

31. Provide economic and community stability through fair allocation
32. Maintain LLP and initiate rights-based management programs (on workplan)
33. Periodically evaluate effectiveness of rights-based management programs
34. Consider efficiency when adopting management measures (on workplan)

FMP amendments related to this goal statement

- Sector allocations for Pacific cod (B85, G83); fixed gear endorsement in GOA (G86)
- Sector allocations and cooperative formation for 3 flatfish species, POP, and Atka mackerel in BSAI (Amendment 80); vessel replacement and cooperative revisions (B80, B90, B93, B97)
- Latent licenses rescinded (B92/82, G86)
- Cooperative program for rockfish in central GOA (G68); program revisions (G78, G85); new program authorized (G88)
- BSAI freezer longline maximum length overall adjustment (B99)
- AI pollock to the Aleut Corporation (B82); Single geographic location amended for pollock motherships (B62, G62); AFA vessel replacement (B106)
- IRIU rescinded in GOA for shallow water flatfish (G72)
- IFQ B quota shareholders can fish on any size vessel (G67), "fish up" in Area 4B (B102)
- Revisions to GOA CQE program entities, revise vessel use caps, allow purchase of small blocks, establish CQE program in Area 4B (G94, G96, B102)
- Allow for a small boat CDQ Pacific cod fishery (B109, *approved by Council but not yet implemented*)
- Allow use of longline pots for sablefish (G101, *approved by Council but not yet implemented*)
- Aleutian Islands Pacific cod catcher vessel fishery and shoreplant delivery requirement (B113, *approved by Council but not yet implemented*)

Regulatory amendments related to this goal statement

- Modify monitoring and reporting requirements for BSAI cod freezer longliners
- BSAI fixed gear parallel fishery management measures
- Minor revisions to AFA, CDQ, IFQ, Rockfish Programs
- GOA pollock trip limits

Other management actions related to this goal statement

- Permit fee authorization (all FMPs)

Increase Alaska Native Consultation

35. Incorporate local and traditional knowledge into fishery management
36. Consider ways to enhance local and traditional knowledge collection
37. Increase Alaska Native participation in fishery management (on workplan)

FMP amendments related to this goal statement

- AI pollock to the Aleut Corporation (B82)
- Revisions to GOA CQE program eligible entities, revise vessel use caps, allow purchase of small blocks, establish CQE program in Area 4B (G94, G96, B102)
- Allow for a small boat CDQ Pacific cod fishery (B109, *approved by Council but not yet implemented*)
- Aleutian Islands Pacific cod catcher vessel fishery and shoreplant delivery requirement (B113, *approved by Council but not yet implemented*)

Other management actions related to this goal statement

- Community outreach and consultation policy adopted by Council in 2008
- Community committee helps prioritize outreach (currently focused on BSAI salmon analyses)
- Website redesigned to include a rural outreach component

Improve Data Quality, Monitoring, and Enforcement

38. Increase utility of observer data (on workplan)
39. Develop equitable funding mechanisms for the NPGOP (on workplan)
40. Increase economic data reporting requirements (on workplan)
41. Improve technology for monitoring and enforcement (on workplan)
42. Encourage development of an ecosystem monitoring program
43. Cooperate with NPRB to identify needed research
44. Promote enforceability
45. Coordinate management and enforcement programs with Federal, State, international, and local partners

FMP amendments related to this goal statement

- Observer program restructuring (B86/G76)
- Remove dark rockfish from FMP, allow management by State of Alaska (B73/G77)
- Change observer coverage category exemptions for small catcher processors (B112/G102, *approved by Council but not yet implemented*)

Regulatory amendments related to this goal statement

- Electronic reporting, online accounting
- Changes to VMS requirements (required for sablefish in BS, no longer required for dinglebar lingcod in GOA)
- Repeal of vessel incentive program
- Changes to observer program to provide flexibility in deployment and improve operational efficiency
- Bering Sea Chinook salmon bycatch economic data collection
- GOA trawl economic data collection

Other management actions related to this goal statement

- Annual refinement of observer data through the deployment plan
- Ongoing work to improve Catch Accounting System
- Discussion paper on VMS use and requirements
- Electronic monitoring is being developed as a tool for catch monitoring. Pre-implementation program approved for 2016.
- Council encourages research through annual research priorities, cooperates with North Pacific Research Board
- Council initiated and participates in Alaska Marine Ecosystem Forum, as well as maintaining other relationships with partner entities

5.3 Changes in groundfish and environmental conditions

The following is a brief summary of Council documents that evaluate groundfish and environmental conditions.

Groundfish SAFE reports

The Council's annual Groundfish Stock Assessment and Fishery Evaluation (SAFE) report provides a detailed analysis of the status of groundfish stocks each year. No groundfish species is currently, nor has been, overfished or subject to overfishing, since the analysis that was conducted in the 2004 PSEIS.

Ecosystem Assessments in the annual Groundfish SAFE report

The AFSC prepares an Ecosystem Considerations appendix to the annual SAFE reports (Zador 2014) that provides a comprehensive overview of environmental conditions in the BSAI and GOA on an annual basis. The appendix includes an ecosystem assessment for the Bering Sea, Aleutian Islands, and Gulf of Alaska, as well as various data series that are ecosystem status and management indicators.

The AFSC staff has developed a format for reporting various indices over time, and comparing the most recent five years against the historical record for each indicator. The first section of the Ecosystem Considerations appendix includes abbreviated report cards for the Eastern Bering Sea and the Aleutian Islands (a report card for the GOA is being prepared), as well as an executive summary of recent trends. The report shows climate indices for the North Pacific, including the Pacific Decadal and Arctic Oscillations, and eastern Bering Sea ice retreat and cold pool volume indices. All of these are within one standard deviation of the historical mean for the data set. The report also shows ecosystem indices for the groundfish fishery regions, and fishery indices for the Bering Sea, Gulf of Alaska, and Aleutian Islands. The 5-year mean is generally within one standard deviation of the historic mean.

2010 EFH 5-year review

Additionally, the 2010 EFH 5-year review (NPFMC and NMFS 2010) evaluated changes in fishing impacts on habitat from the period analyzed in the EFH EIS (and incorporated by reference in the 2004 PSEIS) and the subsequent five-year period. Total trawl fishing effort decreased in all regions for pelagic and non-pelagic trawling, between the period analyzed in the EFH EIS (1998 to 2002) and the subsequent period (2003 to 2007). The report included figures plotting both the average fishing intensity, by five year period, as well as the difference in intensity between periods. The principal shifts in fishing intensity are summarized in the following paragraphs.

<u>Bering Sea trawl</u>: There has been no radical shift in the distribution of nonpelagic trawl fishing intensity in the Bering Sea from the period 1998 to 2002 to the period 2003 to 2007. The large area of the central Bering Sea that was subject to particularly high bottom trawl intensity in 1998 to 2002 received moderately lighter intensity from 2003 to 2007. Four principal areas were subject to increased bottom trawl intensity; (1) along the northwest border of the Pribilof Islands Habitat Conservation Zone, (2) off of Kuskoquim Bay, (3) along the southern border of the King Crab Protection Zone, and (4) western side of the Nushagak Peninsula (inner Bristol Bay). Most of the increases were moderate, though two of eight blocks in the fourth area along the western side of the Nushagak Peninsula (inner Bristol Bay) had strong increases. The area of high intensity effort north of Akutan Island, Unimak Pass and Unimak Island remained a high intensity area. Many of the shifts within that area registered as moderate or strong changes because of the high absolute levels of fishing intensity. The central Bering Sea showed a pattern of higher intensity in pelagic trawling around a central area of lower intensity near the border of management areas 509 and 513. Decreases in fishing intensity occurred on the west side of the Nushagak Peninsula, off of Kuskoquim Bay, northeast of St George Island, and Pervenets Canyon to the far northwest. Intensity dropped in the area north of Akutan Island, Unimak Pass, and Unimak Island, while there were increases on the southwest and eastern sides of that area.

<u>Aleutian Islands trawl</u>: There was a trend of decreases in bottom trawl fishing throughout the region, from the 1998 to 2002 period to the 2003 to 2007 period, with moderate decreases noted in the Adreanof Islands and Petrel Bank, as well as throughout the western portions of Rat Islands. Stronger increases in intensity occurred around Buldir Island and west of Tanaga, with moderate increases found in the Near Islands. Pelagic trawling in the Aleutian Islands decreased from 416 blocks fished in the first period, mainly on the 541/518 (Bering Sea) border, to only 16 blocks fished in the most recent period. Fishing intensity for pelagic trawl fisheries in the Aleutian Islands is currently very minor.

Gulf of Alaska trawl: Moderate decreases were seen in intensity of nonpelagic trawl fishing throughout the region, from the earlier (1998 to 2002) time period to the later (2003 to 2007), with overall blocks fished decreasing by approximately 40 percent. Largest drops in intensity occurred near Chiniak and south of Chirikof Island with moderate increases in intensity to the northwest of Chirikof Island and south of Ugak Island. Very minor changes in intensity were seen in pelagic trawling in the GOA, with moderate increases in Shelikof Strait, but decreases in intensity in most Kodiak nearshore waters, as well as in isolated areas of 610 and 620.

Aleutian Islands Fishery Ecosystem Plan

In December 2007, the Council completed a Fishery Ecosystem Plan (FEP) for the Aleutian Islands ecosystem area. The FEP evaluates physical, biological, and socioeconomic relationships among ecosystem components, to identify areas of uncertainty and associated risk. Key ecosystem interactions, including climate and physical factors, predator-prey relationships, fishing effects, regulatory constraints, and socioeconomic (both fishing and non-fishing) activities occurring in the area are identified and associated with monitoring indicators. These indicators are tracked on an annual basis through the Aleutian Islands Ecosystem Assessment, in the Groundfish SAFE report.

6 Review of conclusions in the 2004 PSEIS

This section summarizes the results from the expert team that reviewed the 2004 PSEIS conclusions. Each expert was asked to review the description of the impacts of the groundfish fisheries on his or her resource component (e.g., assessed species or species complex), based on new information that has become available since the PSEIS analysis was completed. The expert followed a template to consider whether management of or the status of the resource has changed, whether new information is available regarding the impacts of the fisheries on the resource, whether there are new methods of analysis or protocols for evaluating impacts. A copy of the template is included in Appendix 2 of the SIR. Based on these considerations, the expert was asked to conclude whether, based on information available at the time of the review, a new analysis using the latest methods and information would reach a seriously different conclusion.

The sections below synopsize the experts' review of the 2004 PSEIS conclusions. Each section begins with a summary table for the group of resource components, identifying the expert's conclusion and a short rationale. Additional points of rationale are captured in bullets following the summary table. The complete reviews for each resource component are included in Appendix 4 of the SIR. In some instances since the publishing of the draft SIR, and the completion of the reviews, staff have followed up with the expert reviewers to ensure that responses are consistent and complete across all respondents.

6.1 Target groundfish species

Table 12 through Table 15 provide short summaries of the target groundfish species reviews,[36] with respect to whether a new analysis using the latest methods and information would reach a significantly different conclusion than is articulated in the 2004 PSEIS. The tables also provide a short statement of rationale for each species. The complete review for each species may be found in Appendix 4 to this SIR.

[36] Note, in the BSAI FMP and GOA FMP there have been some changes of species names and species complexes since the 2004 PSEIS. A summary of these changes is included in Appendix 3 of this SIR.

Table 12 Summary of expert review of round groundfish species

Species	Would a new analysis reach a significantly different conclusion?		Comments / Rationale
	BSAI	GOA	
pollock	No	Possibly	**BSAI:** A difference with a new analysis would be the increased difficulty in adapting the technical interaction model to account for increased complexity in management and to predict outcomes of the TAC-setting process. **GOA:** Groundfish fisheries and their management have been fairly stable since 2002, which inclines towards an assumption that the conclusions would be similar. There are two changes in the GOA ecosystem that may merit further evaluation, however: increase in abundance of arrowtooth flounder (predator of pollock); and a resurgence of large whales, in particular the humpback whale.
Pacific cod	No	No	**BSAI:** In the future, analysis of the age-structured model for the Aleutian Islands stock, which is under development, will be informative. **GOA:** The stock assessment applies current analytical methods and produces stable and biologically consistent estimates for characterizing the condition of the population.
sablefish	No	No	**BSAI and GOA:** The stock assessment applies current analytical methods and produces stable and biologically consistent estimates for characterizing the condition of the population.
Atka mackerel	No	No	**BSAI and GOA:** New and updated information for the BSAI, and limited new information for the GOA, have been incorporated into the stock assessment, but have not resulted in a different conclusion.

Pollock, Pacific cod, sablefish, and Atka mackerel

Management changes:
- There have been no changes to the harvest control rules for the stocks.
- Some other management changes have affected the timing and/or distribution of the fisheries, including Chinook salmon PSC limits for the pollock fisheries, cod sector allocations, and Steller sea lion harvest restrictions.

Status changes:
- Stocks are within the range of variability estimated in the 2004 PSEIS.

New information on impacts:
- There have been changes in observer coverage requirements, resulting from the salmon bycatch measures in the Bering Sea, and observer restructuring.
- Some added acoustic survey years have provided additional information

New methods to assess impacts:
- Methods are being developed to explore the implications of incorporating stock-specific uncertainty buffers to establish ABCs.

Table 13 Summary of expert review of flatfish species

Species	Would a new analysis reach a significantly different conclusion?		Comments / Rationale
	BSAI	GOA	
yellowfin sole	No	*n/a*	**BSAI:** Some new information regarding temperature-dependent growth has become available, and is incorporated into the assessment, but it has not resulted in a different conclusion about the effect of the fishery on the resource.
greenland turbot	No	*n/a*	**BSAI:** The stock assessment applies current analytical methods and produces stable and biologically consistent estimates for characterizing the condition of the population.
arrowtooth flounder	No	No	**BSAI:** New information may change the estimate of arrowtooth flounder female spawning biomass, but would not change the PSEIS conclusions. **GOA**: Arrowtooth biomass is consistently increasing, as identified in the PSEIS.
Kamchatka flounder	No	*n/a*	**BSAI:** fishery-independent information is on the same order as before, and fisheries mortality remains at a moderate level.
northern and southern rock sole[37]	No	No	**BSAI:** some new information regarding temperature-dependent growth is available and will be incorporated in the assessment, but will not result in a different conclusion. **GOA:** The stock assessment applies current analytical methods and produces stable and biologically consistent estimates for characterizing the condition of the population. The status of stocks is within the range of variability of the 2004 PSEIS analysis.
flathead sole	No	No	**BSAI and GOA:** Qualitatively, the status of flathead sole has not changed since the 2004 PSEIS.
Alaska plaice	No	*n/a*	**BSAI:** The stock assessment applies current analytical methods, and Alaska plaice resource is high in abundance and lightly harvested.
shallow water flatfish	*n/a*	No	**GOA:** The majority of shallow water complex biomass is rock sole, for which an assessment model was developed in 2012. Other flatfish in the complex have been increasing or showing no trend in biomass since 2004.
deepwater flatfish	*n/a*	No	**GOA:** The deepwater flatfish complex is lightly exploited and current methods would reach similar conclusions.

[37] The BSAI assessment is limited to northern rock sole.

Species	Would a new analysis reach a significantly different conclusion?		Comments / Rationale
rex sole	*n/a*	No	**GOA:** Rex sole is lightly exploited and current methods would reach similar conclusions.
other flatfish	No	*n/a*	**BSAI:** The stock assessment applies current analytical methods, and Alaska plaice resource is lightly harvested, primarily as bycatch.

Flatfish

Management changes:
- Implementation of Amendment 80 in the BSAI has significantly changed the timing and utilization of flatfish fisheries.

Status changes:
- Stocks are within the range of variability estimated in the 2004 PSEIS, with the exception of BSAI flathead sole, which has a larger biomass than previously estimated.
- The Greenland turbot stock assessment was revised in 2012.

New information on impacts:
- Trawl sweep modifications in the BS and GOA have reduced the fishery impact on the seafloor, and unobserved mortality of shellfish.
- Observer restructuring has resulted in new observer information, particularly on small boats in the GOA.

New methods to assess impacts:
- Some stocks are now being assessed in a higher tier, resulting in differences in the way the productivity of the stock and risk are incorporated into the ABC calculation.

Table 14 Summary of expert review of rockfish species

Species	Would a new analysis reach a significantly different conclusion?		Comments / Rationale
	BSAI	GOA	
Pacific ocean perch	No	No	**BSAI:** A sharp rise in biomass has occurred in recent years across all spatial subareas. In the future, work on the impact of disproportionate harvest on yield and biomass for stocks that exhibit spatial structure will be informative. **GOA:** The assessment uses the same assessment model as the 2004 PSEIS, and stock status is within the range of variability analyzed in that document.
northern rockfish	No	No	**BSAI:** Future work will be informative for northern rockfish, which exhibits stock structure at spatial scales smaller than our current management units, and which occasionally shows disproportionate harvesting patterns. **GOA:** The stock assessment applies current analytical methods, and the assessment model indicates that conclusions are still valid.
shortraker rockfish	No	No	**BSAI:** Shortraker rockfish exhibit spatial structure, and consistent disproportionate spatial harvesting would be expected to result in reductions of biomass and yield. Limited genetic samples currently exist for shortraker, however, to undertake spatial stock analysis. **GOA:** Stock status can still not be determined. The fishery is not open as a target fishery, and it is unlikely that a conservation concern has developed since the 2004 PSEIS.
blackspotted/ rougheye rockfish	No	Yes	**BSAI:** Future work will be informative for these species, which exhibit stock structure at spatial scales smaller than our current management units, disproportionate harvesting patterns and high subarea exploitation rates, and declines in subarea population abundance. **GOA:** There is now an age-structured stand-alone assessment for these stocks, so the impact of the fisheries on the resource can be better monitored. The impacts of the fishery on change in biomass can be changed from "unknown" to "insignificant."
dusky rockfish	*n/a*	Yes	**GOA:** There is now an age-structured stand-alone assessment for dusky rockfish, so the impact of the fisheries on the resource can be better monitored. The impacts of the fishery on change in biomass can be changed from "unknown" to "insignificant".
demersal shelf rockfish	*n/a*	No	**GOA:** The current analyses indicate that the conclusions of the 2004 PSEIS are still valid, however if demersal shelf rockfish are moved to a different tier status after review of a new model in 2014, then the category "change in biomass level" could change from "unknown" to a different rating.
thornyhead rockfish	*n/a*	Yes	**GOA:** Beginning in 2004, the thornyhead rockfish complex was downgraded to a Tier 5 species, primarily because of uncertainty in the validity of age readings for shortspine thornyhead. As a result, the conclusions of "insignificant" in the 2004 PSEIS should be changed to "unknown." However, it is unlikely that a conservation concern has developed.
other rockfish	No	No	**BSAI:** Given the absence of new information, it is unlikely a new analysis would result in a different conclusion. **GOA:** Data for most "other rockfish" species is sparse. Since the fishery is not opened as a target fishery, it is unlikely that a conservation concern has developed since 2004.

Rockfish

Management changes:	• Implementations of Amendment 80 in the BSAI, and the rockfish programs in the Central GOA, have extended the timing of some rockfish fisheries.
Status changes:	• Stocks are within the range of variability estimated in the 2004 PSEIS, except BSAI Pacific ocean perch, for which the estimated biomass has doubled since 2004.
New information on impacts:	• There is new information about spatial structure for some rockfish species. • The use of pelagic trawl gear in the GOA rockfish fisheries has been increasing, reducing impacts of the fishery on habitat. • Bycatch estimates decreased for the majority of species in the Central GOA following the implementation of the rockfish program.
New methods to assess impacts:	• Some stocks are now being assessed in a higher tier, resulting in differences in the way the status relative to stock size reference points are determined. • A template has been developed for evaluating the types of information to be considered when defining the spatial bounds of "stocks," and which is in the process of being applied to many rockfish species.

Table 15 Summary of expert review of squid, octopus, shark, sculpin, and skate species

Species	Would a new analysis reach a significantly different conclusion?		Comments / Rationale
	BSAI	GOA	
squid	No	No	Some new information is available from the observer program, and a separate squid complex in the GOA will improve management, but these are not likely to result in a different conclusion.
octopus	No	No	Since the status of octopus is unknown, the effect of the fishery remains unknown.
sharks	No	No	The status of sharks remains unknown, and it is unlikely that a conservation concern has developed since 2004.
sculpins	No	No	Alternative methodologies have been explored in the assessment, but they do not result in significantly different conclusions.
skates	No	No	A new analysis could provide more detailed description of impacts, but would not reach a different conclusion.

Squid, octopus, sharks, sculpins, skates

Management changes:	• These species are now all managed as separate target species assemblages, rather than under the "other species" group.
Status changes:	• Status remains unknown for most stocks within these complexes. Where more is known, there is estimates of abundance have not changed significantly since 2004.
New information on impacts:	• Species-level identification within the complexes and recording of other biological information has improved. • For octopus, recent discard mortality information suggests that the impacts of the fishery on the resource have been overestimated. • Observer restructuring has resulted in improved coverage of fisheries that encounter some of these species.
New methods to assess impacts:	• Assessments have been developed for some species within the complexes. • Development of ecosystem models has allowed greater exploration of how various ecosystem impacts might affect stocks and their predators.

6.2 Ecosystem component (prohibited and forage fish) and non-specified fish species

Table 16 provides a short summary of the reviews for prohibited species, forage fish, and grenadiers. Additional points of rationale are captured in bullets following the summary table. The complete reviews for each resource component are included in Appendix 4.

Table 16 Summary of expert review of prohibited species, forage fish, unspecified species

Species	Would a new analysis reach a significantly different conclusion?	Comments / rationale
Pacific halibut	No	No new information concerning bycatch impacts is currently available. International Pacific Halibut Commission is investigating the relationship of bycatch mortality to long-term yield from the halibut resource. Bycatch of all sizes comprises a larger fraction of total mortality than in previous analyses, due to the decrease in total abundance of halibut since the 2004 PSEIS, and as a result the Council has analyzed and reduced halibut PSC limits in both the BSAI and the GOA.
Pacific salmon	Possibly	New stock origin information provides finer resolution to groundfish fishery impacts on Chinook salmon, highlighting that the stock composition of intercepted salmon in the BS and GOA trawl fisheries are very different, and providing a basis to analyze the impact of the BS pollock fishery on BS Chinook and chum salmon. The analysis, contained in the Chinook and chum salmon EA and other reports to the Council, shows very low impact of the fishery on aggregate returns.
Pacific herring	No	The 2004 PSEIS concluded that the groundfish fishery impacts on herring are insignificant. Mortality of herring in the BSAI is capped at 1% of biomass, and while BSAI herring biomass is currently known with considerably less certainty than 2004, it is still expected that the 1% limit will not adversely affect the population.
BSAI king crab	No	Abundance of king crab stocks has varied over the years, but the status of these stocks relative to the status determination criteria has not changed.
BSAI Snow crab	No	Since 2004, the snow crab stock has been declared rebuilt, based on a new assessment model. Stock assessment models have improved greatly, and crab bycatch is accounted for in the estimate of total catch used in stock assessment models.
BSAI Tanner crab	No	Effective status remains unchanged; however, the stock is no longer overfished. It remains at a relatively low abundance compared with historical levels. Stock assessment models have improved greatly, and crab bycatch is accounted for in the estimate of total catch used in stock assessment models.
GOA king and Tanner crab	No	The abundance of GOA crab stocks is similar to that reported in the 2004 PSEIS, and the prevailing conditions that likely drive these trends remain unchanged.
forage fish complex	No	Forage fishes continue to be caught only incidentally, and there is no new data to suggest that their status has changed.
grenadiers	No	Catch in the groundfish fisheries is low compared to estimated biomass of grenadiers.

Pacific halibut

Management changes:

- PSC limits for halibut in the GOA groundfish fisheries are being reduced over the 2014 to 2016 period.
- PSC limits for halibut in the BSAI longline and trawl groundfish fisheries will be reduced with the approval and implementation of BSAI FMP Amendment 111, likely in 2016.
- A limited access program for the charter fishery, and a catch sharing plan between the commercial and guided recreational harvesters, have been implemented in southeast and southcentral Alaska in 2014.

Status changes:

- Current status is within the range of historic assessments, near the long-term average abundance for the stock, but has declined from historic high levels in the late 1990s.

New information on impacts:

- Impacts of groundfish fisheries on the halibut resource are believed to have decreased since 2004, due to reductions in estimated halibut mortality in groundfish trawl fisheries (particularly in the BSAI Amendment 80 trawl fleet).

New methods to assess impacts:

- The IPHC has conducted additional analyses of the impacts of trawl bycatch mortality on lost yield and spawning biomass for the halibut stock. This information was included in the NEPA analysis accompanying GOA FMP Amendment 95 (reducing halibut PSC limits in the GOA) and that accompanying BSAI Amendment 111. Beginning in 2013, observers are now deployed in small boat groundfish and halibut fisheries to assess halibut mortality and discards.

Pacific salmon or steelhead trout

Management changes:

- The Council and NMFS implemented new Chinook salmon PSC limits in the Bering Sea and the GOA, and requirements for incentive plan agreements to reduce Chinook and chum salmon encounters for Bering Sea pollock fishery participants.

Status changes:

- Various Alaska Chinook salmon stocks have declined since 2004.
- The annual run size of the chum salmon indicator species has varied significantly since 2004, but is generally trending back to 2004 levels in recent years.

New information on impacts:

- New genetic stock composition analyses are available for the bycatch of Bering Sea Chinook and chum salmon, and GOA Chinook salmon, and more robust sampling protocols have been instituted.

New methods to assess impacts:

- Impacts of Bering Sea Chinook and chum salmon bycatch relative to escapement and maturity have been completed and reported in the Chinook EIS and EA for Chinook and chum salmon PSC limit measures.

BSAI King Crab

Management changes:	• Management is essentially unchanged; however the implementation of BSAI Amendment 80 has changed fishing patterns and partitioned the red king crab PSC limit among fishery cooperatives. • A trawl sweep modification requirement was implemented in the BS flatfish fishery in 2011. Research has demonstrated that this reduces unobserved mortality of crab. • New overfishing definitions and total catch accounting were implemented for BSAI crab stocks in 2008, and annual catch limits have been set since 2011.
Status changes:	• Abundance of king crab stocks has varied over the years, but the status of these stocks relative to the status determination criteria has not changed.
New information on impacts:	• The implementation of Amendment 80 has reduced the rate of bycatch per target catch metric ton. • The Council is in the process of evaluating the historical bycatch of crab stocks by groundfish fisheries.
New methods to assess impacts:	• Stock assessment models have improved greatly, and crab bycatch is accounted for in the estimate of total catch used in stock assessment models.

BSAI Snow Crab

Management changes:	• Management is essentially unchanged; however, the implementation of Amendment 80 has reduced the rate of snow crab bycatch per target catch metric ton.
Status changes:	• Since 2004, the snow crab stock has been declared rebuilt, based on a new assessment model.
New information on impacts:	• A trawl sweep modification requirement in the flatfish fishery was implemented in 2011. Research has demonstrated that this reduces unobserved mortality of crab.
New methods to assess impacts:	• Stock assessment models have improved greatly, and crab bycatch is accounted for in the estimate of total catch used in stock assessment models.

BSAI Tanner Crab

Management changes:	● Management is essentially unchanged; however, the implementation of Amendment 80 has reduced the rate of Tanner crab bycatch per target catch metric ton.
Status changes:	● Effective status remains unchanged, however the stock is no longer overfished. It remains at a relatively low abundance compared with historical levels.
New information on impacts:	● A trawl sweep modification requirement in the flatfish fishery was implemented in 2011. Research has demonstrated that this reduces unobserved mortality of crab.
New methods to assess impacts:	● Stock assessment models have improved greatly, and crab bycatch is accounted for in the estimate of total catch used in stock assessment models.

GOA Crab

Management changes:	● Management is essentially unchanged; however, the Council closed Marmot Bay to protect Tanner crab.
Status changes:	● GOA red king crab remains at historically low levels and the Tanner crab stock continues to show high variability in recruitment. Little is known about golden or blue king crab. The prevailing conditions identified in the 2004 PSEIS that likely drive these trends remain unchanged.
New information on impacts:	● The Council analyzed impacts of the GOA groundfish fisheries on Tanner crab in two NEPA analyses, and instituted a trawl-gear area closure and a trawl sweep modification requirement in the GOA flatfish fishery. Research has demonstrated that the sweep modification reduces unobserved mortality of crab. ● Changes to observer coverage requirements may shed additional light on groundfish fishery interactions with crab in the future.
New methods to assess impacts:	● No. There have been no changes to the state assessment methodology, and no regulatory changes to the harvest strategy or management structure.

Pacific herring

Management changes:	• Management of Pacific herring under the groundfish FMPs has not changed since 2004.
Status changes:	• Due to reduced funding for herring surveys and the difficulties of surveying the region, very little is known about the status of Bering Sea herring populations other than the Togiak stock. Climate change and regime shifts are expected to have a direct effect on herring habitat, mortality, and prey, but the magnitude is unknown.
New information on impacts:	• The impacts of groundfish fisheries on the herring resource are believed to be similar to what was analyzed in 2014. Most herring bycatch occurs in the Bering Sea pollock fishery.
New methods to assess impacts:	• No new methods have been developed for evaluating the impacts of the groundfish fisheries on herring.

Forage fish

Management changes:	• No, although forage fish are now listed as part of the "ecosystem component" in the FMP.
Status changes:	• There continues to be very little information on the status of forage fishes, including no reliable estimates of forage fish abundance.
New information on impacts:	• More information is provided on a biennial basis as an appendix to the SAFE reports, including information on state-waters removals, and species' vulnerability in the Pacific Northwest. • Available evidence suggests that forage fish abundance fluctuates independent of fishery activities.
New methods to assess impacts:	• None.

Grenadiers

Management changes:	• Unofficial assessment reports have been prepared for grenadiers since 2006, and the FMPs were amended in 2014 to include grenadiers as an ecosystem component, which prompted increased data collection on grenadier catch in the groundfish fisheries.
Status changes:	• The status of non-specified species was unknown in the 2004 PSEIS; grenadier assessment reports now track indices of abundance, which indicate that population trends are stable.
New information on impacts:	• There is a disproportionate catch of females in surveys and the fishery; however, all data indicate that catch of grenadier has not affected the stock status. • Impacts of groundfish fisheries have decreased in recent years, since grenadiers are primarily caught in the sablefish longline fishery, and ABCs and TACs for sablefish have decreased. • New catch information is available from smaller vessels fishing for halibut, under the restructured observer program.
New methods to assess impacts:	• In the assessment reports, catch, biomass, fishery and survey length frequencies, and indices of abundance are now tracked.

6.3 Marine Mammals and Seabirds

Table 17 provides a short summary of the reviews for marine mammals and seabirds. Additional points of rationale are captured in bullets following the summary table. The complete reviews for each resource component are included in Appendix 4.

Table 17 Summary of expert review of marine mammals and seabirds

Species	Would a new analysis reach a significantly different conclusion?	Comments / rationale
Steller sea lions	No	Extensive new analysis of the impacts of the groundfish fisheries on SSLs was undertaken in the 2014 Biological Opinions (NMFS 2014a), and the 2014 SSL EIS (NMFS 2014b). These analyses, and the subsequent regulatory changes, result in fisheries that continue to avoid jeopardy and adverse modification of critical habitat, which is consistent with the conclusions in the PSEIS.
Northern fur seals	No	Ongoing research is evaluating whether there is evidence of a strong link between commercial fisheries and the decline of northern fur seals, but currently, the cause of the ongoing decline remains unknown.
Harbor seals	No	Continued paucity of information about the foraging ecology of this species, especially in the Aleutian Islands.
Ice-associated seals	No	An evaluation of newly available food habits data might identify further impacts from commercial fisheries, but firm conclusions would be difficult to develop with the limited information.
Northern elephant seals	No	The California breeding population appears to be continuing to grow.
Pacific walrus	No	The latest available estimate of Pacific walrus take is within the range analyzed in the PSEIS, and is considered insignificant.
Whales	Possibly	The ESA listing of Cook Inlet beluga whales and designation of critical habitat caused a new analysis of the impacts of the groundfish fisheries, but the conclusion was similar to that in the PSEIS. Also, fishery interactions with Bering Sea harbor porpoise, western North Pacific stock of humpback whales, western gray whales, and killer whales may have increased.
Sea otters	No	NMFS conducted a new analysis for the Biological Assessment (NMFS 2013) and arrived at a similar conclusion as the PSEIS.
Seabirds	No	Neither new information nor new approach to estimation will change the conclusions of the PSEIS that impacts are insignificant.

Marine mammals – Steller sea lions

Management changes:
- Closures and restrictions on Atka mackerel. Pacific cod, and pollock fisheries in the Aleutian Islands, resulting from the 2014 Biological Opinion (NMFS 2014a) and 2014 SSL EIS (NMFS 2014b).

Status changes:
- Abundance of SSLs has increased, and regionally, trends in population have changed.
- New information available on food habits, abundance, foraging behavior, contaminants, and vital rates.
- The eastern distinct population segment of SSL has been delisted.

New information on impacts:
- 2014 Biological Opinion and 2014 EIS update changes in the impacts of groundfish fisheries on SSLs, especially in the AI.

New methods to assess impacts:
- No, but more recent analyses using conventional methods have been undertaken.

Marine mammals – Northern fur seals

Management changes:	• None
Status changes:	• Significant declines on both Pribilof Islands in the last 15 years, at just under 5 percent annually; partially offset by an increase in abundance on Bogoslof Island, where the population of pups now exceeds St George Island.
New information on impacts:	• It is unknown if the fisheries are affecting northern fur seals, but there is additional published literature available indicating similar habitat and prey use by both consumers.
New methods to assess impacts:	• No, but more recent analyses using conventional methods have been undertaken.

Marine mammals – Harbor seals

Management changes:	• None
Status changes:	• Three previously-recognized stocks of harbor seals were subdivided into 12 stocks. • Harbor seals in Lake Iliamna have been petitioned for listing under the ESA. • Harbor seals in the Aleutian Islands have declined substantially since the early 1980s, especially in the western Aleutians; similar geographic pattern as SSLs.
New information on impacts:	• Splitting into 12 stocks has led to individual stocks with lower abundance and the potential for groundfish fisheries to have significant impacts on individual stocks, but there is no new information.
New methods to assess impacts:	• None

Marine mammals – Ice-associated seals

Management changes:	• None
Status changes:	• In response to a petition for listing all four species under the ESA, NMFS listed ringed and bearded seals as threatened. NMFS is currently considering critical habitat designations.
New information on impacts:	• The ESA status reviews identified food habits studies indicating that various species of groundfish are important to ribbon and bearded seals, in some areas, seasons, and/or years.
New methods to assess impacts:	• None

Marine mammals – Northern elephant seals

Management changes:	• None
Status changes:	• The California breeding population appears to be continuing to grow.
New information on impacts:	• Unchanged since 2004; no recent reports of takes in Alaska fisheries.
New methods to assess impacts:	• None

Marine mammals – Pacific walrus

Management changes:	• No adverse changes. New protection areas at Round Island and Cape Pierce have been implemented to minimize levels of disturbance from Federal vessels.
Status changes:	• Walrus remains a candidate species for listing under the ESA. Uncertainty about current population estimates is very high.
New information on impacts:	• Unchanged since 2004. Estimated take of walrus in the Alaskan fisheries is considered insignificant.
New methods to assess impacts:	• None

Marine mammals – killer whale (transients), other toothed whales, baleen whales

Management changes:	• None
Status changes:	• Killer whales: new information on transient killer whale counts. Resident stock continues to increase in population size, with exception of a few pods. • Toothed whales: Cook Inlet belugas have continued to decline, are now listed under the ESA, and have critical habitat designated through much of Cook Inlet. Bristol Bay belugas continue to increase in size. No new information on other toothed whales. • Baleen whales: North Pacific right whales are now relisted under the ESA, and critical habitat has been designated. Western Arctic bowhead population has been increasing. A large-scale study of humpback whales is being evaluated. The eastern N Pacific gray whale status remains the same; however, the western North Pacific population, once thought extinct, has been rediscovered. No new information on other baleen whales.
New information on impacts:	• More specific information is now available on which target fishery is impacting which killer whale stocks. • One observed mortality of a harbor porpoise and one injury of a sperm whale, occurred in recent years due to groundfish fishery interactions. Also, the estimate of fisheries-related mortality to humpback whales is not significant. No other serious injuries or mortalities reported for other toothed or baleen whales, although information is lacking for belugas and western gray whales.
New methods to assess impacts:	• None

Marine mammals – sea otters

Management changes:	• Yes – the southwest distinct population segment of the northern sea otter were listed as threatened under the ESA in 2005. Critical habitat was designated in nearshore marine waters.
Status changes:	• Despite the listing of sea otters under the ESA, population abundance and trends have generally not notably changed since the early 2000s.
New information on impacts:	• A 2006 ESA consultation concluded that groundfish fisheries are not likely to adversely affect sea otters. The consultation was reinitiated, with the same conclusion pronounced in 2013 (NMFS 2013).
New methods to assess impacts:	• None

Seabirds

Management changes:	• Measures to manage seabird interactions with the fisheries are unchanged. • The 2013 implementation of restructured observer program will provide for better evaluation of total fishery impacts in the future.
Status changes:	• Status of various seabird species groups remains unchanged.
New information on impacts:	• Impacts reduced in the demersal longline fisheries. • Bycatch from trawl vessels higher than reported (estimates under evaluation), but still far less than the reduced impact in the longline fisheries. • Impact from vessels under 60 ft LOA are being evaluated with observer data beginning with 2013.
New methods to assess impacts:	• Annual estimates of seabird bycatch from observer species composition now generated through the Catch Accounting System for longline vessels, and estimates being developed for similar procedure for trawl vessels

6.4 Habitat, Socioeconomics, Ecosystem

Table 18 provides a short summary of the reviews for habitat, socioeconomics, and the ecosystem. Additional points of rationale are captured in bullets following the summary table. The complete reviews for each resource component are included in Appendix 4.

Table 18 Summary of expert review of habitat, socioeconomics, and ecosystem components

Species	Would a new analysis reach a significantly different conclusion?	Comments / rationale
Habitat	No	Analyses and research subsequent to the 2004 PSEIS have largely confirmed its general conclusions. A new analysis would provide more specific estimates with less uncertainty, but is not likely to reach seriously different conclusions.
Socioeconomics	No	The fundamental impacts of rationalizing fisheries (e.g., on overcapacity, efficiency, and the nature of the jobs) or closing areas to fishing is correct in the 2004 PSEIS. The 2004 PSEIS relies on predicting the results of rationalization programs, and a new analysis could provide actual results, likely with a smaller magnitude of benefits. But the basic understanding of effects is correct.
Ecosystem	No	The new research and information will enable improved monitoring of the ecosystem research, but to date does not suggest that the conclusions of the 2004 PSEIS would differ substantially.

Habitat

Management changes:

- Substantial changes to management have included implementation of regulations to protect habitat that provides structural relief, and gear modifications to limit adverse impacts of trawling on the seafloor.

Status changes:

- The current status of habitat is the same as in the PSEIS because long-lived, slow-growing species have likely not recovered from the impacts of historical fishing, and impacts continue in areas that are open to bottom trawling.
- In 2012, NMFS received a petition to list 44 species of cold water corals off Alaska as threatened or endangered in response to changing environmental conditions, the presence of commercial fisheries, and other factors. Based on the scientific information available, NMFS determined that such a designation was not warranted. NMFS analyzed whether threats are impeding the survival and recovery of coral species and warrant their protection under the ESA, including ocean warming, ocean acidification, commercial fishing, and oil spills (78 FR 10601, February 14, 2013). Coral species in Alaska are non-reef building and are less susceptible to the effects of ocean acidification as other organisms, and scientists noted that fishing closures in certain areas in the BSAI and GOA provide substantial protection for corals and cold water coral habitat.

New information on impacts:

- There has been additional research on the habitat requirements of different species, on trawl gear modifications to reduce habitat effects, and some limited research on the recovery of habitat in the eastern GOA that was damaged with trawl gear. There is improved resolution of data on the distribution of fishing effort due to broader implementation of VMS. There is also additional information on the distribution of habitat types and features, through better technology and habitat mapping.

New methods to assess impacts:

- The EFH EIS (NMFS 2005) used a different methodology than the PSEIS to assess the effects of fishing on habitat from the perspective of managed species that are dependent on habitat features. The 2005 EFH EIS fishing effects methodology is also being updated for the 2015 EFH 5-year review, which is currently under development.

Ecosystem

Management changes:	• Management changes to protect ecosystem components are referenced in the sections above. The Council has adopted an ecosystem vision statement as a Council policy, and has established guidelines for including ecosystem considerations in stock assessment reports and analytical documents.
Status changes:	• While there have been short-term changes in some ecosystem indicators, there is no evidence that these variations are outside short- or medium-term (3 to 5 year) range of natural variability, as measured over the last 30 years.
New information on impacts:	• There has been substantial new world-wide research on energy flow within ecosystems; however, this information does not suggest that impacts of the groundfish fisheries on Alaska ecosystems have significantly changed.
New methods to assess impacts:	• Significant improvements have been made in monitoring critical aspects of the ecosystem, through the development of annual Ecosystem Assessments and Report Cards, and management strategy evaluations on different ecosystem aspects. Ecosystems research at the AFSC is being developed as an Integrated Ecosystem Assessment program, which provides a formal method for evaluating climate impacts on Alaska's large marine ecosystems.

Socioeconomics

Management changes:	• The PSEIS refers to several fisheries that have since been rationalized, and there have also been management changes resulting from Chinook salmon bycatch avoidance and Steller sea lion protection measures.
Status changes:	• The PSEIS projects many then-recent trends in species biomass, and the impacts of climate change, which have since changed.
New information on impacts:	• Information is available on impacts in fisheries that have rationalized since the PSEIS, or been subject to other management changes (e.g., salmon or SSL closures). There are some impacts that the PSEIS does not address, but which have become issues of concern for the public and the Council, for example, the impacts of rationalization on crew members.
New methods to assess impacts:	• A new economic impact model has been developed as part of the analysis of Steller sea lion closures, and several papers have been written on the impacts of rationalization programs.

7 Public Comments

This SIR was first released as a draft in April 2014 for public and Council review. The review process was to ensure that all the relevant facts and information are compiled in the SIR, as a basis for decision makers to reach a conclusion as to whether a supplemental PEIS is required. In response to public testimony at the April 2014 Council meeting, NMFS noted that the agency would consider public comments on the SIR before making their final determination. NMFS received public comment letters from the Center for Biological Diversity, The Boat Company, and Oceana. The comments from each have been paraphrased and similar comments have been grouped to avoid redundancy in the responses.

Comment 1: The individual NEPA analyses that have accompanied the numerous changes in management since 2004 are not an adequate substitute for a programmatic update. The SIR incorrectly characterizes these management changes as not substantial relative to environmental concerns and incorrectly concludes that the management changes are consistent with the 2004 PSEIS. The 2004 PSEIS should be updated to be consistent with the current management regime.

> **Response:** Section 3 of the SIR recognizes that there have been a number of changes to the management program since issuance of the 2004 PSEIS and states, "All management changes since 2004 have been subject to NEPA analysis." However, the Council and the agency did not simply rely on these NEPA analyses to conclude that a supplement to the 2004 PSEIS is not required at this time. The SIR clearly demonstrates that the Council and the agency comprehensively evaluated whether the management changes that have occurred since 2004 have resulted in a substantial change in the proposed action that is relevant to environmental concerns, as required by NEPA.
>
> Section 5 of the SIR identifies the management changes that have occurred since 2004 and compares these changes with the proposed action of the 2004 PSEIS (i.e., the management of the Federal groundfish fisheries) and the preferred alternative for that action – adopt a conservative, precautionary approach to ecosystem-based fisheries management. Based on this information, the SSC, Council, and NMFS concluded that considerable progress has been made toward achieving the goals and objectives of the preferred alternative, and determined that the management measures implemented since 2004 are consistent with the preferred alternative. This information and analysis led the Council and NMFS to conclude that neither the management changes individually nor all of the management changes cumulatively since 2004 represent a substantial change in the proposed action.
>
> As explained in Section 2.3 of this SIR, not every change requires the preparation of a supplement; only those changes that cause effects which are significantly different from those already studied require supplementary consideration. Therefore, in addition to determining whether a substantial change in the proposed action occurred, the SIR also examines whether any of the changes made since 2004 have caused effects that are significantly different than those analyzed and predicted in the 2004 PSEIS. This information is presented in Section 6 of the SIR and demonstrates that none of the management changes since 2004 have caused effects significantly different from those identified in the 2004 PSEIS.

Comment 2: Given the significant new information from recent scientific literature on ocean acidification and climate change, NMFS must supplement the 2004 PSEIS to consider the impacts of these changes on Alaska's groundfish fisheries.

> **Response:** EISs do not need to be supplemented because information has accumulated. Rather, a PSEIS should be supplemented if the information brings new bearing on the management of the groundfish fisheries or the impacts of the groundfish fisheries on the human environment. In the 2004 PSEIS, the expected direct, indirect, and cumulative impacts of the groundfish fisheries on the environment were assessed within a broad range of historical and future environmental conditions.

The 2004 PSEIS evaluates a groundfish management program that is both comprehensive and adaptive. The management program builds in the flexibility to adapt to changing environmental circumstances through a harvest specifications process that is based on the best available scientific information and responds to environmental variability. The groundfish policy objectives oblige the Council and NMFS to implement appropriate protection measures when resource components are adversely affected as a result of the groundfish fisheries.

This SIR considers whether recent information, about climate change or other topics, would cause analysts to reach significantly different conclusions about the impacts of the groundfish fisheries on the environment. The SIR finds that the conclusions characterized in the 2004 PSEIS are still appropriate, and that the trigger requiring a supplement to the 2004 PSEIS has not been met.

NOAA is a world leader in ocean acidification and climate change research and this scientific work in Alaska is available on the AFSC Web site at *http://www.afsc.noaa.gov/*.

Comment 3: The growing scientific understanding of cold water coral's important ecosystem role, the devastating impacts of bottom contact fisheries, and the resulting loss of important groundfish habitat, may support different conclusions about the impacts of bottom trawling and climate change than were considered in the 2004 PSEIS, and should be examined in a supplemental EIS.

Response: The 2004 PSEIS established the policy goal statement to reduce and avoid impacts to habitat. As a direct result, the Council and NMFS have implemented FMP amendments to identify and protect concentrations of deep sea coral and other living substrate from fishery impacts. The management policy will continue to guide the Council as it actively assesses any further protections needed for minimizing the impacts of fishing activities on deep sea coral. The habitat protection actions implemented under the management policy include establishing gear mitigation and coral protection areas in the Aleutian Islands and the GOA (BSAI/GOA Amendments 78/73; NMFS 2005), implementing habitat conservation areas in the BSAI (BSAI Amendment 89; NMFS 2007b), and requiring trawl gear modifications to reduce bottom contact (BSAI/GOA Amendments 94/89; NMFS 2009b/NMFS 2010). This SIR examined these changes in fishery management and concluded that these actions maintain and support the 2004 PSEIS's conclusions that the groundfish fishery has an insignificant impact on habitat, including corals.

The 2004 PSEIS also evaluated a more conservative policy alternative which, although not ultimately selected, took a more precautionary approach to uncertainty about the potential impact of the fisheries on bottom habitat. The conclusions of the 2004 PSEIS with respect to both the Preferred Alternative and other alternatives remain apposite with respect to the impacts of the groundfish fisheries on corals and groundfish habitat.

The 2004 PSEIS acknowledges the importance of coral and other living substrate, and assesses the impacts of bottom contact fisheries on habitat. New information exists regarding the impacts of the groundfish fisheries on habitat, including corals. The EFH EIS further analyzes the impacts of all groundfish fisheries, including bottom contact fisheries, on habitat, including cold water coral (NMFS 2005). NMFS analyzed whether threats are impeding the survival and recovery of coral species and warrant their protection under the ESA, including ocean warming, ocean acidification, commercial fishing, and oil spills (78 FR 10601, February 14, 2013). NMFS found that scientific or commercial information does not warrant protection under the ESA.

The Council has also initiated scientific research fieldwork and analysis of coral concentrations in the Bering Sea canyons (NMFS 2015). The management actions taken to protect cold water coral and

habitat are informed by ongoing scientific research conducted by the AFSC. For additional information, please see AFSC Web site at
http://www.afsc.noaa.gov/News/Aleutian_corals.htm.

This SIR examined this new information and whether the groundfish fisheries are affecting habitat and corals differently than described in the 2004 PSEIS. Section 6 of this SIR summarizes the results of that analysis. No information indicates that the new analysis would conclude that there is now a significant impact where the 2004 PSEIS concludes that the impact was insignificant. Additionally, most of this new information has been analyzed in a subsequent NEPA or ESA analysis. Based on this work, the available new scientific information and research does not suggest a substantial change in our understanding of the impacts of the groundfish fisheries on the habitat in the BSAI and GOA.

Comment 4: New adverse effects to threatened or endangered species or new information about adverse effects require NMFS to supplement an EIS. NMFS must explore these adverse effects through a full SEIS at the programmatic level, to ensure that cumulative impacts to endangered or threatened species are properly taken into account.

Response: Avoiding impacts to seabirds and marine mammals is a specific policy goal identified in the PSEIS, as described in Section 5.2 of this SIR. That goal, as well as obligations under the ESA and Marine Mammal Protection Act, continue to be fulfilled in the Council and NMFS's consideration of information regarding the status of threatened and endangered species and both the proximal and cumulative impacts of groundfish fishery actions on those species. As appropriate, the Council and NMFS have comprehensively evaluated the effects of the groundfish fisheries on threatened and endangered species that have changed their listing status since the issuance of the 2004 PSEIS, including cumulative impacts, as described in Section 6.3 of this SIR. Where warranted the Council and NMFS have taken action to further reduce fishery interactions with endangered or threatened species and their critical habitat. This SIR examined these changes in fishery management and concluded that these actions maintain and support the 2004 PSEIS's conclusions that the groundfish fishery has an insignificant impact on endangered or threatened species.

This SIR examined new information and whether the groundfish fisheries are affecting threatened or endangered species differently than described in the 2004 PSEIS. Section 6 of this SIR summarizes the results of that analysis. No information indicates that the new analysis would conclude that there is now a significant impact where the 2004 PSEIS concludes that the impact was insignificant. Additionally, most of this new information has been analyzed in a subsequent NEPA or ESA analysis. Based on this work, the available new scientific information and research does not suggest a substantial change in our understanding of the impacts of the groundfish fisheries on threatened or endangered species in the BSAI and GOA.

Comment 5: Significant declines in PSC species have changed the human environment in a substantial way compared to the 2004 analysis and necessitate re-examination in an SEIS of the biological and socio-economic impacts, including cumulative impacts, of the groundfish fisheries.

Response: The 2004 PSEIS established the policy goal to manage incidental catch and reduce bycatch and waste, as described in Section 5.2 of this SIR. This policy goal continues to guide the decision making with regard to ongoing management of the groundfish fisheries. As described under Comment 1, the 2004 PSEIS analyzed an adaptive management program with the ability to react to change in environmental circumstances. Changes include consideration of any changes in the status of those resources as well as cumulative impacts of past, present, and reasonably foreseeable future actions. Consistent with the Council's policy, the Council and NMFS have conducted comprehensive analyses and implemented actions to further reduce Chinook salmon, chum salmon, and halibut PSC and thereby reduce the impacts of the groundfish fisheries to these species, as described in Section 6.2

of this SIR. This SIR examined these changes in fishery management and concluded that these actions maintain and support the 2004 PSEIS's conclusions that the groundfish fishery has an insignificant impact on endangered or threatened species.

This SIR examined this new information and whether the groundfish fisheries are affecting PSC species differently than described in the 2004 PSEIS. Section 6 of this SIR summarizes the results of that analysis. No information indicates that the new analysis would conclude that there is now a significant impact where the 2004 PSEIS concludes that the impact was insignificant. Additionally, most of this new information has been analyzed in a subsequent NEPA analysis. Based on this work, the available new scientific information and research does not suggest a substantial change in our understanding of the impacts of the groundfish fisheries on PSC species in the BSAI and GOA.

Comment 6: Important changes in our understanding of climate change, ocean acidification, and the status of several protected or non-target species (Steller sea lions, northern fur seals, Chinook salmon, halibut) have implications on the "significance" determination. The SIR determination that none of the new circumstances and information is "significant" within the meaning of NEPA is based on an incorrect approach to determining significance. The SIR incorrectly examines whether a "seriously different conclusion" is expected from the new information rather than whether the new information may "raise substantial questions" about the potential for significant effects.

Response: The SIR examines information and circumstances that have occurred since 2004 that are relevant to environmental concerns and bearing on the management of the groundfish fisheries or their impacts, and evaluates whether the new information and circumstances show that the groundfish fisheries will affect the quality of the human environment in a significant manner or to a significant extent not already considered, as required under NEPA. As explained in Section 3, the SIR approaches the "significance" determination by posing two overarching questions: "Are the impacts predicted in the 2004 PSEIS for the preferred alternative still valid, given any changes since 2004" and "Does the new information present a seriously different picture of the likely impacts of the groundfish fisheries on a particular resource, compared to what was considered in the 2004 PSEIS." New information and circumstances with regard to target groundfish species, non-target groundfish species (including Chinook salmon and Pacific halibut), marine mammals (including Steller sea lions and northern fur seals) and seabirds, habitats, socioeconomics, and ecosystems (including climate change and ocean acidification) were examined and evaluated in light of these two overarching questions (see Section 6 and Appendices 2 and 4 of the SIR). Based on this examination and evaluation, the Council and NMFS determined that that none of the new circumstances and information is "significant" under NEPA.

The SIR's use of "seriously different conclusion" as the standard for determining significance is consistent with NEPA and case law. Furthermore, this standard encompasses and does not preclude or prevent a determination that new information may raise substantial questions about the potential for significant effects. Evidence of this is seen in Appendix 2 of the SIR. In answering the question "Would a new analysis using the latest methods and information reach a seriously different conclusion," analysts were specifically asked to provide some discussion if the analyst thought the issue needed further investigation. This clearly supports the ability of an analyst to conclude that the new information raises substantial questions about the potential for significant effects.

Comment 7: A new SEIS should be prepared as the supporting analysis to help facilitate the transition to ecosystem-based fishery management in Alaska.

Response: The 2004 PSEIS characterized what is today called ecosystem-based fishery management, and served as the vehicle for refining the groundfish management program to address ecosystem considerations in management decisions. The 2004 PSEIS established policy goals that advance ecosystem-based fishery management, as described in Section 5.2 of this SIR. These policy goals continue to guide the decision making with regard to ongoing management of the groundfish fisheries. Consistent with the Council's policy, the Council and NMFS have taken a number of actions that improve ecosystem-based management in Alaska by minimizing the groundfish fisheries' impacts on ecosystem components, and incorporating ecosystem information into decision-making, as described in Section 6.4 of this SIR.

Additionally, reflective of the Council's ongoing efforts to continue the transition to ecosystem-based fishery management, the Council has adopted an Aleutian Islands Fishery Ecosystem Plan (NPFMC 2007) and is developing a Bering Sea Fishery Ecosystem Plan. Both the AI FEP and the developing BS FEP are action-informing mechanisms that provide a framework for addressing ecosystem considerations in future management decisions. The summary of the preferred alternative from the 2004 PSEIS to the transition to ecosystem-based fishery management can be found in Table 1 of this SIR.

8 Conclusions

The objective of this SIR is to synthesize relevant information for the Council and NMFS to determine whether there is a need to supplement the 2004 PSEIS for the Alaska groundfish fisheries. Note, the Council and NMFS may choose to supplement the 2004 PSEIS at any time for a variety of reasons; this SIR simply focuses on whether the triggers have been met that would require the Council and NMFS to supplement the 2004 PSEIS.

As described in Chapter 3, there are two conditions that would require supplementing an EIS:

1. if NMFS and the Council have made a substantial change in the proposed action (i.e., the management of the Federal groundfish fisheries) that is relevant to environmental concerns, or
2. if there are significant new circumstances or information relevant to environmental concerns and bearing on the management of the groundfish fisheries or their impacts.

With respect to the first condition, Section 5 of this SIR identifies the changes to the management program since 2004. All management changes since 2004 have been subject to NEPA analysis. The Council considered these changes in their discussions of this issue in 2012. The SSC discussed the management changes at the March 2012 meeting, and determined that they are all consistent with the preferred alternative evaluated in the 204 PSEIS. As a result, these changes do not represent a substantial change to the management of the Federal groundfish fisheries that is relevant to environmental concerns.

With respect to the second condition, the SIR includes a comprehensive overview of new circumstances and information relevant to environmental concerns, and bearing on the management of the groundfish fisheries or their impacts. Section 6 summarizes the review process undertaken for each of the resource components analyzed in the 2004 PSEIS, which were considered to be impacted by the management of the groundfish fisheries. These include target and non-target fish species, marine mammals and seabirds, habitat, socioeconomic components, and the ecosystem. For each of these components, experts considered whether the status of the component has changed, and whether new information or methods are available to better understand the impacts of the fisheries on that component. Based on this review, experts were asked to identify whether a new analysis, using the latest methods and information, would reach a significantly different conclusion regarding the impact of the groundfish fisheries. A brief summary of their findings is included in Table 19.

Table 19 Summary of changes to the PSEIS impacts resulting from the SIR review

Resource component	Would a new analysis using the latest methods and information reach a significantly different conclusion	Which components have a "possibly" response
BSAI and GOA target groundfish species	No/possibly	• GOA pollock • GOA blackspotted/rougheye rockfish, dusky rockfish, thornyhead rockfish
Prohibited species	No/possibly	• Pacific salmon
Other fish species	No	
Marine Mammals	No/possibly	• Whales
Seabirds	No	
Habitat	No	
Socioeconomics	No	
Ecosystem	No	

For most resource components, the new information reported in this SIR does not suggest that a new analysis would result in a significantly different conclusion for impacted resource components. There are some responses that indicate that there is now more information available that might further refine the conclusions in the 2004 PSEIS for their resource component (GOA blackspotted/rougheye rockfish, GOA dusky rockfish, and Pacific salmon). For the two GOA rockfish species, an age-structured model is now available which changes some "unknown" conclusions to "insignificant." For Pacific salmon, stock of origin information is now available to differentiate bycatch impacts from Bering Sea versus GOA trawl fishing, however new information does not suggest that there is any increase in adverse environmental impact than previously understood, and groundfish fishery impacts have been minimized, to the extent practicable, through management measures.

There are three other responses that indicated the possibility that a new analysis might reach a different conclusion. The first of these is GOA thornyhead rockfish; in this case, uncertainty has developed about the validity of data allowing an age-structured model, so the expert suggests that the "insignificant" conclusion should be changed to "unknown." The expert does not consider the impacts of the groundfish fishery to be a conservation concern, however. Secondly, with respect to whales, there has been a documented instance of interaction of a groundfish fishery with a harbor porpoise and a sperm whale in recent years, which was not considered at the time of the 2004 PSEIS. There has also been an increase in fisheries-related mortality to humpback whales. These changes indicated some uncertainty for the expert in evaluating the conclusions of the 2004 PSEIS with respect to whales. And finally, the rationale for GOA pollock includes signs of ecosystem change in the GOA as a source of uncertainty about a new conclusion, especially the resurgence of large whales (particularly the humpback whale), and an increase in abundance of arrowtooth flounder.

While the expert reviewers have considered new information specifically from the perspective of each of their resource components, **the decision as to whether to supplement the PSEIS must be based on a consideration of the proposed action as a whole**, that is, the perspective of the overall groundfish management program. As a result, it is incumbent on the Council and NMFS to consider the individual expert reviews, and consolidate them to the level of the overall groundfish management program. From a programmatic perspective, has there been a substantial change in the management of the groundfish fisheries, relevant to environmental concerns? Is the new information on the impact of the groundfish fisheries, relevant to environmental concerns, significant? These are the questions that the Council and NMFS considered.

In April 2014, the Council evaluated the information in the draft SIR, and concluded that a supplemental EIS was not required and that they would not reinitiate a new PSEIS. The Council first evaluated the management program in 2012, to see whether there had been substantial changes, and concluded that the management program is still consistent with the 2004 PSEIS's PA. The PA is described in Section 4.2 of this SIR, and the management changes are documented in Sections 5.1 and 5.2 of this SIR. In the Council's view, the updated information is still consistent with the Council's initial conclusion.

Regarding new information on the impact of the groundfish fisheries relevant to environmental concerns, the SIR synthesizes new information for each of the resource components. Based on this evaluation, the Council concluded that there has not been significantly new information to trigger the need for supplementing the PSEIS at this time. The Council acknowledged the SIR's comprehensive review of the resource components that were evaluated in the 2004 PSEIS, and noted that for almost all resource components the new information does not suggest a new analysis would result in significantly different conclusions. For a few components there may be a new conclusion, but the experts mostly noted that it is not a conclusion that the groundfish fisheries are having a significant impact on that component. Taking the SIR review as a whole, then, to evaluate the overall groundfish program, the Council concluded that the new information documented in the SIR would not result in a significantly different conclusion regarding the environmental impact of the fisheries.

In preparation for the final SIR, some additional information has been included in the report in response to Council and public comment, and staff has worked with the expert reviewers, in some instances, to ensure that the reviewers have consistently evaluated the 2004 PSEIS conclusions in the light of new information. In the draft SIR, there were several instances where an expert had identified uncertainty as to the outcome of a new programmatic analysis based on a discussion of future work, or ongoing but not yet concluded research, which may have bearing on the resource component. The SIR approach is to consider each resource component based on information that is available at present. To finalize the draft SIR, staff worked with the expert reviewers to ascertain that the reviewers understood the SIR approach, and to update the review to capture work that has been completed to date and to clarify the expert's conclusion, if appropriate.

9 Determination

The 2004 PSEIS continues to provide NEPA compliance for the groundfish FMPs and a supplemental NEPA document is not necessary. After reviewing the information presented in the SIR, I determine that—

(1) The management changes since 2004 do not constitute a substantial change in the action analyzed in the 2004 PSEIS. In analyzing the preferred alternative in the PSEIS, the Council and NMFS recognized that fishery management is dynamic and adaptive. Largely, every management change is related to and advances one or more of the Council's policy goals and objectives and all changes are consistent with the preferred alternative evaluated in the PSEIS.

(2) The current status of the resources can be considered within the range of variability analyzed in the 2004 PSEIS. For species where there has been a change of status, such as for some marine mammals, NMFS and the Council have responded with the appropriate analysis and action that maintain and support the 2004 PSEIS's conclusions that the groundfish fishery has an insignificant impact on these species with a change in status.

(3) New information exists regarding the impacts of the groundfish fisheries on resources. Analysts looked at whether the groundfish fisheries are affecting each resource differently than described in the 2004 PSEIS. Section 6 of this SIR summarizes the results of that analysis. According to this analysis, there are a few areas where a new analysis may lead to a different conclusion. However, no information indicates that the new analysis would conclude that there is now a significant impact where the 2004 PSEIS concludes that the impact was insignificant. Additionally, most of this new information has been analyzed in a subsequent NEPA or ESA analysis. Based on this work, the available new scientific information and research does not suggest a substantial change in our understanding of the impacts of the groundfish fisheries on the resources in the BSAI and GOA and does not present significant new circumstances or information relevant to environmental concerns and bearing on the management of the groundfish fisheries or their impacts.

APPENDICES

Appendix 1 BSAI and GOA groundfish management policy

The Council's management policy is in the BSAI and GOA groundfish FMPs. The policy is excerpted below.

2.2 Management Approach for the BSAI [GOA] Groundfish Fisheries

The Council's policy is to apply judicious and responsible fisheries management practices, based on sound scientific research and analysis, proactively rather than reactively, to ensure the sustainability of fishery resources and associated ecosystems for the benefit of future, as well as current generations. The productivity of the North Pacific ecosystem is acknowledged to be among the highest in the world. For the past 25 years, the Council management approach has incorporated forward looking conservation measures that address differing levels of uncertainty. This management approach has in recent years been labeled the precautionary approach. Recognizing that potential changes in productivity may be caused by fluctuations in natural oceanographic conditions, fisheries, and other, non-fishing activities, the Council intends to continue to take appropriate measures to insure the continued sustainability of the managed species. It will carry out this objective by considering reasonable, adaptive management measures, as described in the Magnuson-Stevens Act and in conformance with the National Standards, the Endangered Species Act (ESA), the National Environmental Policy Act, and other applicable law. This management approach takes into account the National Academy of Science's recommendations on Sustainable Fisheries Policy.

As part of its policy, the Council intends to consider and adopt, as appropriate, measures that accelerate the Council's precautionary, adaptive management approach through community-based or rights-based management, ecosystem-based management principles that protect managed species from overfishing, and where appropriate and practicable, increase habitat protection and bycatch constraints. All management measures will be based on the best scientific information available. Given this intent, the fishery management goal is to provide sound conservation of the living marine resources; provide socially and economically viable fisheries for the well-being of fishing communities; minimize human-caused threats to protected species; maintain a healthy marine resource habitat; and incorporate ecosystem-based considerations into management decisions.

This management approach recognizes the need to balance many competing uses of marine resources and different social and economic goals for sustainable fishery management, including protection of the long-term health of the resource and the optimization of yield. This policy will use and improve upon the Council's existing open and transparent process of public involvement in decision-making.

2.2.1 Management Objectives

Adaptive management requires regular and periodic review. Objectives identified in this policy statement will be reviewed annually by the Council. The Council will also review, modify, eliminate, or consider new issues, as appropriate, to best carry out the goals and objectives of this management policy.

To meet the goals of this overall management approach, the Council and NMFS will use the Alaska Groundfish Fisheries Programmatic Supplemental Environmental Impact Statement (PSEIS) (NMFS 2004) as a planning document. To help focus consideration of potential management measures, the Council and NMFS will use the following objectives as guideposts, to be re-evaluated, as amendments to the FMP are considered over the life of the PSEIS.

Prevent Overfishing:

1. Adopt conservative harvest levels for multi-species and single species fisheries and specify optimum yield.
2. Continue to use the 2 million mt optimum yield cap for the BSAI groundfish fisheries. [Continue to use the existing optimum yield cap for the GOA groundfish fisheries.]
3. Provide for adaptive management by continuing to specify optimum yield as a range.
4. Provide for periodic reviews of the adequacy of F_{40} and adopt improvements, as appropriate.
5. Continue to improve the management of species through species categories.

Promote Sustainable Fisheries and Communities:

6. Promote conservation while providing for optimum yield in terms of the greatest overall benefit to the nation with particular reference to food production, and sustainable opportunities for recreational, subsistence, and commercial fishing participants and fishing communities.
7. Promote management measures that, while meeting conservation objectives, are also designed to avoid significant disruption of existing social and economic structures.
8. Promote fair and equitable allocation of identified available resources in a manner such that no particular sector, group or entity acquires an excessive share of the privileges.
9. Promote increased safety at sea.

Preserve Food Web:

10. Develop indices of ecosystem health as targets for management.
11. Improve the procedure to adjust acceptable biological catch levels as necessary to account for uncertainty and ecosystem factors.
12. Continue to protect the integrity of the food web through limits on harvest of forage species.
13. Incorporate ecosystem-based considerations into fishery management decisions, as appropriate.

Manage Incidental Catch and Reduce Bycatch and Waste:

14. Continue and improve current incidental catch and bycatch management program.
15. Develop incentive programs for bycatch reduction including the development of mechanisms to facilitate the formation of bycatch pools, vessel bycatch allowances, or other bycatch incentive systems.
16. Encourage research programs to evaluate current population estimates for non-target species with a view to setting appropriate bycatch limits, as information becomes available.
17. Continue program to reduce discards by developing management measures that encourage the use of gear and fishing techniques that reduce bycatch which includes economic discards.
18. Continue to manage incidental catch and bycatch through seasonal distribution of total allowable catch and geographical gear restrictions.

19. Continue to account for bycatch mortality in total allowable catch accounting and improve the accuracy of mortality assessments for target, prohibited species catch, and non-commercial species.
20. Control the bycatch of prohibited species through prohibited species catch limits or other appropriate measures.
21. Reduce waste to biologically and socially acceptable levels.

Avoid Impacts to Seabirds and Marine Mammals:

22. Continue to cooperate with U.S. Fish and Wildlife Service (USFWS) to protect ESA-listed species, and if appropriate and practicable, other seabird species.
23. Maintain or adjust current protection measures as appropriate to avoid jeopardy of extinction or adverse modification to critical habitat for ESA-listed Steller sea lions.
24. Encourage programs to review status of endangered or threatened marine mammal stocks and fishing interactions and develop fishery management measures as appropriate.
25. Continue to cooperate with NMFS and USFWS to protect ESA-listed marine mammal species, and if appropriate and practicable, other marine mammal species.

Reduce and Avoid Impacts to Habitat:

26. Review and evaluate efficacy of existing habitat protection measures for managed species.
27. Identify and designate essential fish habitat and habitat areas of particular concern pursuant to Magnuson-Stevens Act rules, and mitigate fishery impacts as necessary and practicable to continue the sustainability of managed species.
28. Develop a Marine Protected Area policy in coordination with national and state policies.
29. Encourage development of a research program to identify regional baseline habitat information and mapping, subject to funding and staff availability.
30. Develop goals, objectives and criteria to evaluate the efficacy and suitable design of marine protected areas and no-take marine reserves as tools to maintain abundance, diversity, and productivity. Implement marine protected areas if and where appropriate.

Promote Equitable and Efficient Use of Fishery Resources:

31. Provide economic and community stability to harvesting and processing sectors through fair allocation of fishery resources.
32. Maintain the license limitation program, modified as necessary, and further decrease excess fishing capacity and overcapitalization by eliminating latent licences and extending programs such as community or rights-based management to some or all groundfish fisheries.
33. Provide for adaptive management by periodically evaluating the effectiveness of rationalization programs and the allocation of access rights based on performance.
34. Develop management measures that, when practicable, consider the efficient use of fishery resources taking into account the interest of harvesters, processors, and communities.

Increase Alaska Native Consultation:

35. Continue to incorporate local and traditional knowledge in fishery management.
36. Consider ways to enhance collection of local and traditional knowledge from communities, and incorporate such knowledge in fishery management where appropriate.
37. Increase Alaska Native participation and consultation in fishery management.

Improve Data Quality, Monitoring and Enforcement:

38. Increase the utility of groundfish fishery observer data for the conservation and management of living marine resources.
39. Develop funding mechanisms that achieve equitable costs to the industry for implementation of the North Pacific Groundfish Observer Program.
40. Improve community and regional economic impact costs and benefits through increased data reporting requirements.
41. Increase the quality of monitoring and enforcement data through improved technology.
42. Encourage a coordinated, long-term ecosystem monitoring program to collect baseline information and compile existing information from a variety of ongoing research initiatives, subject to funding and staff availability.
43. Cooperate with research institutions such as the North Pacific Research Board in identifying research needs to address pressing fishery issues.
44. Promote enhanced enforceability.
45. Continue to cooperate and coordinate management and enforcement programs with the Alaska Board of Fish, Alaska Department of Fish and Game, and Alaska Fish and Wildlife Protection, the U.S. Coast Guard, NMFS Enforcement, International Pacific Halibut Commission, Federal agencies, and other organizations to meet conservation requirements; promote economically healthy and sustainable fisheries and fishing communities; and maximize efficiencies in management and enforcement programs through continued consultation, coordination, and cooperation.

Appendix 2 Template for PSEIS SIR – review of conclusions in 2004 PSEIS

What resource component is this review for? ___________________
What sections of the PSEIS were reviewed? ___________________

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not, or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

Appendix 3 Changes in target species and species complexes between 2004 and present

The tables below list the species and species complexes that are currently identified in the BSAI and GOA Groundfish FMPs, and compare them to the species or species complexes that were assessed in the 2004 PSEIS. In a few cases, there are discrepancies. For example, shortraker and rougheye rockfish were managed as a complex in 2004, but are now managed separately (in fact, rougheye rockfish is managed as a complex with blackspotted rockfish).

Table 20 Species or species complexes that are currently identified in the BSAI SAFE report, compared to species or species complexes that were assessed in the 2004 PSEIS

Species or complexes that were assessed in the 2004 PSEIS		Species or complexes that are now identified in the BSAI SAFE report	
Target species	pollock	**Target species**	pollock (EBS, AI, Bogoslof)
	pacific cod		pacific cod
	sablefish		sablefish
	yellowfin sole		yellowfin sole
	greenland turbot		greenland turbot
	arrowtooth flounder		arrowtooth flounder
			Kamchatka flounder
	rock sole		Northern rock sole
	flathead sole		flathead sole
	alaska plaice		alaska plaice
	rex sole		other flatfish
	dover sole		
	Pacific ocean perch		Pacific ocean perch
	northern rockfish		northern rockfish
	shortraker/ rougheye rockfish		shortraker rockfish
			blackspotted/ rougheye rockfish
	yelloweye rockfish		other rockfish
	dusky rockfish		
	thornyhead rockfish		
	atka mackerel		atka mackerel
	squid		squid
Other species	octopus		octopus
	sharks		sharks
	sculpins		sculpins
	skates		skates
Forage fish	forage fish complex	**Ecosystem Component**	forage fish complex
Non-specified species	(specific species not listed)		grenadiers[38]

[38] The Council has approved, and NMFS has implemented, an FMP amendment to include grenadiers in the ecosystem component of the BSAI FMP and GOA FMP.

Table 21 Species or species complexes that are currently identified in the GOA SAFE report, compared to species or species complexes that were assessed in the 2004 PSEIS

Species or complexes that were assessed in the 2004 PSEIS		Species or complexes that are identified in the GOA SAFE report	
Target Species	pollock	**Target species**	pollock
	pacific cod		pacific cod
	sablefish		sablefish
	yellowfin sole		shallow water flatfish
	rock sole		
	Alaska plaice		
	dover sole		deep water flatfish
	greenland turbot		
	rex sole		rex sole
	arrowtooth flounder		arrowtooth flounder
	flathead sole		flathead sole
	Pacific ocean perch		Pacific ocean perch
	northern rockfish		northern rockfish
	shortraker/ rougheye rockfish		shortraker/ other slope rockfish
			dusky rockfish
			blackspotted and rougheye rockfish
	dusky rockfish		pelagic shelf rockfish
	yelloweye rockfish		demersal shelf rockfish

Marine mammals and seabirds

Habitat, Socioeconomics, Ecosystem

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/19/13

What resource component is this review for? EBS Pollock
What sections of the PSEIS were reviewed? 4.9.1.1

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The control rules governing the over-arching management regulations are unchanged relative to those analyzed in 2004. The principal factors affecting pollock fishery management include: seasonal apportionments (40% during the winter, 60% from June 10-October 31st), bycatch of pollock in other fisheries (count against the TAC), the sector-specific TAC allocations (i.e., CDQ, mother-ship, catcher-processors, and shore-based catcher boats), the 2-million t OY cap (which limits pollock TAC to about 1.5 million t), the "Tier 1" ABC/OFL control rules (amendment 56) from the single species assessment, and salmon bycatch avoidance. The control rule (which explicitly takes into account uncertainty in estimation of F_{MSY}) constrained the TAC for a couple of years (2009 and 2010) during a period when the stock dropped below the target level (and the upper limit of the harvest rate was required to be adjusted downwards). Specific management actions affect the EBS pollock fishery includes Amendment 91 (implemented in 2011) which set a cap for the number of Chinook salmon that can be taken incidentally. The indirect effect of this measure has amounted to shifts to fishing earlier in the B-season since bycatch rates (in terms of numbers of Chinook salmon per ton of pollock) increases in late September through October. Also, within-industry measures to close salmon bycatch "hot-spots" have affected the areas where pollock fishing can occur.

2 Has the status of the resource changed?

The status of the pollock stocks have fluctuated over time since the 2004 PSEIS but remains within the expected range of stock variability estimated at that time. As noted above, the stock has dropped below the target level in the past 10 years but this is as expected.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The observer coverage for the entire fleet switched to 100% in 2011 as part of the salmon bycatch measures. Previously the shore-based catcher vessels smaller than 125 feet had about 50% of their operations covered by scientific observers (even though the legal mandate was to have only 30% coverage in each quarter of the year).

In addition to the annual bottom-trawl surveys that cover the period 1982-2012, the supplemental dedicated acoustic-trawl surveys ran each summer 2006-2010 as part of a large-scale Bering Sea Integrated Ecosystem Research Program (BSIERP) funded by the North Pacific Research Board (NPRB). Prior to 2006 this acoustic survey ran (typically) every other year. This survey provides valuable direct observations on pre-recruit pollock and improves the information available to make near-term projections of fishing conditions and stock status (for spawning biomass conservation measures). Additionally, these added survey years allowed the development of valuable opportunistic data collection programs. These opportunistic acoustic data are presently collected on the chartered bottom-trawl survey vessels to provide an alternative index in years that the dedicated research vessel is unavailable. Also, acoustic data are collected from commercial vessels and have proven valuable for evaluating the turnover-rate of pollock abundance during the winter season. This study is of particular importance to help provide information on the forage available to Steller sea lions during their over-wintering period within their critical habitat. This information improves NMFS ability to evaluate fishery impacts and to provide better more-timely advice on stock status and catch limit recommendations.

4 Are there new methods of analysis or protocols for evaluating impacts?

The main assessment methodology is similar to that done for the 2004 PSEIS. However, the data collection and evaluations have improved on comprise new methods (e.g., developing an index from opportunistically collected acoustic data). Techniques to test assessment-management approaches which involve the development of operating models is underway and have been applied (e.g., decision tables, climate change effects etc.). The technical interactions model used for the PSEIS remains unchanged but presently research is underway to improve that approach and update the data streams used for that model.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Results from new analyses using an updated technical interaction model would likely be provide a similar conclusions. Anticipated differences would include added complexity to the management (e.g., due to salmon bycatch regulation changes). Difficulties in appropriately mimicking the TAC setting process may also be greater than in the past due to the larger number of constraints and having information that would predict recent trends (e.g., using different gear configurations to avoid salmon and/or crab and halibut.

PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/13

What resource component is this review for? BSAI Pacific cod
What sections of the PSEIS were reviewed? 4.9.1.2

1 Has management of the resource changed?

The only two FMP amendments since 2004 (inclusive) that reference Pacific cod explicitly are Amendments 77 and 85.

Amendment 77 was implemented January 1, 2004. This amendment revised Amendment 64. It implemented a Pacific cod fixed gear allocation between hook and line catcher processors (80 percent), hook and line catcher vessels (0.3 percent), pot catcher processors (3.3 percent), pot catcher vessels (15 percent), and catcher vessels (pot or hook and line) less than 60 feet (1.4 percent).

Amendment 85 was partially implemented on March 5, 2007. This amendment superseded Amendments 46 and 77. It implemented a gear allocation among all non-CDQ fishery sectors participating in the directed fishery for Pacific cod. After deduction of the CDQ allocation, the Pacific cod TAC is apportioned to vessels using jig gear (1.4 percent); catcher processors using trawl gear listed in Section 208(e)(1)-(20) of the AFA (2.3 percent); catcher processors using trawl gear as defined in Section 219(a)(7) of the Consolidated Appropriations Act, 2005 (Public Law 108-447) (13.4 percent); catcher vessels using trawl gear (22.1 percent); catcher processors using hook-and-line gear (48.7 percent); catcher vessels ≥60’ LOA using hook-and-line gear (0.2 percent); catcher processors using pot gear (1.5 percent); catcher vessels ≥60’ LOA using pot gear (8.4 percent); and catcher vessels <60’ LOA that use either hook-and-line gear or pot gear (2.0 percent).

Attachment 2.3 to the 2012 BSAI Pacific cod assessment describes regulations specific to the BSAI Pacific cod fisheries.

2 Has the status of the resource changed?

Relative to MSST, the status of BSAI Pacific cod remains the same, qualitatively speaking. Based on the 2012 stock assessment, projections for the 2013-2017 time period are fairly similar to the projections for 2007 contained in the 2004 PSEIS. For example, projected total biomass is within 10-19% of the value projected previously under PA.1 and within 12-21% of the value projected previously under PA.2, projected spawning biomass is within 5-11% of the value projected previously under PA.1 and within 7-9% of the value projected previously under PA.2, projected fishing mortality is within 8% of the value projected previously under PA.1 and within 14% of the value projected previously under PA.2, and projected average age (exlusive of age zero) is within 2-11% of the value projected previously under PA.1 and within 3-10% of the value projected previously under PA.2.

A related issue is how “the resource” should be defined in the case of BSAI Pacific cod. Although BSAI Pacific cod has, and continues to be, managed as a unit stock, recent research suggests that AI Pacific cod would be more appropriately managed as a separate stock, and it is likely that management will be split into separate EBS and AI units in the very near future. However, no age-structured model of the AI stock has been accepted by the SSC, and stock status continues to be determined on a BSAI-wide basis at the present time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

New information regarding impacts of the groundfish fishery on the resource is incorporated annually in the stock assessment. This new information consists primarily of total catch weight (including discards), stratified by year, season, and gear; and catch length composition, stratified by the same three factors. In addition, research by Ingrid Spies (PhD dissertation, in prep.) is evaluating potential impacts of differential fishing mortality rates on Pacific cod in the EBS and AI.

4 Are there new methods of analysis or protocols for evaluating impacts?

The model used in the stock assessment has changed considerably since 2002. These changes are documented in the 2012 stock assessment, beginning on page 254.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

I doubt it. Of course, it is not possible to predict the results of a future analysis based on a yet-to-be-developed age-structured model for the AI stock.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 5/30/2013

What resource component is this review for? ____Sablefish
What sections of the PSEIS were reviewed? ___4.9.1.3

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

A minor change in gear restrictions occurred in 2008, when the pot fishing ban was repealed for the Bering Sea during June 1-30 (74 FR 28733). This should have no significant impact on the resource.

2 Has the status of the resource changed?

The status of the sablefish stock is similar to the status during the 2004 PSEIS and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There was an increase in the BSAI fisheries in the use of pot gear to catch sablefish during 2004-2008, which has recently decreased again. The catch from pot gear was analyzed and shown to have minimal differences from longline gear and size of fish harvested (Sablefish SAFE, Hanselman et al. 2009).

4 Are there new methods of analysis or protocols for evaluating impacts?

The methodology is similar to the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses modern methods and the sablefish assessment model is relatively robust to the assumptions of the analysis.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/5/2013

What resource component is this review for? **BSAI Atka mackerel**
What sections of the PSEIS were reviewed? **Section 4.9.1.4 Atka Mackerel**

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the BSAI Atka mackerel fishery changed significantly in 2011 due to the implementation of Reasonable and Prudent Alternatives included in the 2010 Biological Opinion which required changes in groundfish fishery management in Management Sub-areas 543, 542, and 541 in the Aleutian Islands Management Area. In area 543, retention of Atka mackerel and Pacific cod is prohibited. In area 542, the TAC for Atka mackerel is set to no more than 47 percent of the Area 542 acceptable biological catch (ABC). Additionally, there are year round closures to directed fishing for Atka mackerel in defined areas of critical habitat and limits within defined areas of critical habitat for vessels participating in harvest cooperatives or CDQ fisheries. In area 541 the Bering Sea subarea is closed to year round fishing for the directed Atka mackerel fishery.

Amendment 80 to the BSAI Groundfish FMP was adopted by the Council in June 2006 and implemented for the 2008 fishing year. This action allocated several BSAI non-pollock trawl groundfish species among trawl fishery sectors, and facilitated the formation of harvesting cooperatives in the non-American Fisheries Act (non-AFA) trawl catcher/processor sector. Bering Sea/Aleutian Islands Atka mackerel is one of the groundfish species directly affected by Amendment 80.

2 Has the status of the resource changed?

The status of the BSAI Atka mackerel stock is higher than the status described in the 2004 PSEIS due to the impact of strong year classes, most notably the 1999, 2000, 2001, and 2006 year classes. Also, due to changes in the stock assessment model configuration since 2004, our knowledge and perception of the stock status has improved. The status of the BSAI Atka mackerel stock is within the range of variability estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The BSAI Atka mackerel fishery changed significantly since 2004 due to the implementation of Reasonable and Prudent Alternatives included in the 2010 Biological Opinion which required changes in groundfish fishery management in Management Sub-areas 543, 542, and 541 in the Aleutian Islands Management Area. The fishery and the impacts of the fishery were analyzed in the 2010 Biological Opinion and in the Draft Stellar Sea Lion Protection Measures Environmental Impact Statement (SSL EIS). Changes to the fishery have been described and modeled in the BSAI stock assessment on an annual basis.

4 Are there new methods of analysis or protocols for evaluating impacts?

The basic methodology for evaluating impacts (age-structured model) is similar to the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

New and updated fishery information and improvements to the age structured model are incorporated into the stock assessment, but has not resulted in a different conclusion about the effect of the groundfish fisheries on the resource.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____Gulf of Alaska walleye pollock
What sections of the PSEIS were reviewed? ___ 4.9.1.1

1 Has management of the resource changed?

There have been no changes to the harvest control rules specifying the OFL harvest rate, the maximum acceptable ABC, and the author's recommended ABC since the 2002 stock assessment for GOA pollock. Other features of the management system, such as the B20% limit for the target fishery, and the procedure for spatially and temporally allocating the ABC are also unchanged. Additional survey information is available for allocating the ABC between areas during the winter fishery (A and B seasons). Since the harvest control rule depends on estimated quantities from the stock assessment (such as mean recruitment, weight at age, and fishery selectivity), the values used to specify the harvest control rule, such as B35%, F40%, have changed. However the process used to calculate them has not.

With respect to in-season management of the pollock fishery, the trip limit regulation for the pollock target fishery in the GOA was fine-tuned to better achieve its original intent. Also Chinook salmon bycatch limits were established for the GOA pollock fishery by FMP Amendment.

2 Has the status of the resource changed?

The current status of the Gulf of Alaska walleye pollock stock is similar to the status during the 2004 PSEIS, and is within the range of variability of the estimates at that time. In the 2002 assessment, pollock was estimated to be at 28% of unfished spawning biomass in 2003. In the 2012 assessment, GOA pollock was estimated to be at 35.1% of unfished spawning biomass. Pollock biomass has been relatively stable during the last decade, but in the last couple of years has shown an increasing trend.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Ongoing fishing impacts on groundfish EFH were evaluated during the 5-year EFH review. Results of this analysis may be useful in future EIS evaluations.

4 Are there new methods of analysis or protocols for evaluating impacts?

Methods are being developed at AFSC to explore the implications of incorporating stock-specific uncertainty buffers to establish ABCs.

Teresa A'mar completed her dissertation in 2009 on a Management Strategy Evaluation of GOA pollock . Her work evaluated the performance of the current stock assessment methodology and management system (references below) .

No new methods of analysis have been used in NEPA analyses of management actions.

A'mar, Z.T., A.E. Punt, and M.W. Dorn. 2010. Incorporating ecosystem forcing through predation into a Management Strategy Evaluation for the Gulf of Alaska walleye pollock (Theragra chalcogramma) fishery. Fisheries Research, 102(1-2): 98-114.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

It is difficult to say what the outcome of a new analysis would be. The GOA pollock MSE mentioned above did not find any serious failings of the current assessment and management system. In general, groundfish fisheries in the Gulf of Alaska have been fairly stable since 2002, and the changes that have been implemented were contemplated by two bookend alternatives in the PSEIS. Therefore it might be reasonable to expect that a new analysis would reach similar conclusions to the 2004 PSEIS.

There two changes in the GOA ecosystem that may merit further evaluation. The first is the continued increase in abundance of arrowtooth flounder, a major predator of pollock in the GOA. The second is the resurgence of large whales in the GOA ecosystem, in particular, humpback whales (*Megaptera novaeangliae*).

PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____GOA Pacific cod
What sections of the PSEIS were reviewed? ___4.9.1.2

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

An adjustment among gear and operational sectors occurred in 2012, when Amendment 83 of the GOA Groundfish FMP was enacted. This should have no significant impact on the resource.

2 Has the status of the resource changed?

The status of the GOA Pacific cod stock is similar to the status during the 2004 PSEIS and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The fisheries observer program was restructured in 2013. This change will result in differences in the fishery data collected, and the significance of these changes for the GOA Pacific cod stock will not be determined for several years.

4 Are there new methods of analysis or protocols for evaluating impacts?

The methodology is similar to the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses modern methods and the GOA Pacific cod assessment model is relatively robust to the assumptions of the analysis.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/5/13

What resource component is this review for? **GOA Atka mackerel**
What sections of the PSEIS were reviewed? **Section 4.9.1.4 Atka Mackerel**

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

No, Gulf of Alaska (GOA) Atka mackerel has been managed under Tier 6 specifications since 1996 due to the lack of reliable estimates of current biomass. Gulf of Alaska Atka mackerel are managed as a bycatch species. The total allowable catch (TAC) for GOA Atka mackerel is intended to provide for anticipated bycatch needs of other fisheries, principally for Pacific cod, rockfish and pollock, and to only allow for minimal targeting. The TACs for 2004-2005 were 600 t, 1,500 t for 2006-2008, and have been set at 2,000 t for 2009 to 2013.

Gulf of Alaska Atka mackerel has been moved to a biennial stock assessment schedule to coincide with the availability of new survey data from the biennial trawl survey. A full assessment is presented in odd years. On alternate (even) years an executive summary is presented with updated catch, the previous year's key assessment parameters, any significant new information available in the interim, and projections for the upcoming year.

2 Has the status of the resource changed?

Information for GOA Atka mackerel is very limited and consists of catch information and small samples of age data. The data show fluctuations in the catches and distribution of GOA Atka mackerel coinciding with strong year classes observed in the Aleutian Islands. The strong year classes observed in the Aleutian Islands dominate the limited age compositions of GOA Atka mackerel.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

No, there has not been a directed fishery for Atka mackerel since 1996. Annual changes in the GOA Atka mackerel catches reflect shift in catches of other species which catch Atka mackerel as bycatch.

4 Are there new methods of analysis or protocols for evaluating impacts?

No, there have been no changes to the assessment methodology. Gulf of Alaska Atka mackerel have been assessed and managed under Tier 6 specifications since 1996 due to lack of reliable estimates of current biomass.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No, limited new and updated fishery information are discussed in the stock assessment, but has not resulted in a different conclusion about the effect of the groundfish fisheries on the resource.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/3/2013

What resource component is this review for? **BSAI yellowfin sole**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.5***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the yellowfin sole fishery changed significantly in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. In addition, Amendment 80 also mandated additional monitoring requirements which included observer coverage on all hauls, motion-compensating scales for weighing samples, flow scales to obtain accurate catch weight estimates for the entire catch, no mixing of hauls and no on-deck sorting. The partitioning of TAC and PSC (prohibited species catch) among cooperatives has significantly changed the way the annual catch has accumulated (slower and more evenly) and the rate of target catch per bycatch ton (less).

2 Has the status of the resource changed?

The status of the BSAI yellowfin sole stock is similar to the status during the 2004 PSEIS, well above the target reference points and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting is less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps, to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

Since 2004 the yellowfin sole stock assessment analysis has changed from Tier 3 methodology to Tier 1 resulting in differences in the way the productivity of the stock and risk is incorporated into the ABC calculation.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Some new information regarding temperature-dependent growth has become available and is incorporated into the stock assessment but it has not resulted in a different conclusion about the effect of the groundfish fisheries on the resource.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/10/2013

What resource component is this review for? ____BSAI Greenland turbot
What sections of the PSEIS were reviewed? ___4.9.1.9

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

There have been no changes to management of the BSAI Greenland turbot stock since 2004.

2 Has the status of the resource changed?

Although the stock spawning biomass has declined the status of the BSAI Greenland turbot is similar to the status during the 2004 PSEIS and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There has been no new information regarding the impacts of the groundfish fisheries on this stock.

4 Are there new methods of analysis or protocols for evaluating impacts?

The methodology is similar to the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses modern methods and the BSAI Greenland turbot assessment model is relatively robust to the assumptions of the analysis.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/10/2013

What resource component is this review for? **BSAI arrowtooth flounder**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.8***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

No, BSAI arrowtooth flounder were assessed and managed under Tier 3a in 2002 and continue to be managed with this methodology. The same model has been used since 2002.

2 Has the status of the resource changed?

The status of the resource has been consistently increasing since 2002. The spawning biomass of female BSAI arrowtooth flounder was estimated to be 475,900 mt at the beginning of 2002. At the beginning of 2013, female spawning biomass was estimated at 638,377 mt.

2 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The model estimates the fishing mortality rate on arrowtooth flounder by the fishery, both as a targeted fishery and as bycatch. The estimated fishing mortality rate was 0.015 in 2002 and 0.014 in 2013, and remained stable during the intervening period. Only a fraction of the recommended ABC is taken in the fishery; the estimated catch from 2002 – 2013 has been less than 20,000 mt even though the ABC has been over 100,000 mt for each of those years.

New information from NMFS research surveys and fishery length data are used in the assessment; EBS slope survey was conducted in 2002 2004 2008 2010 2012, the Aleutian Islands survey was conducted in 2002 2004 2006 2010 2012, and the EBS shelf survey was conducted every year since 2002. New fishery length data is incorporated from each year since 2002.

3 Are there new methods of analysis or protocols for evaluating impacts?

No significant new analyses have been implemented to assess the effect of the groundfish fishery on arrowtooth flounder.

4 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Recently, a new maturity ogive was published for female arrowtooth flounder (Stark, J. 2008. Age- and length-at-maturity of female arrowtooth flounder (*Atheresthes stomias)* in the Gulf of Alaska. Fish. Bull. 106: 328–333). This work motivated a re-analysis of the estimated arrowtooth flounder biomass using the current model with several different maturity ogives. Although maturity ogives have a significant effect on the estimate of female spawning biomass, all estimates were well above $B_{40\%}$ and all showed in increasing trend in arrowtooth female spawning biomass since 2002.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/3/2013

What resource component is this review for? **BSAI Kamchatka flounder**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.8***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the Kamchatka flounder fishery has changed significantly since 2004. In the eastern part of their range, Kamchatka flounder overlap with arrowtooth flounder (*Atheresthes stomias*) which are very similar in appearance and were not routinely distinguished in the commercial catches until 2007. Until about 1992, these species were also not consistently separated in trawl survey catches and were combined in the arrowtooth flounder stock assessment (Wilderbuer et al. 2009). However, managing the two species as a complex became undesirable in 2010 due to the emergence of a directed fishery for Kamchatka flounder in the BSAI management area. Since the ABC was determined by the large amount of arrowtooth flounder relative to Kamchatka flounder (complex is about 93% arrowtooth flounder) the possibility arose of an overharvest of Kamchatka flounder as the *Atheresthes sp*. ABC exceeded the Kamchatka flounder biomass. Arrowtooth and Kamchatka flounder have been managed separately since 2011.

2 Has the status of the resource changed?

The status of the BSAI Kamchatka flounder stock is similar to the status during the 2004 PSEIS as indicated by the results of the Bering Sea shelf, slope and Aleutian Islands surveys. The stock biomass is estimated to have increased or remained at the same level in all three areas and remains within the range of variability of the estimates from 2004.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fisheries resulting is less impact to the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps, to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

The Kamchatka flounder assessment is presently a Tier 5 assessment reliant upon survey biomass estimates and an estimate of natural mortality to set the annual ABC and OFL levels. Work is progressing to elevate the assessment to a Tier 3 level for the 2014 fishing season by utilizing age, size, growth, maturity and improved natural mortality information as well as survey abundance and fishery catch.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Although new information and modeling techniques will improve the stock assessment it is not expected that a seriously different conclusion regarding stock condition will result since the fishery-independent information is on the same order as before and the fisheries mortality remains at a moderate level.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/3/2013

What resource component is this review for? **BSAI northern rock sole**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.6***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the northern rock sole fishery changed significantly in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. In addition, Amendment 80 also mandated additional monitoring requirements which included observer coverage on all hauls, motion-compensating scales for weighing samples, flow scales to obtain accurate catch weight estimates for the entire catch, no mixing of hauls and no on-deck sorting. The partitioning of TAC and PSC (prohibited species catch) among cooperatives has significantly changed the way the annual catch has accumulated (slower and more evenly) and the rate of target catch per bycatch ton (less).

2 Has the status of the resource changed?

The status of the BSAI northern rock sole stock is similar to the status during the 2004 PSEIS, well above the target reference points and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting is less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps, to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

Since 2004 the northern rock sole stock assessment analysis has changed from a Tier 3 methodology to a Tier 1 approach resulting in differences in the way the productivity of the stock and risk is incorporated into the ABC calculation (northern rock sole SAFE, Wilderbuer et al. 2012).

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Some new information regarding temperature-dependent growth has become available for northern rock sole and is planned be incorporated into the stock assessment but it is unlikely that it will result in a different conclusion about the effect of the groundfish fisheries on the resource.

Review of Conclusions in 2004 PSEIS

draft 6/19/2013

What resource component is this review for? **BSAI flathead sole**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.7***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the flathead sole fishery changed significantly in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. In addition, Amendment 80 also mandated additional monitoring requirements which included observer coverage on all hauls, motion-compensating scales for weighing samples, flow scales to obtain accurate catch weight estimates for the entire catch, no mixing of hauls and no on-deck sorting. The partitioning of TAC and PSC (prohibited species catch) among cooperatives has significantly changed the way the annual catch has accumulated (slower and more evenly) and the rate of bycatch per target catch ton (less).

2 Has the status of the resource changed?

Total biomass of the BSAI flathead sole stock at the beginning of 2013 (Stockhausen and Nichol, 2012) was projected in 2012 to be ~750,000 t, almost 50% larger than that considered in the 2004 PSEIS (513,000 t). Female spawning biomass in 2013 was projected in 2012 (Stockhausen and Nichol, 2012) to be almost 250,000 t, whereas the spawning biomass considered in the 2004 PSEIS was approximately 230,000 t. Thus, both spawning biomass and total biomass are currently larger than that considered in the 2004 PSEIS. In addition, spawning biomass is substantially larger than $B_{35\%}$ for this stock. Qualitatively, then, the status of the resource has not changed since the 2004 PSEIS.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting in less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

Yes. For the purposes of the 2004 PSEIS, BSAI flathead sole was evaluated as a Tier 4 stock. Beginning in 2004, and in subsequent years, flathead sole was evaluated as a Tier 3 stock (e.g., Stockhausen and Nichol, 2012). As such, reliable estimates of $B_{35\%}$ (i.e., a proxy for B_{msy}) are now available that were not at the time of the 2004 PSEIS. However, similar conclusions would be reached with these (Tier 3) methods as were reached in the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

draft 6/3/2013

What resource component is this review for? **BSAI Alaska plaice**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.10***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the Alaska plaice fishery changed significantly in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. In addition, Amendment 80 also mandated additional monitoring requirements which included observer coverage on all hauls, motion-compensating scales for weighing samples, flow scales to obtain accurate catch weight estimates for the entire catch, no mixing of hauls and no on-deck sorting. The partitioning of TAC and PSC (prohibited species catch) among cooperatives has significantly changed the way the annual catch has accumulated (slower and more evenly) and the rate of target catch per bycatch ton (less).

2 Has the status of the resource changed?

The status of the BSAI Alaska plaice stock is similar to the status during the 2004 PSEIS, well above the target reference points and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting is less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps, to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

The stock assessment methods and protocols in the latest assessment do not differ substantially from those used in 2004. The annual trawl survey was extended into the northern Bering Sea in 2010 and indicated about 38% of the Bering Sea resource inhabit the northern waters which are currently unavailable to the fishery.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses modern methods to assess the Alaska plaice resource which is high in abundance and lightly harvested.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/3/2013

What resource component is this review for? **BSAI Other flatfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.10***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management of the Alaska plaice fishery changed significantly in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. In addition, Amendment 80 also mandated additional monitoring requirements which included observer coverage on all hauls, motion-compensating scales for weighing samples, flow scales to obtain accurate catch weight estimates for the entire catch, no mixing of hauls and no on-deck sorting. The partitioning of TAC and PSC (prohibited species catch) among cooperatives has significantly changed the way the annual catch has accumulated (slower and more evenly) and the rate of target catch per bycatch ton (less). Although the species of this complex are not directly targeted, the increased observer information should guard against the unintended consequences of managing a complex of species where disproportionate harvest can occur.

2 Has the status of the resource changed?

The status of the BSAI Other flatfish complex is similar to the status during the 2004 PSEIS, both in terms of biomass and catch levels.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting is less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps, to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

The stock assessment methods and protocols in the latest assessment do not differ substantially from those used in 2004. The present assessment using survey averaging of the past 7 years to calculate the ABC compared to using just the present year as was done in 2004.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses annual survey methods to assess the BSAI Other flatfish resource which is lightly harvested, primarily as bycatch in pursuit of other targeted species.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/10/2013

What resource component is this review for? **GOA arrowtooth flounder**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.8***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

GOA arrowtooth flounder were assessed and managed under Tier 3a in 2002 and continues to be managed with this methodology. The same model has been used since 2002. In 2006, the Gulf of Alaska arrowtooth flounder (*Atheresthes stomias)* stock was moved to a biennial stock assessment schedule to coincide with new survey data.

2 Has the status of the resource changed?

The status of the resource has been consistently increasing since 2002. The estimated total biomass of GOA arrowtooth flounder was estimated to be 1,816,000 mt at the beginning of 2002. Total biomass has been consistently increasing since that time and was estimated to be 2,055,560 mt at the beginning of 2013.

2 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The Gulf of Alaska NMFS research survey takes place on a biennial basis; therefore, new survey information is available in even years. These surveys are expected to reflect the impact of groundfish fisheries on the resource. New fishery length data has been incorporated each year since 2002.

3 Are there new methods of analysis or protocols for evaluating impacts?

No significant new analyses have been implemented to assess the effect of the groundfish fishery on arrowtooth flounder.

4 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____GOA northern and southern rock sole
What sections of the PSEIS were reviewed? ___4.9.1.6

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The GOA northern and southern rock sole stocks were moved from NPFMC Tier 4 to Tier 3 in 2012. This change should have no significant impact on the resource, as the stocks are still managed as part of the GOA shallow-water flatfish complex.

2 Has the status of the resource changed?

The status of the GOA northern and southern rock sole stocks is similar to the status of the GOA shallow-water flatfish complex during the 2004 PSEIS and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There are length and age composition data from the GOA NMFS bottom trawl survey for northern and southern rock sole for all survey years, although the data before 1996 are for undifferentiated rock sole. In addition, the fisheries observer program was restructured in 2013. This change will result in differences in the fishery data collected, and the significance of these changes for the GOA northern and southern rock sole stocks will not be determined for several years.

4 Are there new methods of analysis or protocols for evaluating impacts?

The methodology is similar to the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses modern methods and the GOA northern and southern rock sole assessment model is relatively robust to the assumptions of the analysis.

Review of Conclusions in 2004 PSEIS

draft 6/11/2013

What resource component is this review for? **GOA flathead sole**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.7***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Amendment 75 to the GOA Groundfish FMP (implemented June, 2005) revised the FMP to require that TACs be set equal or less than ABC (FMP Appendices, 2012). Amendment 87 (implemented Nov., 2010) revised the FMP to require annual catch limits (ACLs) and the use of accountability measures to ensure that ACLs are not exceeded, in accordance with National Standard 1 guidelines.

2 Has the status of the resource changed?

Based on a Tier 3 analysis, total biomass of the GOA flathead sole stock at the beginning of 2012 was projected in 2011 to be ~325,000 t, while female spawning biomass was projected to be almost ~110,000 t. The latter is almost 3*x* $B_{35\%}$ (a proxy for B_{msy}) for this stock. Similar values were not available for the 2004 PSEIS, thus a determination of whether the stock was "overfished" could not be made. However, estimates of the trend ion survey biomass indicate that the population has increased since the 2004 PSEIS.

The catch taken in 2010 (3,842 t) was less than 10% of the ABC (47,422 t). While larger than the catch taken in 2002 (2,000 t; 2004 PSEIS, Section 4.9.1.7), the catch in 2010 was also well below the ABC, indicating that the stock continues to be only lightly exploited.

Qualitatively, then, it seems almost certain that the status of the resource has not changed since the 2004 PSEIS.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes. Estimates of total biomass and spawning biomass, as well as age and size composition, were not available for GOA flathead sole in the 2004 PSEIS. Estimates of these quantities are now available (Stockhausen et al., 2011).

4 Are there new methods of analysis or protocols for evaluating impacts?

Yes. For the purposes of the 2004 PSEIS, GOA flathead sole was evaluated as a Tier 4 stock. Beginning in 2003, and in subsequent years, GOA flathead sole has been evaluated as a Tier 3 stock (Stockhausen et al., 2011). As such, reliable estimates of $B_{35\%}$ (i.e., a proxy for B_{msy}) are now available that were not at the time of the 2004 PSEIS. However, GOA flathead sole is lightly exploited and similar conclusions would be reached with these (Tier 3) methods as were reached in the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

draft 6/27/2013

What resource component is this review for? **GOA shallow water flatfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.8***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

GOA shallow-water flatfish are managed as a complex, however species ABC's are determined under different tiers. The majority of the biomass is northern and southern rock sole which have been moved to Tier 3 in 2012 with the development of an assessment model. Other species in the complex are managed under Tier 5.

2 Has the status of the resource changed?

Rock sole survey biomass increased to 2009, then decreased in 2011. Other flatfish in the complex have generally been increasing or show no trend since 2004.

2 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The Gulf of Alaska NMFS research survey takes place on a biennial basis. These surveys are expected to reflect the impact of groundfish fisheries on the resource.

3 Are there new methods of analysis or protocols for evaluating impacts?

No significant new analyses have been implemented to assess the effect of the groundfish fishery on the GOA shallow-water complex.

4 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

Review of Conclusions in 2004 PSEIS

draft 6/11/2013

What resource component is this review for? **GOA deepwater flatfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.9***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Yes. Amendment 75 to the GOA Groundfish FMP (implemented June, 2005) revised the FMP to require that TACs be set equal or less than ABC (FMP Appendices, 2012). Amendment 87 (implemented Nov., 2010) revised the FMP to require annual catch limits (ACLs) and the use of accountability measures to ensure that ACLs are not exceeded, in accordance with National Standard 1 guidelines.

2 Has the status of the resource changed?

No. Although an age-structured assessment model now exists for GOA rex sole, this stock remains a Tier 5 species because a reliable estimate for $F_{35\%}$ does not exist--the fishery is selective only for mature fish and this renders an estimate of $F_{35\%}$ highly uncertain. Estimates of the trends in total and spawning biomass, as well as survey biomass from the GOA groundfish trawl survey, indicate that the population has increased since the 2004 PSEIS (Stockhausen et al., 2011). The catch taken in 2010 (3,636 t) was less than the ABC (9,729 t). While larger than the catch taken in 2002 (3,000 t; 2004 PSEIS, Section 4.9.1.10), the catch in 2010 was also well below the ABC, indicating that the stock continues to be only lightly exploited. Qualitatively, then, it seems almost certain that the status of the resource has not changed since the 2004 PSEIS.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes. Estimates of current total biomass and spawning biomass, as well as age and size composition, were not available for GOA rex sole in the 2004 PSEIS. Estimates of these quantities are now available (Stockhausen et al., 2011).

4 Are there new methods of analysis or protocols for evaluating impacts?

Yes. Subsequent to the 2004 PSEIS, an age-structured assessment model was developed for GOA rex sole. This model provides time series estimates of total and spawning stock biomass. Current year estimates of total and spawning stock biomass are both currently at high levels relative to estimates for 2004.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The GOA deepwater flatfish stock complex is lightly exploited and similar conclusions would be reached with the current methods as were reached in the 2004 PSEIS.

Review of Conclusions in 2004 PSEIS

draft 6/11/2013

What resource component is this review for? **GOA rex sole**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.10***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Yes. Amendment 75 to the GOA Groundfish FMP (implemented June, 2005) revised the FMP to require that TACs be set equal or less than ABC (FMP Appendices, 2012). Amendment 87 (implemented Nov., 2010) revised the FMP to require annual catch limits (ACLs) and the use of accountability measures to ensure that ACLs are not exceeded, in accordance with National Standard 1 guidelines.

2 Has the status of the resource changed?

No. Although an age-structured assessment model now exists for GOA rex sole, this stock remains a Tier 5 species because a reliable estimate for $F_{35\%}$ does not exist--the fishery is selective only for mature fish and this renders an estimate of $F_{35\%}$ highly uncertain. Estimates of the trends in total and spawning biomass, as well as survey biomass from the GOA groundfish trawl survey, indicate that the population has increased since the 2004 PSEIS (Stockhausen et al., 2011). The catch taken in 2010 (3,636 t) was less than the ABC (9,729 t). While larger than the catch taken in 2002 (3,000 t; 2004 PSEIS, Section 4.9.1.10), the catch in 2010 was also well below the ABC, indicating that the stock continues to be only lightly exploited. Qualitatively, then, it seems almost certain that the status of the resource has not changed since the 2004 PSEIS.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes. Estimates of current total biomass and spawning biomass, as well as age and size composition, were not available for GOA rex sole in the 2004 PSEIS. Estimates of these quantities are now available (Stockhausen et al., 2011).

4 Are there new methods of analysis or protocols for evaluating impacts?

Yes. Subsequent to the 2004 PSEIS, an age-structured assessment model was developed for GOA rex sole. This model provides time series estimates of total and spawning stock biomass. Current year estimates of total and spawning stock biomass are both currently at high levels relative to estimates for 2004.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The GOA rex sole stock is lightly exploited and similar conclusions would be reached with the current methods as were reached in the 2004 PSEIS.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/13

What resource component is this review for? **BSAI Pacific ocean perch (POP)**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.11***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management several BSAI trawl fisheries changed in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. The partitioning of TAC among cooperatives has allowed fishing for POP to occur more gradually throughout the year.

2 Has the status of the resource changed?

The estimated biomass of the BSAI Pacific ocean perch stock has approximately doubled since the 2004 stock assessment, due to high recent survey biomass estimates and evidence of relatively large recent year classes.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is new scientific information indicating that the population structure for Pacific ocean perch may be at a smaller spatial scale (70 – 400 km; Palof et al. 2011) than the spatial scale for defining the stock or spatially allocating the ABC, which could potentially lead to reductions in yield and biomass if harvest was spatially disproportionate to biomass.

4 Are there new methods of analysis or protocols for evaluating impacts?

In 2010, a Plan Team –SSC stock structure committee developed a template for evaluating the types of information to be considered when defining the spatial bounds of "stocks" (Spencer et al 2010). Part of this template consists of evaluating spatial harvest patterns and whether disproportionate spatial harvesting patterns, if they exist, pose concerns regarding the impact of the fishery within management subareas.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

The stock structure template has not been applied to BSAI POP, in part because the ABC for this stock has a higher degree of spatial partitioning than other BSAI rockfish stocks, which have thus received higher priority for application of the template. Given the sharp rise in biomass in recent years (which has occurred across all spatial subareas), it appears unlikely that conclusions from 2004 PSEIS would be affected from the new information. A full analysis of the impact of disproportionate harvest on yield and biomass for stock stocks which exhibit spatial structure would require population models that accounted for connectivity of populations of fish between subareas, and would be more complex than the models used for the 2004 PSEIS. However, work has begun on developing these types of models to simulate the types of impacts of disproportionate harvesting upon yield and stock size (I. Spies, AFSC, in prep).

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/13

What resource component is this review for? **BSAI Northern rockfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.13***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management several BSAI trawl fisheries changed in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. BSAI northern rockfish are harvested largely as bycatch in the Atka mackerel fishery, which has been affected by Amendment 80. In 2010, the western Aleutian Islands subarea was closed for harvesting Atka mackerel, which has substantially reduced northern rockfish harvest in this area.

2 Has the status of the resource changed?

Northern rockfish were classified in Tier 5 when analysis for the 2004 PSEIS occurred, so status relative to stock size reference points were not available at that time. Beginning in 2004, northern rockfish have been classified in Tier 3 and an age-structure model has been used for their assessment. The estimated stock size has been relatively flat since 2000, with the stock size exceeding $B_{40\%}$ and the fishing mortality rates less than $F_{40\%}$.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is new scientific information indicating that the population structure for BSAI northern rockfish may be at a smaller spatial scale (100 – 200 km; Gharrett et al. 2012) than the spatial scale for defining the stock or spatially allocating the ABC, which could potentially lead to reductions in yield and biomass if harvest was spatially disproportionate to biomass.

4 Are there new methods of analysis or protocols for evaluating impacts?

In 2010, a Plan Team –SSC stock structure committee developed a template for evaluating the types of information to be considered when defining the spatial bounds of "stocks" (Spencer et al. 2010). Part of this template consists of evaluating spatial harvest patterns and whether disproportionate spatial harvesting patterns, if they exist, pose concerns regarding the impact of the fishery within management subareas. This template was applied to BSAI northern rockfish in 2012, and indicated that disproportionate harvesting has occurred in some years in the central and eastern Aleutian Islands (Appendix A in Spencer and Ianelli 2012).

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

The 2004 PSEIS evaluated the impact of spatial concentration of the catch with respect to, in part, reductions in “genetic diversity”. Given that reductions in genetic diversity would be expected to occur at very low stock sizes, it is not clear that the conclusions from the 2004 PSEIS using this criterion would be affected from new information on stock structure. However, in developing the stock structure template, Spencer et al. (2010) focused on the potential loss of biomass and yield that may occur from harvests that are spatially disproportionate for biomass for stocks that exhibit spatial structure. Under this criterion, it would be expected that consistent disproportionate spatial harvesting would be expected to result in reductions of biomass and yield in subareas with high exploitation rates. A full analysis of these impacts would require population models that accounted for connectivity of populations of fish between subareas, and would be more complex than the models used for the 2004 PSEIS. However, work has begun on developing these types of models to simulate the types of impacts of disproportionate harvesting upon yield and stock size (I. Spies, AFSC, in prep).

In 2013, a workshop was held to discuss how information on stock structure could be used to inform management decisions, with consideration to a variety of risks to the underlying stock and the resource users. The report from this workshop will hopefully provide some guidance for how to evaluate our management policy for stocks like BSAI northern rockfish, which exhibit stock structure at spatial scales smaller than our current management units, and have occasionally shown disproportionate harvesting patterns.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/13

What resource component is this review for? **BSAI Shortraker rockfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.13***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Shortraker rockfish are harvested as bycatch in other target fisheries, primarily the BSAI POP fishery. The management of the BSAI POP, and several other BSAI trawl fisheries, changed in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. These management changes have affected the seasonal distribution of harvest, with relatively more harvest occurring in the fall than in previous years.

Additionally, BSAI shortraker rockfish were managed as part of the BSAI rougheye/shortraker species complex when the 2004 PSEIS was completed, and are now managed within their own single-species management category.

2 Has the status of the resource changed?

Shortraker rockfish are managed under Tier 5, and the 2004 PSEIS states that reliable estimates of total and spawning biomass are not available. However, estimates of biomass are obtained from the Tier 5 stock assessments, and are based on smoothing survey biomass estimates. The estimated biomass for 2012 (17,000 t) is a slight decrease from the estimate for 2004 (20,000 t).

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is no new information regarding the impacts of the groundfish fisheries on BSAI shortraker rockfish.

4 Are there new methods of analysis or protocols for evaluating impacts?

In 2010, a Plan Team –SSC stock structure committee developed a template for evaluating the types of information to be considered when defining the spatial bounds of “stocks” (Spencer et al 2010). Part of this template consists of evaluating spatial harvest patterns and whether disproportionate spatial harvesting patterns, if they exist, pose concerns regarding the impact of the fishery within management subareas. This template is scheduled to be applied to BSAI shortraker rockfish in 2013.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

The 2004 PSEIS evaluated the impact of spatial concentration of the catch with respect to, in part, reductions in “genetic diversity”. Given that reductions in genetic diversity would be expected to occur at very low stock sizes, it is not clear that the conclusions from the 2004 PSEIS using this criterion would be affected from new information on stock structure. However, in developing the stock structure template, Spencer et al. (2010) focused on the potential loss of biomass and yield that may occur from harvests that are spatially disproportionate for biomass for stocks that exhibit spatial structure. Under this criterion, it would be expected that consistent disproportionate spatial harvesting for stocks with spatial structure would be expected to result in reductions of biomass and yield. Limited genetic samples currently exist for BSAI shortraker rockfish.

In 2013, a workshop was held to discuss how information on stock structure could be used to inform management decisions, with consideration to a variety of risks to the underlying stock and the resource users. The report from this workshop will hopefully provide some guidance for how to evaluate our management policy for BSAI rockfish.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/13

What resource component is this review for? **BSAI Blackspotted/rougheye rockfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.13***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Blackspotted/rougheye rockfish are harvested as bycatch in other target fisheries, primarily the BSAI POP fishery. The management of the BSAI POP, and several other BSAI trawl fisheries, changed in 2008 with the implementation of Amendment 80 to the BSAI Fisheries Management Plan. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. These management changes have affected the seasonal distribution of harvest, with relatively more harvest occurring in the fall than in previous years. However, in 2010 the western Aleutian Islands was closed for harvesting Atka mackerel, and many of the vessels that target Atka mackerel also target POP. This has resulted in harvesting of western Aleutian Islands POP, and thus the bycatch of blackspotted/rougheye, primarily during the summer in recent years in this subarea.

Additionally, BSAI blackspotted/rougheye rockfish were managed as part of the BSAI rougheye/shortraker species complex when the 2004 PSEIS was completed, and are now managed within their own management category. Fish formerly referred to as rougheye rockfish were found to comprise two species, with the new species blackspotted rockfish being identified. Finally, in 2010 the BSAI ABC for blackspotted/rougheye was partitioned between a Western and Central AI ABC, and an Eastern AI and EBS ABC.

2 Has the status of the resource changed?

Blackspotted/rougheye rockfish were classified in Tier 5 when analysis for the 2004 PSEIS occurred, so status relative to stock size reference points were not available at that time. Beginning in 2009, blackspotted/rougheye rockfish have been classified in Tier 3 and an age-structure model has been used for their assessment. The estimated BSAI stock size has increased since 2000, based largely upon the age and size composition data indicating relatively strong recent year classes.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is new scientific information indicating that the population structure for BSAI blackspotted rockfish may be at a smaller spatial scale (< 500 km; Appendix A in Spencer and Rooper 2010) than the spatial scale of the BSAI area, and this information led to the partitioning the ABC within the BSAI. Subsequent analyses (Appendix A in Spencer and Rooper 2012) have revealed disproportionate harvesting and a consistent pattern of high exploitation rates in the western Aleutian Islands that exceed those corresponding to the $F_{40\%}$ reference points. Since 2004, approximately 43% of the Aleutian Islands blackspotted/rougheye harvest has occurred in the western Aleutian Islands, an area with approximately 8% of the AI survey biomass. A decline in the western AI survey biomass has occurred since the early 1990s; each of the biomass estimates from 2000 – 2010 (averaging 1,059 t) is below each of the biomass estimates from 1991-1997 (averaging 3,156 t), and the 2012 survey estimate has declined to 335 t, the lowest value on record for this subarea.

4 Are there new methods of analysis or protocols for evaluating impacts?

In 2010, a Plan Team –SSC stock structure committee developed a template for evaluating the types of information to be considered when defining the spatial bounds of “stocks” (Spencer et al. 2010). This template was applied to BSAI blackspotted/rougheye rockfish in 2010, and documents existing genetic information that indicates that the spatial structure is estimated to not exceed ~ 500 km. Additional analyses (Appendix A in Spencer and Rooper 2012) have generated area-specific exploitation rates, and reference exploitation rates that correspond harvesting at $F_{40\%}$.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

The 2004 PSEIS evaluated the impact of spatial concentration of the catch with respect to, in part, reductions in “genetic diversity”. Given that reductions in genetic diversity would be expected to occur at very low stock sizes, it is not clear that the conclusions from the 2004 PSEIS using this criterion would be affected from new information on stock structure. However, in developing the stock structure template, Spencer et al. (2010) focused on the potential loss of biomass and yield that may occur from harvests that are spatially disproportionate to biomass for stocks that exhibit spatial structure. Under this criterion, it would be expected that consistent disproportionate spatial harvesting would be expected to result in reductions of biomass and yield in subareas with high exploitation rates. A full analysis of these impacts would require population models that accounted for connectivity of populations of fish between subareas, and would be more complex than the models used for the 2004 PSEIS. However, work has begun on developing these types of models to simulate the types of impacts of disproportionate harvesting upon yield and stock size (I. Spies, AFSC, in prep).

In 2013, a workshop was held to discuss how information on stock structure could be used to inform management decisions, with consideration to a variety of risks to the underlying stock and the resource users. The report from this workshop will hopefully provide guidance for how to evaluate our management policy for stocks like BSAI blackspotted/rougheye rockfish, which exhibit: 1) stock structure at spatial scales smaller than our current management units; 2) disproportionate harvesting patterns and high subarea exploitation rates; and 3) declines in subarea population abundance.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/13

What resource component is this review for? **BSAI other rockfish**
What sections of the PSEIS were reviewed**?** ***Section 4.9.1.13***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Since the 2004 PSEIS, there has not been substantial management changes that has affected BSAI Other Rockfish.

2 Has the status of the resource changed?

BSAI Other Rockfish are managed under Tier 5, and the 2004 PSEIS states that reliable estimates of total and spawning biomass are not available. However, estimates of biomass are obtained from the Tier 5 stock assessments, and are based on smoothing survey biomass estimates. The AI survey biomass estimate for Other Rockfish in 2012 is similar to estimates in the early 2000s, whereas the estimates from the EBS slope survey have increased from 17,000 t in 2002 to 30,000 t in 2012.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is no new information regarding the impacts of the groundfish fisheries on BSAI Other Rockfish.

4 Are there new methods of analysis or protocols for evaluating impacts?

There are no new methods for evaluating fishery impacts upon BSAI Other Rockfish.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Given the criteria used for the 2004 PSEIS and the absence of new information for BSAI Other Rockfish, it is unlikely that a reanalysis would yield a seriously different conclusion regarding the impact to the stock.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____Gulf of Alaska Pacific ocean perch
What sections of the PSEIS were reviewed? ___4.9.1.11

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In November, 2006, NMFS issued a final rule to implement Amendment 68 of the GOA groundfish Fishery Management Plan for 2007 through 2011. This action implemented the Central GOA Rockfish Pilot Program (RPP). The intention of this program is to enhance resource conservation and improve economic efficiency for harvesters and processors in the rockfish fishery. This should spread out the fishery in time and space, allowing for better prices for product and reducing the pressure of what was an approximately two week fishery in July. In a comparison of catches in the four years before the RPP to the four years after, it appears some effort has shifted to area 620 (Chirikof) from area 630 (Kodiak).

In 2012 this was implemented permanently as the Rockfish Program. The Rockfish Program assigns quota shares for primary rockfish species and secondary target species. Primary rockfish species are northern rockfish, Pacific ocean perch, and pelagic shelf rockfish (now dusky rockfish). Secondary target species are Pacific cod, rougheye/blackspotted rockfish, shortraker rockfish, sablefish, and thornyhead rockfish. Each year the quota shares are assigned to a rockfish cooperative. Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

2 Has the status of the resource changed?

The status of the GOA Pacific ocean perch stock is similar to the status during the 2004 PSEIS and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Use of pelagic trawl gear has increased gradually over time and is now 31% of effort for POP in the Gulf of Alaska (GOA POP SAFE, Hanselman et al. 2011). This should reduce any potential effects of the POP fishery on habitat suitability for GOA POP. Several genetic analyses of POP stock structure have suggested that POP are at risk of localized depletion because of very low estimated lifetime movement potential. However, an analysis of localized depletion using fishery catch-per-unit effort data showed that large areas filled back in with similar amounts of fish in subsequent years. The rockfish fishery, which is the main source of mortality for GOA POP, is prosecuted over a longer period of time.

4 Are there new methods of analysis or protocols for evaluating impacts?

The stock assessment and projection models are similar to those used in the PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The previous analysis in the 2004 PSEIS was based on the standard projection model which is still used, and the stock assessment that the projection was based on is similar to the one used now.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____Gulf of Alaska northern rockfish
What sections of the PSEIS were reviewed? ___4.9.1.13

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In November, 2006, NMFS issued a final rule to implement Amendment 68 of the GOA groundfish Fishery Management Plan for 2007 through 2011. This action implemented the Central GOA Rockfish Pilot Program (RPP). The intention of this program is to enhance resource conservation and improve economic efficiency for harvesters and processors in the rockfish fishery. This should spread out the fishery in time and space, allowing for better prices for product and reducing the pressure of what was an approximately two week fishery in July. In a comparison of catches in the four years before the RPP to the four years after, it appears that average catches have increased overall (although, this may be due to increased observer coverage) and have spread out spatially in the western and central Gulf.

In 2012 this was implemented permanently as the Rockfish Program. The Rockfish Program assigns quota shares for primary rockfish species and secondary target species. Primary rockfish species are northern rockfish, Pacific ocean perch, and pelagic shelf rockfish (now dusky rockfish). Secondary target species are Pacific cod, rougheye/blackspotted rockfish, shortraker rockfish, sablefish, and thornyhead rockfish. Each year the quota shares are assigned to a rockfish cooperative. Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

2 Has the status of the resource changed?

The status of the GOA northern rockfish stock is similar to the status during the 2004 PSEIS and within the range of variability of the estimates at that time.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Use of pelagic trawl gear has increased gradually over time in the Gulf of Alaska (GOA Northern rockfish SAFE, Huslon et al. 2011). This should reduce the chance for any effects on habitat suitability from the GOA northern rockfish fishery.

4 Are there new methods of analysis or protocols for evaluating impacts?

The methodology is similar to the 2004 PSEIS.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current analysis uses modern methods and the Gulf of Alaska northern rockfish assessment model indicates that the conclusions of the 2004 PSEIS are still valid.

Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

Starting in 2005, Gulf of Alaska shortraker rockfish was separated from the shortraker and rougheye rockfish complex. Shortraker is a stand-alone Tier 5 assessment because of its relatively high value, but is not able to be elevated to a higher tier, primarily because of uncertainty in the validity of age readings. There is no target fishery for shortraker rockfish, but they are retained in the Rockfish program and by longliners fishing sablefish.

2 Has the status of the resource changed?

Because the shortraker rockfish stock is in Tier 5, its stock status cannot be determined. As in the 2004 PSEIS, overfishing is not occurring for the GOA shortraker rockfish stock.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes, the stock is now managed separately so catch is better accounted for and impact of the fishery can be is monitored more closely.

4 Are there new methods of analysis or protocols for evaluating impacts?

There has been additional work on determining age compositions of shortraker rockfish and there is also potential to attempt length-based methods to be able to better assess stock status.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. Since the fishery is not opened as a target fishery, it is unlikely that a conservation concern has developed since the 2004 PSEIS.

draft 6-13-13

What resource component is this review for? ____Gulf of Alaska rougheye/blackspotted rockfish
What sections of the PSEIS were reviewed? ___4.9.1.13

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In November, 2006, NMFS issued a final rule to implement Amendment 68 of the GOA groundfish Fishery Management Plan for 2007 through 2011. This action implemented the Central GOA Rockfish Pilot Program (RPP). The intention of this program is to enhance resource conservation and improve economic efficiency for harvesters and processors in the rockfish fishery. This should spread out the fishery in time and space, allowing for better prices for product and reducing the pressure of what was an approximately two week fishery in July.

In 2012 this was implemented permanently as the Rockfish Program. The Rockfish Program assigns quota shares for primary rockfish species and secondary target species. Primary rockfish species are northern rockfish, Pacific ocean perch, and pelagic shelf rockfish (now dusky rockfish). Secondary target species are Pacific cod, rougheye/blackspotted rockfish, shortraker rockfish, sablefish, and thornyhead rockfish. Each year the quota shares are assigned to a rockfish cooperative. Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

Starting in 2004, shortraker and rougheye rockfish were divided into separate subgroups and assigned individual ABCs and TACs. In 2005, rougheye was moved to Tier 3 status as an age structured model was accepted for determining ABC and OFL. It can now be identified that overfishing is not occurring for this stock, and that the stock is not overfished. In 2008, the rougheye rockfish was formally identified as a complex of two sibling species called rougheye (*Sebastes aleutianus*) and blackspotted (*S. melanostictus*) rockfish. They continue to be assessed as a Tier 3 stock complex.

2 Has the status of the resource changed?

Because the rougheye and blackspotted complex is in Tier 3, it can now be identified that overfishing is not occurring, and the stock is not overfished. This status would have been unknown during the 2004 PSEIS.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes, the complex is now managed separately from shortraker rockfish so catch is better accounted for and impact of the fishery can be monitored more closely.

4 Are there new methods of analysis or protocols for evaluating impacts?

The 2004 PSEIS used a projection model for Tier 3 stocks. The rougheye/blackspotted assessment is now an age-structured stand-alone assessment in Tier 3, so impacts of the fishery on the resource can be better monitored and the 2004 projection analysis could be repeated including the RE/BS complex.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Yes. The change in biomass category could be changed from “unknown” to “insignificant” for both direct/indirect and cumulative effects.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____Gulf of Alaska dusky rockfish
What sections of the PSEIS were reviewed? ___4.9.1.13

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In November, 2006, NMFS issued a final rule to implement Amendment 68 of the GOA groundfish Fishery Management Plan for 2007 through 2011. This action implemented the Central GOA Rockfish Pilot Program (RPP). The intention of this program is to enhance resource conservation and improve economic efficiency for harvesters and processors in the rockfish fishery. This should spread out the fishery in time and space, allowing for better prices for product and reducing the pressure of what was an approximately two week fishery in July. In a comparison of catches in the four years before the RPP to the four years after, it appears that average catches have increased overall (although, this may be due to increased observer coverage) and have spread out spatially in the western and central Gulf.

In 2012 this was implemented permanently as the Rockfish Program. The Rockfish Program assigns quota shares for primary rockfish species and secondary target species. Primary rockfish species are northern rockfish, Pacific ocean perch, and pelagic shelf rockfish (now dusky rockfish). Secondary target species are Pacific cod, rougheye/blackspotted rockfish, shortraker rockfish, sablefish, and thornyhead rockfish. Each year the quota shares are assigned to a rockfish cooperative. Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

For 2012, widow and yellowtail rockfish were removed from the pelagic shelf rockfish complex effectively leaving dusky rockfish as a stand-alone Tier 3 species. Widow and yellowtail rockfish were moved to a new “Other rockfish” category with the old “Slope rockfish” category species.
Because dusky rockfish is in Tier 3, it can now be identified that overfishing is not occurring, and the stock is not overfished.

2 Has the status of the resource changed?

Because dusky rockfish is in Tier 3, it can now be identified that overfishing is not occurring, and the stock is not overfished. This status would have been unknown during the 2004 PSEIS.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Bycatch estimates decreased for the majority of species in the Central GOA following the implementation of the Rockfish Pilot Program. Use of pelagic trawl gear has increased gradually over time in the Gulf of Alaska (GOA dusky rockfish SAFE, Lunsford et al. 2011). This should reduce the chance for any effects on habitat suitability from the GOA dusky fishery.

4 Are there new methods of analysis or protocols for evaluating impacts?

The 2004 PSEIS used a projection model for Tier 3 stocks. The dusky rockfish assessment is now an age-structured stand-alone assessment in Tier 3, so impacts of the fishery on the resource can be better monitored and the 2004 projection analysis could be repeated including the GOA dusky rockfish stock.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Yes. The change in biomass category could be changed from “unknown” to “insignificant” for both direct/indirect and cumulative effects.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 3/13/14

What resource component is this review for? Demersal Shelf Rockfish
What sections of the PSEIS were reviewed? 4.9.1.13

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In 1998 the NPFMC passed an amendment to require full retention of DSR in federal waters. Seven years later, in mid-season 2005, the final rule was published and fishermen must now retain and report all DSR caught in federal waters; any poundage above the 10% bycatch allowance may be donated or kept for personal use but may not enter commerce. The requirement for full retention of rockfish in both federal and state waters allows for better accounting of total mortality.

In 2006 the Alaska Board of Fisheries implemented a regulation to allocate the DSR Total Allowable Catch (TAC) as follows: 16% to the recreational fishery, and 84% to the commercial fisheries.

In 2009, the Alaska Board of Fisheries implemented a regulation that required the estimated harvest of DSR subsistence catch to be deducted from the acceptable biological catch (ABC) of DSR prior to allocation of the TAC.

2 Has the status of the resource changed?

As in 2004, DSR remains in Tier 4, thus stock status cannot be determined. As in the 2004 PSEIS, overfishing is not occurring for the DSR. However, survey estimates have indicated a decline in population biomass despite the continued use of a harvest rate lower than the maximum allowed under Tier 4. Under Tier 4 definitions for setting ABC, $F_{40\%}=0.026$ would be used, but we continue to use a more conservative approach (F=M=0.02).

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

A large proportion of the DSR total mortality is from bycatch in the IFQ halibut fishery. Decreasing halibut quotas in area 3A and 2C have reduced the DSR bycatch in these fisheries as well. New information from the expanded observer program may shed light on whether the full retention rockfish regulation is being complied with.

4 Are there new methods of analysis or protocols for evaluating impacts?

Historically, and at the time of the 2004 PSEIS , the R/V *Delta*, a manned submersible, was used to assess DSR during line transect surveys. Since 2012, the submersible has been replaced with a Remote Operated Vehicle (ROV) since the *Delta* is no longer available for charter. We are using the same survey techniques and survey design with the new vehicle, however we will be including both the submersible and ROV data survey estimates, total catch, and biological data into an age structured assessment (ASA) model is for the 2014 assessment cycle. If this ASA model is accepted it is likely the DSR complex would be moved to Tier 3 and impacts of the fishery on the resource can be better assessed. The ROV is outfitted with a pair of stereo cameras, which allows us to record fish length from the survey, which was previously unavailable.

Also, additional habitat mapping has been conducted since 2004 which allows us to better refine our rockfish habitat estimation.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

The current analyses indicates that the conclusions of the 2004 PSEIS are still valid, however if DSR are moved to a different Tier status after review of the ASA model in 2014, then it is possible that the Category “change in biomass level” could change from unknown to a different rating.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____Gulf of Alaska thornyhead rockfish complex
What sections of the PSEIS were reviewed? ___4.9.1.12

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In November, 2006, NMFS issued a final rule to implement Amendment 68 of the GOA groundfish Fishery Management Plan for 2007 through 2011. This action implemented the Central GOA Rockfish Pilot Program (RPP). The intention of this program is to enhance resource conservation and improve economic efficiency for harvesters and processors in the rockfish fishery. This should spread out the fishery in time and space, allowing for better prices for product and reducing the pressure of what was an approximately two week fishery in July. In 2012 this was implemented permanently as the Rockfish Program. The Rockfish Program assigns quota shares for primary rockfish species and secondary target species. Primary rockfish species are northern rockfish, Pacific ocean perch, and pelagic shelf rockfish (now dusky rockfish). Secondary target species are Pacific cod, rougheye/blackspotted rockfish, shortraker rockfish, sablefish, and thornyhead rockfish. Each year the quota shares are assigned to a rockfish cooperative. Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

Starting in 2004, Gulf of Alaska thornyhead rockfish complex was downgraded from Tier 3 to Tier 5, primarily because of uncertainty in the validity of age readings for shortstpine thornyhead . There is no target fishery opened for thornyhead rockfish, but they are retained in the Rockfish program and by longliners targeting sablefish.

2 Has the status of the resource changed?

Because the thornyhead complex is now in Tier 5, it can no longer be identified whether the stock is overfished. For 2004 PSEIS, the thornyhead complex was identified as not overfished.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

No.

4 Are there new methods of analysis or protocols for evaluating impacts?

There has been additional tag recovery data collected and there is potential to attempt length-based methods to be able to better assess stock status.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

Yes. Since the fishery is now a tier 5 stock the conclusions reached for the categories **change in biomass**, **spatial/temporal concentration of catch-change in genetic structure**, **spatial/temporal concentration of catch-change in reproductive success, change in prey availability, and change in habitat** would be moved from a finding of “Insignificant” to a finding of “Unknown”. However, it is unlikely that a conservation concern has developed since the 2004 PSEIS.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/13/13

What resource component is this review for? ____Gulf of Alaska other rockfish
What sections of the PSEIS were reviewed? ___4.9.1.13

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

In November, 2006, NMFS issued a final rule to implement Amendment 68 of the GOA groundfish Fishery Management Plan for 2007 through 2011. This action implemented the Central GOA Rockfish Pilot Program (RPP). The intention of this program is to enhance resource conservation and improve economic efficiency for harvesters and processors in the rockfish fishery. This should spread out the fishery in time and space, allowing for better prices for product and reducing the pressure of what was an approximately two week fishery in July.

In 2012 this was implemented permanently as the Rockfish Program. The Rockfish Program assigns quota shares for primary rockfish species and secondary target species. Primary rockfish species are northern rockfish, Pacific ocean perch, and pelagic shelf rockfish (now dusky rockfish). Secondary target species are Pacific cod, rougheye/blackspotted rockfish, shortraker rockfish, sablefish, and thornyhead rockfish. Each year the quota shares are assigned to a rockfish cooperative. Each rockfish cooperative receives an annual cooperative fishing quota, which is an amount of primary and secondary rockfish species the cooperative is able to harvest in that fishing year. Halibut Prohibited Species Catch is also allocated to participants based on historic halibut mortality rates in the primary rockfish species fisheries. Shore-based processors receiving rockfish quota share must be located within the boundaries of the City of Kodiak. The rockfish cooperative fishing season is authorized May 1 through November 15 of each year, whereas in the past, a very short season in July was prosecuted.

Starting in 2012, Gulf of Alaska “Slope rockfish” and the remainder of the “Pelagic shelf rockfish” complex after removing dusky rockfish were reorganized under a new management group called “Other Rockfish”. This group is a catch-all for the remainder of Gulf of Alaska rockfish that are in Tiers 4 and 5. There is a range of life history variants in this complex, and the complex composition changes over geographic clines.

2 Has the status of the resource changed?

Because the other rockfish complex has stocks is in Tiers 4 and 5, its stock status cannot be determined. As in the 2004 PSEIS of “Slope rockfish”, overfishing is not occurring for the GOA other rockfish stock complex.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Improvements in the observer program and catch accounting have yielded better estimates of minor rockfish species catches.

4 Are there new methods of analysis or protocols for evaluating impacts?

Data for most "other rockfish" species is sparse and survey biomass estimates are too imprecise to further develop new more detailed assessments.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. Since the fishery is not opened as a target fishery, it is unlikely that a conservation concern has developed since the 2004 PSEIS.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

~6/19/2013

What resource component is this review for? __**GOA & BSAI squids**________________
What sections of the PSEIS were reviewed? _______**4.9.3**____________

1 Has management of the resource changed?

Management of squids in the BSAI has not changed since 2004; they continue to be managed as a separate stock. In the GOA, squids are now also managed as a separate stock as a result of NPFMC Amendment 87 (http://www.fakr.noaa.gov/sustainablefisheries/amds/95-96-87/amd87.pdf). In both the BSAI and GOA, squids are managed under Tier 6. The OFL in the BSAI is the average catch from 1978-1995; the OFL in the GOA is the maximum catch during 1997-2007.

2 Has the status of the resource changed?

As described in the 2004 PSEIS (section 3.5.3.1), very little information is available regarding the status of squid populations. Catches of squids have been relatively low since 2013 in both areas, but this likely reflects fishery behavior rather than changes in abundance.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Beginning in 2009, the fishery observer program records lengths of squids caught incidentally in groundfish fisheries. This has allowed a better understanding of which species/ life stages are most likely to be caught incidentally. Otherwise, the assessment of impacts in the PSEIS remains unchanged.

4 Are there new methods of analysis or protocols for evaluating impacts?

The development of ecosystem models for the BSAI and GOA has allowed greater exploration of how various ecosystem impacts might affect squid stocks and their predators. In addition, the establishment of a separate squid complex in the GOA allows an evaluation of whether overfishing is occurring.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

It is unlikely that a new analysis would reach a seriously different conclusion. It is likely that many of the potential benefits of Preferred Alternative 2 (which included separate specifications for species groups within the “Other Species” group) will be realized under the new management approach in the GOA.

PSEIS SIR – review of conclusions in 2004 PSEIS

~6/19/2013

What resource component is this review for? **BSAI and GOA Octopus** ____
What sections of the PSEIS were reviewed? __**4.9.3 Other Species**, including

- ***Table 4.1-1 for Significance rating criteria*** *for target species, other species*, forage fish, non-specified species, Pacific halibut, and Pacific herring*
- ***Table 4.9-2 Significance ratings for prohibited, other*, forage, and non-specified species*** *under Preferred Alternative PA.1 and PA.2*
- ***Table 4.10-2b PA.1 and PA.2-impacts of Preferred Alt example FMP bookends***

1 Has management of the resource changed?

There have been substantial changes in management and monitoring of this species assemblage. The "other species" group has been removed from the FMP and replaced with separate regulation for sculpins, sharks, squids, skates, and octopus. The octopus complex, which includes all species of octopus, is now managed as a separate category in the FMPs and has its own annual OFL, ABC, and TAC limits. This management change was implemented in both the BSAI and GOA in 2012. Separate catch accounting for the octopus assemblage has been conducted since 2003. Identification of octopus on AFSC bottom trawl surveys has been improved to the species level, and more data has been collected on size ranges (in weight) of the different species. Identification of octopus in observer and fish ticket data is still collected at the assemblage level (all octopus), but special projects have provided data that indicate that the majority of the commercial catch is one species, *Enteroctopus dofleini*, which is used as the indicator species for the assemblage.

It is unknown whether this management change has affected the resource. Both reporting rates of incidental catch and retention of catch for sale and bait are believed to have increased over the period 2004-2012, but overall incidental catch rates are still believed to be very low in relation to population biomass (see BSAI and GOA SAFEs).

2 Has the status of the resource changed?

No. The status of the resource is still unknown, as listed for the entire "other species" complex in 2004 (Table 9.4-2). While knowledge of the indicator species has improved since 2004, there is still no reliable estimate of biomass for the assemblage or time series of abundance indicators. There is still little information on overall mortality or on changes in biomass, habitat, reproductive success, or genetic structure.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is substantial new information about the biology of the indicator species for the assemblage, due to completed and ongoing directed research (see the BSAI and GOA Octopus SAFE; NPRB projects 906, 1005, and 1203; and NOAA Cooperative research projects for 2009, 2012, and 2013). None of the new information suggests any change in effects of the fishery on the resource, as fishery practices have changed only slightly since the mid- 1990s (there is no directed fishing for octopus). Since the status of the resource is unknown, the effect of the fishery on the resource remains unknown.

4 Are there new methods of analysis or protocols for evaluating impacts?

Recent information on the discard mortality of octopus suggests that current catch accounting practices (100% mortality assumed) are highly conservative for this assemblage, which would suggest that impacts of the fishery on the resource have been overestimated. This is true for both the period of review for the 2004 PSEIS and the period 2004-2013. In both cases, there is no reason to expect any increase in fishery impacts on the assemblage since 2004

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. Since the status of the resource is unknown, the effect of the fishery on the resource remains unknown. If new information on discard mortality were used, the estimated fishing mortality of the assemblage would be reduced, but the overall mortality rate for the assemblage is still unknown.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/12/13

What resource component is this review for? ___**Sharks**
What sections of the PSEIS were reviewed? ___**Section 4.9.3**

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

As part of the reauthorization of the Magnuson Stevens Fishery Conservation and Management Act, the NPFMC passed amendment 87 (http://www.fakr.noaa.gov/sustainablefisheries/amds/95-96-87/amd87.pdf), which dissolved the Other Species Complex. Sharks are now managed as a separate complex. The effect of this is that the shark complex has a separate ABC set for it.

2 Has the status of the resource changed?

The status of the shark complex in the PSEIS was determined to be unknown. Currently, the shark complex is composed of Tier 6 species and the status of the stock cannot be determined. As in the 2004 PESIS of Other Species/Sharks, overfishing is not occurring in either the GOA or BSAI shark stocks.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes, the sharks are now a separate complex. Restructuring of the observer program (which began in 2013) improved observer coverage of fisheries that encounter sharks and will likely result in better catch accounting of this complex.

4 Are there new methods of analysis or protocols for evaluating impacts?

At the time of the 2004 PSEIS the shark stock assessments were based only on catch history. Now, spiny dogfish (*Squalus suckleyi*) is assessed using survey biomass. Modeling methods are being evaluated for spiny dogfish to better assess the status of the stock.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The previous status of the sharks was “unknown”. The shark complex is on a bycatch only status and it is unlikely that a conservation concern has developed since the 2004 PESIS.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/10/2013

What resource component is this review for? **BSAI sculpins**
What sections of the PSEIS were reviewed**?** ***Section 4.9.3***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Historically, sculpins have been managed as part of the BSAI Other Species complex (sculpins, skates, sharks, and octopus). Specifications for this group were set by summing the individual ABCs and OFLs for each species group to create an aggregate OFL, ABC, and TAC. In 2010, the North Pacific Fishery Management Council passed amendment 87 to the BSAI Fishery Management Plan, which separated the Other Species complex into its constituent species groups. Since that time, BSAI sculpins have been managed as an independent complex with its own harvest specifications.

2 Has the status of the resource changed?

The status of the BSAI sculpin complex is similar to the status during the 2004 PSEIS, based on research survey estimates. The sculpin complex in the BSAI includes 48 species, but the six of the largest species comprise over 85% of the total sculpin biomass (bigmouth *(Hemitripterus bolini),* great *(Myoxocephalus polyacanthocephalus),* plain *(Myoxocephalus jaok),* threaded *(Gymnocanthus pistilliger),* warty *(Myoxocephalus verrucosus),* and yellow Irish lord *(Hemilepidotus jordani)*.. These six species are also assumed to have higher catchabilities than the remaining species because smaller species are likely to pass through the net and are difficult to assess in NMFS research surveys. Estimates of the abundance of each of these species, as well as the overall sculpin complex biomass, have not changed significantly since 2004.

2 Is there new information regarding the impacts of the groundfish fisheries on the resource?

BSAI sculpins were not assessed as a separate complex until 2010. Information on the impact of the groundfish fisheries on the resource comes directly from observer data. Two analyses performed on survey data and observer data were highly consistent: 1. length frequencies and 2. relative abundance of each species relative to the total sculpin abundance of the six species, specifically bigmouth *(Hemitripterus bolini),* great *(Myoxocephalus polyacanthocephalus),* plain *(Myoxocephalus jaok),* threaded *(Gymnocanthus pistilliger),* warty *(Myoxocephalus verrucosus),* and yellow Irish lord *(Hemilepidotus jordani).* This suggests that data used in the assessment accurately captures the impacts of the groundfish fisheries on this resource.

3 Are there new methods of analysis or protocols for evaluating impacts?

Since 2010 the sculpin stock assessment has been performed under Tier 5 methodology, and protocols have remained consistent for the 2010-2012 assessments.

4 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current assessment uses a weighted average of sculpin survey biomass from the past three years in which all three BSAI surveys were performed. Alternative methods were explored, including a weighted average of the most three recent years of each survey and a random effects model, but the resulting ABC and TAC were not significantly different than that achieved with the current methodology.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/10/2013

What resource component is this review for? **GOA sculpins**
What sections of the PSEIS were reviewed**?** ***Section 4.9.3***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Historically, sculpins have been managed as part of the GOA Other Species complex (sculpins, skates, sharks, squid, and octopus). Specifications for this group were set by summing the individual ABCs and OFLs for each species group to create an aggregate OFL, ABC, and TAC. In 2010, the North Pacific Fishery Management Council passed amendment 87 to the GOA Fishery Management Plan, which separated the Other Species complex into its constituent species groups. Since that time, GOA sculpins have been managed as an independent complex with its own harvest specifications.

2 Has the status of the resource changed?

The status of the GOA sculpin complex is similar to the status during the 2004 PSEIS, based on research survey estimates. The sculpin complex in the GOA includes 48 species, but the four largest species comprise over 95% of the total sculpin biomass (bigmouth (*Hemitripterus bolini*), great (*Myoxocephalus polyacanthocephalus*), plain (*Myoxocephalus jaok*), and yellow Irish lord (*Hemilepidotus jordani*).. These four species are also assumed to have higher catchabilities than the remaining species because smaller species are likely to pass through the net and are difficult to assess in NMFS research surveys. Estimates of the abundance of each of these species, as well as the overall sculpin complex biomass, have not changed significantly since 2004.

2 Is there new information regarding the impacts of the groundfish fisheries on the resource?

GOA sculpins were not assessed as a separate complex until 2010. Information on the impact of the groundfish fisheries on the resource comes directly from observer data. Two analyses performed on survey data and observer data were highly consistent: 1. length frequencies and 2. relative abundance of each species relative to the total sculpin abundance of the four species, specifically bigmouth *(Hemitripterus bolini)*, great *(Myoxocephalus polyacanthocephalus)*, plain *(Myoxocephalus jaok)*, and yellow Irish lord *(Hemilepidotus jordani)*. This suggests that data used in the assessment accurately captures the impacts of the groundfish fisheries on this resource.

3 Are there new methods of analysis or protocols for evaluating impacts?

Since 2010 the sculpin stock assessment has been performed under Tier 5 methodology, and protocols have remained consistent for the 2010-2012 assessments.

4 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The current assessment uses a weighted average of sculpin biomass from the past three years in which all three GOA surveys were performed. A random effects model was recently explored as an alternative to the current methodology, but the resulting ABC and TAC were not significantly different than currently estimated.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft ~6/19/2013

What resource component is this review for? **BSAI skates**
What sections of the PSEIS were reviewed? **4.9.3**

1 Has management of the resource changed?

In 2011, the "Other Species" category was broken up and a separate skate complex was established (http://www.fakr.noaa.gov/sustainablefisheries/amds/95-96-87/amd87.pdf). A single set of harvest specifications is applied to the entire skate complex. Assessment of the Alaska skate (*Bathyraja parmifera*, which constitutes over 90% of the BSAI skate biomass) is achieved using an age-structured model, allowing a Tier 3 determination of harvest specifications for that species. The remaining skate species ("other skates") are managed under Tier 5. The Tier 3 and Tier 5 specifications are combined to create a single skate complex set of specifications.

2 Has the status of the resource changed?

The 2004 PSEIS documented the difficulty of studying trends in the status of skate species in the BSAI, due to a general lack of biological information on skates and a specific lack of species identification for skates in the trawl survey before 2000 (PSEIS section 3.5.3.4). Skate biomass increased dramatically in the BSAI during the 1980s, and has since then remained relatively stable. Current survey methods and catch reporting allow enhanced monitoring of skate populations in the BSAI, but the conclusions in the PSEIS regarding the status of skates remain essentially unchanged.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The fisheries that affect skates in the BSAI remain largely the same as in 2004. Skate catches likely depend mainly on the scale of the target fisheries where they are incidentally caught, i.e. the Pacific cod and flatfish fisheries.

4 Are there new methods of analysis or protocols for evaluating impacts?

The changes in BSAI skate assessment and management allow an improved monitoring of skate stock status. The Alaska skate model permits an evaluation of both overfishing and whether the population is overfished; the Tier 5 status of "other skates" permits an evaluation of overfishing. The Alaska skate stock is not in an overfished condition and no skates have experienced overfishing since the new management measures were adopted.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

The 2004 PSEIS listed the potential impacts on skate stocks (as part of "Other Species") as "unknown". It is likely that a new analysis would be able to provide a more detailed description of such impacts. However, due to the remaining uncertainties regarding bycatch and stock status**, it is unlikely that a new analysis would reach a seriously different conclusion**. It is likely that many of the potential benefits of Preferred Alternative 2 (which included separate specifications for species groups within the "Other Species" group) will be realized under the new management approach.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

~6/19/2013

What resource component is this review for? ___**GOA skates**________________
What sections of the PSEIS were reviewed? _____**4.9.3**_______________

1 Has management of the resource changed?

There have been numerous changes to the management of skates in the GOA since the PSEIS was published (see the 2011 GOA skate SAFE at www.afsc.noaa.gov/refm/stocks/2011_assessments.htm). In 2004, big skates (*Raja binoculata*) and longnose skates (*Raja rhina*) were moved to a separate management category and managed together under a single TAC in the Central GOA where a directed skate fishery had emerged in 2003. The remaining skates were managed as an "other skates" species complex in the Central GOA, and all skates including big and longnose skates were managed as a single skate complex in the Western and Eastern GOA. In 2005, the current management scheme was established:

- Big and longnose skates are each managed as single stocks, with harvest specifications for each stock.
- Separate ABCs and TACs for big and longnose skates are established for each GOA regulatory area.
- Big and longnose OFLs are established on a GOA-wide basis.
- The remaining skate species in the skate complex are managed as a single "other skates" stock, with GOA-wide specifications.
- Directed fishing is prohibited for all skate species in the GOA

2 Has the status of the resource changed?

The 2004 PSEIS documented the difficulty of studying trends in the status of skate species in the GOA, due to a general lack of biological information on skates and a specific lack of species identification for skates in the trawl survey before 2000 (PSEIS section 3.5.3.4). In general, skate species increased during the 1980s and the various populations have remained relatively stable since then. Current survey methods and catch reporting allow enhanced monitoring of skate populations in the GOA, but the conclusions in the PSEIS regarding the status of skates remain essentially unchanged.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The fisheries that affect skates in the GOA remain largely the same as in 2004, with the exception that directed fishing for skates is currently prohibited. A small-scale state-waters fishery was conducted in 2009 & 2010, but has been discontinued. There continues to be interest in developing a directed skate fishery in the GOA. As described in the 2004 PSEIS, incidental catches of skates in the IPHC halibut fishery continue to be a large source of uncertainty regarding total skate catches. As described in the 2011 GOA skate SAFE, an analysis that applied IPHC longline survey species composition data to IPHC halibut catch records estimated a substantial amount of halibut fishery bycatch; however this analysis was deemed insufficient for inclusion in the official catch reporting. Changes to the fishery observer program implemented in 2013 will likely enhance the accounting of skate bycatch in the GOA. Other than those changes, the information regarding potential impacts on GOA skates remains unchanged from the 2004 PSEIS.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Draft 18 March 2014
compiled by IPHC staff

What resource component is this review for? Pacific Halibut
What sections of the PSEIS were reviewed? ___________________

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

The most significant change has been the implementation of (1) a license limited access program for the halibut sport guided (charter) fishery in IPHC Areas 2C (southeast Alaska) and 3A (southcentral Alaska) (2011), and (2) a Catch Sharing Plan between commercial and guided recreational halibut harvesters for Areas 2C and 3A, beginning in 2014. Management measures to restrict harvest within the guided sector included both size limits and daily effort controls.

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

The resource has declined from historic high levels in the late 1990s and is now near the long-term average abundance for the stock. The decrease in abundance is largely related to the passing through the stock of extremely strong cohorts generated in the late 1980s. Subsequent recruitments have been average to below-average, resulting in the stock returning to average levels. Current status is within the range of historic assessments.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

Impacts of groundfish fisheries on the halibut resource are believed to have decreased since 2004, due to reductions in estimated halibut mortality in groundfish trawl fisheries. Most of this decline is associated with improved bycatch controls in the Bering Sea/Aleutian Islands Amendment 80 trawl fleet, through the use of fishery cooperatives, which include bycatch mortality pools. The International Pacific Halibut

Commission conducted additional analyses of the impacts of trawl bycatch mortality on lost yield and spawning biomass for the halibut stock.

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

The International Pacific Halibut Commission analyses referred to item 3 helped inform the reduction in halibut PSC limits for the Gulf of Alaska, scheduled for implementation over the 2014-2016 period. That information was included in the NEPA analysis conducted as part of GOA FMP Amendment 95.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

No new information concerning bycatch impacts is currently available; however, the relationship of bycatch mortality to long-term yield from the halibut resource is currently being investigated within a Management Strategy Evaluation. It is uncertain at this point whether the impact of the halibut bycatch mortality will be less or more but that evaluation is being undertaken as a part of the International Pacific Halibut Commission's ongoing research. Although the IPHC includes all sources of mortality in annual stock assessments, and therefore accounts for bycatch in estimated fishery yields, mortality of halibut <26 inches is not included in IPHC's annual limits. The degree that this source of mortality has become more influential in population trends is largely unknown; however, bycatch of all sizes currently comprises a larger fraction of the total mortality than in previous analyses (20% of the projected 2014 removals from all sources). There is the potential, even under current PSC limits, that bycatch mortality could preclude all directed fishery activities in specific regulatory areas if further declines in apportioned biomass estimates are observed.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

Jeff Guyon –June 10, 2013
NMFS/AFSC/ABL

What resource component is this review for? ____**Prohibited Species**____
What sections of the PSEIS were reviewed? ___**4.9.2.2 Pacific Salmon or Steelhead Trout** ____

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Since the 2004 PSEIS, the following fishery management plan amendments have been made regarding the salmon bycatch:

1. Amendment 91 to the Fishery Management Plan for Groundfish of the Bering Sea and Aleutian Islands Management Area (implemented in 2011) and
2. Amendment 93 to the Fishery Management Plan for Groundfish of the Gulf of Alaska (implemented in 2012).

These amendments set a cap for the number of Chinook salmon that can be caught as bycatch in both the Bering Sea and the Gulf of Alaska.

2 Has the status of the resource changed?

The 2004 PSEIS focuses on both Chinook and chum salmon and specifically highlights issues for western Alaska. Since 2004, Yukon and Kuskokwim River Chinook salmon escapements have declined through 2011 to about a third of what they were in 2004 (2012 ADF&G Chinook Research Plan – see Figures 13 and 14 in http://www.adfg.alaska.gov/static/home/news/hottopics/pdfs/chinook_research_plan.pdf). Federal commercial fishing disaster declarations have been issued for Yukon River Chinook salmon for each year through 2008-2012. Other disaster declarations have also been issued for the Kuskokwim and Cook Inlet areas.

The Upper Yukon stock of chum salmon, also known as the fall stock, is a general indicator species which is monitored for treaty purposes. Since 2004 when the run size was 614 thousand fish, the estimated run size for fall Yukon River chum salmon has varied significantly with the run peaking over 2.3 million fish in 2005, but generally trending back to 2004 levels in more recent years (The United States and Canada Yukon River Joint Technical Committee – Yukon River Salmon 2011 Season Summary and 2012 Season Outlook -Table 18 in http://yukonriverpanel.com/salmon/wp-content/uploads/2009/03/jtc-report-summary-2011-preseason-2012.pdf)

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2004, there was limited stock composition information available for both the Chinook and chum salmon bycatch in the Bering Sea and Gulf of Alaska trawl fisheries. Since then, there have been a number of genetic stock composition analyses completed for sample sets from the 2005-2011 Bering Sea Chinook salmon bycatch, 2010-2011 Gulf of Alaska Chinook salmon bycatch (very limited sample sets), and 2005-2011 Bering Sea chum salmon bycatch. These analyses were completed using more refined baselines than available in 2004. In addition, coded wire tags (CWTs) recovered from Chinook salmon caught in the trawl bycatch have been analyzed each year through 2012. Additionally, for 2011, the North Pacific Observer Program instituted a systematic random sampling protocol for the collection of genetic and CWT samples in the Bering Sea. This has produced the most representative genetic sample set available to date for understanding the stock composition of the Chinook and chum salmon bycatch in the Bering Sea.

4 Are there new methods of analysis or protocols for evaluating impacts?

Since 2004, the impacts of the both the Bering Sea Chinook and chum salmon bycatch relative to escapement and maturity have been completed and incorporated into the associated EIS (Chinook salmon) and draft EA (chum salmon).

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

There has been a considerable amount of information learned since 2004 about the stock origin of salmon caught in the Alaska groundfish trawl bycatch. For the PSEIS, the impacts for chum salmon could be updated using the most current impact analysis drafted for the Environmental Assessment. In addition, the Gulf of Alaska salmon bycatch for both Chinook and chum salmon was thought in 2004 to be composed of a similar stock origin as that in the Bering Sea. We now know that the stock origins for Chinook salmon are very different between these two areas. Consequently, this section could be updated to include the most current information and assessments.

Review of Conclusions in 2004 PSEIS

What resource component is this review for? **BSAI king crab**
What sections of the PSEIS were reviewed**?** ***Section 4.5.2.4 and 4.9.2.4***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

The management measures regulating BSAI king crab as a prohibited species in groundfish fisheries are unchanged since 2004. BSAI king crab remains a Prohibited Species in the BSAI groundfish fisheries. However, implementation of Amendment 80 to the BSAI Groundfish FMP has had some impact on the bycatch of BSAI king crab. Amendment 80 directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-American Fisheries Act (AFA) trawl catcher/processor fleet. This was accomplished by providing the ability to form cooperatives within the newly formed Amendment 80 sector. The partitioning of PSC (prohibited species catch) among the fishery cooperatives has reduced the rate of bycatch per target catch ton.

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery to reduce impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, southern Tanner crab, and snow crab.

New overfishing definitions and total catch accounting for BSAI crab stocks were implemented in 2008 with Amendment 24. Reference points and biomass values for BSAI king crab are estimated using an assessment model and a 5 Tier system. Starting in 2011, with the implementation of Amendment 38, annual catch limits are set for BSAI crab stocks in addition to OFLs.

2 Has the status of the resource changed?

BSAI king crab species include red king crab (*Paralithodes camtschaticus*), blue king crab (*Paralithodes platypus*), and golden (or brown) king crab (*Lithodes aequispinus*). The status of these stocks are evaluated and reported annually in the Council's SAFE report. Although abundance has been variable since 2004, the status of the majority of these king crabs relative to the status determination criteria has not changed, with the exception of St Matthew blue king crab, which was declared rebuilt in 2009 (NPFMC 2013). Pribilof Islands blue king crab, which was subject to a rebuilding plan, failed to rebuild within the ten year time frame ending in 2011.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2012, a Council discussion paper considered the importance of trawl effort on Bristol Bay red king crab to assess the essential fish habitat of red king crab. The Council recommended continued research on the definition of red king crab habitat at multiple life stages and also continued evaluation of existing Bristol Bay red king crab closure areas.

The Council is also assessing the historical bycatch of crab stocks by groundfish fisheries by gear and the measures currently employed under the BSAI FMP and NMFS regulations to limit the bycatch by crab stock. In February 2014, the Council reviewed a discussion paper that evaluates the existing closure areas for Bristol Bay red king crab, Bering Sea Tanner crab, Bering Sea snow crab, and St. Matthew blue king crab, including information on recent stock distribution and the distribution and amount of crab bycatch in the trawl and fixed gear groundfish fisheries. The discussion paper included review of the proportion of bycatch by trawl and fixed gear fisheries inside and outside of the closure areas and a more detailed history of the closures to help identify the fraction of historical fisheries that occurred in these areas as well as their crab bycatch. This discussion paper is intended to assist the Council in deciding what, if any, action to take to modify the existing management measures for these 4 stocks.

4 Are there new methods of analysis or protocols for evaluating impacts?

No. Since 2004, the stock assessment models have improved greatly. Crab bycatch is accounted for in the estimate of total catch used in the stock assessment models and to evaluate total catch relative to the annual catch limits.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

Review of Conclusions in 2004 PSEIS

draft 6/19/2013

What resource component is this review for? **BSAI Snow crab**
What sections of the PSEIS were reviewed**?** ***Section 4.9.2.4***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

From the perspective of the BSAI Groundfish FMP, management of the BSAI snow crab is qualitatively unchanged. BSAI snow crab remains a Prohibited Species in the BSAI groundfish fisheries. However, implementation of Amendment 80 to the BSAI FMP has had some impact on the bycatch of BSAI snow crab. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. The partitioning of PSC (prohibited species catch) among the fishery cooperatives has reduced the rate of bycatch per target catch ton. New overfishing definitions and total catch accounting for BSAI crab stocks were implemented in 2008 with Amendment 24. Reference points and biomass values for BSAI snow crab are estimated using an assessment model and a 5 Tier system, where snow crab is a Tier 3 stock (Turnock and Rugolo 2011). ABC values are now established for BSAI crab stocks in addition to OFL starting in 2011 with the implementation of Amendment 38.

2 Has the status of the resource changed?

The status of the BSAI snow crab resource has changed since the 2004 PSEIS. BSAI snow crab was considered overfished prior to the 2004 PSEIS and the directed fishery for this stock was under a rebuilding plan. In 2011, the stock was declared rebuilt based on a new assessment model (Turnock and Rugolo, 2011).

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting in less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

No.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

North Pacific Fishery Management Council, 605 W. 4th Avenue, #306, Anchorage, AK 99501. pp. 37-168.

Review of Conclusions in 2004 PSEIS

draft 6/19/2013

What resource component is this review for? **BSAI Tanner crab**
What sections of the PSEIS were reviewed**?** ***Section 4.9.2.4***

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

From the perspective of the BSAI Groundfish FMP, management of the BSAI bairdi Tanner crab is qualitatively unchanged. BSAI bairdi Tanner crab remains a Prohibited Species in the BSAI groundfish fisheries. However, implementation of Amendment 80 to the BSAI FMP has had some impact on the bycatch of BSAI bairdi Tanner crab. The Amendment directly allocated fishery resources among BSAI trawl harvesters in consideration of their historic harvest patterns and future harvest needs in order to improve retention and utilization of fishery resources by the non-AFA trawl catcher/processor fleet. This was accomplished by extending the groundfish retention standards to all H&G vessels and also by providing the ability to form cooperatives within the newly formed Amendment 80 sector. The partitioning of PSC (prohibited species catch) among the fishery cooperatives has reduced the rate of bycatch per target catch ton.

In addition, Amendment 24 (June, 2008) to the BSAI Crab FMP established a 5-tier system for determining the status of crab stocks managed under the FMP, including BSAI bairdi Tanner crab stock. It also established a process for assigning each managed crab stock to a tier and for setting overfishing and overfished levels based on the assigned tier. BSAI bairdi Tanner crab is currently in Tier 3 and is not overfished, nor is overfishing occurring (Rugolo and Turnock, 2012).

2 Has the status of the resource changed?

The technical status of the BSAI bairdi Tanner crab resource has changed since the 2004 PSEIS, although its effective status remains the same. BSAI bairdi Tanner crab was considered overfished prior to the 2004 PSEIS and the directed fishery for this stock was closed (1997/98-2004/05). Subsequently, the directed fishery has been both open (2005/06-2009/10) and closed (2010/11-2011/12). In 2012, the stock was declared rebuilt based on a new assessment model (Rugolo and Turnock, 2012). However, stock abundance remains relatively low compared with historic levels and the State of Alaska did not allow a directed fishery in 2012/13.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

In 2011, a trawl sweep modification requirement was implemented for vessels participating in the Bering Sea flatfish fishery resulting in less impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor. Research has demonstrated that this gear modification reduces unobserved mortality of red king crab, Tanner crab, and snow crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

No.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No.

In: Stock Assessment and Fishery Evaluation Report for the King And Tanner Crab Fisheries of the Bering Sea and Aleutian Islands Regions: 2012 Crab SAFE. North Pacific Fishery Management Council, 605 W. 4th Avenue, #306, Anchorage, AK 99501. pp. 267-416.

Review of Conclusions in 2004 PSEIS

What resource component is this review for? **GOA king and Tanner crab**
What sections of the PSEIS were reviewed**?** ***Section 4.9.2.4***

1 Has management of the resource changed?

Crab remain a Prohibited Species in the GOA groundfish fisheries. Additionally, the Council approved an area closure in Marmot Bay in 2010, to protect Tanner crab from impacts of the groundfish trawl fisheries (implemented in 2014).

Also in 2014, a trawl sweep modification requirement was implemented for vessels participating in the GOA flatfish fishery to reduce impact of the fishery on the seafloor. Elevating devices (e.g., discs or bobbins) are now required to be used on the trawl sweeps to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor.

2 Has the status of the resource changed?

The GOA red king crab species remains at historically low levels, and the Tanner crab stock continues to show high variability in recruitment. Little is known about golden or blue king crab. There have been no changes to the state assessment methodology, and no regulatory changes to the harvest strategy or management structure. The prevailing conditions identified in the 2004 document that likely drive these trends remain unchanged.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There is no substantive new information regarding the impacts of the groundfish fisheries on the resources with respect to state-managed fisheries. More observer coverage is available under the federal restructured observer program. The Council analyzed impacts of the GOA groundfish fisheries on Tanner crab in two NEPA analyses, and instituted a trawl-gear area closure, and the trawl sweep modification requirement in the GOA flatfish fishery. Research has demonstrated that this gear modification reduces unobserved mortality of king and Tanner crab.

4 Are there new methods of analysis or protocols for evaluating impacts?

No. There have been no changes to the state assessment methodology, and no regulatory changes to the harvest strategy or management structure.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The abundance of GOA crab stocks is similar to that reported in the 2004 PSEIS.

What sections of the PSEIS were reviewed? ______**4.9.4**______________

1 Has management of the resource changed?

Forage fish management has not changed in either the BSAI or GOA, except in the way that they are designated in the FMP: they are now listed as "Ecosystem Components" and explicitly removed from the requirement for harvest specifications. As described in the 2004 PSEIS, directed fishing for forage fishes is prohibited and there are strict limits on retention and processing. There are now forage fish reports for both the BSAI and GOA that are published on a biennial basis as appendices to the SAFE documents.

2 Has the status of the resource changed?

As described in the 2004 PSEIS, very little information exists regarding the status of forage fishes (section 3.5.4). While the forage fish reports have been improved with substantial amounts of new information, there remain no reliable estimates of forage fish abundance. The available evidence suggests that forage fish abundance fluctuates independent of fishery activities.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

The forage fish reports now include more detailed information regarding state-waters removals of eulachon; as estimated in the original PSEIS these removals are on a small scale. The eulachon population in the Pacific Northwest has been declared "threatened" under the Endangered Species Act (75 FR 13012). The causes of eulachon declines in the PNW are unknown but are thought to include habitat destruction, overfishing, and climate change effects. Although the threatened population is thought to be discrete from eulachon stocks in Alaska, this development emphasizes the importance of continuing the conservation measures established in the BSAI and GOA FMPs.

4 Are there new methods of analysis or protocols for evaluating impacts?

No new methodologies exist for evaluating impacts. It is hoped that current research regarding forage fish abundance and distribution will provide a better understanding of forage fish populations, but it is unlikely that a reliable index of status will be available in the near future.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

It is unlikely that a new analysis would reach a seriously different conclusion. Forage fishes continue to be caught only incidentally, and there are no new data to suggest that their status has changed.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/7/13

What resource component is this review for? ___**non-specified**________________
What sections of the PSEIS were reviewed? ___**4.9.5**________________

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

There have been no changes to the management of non-specified species. Unofficial Stock Assessment and Fishery Evaluation Reports (SAFEs) have been prepared for grenadiers since 2006. These have undergone annual review by the Plan Team and SSC, but the recommendations are not used for management.

2 Has the status of the resource changed?

The status of unspecified species was unknown due to a lack of data in the PSEIS in 2004. In the unofficial grenadier SAFE reports conducted since 2006, catch, biomass, fishery and survey length frequencies, and indices of abundance are tracked. These data indicate that population trends are stable; catch relative to abundance is < 2%. There is disproportionate catch of females in surveys and in the fishery; however, all data indicate that catch of grenadier has not affected the stock status. Catch of giant grenadier continue to be the vast majority of the grenadier catch.

Age at maturity and natural mortality information is now available for grenadiers. Natural mortality is low, the species are long-lived (at least 58 years maximum age), and the age at which 50% of females are mature is older than most groundfish (23 years).

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Since grenadiers are caught primarily in the sablefish longline fishery and the ABCs and TACs for sablefish have decreased in recent years, the impacts of groundfish fisheries have decreased.

4 Are there new methods of analysis or protocols for evaluating impacts?

In the unofficial grenadier SAFE reports catch, biomass, fishery and survey length frequencies, and indices of abundance are now tracked.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

There is no new information available currently. With the implementation of the observer restructuring in 2013, more information on catch on smaller vessels as well as catch in the Pacific halibut fishery will be available. Since catch has been very low compared to the estimated biomass for grenadier, adding these new catch estimates should not change the conclusion of no observed impact of groundfish fisheries on grenadiers.

draft 6/5/13

What resource component is this review for? _**Marine Mammals**__________________
What sections of the PSEIS were reviewed? **Steller sea lions western and eastern population segments**

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

*Yes, With regard to western dps of Steller sea lions there was a recent change in fisheries management due to the conclusions of the 2010 Ground fish biological opinion which found that the management regimes in place at the time "**were likely to adversely modify the designated critical habitat for the western DPS of Steller sea lion" (http://alaskafisheries.noaa.gov/protectedresources/stellers/esa/biop/final/biop1210_chapters.pdf).** This included new closures and restrictions on atka mackerel and Pacific cod fisheries in areas 541 – 543. There is currently a new EIS and likely a new biological opinion due out in the next six months that will again review these closures and potentially propose new fishery regulations. The most up to date source for all of this will be the draft environmental impact statement for the Bering Sea and Aleutain Islands Management Area. (http://alaskafisheries.noaa.gov/newsreleases/2013/sslpmeis051413.htm). Once a preferred alternative is chosen, a new biological evaluation may also be released (depending on whether the chosen alternative is different from the status quo) which will again incorporate all recent information pertinent to this topic.*

There has not been a change in management of the eastern DPS however it should be noted that the eastern dps has been proposed for de-listing from the endangered species list (http://alaskafisheries.noaa.gov/newsreleases/2012/ssledps041812.htm). The final decision on this proposal is expected sometime in the summer of 2013.

Overall, these two documents should serve to update virtually everything in this PEIS review given that they have been put together in the last 12 months and are by far the most comprehensive and up to date sources of information for the western stock of Steller sea lions. In addition the Steller Sea Lion Recovery Plan was re-written in 2008.

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

Yes, the status has changed with regard to the abundance and regionally with regard to the trends. This is all reported in both the EIS and Biop noted above for the western DPS and in the delisting information *for the eastern DPS. Both stocks have increased in number overall. This change in abundance will have a concurrent change in PBR (See 2012 Stock Assessment Report, Allen and Angliss, 2013, http://www.nmfs.noaa.gov/pr/sars/pdf/ak2012.pdf)*

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

*Yes, based on the conclusions of the 2010 Groundfish Biological Opinion, the fisheries were affecting the resource differently in 2010. This may again be changing depending on the final EIS of 2013 and the subsequent Biological Opinion of 2014. Both of these documents should be used to guide this particular topic when necessary. For example, a paper by Zeppelin et la. In 2004 demonstrated that there was, "*Considerable overlap (>51%) in the size of walleye pollock and Atka mackerel taken by Steller sea lions and found in scat, and the sizes of these species caught by the commercial trawl fishery" (Zeppelin et al. 2004).

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

There are no new methods per se but there have been more recent analyses using conventional methods since this document was written. In addition, there have been a number of publications on food habits, abundance, foraging behavior, contamitnants, and vital rates since 2004. These and others are all summarized in the EIS and BiOp noted above.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not, or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

Possibly, As noted previously, there has been quite a bit of information gathering completed on western DPS Steller sea lions especially since 2004 and is all summarized in the EIS and 2010 BiOp and will be again in the 2014 BiOp. I would suggest a review of those documents rather than a new analysis. A Status Review of the eastern DPS has also been completed as well as a draft Post-delisiting Monitoring Plan. These documents should be sufficient for updating this particular document.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS
draft 6/5/12

What resource component is this review for? _**Marine Mammals**__________________
What sections of the PSEIS were reviewed? **Northern Fur Seals**
Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

No, the management program has not changed, but the population has continued to decline. The Eastern Pacific stock of northern fur seals are still considered depleted under the Marine Mammal Protection act and still declining at just under 5% annually (between 1998 – 2012; Towell et al. 2013 (http://www.afsc.noaa.gov/nmml/pdf/2012-nfs-pup-adult-counts-pribs.pdf). In 2007 NMFS published a new conservation plan (National Marine Fisheries Service. 2007. Conservation plan for the Eastern Pacific stock of northern fur seal (Callorhinus ursinus)) that summarized all relevant information to date at the time. National Marine Fisheries Service, Juneau, Alaska. In addition, the 2012 Stock Assessment Report. Subsistence harvest has declined significantly since the dates listed in the 2004 version of this document. In 2012 less than 500 sub adult males were taken for the subsistence harvest in the Pribilof Islands.

A recent petition to change the harvest regulations for both islands would, if approved, potentially increase the number of harvested fur seals on both islands. This is most notable by the request to harvest fur seal pups on both islands (http://alaskafisheries.noaa.gov/protectedresources/seals/fur/analysis/ea0412.pdf).

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

Yes, the status has changed with regard to the abundance with significant declines on both Pribilof islands in the last 15 years. This decline for the stock has been partially offset by an increase in abundance on Bogoslof Island where an annual rate of increase of 38% has occurred since 1980 and the population estimate of almost 23,000 pups now exceeds that of St. George Island (Towell and Ream, 2012, http://www.afsc.noaa.gov/nmml/PDF/BogPupMem11_final.pdf) I cannot tell given the information provided if this change in status is within the range of variability analyzed in the 2004 PSEIS nor is there definitive information as to what may have affected this change in status or what caused it.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

It is unknown if the fisheries are affecting northern fur seals differently now than in 2004 but there is additional published literature available indicating similar habitat and prey use by both consumers (see list below). To my knowledge there has not been subsequent NEPA analysis. A paper published in 2006 by C. Gudmndson et al described an analysis of northern fur seal prey habits that included scat and spew samples. This study found that prey remains from adult pollock did not appear as often in the scat as in spew samples. "The differences in walleye pollock age classes between scat and spew samples seem to indicate that size estimations of pollock consumed by northern fur seals have likely been underestimated in previous studies using G.I. tracts and scat" (Gudmundson et al. 2006). In fact the study reported that the percent overlap between age classes of walleye Pollock caught by the commercial trawl fishery and those found in northern fur seal scat on the Pribilof Islands was between 4 – 15% while it was between 89 – 95% for spews.

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

There are no new methods per se but there have been more recent analyses using conventional methods since this document was written. In addition, there have been a number of publications on food habits, abundance, foraging behavior, and disease since 2004 (see list below). I don't know of any new NEPA analysis of management actions since the 2004 PSEIS.

Would a new analysis using the latest methods and information reach a seriously different conclusion? If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not, or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

Possibly. If an analysis were to be completed that showed a strong link between commercial fisheries and the decline of northern fur seals it would likely have some effect on management decisions. There is ongoing research looking at this topic or at least looking for correlates and associations that would lead to further examination. Currently the cause of the ongoing decline is unknown.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/24/13

What resource component is this review for? _Marine Mammals
What sections of the PSEIS were reviewed? _Harbor seals, Other Pinnipeds (but only the four ice-associated seals: bearded, ribbon, ringed and spotted. Not walrus, elephant seals or sea otters).

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

Harbor seals: Yes, in 2010 the three previously recognized stocks of harbor seals in Alaskan waters were subdivided into twelve stocks (Allen and Angliss 2012).

Ice-associated seals: In October, 2006, NMFS entered into an agreement with the Ice Seal Committee, an Alaska Native Organization representing five coastal regions of communities that use ice-associated seals for nutritional and cultural purposes. Also, see #2 for the potential for critical habitat designation for bearded and ringed seals.

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

Harbor seals: Prior to subdividing the three stocks into twelve (see #1), harbor seals in Bristol Bay, the Pribilof Islands and Lake Iliamna, AK were part of a single Bering Sea stock. Harbor seals in Lake Iliamna have recently been petitioned for listing as "threatened" or 'endangered' under the Endangered Species Act (ESA), and the NMFS is currently preparing a Status Review of that population to aid in a listing decision. Harbor seals in the Aleutian Islands have declined substantially since the early 1980s, especially in the western Aleutians (Small et al. 2008).

Ice-associated seals: Mostly out of concerns about effects of climate change on sea ice habitat, all four ice-associated seal species were the subjects of petitions for listing under the ESA. The NMFS prepared Status Reviews on each of the four species and determined that:

1) **Ribbon seals** should not be listed under the ESA (Boveng et al. 2008). However, NMFS is currently revisiting this determination (National Marine Fisheries Service 2011) and will publish an updated Status Review and proposed decision in July, 2013.
2) **Spotted seals** should not be listed in Alaskan waters, but a small Asian population was listed as "threatened" (Boveng et al. 2009, National Marine Fisheries Service 2010).
3) The Arctic subspecies of **ringed seals** (*P. h. hispida*) including all ringed seals in Alaskan waters, was listed as "threatened" (Kelly et al. 2010, National Marine Fisheries Service 2012a). The NMFS is currently considering critical habitat designations.

4) The “Beringia” Distinct Population Segment (DPS) of **bearded seals**, including the Bering, Chukchi, Beaufort, and East Siberian Seas, was listed as “threatened” (Cameron et al. 2010, National Marine Fisheries Service 2012b). The NMFS is currently considering critical habitat designations.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

Harbor seals: Splitting the three stocks into twelve led to individual stocks with lower abundance. For example, the Pribilof Island stock of harbor seals (which used to belong to the larger Bering Sea stock) is small, with a population estimate of only 232 (Allen and Angliss 2012). Such a low population suggests the potential for groundfish fisheries to have significant impacts on this stock, but there is no new information on the issue or management plan. Declines of harbor seals in the Aleutian Islands show the same geographic pattern as declines in Steller sea lions, with the strongest declines in the west, and less severe declines to the East. Although the cause of these declines has not been determined, the geographic pattern suggests a possible connection to the mechanism(s) responsible for the sea lion decline.

Ice-associated seals: Although not “new” information, the Status Reviews referenced in #2 were more comprehensive summaries of the available literature on the food habits of ice-associated seals. For example, in contrast to the PSEIS, the status reviews indicate that various species of demersal/groundfish are important to both ribbon and bearded seals, at least in some areas, seasons and/or years.

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

No. New and unique analyses are not required; the need is for good data. New field efforts are required.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not, or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

Harbor seals: Given the paucity of information about the foraging ecology of this species, especially in the Aleutian Islands, it is unlikely that new methods of analysis would lead to a different conclusion about the effects of groundfish fisheries..

Ice-associated seals: The “new” information referenced in #3 is limited (e.g., small sample sizes, little to no indication of size/age of prey taken, contrasting study results), so firm conclusions would be difficult or impossible to develop. But given the more comprehensive, and in some cases differing, reviews of food habits presented in the status reviews, a re-analysis may be warranted.

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 6/4/13

What resource component is this review for? _Marine Mammals__________________
What sections of the PSEIS were reviewed? Killer whale (transients), Other toothed whales, Baleen whales

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

No

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

Killer Whale (Transients):

In January 2004 the North Gulf Oceanic Society (NGOS) and the National Marine Mammal Laboratory (NMML) held a joint workshop to match identification photographs of transient killer whales from this population. That analysis of photographic data resulted in the following minimum counts for 'transient' killer whales belonging to the Gulf of Alaska, Aleutian Islands, and Bering Sea Transient stock. A total count of 552 individual whales have been identified in the Gulf of Alaska, Aleutian Islands, and Bering Sea transient killer whale stock (Allen and Angliss, 2013). Line transect surveys from 2001-2003 estimated transient killer whale abundance at 249 (CV = 0.50), with 95% confidence interval of 99-628 (Zerbini et al. 2007). Unclear how this new information would affect the analysis in the 2004 PSEIS.

AT1 transients: At least 11 animals were alive in 1998, but it appears that as of 2009, only 7 individuals remain alive. The AT1 group has been reduced to 32% (7/22) of its 1984 level (Matkin et al. 2008). This should not change the conclusions reached in the 2004 PSEIS.

Other Toothed Whales:

The Alaska Resident stock of killer whales in general continues to increase in population size. However, a few pods in Prince William Sound have declined by a few animals (i.e., AB25, AE, AN20, AS30, AY: Allen and Angliss, 2013). Unclear how this new information would affect the analysis in the 2004 PSEIS.

Harbor porpoise: Because the most recent abundance estimates are 11-13 years old and information on incidental harbor porpoise mortality in commercial fisheries is not well understood, all Alaska stocks of harbor porpoise (Gulf of Alaska, Bering Sea, and Southeast) are classified as strategic stocks. Unclear how this new information would affect the analysis in the 2004 PSEIS.

In the 2004 PSEIS, Cook Inlet belugas were listed as depleted under the MMPA. The population has continued to decline. Cook Inlet beluga whales were listed as a Distinct Population Segment under the Endangered Species Act in 2008 and Critical Habitat was designated throughout much of Cook Inlet in 2011. This change in status may require reanalysis.

The Bristol Bay beluga stock continues to increase in size. The Alaska Department of Fish and Game and the Alaska Beluga Whale Committee conducted beluga surveys in Bristol Bay in 1999, 2000, 2004 and 2005, with maximum counts of 690, 531, 794, and 1,067 (Lowry et al. 2008). Using the correction factors described above and the maximum counts for 2004 and 2005 gives population estimates of 2,455 and 3,299 (L. Lowry, University of Alaska Fairbanks, pers. comm.).

No new information on Pacific white-sided dolphins, Dall's porpoise, sperm whales, or beaked whales (Allen and Angliss, 2013).

<u>Baleen Whales</u>:

Humpback whales: A large-scale study of humpback whales throughout the North Pacific was conducted in 2004-06 (the Structure of Populations, Levels of Abundance, and Status of Humpbacks (SPLASH) project). Initial results from this project (Calambokidis et al. 2008, Barlow et al. 2011), including abundance estimates and movement information, have been reported in Baker et al. (2008), and are also summarized in Fleming and Jackson (2011); however, these results are still being considered for stock structure analysis (Allen and Angliss, 2013). This may require reanalysis.

North Pacific right whales were relisted under the ESA as a species in 2008 and Critical Habitat was designated in the Bering Sea and Gulf of Alaska in 2006. Abundance estimates as of 2008 indicate fewer than 60 whales in Alaska waters (Wade et al., 2011). This change in status should not affect the conclusions reached in the 2004 PSEIS.

The Western Arctic bowhead whale stock has been increasing in recent years; the estimate of 12,631 (in 2004) is between 22% and 124% of the pre-exploitation abundance (estimates ranging roughly from 10,000 to 55,000), and this stock may now be approaching its carrying capacity (Brandon and Wade 2004, 2006). This should not affect the conclusions reached in the 2004 PSEIS.

For Eastern North Pacific gray whale, the most recent estimate of abundance is from the 2006/2007 southbound survey, or 19,126 (CV=7.1%) whales (Laake et al. 2009). Because of observed interannual differences in correction factors used to correct for bias in estimating pod size (Rugh et al. 2008), the time series of abundance estimates dating back to 1967 was reanalyzed. Laake et al. (2009) developed a more consistent approach to abundance estimation that used a better model for pod size bias and applied their estimation approach to reestimate abundance for all 23 surveys. This reanalysis did not change the current status of Eastern North Pacific gray whales which is continuing to increase at about 3.2% per year (Punt and Wade 2010). This should not affect the conclusions reached in the 2004 PSEIS. However, three gray whales from the western North Pacific that were tagged with satellite transmitters (one in 2010, two in 2011) migrated from Russian waters crossing the Bering Sea and Gulf of Alaska after passing through Unimak and Umnak passes, following eastern North Pacific gray whales during their southbound migration to Mexico (see Mate et al. 2011; Mate and Ilyashenko, unpublished data, http://mmi.oregonstate.edu/sakhalin2010Map). On the northward migration, the one whale still transmitting locations followed the coastline from Mexico to Alaska before entering the Bering Sea through Unimak Pass then returning along the ice edge to Russian waters. Since this discovery additional photographic matches have been found between whales observed off Sakhalin Island, Russia, and in the Mexico lagoons. The western population of North Pacific gray whales (WGW), once thought extinct, is now estimated at 130 individuals and feeds primarily off northeastern Sakhalin Island, Russia, during summer.

No new information on fin whales, sei whales, minke whales (Allen and Angliss, 2013) or blue whales (Carretta et al. 2012).

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

Killer Whale (Transients):

In previous assessments, there were six different federal commercial fisheries in Alaska that could have had incidental serious injuries or mortalities of killer whales and were observed. In 2004, the definitions of these fisheries were changed to reflect target species; these new definitions have resulted in the identification of 22 observed fisheries that use trawl, longline, or pot gear. Of these fisheries, there were two which incurred serious injury and mortality of killer whales (any stock) between 2007 and 2009: the BSAI flatfish trawl and the BSAI Greenland turbot longline. The mean annual (total) mortality rate for all fisheries for 2007-2009 was 1.5 (CV =0.19) (note: This does not include the AT1 pod with a known range limited to waters of Prince William Sound and Kenai Fjords where there are no federally managed commercial fisheries). Unclear how this new information would affect the analysis in the 2004 PSEIS.

Other Toothed Whales:

Over the past few years, observers have collected tissue samples of many of the killer whales which were killed incidental to commercial fisheries. Genetics analyses of samples from the killer whales have indicated that the mortalities incidental to the BSAI flatfish trawl and the BSAI Pacific cod fisheries are of the “resident” type, and mortalities incidental to the BSAI pollock trawl fishery are of the “transient” type (M. Dahlheim, pers. comm., National Marine Mammal Laboratory, Alaska Fisheries Science Center, 7600 Sand Point Way, NE, Seattle, WA 98105). The mean annual estimated level of serious injury and mortality of Alaska resident killer whales is 1.49/year (Allen and Angliss, 2013). There are many reports of killer whales consuming the processing waste of Bering Sea groundfish trawl fishing vessels (Perez 2006). However, the ‘resident’ stock of killer whales is most likely to be involved in such fishery interactions since these whales are known to be fish eaters, while ‘transient’ whales have only been observed feeding on marine mammals. Recently, several fisheries observers reported that large groups of killer whales in the Bering Sea have followed vessels for days at a time, actively consuming the processing waste (Fishery Observer Program, unpubl. data, Alaska Fisheries Science Center, 7600 Sand Point Way NE, Seattle, WA 98115). On some vessels, the waste is discharged in the vicinity of the vessel’s propeller (NMFS unpublished data); consumption of the processing waste in the vicinity of the propeller may be the cause of the propeller-caused mortalities of resident killer whales in the BSAI flatfish trawl fishery. Unclear how this new information would affect the analysis in the 2004 PSEIS.

One harbor porpoise mortality was observed in 2007 in the Bering Sea/Aleutian Islands flatfish trawl, which is the only harbor porpoise mortality observed during the 2007-2010 period. Therefore, the mean annual (total) mortality rate resulting from observed mortalities was 0.53 (Allen and Angliss, 2013). Because the abundance estimates are 13 years old and information on incidental mortality in commercial fisheries is sparse, the Bering Sea stock of harbor porpoise is classified as a strategic stock. Unclear how this new information would affect the analysis in the 2004 PSEIS.

Between 2007 and 2010, there was one observed serious injury of a sperm whale in the Gulf of Alaska sablefish longline fishery (Allen and Angliss, 2013). This animal was designated as seriously injured because it became caught in the gear, and was released alive with trailing gear. Unclear how this new information would affect the analysis in the 2004 PSEIS.

There were no serious injuries or mortalities incidental to observed commercial fisheries reported for Pacific white-sided dolphins, beluga whales, or any of the beaked whales (Perez 2006; Allen and Angliss, 2013). However, for Bristol Bay belugas it is unknown whether the U. S. commercial fishery-related mortality level is insignificant and approaching zero mortality and serious injury rate (i.e., 10% of PBR; less than 4.9 per year) because a reliable estimate of the mortality rate incidental to commercial fisheries is currently unavailable. Similarly, current observer data on fisheries within Cook Inlet are lacking; however, no mortalities in U. S. commercial fisheries have been reported for this beluga stock. Thus annual mortality levels are considered insignificant and approaching zero mortality and serious injury rate, although the lack of recent fisheries data is a concern for this small population.

Baleen Whales:

Humpback whales: For the Western North Pacific stock, the estimated human-related mortality rate based solely on mortalities that occurred incidental to U. S. commercial fisheries is 0.37; therefore, the estimated fishery mortality and serious injury rate exceeds 10% of the PBR (0.2) and cannot be considered insignificant and approaching zero (Allen and Angliss, 2013). This may require reanalysis.

No mortalities or serious injuries by groundfish commercial fisheries were reported for fin whales, minke whales, North Pacific right whales, bowhead whales (Allen and Angliss, 2013), gray whales, or blue whales (Carretta et al. 2012). However, there is little information on western gray whales that may migrate through Alaska waters during the winter months.

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

No

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not, or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

Potentially for Cook Inlet beluga whales now listed as a DPS under ESA.

Also, Bering Sea harbor porpoise, Western North Pacific stock of humpback whales, western gray whales, and killer whales (see notes above).

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

What resource component is this review for? _Marine Mammals – Sea otters___________________
What sections of the PSEIS were reviewed? 4.9.8.9

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Yes. On August 9, 2005, U.S. Fish and Wildlife Service (USFWS) published a final rule (70 FR 46366) to list the southwest Alaska Distinct Population Segment (DPS) of the northern sea otter (*Enhydra lutris kenyoni*) as threatened under the Endangered Species Act.

On October 8, 2009, the USFWS published a final rule designating 15,164 square kilometers (5,855 square miles) as critical habitat for the southwest Alaska DPS of the northern sea otter (74 FR 51988). The critical habitat rule became effective on November 9, 2009. The critical habitat is designated in five units: the Western Aleutian Unit; the Eastern Aleutian Unit; the South Alaska Peninsula Unit; the Bristol Bay Unit; and the Kodiak, Kamishak, Alaska Peninsula Unit. Within these units, critical habitat occurs in nearshore marine waters ranging from the mean high tide line seaward for a distance of 100 meters, or to a water depth of 20 meters. While sea otter critical habitat predominately occurs within state waters, DOI has designated some critical habitat within federal waters where water depth is 20 meters or less.

On September 6, 2013, the USFWS announced the availability of the recovery plan for the southwest Alaska DPS of the northern sea otter (78 FR 54905). The recovery plan describes the status, current management, recovery objectives and criteria, and specific actions needed to enable us to delist the southwest Alaska DPS of the northern sea otter (USFWS 2013a).

2 Has the status of the resource changed?

Yes. The southwest Alaska DPS of the northern sea is now listed as threatened under the Endangered Species Act. However, based on the most recent comprehensive assessment of the northern sea otter status in the 2013 Recovery Plan, the population abundance and trends have generally not notably changed since the early 2000s (USFWS 2013a).

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Yes. In 2006, NMFS and the USFWS consulted on the southwest Alaska DPS of the northern sea otter and the consultation concluded that the groundfish, crab, and scallop fisheries are not likely to adversely affect sea otters.

In response to the designation of critical habitat, NMFS reinitiated Section 7 consultation. The biological assessment evaluated the potential effect of the BSAI Groundfish and GOA Groundfish FMPs on the southwest Alaska DPS of the northern sea otter and its critical habitat. The analysis concluded that the Alaska federally managed fisheries authorized by the FMPs and State of Alaska parallel groundfish fisheries are not likely to adversely affect the southwest Alaska DPS of the northern sea otter or its designated critical habitat. On July 10, 2013, the USFWS concurred with NMFS's determination that authorization of the specified fisheries is not likely to adversely affect the southwest Alaska DPS of the northern sea otter and will not result in adverse modification of sea otter critical habitat (NMFS 2013, USFWS 2013b).

4 Are there new methods of analysis or protocols for evaluating impacts?

No.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. NMFS conducted a new analysis for the Biological Assessment and arrived at a practically similar conclusion (NMFS 2013).

Template for PSEIS SIR – review of conclusions in 2004 PSEIS

draft 7/17/13

What resource component is this review for? Seabirds
What sections of the PSEIS were reviewed? Short-tailed Albatross; Laysan and Black-footed Albatross; shearwaters; Northern fulmars; Species of management concern (Red-legged Kittiwakes, Marbled and Kittlitz's murrelets); Other piscivorous species (most alcids, gulls, and cormorants); other planktivorous species (Storm-petrels and most Auklets); Spectacled Eiders and Steller's Eiders

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

The primary management action affecting seabird resources was the requirement for longline vessels to use seabird mitigation measures (i.e., streamer lines). This was implemented in February 2004, just before release of the PSEIS. The Freezer Longline fleet had largely adopted the practice of deploying streamer lines in 2002, taking advantage of free streamer lines supplied first by the US Fish and Wildlife Service and later by NOAA Fisheries. Use of seabird avoidance gear has likely reduced overall bycatch by 100,000 birds since implementation (Fitzgerald, pers comm). An analysis of the reduced overall bycatch and reduction in bycatch rates is currently underway at the AFSC in partnership with Washington Sea Grant Program. Another management change – implementation of the restructured observer program in 2013 – will allow a better evaluation of total fishery impacts on the resource in the future.

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

Status of the various seabird species groups remains unchanged. The short-tailed albatross population continues to grow at an ca 7.5% rate and is currently estimated to be 4,023 individuals (STAL Recovery Team information). The USFWS and Japanese counterparts have spent 5 years rearing and fledging translocated Short-tailed albatross chicks on Mukojima Island. The project translocated 70 chicks and 69 fledged. In 2012/13 one nesting attempt occurred but failed. This was a 2008 bird. Re-establishing a colony on the island is a goal of the Short-tailed albatross recovery team. The USFWS was petitioned to list the Black-footed albatross at threatened under the ESA. A review was completed on 7 October, 2011 where the FWS determined that listing was not warranted at the time (Federal Register Vol 76, No. 195: 62504-62565). Populations of other birds, such as Northern Fulmars, are extremely difficult to survey and assess due to the remote locations and difficult terrain of their colonies. Trend information for many of these species is not available.

Review of conclusions in 2004 PSEIS SIR

~6/19/2013

What resource component is this review for? __**Habitat**___________
What sections of the PSEIS were reviewed? **3.6,_4.1__4.4**________________

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

Substantial changes to the management of habitat have included implementation of regulations to protect habitat that provides structural relief and gear modifications to limit adverse impacts of trawling on the seafloor. In 2005 in the Aleutian Islands, closure areas that prohibit all bottom trawling in the Aleutians, except in small discrete "open" areas were implemented, and Habitat Conservation Zones with high density coral and sponge habitat were closed to all bottom-contact fishing gear. In 2008 in the Bering Sea, measures were enacted to conserve benthic fish habitat by "freezing the footprint" of bottom trawling by limiting trawl effort only to those areas more recently trawled. A deep slope and basin area and three habitat conservation areas around St Matthew Island, St Lawrence Island were closed to bottom trawling. In 2005 in the Gulf of Alaska several new HAPCs were implemented; the Slope Habitat Conservation Areas, Seamount Habitat Protection Areas, and the Gulf of Alaska Coral Habitat Protection Areas. In 2011 for the Bering sea flatfish fishery elevating devices (e.g., discs or bobbins) are required to be used on the trawl sweeps, to raise the sweeps off the seabed and limit adverse impacts of trawling on the seafloor.

For more information see

http://alaskafisheries.noaa.gov/npfmc/conservation-issues/habitat-protections.html
and
http://alaskafisheries.noaa.gov/npfmc/conservation-issues/gear-mods.html

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

The status or condition of habitat described in the PSEIS was rated as "conditionally significant adverse". This status was based on the conclusion that, coupled with historical impacts, impacts to long-lived slow growing species (i.e. corals) could cause long-term damage and possibly irreversible loss of living habitat. The word "conditionally" was used to indicate that a significant impact is based on credible scientific information and professional judgement, but more complete information is need for certainty. The current status of habitat is the same as in the 2004 PSEIS because long lived slow growing species have likely not recovered from the impacts of historical fishing and impacts continue in areas that are open to bottom trawling.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

As mentioned in the PSEIS, a separate analysis of Essential Fish Habitat (EFH) overlapped PSEIS development. This analysis, resulting in the 2005 EFH EIS, carried out many of the overarching policies anticipated in the preferred alternative. It updated and detailed the designation of EFH for all species managed under the Management Plans, established a process for considering proposed habitats for designation as Habitats of Particular Concern (HAPC), analyzed the effects of fisheries on EFH, and proposed precautionary actions to minimize those effects. That analysis and its subsequent reconsideration in 2009 clearly represent new information regarding the impacts of groundfish fisheries on habitat.

Some additional research on effects of fishing

Additional research on the habitat requirements of different species
EFH funded habitat research – e.g., flatfish juvenile habitat

Research and development of modifications to trawl gear to reduce effects on habitat
Bottom trawl sweep modifications to reduce effects on structure and epifauna, implemented through regulations for Bering Sea and GOA flatfish fisheries.

Limited additional research on the recovery of habitat from damage due to trawl gear
Some EFH funded research
Revisting sites that were trawled 13 years ago in the eastern Gulf of Alaska to evaluate long term effects of trawling on sponge habitat

Improved resolution of data on the distribution of fishing effort due to broader implementation of VMS in Alaska fisheries.
Vast majority of fishing effort is now tracked with VMS, providing much higher resolution of the footprint of those efforts. Full use of such data would likely indicate more area unaffected by fishing but fished areas having higher fishing intensities over analyses based on averaging effort over larger spatial scales. The net effect would be a lowering of LEI estimates, albeit likely small.

Additional information on the distribution of habitat types and features
Efforts to provide better technology for characterizing habitats
Detailed habitat mapping in the Gulf of Alaska and Aleutian Islands in the vicinity of fishing activities and for studies of corals

Development of an Alaska Essential Fish Habitat Research Plan (Sigler et al 2012)

Consideration of the EFH EIS analysis resulted in a number of precautionary management actions to reduce the effects of fishing on habitat. This included a number of new areas closed to fishing, particularly bottom trawling, and modifications to fishing gear, specifically trawl sweeps. The existence of those actions will also affect any new analysis of the effects of fishing on habitat.

4 Are there new methods of analysis or protocols for evaluating impacts?

The 2005 EFH EIS included a detailed analysis of the effects of fishing on EFH of Alaska marine species managed under FMPs. This analysis, described in Appendix B of the EIS, included 1) an analysis of the distribution and intensity of the effects of fishing on classes of features that function as habitat for fish (infaunal prey, epifaunal prey, biological structure and non-living structure) and 2) expert assessments of the potential for that distribution of effects to affect the life history functions of spawning, breeding, feeding, and growth to maturity for each of the managed species. Those assessments were made against the standard of whether they exceeded effects that were 'more than minimal and not temporary'.

The effects of fishing analysis was based on a model developed by Jeff Fujioka (Fujioka 2006), that considered the combination of fishing intensity, sensitivity of habitat features to fishing, and recovery rates of habitat features to estimate a long-term effects index (LEI), representing the proportional reduction in the habitat feature from the unfished state should that fishing intensity be continued indefinitely. The spatial distribution of LEI values for each habitat features class provided a useful and accessible description of fishing's effects on habitat, which could then be considered by experts on each managed species to assess the potential for significant effects on life-history processes. A significant limitation on this assessment was the lack of comprehensive data to map the distribution of functional habitat features or the distribution of their use by each life-history stage of the species. These limited the assessment to use of a map of the proportional reduction of such features (LEI) and expert knowledge of the biological needs of each species.

Although this methodology for evaluating impacts is different from that used in the PSEIS, it is important to note that the scope of PSEIS is broader than the EFH EIS. The EFH EIS considered impacts of fishing on benthic marine habitat from the perspective of managed species that are dependent on habitat features. The scope of the PSEIS was broader and considered adverse impacts to marine benthic habitat from the perspective of ecosystem structure and function, as well as managed species.

Other models for the effects of fishing have been proposed and applied in different areas. Such models either provide less specific information or require information that is not available for Alaska fisheries e.g., distribution of habitat features or growth rates of such features). At this point, the Fujioka model remains a good fit for analysis of the effects of Alaska's fisheries on EFH. Nevertheless, the next cyclical reassessment of the EFH EIS analysis has just begun and may identify an improved or superior model.

Fujioka, J.T. 2006. A model for evaluating fishing impacts on habitat and comparing fishing closure strategies. Can. J. Fish. Aquat. Sci. 63:2330-2342

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

By and large, analyses and research subsequent to the PSEIS have confirmed its general conclusions. In fact, the PSEIS used much of the same fishing data and an early version of the Fujioka model in its analyses. Both the PSEIS and the EFH EIS identified that fishing reduced habitat features.
The EFH EIS also assessed whether the distribution and intensity of those effects matched with life-history requirements of managed species in a way that indicated that their habitat was affected in a way that was more than minimal and not temporary. That assessment, and a subsequent reassessment in 2009, identified few places indicating that standard had been exceeded. (A specific area of concern for red king crab in the Amak Island area is receiving further review). Appropriately, many assessments indicated substantial uncertainty, primarily due to lack of specific knowledge of the distribution of fish use of habitat features, particularly for juveniles and spawning concentrations. This uncertainty motivated precautionary management actions to reduce fishing effects on habitat. Those actions, and a general reduction in fishing intensity, if anything, may result in some reduction of the estimated effects on reanalysis.

In a similar way, further research studies on the processes that underlie the effects of fishing on benthic habitat, while increasing the specificity and certainty of knowledge, have not demonstrated any substantial errors in the information used in the 2005 EFH EIS or the PSEIS analysis. A subsequent analysis will provide more specific estimates with less uncertainty, but is not likely reach seriously different conclusions.

draft 6/5/13

What resource component is this review for? _**Socioeconomics**______
What sections of the PSEIS were reviewed? _**4.9-235 through 4.9351; Table 4.10-2b; Table 4.9-6; Table 4.2-2_**

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

Have there been substantial changes in the management program that have affected the resource, since the 2004 PSEIS (e.g., species is now managed independently, rather than as part of a complex; implementation of catch share privileges or closure areas affecting fisheries targeting resource)?

The document (Section 4.9, Socioeconomics pages 235-351, in particular) makes references to increasing the number of fisheries that will be rationalized in the coming years. Since 2004, we have seen the rationalization of AM80 groundfish, the rockfish fishery, and the P. cod freezer longliners. BSAI crab has also been rationalized, though it is obviously not part of the groundfish FMP, but references are made to crab stocks at points throughout this resource component and to excess capacity in the crab fisheries (now essentially gone). As such, much of the speculation about potential rationalization programs, or unrealized benefits or costs of such programs, can be better articulated at this time. Accordingly, statements about unrealized benefits and the amount of those benefits should probably be toned down a bit, as fishery rationalization has already occurred in many fisheries and there is not nearly as much unexplored territory as back in 2004.

Bycatch management in this document could be updated to reflect the new Chinook salmon bycatch IPA's and hard cap as well as Steller sea lion closures.

2 Has the status of the resource changed?

Is the status of the resource different than described in the 2004 PSEIS, and if so, how? What has affected the change in status? Is the current status within the range of variability analyzed in the 2004 PSEIS?

The document makes reference to projected trends in particular species repeatedly in different parts of this section (there are too many instances to mention; this document restates much of the same information and conclusions in each section of the Socioeconomics portion). Basically, you'll need to read through the specific references to species trends and see if the projected trends based upon the information in 2004 have played out. Similarly, references are made to the impacts of climate change and I believe we have seen more of the impacts of climate change since this document was published.

Specific statements that appear repeatedly and should be checked include:

- *Downward trends in salmon and crab fisheries
- *Significant decreases in sablefish and rockfish
- *Large increases in catch of P.cod expected

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

Are the fisheries affecting the resource differently than described in the 2004 PSEIS? Is this difference within the range of variability analyzed in the 2004 PSEIS? Has the difference been analyzed in a subsequent NEPA analysis (e.g., the difference in impact is the result of a management change for which an EA or EIS was written)? Is there new scientific information or research indicating or suggesting a change in our understanding of the impact of the fisheries on the resource?

There are some impacts that the document doesn't address which have become issues of concern for the public and considered by the Council. For example, in the analysis of the preferred alternatives in Section 4.9.9.1.1, there is no discussion of the impacts of rationalization on crew and the concerns that have arisen about the way in which high lease rates affect the financial return or average daily wages for crew members aboard vessels. Sections about "Employment and Payments to Labor" assume impacts are insignificant. It is sort of assumed that crew are not adversely impacted but I think we have seen many crew feel as though their compensation has decreased per day. This may be true and it may be due to excess crew labor relative to boats on the water, but it should be addressed in the document or at least acknowledged.

This section repeatedly makes reference to "model results" that predict changes in vessel landings, by species, with accompanying estimates of changes in catch and revenue. It seems as though whatever model generated these predictions could be updated to reflect data covering the last 7 or so years. I doubt any of the specific estimates (e.g., P.cod is expected to increase by about 29%, 44% or 49% -- different numbers are given in two paragraphs on page 4.9-301 and on page 4.9-321) are likely to be accurate today (errors notwithstanding). It's probably worthwhile noting that the P.cod longline CP fleet has been rationalized.

Comments are also made about decreases in ex-vessel value occurring with rockfish and sablefish, but this doesn't appear to be accurate. There is no recognition of rockfish being rationalized.

Comments are made on 49-308 about what will happen if head-and-gut fisheries are rationalized (and they were through AM80) and one should check to see if the species-specific predictions listed there are accurate or can be updated.

4.9-313 comments about significant reductions in excess capacity among CPs seems overstated, as nearly all CPs are rationalized at this point.

Impacts of salmon closures on Average Cost sections of the document should be included/addressed.

The entire section on Regional Socioeconomic Effects beginning on page 4.9-325 makes very specific statements about community impacts coming from a model. I would recommend running this model with newer data to see if the same trends arise. Given the specificity here, it's likely to be stale.

4 Are there new methods of analysis or protocols for evaluating impacts?

Has a new methodology been developed for better understanding or evaluating impacts of the fisheries on the resource? Has that methodology been used in NEPA analyses of management actions affecting the resource, since the 2004 PSEIS?

You may want to check with AKR staff, but I believe Ben Muse has developed economic impact models for the most recent Steller sea lion closures. The Biop has also been released. There are also published papers describing the impacts of crab rationalization:
Abbott, Joshua K.; Garber-Yonts, Brian; Wilen, James E.; Marine Resource Economics, 2010, v. 25, iss. 4, pp. 333-54
Matulich, Scott C.; Marine Resource Economics, 2009, v. 24, iss. 2, pp. 187-93
Matulich, Scott C.; Marine Resource Economics, 2008, v. 23, iss. 3, pp. 253-71

I recognize that crab is not part of this PSEIS, but there are interesting insights into effects of rationalization on various groups.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

If new information is available, consider whether taking that information into account would cause you to reach a different conclusion about the effect of the groundfish fisheries on the resource. Provide a rationale if you conclude that it would not, or some discussion if you think this issue needs further investigation. We are not asking for the new analysis to be undertaken, only for you to provide a discussion of whether it is merited.

I don't believe the fundamental impacts of rationalizing fisheries or closing areas to fishing are incorrect in this document. I believe that the Council has essentially slowly implemented many of the policies laid out in this document and that the basic understanding of the effects of rationalization on overcapacity, efficiency, and the nature of the jobs is correct. However, the document seems to reflect the understanding a decade ago of who would win and lose as a result of rationalization; there are some relatively specific predictions about regional economies and how crew and vessel owners will be affected. There are also very specific model results and statements about species trends that could be updated. I believe that given the number of rationalization programs that have been implemented we don't need to rely on those predictions as heavily today, and could likely appeal to actual results rather than predictions. I think the magnitude of the benefits of the preferred alternatives is likely much smaller today given how much of the fishery has already been rationalized, and we also have a better idea of the economic costs of spatial closures due to work done by regional economists estimating, for example, the costs of Steller sea lion closures.

draft 6/6/13

What resource component is this review for? _**Ecosystems**__________________
What sections of the PSEIS were reviewed? __**4.9.10**_________________

Please answer the following questions with respect to the resource component in question.

- Please provide rationale and discussion of your response, while at the same time keeping it fairly succinct.
- Where appropriate, reference other documents where analysis can be found in detail.
- Responses can be written out, or in bullets.
- In most cases, we are expecting something in the range of 2-5 pages for a particular resource component.

1 Has management of the resource changed?

No.

2 Has the status of the resource changed?

The Ecosystem Indicators of status, including energy flow, diversity, aggregate top predators, and forage fish have been monitored through the annual publication of the Ecosystem Chapter in the SAFE (e.g. Zador et al. 2012). This has monitored short-term changes in properties – for example, forage fish biomass was significantly below average for 2004-2008, and has since returned towards average. There is no evidence that these variations are outside short or medium-term (3-5 year) range of natural variability as measured over the last 30 years.

3 Is there new information regarding the impacts of the groundfish fisheries on the resource?

There has been substantial new world-wide research (e.g. comparisons between ecosystems) on energy flow within ecosystems, for example, the importance of trophic structure or necessary minimum forage fish biomass required to feed top predators within ecosystems. However, this information does not suggest that impacts of the groundfish fishery on the Alaska ecosystems specifically (BSAI and GOA) have significantly changed. Impacts on ecosystems have been analyzed in multiple EAs on specific management changes and no significant differences have been noted in those EAs.

4 Are there new methods of analysis or protocols for evaluating impacts?

Significant improvements have been made to monitoring critical aspects of the ecosystem through the development of annual Ecosystem Assessments and Report Cards (e.g. Zador et al. 2012). Furthermore, these improvements have been carried forward into Management Strategy Analyses (MSEs) of the impacts of management strategies on different ecosystem aspects. The ecosystem research is currently being developed within the Alaska Fisheries Science Center as an extended Integrated Ecosystem Assessment (IEA) program to provide data for 'end to end' models that connect climate variability to groundfish and salmon (Chinook and chum; prohibited species catch) recruitment. The modeling effort and ecosystem data provide a formal method for evaluating climate impacts on Alaska's large marine ecosystems.

5 Would a new analysis using the latest methods and information reach a seriously different conclusion?

No. The new research and information will enable improved monitoring of the ecosystem research, but to date does not suggest that the conclusions of section 4.9.10 would differ substantially.

RECORD OF DECISION

FINAL ALASKA GROUNDFISH FISHERIES PROGRAMMATIC
SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT

National Marine Fisheries Service
Alaska Region

1. INTRODUCTION

This Record of Decision (ROD) documents the decision by the National Marine Fisheries Service (hereinafter referred to as NOAA Fisheries) to select the Preferred Alternative set forth in the Alaska Groundfish Fisheries Final Programmatic Supplemental Environmental Impact Statement (PSEIS) as its policy choice for the management of the Bering Sea and Aleutian Islands (BSAI) and Gulf of Alaska (GOA) groundfish fisheries. As a first step, NOAA Fisheries approves Amendment 74 to the GOA Fishery Management Plan (FMPs) and Amendment 81 to the BSAI FMP, which amend the previous FMPs to include the management approaches, goals and objectives contained in the Preferred Alternative.

2. BACKGROUND

A. Purpose, Need and Federal Action Addressed in the PSEIS

Environmental Impact Statements (EISs) for the GOA and BSAI Groundfish FMPs were prepared in 1978 and 1981, respectively. The National Environmental Policy Act (NEPA) requires preparation of an EIS or Supplemental EIS (SEIS) when significant environmental changes have occurred. Significant changes have occurred in the GOA and BSAI groundfish fisheries and the GOA and the BSAI environment since the original EISs for the GOA and BSAI FMPs were published approximately 25 years ago. These changes include (but are not limited to) the following: the fisheries have shifted from primarily foreign fisheries to completely domestic fisheries; the FMPs governing the fisheries have been amended numerous times; new information is available about the ecosystem; the science of fisheries management has progressed substantially; public opinion about the management of these fisheries has changed; and several bird and marine mammal species have been listed as threatened or endangered under the Endangered Species Act (ESA).

While Environmental Assessments (EAs) and several EISs have been prepared for BSAI and GOA FMP amendments over the ensuing years, none have comprehensively examined the groundfish FMPs at a programmatic level. In 1999, U.S. District Court Judge Thomas S. Zilly issued a ruling in *Greenpeace v. National Marine Fisheries Service,* 55 F.Supp.2d 1248 (W.D.Wash.1999) that a 1998 SEIS prepared for BSAI and GOA FMPs was legally inadequate and remanded the document to NOAA for additional analyses, directing NOAA Fisheries to produce a "programmatic" SEIS.
The Alaska Groundfish Fisheries PSEIS has multiple purposes. First, it serves as the central

environmental document supporting the management of the BSAI and GOA groundfish fisheries. The historical and scientific information and analytical discussions contained therein are intended to provide a broad, comprehensive analysis of the general environmental consequences of fisheries management in the Exclusive Economic Zone (EEZ) off Alaska. The document also provides Agency decision-makers and the public with an analytical reference document necessary for making informed policy decisions in managing the groundfish fisheries and sets the stage for future management actions. In addition, it describes and analyzes current knowledge about the physical, biological, and human environment in order to assess impacts resulting from past and present fishery activities. The PSEIS is intended to bring both the decision-maker and the public up to date on the current state of the environment, while describing the potential environmental consequences of alternative policy approaches and their corresponding management regimes for management of the groundfish fisheries off Alaska. In doing so, it serves as the overarching analytical framework that will be used to define future management policy with a range of potential management actions.

The federal action addressed in the PSEIS is defined as the management of groundfish fisheries and the authorization of groundfish fishery activities off Alaska, pursuant to the Fishery Management Plan for the Groundfish Fishery of the Bering Sea and Aleutian Islands Area and the Fishery Management Plan for the Gulf of Alaska Groundfish Fishery.

B. Roles of the Department of Commerce/NOAA and North Pacific Fishery Management Council in the EIS Process

The roles of the Secretary of Commerce, NOAA Fisheries, the North Pacific Fishery Management Council (NPFMC) and stakeholders in the decision-making and fisheries management process are explained in detail in the Final PSEIS, Section 2.4 and Appendix B, Sections B.3.1.1 and B.3.1.2. The Secretary of Commerce, Department of Commerce (DOC) is responsible for marine fisheries management in the United States as prescribed by the Magnuson-Stevens Fishery Conservation and Management Act (MSA) (16 USC 1801, *et. seq*.). NOAA Fisheries is responsible for executing the day-to-day management of the fisheries as well as the enforcement of fisheries management regulations (in conjunction with the U.S. Coast Guard). The MSA established and defined the role of the NPFMC as recommending FMPs, FMP amendments and regulations to the Secretary of Commerce for approval.

Through this NEPA process and Amendments 74 and 81, the NPFMC is setting a course to follow in the future management of the groundfish fisheries of the North Pacific. Future assessments of the impacts and results obtained from such future fishery management actions recommended by the NPFMC and undertaken by NOAA Fisheries will be based on future NEPA analyses. Also, the authority given to the Secretary by the MSA to approve or—if the proposed FMPs or FMP amendments are inconsistent with applicable law—to disapprove or partially approve the FMPs or FMP amendments submitted by the NPFMC for consideration ensures that NPFMC-recommended management measures comply with applicable law.

C. Procedural History of the PSEIS and Amendments 81/74

A Notice of Intent to prepare a PSEIS on the Alaska groundfish fisheries was published in the *Federal Register* on October 1, 1999 (64 FR 53305). NOAA Fisheries released a Draft PSEIS on the Alaska groundfish fisheries for public review and comment in January 2001(February 2, 2001, 66 FR 8788). In November 2001, NOAA Fisheries announced its intent to revise the 2001 Draft PSEIS (November 27, 2001, 66 FR 59228). Based on its review and preliminary analysis of the comments received on the 2001 Draft PSEIS, NOAA Fisheries determined that the Draft PSEIS should be revised to include additional analyses concerning environmental, economic and cumulative impacts; that the alternatives examined in the Draft PSEIS should be restructured from single-focus alternatives to more comprehensive, multiple-component alternatives; and that it should be edited to evaluate more concisely the proposed action. Given these decisions, NOAA Fisheries determined that it would release a revised Draft PSEIS for public review and comment before issuing the Final PSEIS. After extensive public input in the development of the alternatives to be analyzed in the revised Draft PSEIS, NOAA Fisheries released the revised Draft PSEIS for public review and comment in August 2003 (August 29, 2003; 68 FR 52018).

At its April 2004 meeting, the NPFMC recommended that the preliminary Preferred Alternative identified in the 2003 Draft PSEIS be modified, recommended that the modified alternative be identified as the Preferred Alternative in the Final PSEIS, and adopted Amendments 81/74 to the FMPs. The NPFMC's recommendations were based on its review of the findings contained in the 2003 Draft PSEIS and public comment. The NPFMC submitted Amendments 81/74 for Secretarial and public review, and consistent with the requirements of the MSA, NOAA Fisheries published in the *Federal Register* a Notice of Availability of Amendments 81/74 and solicited public comments on the Amendments (June 2, 2004; 69 FR 31091). The Notice of Availability for the Final PSEIS was published by the Environmental Protection Agency on June 4, 2004 (69 FR 31613). While not specifically requesting public comments on the Final PSEIS, NOAA did provide the public with an address and a July 6, 2004, deadline for submitting comments on the document should they wish to do so. The public comment period on Amendments 81/74 closed on August 2, 2004.

As approved by the Secretary of Commerce, Amendments 81/74 amend the existing Goals and Objectives sections of the FMPs to incorporate the management approach and objectives contained in the Preferred Alternative of the Final PSEIS.

D. PSEIS as a Planning Tool

For purposes of the PSEIS, NOAA Fisheries presumes that the Alaska groundfish fisheries result in some significant effects, both positive and negative, to the natural and socio-economic environments. The PSEIS has been structured in a manner that identifies these effects (direct, indirect, and cumulative) to the extent possible and explores alternative fisheries policies and specific management actions that might serve to mitigate adverse impacts. It is expected that managers and the public will work together in determining the most efficient ways of achieving the goals and objectives stated in the FMPs.

Producing this PSEIS has served its purpose of informing the decision-maker and the public on the issues and potential environmental consequences of the Preferred Alternative and other alternatives. This PSEIS will also serve managers and the public in the future as a reference and guide for the mutual development of FMP amendments. To the degree that the effects of proposed management measures already fall within the Preferred Alternative FMP bookends, or within the range illustrated by the bookends, anticipated efficiencies in preparing second-level tiered EAs or EISs can be achieved to the benefit of managers, the public, and the resource. The Agency recognizes that the PSEIS will require periodic updates as new information becomes available and/or significant changes occur in relation to the fisheries or the environment.

The lead agency for the PSEIS is the Alaska Region of NOAA Fisheries. The Alaska Department of Fish & Game (ADF&G) and the U.S. Fish & Wildlife Service (USFWS) were cooperating agencies under NEPA regulations at 40 CFR section 1501.6.

3. ALTERNATIVES CONSIDERED

The following is a brief summary of the programmatic alternatives considered in detail in the Final PSEIS (including the no action alternative) and other alternatives considered but eliminated from detailed study in the PSEIS. Further detailed information on the programmatic alternatives may be found in Chapter 2 (Section 2.6) and Chapter 4 (Sections 4.2 and 4.3) of the PSEIS and a description of the evolution of the alternatives considered in detail in the Final PSEIS may be found on pages 2-44 of the Final PSEIS. NOAA Fisheries is selecting the Preferred Alternative in the Final PSEIS as the groundfish fisheries management policy for the GOA and BSAI groundfish fisheries off Alaska.

As mentioned above, two Draft PSEISs were prepared and released to the public for review and comment. In the 2001 Draft PSEIS, six alternatives to status quo were considered in detail. Based on public comment, those alternatives were modified from single-focus alternatives to more comprehensive, multiple component alternatives. The 2003 revised Draft PSEIS analyzed five alternatives: a no action alternative (Alternative 1), an aggressive harvest management alternative (Alternative 2), a precautionary management alternative (Alternative 3), a highly precautionary alternative (Alternative 4) and a preliminarily Preferred Alternative that is a modified version of Alternative 3 that also incorporates elements of Alternatives 1 and 4. The Final PSEIS also presents an analysis of five alternatives. With the exception of the Preferred Alternative, the alternatives in the Final PSEIS are identical to those presented in the 2003 Draft PSEIS. The preliminarily Preferred Alternative presented in the 2003 Draft PSEIS was modified in response to public comments and finalized as the Preferred Alternative in the Final PSEIS.

The alternatives analyzed in the Final PSEIS are comprised of three elements: a management approach statement that describes the goals, rationale, and assumptions behind the alternative; a set of management objectives that complement and further refine the goals set forth in the management approach; and, except for the no action/status quo alternative (Alternative 1), a pair of example FMP "bookends" that illustrate and frame the range of implementing management measures for that alternative.

The management approach statement and objectives serve to define the policy direction NOAA Fisheries and the NPFMC will follow in the management of the fisheries under each alternative. The example FMP bookends serve two purposes: first, they provide an additional level of analytical detail that facilitates the comparison of the physical, biological and socioeconomic effects of the alternatives in relation to the environmental baseline (i.e., the condition of the environment and the fisheries up through 2001 and 2002); and second, they provide the public with an illustration of the types and range of management measures NOAA Fisheries and the NPFMC envision using to achieve the goals of the alternative in 2004 and beyond. It is important to note that because the FMP bookends and the associated management measures are illustrative in nature (i.e. they are not binding to NOAA Fisheries or the NPFMC), they are not integral to Amendments 81/74 and will not be included in the revised FMPs. As programmatic policies, the alternatives provide NOAA Fisheries and the NPFMC with a range of potential management measures that allows flexibility under the MSA to adaptively manage the groundfish fishery through more specific FMP amendments.

A. No Action Alternative

Alternative 1. Alternative 1 is the no action alternative for the PSEIS. Under this alternative, the groundfish fisheries would continue to be managed based upon the present risk-averse policy. This policy assumes that fishing does result in some adverse impacts to the environment and that, as these impacts become known, mitigation measures will be developed and appropriate FMP amendments will be implemented.

Alternative 1(a) represents the policy language currently stated in the FMPs, dating from 1979 and 1985 for the BSAI and GOA FMPs, respectively.

Alternative 1(b) is a substitute for the written policy language in the current FMPs and would include objectives that explicitly address the variety of concerns that are balanced by the NPFMC and NOAA Fisheries in current management considerations. Alternative 1(b) encapsulates a risk-averse conservation and management program that is based on a conservative harvest strategy. The Alternative 1(a) and 1(b) policies are both represented by current BSAI and the GOA FMPs (i.e. FMP 1) and incorporate and analyze all of the management measures adopted by the NPFMC through its June 2002 meeting.

In the current FMPs, the total allowable catch (TAC) is determined annually based on a conservative harvest strategy that calculates the overfishing level (OFL) and maximum acceptable biological catch level (*max* ABC) by means of a six-tier system wherein the amount and quality of information available for a given stock or stock complex determines the formula that is used to define the rate of fishing mortality and the size of buffer between OFL and ABC. The status of each stock (in Tiers 1-3) is also examined annually with respect to the minimum stock size threshold (MSST), as defined in the National Standard Guidelines.

Optimum yield (OY) is specified in the current FMPs as a range that is aggregated across all stocks and does not vary with biomass. The current FMPs require the sum of the individual groundfish

TACs to fall within the OY range specified in the plan (2 million metric ton (mt) cap in the BSAI; 800,000 mt cap in the GOA). Taking into account the ecosystem considerations of the food web, the FMPs also prohibit directed fishing for forage fish species. Through amendments over the last 25 years, the current FMPs have built up a network of spatial and temporal closures, intended to protect resources of concern, as well as to minimize gear conflicts. In the BSAI, various areas around the Pribilof Islands and in Bristol Bay are closed year-round to trawling in order to protect red and blue king crab habitat, and areas of historically high bycatch of chinook and chum salmon are closed seasonally. Also in the BSAI, waters within 12 nautical miles (nm) of Walrus Islands are closed to groundfish fishing to minimize fishery disturbance of walrus haulouts sites. In the BSAI and the GOA, Steller sea lion protection measures permanently close the area within 3 nm of rookeries to all fishing. Additionally, these measures impose trawl prohibitions within 3 to 20 nm of most sea lion rookeries and haulouts, and prohibit fishing in Seguam Pass to address concerns over the potential loss of sea lion prey species to commercial fishing. In the GOA, trawling is prohibited in southeast Alaska east of 140° W, and a 2.5 nm^2 area designated as the Sitka Pinnacles Marine Reserve is closed to groundfish fishing to protect habitat for rockfish and lingcod.

The current BSAI FMP prohibits directed fishing for pollock with non-pelagic trawl gear. Directed fishing for sablefish with pot gear is prohibited in the GOA. Non-pelagic trawling is prohibited in the Bristol Bay Red King Crab Savings Area in the BSAI and in Cook Inlet in the GOA. Additionally, various areas around Kodiak Island are closed to non-pelagic trawling either year-round or seasonally to protect crab stocks.

Groundfish fisheries in the BSAI and GOA are required to discard any incidental catch of halibut, Pacific salmon (including steelhead trout), crab, and herring. These species are known collectively as prohibited species. The FMPs currently set prohibited species catch (PSC) limits on many of these species, with penalties ranging from closure of a particular zone or of the whole management area to a directed fishery or fisheries for a specified season or the remainder of the year. Also under FMP 1, the Improved Retention/Improved Utilization (IR/IU) program requires full retention, by vessels fishing for groundfish, of all incidentally caught pollock and Pacific cod fit for human consumption, as well as full utilization of the two species by inshore processors. A minimum utilization standard of 15 percent is set for all at-sea processors. The NPFMC has also adopted a policy to require full retention of demersal shelf rockfish by longline and jig vessels in the southeast Outside District of the GOA. A Vessel Incentive Program encourages bycatch reduction by setting bycatch reduction standards biannually. Inseason bycatch management measures establish fishing seasons for bycatch management and give the Regional Administrator, NOAA Fisheries Alaska, the authority to close areas with high bycatch.

“The Reasonable and Prudent Measures” adopted from the most recent USFWS Biological Opinion for short-tailed albatross stipulate the use of certain seabird avoidance measures and require that take of more than four short-tailed albatross within two years trigger consultation with the USFWS. Pending the results of the consultation, there is potential for the fisheries to close. To further reduce the possibility of the take of albatross impacting the fisheries, in 2001 the NPFMC adopted a policy to require all longline vessels to adopt more stringent seabird avoidance methods.

A License Limitation Program for groundfish vessels over 32 feet (ft) length overall (LOA) (with certain jig gear exceptions) and a moratorium on entry into the groundfish fisheries are in place for the BSAI and the GOA. An Individual Fishing Quota (IFQ) program is in place for sablefish in the BSAI and GOA, which includes provisions for community purchase of quota share. In the BSAI, the directed fishery for pollock is organized into cooperatives as authorized under the American Fisheries Act (AFA). A multi-species Community Development Quota (CDQ) program apportions 7.5 to 10 percent of all BSAI groundfish quota to 65 western Alaska communities currently participating in the CDQ Program.

Alternative 1 monitors the groundfish fishing effort through federal and state reporting requirements and through the use of the North Pacific Groundfish Observer Program. All vessels equal to or more than 60 ft but less than 125 ft LOA are required by regulation to have an observer on board 30 percent of the time; for vessels 125 ft or more LOA, this increases to 100 percent. For AFA and CDQ catcher boats greater than 60 ft LOA, one observer must be on board at all times, and for catcher processors and motherships, two observers must be on board at all times. The program also has observers at inshore processing plants. Additional monitoring tools include reporting requirements for BSAI and GOA vessels that submit daily or weekly logbooks including information on the composition of catch and the locations of the hauls. The ADF&G also collects data from fish tickets at the point that catch is sold. Mandatory vessel monitoring systems for all directed Atka mackerel, pollock, and Pacific cod fishing verify vessel location. FMP 1 is described in full in Table 4.2-1 of the Final PSEIS.

B. Other Policy Alternatives Considered in Detail

Alternative 2. This alternative represents a more aggressive harvest management policy than Alternative 1. This alternative would maximize biological and economic yield from the resource while still preventing overfishing of the groundfish stocks. Such a management approach would, among other things, be based on the best scientific information available, take into account individual stock and ecosystem variability, and continue the cooperation between NOAA Fisheries and other agencies in protecting threatened and endangered species. A more aggressive harvest strategy would be implemented based upon the concept that the present policy is overly conservative and that higher harvests can be taken without overfishing the target groundfish stocks. This policy alternative assumes that fishing at the recommended levels would have no adverse impact on the environment, except in specific cases that are known and mitigated.

Example FMP 2.1 illustrates a more aggressive harvest strategy than Alternative 1 by removing many of the existing constraints from the fisheries. As the policy is based on an assumption that the impacts of fishing on the environment are generally known and mitigated, the precautions currently built into the existing TAC-setting process would be alleviated. The buffer between the ABC level and the OFL is removed, and the maximum OY for the groundfish stocks in the BSAI is released from its two million mt cap and allowed to float as the sum of the OFLs for the BSAI groundfish stocks.

Example FMP 2.1 also removes physical constraints from the fisheries by repealing the various closure areas currently in place. The fishery would be returned to an open-access scenario, where time and area closures, gear restrictions, and PSC restrictions are repealed. The potential impact of the groundfish fisheries on Steller sea lions, however, means that the current mitigating suite of protection measures that constrain fishing around rookeries and haulouts and protect Steller sea lion prey species (pollock, Pacific cod and Atka mackerel) when at low biomass levels would remain in place (Figures 4.2-2 and 4.6-1; specific details on the example FMP 2.1 map are provided in Section 4.2.3 of the Final PSEIS). This is required by the ESA to avoid determinations of jeopardy and adverse modification. The same applies to the impact of groundfish fishing on short-tailed albatross, with the consequent take limits remaining in effect.

The federally-mandated effort limitation program for the directed BSAI pollock fishery, enacted under the AFA, would remain in place, with its accompanying CDQ allocation, but all other effort limitation programs (such as the sablefish IFQ program and the multi-species CDQ program) would be repealed. Reporting requirements would remain in place, in order to keep track of the impact of the fisheries, but the Observer Program, except as federally mandated by the AFA, would be repealed, as would vessel monitoring system requirements. Example FMP 2.1 is described in full in Table 4.2-1 of the Final PSEIS.

Example FMP 2.2 represents a more moderate illustration of Alternative 2, but continues the policy of a more aggressive harvest strategy than Alternative 1. In this case, the mechanisms for setting ABC and TAC remain the same as in the current FMPs (see Alternative 1 for further detail), but the existing regulatory-capped maximum OY of 2 million mt in the BSAI would be removed in favor of a maximum OY equaling the sum of individual groundfish ABCs in the BSAI. Additionally, bycatch reduction incentives and bycatch restrictions would be repealed, other than those related to PSC limits or IR/IU. Under the assumption that fishing does not have an impact on the environment other than what is generally known and mitigated, the NPFMC's more stringent seabird avoidance measures recommended in 2001 would be repealed, leaving only the mitigation measures recommended by USFWS to avoid jeopardy or adverse modification for short-tailed albatross. Closure areas in example FMP 2.2 mirror those in Alternative 1. Example FMP 2.2 is described in full in Table 4.2.-1 of the Final PSEIS.

Alternative 3. This alternative represents a more precautionary management policy than Alternative 1. This alternative would accelerate the existing precautionary management measures through community or rights-based management, ecosystem-based management principles and, where appropriate and practicable, increased habitat protection and additional bycatch constraints. Under this approach, additional conservation and management measures would be adopted as necessary to respond to social, economic or conservation needs, or if scientific evidence indicated that the fishery was negatively impacting the environment. This policy recognizes the need to balance many competing uses of marine resources and different social and economic goals for fishery management.

Example FMP 3.1 illustrates a management approach that accelerates precautionary management measures by increasing conservation-oriented constraints on the fisheries where necessary, formalizing precautionary practices in the FMPs, and initiating scientific review of existing practices as a necessary precursor to the decision of how best to incorporate adequate precautions.

Example FMP 3.1 would implement changes to the TAC-setting process following a comprehensive review of existing TAC-setting processes. Precautionary measures such as setting TAC less than or equal to the ABC and specifying MSSTs for Tiers 1 through 3 in accordance with National Standard Guidelines, would be formalized in the FMP. Sharks and skates would be removed from the Other Species management category and given their own TACs, and criteria to do the same for other target stocks would be developed. Efforts would be accelerated to develop ecosystem indicators for setting TAC limits, as per ecosystem management principles.

In order to balance the needs of social and economic stability with habitat protection and resource conservation, a review would be conducted of the existing closure areas in the BSAI and the GOA (for closure areas under FMP 3.1, see Figure 4.2-4 and Section 4.2.3 of the Final PSEIS). The closure areas would be evaluated against a Marine Protected Area (MPA) methodology, which would be developed as part of this alternative. The NPFMC and NOAA Fisheries would also seek to initiate joint consultation and research with USFWS to develop fishing methods that reduce incidental take of threatened and endangered species. To mitigate any adverse impacts of fisheries management decisions on fishing communities, and to comply with other national directives, formal procedures would be implemented to encourage increased participation of Alaska Natives in fishery management.

Example FMP 3.1 recognizes that the anticipated community or rights-based management programs may ultimately address bycatch reduction objectives (a review of bycatch rates under current programs has already begun) but, a moderate reduction of PSC limits will be pursued as an intermediary step. Additionally, PSC limits for crab, herring, and salmon would be authorized in the GOA, in addition to the halibut PSC limits authorized under the current GOA FMP. Effective monitoring and timely reaction to change in the environment and the fisheries would be enhanced through improvements in the Observer Program and third party verification of economic data. Example FMP 3.1 is described in full in Table 4.2-1 of the Final PSEIS.

Example FMP 3.2 implements the acceleration of existing precautionary measures on a more rapid timeline than Example FMP 3.1. Rather than reviewing existing practices prior to incorporating increased precaution, this bookend implements changes to many aspects of the FMPs concurrently with the initiation of scientific research efforts necessary to bring management measures in line with a precautionary policy.

Example FMP 3.2 significantly accelerates precautionary management by incorporating an uncertainty correction into the estimation of ABC for all species. Additionally, OY would be specified separately for each stock or stock complex rather than for the groundfish complex as a whole (i.e., OY would be set as a formula rather than as a range, eliminating the BSAI 2 million mt cap), and would be set equal to the respective stock or stock complex's TAC. The current precautionary practice of setting TAC less than or equal to ABC would be formalized in the FMP. Example FMP 3.2 would also incorporate stock-specific biological reference points in the tier system where scientifically justifiable. This could result in Tier 3 rockfish stocks, for example, being capped at $F_{60\%}$, a lower and more conservative harvest rate, compared to $F_{40\%}$, the rate currently used. In implementing this bookend, criteria would be developed for specifying MSSTs for Tiers 4 through 6, along with a list of priority candidate stocks; and the development of criteria for moving stocks from the Other Species and Non-specified Species management categories would minimally result in sharks and skates being given their own TACs.

Example FMP 3.2 also reexamines the existing closure system in the BSAI and the GOA. The bookend sets a guideline of 0 to 20 percent of the EEZ (3 to 200 nm) to be closed as an MPA, of which no more than five percent should be completely closed to commercial fishing as a designated No-Take Marine Reserve. The remainder of the closed area would be designated as a no-bottom-contact MPA. The objective of these measures would be to provide greater protection to a full range of marine habitats within the 1,000 m bathymetric line (Figure 4.2-5; specific details on the example FMP 3.2 map are provided in Section 4.2.3 of the Final PSEIS). The guideline aims to provide greater protection for a wide range of species, from Steller sea lions to slope rockfish to prohibited species, while at the same time respecting traditional fishing grounds and maintaining open area access for coastal communities. Additionally, the bookend would extend the existing bottom-trawl ban on pollock to the GOA.

Additional conservation benefits would be realized in example FMP 3.2 through the comprehensive rationalization of all fisheries (except those already part of a cooperative or IFQ program.) In adopting rationalization programs such as cooperative-style programs with built-in community protections, habitat and bycatch concerns would also be addressed by reducing concentrated effort in the fisheries. To increase precautions regarding bycatch, PSC limits would be significantly reduced (and set for all prohibited species in the GOA), but would not be expected to act as a proportionate restraint on the fisheries due to the incentives for bycatch reduction under cooperatives, or other bycatch incentive programs implemented as necessary under this bookend.

In accordance with ecosystem principles, the NPFMC and NOAA Fisheries would seek to initiate joint consultation and research with USFWS to develop fishing methods that reduce incidental take of all seabird species. Formal procedures would also be implemented to increase consultation with and representation of Alaska Natives in fishery management. Example FMP 3.2 is described in full in Table 4.2-1 of the Final PSEIS.

Alternative 4. This policy alternative represents a highly precautionary approach to managing fisheries when faced with scientific uncertainty. This alternative policy shifts the burden of proof to the users of the resource, the NPFMC, and NOAA Fisheries, to demonstrate that the fisheries would not have a detrimental effect on the environment. It would involve a strict interpretation of the precautionary principle. Management decisions would involve and be responsive to the public, but would decrease emphasis on industry and community concerns in favor of ecosystem processes and principles. This policy assumes that fishing does produce adverse impacts on the environment, but due to a lack of information and uncertainty, characterization of these impacts is difficult. The initial restrictive and precautionary conservation and management measures would be modified or relaxed when additional, reliable scientific information becomes available that indicates that such measures are no longer necessary to protect the resource from potentially adverse impacts caused by fishing.

Example FMP 4.1 illustrates an FMP where current levels of fishing are significantly reduced and other precautionary restrictions are implemented until scientific research shows that the fisheries have no adverse effect on the sustainability of the resource and its environment. A modified TAC-setting process would create a more substantial buffer between ABC and the OFL by setting a fishing mortality rate at a very low level ($F_{75\%}$) for all Steller sea lion prey species and for rockfish (a long-lived, slow-growing species). Also, the ABC for each stock or stock complex in Tiers 1 through 5 would be adjusted downward based on the lower bound of a confidence interval surrounding the survey biomass estimate. OY would be specified separately for each stock or stock complex rather than for the groundfish complex as a whole (i.e., OY would be set as a formula rather than as a range, eliminating the BSAI 2 million mt cap), and would be set equal to the respective stock or stock complex TAC. The current precautionary practice of setting TAC less than or equal to ABC would be formalized in the FMP. For species managed as members of a stock complex, rather than setting TAC as the aggregate of the individual members' ABCs, the maximum ABC value for each stock would be determined and the TAC set equal to the lowest value among the group. Where sufficient biological information is available, such as with eastern Bering Sea pollock, TAC would be distributed on a smaller spatial scale. MSSTs would be determined for all tiers.

To further mitigate the possibility of the fisheries having a detrimental biological and ecosystem impact, 20 to 50 percent of the EEZ would be designated as no-take marine reserves (i.e., no commercial fishing), covering the full range of marine habitats within the 1,000-m bathymetric line (Figure 4.2-6 of the Final PSEIS; specific details on the example FMP 4.1 maps are provided in Section 4.2.3 of the Final PSEIS). As part of this area in the Aleutian Islands, a Special Management Area would be established to protect coral and other live bottom habitats. The closed area would include spawning reserve areas for intensively fished species. Under the FMP 4.1 example, comprehensive trawl exclusion zones would be set to protect all Steller sea lion critical habitat, and trawling would be restricted to only those fisheries that cannot be prosecuted with other gear types (i.e, the flatfish fisheries).

In an effort to reduce waste and the risk of adverse impact to the environment, existing PSC limits would be halved under this bookend, as would bycatch (discard) and incidental catch rates. IR/IU would be extended to all target species. Stringent PSC limits would be set for salmon, crab, and herring in the GOA, and as information becomes available, bycatch limits would be set for non-target species also. Protection measures would be set for all seabird species.

Because this policy alternative necessitates greater research and data-gathering efforts, example FMP 4.1 would expand observer coverage to 100 percent for all vessels over 60 ft LOA and require 30 percent observer coverage on vessels presently exempted from observer coverage (i.e., vessels under 60 ft LOA). Vessel monitoring systems would be made mandatory for all groundfish vessels, as would motion-compensated scales for weighing all catches at sea or at shore-based processors. Cooperative research and data-gathering programs would be initiated as well to expand the use of Traditional Knowledge in fisheries management. Example FMP 4.1 is described in full in Table 4.2-1 of the Final PSEIS.

Example FMP 4.2 expands the precautionary principles of Alternative 4 by temporarily suspending all fishing until the fisheries can be shown to have no adverse effect on the resource and its environment. Scientific research and data-gathering efforts would continue under this FMP. The Agency would conduct an environmental review of each groundfish fishery. Such an environmental review would likely require up to two years to complete. Until such a review is completed and a fishery certified, the TAC for all species in that fishery would be set at zero. All areas of the EEZ would be closed to all fishing (i.e. commercial, recreational, and subsistence); bycatch and incidental catch, as well as the take of seabirds and marine mammals, would then necessarily be reduced to zero in the short-term. Once the reviews are completed, those fisheries that are found to have no significant adverse impacts on the environment would be authorized under a specific set of regulations. If a fishery is found by this review to produce significantly adverse environmental effects, and mitigation measures can not be designed to mitigate those effects, that fishery would not be certified and would remain closed until more scientific information is known. Example FMP 4.2 is described in full in Table 4.2-1 of the Final PSEIS.

Preferred Alternative. The Preferred Alternative and its example FMPs represent a management approach that incorporates forward looking conservation measures that address differing levels of uncertainty about the effects of fishing and the marine ecosystem. It is a modified version of Alternative 3 that also incorporates elements of Alternatives 1 and 4.

For purposes of soliciting public comment, the NPFMC and NOAA Fisheries identified a Preferred Alternative (preliminary) in the 2003 Draft PSEIS. Comments received on the preliminary Preferred Alternative were used by the NPFMC to further refine the alternative. The Preferred Alternative in the Final PSEIS maintains the ecosystem approach embodied in the preliminary preferred alternative, while expanding on the protection of non-ESA-listed seabirds and marine mammals, and emphasizing the importance of cooperation and consultation with state and federal agencies and organizations. The NPFMC and NOAA Fisheries believe that the Preferred Alternative identified in the Final PSEIS is a realistic and responsible approach that addresses and complies with the various goals, objectives, and requirements of the MSA and other applicable law. The policy elements contained in the Preferred Alternative are consistent with the National Standards and reasonably balance the competing interests reflected therein.

The management approach and the objectives in the Preferred Alternative reflect a conservative precautionary approach to fisheries management and communicate a policy direction for the future. This management approach has, in recent years, been labeled the precautionary approach. As part of the policy, measures will be considered and adopted, as appropriate, which accelerate the precautionary adaptive management approach through community or rights-based management, ecosystem-based management principles that protect managed species from overfishing, and, where appropriate and practicable, increased habitat protection and bycatch constraints. All management measures will be based on the best scientific information available. Given this intent, the fishery management goal is to provide sound conservation of the living marine resources; provide socially and economically viable fisheries and fishing communities; minimize human-caused threats to protected species; maintain a healthy marine resource habitat; and incorporate ecosystem-based considerations into management decisions. This management approach recognizes the need to balance many competing uses of marine resources and different social and economic goals for fishery management, and will utilize and improve upon the NPFMC and NOAA Fisheries' existing open process to involve the public in decision-making. For the full text of the alternative, including a description of the example FMP bookends for the Preferred Alternative, see Section 2.6.9 of the Final PSEIS.

The example FMP bookends for the Preferred Alternative (FMP PA.1 and PA.2) serve to illustrate management concepts and future actions that logically flow from the Preferred Alternative and provide sufficient detail to allow for focused analysis of their environmental consequences. Example FMP PA.1 and FMP PA.2 are described in full in Table 4.2-2 of the Final PSEIS.

Example FMP PA.1 illustrates a conservative management approach that continues current risk-averse practices, increases conservation-oriented constraints on the fisheries as appropriate, formalizes precautionary practices in the FMPs, and initiates scientific review of existing practices to assess and improve fishery management.

FMP PA.1 implements changes to the TAC-setting process following a comprehensive review. Precautionary practices such as setting TAC less than or equal to the ABC, and specifying MSSTs for Tiers 1-3 in accordance with National Standard Guidelines, would be formalized in the FMP. The NPFMC and NOAA Fisheries would continue to use and improve harvest control rules to maintain a spawning stock biomass with the potential to produce sustained yields on a continuing basis, and to distribute allocations by area, season, and gear as appropriate. Efforts to develop ecosystem indicators to be used in TAC-setting, as per ecosystem management principles, would be continued.

To balance the needs of social and economic stability with habitat protection and resource conservation, the NPFMC and NOAA Fisheries would develop an MPA efficacy methodology, including the development of definitions, program goals, objectives, and criteria for establishing MPAs. Additionally, the existing habitat and bycatch area restrictions would be maintained. Measures are also retained to protect ESA-listed species. To minimize bycatch, a moderate reduction of PSC limits in the BSAI will be initiated, and PSC limits or other appropriate measures for protection of crab, herring and salmon would be authorized in the GOA. Effective monitoring and timely reaction to change in the environment and the fisheries would be enhanced through improvements in the Observer Program and existing reporting requirements.

Existing programs addressing excess capacity and overcapitalization are maintained under this example FMP, with continued development of rights-based management to be undertaken as needed. In order to mitigate adverse impacts of fisheries management decisions on fishing communities and to comply with other national directives, procedures to encourage increased participation of Alaska Natives in fishery management would be pursued.

Example FMP PA.2 accelerates adaptive precautionary management by increasing conservation measures that provide a buffer against uncertainty, instituting research and review of existing measures, and expanding data collection and monitoring programs. Example FMP PA.2 significantly accelerates precautionary management by incorporating an uncertainty correction into the estimation of ABC for all species. The current precautionary practice of setting TAC less than or equal to ABC would be formalized in the FMP. The calculation of the OY caps would be periodically reviewed to determine their relevancy to current environmental conditions and stock levels. Example FMP PA.2 would also develop and implement criteria for using key ecosystem indicators in TAC-setting, and other precautionary practices such as developing appropriate harvest strategies for rockfish stocks. In implementing this bookend, data would be collected and analysis undertaken to allow the specification of MSSTs for priority stocks in Tiers 4-5. The development of criteria to manage target and non-target species consistently, and for removing some stocks from the Other Species and Non-specified Species management categories, would initially consider breaking sharks out of the Other Species category for TAC-setting and management purposes in the BSAI, as well as consider breaking sharks and skates out of the Other Species category in the GOA.

FMP PA.2 also re-examines area restrictions in the BSAI and the GOA by reviewing the existing system of closure areas in the BSAI and the GOA (see Section 4.2.3 of the Final PSEIS), and evaluating them in conjunction with developing MPAs. The example FMP considers adopting MPAs, with a guideline of 0 to 20 percent of the EEZ (3 to 200 nm) to be closed as a MPA. The objective of these measures is to provide greater protection to a full range of marine habitats within the 1,000-m bathymetric line. This area would incorporate an Aleutian Islands Special Management Area to protect coral and living bottom habitat, and also any modification to the 2002 Steller sea lion closures. The closed area may also mitigate adverse effects that occur due to fishing. The guideline aims to provide greater protection for a wide range of species, from Steller sea lions to slope rockfish to prohibited species, while at the same time respecting traditional fishing grounds and maintaining open area access for coastal communities. Additionally, the bookend would extend the existing BSAI bottom-trawl ban on pollock to the GOA.

To increase precaution regarding bycatch, existing PSC limits would be reduced, and limits would be set for all prohibited species in the GOA, with appropriate in-season closure areas. The achievement of these bycatch reductions is expected to be realized through the comprehensive rationalization of all fisheries (except those already part of a cooperative or IFQ program), which reduces concentrated effort in the fisheries, or through bycatch incentive programs implemented in this example FMP.

In accordance with ecosystem principles, the NPFMC and NOAA Fisheries would seek to cooperate with USFWS to develop fishing methods that reduce incidental take of seabird and marine mammal species in the groundfish fisheries, if appropriate and practicable. Procedures would also be pursued to increase consultation with and representation of Alaska Natives in fishery management.

Increases in observer coverage and improvements to the observer data that are collected would enhance effective monitoring and timely reaction to change in the environment and the fisheries. Additionally, the bookend explores programs that would expand the mandatory economic data collected from industry.

C. Alternatives Not Considered in Detail

A No-fishing Policy. A permanent "no-fishing" policy would end all commercial groundfish fishing in the EEZ off Alaska. Adoption of such a policy would be inconsistent with one stated purpose of the MSA: "to promote domestic commercial and recreational fishing under sound conservation and management principles." When the NPFMC first prepared its GOA and BSAI groundfish FMPs, it considered a no-fishing policy. In its analysis of this alternative, the NPFMC found that adopting this policy would result in the economic ruin of the fishing industry and place great hardship on fishing communities economically and socially dependent upon the BSAI and GOA groundfish resources. The NPFMC believed this policy violated the MSA by preventing the U.S. from exploiting the social and economic benefits of groundfish of the BSAI and GOA in the Nation's interest.

NOAA Fisheries subsequently reviewed and prepared a detailed analysis of the effects of a no-fishing policy in its 1998 Final SEIS. Such a policy would reduce EEZ fishing mortality to zero for all target groundfish and non-target species, resulting in no commercial catch except for harvests within the State of Alaska's jurisdiction and beyond 200 miles. The primary impact of this action would be to eliminate the impact of fishing on the physical and biological environment in the EEZ.

However, closing the BSAI and GOA groundfish fisheries would likely result in alterations to existing predator–prey relationships, which over time could influence the population dynamics of particular marine resources. Some fish stocks could decline below current levels. A no-fishing policy also would eliminate thousands of jobs in the groundfish harvesting, processing, and support sectors. It would idle over $1 billion of harvesting and processing capital, decrease the income of groundfish fishermen and processing plant employees by several hundred millions of dollars, and decrease the value of U.S. seafood exports by more than $500 million. Few opportunities appear to offset these losses to the fishing industry, to the communities that depend on the fisheries, and to the Nation. In short, implementation of such a policy would have widespread effects on the natural, physical and socio-economic environment.

NOAA Fisheries concluded that such a policy was not a reasonable choice among the alternatives considered in its 1998 SEIS. NOAA Fisheries again considered "no fishing" as a policy alternative during the development of this PSEIS but rejected full consideration of such a policy alternative because it would be based on the premise that no fishing could occur in the Federal groundfish fisheries off Alaska regardless of the level of scientific data demonstrating the sustainability of such a fishery. Such a policy runs counter to the MSA requirement that conservation and management measures prevent overfishing while achieving, on a continuing basis, OY from each fishery for the U.S. fishing industry (16 USC 1851(a)(1)). In contrast, approval of Alternative 4 would establish an extremely precautionary policy to fisheries management that permits fishing when it can be demonstrated that the fishery would not have a detrimental effect on the environment and that relieves restrictions on fishing when new scientific data support such a change.

Alternatives that Result in Specific Fishery Regulations. A number of public comments received either during the scoping process or on the 2001 and 2003 Draft PSEISs requested the development of alternatives that go beyond policy and actually include regulatory changes to the fisheries. NOAA Fisheries rejected these requests as beyond the scope and purpose of this programmatic EIS. As explained in the PSEIS, NOAA Fisheries prepared this NEPA analysis by applying the applicable guidelines and procedures found in the Council on Environmental Quality's (CEQ) NEPA implementing regulations at 40 CFR 1500 *et seq*. (CEQ regulations). The specific regulatory changes requested by some members of the public qualify as action-specific federal actions that fall outside the scope of a programmatic EIS and will require individual NEPA analyses tiered to this programmatic document, should they be adopted. Accordingly, such analyses will tier to this document under applicable regulations.

A PSEIS on the federal groundfish fisheries off Alaska that included specific regulatory changes would require an intricate level of detailed alternatives and a commensurately detailed analysis. However, neither NEPA nor the courts require NOAA Fisheries to prepare such a document. NOAA's own NEPA guidelines (NAO 216-6 Section 5.09a) state that "a programmatic environmental review should analyze the broad scope of actions within a policy or programmatic context by defining the various programs and analyzing the <u>policy alternatives</u> under consideration and the <u>general</u> environmental consequences of each" (emphasis added). Furthermore, the court stated that ". . . a programmatic analysis would not require consideration of detailed alternatives with respect to each aspect of the plan—otherwise a programmatic analysis would be impossible to prepare and would merely be a vast series of site-specific analyses," *Greenpeace v. National Marine Fisheries Service*, 55 F. Supp. 2d 1248, 1276 (W.D. Wash. 1999).

NOAA Fisheries has determined that a PSEIS for the federal groundfish fisheries off Alaska should essentially be a broad environmental review of the GOA and BSAI groundfish FMPs and alternatives to them. The PSEIS includes a cumulative impact analysis of management actions as a whole, and examines policies and potential future actions from a variety of environmental perspectives. The

PSEIS therefore provides a broad look at the long-range policy alternatives and the associated issues and is therefore more qualitative in nature.

Findings contained within this analysis could result in FMP amendments that, in turn, could lead to formal rule-making and implementation of regulatory changes to the current management regime governing the groundfish fisheries off Alaska. Such specific regulatory changes will be attended by case-specific, detailed analyses in subsequent second-level tiered EAs or EISs. In this PSEIS, however, NOAA Fisheries' goal is to provide the public with insight into the environmental effects that result from the current management regime as a whole as well as from alternative management regimes at a broad, programmatic level.

The Oceans Alternative. In a letter dated November 6, 2003, and in more than three thousand form letters, a collection of environmental interest groups, as part of their comments in the 2003 Draft PSEIS, submitted the "Oceans Alternative." The interest groups included the Alaska Oceans Program, Center for Biological Diversity, Earthjustice, Greenpeace USA, National Environmental Trust, The Ocean Conservancy, and Trustees for Alaska. Attachment E of the Final PSEIS Comment Analysis Report (Appendix G of the Final PSEIS) provides an excerpt of the joint submission, which outlines the specific elements of the Oceans Alternative. For the most part, these are the same environmental groups who had previously submitted comments on the alternatives contained in the 2001 Draft PSEIS. Their 2001 comments served, in part, as the basis for restructuring Alternatives 3 and 4 for analysis in the 2003 Draft PSEIS. The November 2003 letter, as well as letters, were provided in their entirety to members of the NPFMC and NOAA Fisheries officials prior to their making a final decision on the Preferred Alternative. Using the description of the alternative as stated in the form letters, the Oceans Alternative can be summarized as a management policy that "requires resource managers to: 1) proactively avoid harm rather than assuming that fisheries cause no harm; 2) maintain large margins of safety to avoid unforeseen impacts; and 3) protect all types of marine habitat, reduce overall catch levels, conserve biological diversity, ensure the integrity of the food web, protect marine fish, birds, mammals and invertebrates (such as crab and corals), and provide for ecologically sustainable fishing opportunities across generations."

Upon receipt of these comment letters, NOAA Fisheries carefully reviewed them to determine whether the Oceans Alternative was in fact a new alternative distinguishable from the range of alternatives already defined and analyzed in the 2003 Draft PSEIS. The Agency has concluded that it is not. The determination is based on a number of factors. The first component of the Oceans Alternative is to pro-actively avoid harm rather than assume that fisheries cause no harm. This component of the Oceans Alternative is embodied in the Preferred Alternative as well as Alternatives 1, 3, and 4 in the Final PSEIS. Under the existing management policy, neither NOAA Fisheries nor the NPFMC assume that fisheries cause no harm. Fisheries can be found to certainly cause harm at the level of individual fishes. However, the analysis of the federal groundfish fisheries off Alaska has shown there is no evidence that groundfish fishing causes harm at the target groundfish stock or population level. This PSEIS and prior MSA and NEPA documents show that there is considerable uncertainty with regard to the impacts of the groundfish fishery on non-target and non-specified species. Any fisheries-induced adverse impacts on these species are unknown at this time. For this reason, NOAA Fisheries and the NPFMC have taken management actions to reduce these potential impacts by setting bycatch limits, restricting certain gear types, and establishing closed areas. All the PSEIS alternatives, as well as the Oceans Alternative, incorporate an adaptive management strategy whereby managers will revise the FMPs based on new scientific information and public input.

The second component of the Oceans Alternative is to maintain large margins of safety to avoid unforeseen impacts. This component also can be found in Alternatives 1, 3, 4 and the Preferred Alternative. Each of these alternatives differs in matters of degree. The PSEIS describes the steps scientists and managers take to insert a protective buffer between the ecosystem and the commercial groundfish fisheries. For example, the NPFMC and NOAA Fisheries routinely adopt groundfish TAC levels that are below a target species ABC. The determination of a species ABC has built-in safety margins to reduce the risk of adverse impacts, although under Alternative 1, most of these precautionary measures are not formalized. Alternatives 3 and 4 differ from Alternative 1 by instituting formal precautionary measures in the TAC-setting process, with Alternative 4 representing the most highly precautionary management approach. Other examples also are provided in the PSEIS for each alternative and by their FMP bookends. Therefore, the concept of establishing a certain margin of safety is already captured in the range of alternatives and need not be analyzed further at the programmatic level.

The third component of the Oceans Alternative, "protect all types of marine habitat, reduce overall catch levels, conserve biological diversity, ensure the integrity of the food web, protect marine fish, birds, mammals and invertebrates (such as crab and corals), and provide for ecologically sustainable fishing opportunities across generations," can reasonably be shortened to "maintaining healthy ecosystems and sustainable fisheries." It is important to point out that this component encompasses key elements of the MSA, the Sustainable Fisheries Act (SFA), the NOAA Fisheries Strategic Plan, and many of the recommendations of the National Research Council (NRC). NOAA Fisheries relied heavily on all these documents in its restructuring of the programmatic alternatives adopted in June 2002 and analyzed in the 2003 Draft PSEIS, and indeed this component is encompassed to a greater or lesser degree in all the alternatives.

NOAA Fisheries evaluated each of the alternatives and the Preferred Alternative against federal statutory requirements, the NOAA Fisheries Strategic Plan, the recommendations of the Agency's Ecosystem Principles Advisory Panel and the National Research Council in Section 4.11.1 of the Final PSEIS. As stated previously, Alternatives 1, 3, 4 and the Preferred Alternative all contain the basic components of ecosystem-based management, but to varying degrees, with Alternatives 3, 4 and the Preferred Alternative providing the strongest examples of this approach. The Oceans Alternative recommends both policy changes as well as specific management tools and measures that illustrate the alternative. The recommended policy changes are very similar to those presented in the organizations' earlier comments and in Alternative 4. All the ecosystem-based management concepts are captured in Alternative 4. All the Oceans Alternative recommended management measures are either already reflected in the Alternative 4 FMP bookends, or fall within the range of actions that could be considered under the Alternative 4 policy. It also was determined that some, but not all, of the recommended management goals and measures in the Oceans Alternative could also be considered within the range of the Preferred Alternative FMP bookends. For example, the organizations recommend that a way to implement the Oceans Alternative policy goal of reducing the bycatch of prohibited species is to reduce the PSC caps by 10 percent over five years. Currently the Agency's Preferred Alternative contains an identical goal with FMP bookends illustrating a range of actions ranging from maintaining the PSC caps at existing levels to reducing them by as much as 20 percent (no time limit specified); thus the proposed measure provided in the Oceans Alternative clearly fits within the range of actions to be pursued by managers in the years ahead as the Preferred Alternative.

Similarly, to achieve the Oceans Alternative goal to protect habitat, the organizations have proposed filling necessary data gaps and establishing a network of MPAs, understood as no-take reserves, to protect 20 to 50 percent of the fishable EEZ. Under Alternative 4, an identical goal exists and in its

FMP bookends the Agency illustrated and analyzed a management plan where 50 percent of the fishable area was designated as no-take marine reserves. This scenario was developed using proposed site locations obtained from Greenpeace and other public comments. NOAA Fisheries also analyzed as part of Alternative 3, FMP 3.2, a less restrictive MPA scenario. The Agency believes these differences provided sufficient contrast for comparing the programmatic alternatives and the environmental consequences of different MPA proposals including the Oceans Alternative. The Agency's conclusion at both the policy and FMP-level was that the Oceans Alternative would be indistinguishable from Alternative 4.

4. THE ENVIRONMENTALLY PREFERRED ALTERNATIVE

The CEQ regulations require that the ROD specify "the alternative or alternatives which were considered to be environmentally preferable" (40 CFR 1505.2(b)). This alternative has generally been interpreted to be the alternative that will promote the national environmental policy as expressed in section 101 of NEPA. Ordinarily, this means that the alternative causes the least damage to the physical and biological environment and is the alternative that best protects, preserves, and enhances historic, cultural, and natural resources.

Alternative 4 of the Final PSEIS, which is described in the earlier section on alternatives, is the environmentally preferred alternative. Alternative 4 represents a highly precautionary management policy. Alternative 4 explicitly shifts the burden of proof from the resource to the managers and users of the federal groundfish resources off Alaska. This alternative, as defined by its policy goals and objectives and illustrated by its FMP bookends, would substantially reduce the harvest levels in the fisheries, establish a system of marine reserves where a large portion of the continental shelf would be closed to all commercial fishing, phase out bottom trawl gear, and establish lower bycatch limits. As a result, this alternative would produce the lowest amount of fish harvest, the least amount of bycatch, the least adverse impact to marine mammals, seabirds, and species listed under the ESA, and the least adverse impact to benthic habitat.

5. NOAA FISHERIES DECISION AND FACTORS CONSIDERED IN THE DECISION

A. Public Comments

NOAA Fisheries received two letters from the public on the Final PSEIS. Oceana and the Trustees for Alaska continued to express their concern that, in their opinion, the PSEIS is legally deficient and cannot serve as the basis for legitimate decision-making. Both organizations recommend Secretarial approval of the Oceans Alternative and submitted (by reference) their previously submitted letters on the Draft PSEIS.

The commentors continue to believe that significant changes to the management of the Alaska groundfish fisheries are necessary and that the Preferred Alternative will not bring about those changes. NOAA Fisheries disagrees. The Agency believes that the PSEIS is fully compliant with NEPA, MSA, MMPA, ESA, and other applicable law. NOAA Fisheries also believes that the Preferred Alternative would institute a new policy framework that would apply the principles of ecosystem-based management to these fisheries. The NPFMC is developing a list of management priorities as a workplan for achieving the new policy direction.

The Trustees letter provided comments on the Agency's formal response to their earlier comments. NOAA Fisheries believes that the response to comments as published in the 2004 Comment Analysis Report (Appendix G of the Final PSEIS) adequately addresses those comments and issues. The Trustee's letter did introduce two new comments that are addressed in the following paragraphs.

Final PSEIS New Comment 1: NOAA Fisheries failed to provide information in a format decision makers and the public can readily understand, and failed to reduce paperwork.

Response: NOAA Fisheries disagrees. The Agency recognizes that the seven volume document is substantial and somewhat complex, but its length and level of complexity are commensurate with the scope of the action, the analyses and the complex nature of the subject matter as well as the Agency's NEPA requirements that the PSEIS "... shall provide [a] full and fair discussion of significant environmental impacts and shall inform decision-makers and the public of reasonable alternatives..." (40 CFR 1502.1) and shall "...rigorously explore and objectively evaluate..." (40 CFR 1502.14(a)) those alternatives while "...devoting substantial treatment to each alternative considered in detail..." (40 CFR 1502.14(b)). NEPA also requires that the PSEIS "...succinctly describe the environment of the areas to be affected...by the alternatives under consideration." (40 CFR 1502.15). To meet these NEPA requirements, the PSEIS describes one of the most complex and little understood environments with which humans interact and analyzes the environmental effects of five different alternatives at a policy level and nine FMPs at a management measures level. In preparing the document, the Agency attempted to present all the information and analyses required of it by NEPA in as accessible a format as possible without sacrificing the integrity and usefulness of that information and those analyses.

In recognition of the potential complexity of the PSEIS, a professional editor was utilized to translate highly technical information in an effort to ensure the information is accessible to the lay person. The editor also supervised the document layout, ensuring that each section of the document was prefaced by an informative summary, that the document was organized in a logical manner, and that useful and descriptive tables of contents and indexes were provided for easy navigation through the document. In response to public comments, the graphics and tables were moved from the body of the document and published in their own separate volume, with all figures and tables numerically indexed to make it easier for a reader to use these often referred-to illustrations no matter where in the document they were reading. Also in response to public comments, analyses and information not considered fundamental to the impact statement were moved to appendices or referenced. In preparing the Final PSEIS, the Agency made the document readily available in both printed and electronic formats. In the electronic version, links were inserted that would take the reader to each cited figure, table, or reference.

In order to comply with the reduction of excessive paperwork requirements of NEPA (40 CFR 1500.4) and in addition to the editorial elements and changes discussed above, the Agency, among other things, reduced the number of pages from approximately 7,000 in the 2003 Draft to about 6,000 pages in the Final, encouraged the use of CD or Internet copies of the PSEIS, rather than printed copies, conducted an extensive scoping process to identify and narrow the scope of significant issues and, in response to public comments, reduced the number of alternatives and subalternatives in the 2001 draft from six to five in the Final PSEIS. The PSEIS also includes an Executive Summary on which interested parties could rely to inform them of the purpose and scope of the document, the action being addressed, the results of the analyses and the final Agency action. In the Executive Summary the Agency published a list of "fifty frequently asked questions and answers " as a method of improving the transfer of information contained in the document as well as to better inform the public as to the public decision-making process being followed by NOAA Fisheries. In taking these steps, NOAA Fisheries has, to the extent practicable, reduced excessive paperwork and fully complied with the NEPA paperwork reduction requirements.

Final PSEIS New Comment 2: NOAA Fisheries failed to objectively evaluate environmental impacts.

Response: NOAA Fisheries disagrees. The Agency used scientifically sound and accepted methods for analyzing the alternatives and their FMP bookends. The entire PSEIS, including sections describing new methodology, was submitted to the NPFMC Scientific and Statistical Committee for review. NOAA Fisheries also subjected the 2001 Draft PSEIS to an external review by nationally recognized experts on NEPA prior to its release to the public. The results were generally positive, and where improvements and clarifications were recommended, the PSEIS was revised accordingly. The claim that NOAA Fisheries "...violated NEPA by failing to draw conclusions where adverse data or data gaps indicate significant adverse impacts", is inaccurate. The commentors provided no specific examples of where NOAA Fisheries has "...violated NEPA by failing to draw conclusions where adverse data or data gaps indicate significant adverse impacts." Impact tables based on our analysis of each of the alternatives are found in Sections 4.5 – 4.9 and in Appendix A of the PSEIS (Tables 4.1-1 through 4.9-7). In fact, the Agency has received national recognition by the American

Association of Environmental Professionals for introducing a new finding category (conditionally significant adverse effect). Where in the past the traditional NEPA finding of "unknown" would have been used in cases where there was insufficient data to definitively conclude the significance of an effect, NOAA Fisheries chose in this PSEIS to instead elevate those fishery effects where professional opinion suggests that significant adverse effects might be occurring. In doing so, the Agency is applying a precautionary approach in this PSEIS and believes that both the decision-maker and the public are better informed as to the data gaps and uncertainties of fishery impacts on the environment. NOAA Fisheries considers this an appropriate and reasonable approach for evaluating the different policy alternatives in the PSEIS. In cases where the Agency found conditionally significant effects, NOAA Fisheries has recommended that these effects serve as topics for further research so that in the future the data can be available to determine the significance of an effect.

B. The Decision

NOAA Fisheries selects the Preferred Alternative in the Final PSEIS as its policy choice for management of the BSAI and GOA groundfish fisheries. As a first step, NOAA Fisheries approves Amendments 81 and 74 to the BSAI and GOA FMPs, which amend the FMPs to contain the management approach and goals and objectives contained in the Preferred Alternative. The rationale for this decision is discussed below. The rationale is fully supported by the environmental analysis documented in the Final PSEIS, as required by law and regulation.

NOAA Fisheries has made this decision after careful review of the public comments on a series of draft environmental impact statements prepared pursuant to NEPA, including the Draft PSEIS issued January 2001 and the revised Draft PSEIS issued August 2003.

C. Rationale for the Decision

NOAA Fisheries' decision to select the Preferred Alternative in the Final PSEIS and thereby approve Amendments 81/74, was reached after a comprehensive review of the relevant environmental, economic, and social consequences of the Final PSEIS alternatives. Taking into account the MSA National Standards, the MMPA, the ESA, other applicable statutory and policy considerations, and all public comment, NOAA Fisheries identified a number of key fisheries management issues upon which to base its decision to approve the Preferred Alternative (Amendments 81 and 74 to the BSAI and GOA FMPs). Listed below is a description of each of the key fisheries management issues considered by NOAA Fisheries, as well as a brief explanation of how the fisheries management policies embodied in the Preferred Alternative successfully address each of the issues. The Preferred Alternative, taken as a whole, is the alternative that best balances its suite of management measures to enable NOAA Fisheries and the NPFMC to address the key management issues while meeting their statutory, regulatory, and national policy requirements, goals, and objectives.

Precautionary Management In Light of Scientific Uncertainty.

NOAA Fisheries has concluded that the Preferred Alternative in the Final PSEIS is substantially more precautionary than Alternative 2 and more precautionary than Alternative 1 (no action/status quo). Although the Preferred Alternative is less precautionary than Alternative 4, the Preferred Alternative is a sufficiently precautionary approach in light of the scientific uncertainty associated with fisheries management, as the Preferred Alternative incorporates forward looking conservation measures that address differing levels of uncertainty. Under this approach, NOAA Fisheries and the NPFMC will seek to accelerate precautionary management measures through community or rights-based management, ecosystem-based management principles that protect managed species from overfishing, and, where appropriate and practicable, increased habitat protection and bycatch constraints (the Preferred Alternative policy is illustrated by FMP PA.1 and FMP PA.2). Predictions about the impacts under the Preferred Alternative are difficult to describe at this time due to the uncertainties involved in defining ecosystem management and the impacts of protecting areas. The Preferred Alternative's increased emphasis on relatively less abundant species, through protection measures and increased monitoring, represents an approach towards ecosystem management. Because the implications of such management are uncertain, the tendency under the Preferred Alternative will be to tread cautiously while accelerating research and data-gathering. The large potential gain in flexibility in industry fishing practices from rationalization has the potential to create ecosystem benefits, thus enhancing the precautionary aspects of the Preferred Alternative.

Prevention of Overfishing.

While all the alternatives contain various measures to prevent overfishing at differing levels of risk, NOAA Fisheries has determined that, of the alternatives analyzed in the Final PSEIS, the Preferred Alternative represents the best balance between the prevention of overfishing and the achievement of OY on a continuing basis. Each example FMP for the Preferred Alternative contains a number of management measures that promote the sustainability of fisheries and fishery resources while providing economic and social benefits to the Nation. Also, the bookends represent a range of actions that could impose additional constraints to fishery removals beyond those currently in place, further advancing the prevention of overfishing.

Promotion of Sustainable Fisheries.

The goal of promoting sustainable fisheries and communities under the Preferred Alternative is likely to be successful. The precautionary adjustments made to quota management decrease the risk of inadvertently overfishing managed species. Additionally, the transition to rights-based management under this alternative will promote the objectives of increasing efficiency, stability, and safety in the long-term.

Preservation of the Food Web.

As a whole, through its goal to accelerate precautionary management measures through ecosystem-based principles, and its objectives to develop indices of ecosystem health and to take ecosystem factors into account in ABC-setting, NOAA Fisheries determined that the Preferred Alternative will make many improvements beyond the status quo in achieving the goal of preserving the food web. The emphasis in the Preferred Alternative is on using the best scientific information available to determine catch levels, and on providing additional protection against uncertainty by the designation of MPAs and reserves. Although Alternative 4 contains a highly precautionary approach to preserving the food web, the Preferred Alternative is likely to provide protection to a broad range of food web components given the improvements that are likely to be implemented under its management strategy.

Management of Incidental Catch and Reduction of Bycatch and Waste.

Several policy changes adopted in the Preferred Alternative would change the incidental catch of target and non-target species, and bycatch (regulatory and economic discards). Under FMP PA.1, the cap on OY is maintained, so the absolute amount of target and non-target groundfish catch is unlikely to change. The calculation of OY caps would be revisited under FMP PA.2 to determine if the caps are still relevant to environmental conditions and the current knowledge of stock levels. However, the amount of incidental catch of groundfish and subsequent discard of groundfish (bycatch) is likely to decrease due to the policy emphasis on rationalization. Other measures would likely lead to reductions of incidental catch for various species. These additional measures include reductions in PSC limits for prohibited species, the uncertainty correction used to calculate ABC, reduced rockfish harvest rates, and the separation of sharks and skates from the other species complex. The latter would ensure that these species are not harvested above the maximum fishing mortality threshold. Furthermore, criteria would be developed for defining the membership within species complexes and the circumstances when species should be broken out of complexes. NOAA Fisheries determined that, of all the alternatives considered, the Preferred Alternative contains the best approach to managing incidental catch and reducing bycatch and waste to the extent practicable given other management concerns such as the economic and social costs to the commercial fishing industry and fishery-dependent communities.

Avoidance of Impacts to Marine Mammal and Seabirds.

The goal of minimizing human-caused threats to protected species and, if appropriate and practicable, other seabird and marine mammal species, is met in the Preferred Alternative by actively adjusting seabird and marine mammal protection measures, and by conducting periodic reviews of endangered and threatened marine mammal fishery interactions. This approach, which may provide additional conservation measures in response to scientific evidence, is expected to continue protection to ESA-listed marine mammals and seabirds and may increase protection for other seabirds and marine mammals.

Reduction and Avoidance of Impacts to Habitat.

The Preferred Alternative has the potential to reduce and avoid impacts to habitat by careful placement of MPAs. The analysis contained in the Final PSEIS demonstrates that careful placement of MPAs is required to avoid unintended consequences (see section 4.10). Under the Preferred

Alternative, placement of MPAs in lightly fished or not fished areas will provide mitigation and result in avoidance of future habitat impacts if fisheries were to move effort into surrounding areas; MPAs established in heavily fished areas likely would not encompass entire habitat types or areas of fishing intensity but likely would be kept small to minimize the displacement of large amounts of fishing effort into surrounding areas. In the short-term, information from the Observer Program could be used to identify candidate MPA sites. Although not providing the highly precautionary approach to protecting habitat contained in Alternative 4, NOAA Fisheries determined that the Preferred Alternative will result in improvements beyond the status quo in achieving the goal of reduction and avoidance of impacts to habitat that will promote the ecosystem and the sustainability of the groundfish fisheries.

Promoting Equitable and Efficient Use of Fishery Resources.

NOAA Fisheries determined that the Preferred Alternative best promotes increased social and economic benefits through the elimination of the race-for-fish while also emphasizing the long-term economic value of the fishery through the promotion of rights-based allocations to individuals, sectors, and communities. In addition, the Preferred Alternative promotes ecosystem-based management and is likely to increase non-market, recreational, and tourism values assigned to the ecosystem. It is not possible to determine the long-term effect on overall ecosystem value (commercial and non-market values combined) because it is not known whether the fishing sectors, even with rights-based allocations, will be able to adapt to the changes resulting from the increased emphasis on ecosystem tools and, in particular, the potential increase in the number and significance of closed areas.

Increasing Alaska Native Participation.

The goals and policies for Alaska Native consultation and participation in fishery management under the Preferred Alternative would increase from current levels by expanding informal and formal consultation between NOAA Fisheries and the NPFMC, and Alaska Native participants and tribal governments. Local and Traditional Knowledge would be more formally incorporated in fishery management and additional data would be collected. Other goals and objectives in the Preferred Alternative, such as reductions in PSC limits, may benefit subsistence salmon use by reducing bycatch levels in the groundfish fisheries.

Improving Data Quality, Monitoring and Enforcement.

The Preferred Alternative data quality, monitoring, and enforcement objectives conform with the overall policy intent of the alternative, namely to accelerate precautionary management in two ways: where appropriate, to take steps to incorporate uncertainty and ecosystem considerations into fishery management, and at the same time, to increase efforts to improve scientific understanding and diminish uncertainty. The objectives in the Preferred Alternative result in data collection on direct fishery impacts and interactions as well as on broader ecosystem relationships and indirect effects, and emphasize the importance of enforcement concerns in fishery management.

By selecting the Preferred Alternative and approving Amendments 81 and 74 to the BSAI and GOA groundfish FMPs, respectively, both the Agency and the NPFMC will apply the new policy to all actions currently under consideration by the Agency and the NPFMC and that all future actions must be consistent with this policy or a reasonable explanation must be provided as to why a deviation from the policy is warranted. Furthermore, the NPFMC has developed a list of priorities as part of its workplan for addressing those aspects of the new fisheries management policy that are not sufficiently addressed in the FMPs. For information on the NPFMC's workplan, see its website at http://www.fakr.noaa.gov/npfmc.

D. National Policy Considerations

NOAA Fisheries is mandated by a variety of federal statutes to manage, conserve, and protect the Nation's living marine resources. Some of the main tenets of the Agency's legislative mandates require a balancing of objectives. For instance, the MSA directs the Agency to manage living marine resources for optimum sustainable utilization, while the Marine Mammals Protection Act (MMPA) prohibits exploitation of marine mammals and directs the Agency to protect and maintain them at optimum sustainable population levels. The alternatives analyzed in the PSEIS consider all of the statutory requirements and Executive Order (EO) mandates relevant to fisheries management. The alternatives represent different ways in which the objectives embodied in the statutes and EOs can be balanced. The following statutes and EOs are at the heart of federal fisheries management and play an integral part in defining the scope of the policies, goals, and objectives contained in, and management measures that flow from, an FMP. The Preferred Alternative complies with each of these national policies as described below as well as in Table 4.11-1 of the Final PSEIS.

The Magnuson Stevens Fishery Conservation and Management Act of 1976 (MSA).

The Preferred Alternative seeks to provide sound conservation of living marine resources, provide socially and economically viable fisheries and fishing communities, minimize threats to listed species, and maintain a healthy habitat (see Table 4.11-1 of the Final PSEIS for further details).

Endangered Species Act of 1973 (ESA).

Protection to threatened and endangered species is explicitly incorporated into the Preferred Alternative policy with a commitment to modify its FMPs as new scientific evidence becomes available.

Marine Mammal Protection Act (MMPA).

The Preferred Alternative policy statement sets as a goal the periodic review of marine mammal populations and fishing interactions and to develop fishery management measures as necessary.

Regulatory Flexibility Act (RFA).

Initial Regulatory Flexibility Act analyses or certifications will continue to be prepared on all future regulatory packages.

EO 12866 – Regulatory Planning and Review.

Regulatory Impact Reviews will continue to be included in all regulatory packages.

EO 12898 – Environmental Justice Guidance Under NEPA.

The Preferred Alternative policy explicitly recognizes that Alaska Native consultation is an important part of the decision-making process.

EO 13084 – Consultation and Coordination with Indian Tribal Governments.

The Preferred Alternative policy explicitly recognizes that Alaska Native consultation is an important part of the decision-making process.

EO 13158 – Marine Protected Areas.

The Preferred Alternative policy seeks to maintain and protect EFH and will consider implementation of a MPA program to mitigate adverse effects and protect habitat areas of particular concern. An MPA program would review and certify existing areas and consider additional use of MPAs and No-Take Reserves.

While the statutes, EOs, and regulations under which NOAA Fisheries operates define the national fisheries management policies considered in choosing the management direction captured by the Preferred Alternative, NOAA Fisheries also incorporated into its decision-making process national policy considerations outside the statutory context, such as those recommended by the NRC and by NOAA Fisheries' own Ecosystem Principles Advisory Panel.

The NOAA Fisheries Ecosystems Advisory Panel was established under the SFA and tasked with proposing ways of expanding the application of ecosystem principles in fishery conservation and management. The Panel's report, published in 1999, developed six general ecosystem-based management policies, which have been used to guide development of the alternatives analyzed in the PSEIS and, to some degree, the selection of the final Preferred Alternative.

In 1999, the NRC published recommendations for new performance standards for fishery management in "Sustaining Marine Fisheries" (NRC 1999). Overall, the NRC recommended the adoption of an ecosystem-based approach to fishery management with the goal to "rebuild and sustain populations, species, biological communities, and marine ecosystems at high levels of productivity and biological diversity . . . while providing food, revenue, and recreations for humans"

(NRC 1999). The NRC's recommendations have also guided development of the alternatives and, to some degree, the selection of the Preferred Alternative.

The recommendations of the NRC and the Ecosystems Advisory Panel have not been formally incorporated into statute, but the policy considerations they recommend are to some extent already embodied in the MSA, MMPA, and other statutes. These policy considerations have provided significant guidance throughout the preparation of the PSEIS, the evaluation of the alternatives, and the selection of the final Preferred Alternative. See PSEIS section 4.11 for a discussion of the statutory and non-statutory National policy considerations and a detailed comparison of the recommendations of the NRC and the Ecosystems Advisory Panel and the policies encapsulated in the Preferred Alternative.

6. MITIGATION MEASURES AND MONITORING

Section 4.9 in the Final PSEIS describes a number of ways that the Preferred Alternative, as a policy framework, will mitigate the adverse effects of fishing and produce benefits to the environment over time (see generally the direct/indirect and cumulative effects analyses and discussions in Section 4.9). Using the more precautionary management approach, NOAA Fisheries and the NPFMC anticipate fully considering the ecosystem when taking future management and regulatory actions. The MSA and NEPA analyses, which will be prepared on all future actions, will explicitly evaluate each alternative in its ability to achieve the policy goals and objectives approved in the Preferred Alternative.

The PSEIS identifies numerous information gaps and scientific data needs (see Chapter 5 of the Final PSEIS). The Agency acknowledges that expanded research to collect new information and fill existing data gaps is dependent on the Agency's receiving additional research funding. While additional funds are not certain, NOAA Fisheries intends to pursue the funding necessary to meet future research needs and improve the scientific information available for managing the fisheries. With that improved knowledge, future fisheries management will have the ability to address the public's concerns about the sustainability of the Alaska groundfish fisheries and a healthy marine ecosystem. Through data collection measures that will result in reducing uncertainty, the Preferred Alternative is likely to be effective in achieving the goal of accelerating the use of precautionary management measures. The objectives to improve the Observer Program and observer data will increase the quality of fishery data by implementing increased flexibility of, and potentially expanding, observer coverage. Additionally, the expanded collection of economic data and the potential for independent verification will allow for more accurate and credible assessments of economic impacts.

The alternative also emphasizes the importance of enforcement concerns in fishery management. NOAA Fisheries Office for Law Enforcement will continue to enforce all federal fishing regulations in Alaska. Future management actions will consider the impacts of such actions on the Agency's law enforcement capabilities.

7 CONCLUSION

Through the PSEIS and documented in this ROD, NOAA Fisheries has analyzed programmatic alternatives, associated environmental consequences, the extent to which those impacts can be mitigated, and has considered the objectives of the proposed action. NOAA Fisheries also has considered public and agency comments received during the PSEIS review periods. Consequently, NOAA Fisheries concludes that at a policy level, the Preferred Alternative adopts reasonable, practical means to avoid, minimize, or compensate for environmental harm from the action. Future action-specific alternatives consistent with the approved management framework will be carefully considered following the procedures authorized by the MSA and NEPA.

MAY 18 2004

Dear Reviewer:

In accordance with provisions of the National Environmental Policy Act of 1969 (NEPA), we enclose for your review the Final Alaska Groundfish Fisheries Programmatic Supplemental Environmental Impact Statement (PSEIS).

This PSEIS has several purposes. First, it serves as the primary decision document for determining the future overarching management policies and directions of the Fishery Management Plan for the Groundfish Fishery of the Gulf of Alaska and the Fishery Management Plan for the Groundfish Fishery of the Bering Sea and Aleutian Islands Area (FMPs). These FMPs were developed by the North Pacific Fishery Management Council (Council) and approved and implemented by the Secretary of Commerce. In serving this decision making purpose and as a NEPA document, the PSEIS will provide the Council, NOAA Fisheries, and the public with critical information on the status of these fisheries' and environmental impacts necessary to determine preferred policies and approaches for the Alaska groundfish management program. Thus, the PSEIS will guide specific future fishery management actions.

The PSEIS also serves as the current primary environmental review document supporting the FMPs. It summarizes and analyzes the best scientific information about the natural and physical environment in the Gulf of Alaska and Bering Sea and Aleutians Islands areas and the relationship of people with that environment. It assesses the environmental impacts resulting from past and present fishery management regimes and from the expected impacts of alternative future fishery management regimes. Significant environmental and fishery changes have occurred since the original Environmental Impact Statements (EISs) for the FMPs were prepared approximately 25 years ago.

Additional copies of the Final PSEIS may be obtained from Steven K. Davis at NOAA Fisheries, P.O. Box 21668, Juneau, AK 99802, (907) 271-3523 or Anne Maki at (907) 261-9741. The document is also accessible electronically through the Alaska Region's website at http://www.fakr.noaa.gov/.

Comments or questions on this document submitted during the agency's 30-day review period for the Final PSEIS must be received by July 3, 2004. Written comments on the Final PSEIS should be submitted by mail to James W. Balsiger, Alaska Regional Administrator, NOAA Fisheries, P.O. Box 21668, Juneau, AK 99802. Electronic comments may be submitted by e-mail to groundfish.final_pseis@noaa.gov; include in the comment subject line the following Final PSEIS identifier: Final PSEIS Groundfish. A copy of your comments should be submitted to me by mail to the NOAA Strategic Planning Office (PPI/SP), SSMC3, Room 15603, 1315 East-West Highway, Silver Spring, Maryland 20910; by fax to 301-713-0585; or by e-mail to nepa.comments@noaa.gov.

Printed on Recycled Paper

NOAA Fisheries is not required to respond to comments received as a result of the issuance of the Final PSEIS. Comments received will be reviewed and considered for their impact on the issuance of a Record of Decision (ROD) and will made part of our administrative record.

Sincerely,

Susan A. Kennedy
Acting NEPA Coordinator

Abstract: The environmental impact statements for the Gulf of Alaska and Bering Sea Aleutian Islands groundfish Fishery Management Plans (FMPs) were prepared in 1978 and 1981, respectively. During the intervening years, numerous changes have occurred that warrant preparation of a Programmatic Supplemental Environmental Impact Statement (PSEIS). These changes include the shift from primarily foreign fisheries to completely domestic fisheries; that the FMPs governing the fisheries have been amended numerous times; that new information is available about the ecosystem; that the science of fisheries management has progressed substantially; that public opinion about management of these fisheries has changed; and that several bird and marine mammal species have been listed as threatened or endangered under the Endangered Species Act. This PSEIS was prepared to establish a new baseline of environmental and economic information, bringing the federally managed groundfish fisheries into compliance with the National Environmental Policy Act as well as serve as the supporting document for the reauthorization of the Alaska groundfish fisheries. This PSEIS presents the impacts of groundfish fishing on the biological and economic environments that result from a broad array of policy-level programmatic fisheries management alternatives. Included in this final PSEIS is the recommended preferred alternative of the North Pacific Fishery Management Council, and its environmental consequences. Impacts are disclosed, both significantly beneficial and significantly adverse as required by the National Environmental Policy Act. The preferred alternative is a new policy framework that represents a conservative, precautionary approach to ecosystem-based fisheries management, and communicates a policy direction for the future. The preferred alternative is a realistic and responsible approach that addresses and complies with the various goals, objectives and requirements of the

Magnuson-Stevens Act and other applicable law. A biological assessment on the preferred alternative was prepared according to procedures implementing the Endangered Species Act, and it is included in the PSEIS appendix.

ES 1.0 Introduction

This executive summary provides an overview of the findings contained in the final Alaska Groundfish Fisheries Programmatic Supplemental Environment Impact Statement (Programmatic SEIS). For more detailed information, the reader should refer to the final Programmatic SEIS and its appendices.

This Programmatic SEIS has multiple purposes. First, it serves as the central environmental document supporting the Fishery Management Plan (FMP) for the groundfish fishery in the Bering Sea and Aleutian Islands Area (BSAI) and the FMP for the Gulf of Alaska (GOA) groundfish fishery. The historical and scientific information and analytical discussions contained herein are intended to provide a broad, comprehensive analysis of the general environmental consequences of fisheries management in the Exclusive Economic Zone (EEZ) off Alaska. This document also provides agency decision-makers and the public with information necessary for making informed decisions in managing the groundfish fisheries, and sets the stage for future management actions. In addition, it describes and analyzes current knowledge about the physical, biological, and human environment in order to assess impacts resulting from past and present fishery activities. Significant changes have occurred in the environment since the original Environmental Impact Statements (EISs) for the GOA FMP and BSAI FMP were published approximately 25 years ago. While Environmental Assessments (EA) and several EISs have been prepared for FMP amendments over the ensuing years, none have examined the groundfish FMPs at a programmatic level. The National Environmental Policy Act (NEPA) requires preparation of an EIS or Supplemental EIS (SEIS) when significant environmental changes have occurred. Significant changes have certainly occurred in the environment as well as within the fisheries themselves. This Programmatic SEIS is intended to bring both the decision-maker and the public up-to-date on the current state of the environment, while describing the potential environmental consequences of different policy approaches to managing the groundfish fisheries off Alaska. In doing so, it serves as the overarching analytical framework that will be used to define future management policy with a range of potential management actions.

Additionally, this Programmatic SEIS explains the effects of the current groundfish fishery management regime and selected alternative management regimes, on the human environment. These effects are considered in order to assess whether a different type of management regime should be implemented. These alternative management regimes are illustrated by example “bookend” FMPs that represent a reasonable range of management actions that best demonstrate the types of tools and measures that the North Pacific Fishery Management Council (NPFMC) and the National Marine Fisheries Service (NMFS or NOAA [National Oceanic and Atmospheric Administration] Fisheries) would use to implement the policies in the various alternatives. For purposes of this Programmatic SEIS, NOAA Fisheries presumes that the Alaska groundfish fisheries result in some significant effects, both beneficial and adverse, to the human and natural environments. This Programmatic SEIS has been structured in a manner that identifies these effects (direct, indirect, and cumulative) to the extent possible, and explores alternative policies and specific management actions that might serve to mitigate adverse impacts. It is anticipated that future NEPA documents analyzing actions in the Alaska groundfish fisheries will reference this Programmatic SEIS. The Programmatic SEIS will require periodic updates as new information and/or significant changes occur in relation to the fisheries or the environment.

ES 2.0 Defining the Problem

A number of pressing issues face those who participate in and manage the Alaska groundfish fisheries. The range of issues include the effects of the groundfish fisheries on declining Steller sea lion populations and other protected species, the effects of fishing gear on benthic habitat, excess fishing and processing capacity, and the effects of harvesting fish on the North Pacific marine ecosystem. Other notable issues include maintaining sustainable fisheries, reducing bycatch and waste, improving data collection, enforcing regulations, and providing economic stability for fishing communities. These ongoing issues have been targeted by NOAA Fisheries and the NPFMC as a research and management focus.

NEPA requires that a significant federal action (such as a federally authorized fishery) be evaluated for its potential effects on the human environment, which include physical, biological and socioeconomic components. This goal has been achieved by:

- Updating the information contained in the original EISs by providing a historical review of how the groundfish fisheries and the environment have changed since publication of the original EISs.

- Describing how new scientific and fishery information is being utilized.

- Describing the cumulative effects of past, present, and reasonably foreseeable future groundfish fisheries management on the marine ecosystem and the environment (to the extent possible).

- Analyzing the current and alternative management regimes to determine the potential impacts on the human environment.

ES 2.1 The Federal Action: Management and Authorization of the Alaska Groundfish Fisheries

The federal action in this Programmatic SEIS is defined as the management of groundfish fisheries and the authorization of groundfish fishery activities off Alaska, pursuant to the *Fishery Management Plan for the Groundfish Fishery of the Bering Sea and Aleutian Islands Area* and the *Fishery Management Plan for the Gulf of Alaska Groundfish Fishery* (Section 1.2).

These FMPs were prepared by the NPFMC and approved by the Secretary of Commerce in 1978 and 1981, respectively. The GOA FMP has been amended over 55 times and BSAI FMP over 65 times (Section 3.2). As necessary, rules and regulations were prepared to implement each of the FMP amendments. To comply with NEPA, EISs were prepared for the original FMPs prior to their approval by the Secretary of Commerce (NPFMC 1978, NPFMC 1981). An EIS or an EA was also prepared for nearly every plan amendment (Appendix C and Appendix D), and each time a regulation was changed (Appendix E). Since 1991, EAs resulting in a finding of no significant impact have been written for each year's Total Allowable Catch (TAC) specifications. An analysis of these historical FMP amendments has been conducted as part of this Programmatic SEIS. An overview of this analysis is presented in Section 3.2.

ES 3.0 What is the Supplemental Programmatic Environmental Impact Statement?

A Programmatic EIS is typically a broad environmental evaluation that examines a program, such as fisheries management, on a large scale. Federal agencies have been encouraged to develop "multi-tiered" EISs to streamline the NEPA process. This approach avoids repetition by referencing broad, program-oriented issue analyses in the Programmatic SEIS when preparing subsequent EAs or EISs that focus on specific proposed federal actions. A programmatic EIS is usually prepared at the onset of a new federal program. In this case, the GOA and BSAI FMPs have been in place for approximately 25 years, during which time significant changes have occurred in the environment and in the fisheries. Therefore, this Programmatic SEIS has been prepared to provide a comprehensive review of the FMPs.

Review and Synthesis of Public Comments	July through October 2001
NOAA Fisheries Decides to Revise Draft Programmatic SEIS and its Alternatives	November 2001
Preparation of Second Draft Programmatic SEIS	January 2002 through August 2003
Distribution of Second Draft Programmatic SEIS	September 2003
Public Meetings	September & October 2003
Completion of Public Review of Revised Draft Programmatic SEIS	November 2003
Review and Synthesis of Public Comments	November 2003 through March 2004
Final NPFMC Action on Preferred Alternative	April 2004
Final Programmatic SEIS Released	June 2004
Record of Decision issued by NOAA Fisheries	On or before September 1, 2004

ES 3.1 Scope of this Programmatic Supplemental Environmental Impact Statement

NOAA Fisheries determined that the Programmatic SEIS for the Alaska groundfish fisheries should provide a broad analysis of the effects of the GOA and BSAI FMPs on the areas under their management. The Programmatic SEIS includes a cumulative impact analysis of actions that have occurred, and examines policies and potential future actions from a variety of environmental perspectives. By its programmatic nature, this document takes a broad look at the issues and the alternatives, and is somewhat qualitative in nature. More case-specific, detailed analyses can be expected in the future as proposed management actions are evaluated in subsequent second-level tiered EAs or EISs. This Programmatic SEIS provides the Agency and the public with an analytical framework to examine environmental effects resulting from other potential fisheries management regimes. Findings that flow from this analysis are likely to result in a change to the FMP management policy and therefore, FMP and regulatory amendments to implement the policies are anticipated. Future amendments will be developed using the NPFMC process.

ES 3.2 Organization of this Document

The management of the Alaska groundfish fisheries is a large, complex program that continues to evolve as more information is obtained on the fishery resources, the marine ecosystem, and from those that derive benefits from both. The Programmatic SEIS provides a means for informing the public about Alaska groundfish management, the current regime, alternative regimes, known and unknown elements of the ecosystem, and the complex set of laws and regulations that apply to federal fisheries management. To meet its objectives, the document has been organized into a series of chapters and sections, as follows:

Chapter 1 establishes the purpose of and need for the federal action supported by this Programmatic SEIS. It provides an overview of NEPA and its procedural requirements, a history of this document including NOAA Fisheries' methods for conducting the NEPA scoping process and addressing public comments.

Chapter 2 presents the programmatic alternatives that are the focus of this document, beginning with a detailed explanation of the body of fisheries management policies, practices, tools, and methods that will give readers the foundation for a better understanding of the alternatives. This chapter also identifies the NPFMC's and NOAA Fisheries' preferred alternative (PA).

Chapter 3 describes the physical, biological, and socioeconomic resource components of the BSAI and GOA environments, and the eastern Bering Sea (EBS) and eastern North Pacific ecosystems. The objective of this chapter is to present a description of the relevant history and current status of the resources and environment that will serve as the baseline for the analyses of the alternatives. This chapter also includes a discussion of the past cumulative effects on the human environment, as they contribute to the existing baseline condition.

Chapter 4 discusses the effects of groundfish fishing on the environment under the different alternatives and their associated FMP bookends. The analyses examine the direct, indirect, and cumulative effects of each of the hypothetical FMPs that serve as bookends for the range of management actions appropriate to the particular policy alternative. This chapter then builds on these analyses and presents conclusions regarding the overall effects of the policy alternatives.

Section 4.1 provides a description of the methods used to determine the significance of potential consequences, the methods used to analyze the alternatives, and the application of the model output. The analysis of these model regimes and their contrast to the baseline condition established in Chapter 3 is intended to illustrate the general environmental effects of each programmatic policy alternative. In so doing, this Programmatic SEIS will provide the NPFMC and NOAA Fisheries, as well as the public, with information that can be used to guide future policy decisions.

Section 4.2 presents the analytical framework used to evaluate the alternatives. FMP bookends for each alternative were used as proxies for analyzing the policy alternatives. This section describes the FMP bookends and also presents maps that were developed to interpret the policy alternatives and depict some of the differences, such as closure areas, between the alternatives.

Section 4.3 presents abstracts of eleven Qualitative Analysis papers prepared to analyze the FMP components as they relate to the alternatives. These papers describe, in a qualitative manner, the effects of the alternative FMPs on key issues, such as fishing bycatch or overcapacity (the full text of these papers is included as Appendix F).

Section 4.4 provides a review of the comparative baseline statements carried forward for cumulative effects analysis for each key issue category.

Sections 4.5 through 4.9 present, by alternative, a detailed examination of the example FMP bookends and the likely environmental consequences of each alternative.

Section 4.10 analyzes each alternative from a policy-level perspective, drawing on the results from the previous analyses, and Section 4.11 compares the alternatives at the policy-level, presenting the major conclusions of the findings on environmental and social issues.

Chapter 5 focuses on research and management, and provides a brief description of existing research priorities in fisheries management, as well as a list of data gaps and research needs for each policy alternative. This section also presents a discussion of management and enforcement considerations for each policy alternative.

Chapter 6 contains a list of preparers of the document while Chapter 7 presents the distribution list for the document. Chapter 8 contains the literature cited, and Chapter 9 provides an index.

The figures and tables of the document are included in Appendix A. Appendices B through E provide historical information on groundfish management. Appendix F contains the Qualitative Analysis papers, and Appendix G includes the comment analysis report for the 2003 Draft Programmatic SEIS. Appendix H contains model output used to analyze the alternatives. Several appendices (I through L) provide copies of the Federal Register notices relating to the preparation of the Programmatic SEIS. Appendices M and N are informational NPFMC documents, and Appendix O is the Biological Assessment that presents the results from the informal Endangered Species Act consultation.

ES 4.0 What Are the Alaska Groundfish Fisheries?

ES 4.1 What Fish are Harvested?

The BSAI and GOA FMPs authorize and regulate the commercial harvest of various groundfish species. All of the finfish and invertebrate species in the area subject to the management plan are grouped into five management categories: target, prohibited, other, forage fish, and non-specified. Harvest quotas, or TACs, are set annually for target species either individually or by species group. Prohibited species catch (PSC) limits are set for certain species (e.g., salmon, herring, halibut, king crab, and Tanner crab) that are the target of other domestic fisheries, but are taken incidentally in groundfish fishing operations.

Principal groundfish fisheries are directed on pollock, Pacific cod, sablefish, flatfish, Atka mackerel, and rockfish. Gear types used to harvest fish include bottom and pelagic trawls, hook-and-line (longlines), pot, and jig. About 2.2 million metric tons (mt) of groundfish are taken annually in the combined BSAI and GOA fisheries, with groundfish harvested well below their overfishing level (OFL). Some of the stocks are at or near their all time high biomass levels (Bering Sea pollock, Pacific cod, and rock sole), while others are at lower levels of abundance (GOA pollock, various rockfish).

ES 4.2 Where Do the Fisheries Occur?

The groundfish fisheries occur in the North Pacific Ocean and Bering Sea in the United States (U.S.) EEZ from 3 to 200 nautical miles (nm) offshore and between 50°N to 65°N latitude (Figure ES-1). The subject waters, or the action area, are divided into two management areas; the BSAI and the GOA (Section 1.2).

The BSAI groundfish fisheries effectively cover all of the Bering Sea under U.S. jurisdiction, extending southward to include the waters south of the Aleutian Islands west of 170°W longitude to the border of the U.S. EEZ. The GOA FMP applies to the U.S. EEZ of the North Pacific Ocean, exclusive of the Bering Sea, between the eastern Aleutian Islands at 170°W longitude and Dixon Entrance at 132°40'W longitude. The area of the EEZ off Alaska is more than 900,000 square miles (mi^2), larger than the combined EEZs of the east and west coasts of the U.S. The largest continental shelf off the United States coast in located within the EEZ off Alaska. For purposes of this Programmatic SEIS, we have defined this shelf and slope as the submarine shelf from shore to a depth of 1000 meters (m). When defined in this way, 41.5 percent of the BSAI EEZ is comprised of waters overlying the continental shelf and slope. This is where most, if not all, the domestic groundfish fishing occurs, and it is referred to in the Programmatic SEIS as the "fishable area" of the EEZ. Similarly, in the GOA, most fishing also occurs over the shelf and slope, although in contrast to the Eastern Bering Sea, the shelf is much more narrow and only comprises about 30 percent of the EEZ. The FMPs address those areas in the EEZ directly affected by fishing. The FMPs also manage those fishing activities in the EEZ that can indirectly affect the harvest of fish from nearby areas. The area affected by the groundfish fisheries necessarily includes adjacent State of Alaska and international waters, although the FMPs themselves do not govern activities in those areas.

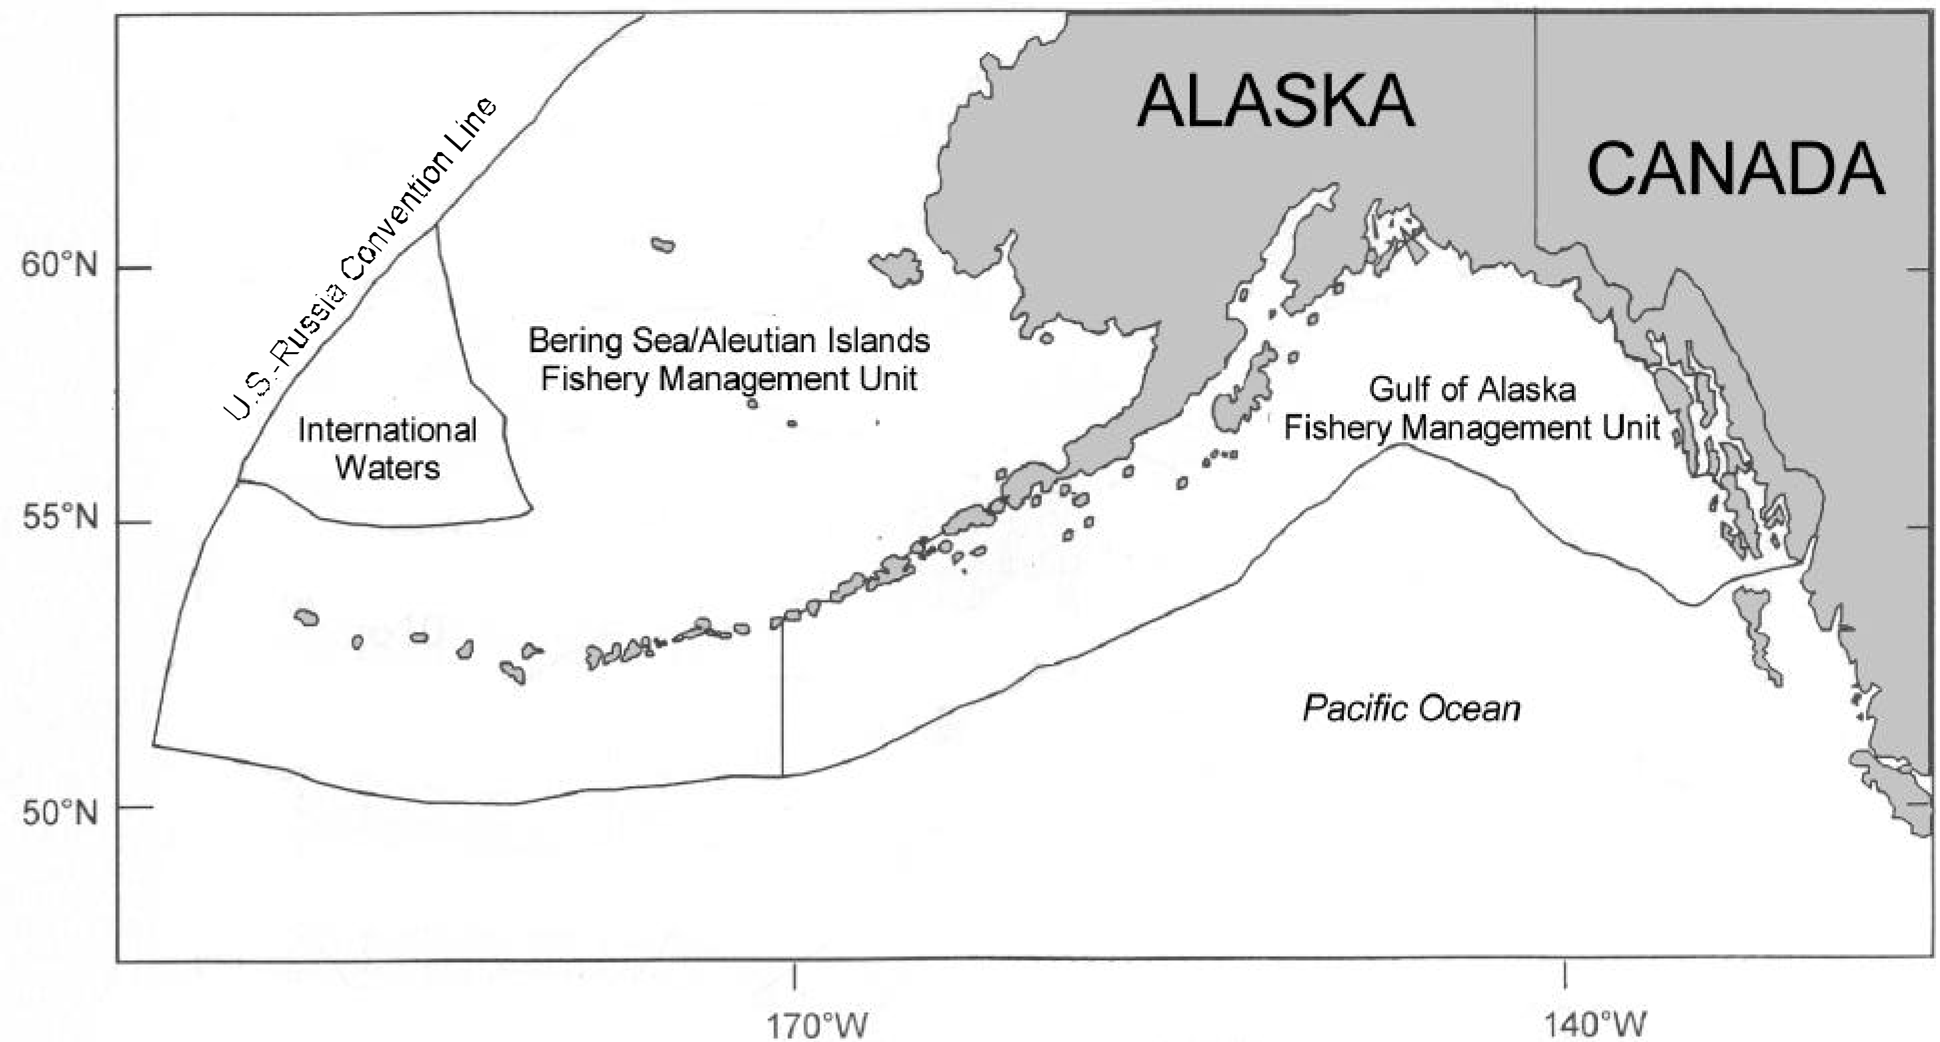

Figure ES-1. SubjectgroundfishfisheriesintheBering Sea andNorth Pacific.

ES 4.3 Who Participates in the Fisheries?

Fishermen and processing workers primarily from the states of Alaska, Washington, and Oregon, participate in BSAI and GOA groundfish harvesting and fish processing (Sections 3.9.2 - 3.9.4). Approximately 2.0 million mt of groundfish were landed in 2001; approximately 91 percent of the harvest came from the Bering Sea, with the remaining nine percent from the GOA. About 73 percent of this catch was pollock. In 2001, the ex-vessel value of the groundfish landed and processed was about $300 million. The approximate wholesale value of the groundfish products produced by the catcher processor and inshore processor/mothership sectors in 2001 was $1.4 billion. Total harvesting and processing employment was estimated at approximately 10,000 full-time equivalent positions, with about 60 percent of the employment going to Alaska residents, and most of the remaining employment going to Washington and Oregon residents. Commercial fishing generates other economic activity in all three states through support services, and generates tax revenue for the State of Alaska and many Alaska communities.

Catcher Vessels: The harvesting sector in 2001 included nine classes of catcher vessels based on primary gear types and fisheries, accounting for 917 vessels. The five trawl classes focus on pollock and, to a lesser extent, Pacific cod. Trawl catcher vessels deliver the vast majority of their fish to at-sea motherships, Bering Sea pollock shore plants, Alaska Peninsula and Aleutian Island shore plants, and Kodiak Island shore plants. Currently, trawlers account for approximately 78 percent of the ex-vessel value of catcher vessel landings. The remaining four vessel classes all use fixed gear. Pot catcher vessels, which are primarily crab vessels that also fish part time in Pacific cod fisheries, account for three percent of the ex-vessel value and payments to labor. Longline catcher vessels focus primarily on high-value sablefish using longline gear in the GOA, and generate approximately six percent of total groundfish ex-vessel value and labor income. The other two fixed-gear catcher vessel classes (vessels less than 32 feet (ft) in length and vessels 33 to 59 ft in length) use longline, pot, and jig gear and have by far the largest number of operations. Both of these fixed-gear classes participate in the groundfish fisheries to augment income from salmon, herring, and halibut fisheries. The larger of these two classes includes more than 514 vessels and generates 12 percent of the total groundfish ex-vessel value, primarily through landings of high-value sablefish and rockfish from the GOA.

Inshore Processors and Motherships: Inshore processing facilities (including shore plants and floating inshore processors) and motherships buy raw fish from catcher vessels and then process and freeze it for future use. In 2001, these operations are estimated to have generated more than $680 million in wholesale product value from groundfish, with nearly $600 million or 87 percent generated by the five classes of shore plants. In addition, these plants generated about $240 million in payments to labor and 4,000 full-time equivalent jobs in 2001. Bering Sea pollock shore plants had by far the largest output value in 2001 (about $415 million in wholesale product value). Shore plants on Kodiak Island were the second largest group of shore plants in projected output value ($81 million wholesale), followed by Alaska Peninsula and Aleutian Islands region shore plants ($49 million wholesale). Shore plants in southcentral and southeast Alaska process relatively small volumes of groundfish (about 6,000 mt each in 2001). Yet, because these plants process a large proportion of high-value species, such as sablefish and rockfish, together they generated about 8 percent of the total wholesale value and payments to labor. Motherships, which process Bering Sea pollock almost exclusively, generated about $77 million in wholesale value in 2001.

Catcher Processors: In 2001, there were 89 catcher processor vessels. Five classes of catcher processors were identified based on primary products and gear types. Catcher processors generated about $740 million in total output (wholesale product value), $266 million in payments to labor, and the equivalent of about 3,900 full-time jobs in 2001. Surimi and fillet trawl catcher processors operate almost exclusively in the BSAI pollock fishery. The twelve surimi vessels generated about 40 percent of total product value for catcher processors, while fillet trawl vessels added ten percent. Head-and-gut trawl catcher processors, which typically focus on flatfish and Atka mackerel, produced about $197 million in wholesale product value. Longline catcher processors, which generally focus on Pacific cod (some also have large sablefish catches), generated approximately $156 million in product in 2001. Pot catcher processors, which fish for Pacific cod when crab fisheries are closed, are comparatively minor participants in the groundfish fisheries, with about $7 million in output value.

Regions and Communities that Benefit from Fishing Activities: In addition to vessels and processors, regions that have significant involvement in BSAI and GOA groundfish fisheries include the Alaska Peninsula and Aleutian Islands, Kodiak archipelago, southcentral Alaska, southeast Alaska, Washington inland waters, and the Oregon coast. In general, regional impacts include not only direct effects from harvesting and processing, but also indirect effects generated through tax payments and as income cycles through the regional economies.

The Alaska Peninsula and Aleutian Islands region is, in several respects, the center of the Alaska groundfish fishery, accounting for more than four times the volume of groundfish processed inshore than in the other Alaska regions combined during 1992-2001. Relative dependence on the groundfish fishery varies: four of Alaska's top five groundfish landing ports are in this region, but some communities have little, if any, direct involvement. Fish tax from groundfish is an important underpinning of the regional economy, and groundfish vessel owners, though few in number, are important contributors to the economies of local communities. Kodiak is the dominant region for groundfish in the GOA, but is also an important region for salmon, halibut, and other non-groundfish species. Groundfish accounts for roughly 40 to 45 percent of local processing and fish tax revenues. Participation in the groundfish fishery in southcentral and southeast Alaska is much more limited than in the Alaska Peninsula and Aleutian Islands and Kodiak Island regions. Both southcentral and southeast Alaska have significantly more diversified economies and relatively greater involvement in non-groundfish fisheries compared to the other two Alaska regions.

Regions in the Pacific Northwest also have important links to Alaska's groundfish fisheries. The Washington inland waters region as a whole, especially the greater Seattle area, is engaged in all aspects of the North Pacific groundfish fishery. While Washington is distant from the harvest areas, it is the organizational center of much of the industrial activity. The human components of the fishery-specific industry sectors based in or linked to Seattle are substantially engaged in or dependent on the groundfish fishery. In terms of vessel and processor ownership, involvement in the Alaska groundfish fishery is arguably greater for Seattle than for any other community. However, if the size and diversity of Seattle's overall economy are considered, the groundfish fishery may be less important or vital for Seattle than for the other communities considered in the Programmatic SEIS. The Oregon coast region has long had significant involvement in the fishery, from the development of joint ventures through the present catcher vessels that participate in a variety of fisheries across the Alaska regions.

In addition, six western Alaska Community Development Quota (CDQ) groups, representing 65 rural Alaskan villages, receive a share of the fisheries allocation to facilitate economic development in rural Alaska. The CDQ groups have provided up to 1,000 jobs annually for western Alaska residents, with annual wages of about $5-8 million; they have also used revenues to fund acquisition of vessels and seafood-related businesses, and to fund infrastructure improvements in western Alaska communities.

ES 5.0 How Are the Fisheries Managed?

The Magnuson-Stevens Act (MSA) established the primary legal framework for the management of the BSAI and GOA groundfish fisheries. FMPs are intended to satisfy the requirements of the MSA as well as other federal mandates including NEPA, the Endangered Species Act (ESA), the Marine Mammal Protection Act, and Executive Order (EO) 12898 on Environmental Justice. The MSA contains ten National Standards that serve as overarching policy goals for federal fisheries management. The NPFMC was established by the MSA to serve as a policy advisor to the Secretary of Commerce. Its many responsibilities include the preparation of FMPs and plan amendments for each fishery that requires fisheries conservation and management. The NPFMC employs a very public-oriented process. Its principal job is to make recommendations while attempting to balance sometimes conflicting policy objectives contained in the MSA with those objectives contained in other federal laws. Fishery issues, information, and public proposals are brought to the NPFMC. A system of scientific and industry experts review and advise the NPFMC on how best to manage the fisheries and address management problems that arise. For a more detailed overview of the MSA, other applicable federal laws, and the NPFMC process, see Appendix B.

Regulations specifically governing the groundfish fisheries in the EEZ off Alaska appear in the Code of Federal Regulations (CFR) in 50 CFR 679. FMPs, amendments to FMPs, and regulatory amendments are developed by the NPFMC, submitted to the Secretary of Commerce for review, and, if approved or partially approved, implemented by federal regulations. Once the regulations are put into effect, NOAA Fisheries has responsibility for the day-to-day management of the fisheries. Enforcement of the regulations is carried out jointly by NOAA Fisheries and the U.S. Coast Guard. In cases where groundfish are harvested and processed in both the EEZ and state waters, these fisheries are cooperatively managed by NOAA Fisheries and the Alaska Department of Fish & Game (ADF&G). For information on how these resources are managed, see Appendix B.

ES 5.1 What Are the Environmental Issues?

The first step in preparing an EIS is scoping. Scoping is designed to provide an opportunity for the public, other federal and state agencies, non-governmental organizations, and other interested groups to provide input on potential issues associated with the federal action. Through both the scoping process and a review of the public comments received on the first draft Programmatic SEIS, ten issues were mentioned frequently, suggesting that these issues are most important to the public (Section 1.5). These issues include:

- Effects on target groundfish species.
- Effects on prohibited species.
- Effects on forage fish species.
- Effects on other species.
- Effects on non-specified species.
- Effects on habitat.
- Effects on seabirds.
- Effects on marine mammals.
- Effects on social economics of the fishery.
- Effects on the marine ecosystem.

All of these important issues are addressed in this Programmatic SEIS and each alternative is evaluated as to its impacts on each of these issues. Therefore, while there will always be other issues that arise and need to be considered and acted upon, the ten most important issues identified through this NEPA process have been addressed by this Programmatic SEIS.

ES 5.2 How Do the Current Management Plans Address These Issues?

Over the last 25 years, fisheries regulations have been modified numerous times to address environmental and economic issues. Such actions include the establishment of:

- Bottom trawl closure areas in the GOA and BSAI based on historic king crab abundance to reduce bycatch and enhance the recovery of depressed crab stocks.
- A constraining cap on optimum yield in the Bering Sea and Aleutian Islands as a buffer against uncertainty.
- A domestic observer program for the purposes of collecting important fishery information.
- Overfishing definitions to protect target groundfish stocks, which reduce the fishing mortality rate when stocks are at low biomass levels.
- A moratorium on new entry into the groundfish fisheries.
- Specific allocations to inshore and offshore processing sectors to prevent preemption and provide economic stability to Alaska coastal communities.
- Closure areas around Steller sea lion rookeries to protect these marine mammals from adverse effects of commercial groundfish fishing.
- PSC limits to reduce bycatch.
- An individual fishing quota (IFQ) Program for the sablefish fishery.
- Allocations of Pacific cod among the various gear types to promote economic stability.
- Closed areas to protect sensitive marine habitat.

A more detailed summary of the actions can be found in Appendix B.

The NPFMC and NOAA Fisheries are not the only resource agencies that have taken action. The U.S. Fish and Wildlife Service (USFWS) conducts research and monitors walrus, short-tailed albatross, and other seabird populations off Alaska. The ADF&G actively monitors and manages all fishing within state waters and has taken numerous actions to protect nearshore habitats from trawling. The U.S. Congress has also prioritized research, expanded programs, and developed measures that have addressed problems including the phasing-out of foreign fishing, the overcapacity of the groundfish harvesting and processing sectors, and the potential adverse effects of groundfish fishing on Steller sea lions.

ES 6.0 What Are the Fisheries Management Alternatives?

This Programmatic SEIS examines four alternative policy statements, each presented in a standard framework that provides management flexibility and allows for adaptation as new information on the ecosystem and the fisheries is obtained. Analyzing environmental impacts of FMPs requires knowing what specific actions could be taken to implement them. Policies are, by definition, high-level, overall statements or plans embracing the general goals and procedures of a government body. Goals and objectives are often used to frame a policy, making it easier to understand, and provide specific directions for implementation through FMP amendments. Still, determining the ways in which a policy might affect the human environment is difficult to analyze without some indication of how it might be implemented.

Each alternative is comprised of three elements: a management approach statement that describes the goals, rationale and assumptions behind the alternative; a set of management objectives that complement and further refine the goals set forth in the management approach; and, except for Alternative 1(status quo), a pair of example FMP "bookends" that illustrate and frame the range of implementing management measures for that alternative. The management approach and objectives serve to define the direction the NPFMC and NOAA Fisheries wish to follow in the management of the fisheries. The example FMP bookends serve two purposes: first, they provide an additional level of analytical detail that will facilitate the comparison of the physical, biological and socioeconomic effects of the alternatives in relation to the environmental baseline (i.e., the condition of the environment and the fisheries in 2001 and 2002 considering past effects); and second, they provide the public with an illustration of the types of management measures the NPFMC and NOAA Fisheries envision they will use to achieve the goals of the alternative in 2004 and beyond. The PA identified in this document includes a policy statement accompanied by a set of management objectives and a set of example FMP bookends that illustrates a range of implementable management actions. This FMP framework structure serves to communicate to the public the intent of the NPFMC and NOAA Fisheries as to how they plan to pursue the policy objectives in the future. By providing, as part of the PA, a range of potential management measures (as illustrated by the example FMP bookends), the NPFMC and NOAA Fisheries retain management flexibility under the MSA to adaptively manage the fishery through FMP amendments.

At its April 2004 meeting, the NPFMC recommended a PA based on its review of the findings contained in the 2003 draft Programmatic SEIS and more than 13,400 public comments. The PA is based on the policy goals and objectives described under Alternative 3, with refinements incorporated from both Alternatives 1 and 4 as well as suggestions taken from public comments. NOAA Fisheries has reviewed the NPFMC recommendation, and has endorsed it as the Agency's PA. The NPFMC intends to submit to the Secretary of Commerce, the policy contained in the PA as an amendment to the policies in the current BSAI and GOA FMPs. For more information on the PA, see Section ES 8.0.

ES 6.1 Alternative 1: Continue Under the Current Risk-Averse Management Policy

Under this alternative, the groundfish fisheries would continue to be managed based upon the present risk-averse policy. Alternative 1(a) represents the policy language currently stated in the FMPs, dating from 1979 and 1985 for the GOA and BSAI FMPs, respectively. These policies, based on the best scientific information available, avoid irreversible or long-term adverse effects on fishery resources and the marine environment, while at the same time providing for optimum yield.

Alternative 1(b) is a substitute for the written policy language in the current FMPs and would include objectives that explicitly address the variety of concerns that are balanced by the NPFMC and NOAA Fisheries in current management considerations. The objectives of this alternative are summarized in Table ES-1. Alternative 1(b) encapsulates a risk-averse conservation and management program that is based on a conservative harvest strategy. This policy assumes that fishing does result in some adverse impacts to the environment and that, as these impacts become known, mitigation measures will be developed and appropriate FMP amendments will be implemented.

FMP 1 (Current BSAI and GOA Groundfish FMPs)

The Alternative 1(a) and 1(b) policies are both represented by FMP 1, which is the current FMP for the BSAI and the GOA and incorporates management measures approved by the NPFMC through the June 2002 meeting.

In the current FMPs, the TAC is determined annually based on a conservative harvest strategy that calculates the OFL and the acceptable biological catch (ABC) for each managed stock or stock complex. The current FMPs specify the OFL and maximum ABC (*max* ABC) by means of a six-tier system wherein the amount and quality of information available for a given stock or stock complex determine the formula that is used to define the rate of fishing mortality that would result in a long-term average yield at the OFL (F_{OFL} or *max* ABC [*max* F_{ABC}]) threshold for Tiers 1-5, and for Tier 6, where the fishing mortality rate is unknown, the OFL and *max* ABC is based on historical catches. Most stocks are currently managed under Tier 3, where *max* F_{ABC} equals $F_{40\%}$, the fishing mortality rate at which long-term average level of spawners per recruit, would be reduced to 40 percent of its level in the absence of any fishing. Precautionary adjustments are made in Tiers 1-3 by decreasing F_{OFL} and F_{ABC} linearly with biomass whenever biomass falls below a tier-specific reference level, but only Tier 1 stocks include an uncertainty variation in *max* ABC. The status of each stock in Tiers 1-3 is also examined annually with respect to the minimum stock size threshold (MSST), as defined in the National Standard Guidelines.

Optimum yield (OY) is specified in the current FMPs as a range that is aggregated across all stocks and does not vary with biomass. The current FMPs require the sum of the individual groundfish TACs to fall within the OY range. In the BSAI, the high end of the range, two million mt, acts as a cap on the TACs, as the aggregated ABCs regularly exceed this limit. In practice, although it is not required in the current FMPs, TACs are never set higher than the corresponding ABCs. Taking into account the ecosystem considerations of the food web, the FMPs also prohibit directed fishing for forage fish species.

Through amendments over the last twenty years, the current FMPs have built up a network of spatial and temporal closures, intended to protect resources of concern, as well as to minimize gear conflicts. In the BSAI, various areas around the Pribilof Islands and in Bristol Bay are closed year-round to trawling in order to protect red and blue king crab habitat, and chinook and chum salmon areas are closed seasonally. Also in the BSAI, waters within 12 nm of Walrus Islands are closed to groundfish fishing to minimize disturbance of walrus haulouts. In the BSAI and the GOA, Steller sea lion protection measures permanently close the area within 3 nm of rookeries to all fishing, as a no-transit zone. Additionally, they impose trawl prohibitions within 10 to 20 nm of all rookeries and haulouts, and prohibit fishing in Seguam Pass. In the GOA, trawling is prohibited in southeast Alaska west of 140° W. Also, a 2.5 nm^2 area designated as the Sitka Pinnacles Marine Reserve in the GOA is closed to groundfish fishing to protect habitat for rockfish and lingcod.

The current BSAI FMP prohibits directed fishing for pollock with non-pelagic trawl gear. There is no similar restriction on pollock trawling in the current GOA FMP. Directed fishing for sablefish with longline pot gear is prohibited in the GOA. Non-pelagic trawling is prohibited in the Bristol Bay Red King Crab Savings Area in the BSAI and in the Cook Inlet in the GOA. Additionally, various areas around Kodiak Island are closed to non-pelagic trawling either year-round or seasonally to protect crab stocks.

Groundfish fisheries in the BSAI and GOA are required to discard any incidental catch of halibut, salmon (or steelhead trout), crab, and herring. These species are known collectively as prohibited species. The FMPs currently set PSC limits on many of these species, with penalties ranging from closure of a particular zone or of the whole management area to a directed fishery or fisheries for a specified season or the remainder of the year. In the BSAI FMP, stairstep limits for trawl bycatch within specified zones are set for red king crab and *C. bairdi* crab. The catch limit varies based on stock abundance. The BSAI FMP also specifies an absolute trawl catch limit for chinook salmon and "other salmon" within specified zones. Once the apportioned PSC limit for a trawl fishery is reached within a zone, the fishery is prohibited from fishing within that zone. The BSAI FMP specifies a trawl catch limit for herring in the BSAI at 1 percent of annual biomass. Catch limits on *C. opilio* crab and halibut bycatch in the BSAI are framed in the FMP and established by regulation. The *C. opilio* catch limit applies to a specified zone and is based on an adjusted percentage of biomass that must fall within a certain range. The halibut catch limit is a BSAI-wide mt limit and is based on halibut mortality. In the GOA FMP, catch limits on halibut bycatch are authorized and set as part of the annual procedure for setting groundfish harvest levels. There are no other PSC limits set in the GOA.

Other bycatch reduction measures are required under FMP 1. The Improved Retention/Improved Utilization (IR/IU) program requires full retention, by vessels fishing for groundfish, of all incidentally caught pollock and Pacific cod fit for human consumption, as well as full utilization of the two species by inshore processors. A minimum utilization standard of 15 percent is set for all at-sea processors. The NPFMC has also adopted a policy to require full retention of demersal shelf rockfish by longline and jig vessels in the southeast Outside District of the GOA. A Vessel Incentive Program encourages bycatch reduction by setting bycatch reduction standards biannually. If a vessel fails to meet these standards, it can be penalized. Inseason bycatch management measures establish fishing seasons for bycatch management and give the NOAA Fisheries Alaska, Regional Administrator the authority to close areas with high bycatch.

Table ES-1. Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements. NOTE: Language taken from text of alternative policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
Philosophy	Management process will be adaptive to new information and reactive to new environmental issues.	Establishes a more aggressive harvest strategy, goal would be to maximize biological and economic yield from the resource.	Additional conservation and management measures will be taken as necessary to respond to social, economic or conservation needs, or if scientific evidence indicates that the fishery is negatively impacting the environment.	Extremely precautionary approach to managing fisheries under scientific uncertainty in which the burden of proof is shifted to the user of the resource.	Forward looking conservation measures that address differing levels of uncertainty; precautionary approach that applies judicious and responsible fisheries management practices, based on sound scientific research and analysis, proactively rather than reactively, to ensure the sustainability of fishery resources and associated ecosystems for the benefit of future as well as current generations.
Assumptions	Based on the assumption that fishing does produce some adverse impact to the environment.	Based on the assumption that fishing does not have an adverse impact on the environment except in specific cases as noted.	Recognizes need to balance many competing uses of marine resources and different social and economic goals for fishery management.	Based on the assumption that fishing does produce adverse impacts on the environment, but due to lack of information and uncertainty, we know little about these impacts.	Recognizes that potential changes in productivity may be caused by fluctuations in natural oceanographic conditions, fisheries, and other, non-fishing activities, and intends to continue to take appropriate measures to insure the continued sustainability of the managed species.
Plan of action	As adverse impacts become known, mitigation measures are developed and Fishery Management Plan (FMP) amendments are implemented; goals will be addressed through existing institutions and processes.		Will utilize and improve upon existing processes to involve a broad range of the public in decisionmaking.	Strategy will result in changes that will significantly curtail the groundfish fisheries until more is knows about impacts; once more is known, initial measures will be modified or relaxed.	Will utilize and improve upon existing open and transparent process to involve the public in decisionmaking; will review, modify, eliminate, or consider new issues as appropriate to best carry out the goals and objectives; objectives will be reviewed annually, and the Programmatic Supplemental Environmental Impact Statement (PSEIS) will be used as a planning document.

Table ES-1 (cont.). Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
			Prevent overfishing		
Harvest strategy	• Conservative harvest levels for single species fisheries.		• Conservative harvest levels for multispecies and single species fisheries. • Evaluate F_{40} and implement improvements.	• Transition from single-species to ecosystem-oriented management of fishing activities. • Establish a program to maintain ecological relationships among exploited, dependent and related species as well as ecosystem processes that sustain them.	• Conservative harvest levels for multispecies and single species fisheries and specify optimal yield (OY). • Scientific review of F_{40} and adopt improvements as appropriate.
OY	• Specify OY as a range with the cap at 2 million (mill) metric tons (mt) in the Bering Sea and Aleutian Islands (BSAI), 0.8 mill mt in the Gulf of Alaska (GOA).	• Specify OY as a range. • Set OY cap at the sum of overfishing levels (OFLs) or acceptable biological catch (ABCs) for each species.	• Specify OY as a range or a formula.		• Specify OY as a range with the cap at 2 mill mt in BSAI (as stated in current law), 0.8 mill mt in GOA.
Other			• Improve biological information necessary to determine minimum stock size threshold (MSSTs) particularly for Tier 4 species.	• Close a percentage of known target stock spawning area.	• Improve the management of species through species categories
			Promote sustainable fisheries and communities[1]		
Benefit to the nation					• Provide for OY in terms of providing the greatest overall benefit to the nation with particular reference to food production.
Stability					• Avoid significant disruption of existing social and economic structures.

Table ES-1 (cont.). Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
Promote sustainable fisheries and communities[1] (cont.)					
Equity					• Promote fair and equitable allocation of identified available resources.
Safety					• Promote increased safety at sea.
Preserve food web					
Ecosystem considerations	• Incorporate ecosystem considerations into fishery management decisions. • Consider the impact of fishing on predator-prey and other ecological relationships.	(none)	• Incorporate ecosystem considerations into fishery management decisions.	• Address the impact of fishing on predator-prey and other important ecological relationships. • Conserve native species and biological diversity.	• Incorporate ecosystem considerations into fishery management decisions as appropriate.
Fishing levels	• Limit harvest of forage species.		• Improve procedure to account for uncertainty and ecosystem factors in ABCs.	• Reduce ABCs/set highly precautionary fishing levels to account for uncertainty and ecological considerations.	• Improve procedure to account for uncertainty and ecosystem factors in ABCs. • Limit harvest of forage species.
Research			• Develop indices of ecosystem health as targets for management. • Initiate research program to identify the habitat needs of the significant food web.	• Develop and implement a fishery ecosystem plan.	• Develop indices of ecosystem health as targets for management.
Manage incidental catch, and reduce bycatch and waste[2]					
Level	• Current bycatch and incidental catch management program. • Require full utilization of target species.		• Continue and improve bycatch and incidental catch program. • Develop incentive programs for bycatch and incidental catch reduction. • Develop management measures that encourage gear or techniques that reduce discards.	• Reduce bycatch, incidental catch and prohibited species catch (PSC). • Phase out fisheries with >25% bycatch or incidental catch.	• Continue and improve bycatch and incidental catch program. • Develop incentive programs for bycatch reduction. • Develop management measures that encourage gear or techniques that reduce bycatch which includes economic discards. • Reduce waste to biologically and socially acceptable levels

Table ES-1 (cont.). Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
Manage incidental catch, and reduce bycatch and waste[2] (cont.)					
Closures	• Manage bycatch and incidental catch through seasonal total allowable catch (TAC) distribution and geographic gear restrictions. • Respond to population and decline by area, gear and seasonal closures.	• Manage incidental catch and bycatch through gear closure areas.			• Manage bycatch and incidental catch through seasonal TAC distribution and geographic gear restrictions.
PSC	• Control PSC through limits.	• Monitor PSC bycatch and adjust or eliminate limits.		• Establish GOA PSC limits for salmon, crab and herring.	• Control PSC through limits or other appropriate measures.
TAC	• Account for bycatch mortality in TAC accounting.			• Include mortality in TAC accounting and improve accuracy of mortality including unobserved.	• Account for bycatch mortality in TAC accounting.
Non-target species			• Encourage research on population estimates for non-target species with a view to setting bycatch limits.	• Set stringent bycatch limits for vulnerable non-target species.	• Encourage research on population estimates for non-target species with a view to setting bycatch limits.
Avoid impacts to seabirds and marine mammals					
Seabirds	• Protect Endangered Species Act (ESA)-listed and other seabird species.	• Maintain protection measures for ESA-listed species.	• Protect ESA-listed and other seabirds. • Joint research program to establish population estimates for all seabird species.	• Set protection measures for all seabirds and develop methods to reduce the incidental take levels. • Joint research program to establish population estimates for all seabird species, and modify protection measures as appropriate.	• Protect ESA-listed and, if appropriate and practicable, other seabird species.

Table ES-1 (cont.). Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
Avoid impacts to seabirds and marine mammals (cont.)					
Marine mammals	• Maintain protection measures to avoid jeopardy to ESA-listed Steller sea lions.	• Maintain protection measures to avoid jeopardy to ESA-listed Steller sea lions.	• Maintain or adjust protection measures for ESA-listed Steller sea lions. • Review status of other marine mammal and fishery interactions and develop appropriate measures.	• Increase Steller sea lion protection measures by further restricting gear in critical habitat and setting more conservative harvest levels for prey base species.	• Protect ESA-listed and, if appropriate and practicable, other marine mammal species • Maintain or adjust protection measures for ESA-listed Steller sea lions. • Review status of endangered and threatened marine mammal and fishery interactions and develop appropriate measures.
Reduce and avoid impacts to habitat					
Closures	• Close important habitat to all fishing in response to new scientific information. • Evaluate candidate areas for Marine Protected Areas (MPAs).	• Evaluate candidate areas for MPAs.	• Develop goals and criteria to evaluate the efficacy MPAs, consider implementation.	• Establish 20-50% of area as no-take marine reserves. • Prohibit trawling where fishery can be prosecuted with other gear types, and establish trawl closure areas.	• Review and evaluate efficacy of existing habitat protection measures for managed species. • Develop a MPA policy in coordination with national and state policies. • Develop goals and criteria to evaluate the efficacy MPAs, implement if and where appropriate.
Essential fish habitat (EFH)		• Identify EFH and determine appropriate habitat measures.	• Identify EFH and habitat areas of particular concern (HAPC).	• Protect habitat including EFH, HAPC, ESA critical habitat, etc.	• Identify EFH and HAPC pursuant to MSA rules. • Mitigate fishery impacts as necessary and practicable to continue the sustainability of managed species.
Research	• Implement research to evaluate impacts of trawl gear on habitat.	• Implement research to evaluate impacts of trawl gear on habitat.	• Implement research to evaluate impacts of all gear on habitat. • Develop regional baseline habitat. information and mapping.	• Manage adaptively, using large no take areas as experimental controls to facilitate learning.	• Encourage development of regional baseline habitat information and mapping.

Table ES-1 (cont.). Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
Promote equitable and efficient use of fishery resources[3]					
	• Provide economic and community stability through maintaining allocation percentages.		• Provide economic and community stability through fair allocation of fishery resources.	• Consider non-consumptive values.	• Provide economic and community stability through fair allocation of fishery resources.
Excess capacity	• Reduce excess capacity, overcapitalization and the adverse effects of the race for fish.	• Maintain American Fisheries Act (AFA) and community development quota (CDQ) as authorized by the Magnuson-Stevens Fishery Conservation and Management Act (MSA).	• Maintain License Limitation Program (LLP) and reduce capacity and other adverse effects of the race for fish by extending rights-based management to some or all fisheries. • Periodically evaluate the effectiveness of rationalization.	• Reduce excess capacity, employ equitable allocative or cooperative programs to end the race for fish, reduce waste, increase safety and promote stability and benefits to communities.	• Maintain LLP and modify as necessary. • Decrease excess capacity and overcapitalization by eliminating latent licences and extending rights-based management to some or all fisheries. • Periodically evaluate the effectiveness of rationalization.
Efficiency					• Increase the efficient use of fishery resources taking into account the interest of harvesters, processors, and communities.
Increase Alaska native consultation					
Traditional knowledge	• Continue incorporating traditional knowledge into fisheries management.	• Continue incorporating traditional knowledge into fisheries management.	• Continue incorporating traditional knowledge into fisheries management, increase traditional knowledge data collection.	• Utilize traditional knowledge, including monitoring and data gathering, through co-management and cooperative research programs.	• Continue incorporating local and Traditional Knowledge into fisheries management, increase local and Traditional Knowledge data collection.
Consultation	• Continue Alaska Native consultation and participation in fisheries management.	• Continue Alaska Native consultation and participation in fisheries management.	• Increase Alaska Native consultation and participation in fisheries management.	• Increase participation of and consultation with Alaska Native subsistence users.	• Increase Alaska Native consultation and participation in fisheries management.

Table ES-1 (cont.). Comparative summary of the philosophy, assumptions, plan of action and goals of the policy statements.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Preferred Alternative (PA)
Improve data quality, monitoring and enforcement[4]					
Observer program	• Continue Observer Program for catch estimates.	• Consider repealing the Observer Program.	• Increase the utility of observer data. • Improve the Observer Program, including the funding mechanism.	• Increase the precision of observer data through increased coverage and enhanced sampling protocols, address the funding issue.	• Increase the utility of observer data. • Improve the Observer Program, including the funding mechanism.
Reporting	• Continue industry reporting, and efforts to improve economic impact assessments.	• Continue industry reporting, and efforts to improve economic impact assessments.	• Increase data and reporting requirements in order to improve economic impact assessments.		• Increase data and reporting requirements in order to improve economic impact costs and benefits.
Technology	• Increase quality of monitoring data through technology.		• Increase quality of monitoring data through technology.	• Improve enforcement and inseason management through technology.	• Increase quality of monitoring data through technology.
Research			• Establish a baseline ecosystem monitoring program. • Adopt recommended research plan in the PSEIS. • Cooperate with research institutions to identify research priorities.	• Establish a baseline monitoring program, use to improve the Fishery Ecosystem Plan. • Adopt recommended research plan in the PSEIS.	• Establish a baseline ecosystem monitoring program. • Cooperate with research institutions to identify research needs and develop programs.
Enforcement					• Promote enhanced enforceability. • Cooperate, consult, coordinate with federal and state agencies and organizations for conservation, sustainability, management and enforcement.

Notes: [1]This heading was added to the PA by the NPFMC
[2]In Alternatives 1 - 4, this heading is: Reduce and Avoid Bycatch
[3]In Alternatives 1 - 4, this heading is: Allocation
[4]In Alternatives 1 - 4, this heading is: Data Quality, Monitoring and Enforcement

"The Reasonable and Prudent Measures" adopted from the most recent USFWS Biological Opinion on the short-tailed albatross stipulate the use of certain seabird avoidance measures and require that the take of more than four short-tailed albatross within two years trigger consultation with the USFWS. Pending the results of the consultation, there is potential for the fisheries to close. To further reduce the possibility of the take of albatross impacting the fisheries, in 2001 the NPFMC adopted a policy to require all longline vessels to adopt more stringent seabird avoidance methods.

A License Limitation Program for groundfish vessels over 32 ft length overall (LOA) (with certain jig gear exceptions) and a moratorium on entry into the groundfish fisheries is in place for the BSAI and the GOA. An IFQ program is in place for sablefish in the BSAI and GOA, which includes provisions for community purchase of quota share. In the BSAI, the directed fishery for pollock is organized into cooperatives as authorized under the American Fisheries Act (AFA). A multi-species CDQ program apportions 7.5-10 percent of all BSAI groundfish quota to 65 eligible western Alaska communities.

FMP 1 monitors the groundfish fishing effort through federal and state reporting requirements and through the use of the North Pacific Groundfish Observer Program. All vessels between 60 ft and 125 ft LOA are required by regulation to have an observer on board 30 percent of the time; for vessels over 125 ft LOA this increases to 100 percent. For AFA and CDQ catcher boats greater than 60 ft LOA, one observer must be on board at all times, and for catcher processors and motherships, two observers must be on board at all times. The program also has observers at inshore processing plants. Additional monitoring tools are the reporting requirements for BSAI and GOA vessels that submit daily or weekly logbooks including information on the composition of catch and the locations of the hauls. The ADF&G also collects data from fish tickets at the point that catch is sold. Mandatory vessel monitoring systems for all directed Atka mackerel, pollock, and Pacific cod fishing verify vessel location.

ES 6.2 Alternative 2: Adopt a More Aggressive Harvest Management Policy

The Alternative 2 policy would maximize biological and economic yield from the resource while still preventing overfishing of the groundfish stocks. Such a management approach would, among other things, be based on the best scientific information available, take into account individual stock and ecosystem variability, and continue to work with other agencies in protecting threatened and endangered species. A more aggressive harvest strategy would be implemented based upon the concept that the present policy is overly conservative and that higher harvests can be taken without overfishing the target groundfish stocks. The objectives of this alternative are summarized in Table ES-1. This policy assumes that fishing at the recommended levels would have no adverse impact on the environment, except in specific cases that are known and mitigated.

Example FMP 2.1

Example FMP 2.1 illustrates a more aggressive harvest strategy than Alternative 1 by removing many of the existing constraints from the fisheries. As the policy is based on an assumption that the impacts of fishing on the environment are generally known and mitigated, the precautions currently built into the existing TAC-setting process will be alleviated. The buffer between the ABC level and the OFL is removed, and the maximum OY for the groundfish stocks in the BSAI is released from its two million mt cap and allowed to float as the sum of the OFLs for the BSAI groundfish stocks. Additionally, example FMP 2.1 removes the precautionary element of the current FMPs that decreases F_{ABC} linearly with biomass when the biomass falls below a specific reference level.

Example FMP 2.1 also removes physical constraints from the fisheries by repealing the various closure areas currently in place. The fishery would be returned to an open-access scenario, where time and area closures, gear restrictions, and PSC restrictions are repealed. The potential impact of the groundfish fisheries on Steller sea lions, however, means that the current mitigation including a suite of protection measures that constrain fishing around rookeries and haulouts, and protect Steller sea lion prey species (pollock, Pacific cod and Atka mackerel) when at low biomass levels, would remain in place. This is required by the ESA to avoid jeopardy and adverse modification of population levels. The same applies to the impact of groundfish fishing on short-tailed albatross, with the consequent take limits remaining in effect.

The federally-mandated effort limitation program for the directed BSAI pollock fishery enacted under the AFA, with its accompanying CDQ allocation, would remain in place and the CDQ program, mandated by the MSA, would be modified to allocate only a percentage of the BSAI TAC for pollock to the CDQ program. All other effort limitation programs such as the sablefish IFQ program would be repealed. Reporting requirements would remain in place, in order to keep track of the impact of the fisheries, but the Observer Program, except as federally mandated by the AFA, would be repealed as would vessel monitoring system requirements.

Example FMP 2.2

A more moderate illustration of Alternative 2, example FMP 2.2, also represents a more aggressive harvest strategy than Alternative 1. In this case, the mechanisms for setting ABC and TAC remain the same as in the current FMPs (see FMP 1 for further detail), but the existing regulatory-capped maximum OY of two million mt in the BSAI would be removed in favor of a maximum OY equaling the sum of individual groundfish ABCs in the BSAI. Additionally, bycatch reduction incentives and bycatch restrictions would be repealed, other than those related to PSC limits or IR/IU. Under the assumption that fishing does not have an impact on the environment other than what is generally known and mitigated, the NPFMC's more stringent seabird avoidance measures recommended in 2001 would be repealed, leaving only the mitigation measures recommended by USFWS to avoid jeopardy or adverse modification for short-tailed albatross. Closure areas in example FMP 2.2 mirror those in FMP 1.

ES 6.3 Alternative 3: Adopt a More Precautionary Management Policy

This policy would seek to accelerate the existing precautionary management measures through community or rights-based management, ecosystem-based management principles and, where appropriate and practicable, increased habitat protection and additional bycatch constraints. Under this approach, additional conservation and management measures would be taken as necessary to respond to social, economic or conservation needs, or if scientific evidence indicated that the fishery was negatively impacting the environment. The objectives of this alternative are summarized in Table ES-1. This policy recognizes the need to balance many competing uses of marine resources and different social and economic goals for fishery management.

Example FMP 3.1

Example FMP 3.1 illustrates a management approach that accelerates precautionary management measures by increasing conservation-oriented constraints on the fisheries where necessary, formalizing precautionary practices in the FMPs, and initiating scientific review of existing practices as a necessary precursor to the decision of how best to incorporate adequate precautions.

Example FMP 3.1 implements changes to the TAC-setting process following a comprehensive review. Precautionary practices such as setting TAC less than or equal to the ABC, and specifying MSSTs for Tiers 1-3 in accordance with National Standard guidelines, would be formalized in the FMP. Sharks and skates would be removed from the other species management category and given their own TACs. Criteria to do the same for other target stocks would also be developed. Efforts to develop ecosystem indicators to be used in TAC-setting, as per ecosystem management principles, would be accelerated.

In order to balance the needs of social and economic stability with habitat protection and resource conservation, a review would be conducted of the existing system of closure areas in the BSAI and the GOA, while evaluating them against a Marine Protected Area (MPA) methodology to be developed as part of this alternative. The NPFMC and NOAA Fisheries would also seek to initiate joint consultation and research with USFWS to develop fishing methods that reduce incidental take of threatened and endangered species. To mitigate adverse impacts of fisheries management decisions on fishing communities, and to comply with other national directives, formal procedures would be implemented to encourage increased participation of Alaska Natives in fishery management.

Example FMP 3.1 recognizes that the anticipated community or rights-based management programs may address bycatch reduction objectives (a review of bycatch rates under existing such programs is initiated), but in the meantime a moderate reduction of PSC limits will be initiated as an intermediary step. PSC limits for crab, herring and salmon would be authorized in the GOA, in addition to the halibut PSC limits authorized under the current GOA FMP. Effective monitoring and timely reaction to change in the environment and the fisheries would be enhanced through improvements in the Observer Program and third party verification of economic data.

Example FMP 3.2

Example FMP 3.2 implements the acceleration of existing precautionary measures on a more rapid timeline than example FMP 3.1. Rather than reviewing existing practices prior to incorporating increased precaution, this bookend implements changes to many aspects of the FMPs concurrently with the initiation of scientific research efforts necessary to bring management measures in line with a precautionary policy.

Example FMP 3.2 significantly accelerates precautionary management by incorporating an uncertainty correction into the estimation of ABC for all species. Additionally, OY would be specified separately for each stock or stock complex rather than for the groundfish complex as a whole (i.e., OY would be set as a formula rather than as a range, eliminating the BSAI two million mt OY cap), and would be set equal to the respective stock or stock complex's TAC. The current precautionary practice of setting TAC less than or equal to ABC would be formalized in the FMP. Example FMP 3.2 would also incorporate stock-specific biological reference points in the tier system where scientifically justifiable. This could result in Tier 3 rockfish stocks, for example, being capped at $F_{60\%}$ rather than $F_{40\%}$. In implementing this bookend, criteria would be developed for specifying MSSTs for Tiers 4-6, along with a list of priority candidate stocks; and the development of criteria for removing some stocks from the other species and non-specified species management categories would minimally result in sharks and skates being given their own TACs.

Example FMP 3.2 also reexamines the existing closure system in the BSAI and the GOA. The bookend sets a guideline of 0-20 percent of the EEZ (3 to 200 nm) to be closed as an MPA.. The objective of these measures is to provide greater protection to a full range of marine habitats within the 1,000-m bathymetric line. The guideline aims to provide greater protection for a wide range of species, from Steller sea lions to slope rockfish to prohibited species, while at the same time respecting traditional fishing grounds and maintaining open area access for coastal communities. Additionally, the bookend would extend the existing bottom-trawl ban on pollock to the GOA.

Additional conservation benefits would be realized in example FMP 3.2 through the comprehensive rationalization of all fisheries (except those already part of a cooperative or IFQ program.) In adopting rationalization programs such as cooperative-style programs with built-in community protections, habitat and bycatch concerns would also be addressed by reducing concentrated effort in the fisheries. To increase precaution regarding bycatch, PSC limits would be significantly reduced (and set for all prohibited species in the GOA), but would not be expected to act as a proportionate restraint on the fisheries due to the incentives for bycatch reduction under cooperatives, or other bycatch incentive programs implemented as necessary under this bookend.

In accordance with ecosystem principles, the NPFMC and NOAA Fisheries would seek to initiate joint consultation and research with USFWS to develop fishing methods that reduce incidental take of all seabird species. Formal procedures would also be implemented to increase consultation with and representation of Alaska Natives in fishery management.

Effective monitoring and timely reaction to change in the environment and the fisheries would be enhanced through increase of coverage and improvements to the Observer Program, as well as an increase in the use of vessel monitoring systems and the range of economic data collected from industry.

ES 6.4 Alternative 4: Adopt a Highly Precautionary Management Policy

This policy represents an extremely precautionary approach to managing fisheries under scientific uncertainty. It shifts the burden of proof to the users of the resource and the NPFMC and NOAA Fisheries to demonstrate that the intended use would not have a detrimental effect on the environment. It would involve a strict interpretation of the precautionary principle. Management decisions would involve and be responsive to the public, but would decrease emphasis on industry and community concerns in favor of ecosystem processes and principles. The objectives of this alternative are summarized in Table ES-1. This policy assumes that fishing does produce adverse impacts on the environment, but due to a lack of information and uncertainty, characterization of these impacts is difficult. The initial restrictive and precautionary conservation and management measures would be modified or relaxed when additional, reliable scientific information becomes available.

Example FMP 4.1

Example FMP 4.1 illustrates an FMP where current levels of fishing are reduced and other precautionary restrictions are implemented until scientific research shows that the fisheries have no adverse effect on the sustainability of the resource and its environment.

Accordingly, example FMP 4.1 would substantially reduce the potential of the fisheries to adversely impact the environment. A modified TAC-setting process would create a more substantial buffer between ABC and the OFL by setting the fishing mortality rate at $F_{75\%}$ for all Steller sea lion prey species (pollock, Pacific cod and Atka mackerel) and for rockfish (as long-lived, slow-growing species). Also, the *max* F_{ABC} for each stock or stock complex in Tiers 1-5 would be adjusted downward based on the lower bound of a confidence interval surrounding the survey biomass estimate. OY would be specified separately for each stock or stock complex rather than for the groundfish complex as a whole (i.e., OY would be set as a formula rather than as a range, eliminating the BSAI two million mt OY cap), and would be set equal to the respective stock or stock complex TAC. The current precautionary practice of setting TAC less than or equal to ABC would be formalized in the FMP. For species managed as members of a stock complex, rather than setting TAC as the aggregate of the individual members' ABCs, the *max* ABC value for each component stock would be determined and the TAC set equal to the lowest value. Where sufficient biological information is available, such as with EBS pollock, TAC would be distributed on a smaller spatial scale. MSSTs would be determined for all tiers.

To further mitigate the possibility of the fisheries having a detrimental biological and ecosystem impact, 20-50 percent of the EEZ would be designated as No-Take Marine Reserves (i.e., no commercial fishing) covering the full range of marine habitats within the 1,000-m bathymetric line. As part of this area in the Aleutian Islands, a Special Management Area would be established to protect coral and other living bottom habitat. The closed area would include spawning reserve areas for intensively fished species. Under example FMP 4.1, comprehensive trawl exclusion zones would be set to protect all Steller sea lion critical habitat, and trawling would be restricted to those fisheries that cannot be prosecuted with other gear types (i.e., the flatfish fisheries).

In an effort to reduce waste and the risk of adverse impact to the environment, existing PSC limits would be halved under this bookend, as would bycatch (discard) and incidental catch rates. IR/IU would be extended to all target species. Stringent PSC limits would be set for salmon, crab and herring in the GOA, and as information becomes available, bycatch limits would also be set for non-target species. Protection measures would be set for all seabird species.

Because this policy alternative necessitates greater research and data-gathering efforts, example FMP 4.1 would expand observer coverage to 100 percent for all vessels over 60 ft LOA and require 30 percent observer coverage on vessels presently exempted from observer coverage (i.e., vessels under 60 ft LOA). Vessel monitoring systems would be made mandatory for all groundfish vessels, as would motion-compensated scales for weighing all catches at sea or at shore-based processors. In addition, cooperative research and data-gathering programs would be initiated to expand the use of Traditional Knowledge in fisheries management.

Example FMP 4.2

Example FMP 4.2 expands the precautionary principles of Alternative 4 by temporarily suspending all fishing until the fisheries can be shown to have no adverse effect on the resource and its environment. The Agency would conduct an environmental review of each groundfish fishery. Until such a review is completed and a fishery certified, the TAC for all species in that fishery would be set at zero. All areas of the EEZ would be closed to all fishing (i.e. commercial, recreational, and subsistence); bycatch and incidental catch, as well as the take of seabirds and marine mammals, would then necessarily be reduced to zero in the short-term. It is estimated that for some fisheries, an environmental review could take as long as two years.

Scientific research and data-gathering efforts would continue under FMP 4.2. Each groundfish fishery would be reviewed to determine whether it results in significant adverse biological and environmental impacts, and if it does, whether those impacts can be mitigated by fishery-specific mitigation measures. If the Agency concludes that the fishery poses no significant threat to the environment, NOAA Fisheries would certify that fishery and authorize fishing to resume under fishery-specific regulations. If a fishery is found by this review to produce significantly adverse environmental effects, and measures cannot be designed to mitigate those effects, that fishery would not be certified and would remain closed until more scientific information is known, or new ways are found to mitigate the effects of fishing.

ES 7.0 Possible Effects of Fishery Management Alternatives

In order to determine the effects of the alternatives, a two-dimensional analytical framework has been developed that defines a range of implementing management measures for each alternative. The framework consists of a set of FMP components (including the TAC-setting process, bycatch and incidental catch restrictions, gear restrictions, etc.) and a set of example FMPs (summarized in the prior section) that include management measures that address each FMP component. Each FMP component focuses on a particular set of policy objectives and is evaluated qualitatively to provide the reader with a general sense of the environmental consequences associated with various management tools and their potential applications in relative isolation of other FMP components, when possible (see Section 4.3 and Appendix F). Each example FMP is then examined as a whole (e.g. a combination of rows), to provide an understanding of how the various components work together to accomplish a number of policy objectives simultaneously (Sections 4.5 to 4.9). Except for Alternative 1, each alternative contains a pair of example FMPs as "bookends" to illustrate and frame the range of that alternative's management measures. Alternatives 1(a) and 1(b), representing status quo, contain just one FMP; the existing management regime in place for the BSAI and GOA, including NPFMC-approved (but not necessarily implemented yet) measures through June 2002. The intention is that the FMP framework structure will represent a range of management measures that address each FMP component and are likely to be implemented under a chosen alternative.

Each of the two dimensions of the framework (the FMP components and the example FMPs) has been analyzed, either qualitatively or quantitatively. Section 4.3 provides a summary of the Qualitative Analysis papers written for each FMP component. Each paper provides background on the choice of management measures used to address that FMP component and describes the range of management measures that are implemented under each example FMP. Additionally, the papers provide a preliminary assessment of the potential impacts of implementing the management measures in a static environment; cumulative or synergistic impacts among FMP components are not analyzed (for the full text of the papers, see Appendix F).

Following this two dimensional analysis, the results of the analysis of each individual FMP are synthesized as a method for assigning environmental benefits and adverse effects to each policy alternative (Section 4.10). We continue this synthesis by incorporating a policy assessment comparing each alternative against the MSA National Standards and other key environmental laws and policy recommendations (Section 4.11.1). And, finally, we present our overall findings of our analysis for each alternative (Section 4.11.2).

Analysis of these alternative regimes is intended to illustrate the types of environmental effects that can be anticipated should specific fisheries management actions be pursued in the future. Many potential combinations of management actions could comprise an FMP. Reliance on Agency experts and public comments received during the preparation of this Programmatic SEIS led to the development of these example FMPs for analytical purposes; they are not intended to represent all possible combinations of actions. As a planning document, this Programmatic SEIS provides the decision-makers and the public with a broad range of potential policy objectives and management actions. The direct, indirect, and cumulative effects analyzed in this Programmatic SEIS illustrate, to the best of our ability, the environmental consequences and risks associated with each policy alternative. However, this Programmatic SEIS does not prevent the NPFMC or NOAA Fisheries from taking other management actions necessary to achieve its policy objectives and to protect the ecosystem. In such cases, future FMP amendments will explore all reasonable alternatives to address the stated problem, and thus accompanying NEPA analyses will fully evaluate the specific proposed action and its environmental impacts. To the extent that such future actions fall within the range of FMP bookends selected as part of the PA, those future actions can tier from the Programmatic SEIS and by doing so, the analysis can be streamlined. In the event a different management tool is designed, or a new environmental issue arises not previously discussed in the Programmatic SEIS, then future NEPA actions will likely require more detailed analysis and discussion.

ES 7.1 Analytical Approach to Evaluating Alternatives

The analytical approach for simulating current groundfish management in the North Pacific EEZ involves considering interactions among a large number of species (including target, non-target, and prohibited), areas, and gear types. To evaluate the consequences of alternative management regimes selected in this Programmatic SEIS, computer modeling was used to predict the likely outcome of management decisions using data on historical catch of different species by gear types and areas, stock assessment surveys, research studies, and industry reported statistics. Management of the Alaska groundfish fisheries is complex given the large numbers of species, areas, and gear types. The managers schedule fisheries openings and closures to maximize catch subject to catch limits and other constraints. These management actions are based on expectations about the array of species likely to be captured by different gear types and the cumulative effect that each fishery has on the allowable catch of each individual target species and other species groups. The groundfish population abundance for each alternative regime was forecast for a five-year period beginning from 2003. Ten and twenty year projections were also predicted, although the confidence intervals surrounding these longer-view projections make them highly questionable.

This approach provides a reasonable representation of the current fisheries management practice for dealing with the multi-species nature of catch in target fisheries and for evaluating the different policy alternatives and their associated FMP bookends on the human environment. In addition to the multi-species model, agency analysts also used other models as tools to evaluate the potential impacts of the policies on habitat, the economics of the fisheries, and the effects on fishing communities. All of these models are still in early stages of development and therefore cannot accurately predict all effects with absolute certainty. Thus, analysts must qualify their findings and often rely on the scientific literature and the professional opinion of fishery experts in their respective fields to perform qualitative assessments. More detailed information on the analytical approach used by the Agency analysts in preparing this Programmatic SEIS can be found in Section 4.1.

ES 7.2 Summary of Environmental Consequences and the Comparison of Alternatives

This section contains a summary of the environmental consequences of each of the alternatives. Table ES-2 presents the information summarized below in table format, and uses a color key to indicate the direction of effect associated with each policy alternative. The intent of the summary below, and Table ES-2, is to provide a broad, policy-level understanding of the general impacts of the alternatives. The analysis deals with effects at the population or fishery level, rather than calling out impacts to individual components (a more detailed analysis of the example FMP bookends presented in Sections 4.5 - 4.9 provides a basis for the policy-level analysis). Where the impacts within a policy goal are substantially different under an example FMP for major components, the color key in the table is split in half and two colors are assigned.

The colors used in Table ES-2 are red, yellow, light green, and dark green. Red indicates an adverse effect or may include adverse conclusions that are based on assumptions. Yellow indicates a high potential for adverse impacts if any of the assumptions used to manage the resource are wrong. Light green indicates a potential beneficial impact, or that the assumptions used to manage the resource incorporate some precaution. Dark green indicates a beneficial effect, or the assumptions used to manage the resource incorporate a high level of precaution against uncertainty.

ES 7.2.1 Summary of Alternative 1

The key policy elements that predominantly influence the impacts under Alternative 1 are: the current harvest strategy that incorporates automatic stock rebuilding (ensuring the sustainability of target stocks); incidental catch and bycatch controls; the existing system of closure areas (to protect a variety of species from groundfish fishery interactions); the objective to reduce the adverse effects of the race-for-fish (resulting in gradual implementation of rationalization); and reporting and monitoring requirements (increasing the accuracy of catch accounting).

Alternative 1 is successful at preventing overfishing of target stocks and thus meeting the goal of ensuring the sustainability of the fisheries. Alternative 1 also includes automatic stock rebuilding provisions which have proven to be effective. A weakness of this alternative is that there is no incentive to research fishery impacts on Tier 4-6 stocks in order to change their management status. It is also possible under this alternative to overharvest a vulnerable member of a stock complex.

This alternative is partially successful in achieving the goal of preserving the food web through its protection measures for dominant target species, forage species, and ESA-listed species. However, it will likely make slow, incremental progress in protecting other food web components. This policy is likely effective in protecting food web components that are more well-studied than others and those that are at critical population thresholds, but it is uncertain whether sufficient protection is provided to other food web components for which less complete information is available.

The bycatch management program under Alternative 1 is effective at limiting incidental catch of non-target species and reducing bycatch through incentive programs and monitoring. The weaknesses of the alternative are that bycatch is often reported as a complex rather than as individual species, and that observers are not present to monitor catch on vessels less than 60 ft LOA, which may result in inaccurate estimates of bycatch. This alternative may therefore not provide adequate protection for non-target species.

Alternative 1 is effective at providing protection to listed seabirds and marine mammals as a result of its explicit objectives for ESA-listed species. Although not an explicit policy goal, some protection may also be provided to non-listed seabirds through reduced incidental take as a result of implementing additional seabird protection measures.

Table ES-2. Comparison of policy-level impacts of the alternatives.

	Alternative 1	**Alternative 2**	**Alternative 3**	**Alternative 4**	Preferred Alternative
NOTE: The implication of a split color rating is that major components within the category will undergo a different impact under the alternative in question. To the extent possible, the rationale is explained in the bullets beneath.					
What is the impact of the policy on the sustainability of target stocks (preventing overfishing)?	• Successful at preventing overfishing of target stocks, ensures sustainable fishery. • No incentive to research those stocks on which impacts of fishing are unknown; possible to overharvest a vulnerable member of a stock complex.	• Maximizes economic yield while preventing overfishing of target stocks, but not effective at preventing stocks from becoming overfished. • Increases the chance of unintentionally overfishing a stock.	• Prevents overfishing of target stocks through precautionary harvest policies. • Acceleration of efforts to identify methods for reducing the number of stocks where the status relative to an overfished condition is unknown.	• Establishes a very conservative harvest policy which is likely to prevent stocks from becoming overfished. • Protects most vulnerable species of a complex, but the resulting management would be difficult to implement.	• Prevents overfishing of target stocks through precautionary harvest policies. • Acceleration of efforts to improve the current harvest strategy.
What is the impact of the policy on the sustainability of fisheries and communities?	• Continues to provide economic and community stability within the current system while adapting management programs when the need arises. • Some fisheries and communities are stressed due to negative effects of the race for fish.	• Long-term sustainability of fisheries and communities may be problematic if scenarios depicted in 2.1 are implemented; in the short-run fisheries and communities will likely see improved economic conditions. • If less aggressive actions are pursued, likely to be no better or worse than Alternative 1.	• Rationalization of fisheries holds the promise of improved fishery and community sustainability. • Extensive area closures associated with more aggressive ecosystem-based management may reduce small-boat and Alaska community involvement in fisheries.	• Extensive total allowable catch (TAC) reductions and area closures reduce viability of fisheries and fishery dependent communities. • Some fisheries may survive if assumptions of impacts are correct.	• Rationalization of fisheries holds the promise of improved fishery and community sustainability. • Incorporation of community protection elements into rationalization and ecosystem-based management programs are likely to ensure coastal community stability.
What is the impact of the policy on the stability of the food web and community structures (preserving the food web)?	• Likely effective in protecting food web components that are more well-studied than others and those that are at critical population thresholds. • Uncertain whether sufficient protection is provided to others for which less-complete information is available.	• High potential to create adverse food web impacts through its lack of precaution for many food web components, which leaves no room for uncertainty.	• Many improvements provide additional protection against uncertainty in order to achieve the goal of preserving the food web. • If implemented, this strategy is likely to provide protection to a broad range of food web components.	• Very successful in meeting the goal of preserving the food web, by providing large buffers against scientific uncertainty about ecosystem impacts. • Achieves protection of virtually all food web components and thus ecosystem function.	• Many improvements provide additional protection against uncertainty in order to achieve the goal of preserving the food web. • If implemented, this strategy is likely to provide protection to a broad range of food web components.
What is the impact of the policy on bycatch (discards) and incidental catch?	• Effective at limiting incidental catch of non-target species and reducing of bycatch. • Insufficient reporting of individual species catch, and catch in shallow water environments.	• May not be consistent with the goal of reducing and avoiding bycatch through developing practical measures that minimize bycatch.	• Likely successful at reducing prohibited species catch. • Reductions likely to be achieved through incentives for more efficient use of fishery resources under cooperatives, comprehensive rationalization of fisheries or other bycatch incentive programs.	• Bycatch and incidental catch reduction policies are effective. • Achieved through extreme reductions in target groundfish catch and strong bycatch and incidental catch limits.	• Likely successful at reducing prohibited species catch. • Reductions likely to be achieved through incentives for more efficient use of fishery resources under cooperatives, comprehensive rationalization of fisheries or other bycatch incentive programs.
What is the impact of the policy on seabird and marine mammal interactions?	• Effective at providing protection to Endangered Species Act (ESA)-listed seabirds and marine mammals. • No objectives for protecting non-listed species.	• Retains protection measures for ESA-listed species, but does not go beyond ESA-required measures. • High potential to increase fishery interactions with seabirds and marine mammals which may result in adverse impacts to those species.	• Goal of minimizing human-caused threats to protected species is largely met. • Likely to provide increased protection to marine mammals and seabirds.	• Very successful at avoiding impacts to seabirds and marine mammals. • Specific objectives to protect all seabirds from fishing interactions, and extend protection measures for Steller sea lion critical habitat and prey base.	• Effective at providing protection to ESA-listed seabirds and marine mammals. • May provide increased protection to seabirds and marine mammals if appropriate and practicable.

Key:

- Adverse impact; may include adverse conclusions that are based on assumptions.
- High potential for adverse impacts if any assumptions used to manage the resource are wrong.
- Potentially beneficial impact; assumptions used to manage the resource incorporate some precaution.
- Beneficial impact; assumptions used to manage the resource incorporate a high level of precaution.

Table ES-2 (cont.). Comparison of policy-level impacts of the alternatives.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4	PA
What is the impact of the policy on protecting marine habitat?	• Likely effective in protecting habitat components that are more well studied than others; uncertain whether sufficient protection provided to habitat components for which there is less complete information. • Concerns exist with continued reduction of long-lived slow growing benthic habitat species and reduced levels of benthic organisms in areas of high fishing intensity.	• Increased impacts to habitat because of less precautionary management measures. • Potential changes may result in adverse impacts that may be hard to reverse, especially for long-lived, slow recovering living habitats.	• Potential to reduce and avoid future impacts to habitat by careful placement of closures. • A careful strategy can minimize geographic redistribution and increases in effort, and thus reduce chances of unintended consequences.	• Combination of highly precautionary measures associated with increasing marine reserves and other closure areas will likely achieve protection of, and avoidance of impacts to, habitat. • A careful strategy can minimize geographic redistribution and increases in effort, and thus reduce chances of unintended consequences.	• Potential to reduce and avoid future impacts to habitat by careful placement of closures. • A careful strategy can minimize geographic redistribution and increases in effort, and thus reduce chances of unintended consequences.
What is the impact of the policy on the value of marine resources (commercial and non-commercial)?	• Continues to generate substantial producer and consumer benefits in the United States (U.S.), while adapting management programs when the need arises. • Continues policies that have generated environmental concerns tending to keep recreation, tourism and non-market values low.	• Potential to increase allowable catches is expected to significantly increase revenues, but would also increase operating costs. • Non-market, recreational, and tourism values are expected to decline because of the reduced emphasis on these benefits.	• Increased social and economic benefits through the elimination of the race-for-fish while also emphasizing the long-term economic value of the fishery. • Promotes ecosystem based management and is likely to increase non-commercial values assigned to the ecosystem.	• Results in substantial reductions in allowable catches and could also result in the closure of large portions of traditional fishing areas, could jeopardize the continued viability of coastal communities. • Goals of incorporating and enhancing non-consumptive use values are met.	• Increased social and economic benefits through the elimination of the race-for-fish while also emphasizing the long-term economic value of the fishery. • Considers ecosystem-based management and is unlikely to decrease non-commercial values assigned to the ecosystem.
What is the impact of the policy on Alaska Native participation in fishery management, and their traditional ways of life?	• Alaska Native consultation and participation in fishery management, and subsistence, would continue to comply with federal law.	• Alaska Native consultation and participation in fishery management, and subsistence, would continue to comply with federal law. • Increased fishing effort would result in increased economic benefits to fishery participants (particularly community development quota [CDQ]), but potentially increased salmon bycatch.	• Increase current participation and consultation in fishery management by expanding informal and formal consultation and traditional knowledge (TK) data collection. • Rationalization and additional area closures may benefit subsistence by reducing salmon bycatch.	• Directly involves Alaska Natives in fishery management through the development of co-management or cooperative research programs. • Other goals, that greatly reduce or eliminate commercial fishing, would adversely impact Native communities.	• Increase current participation and consultation in fishery management by expanding informal and formal consultation and local and Traditional Knowledge data collection. • Rationalization and additional area closures may benefit subsistence by reducing salmon bycatch.
What is the impact of the policy on data quality, monitoring, research, and enforcement requirements?	• Data collection program will continue to meet minimum acceptable standards. • Aspects of the program, such as non-random coverage in the 30% component of the fleet, could be improved.	• Maintains a minimum level of data collection to meet conservation requirements. • Consideration to repeal the Observer Program may compromise management on the best science available.	• Likely to be effective at reducing uncertainty through data collection measures, such as improved observer catch monitoring data of target and non-target species, and expanded economic reporting data.	• Expands research and monitoring programs to fill critical data gaps that may result in the modification of restrictive conservation and management measures. • Expansion of observer program coverage would result in more complete fishery data, particularly on vessels <125 ft length overall (LOA).	• Likely to be effective at reducing uncertainty through improved data collection and monitoring, promotes research to fill data gaps. • Explicitly promotes enforceability.

Key:

- Adverse impact; may include adverse conclusions that are based on assumptions.
- High potential for adverse impacts if any assumptions used to manage the resource are wrong.
- Potentially beneficial impact; assumptions used to manage the resource incorporate some precaution.
- Beneficial impact; assumptions used to manage the resource incorporate a high level of precaution.

This alternative emphasizes incremental implementation of habitat protection measures as scientific information becomes available. As a result, impacts to habitat may be alleviated, albeit slowly. This strategy is likely effective in protecting habitat components that are better-studied than others, but it is uncertain whether sufficient protection will be provided to habitat components for which there is less complete information. Cumulatively, continued adverse impacts result from historical impacts that have potentially caused long-term and possibly irreversible loss of living habitat, especially to long-lived, slow-growing species that are slow to recover.

Alternative 1 is expected to continue to provide economic and community stability within the current management system while adapting management programs when the need arises. The alternative could eliminate the race-for-fish and, by doing so, would increase net revenues to producers and provide benefits to consumers, but would create fewer, although possibly higher paying, fishery related jobs. Non-market, recreation, and tourism values could decrease in the short-term before the transition to rights-based systems is completed.

The goals and policies for Alaska Native consultation and participation in fishery management would continue at the current levels and comply with relevant EOs and other federal law. Traditional Knowledge in fishery management would continue to be incorporated in environmental documents as available and appropriate. Subsistence uses would continue consistent with federal law.

This policy will result in a data collection program that will continue to meet minimum acceptable standards for scientific management of the fisheries. Although aspects of the catch collection program could be improved, such as non-random coverage in the 30 percent component of the fleet, current practices do provide useful data for fishery management while remaining mindful of the cost burden on industry of the monitoring program.

ES 7.2.2 Summary of Alternative 2

The key policy elements that predominantly influence the impacts under Alternative 2 are: the re-setting of the OY cap to the sum of OFL or the sum of ABCs (resulting in increased yield); the absence of an objective to eliminate the race-for-fish (resulting in increased effort); the absence of objectives to maintain existing closure areas (resulting in potentially adverse impacts to areas that have been closed to fishing); and the consideration to repeal the Observer Program (resulting in less monitoring and research data.)

The impacts analysis of Alternative 2 is hampered to a certain extent by the fact that controls and restrictions on the fishery are removed under this alternative. It is more difficult to predict the impact of removing rather than imposing restrictions; consequently, the uncertainty about predicted projections of the fishery and the environment could result in an increased risk to the human environment under this alternative.

Alternative 2 would maximize economic yield while preventing overfishing of target stocks, but is not effective at preventing stocks from becoming overfished. The weaknesses of this alternative are that it increases the chance of unintentionally overfishing a stock and catch estimates may be uncertain under this alternative if the Observer Program is repealed. Also, as in Alternative 1, there is no incentive to change the management status of stocks where the impact of fishing is unknown, and it is still possible to overharvest vulnerable members of a managed stock complex.

There is a high potential to create adverse food web impacts under Alternative 2 due to its lack of precaution, which leaves no room for uncertainty. The lack of catch monitoring results in the potential for adverse food web impacts to go undetected until dramatic food web changes are seen. This alternative provides less precautionary management to many components of the food web.

Alternative 2, as illustrated in example FMP 2.1, would not be consistent with the objective of monitoring PSC, as repeal of the Observer Program would negatively impact catch monitoring. Alternative 2 policies, as illustrated by example FMP 2.2, would be less severe. As in Alternative 1, additional weaknesses of the alternative are that bycatch is often reported as a complex rather than as individual species, and the absence of observer monitoring of catch on vessels less than 60 ft LOA may result in inaccurate estimates of bycatch. Therefore Alternative 2 may not provide adequate protection for non-target species.

Alternative 2 retains seabird and marine mammal protection measures for ESA-listed species, but does not go beyond ESA-required protection measures. Additionally, other goals and objectives under this alternative remove management measures currently in place in the baseline. The more aggressive harvesting policy, the relaxation of area closures, and the possible repeal of the Observer Program create a high potential to increase fishery interactions with seabirds and marine mammals that may result in adverse impacts to those species.

The alternative could result in increased impacts to habitat because of less precautionary management measures. Possible elimination of current closed areas and increases in TAC have the potential to result in adverse impacts to habitat that could be hard to reverse, especially for long-lived, slow recovering, living habitats. The policy goal of developing practical measures to minimize adverse effects to EFH could be difficult to achieve if such irreversible impacts occur.

Alternative 2 has the potential to increase allowable catches to maximum biological levels and could eliminate the cushion between ABC levels and levels that result in OFLs. This alternative is expected to significantly increase revenues but would also increase operating costs with the elimination of the LLP and IFQ programs. While fishery production is maximized, product quality and the health and safety of participants suffer. Of particular importance may be the amount of variability in harvests, which could increase significantly and therefore make it much more difficult to make long-term business and infrastructure decisions. Finally, non-market, recreation, and tourism values that accrue to the ecosystem could be reduced substantially.

As in Alternative 1, the goals and policies for Alaska Native consultation and participation in fishery management under Alternative 2 would continue at the current levels and comply with relevant EOs and other federal law. Traditional Knowledge in fishery management would continue to be incorporated in environmental documents as available and appropriate. Subsistence uses would continue consistent with federal law. Other goals and objectives in Alternative 2 would affect Alaska Natives by the increase in economic benefits accruing to participants in the fishery, particularly the CDQ pollock fishery. The increased fishing effort under this alternative may, however, result in increased salmon bycatch, which could have adverse effects on salmon fisheries particularly in the western Alaska Yukon-Kuskokwim river system.

Alternative 2 objectives maintain a minimum level of data collection to meet conservation requirements. The consideration to repeal the Observer Program may compromise management of the best science available as a result of reduced accuracy and breadth of fishery data. Because the presumed risk of adversely impacting the environment is assumed to be low in this alternative, the costs to industry of funding the Observer Program to gather fishery data may not be considered necessary.

ES 7.2.3 Summary of Alternative 3

The key policy elements that predominantly influence the impacts under Alternative 3 are: the emphasis on rationalizing the fisheries (resulting in increased efficiency and flexibility); the incorporation of ecosystem considerations (increasing the uncertainty buffers in management accounting); and the likelihood of additional closure areas (which may result in a variety of impacts, depending how the closures are situated).

Predictions about the impacts under this alternative are difficult due to the uncertainty involved in defining ecosystem management and predicting the impacts of protecting areas. Increased emphasis on relatively less abundant species, through protection measures and increased monitoring, indicates a tendency towards ecosystem management but as the implications of such management are uncertain, the tendency is to tread cautiously while accelerating research and data-gathering. The large potential gain in flexibility from rationalization has the potential to create ecosystem benefits.

Alternative 3 prevents overfishing of target stocks and reduces the likelihood that stocks will become overfished, through precautionary harvest policies and imposition of rebuilding regulations when stocks fall below the level capable of producing maximum sustainable yield (MSY). This alternative would formally define criteria for determining the status of stocks relative to an overfished condition in order to better satisfy the requirements of the National Standard 1 guidelines. Efforts would be accelerated to identify methods for reducing the number of stocks where the status relative to an overfished condition is unknown.

This alternative is successful in making many improvements relative to the baseline in achieving the goal of preserving the food web. The emphasis of this alternative is not only on using the best scientific information available to determine catch levels but also on providing additional protection against uncertainty by designation of MPAs and marine reserves. If these improvements are implemented, this strategy is likely to provide protection to a broad range of food web components.

The bycatch and incidental catch reduction policies in Alternative 3 are consistent with accelerating precautionary management measures through additional bycatch constraints and monitoring. Bycatch reduction objectives and reductions in incidental catch are likely to be achieved without a major cost to industry due to the incentives for more efficient use of fishery resources under cooperatives, comprehensive rationalization of fisheries, or other bycatch incentive programs implemented under this alternative.

The goal of minimizing human-caused threats to protected species is largely met in this alternative by actively adjusting protection measures, actively reviewing the status of marine mammal fishery interactions, and through research. This approach, which may provide additional conservation measures in response to scientific evidence, is likely to provide increased protection to marine mammals and seabirds.

This alternative has a potential to reduce and avoid impacts to habitat by careful placement of closures. Placement of closures in lightly fished areas or areas not fished at all could result in avoidance of future habitat impacts if fisheries were to move effort into surrounding areas. Placement of closures in heavily fished areas can mitigate impacts, reduce unintended consequences, and achieve overall benefits to habitat if closures do not encompass entire habitat types or areas of fishing intensity. In the short-term, information from the Observer Program could be used to locate such closures. In the long-term, scientific information gained from this policy can potentially lead to modification of the placement of MPAs and help meet the policy objective to assess the necessary and appropriate habitat protection measures. Cumulatively, the alternative results in a split impact rating, as the adverse condition of the habitat baseline is coupled with continued damage and mortality to living habitat; however, the alternative has strong potential to mitigate these adverse impacts.

Alternative 3 promotes increased social and economic benefits through the elimination of the race-for-fish while also emphasizing the long-term economic value of the fishery through the promotion of rights-based allocations to individuals, sectors, and communities. In addition, this alternative promotes ecosystem-based management and is likely to increase non-market, recreational, and tourism values assigned to the ecosystem. It is not possible to determine the long-term effect on overall benefits (commercial and non-market values combined) because it is not known whether the fishing sectors, even with rights-based allocations, will be able to adapt to the changes resulting from the increased emphasis on ecosystem tools and, in particular, the additional number and significance of closed areas.

The goals and policies for Alaska Native consultation and participation in fishery management under Alternative 3 would increase current levels by expanding informal and formal consultation between the NPFMC and NOAA Fisheries and Alaska Native participants and tribal governments. Traditional Knowledge would be more formally incorporated in fishery management and additional data would be collected. Other goals and objectives in Alternative 3, such as reductions in PSC limits, may benefit subsistence salmon use by reducing bycatch levels in the groundfish fisheries.

Through data collection measures that will result in reducing uncertainty, Alternative 3 is likely to be effective in achieving the goal of accelerating the use of precautionary management measures. The objectives to improve the Observer Program and observer data will increase the quality of fishery data by implementing increased flexibility of, and potentially expanding, observer coverage. Additionally, the expanded economic data and potential for independent verification would allow for more accurate and credible economic impact assessments. A funding source would, however, need to be identified to implement improvements to these programs.

ES 7.2.4 Summary of Alternative 4

The key policy element that influences impacts under Alternative 4 is the shift of the burden of proof to the user of the resource to demonstrate that the intended use will not have a detrimental effect on the environment. Such a formal policy would raise the standard of justification required for fishery management actions. Key management objectives that implement this approach are: reduce the ABCs, and in turn the TACs, or consider temporarily suspending the fisheries to account for uncertainty; institute extensive closure areas (resulting in the closure of traditional fishing areas and an increased emphasis on non-consumptive values); phase out fisheries with greater than 25 percent incidental catch and bycatch rates; develop a

Fisheries Ecosystem Plan; and increase data collection and monitoring (in order to fill in data gaps and adjust restrictive measures as appropriate).

Predictions about the impacts under this alternative are difficult due to the uncertainty involved in defining ecosystem management and predicting the impacts of protecting areas. The emphasis is on instituting protective measures, particularly focusing on less abundant or economically valuable species, while at the same time imposing extensive monitoring and data-gathering to increase understanding of fishery impacts.

Alternative 4 establishes a very conservative harvest policy which is likely to prevent overfishing of target stocks and reduce the chance that stocks would become overfished. Constraints to commercial harvest coupled with systems of closed areas would effectively reduce impacts from the race for fish and therefore from spatial and temporal concentration of catch. Catch monitoring would also increase under this alternative, resulting in more complete fisheries data. As with Alternative 3, this alternative would define criteria for determining the status of all managed stocks relative to an overfished condition in order to better satisfy the requirements of the National Standard 1 Guidelines. In the long term, this alternative would protect the most vulnerable species of the complex, but the resulting management of many stocks with low biomass would be difficult to implement.

This alternative is very successful in meeting the goal of preserving the food web, by providing large buffers against scientific uncertainty about ecosystem impacts resulting from fishing. The assumption that the present level of scientific information is insufficient to manage fisheries without excessive risk to the ecosystem results in the implementation of highly precautionary measures. This strategy provides improvements over the baseline and achieves protection of virtually all food web components and thus ecosystem functions. Although the alternative is successful in producing a food web that is less influenced by fishing activity, predictions about the abundance changes of individual food web components that might result are uncertain due to the difficulty in accurately predicting predator-prey relationships.

The bycatch and incidental catch reduction policies under Alternative 4 are effective. Reduced bycatch and incidental catch would be achieved through extreme reductions in target groundfish catch and strong bycatch and incidental catch limits.

Alternative 4 is very successful at avoiding impacts to seabirds and marine mammals through its specific objectives to protect all seabirds from fishing interactions, and extending protection measures for Steller sea lion critical habitat and prey base. This increased level of protection provides a substantial buffer against uncertainty with regards to protection of marine mammals and seabirds.

The emphasis of the Alternative 4 policy on habitat provides large buffers against scientific uncertainty about the impacts of fishing on habitat. The combination of highly precautionary measures associated with increasing marine reserves and other closure areas will likely achieve protection and avoidance of impacts to habitat. Cumulatively, the alternative has a split rating, as the existing adverse condition of the baseline includes damage to slow-growing species unlikely to recover within the time period predicted in this analysis, while providing strong protection for habitat and potential for mitigation.

The Alternative 4 goals of incorporating and enhancing non-consumptive use values are met but at the expense of commercial value and potentially the continued viability of coastal communities. The precautionary policies in Alternative 4 could result in substantial reductions in allowable catch and could also result in the closure of large portions of traditional fishing areas. The alternative is likely to result in a substantial increase in the non-market values of the ecosystem, but may also result in a substantial decrease in efficiency, net revenues, and the number of participants in the fisheries.

Alternative 4 would directly involve Alaska Natives in fishery management through the development of co-management or cooperative research programs. Consultation and participation objectives would focus on subsistence uses and cultural values of living marine resources. However, other goals and objectives in Alternative 4, that greatly reduce or eliminate commercial fishing, would adversely impact Native communities, including CDQ communities, through the loss of employment, economic activity, and community revenues.

Alternative 4 expands research and monitoring programs to obtain information necessary to fulfill the requirements of this alternative. The policy objectives are successful in increasing fisheries data by expanding the Observer Program to full coverage for vessels over 60 ft LOA, and instituting 30 percent coverage on smaller boats. Additionally, the requirements to improve the accuracy of data through technological means such as at-sea scales and VMS will improve monitoring and enforcement under this alternative.

Because of these described effects, NOAA Fisheries has identified Alternative 4 as the environmentally preferable alternative since it would result in the least impact to the physical and biological environment. NEPA requires the Agency to identify such an alternative from among those analyzed fully in the Programmatic SEIS. NEPA does not require the Agency to select the environmentally preferable alternative as its PA. Should it choose not to do so, the Agency must explain why it chose a different alternative as its PA in its Record of Decision.

ES 8.0 The Preferred Alternative and Summary of its Environmental Consequences

The PA for the management policy to govern the BSAI and GOA groundfish fisheries was recommended by the NPFMC after careful consideration of public comments and the analyses of the alternatives in the PSEIS. NOAA Fisheries received more than 13,400 comments during the review period on the revised 2003 Draft Programmatic SEIS, which are synthesized and responded to in Appendix G. The analyses in the PSEIS are based on the best scientific information available. The PA is based on the policy goals and objectives described under Alternative 3, with refinements incorporated from both Alternatives 1 and 4 as well as suggestions taken from public comments. NOAA Fisheries has reviewed the NPFMC recommendation, and has endorsed it as the Agency's PA.

The management approach and the objectives in the PA reflect a conservative, precautionary approach to ecosystem-based fisheries management, and communicate a policy direction for the future. The PA is a realistic and responsible approach that addresses and complies with the various goals, objectives and requirements of the MSA and other applicable law. The policy elements contained in the PA are consistent with, and also achieve a reasonable balance between the competing interests reflected in, the National Standards. The PA continues the commitment by the NPFMC and NOAA Fisheries' to prevent overfishing and, to the extent practicable, protect seabirds and marine mammals and reduce bycatch and habitat impacts. The PA incorporates ecosystem-based management principles into a management approach that recognizes the need to both promote sustainable fisheries and protect fishery-dependent communities. It also retains the strong role of science in fishery management, and fosters a transparent and effective regulatory process where all stakeholders have a meaningful role. The PA is an adaptive management policy which will guide and inform fisheries management decisions made by the NPFMC and NOAA Fisheries. The adaptive nature of the PA also gives the NPFMC and NOAA Fisheries the flexibility to modify policy elements in response to new information or changing circumstances in order to continue to adequately manage the fisheries.

ES 8.1 The North Pacific Fishery Management Council's Recommended Preferred Alternative

The management policy of the PA is included below. The objectives of the PA are also summarized in Table ES-1.

Management Approach

The productivity of the North Pacific ecosystem is acknowledged to be among the highest in the world. For the past 25 years, the NPFMC management approach has incorporated forward looking conservation measures that address differing levels of uncertainty. This management approach has, in recent years, been labeled the p precautionary approach. The NPFMC's precautionary approach is about applying judicious and responsible fisheries management practices, based on sound scientific research and analysis, proactively rather than reactively, to ensure the sustainability of fishery resources and associated ecosystems for the benefit of future as well as current generations. Recognizing that potential changes in productivity may be caused by fluctuations in natural oceanographic conditions, fisheries, and other, non-fishing, activities, the NPFMC intends to continue to take appropriate measures to insure the continued sustainability of the managed species. It will carry out this objective by considering reasonable, adaptive management measures as described in the MSA and in conformance with the National Standards, the Endangered Species Act, the National Environmental Policy Act and other applicable law. This management approach takes into account the National Academy of Science's recommendations on Sustainable Fisheries Policy.

As part of its policy, the NPFMC intends to consider and adopt, as appropriate, measures that accelerate the NPFMC's precautionary, adaptive management approach through community or rights-based management, ecosystem-based management principles that protect managed species from overfishing, and where appropriate and practicable, increase habitat protection and bycatch constraints. All management measures will be based on the best scientific information available. Given this intent, the fishery management goal is to provide sound conservation of the living marine resources; provide socially and economically viable fisheries and fishing communities; minimize human-caused threats to protected species; maintain a healthy marine resource habitat; and incorporate ecosystem-based considerations into management decisions.
This management approach recognizes the need to balance many competing uses of marine resources and different social and economic goals for sustainable fishery management including protection of the long-term health of the resource and the optimization of yield. This policy will utilize and improve upon the NPFMC's existing open and transparent process to involve the public in decision-making.

Adaptive management requires regular and periodic review. Objectives identified in this policy statement will be reviewed annually by the NPFMC. The NPFMC will also review, modify, eliminate or consider new issues as appropriate to best carry out the goals and objectives of this management policy. To meet the goals of this overall management approach, the NPFMC and NOAA Fisheries will use the PSEIS as a planning document. To help focus its consideration of potential management measures, it will use the following objectives as guideposts to be re-evaluated as amendments to the FMP are considered over the life of the PSEIS.

Prevent Overfishing:

1. Adopt conservative harvest levels for multi-species and single species fisheries and specify optimum yield.

2. Continue to use existing optimum yield cap for BSAI (as stated in current law) and GOA groundfish fisheries.

3. Provide for adaptive management by continuing to specify optimum yield as a range.

4. Initiate a scientific review of the adequacy of F40 and adopt improvements as appropriate.

5. Continue to improve the management of species through species categories.

Promote Sustainable Fisheries and Communities:

6. Promote conservation while providing for optimum yield in terms of providing the greatest overall benefit to the nation with particular reference to food production, and sustainable opportunities for recreational, subsistence and commercial fishing participants and fishing communities.

7. Promote management measures that, while meeting conservation objectives, are also designed to avoid significant disruption of existing social and economic structures.

8. Promote fair and equitable allocation of identified available resources in a manner such that no particular sector, group or entity acquires an excessive share of the privileges.

9. Promote increased safety at sea.

Preserve Food Web:

10. Develop indices of ecosystem health as targets for management.

11. Improve the procedure to adjust ABCs as necessary to account for uncertainty and ecosystem factors.

12. Continue to protect the integrity of the food web through limits on harvest of forage species.

13. Incorporate ecosystem-based considerations into fishery management decisions as appropriate.

Manage Incidental Catch and Reduce Bycatch and Waste:

14. Continue and improve current incidental catch and bycatch management program.

15. Develop incentive programs for bycatch reduction including the development of mechanisms to facilitate the formation of bycatch pools, VBAs, or other bycatch incentive systems.

16. Encourage research programs to evaluate current population estimates for non-target species with a view to setting appropriate bycatch limits as information becomes available.

17. Continue program to reduce discards by developing management measures that encourage the use of gear and fishing techniques that reduce bycatch which includes economic discards.

18. Continue to manage incidental catch and bycatch through seasonal distribution of TAC and geographical gear restrictions.

19. Continue to account for bycatch mortality in TAC accounting and improve the accuracy of mortality assessments for target, PSC bycatch, and non-commercial species.

20. Control the bycatch of prohibited species through PSC limits or other appropriate measures.

21. Reduce waste to biologically and socially acceptable levels.

Avoid Impacts to Seabirds and Marine Mammals:

22. Continue to cooperate with USFWS to protect ESA-listed species, and if appropriate and practicable, other seabird species.

23. Maintain or adjust current protection measures as appropriate to avoid jeopardy to ESA-listed Steller sea lions.

24. Encourage programs to review status of endangered or threatened marine mammal stocks and fishing interactions and develop fishery management measures as appropriate.

25. Continue to cooperate with NOAA Fisheries and USFWS to protect ESA-listed marine mammal species, and if appropriate and practicable, other marine mammal species.

Reduce and Avoid Impacts to Habitat:

26. Review and evaluate efficacy of existing habitat protection measures for managed species.

27. Identify and designate EFH and HAPC pursuant toMSA rules, and mitigate fishery impacts as necessary and practicable to continue the sustainability of managed species.

28. Develop a Marine Protected Area policy in coordination with national and state policies.

29. Encourage development of a research program to identify regional baseline habitat information and mapping, subject to funding and staff availability.

30. Develop goals, objectives and criteria to evaluate the efficacy and suitable design of marine protected areas and no-take marine reserves as tools to maintain abundance, diversity, and productivity. Implement marine protected areas if and where appropriate.

Promote Equitable and Efficient Use of Fishery Resources:

31. Provide economic and community stability to harvesting and processing sectors through fair allocation of fishery resources.

32. Maintain LLP program and modify as necessary, and further decrease excess fishing capacity and overcapitalization by eliminating latent licences and extending programs such as community or rights-based management to some or all groundfish fisheries.

33. Provide for adaptive management by periodically evaluating the effectiveness of rationalization programs and the allocation of access rights based on performance.

34. Develop management measures that, when practicable, consider the efficient use of fishery resources taking into account the interest of harvesters, processors, and communities.

Increase Alaska Native Consultation:

35. Continue to incorporate local and Traditional Knowledge in fishery management.

36. Consider ways to enhance collection of local and Traditional Knowledge from communities, and incorporate such knowledge in fishery management where appropriate.

37. Increase Alaska Native participation and consultation in fishery management.

Improve Data Quality, Monitoring and Enforcement:

38. Increase the utility of groundfish fishery observer data for the conservation and management of living marine resources.

39. Improve groundfish Observer Program, and consider ways to address the disproportionate costs associated with the current funding mechanism.

40. Improve community and regional economic impact costs and benefits through increased data reporting requirements.

41. Increase the quality of monitoring and enforcement data through improved technological means.

42. Encourage a coordinated, long-term ecosystem monitoring program to collect baseline information and compile existing information from a variety of ongoing research initiatives, subject to funding and staff availability.

43. Cooperate with research institutions such as the NPRB in identifying research needs to address pressing fishery issues.

44. Promote enhanced enforceability.

45. Continue to cooperate and coordinate management and enforcement programs with the ADF&G, and Alaska Fish and Wildlife Protection, the USCG, NOAA Fisheries Enforcement, IPHC, federal agencies, and other organizations to meet conservation requirements; promote economically healthy and sustainable fisheries and fishing communities; and maximize efficiencies in management and enforcement programs through continued consultation, coordination, and cooperation.

ES 8.2 Example FMP Bookends for the Preferred Alternative

The example FMP bookends PA.1 and PA.2 serve to illustrate management concepts and future actions that logically flow from the PA management policy and provide sufficient detail to allow for focused analysis of their environmental consequences. The example FMP bookends are described below.

Example FMP PA.1

Example FMP PA.1 illustrates a conservative management approach that continues current risk-averse practices, increases conservation-oriented constraints on the fisheries as appropriate, formalizes precautionary practices in the FMPs, and initiates scientific review of existing practices in order to assess and improve fishery management.

FMP PA.1 builds on the existing conservative procedure for determining ABC, annual quotas, and the existing suite of closed areas (Figure ES-2). The example FMP implements changes to the TAC-setting process following a comprehensive review. Precautionary practices such as setting TAC less than or equal to the ABC, and specifying MSSTs for Tiers 1-3 in accordance with National Standard Guidelines, would be formalized in the FMP. The NPFMC and NOAA Fisheries would continue to use and improve harvest control rules to maintain a spawning stock biomass with the potential to produce sustained yields on a continuing basis, and to distribute allocations by area, season, and gear as appropriate. Efforts to develop ecosystem indicators to be used in TAC-setting, as per ecosystem management principles, would be continued.

In order to balance the needs of social and economic stability with habitat protection and resource conservation, the NPFMC and NOAA Fisheries would develop a Marine Protected Area (MPA) efficacy methodology, including the development of definitions, program goals, objectives, and criteria for establishing MPAs. Additionally, the existing habitat and bycatch area restrictions would be maintained. Measures are also retained to protect ESA-listed species. To minimize bycatch, a moderate reduction of PSC limits in the BSAI will be initiated, and PSC limits or other appropriate measures for protection of crab, herring and salmon would be authorized in the GOA. Effective monitoring and timely reaction to change in the environment and the fisheries would be enhanced through improvements in the Observer Program and existing reporting requirements.

Existing programs addressing excess capacity and overcapitalization are maintained under this example FMP, with continued development of rights-based management to be undertaken as needed. In order to mitigate adverse impacts of fisheries management decisions on fishing communities, and to comply with other national directives, procedures to encourage increased participation of Alaska Natives in fishery management, would be pursued.

Example FMP PA.2

FMP PA.2 accelerates adaptive precautionary management by increasing conservation measures that provide a buffer against uncertainty, instituting research and review of existing measures, and expanding data collection and monitoring programs.

FMP PA.2 significantly accelerates precautionary management by incorporating an uncertainty correction into the estimation of ABC for all species. The current precautionary practice of setting TAC less than or equal to ABC would be formalized in the FMP. The calculation of the OY caps would be periodically reviewed to determine their relevancy to current environmental conditions and stock levels. Example FMP PA.2 would also develop and implement criteria for using key ecosystem indicators in TAC-setting, and other precautionary practices such as developing appropriate harvest strategies for rockfish stocks. In implementing this bookend, data would be collected and analysis undertaken to allow the specification of MSSTs for Figure ES-2 (FMP PA.1 map) priority stocks in Tiers 4-5. The development of criteria to manage target and non-target species consistently, and for removing some stocks from the other species and non-specified species management categories, would initially consider breaking sharks out of the other species category for TAC-setting and management purposes in the BSAI, as well as consider breaking sharks and skates out of the other species category in the GOA.

FMP PA.2 also reexamines area restrictions in the BSAI and the GOA by reviewing the existing system of closure areas in the BSAI and the GOA (Figure ES-3 and Section 4.2.3), and evaluating them in conjunction with developing MPAs. PA.2 considers adopting MPAs, with a guideline of 0 to 20 percent of the EEZ (3 to 200 nm) to be closed. The objective of these measures is to provide greater protection to a full range of marine habitats within the 1,000-m bathymetric line (Figure ES-3). This area would incorporate an Aleutian Islands management area to protect coral and living bottom habitat, and also any modification to the 2002 Steller sea lion closures. The closed area may also mitigate adverse effects that occur due to fishing. The guideline aims to provide greater protection for a wide range of species, from Steller sea lions to slope rockfish to prohibited species, while at the same time respecting traditional fishing grounds and maintaining open area access for coastal communities. Additionally, the bookend would extend the existing BSAI bottom-trawl ban on pollock to the GOA.

To increase precaution regarding bycatch, existing PSC limits would be reduced, and limits would be set for all prohibited species in the GOA, with appropriate in-season closure areas. The achievement of these bycatch reductions is expected to be realized through the comprehensive rationalization of all fisheries (except those already part of a cooperative or IFQ program), which reduces concentrated effort in the fisheries, or through bycatch incentive programs implemented in this example FMP.

In accordance with ecosystem principles, the NPFMC and NOAA Fisheries would seek to cooperate with USFWS to develop fishing methods that reduce incidental take of all seabird and marine mammal species in the longline and trawl fisheries. Procedures would also be pursued to increase consultation with and representation of Alaska Natives in fishery management by incorporating local and Traditional Knowledge. Increases in observer coverage and improvements to the observer data that is collected would enhance effective monitoring and timely reaction to change in the environment and the fisheries. Additionally, the bookend explores programs that would expand the mandatory economic data collected from industry while protecting confidentiality.

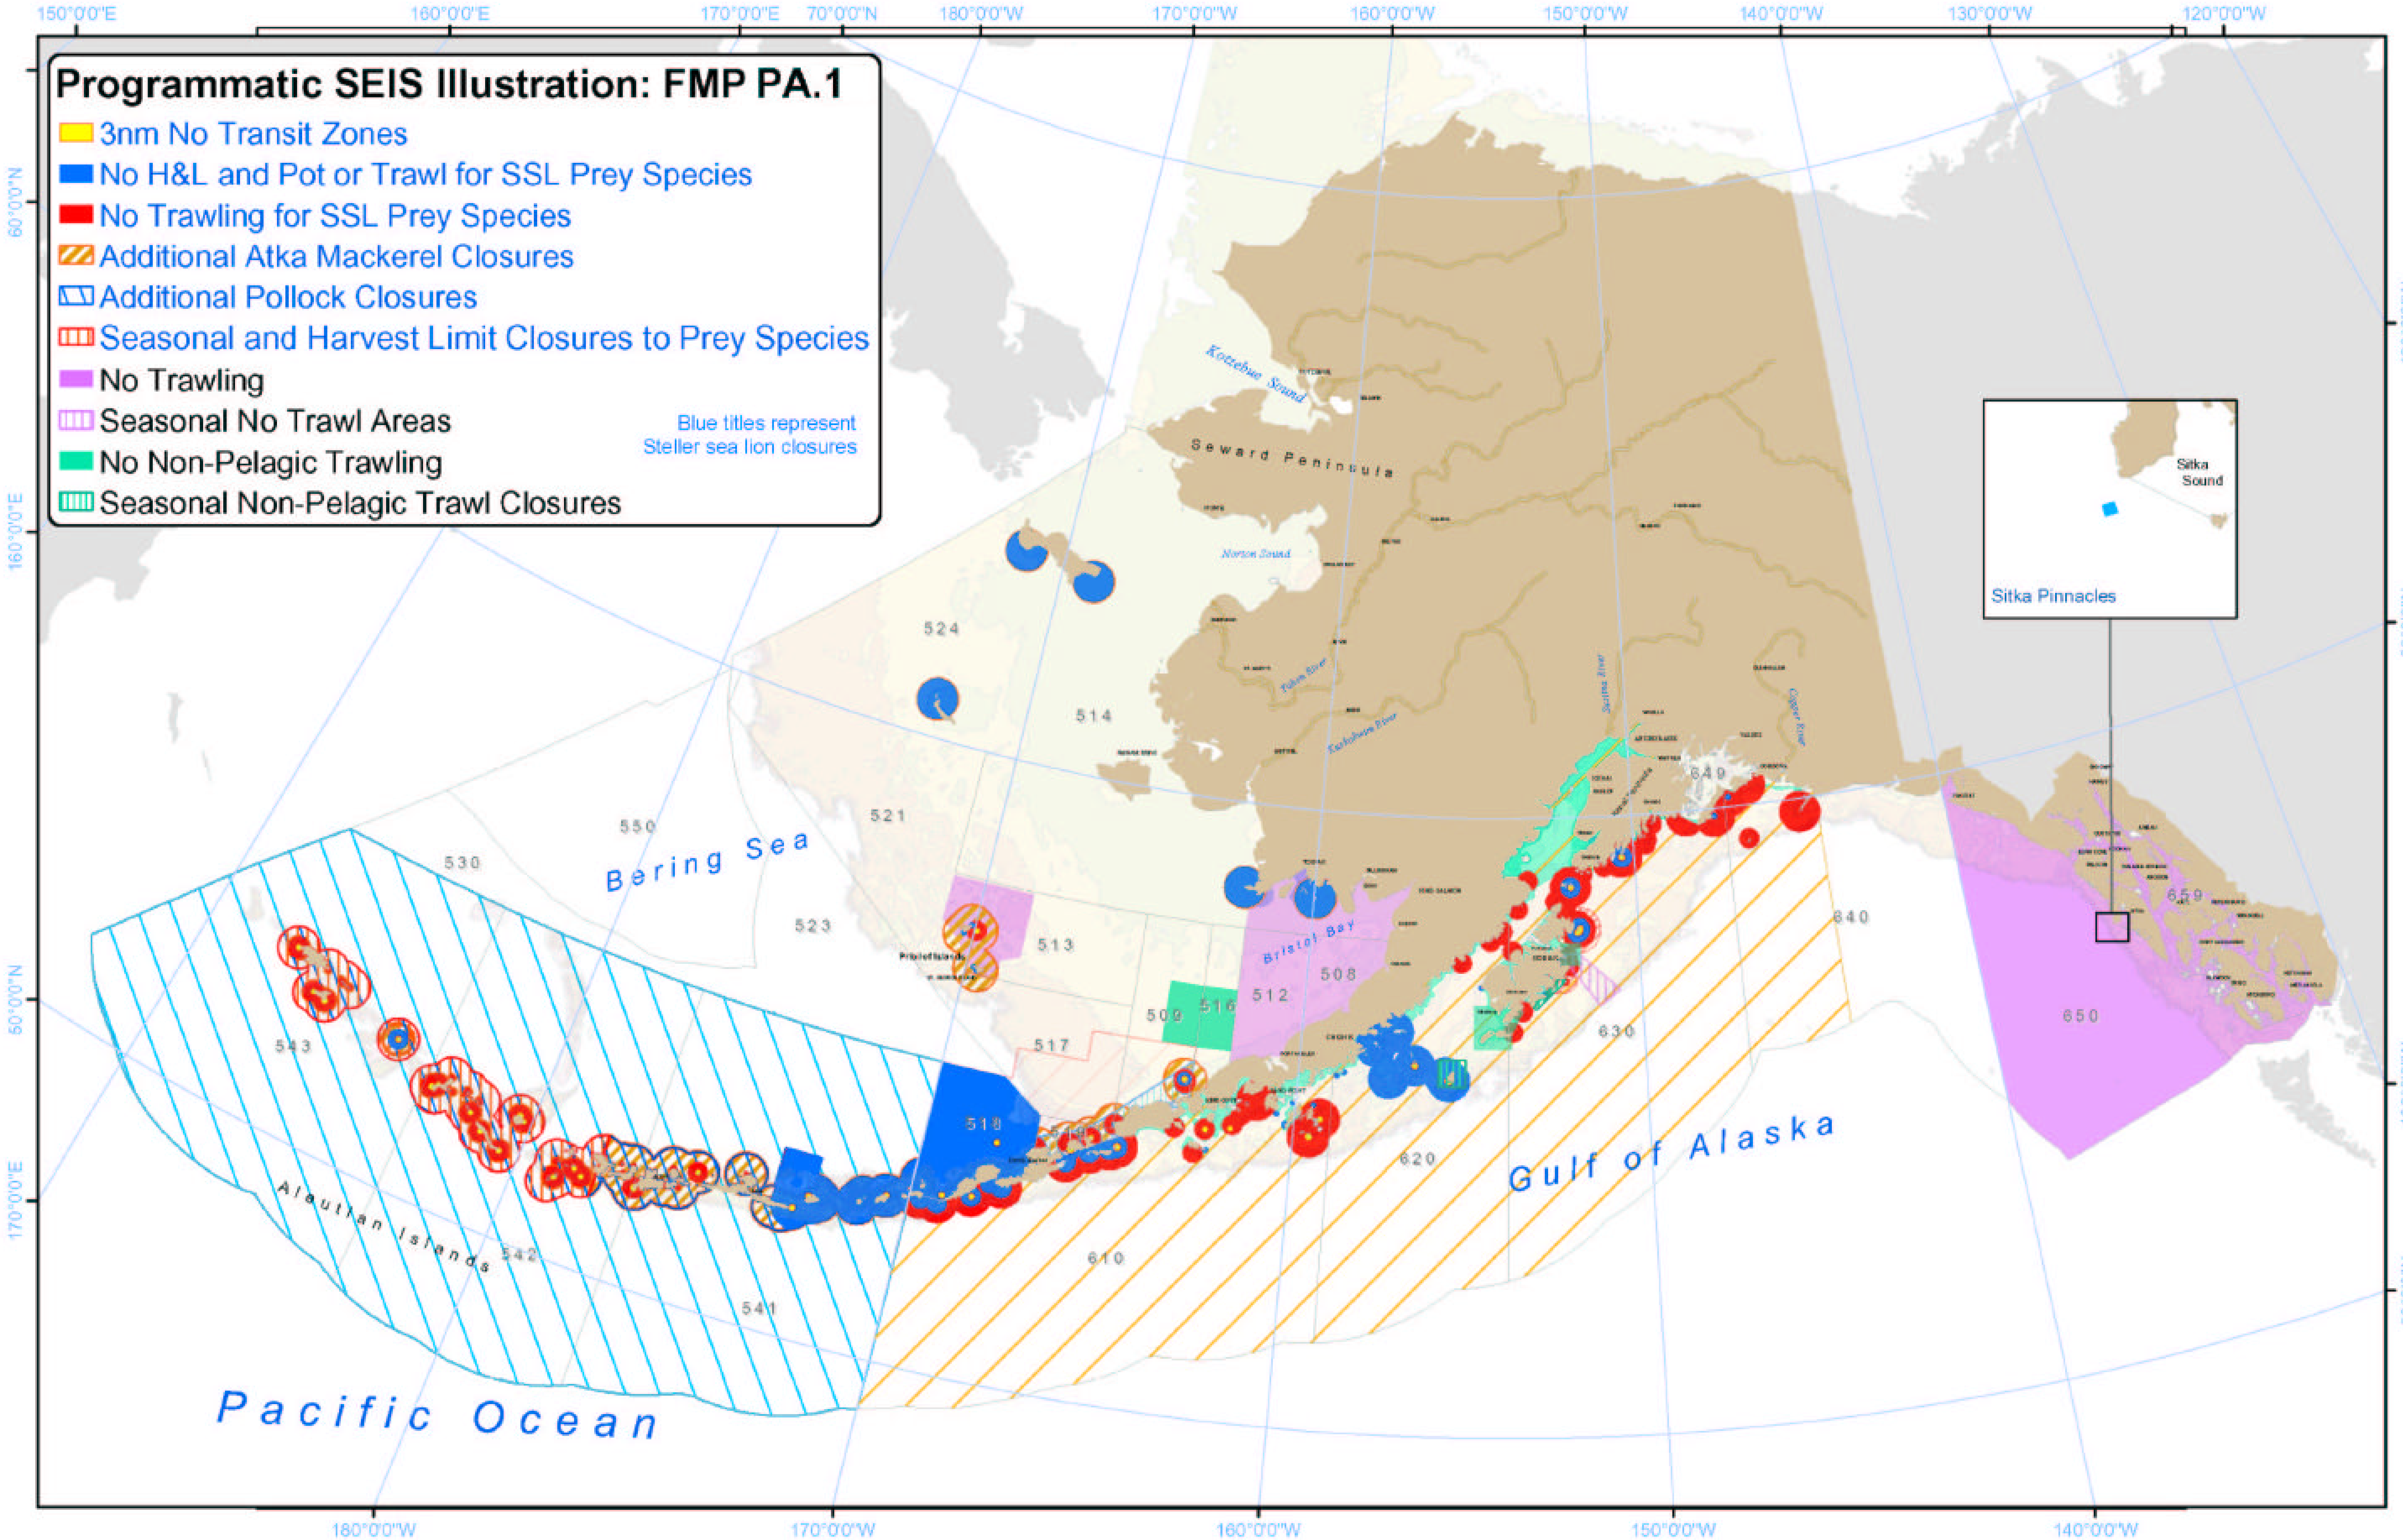

Figure ES-2. Programmatic Supplemental Environmental Impact Statement illustration of closure areas included in Preferred Alternative FMP PA.1.

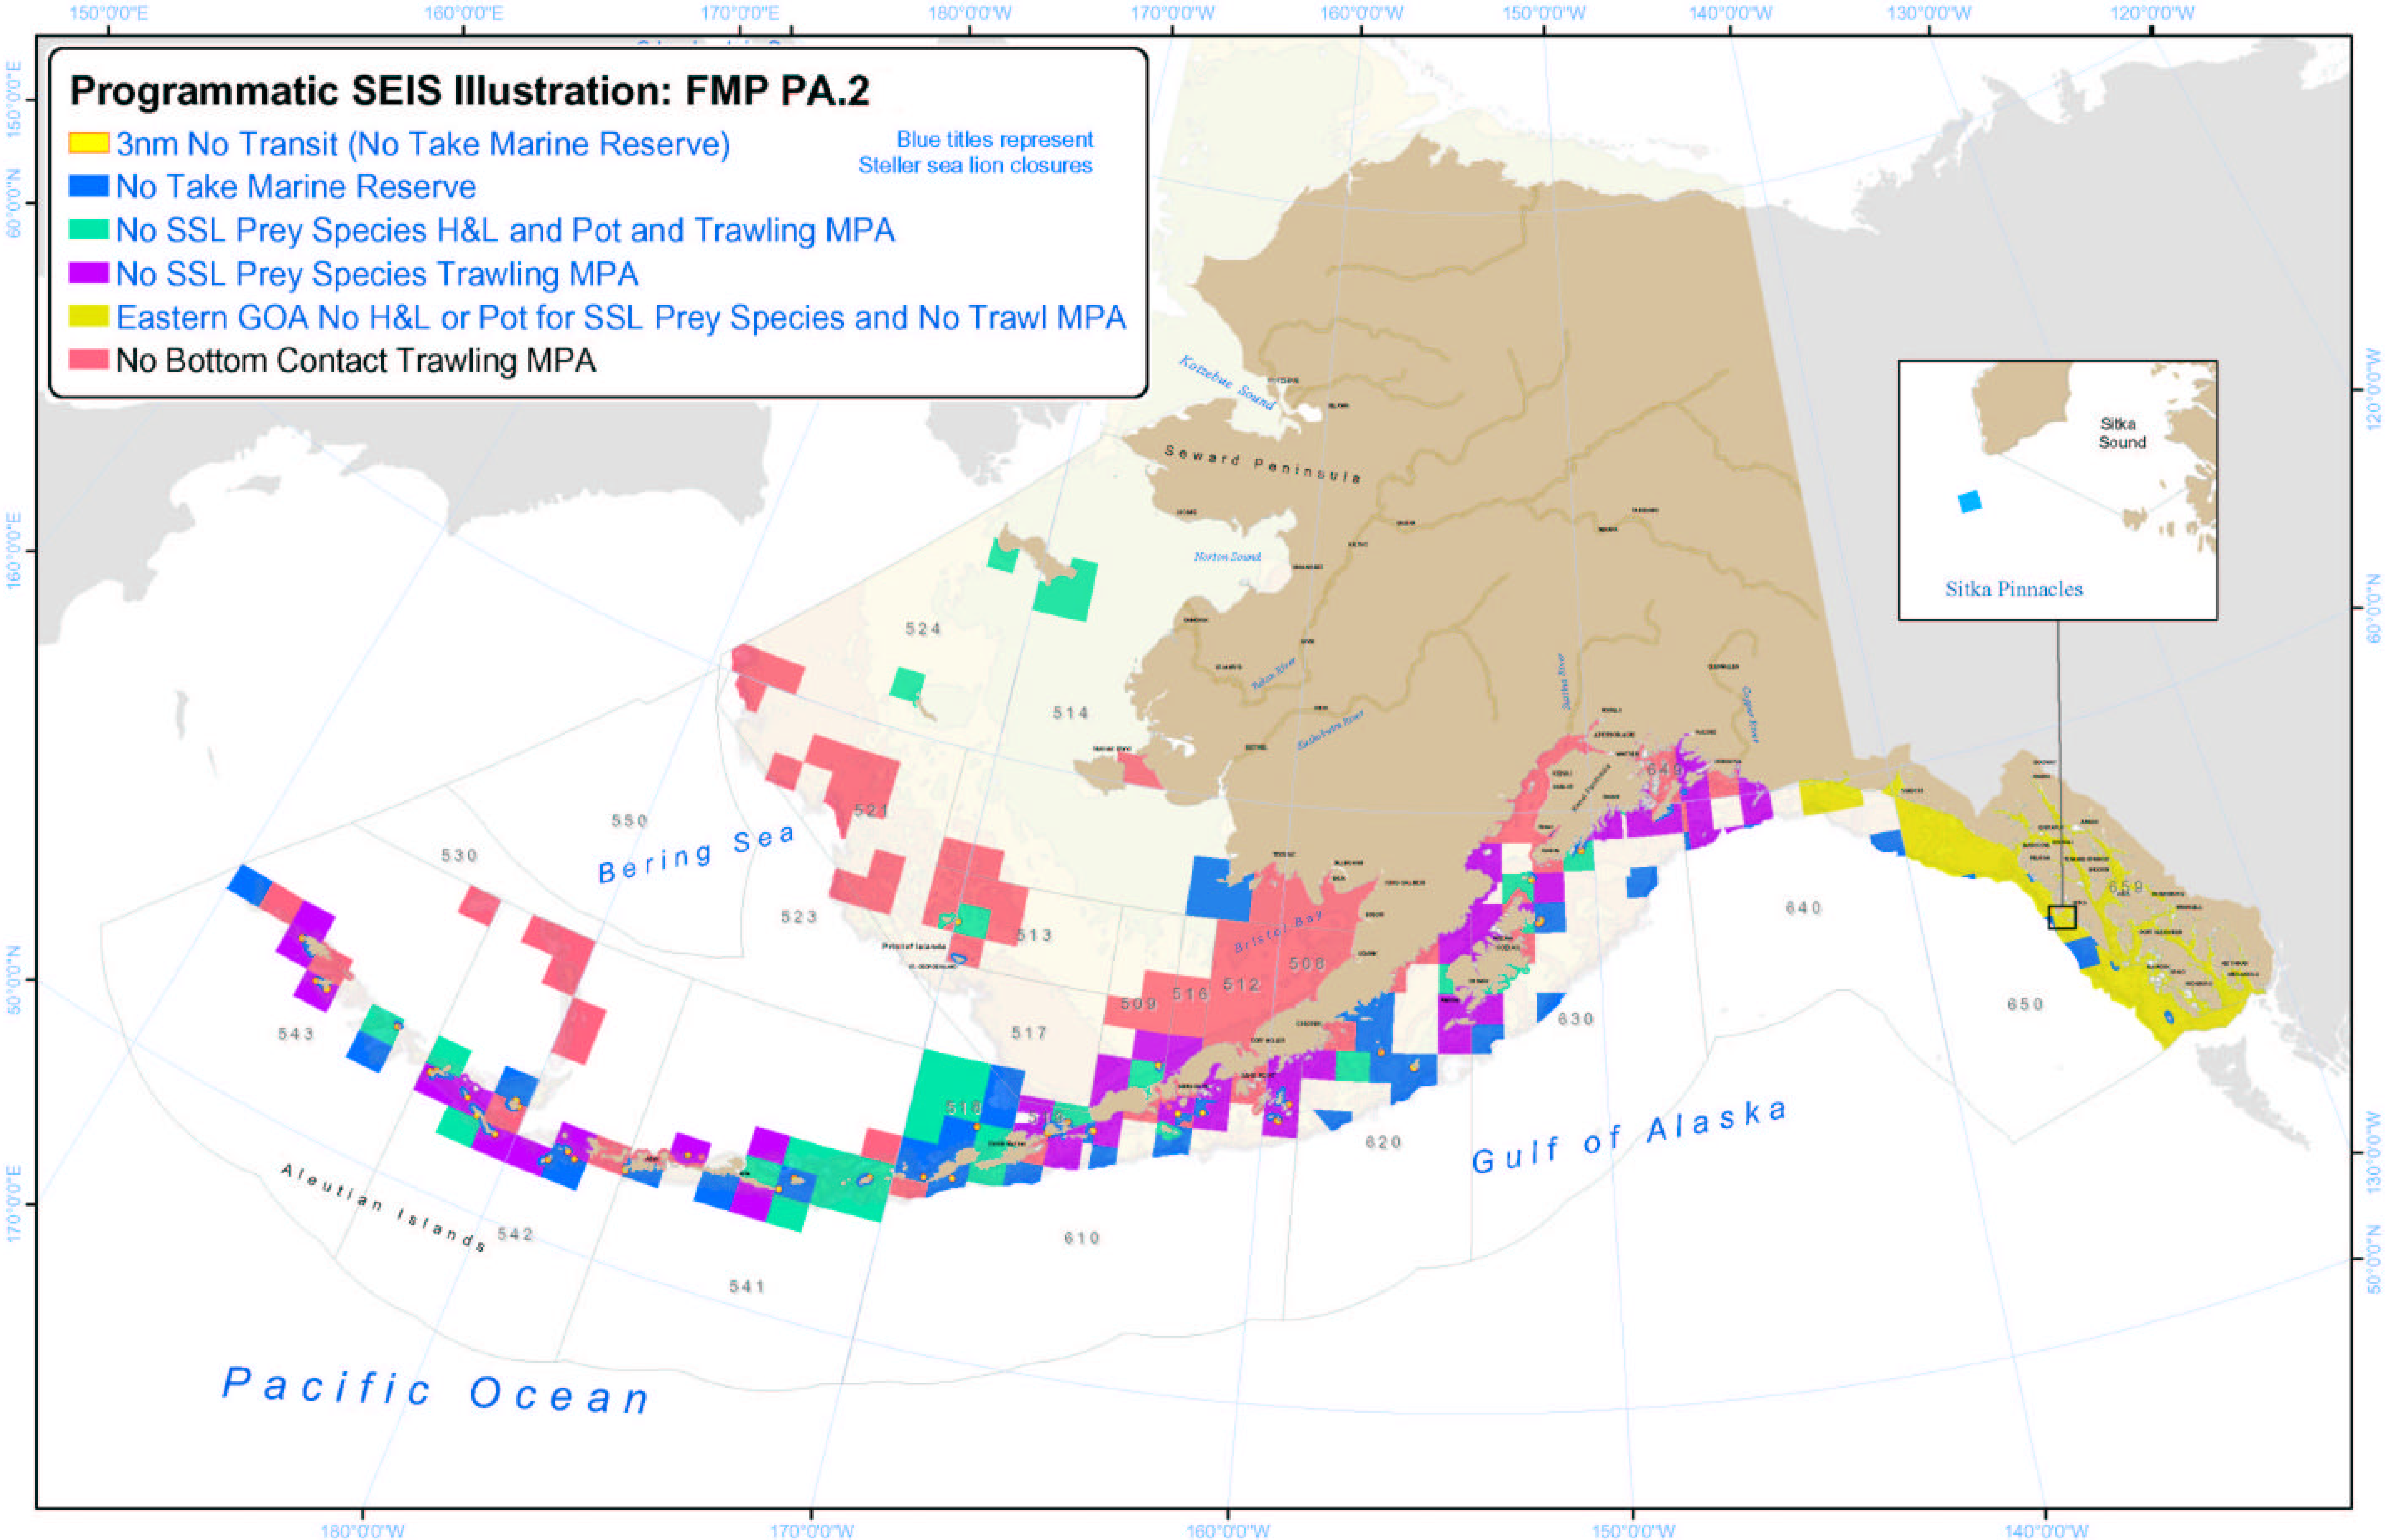

Figure ES-3. Programmatic Supplemental Environmental Impact Statement illustration of closure areas included in Preferred Alternative FMP PA.2.

ES 8.3 Summary of Environmental Consequences of the Preferred Alternative

This section contains a summary of the environmental consequences of the PA at the policy-level. Table ES-2 presents the information summarized below in table format, and uses a color key to indicate the direction of the effects associated with each alternative. The intent of the summary, and Table ES-2, is to provide a broad, policy-level understanding of the general impacts of the alternatives, including the PA. The analysis deals with effects at the population or fishery level, rather than calling out impacts to individual components (a more detailed analysis of the example FMP bookends provides the basis for this policy-level analysis). For more information on the structure of the table and the color key, see the description in Section ES 7.2.

The key policy elements that predominantly influence the impacts under the PA are: the emphasis on rationalizing the fisheries (resulting in increased efficiency and flexibility); the incorporation of ecosystem considerations (increasing the uncertainty buffers in management accounting); and the likelihood of additional closure areas (which may result in a variety of impacts, depending how the closures are situated).

Predictions about the impacts under the PA are difficult due to the uncertainty involved in defining ecosystem management and predicting the impacts of protecting areas. Increased emphasis on relatively less abundant species, through protection measures and increased monitoring, indicates a tendency towards ecosystem management but as the implications of such management are uncertain, the tendency is to tread cautiously while accelerating research and data-gathering. The potential increased flexibility gained by from rationalizing the fisheries may prove beneficial for the ecosystem.

The PA prevents overfishing of target stocks and reduces the likelihood that stocks will become overfished, through precautionary harvest policies, and imposition of rebuilding regulations when stocks fall below the level capable of producing MSY. Efforts would be accelerated to improve the current harvest strategy, including additional procedures to incorporate uncertainty and develop spawning stock biomass estimates, in particular for Tiers 4-5 (PA.2).

The goal of promoting sustainable fisheries and communities under the PA is likely to be successful. The precautionary adjustments made to quota management decrease the risk of inadvertently overfishing managed species. Additionally, the transition to rights-based management under this alternative will promote the objectives to increase efficiency, stability, and safety in the long-term.

As a whole, through its goal to accelerate precautionary management measures through ecosystem-based principles, and its objectives to develop indices of ecosystem health and to take ecosystem factors into account in ABC-setting, the PA is successful in making many improvements beyond the status quo in achieving the goal of preserving the food web. The emphasis in this alternative is on using the best scientific information available to determine catch levels, but also on providing additional protection against uncertainty by designation of MPAs and reserves. If these improvements are implemented, this strategy is likely to provide protection to a broad range of food web components.

The bycatch and incidental catch reduction policies in the PA are consistent with minimizing human-caused threats to protected species and accelerating precaution through additional bycatch constraints, such as reduced PSC limits. Bycatch reduction objectives and reductions in incidental catch are likely to be achieved without a major cost to industry due to the incentives for more efficient use of fishery resources under cooperatives, comprehensive rationalization of fisheries, or other bycatch incentive programs implemented under this alternative.

The goal of minimizing human-caused threats to protected species and if appropriate and practicable, other seabird and marine mammal species, is largely met in the PA by actively adjusting seabird and marine mammal protection measures, and by conducting periodic review of endangered and threatened marine mammal fishery interactions. This approach, which may provide additional conservation measures in response to scientific evidence, is likely to maintain protection to ESA-listed marine mammals and seabirds, and may increase protection for other seabirds and marine mammals.

This alternative has the potential to reduce and avoid impacts to habitat by careful placement of closures. Placement of closures in lightly fished or not fished areas will provide mitigation and result in avoidance of future habitat impacts if fisheries were to move effort into surrounding areas. Closures in heavily fished areas should be small to minimize displaced efforts and reduce chances of unintended consequences. To achieve overall benefits, closures should not encompass entire habitat types or areas of fishing intensity. In the short term, information from the Observer Program could be used to locate such closures. In the long term, scientific information gained from this policy can potentially lead to modification of the placement of MPAs and help meet the policy objective to assess the necessary and appropriate habitat protection measures.

The PA promotes increased social and economic benefits through the elimination of the race-for-fish while also emphasizing the long-term economic value of the fishery through the promotion of rights-based allocations to individuals, sectors, and communities. In addition, this alternative promotes ecosystem-based management and is likely to increase non-market, recreational, and tourism values assigned to the ecosystem. It is not possible to determine the long-term effect on overall ecosystem value (commercial and non-market values combined) because it is not known whether the fishing sectors, even with rights-based allocations, will be able to adapt to the changes resulting from the increased emphasis on ecosystem tools and, in particular, the potential addition to the number and significance of closed areas.

The goals and policies for Alaska Native consultation and participation in fishery management under the PA would increase current levels by expanding informal and formal consultation between the NPFMC and NOAA Fisheries and Alaska Native participants and tribal governments. Local and Traditional Knowledge would be more formally incorporated in fishery management and additional data would be collected. Other goals and objectives in the PA, such as reductions in PSC limits, may benefit subsistence salmon use by reducing bycatch levels in the groundfish fisheries.

Through data collection measures that will result in reducing uncertainty, the PA is likely to be effective in achieving the goal of accelerating the use of precautionary management measures. The objectives to improve the Observer Program and observer data will increase the quality of fishery data by implementing increased flexibility of, and potentially expanding, observer coverage. Additionally, the expanded economic data and potential for independent verification would allow for more accurate and credible assessments of economic impacts while protecting confidentiality of data. A funding source would, however, need to be identified to implement improvements to these programs. The alternative also emphasizes the importance of enforcement concerns in fishery management.

ES 9.0 Overall Conclusions

This Programmatic SEIS represents a broad but comprehensive review of the Alaska groundfish fisheries and its environmental consequences. Due to its large geographic, biological, and regulatory scope, it is necessarily a large document containing many findings and conclusions on numerous issues. This section of the summary however, brings forward thirteen overall conclusions that the Agency wanted to highlight in this Programmatic SEIS of the Alaska groundfish fisheries.

1. The more precautionary you become, the lower the risk of causing adverse effects on the physical/biological environment. This comes with at least a short-term cost to socioeconomic sectors of the environment including fishermen, processors, and coastal communities, although some of this cost could be offset by long-term sustainability of the ecosystem, albeit at lower harvests than today.

2. As TAC is reduced, other FMP components currently used by the NPFMC and NOAA Fisheries become less important and may no longer be necessary. For example, at reduced TAC levels, bycatch of prohibited species and non-target species is decreased. Impacts to the benthic habitat are also decreased. Managers may no longer need to specify PSC limits if the measures themselves no longer constrain the groundfish fisheries because the estimated bycatch is now below threshold. Similarly, with reduced TAC levels, it may no longer be necessary to spend time developing a complex web of spatial closures since the impacts of the fisheries on benthic habitat would likely decrease and such spatial closures may be unwarranted. As a result, the corresponding FMP may be very simplistic compared to today's FMPs.

3. At the policy level, all alternatives have been designed to take into account the requirements of applicable laws, including the MSA, MMPA, and ESA. Some MSA National Standards for socioeconomic resources could realize increased risk as the policy becomes more precautionary with regard to potential physical and biological impacts. Such costs may not be desirable when there is considerable uncertainty regarding the benefits gained by such policies. Similarly, should the NPFMC recommend a more aggressive harvest policy, the risk of overfishing stocks (especially those where there is very little information) increases even though we choose to remain within OFL of target groundfish species.

4. The realities of conducting fishery research often center around funding. It is usually difficult to obtain research funding when you most need it or for all the topics that warrant study. As a result, fishery research has trade-offs—if you investigate some species, others may not be studied. Even if all the required/requested research was funded, it would be difficult to fully implement a large comprehensive program due to the limited number of fishery scientists currently available to do the work.

5. Considerable uncertainty is associated with management of any fishery and these uncertainties continue under all of the alternatives.

6. Under Alternative 2, most controls over the fishery are removed. As a result, it is difficult to predict how the fishery, stocks, and other resources will react to such a shift in management policies. Risk to the human environment increases as a result of uncertainty.

7. Adaptive management often results in unexpected consequences (e.g., the "bulge theory" when you change the fishery in one way to address a specific problem, another problem often develops somewhere else).

8. A large biomass or increased biomass does not necessarily translate to a stable or increased level of sustainability. Spawner recruit relationships and other features of the population suggest that sustainability of a resource (and a fishery dependent on that resource) is dependent on more variables than just size of the population.

9. The "race-for-fish" is less than optimal in terms of the allocation of fishery resources. Lessons learned from past experience has proven that a rationalized fishery provides greater benefits to the nation than an open access fishery.

10. Currently, questions exists on whether fishermen can achieve their TACs when displaced from traditional fishing grounds. This is an area of great uncertainty and it means that predictions of future catches under different closed area scenarios may be incorrect.

11. Closed areas designed as no-take reserves or a form of MPA should be based on the best available science and the NPFMC and NOAA Fisheries should work closely with public stakeholders and coastal communities in seeking the best areas for protection that provide the greatest benefits to habitat while minimizing adverse social and economic consequences.

12. Careful placement of small closures within heavily fished areas can potentially mitigate some habitat impacts and help avoid unintended consequences of displaced effort. The size of the closures, if closures are determined to be necessary, will depend on a number of factors including the distribution of the valued habitat-type, frequency and intensity of impacts, research needs, and enforcement considerations. Such closures could promote scientific understanding of the effects of fishing on habitat and help determine the efficacy of MPAs.

13. A policy is a statement of goals and objectives that provides direction based on values of the people. It should be referred to frequently to ensure that decisions are consistent with the policy. Periodic review and, if necessary, revision of the policy is prudent.

ES 10.0 Some Frequently Asked Questions about the Alaska Groundfish Fisheries and this Programmatic Supplemental Environmental Impact Statement

1. What is the proposed action and how does it meet that purpose and need?

The proposed action is the continued authorization and management of the Alaska groundfish fisheries. We accomplish this by having the NPFMC and NOAA Fisheries review their past management policies and practices and consider updating these policies and practices to better reflect the future direction of the fisheries. Assuming a change is necessary, an FMP amendment will replace the current policy language with a revised policy statement. The policy statement is defined as the management approach statement and its accompanying policy objectives.

2. Is the current policy for managing the Alaska groundfish fisheries conservative and risk-averse?

Yes. Formally, there are mechanisms built into the harvest policy which minimize the likelihood of inadvertently fishing at non-sustainable fishing mortality rates. Furthermore, there are extra measures of protection that limit the overall harvest including an overall cap on the amount of quota that can be specified in a given year, seasonal and area closures, and bycatch limits. Also, the quota management system has a high level of monitoring through the observer program which tracks target and non-target species catch. Monitoring in-season catch levels allows for fishery closures to ensure that allowable species-specific catch levels (which are always specified as being below the OFL) are not exceeded.

3. Can the current management policy statement in the BSAI and GOA groundfish FMPs be improved?

We believe so. The BSAI and GOA policy statements currently in the groundfish FMPs reflect a period in history when foreign dominated fisheries occurred off Alaska. Both national and regional policy emphasis was to encourage the development and expansion of domestic groundfish fisheries. This policy goal was accomplished by the mid-1980s. Since then, other issues have risen to the forefront of the NPFMC and NOAA Fisheries. These include increased environmental awareness, the identification of bycatch, waste, and fishery allocation problems, as well as concerns over the decline of Steller sea lions and the general health of the fisheries due to overcapacity.

4. Must the NPFMC and NOAA Fisheries select the alternative that is the most protective of the physical and biological environment?

No. The NPFMC and NOAA Fisheries are free to choose any of the alternatives as long as they clearly explain the rationale for their decision. NEPA does not require a decision-maker to choose the environmentally PA. MSA requires that NPFMC and NOAA Fisheries balance conservation with needs to harvest OY from the resource. MSA requires that the NPFMC and NOAA Fisheries consider human needs as well as fishery and ecosystem needs. As long as the PA is explained, and its potential environmental consequences identified, the decision-maker is free to select any of the alternatives.

5. What actions are contained in the preferred alternative?

The PA contains two elements: 1) the policy statement and accompanying policy goals and objectives; and 2) the FMP framework, which is a range of management measures defined by two example FMP bookends. In addition to the PA, a schedule for implementation of the selected policy will also be developed by the NPFMC and will serve to illustrate the prioritization of the PA's objectives and to provide the public with a general timeline under which they can reasonably expect certain actions to occur. This timeline will be updated regularly as new issues arise and as certain initiatives and amendments are completed.

6. What is the purpose of the FMP framework and the bookends? Can the NPFMC or NOAA Fisheries go outside the bookends?

The FMP framework, comprised of two example FMPs is provided to illustrate a range of potential actions and a range of environmental consequences associated with the adopted policy statement. The FMP framework will not be included in the plan but used to better communicate to the public the NPFMC and NOAA Fisheries' intentions and overall policy direction. The FMP framework identifies a number of management tools and example applications to provide the public with the likely types of actions and measures the NPFMC and NOAA Fisheries will pursue in order to achieve the selected policy objectives. The FMP framework is provided in the Programmatic SEIS and ROD to illustrate the NPFMC's and NOAA Fisheries' commitment to implementing its policy. The NEPA advantage that we want to gain with this Programmatic SEIS, is more timely and focused preparation of NEPA documents that will analyze the effects of future plan amendment proposals and their alternatives, and ensure they are consistent with a stated policy direction. Providing an FMP framework and illustrating a range of actions and environmental consequences illustrates for the public that fishery managers require flexibility in their management program and must have the ability to adapt to changing environmental conditions or new scientific information. In the event the NPFMC and NOAA Fisheries find that a future plan amendment would fall outside the range of FMP bookends, then follow-up NEPA analyses will need to be broader in scope and will likely require more time to prepare. This was CEQ's goal in developing the Programmatic EIS concept. A Programmatic EIS would allow follow-up tiering as a way to improve efficiency in government processes.

7. **Once a preferred alternative is adopted and a Final Programmatic SEIS released, what happens next?**

   After a minimum of 30 days, NOAA Fisheries will issue its Record of Decision document. This document brings the NEPA process for the Programmatic SEIS to a close. If a new or updated policy is selected, it will contain the Agency's decision and its justification for the decision. The Record of Decision will also contain, in addition to the policy statement, an FMP framework and a set of FMP bookends that will serve to illustrate for the public the NPFMC's and NOAA Fisheries' intentions for implementing the selected policy.

8. **Is the NPFMC committing to the implementation of specific bookend measures when it adopts the preferred alternative in the Programmatic SEIS?**

   No. The example FMPs only serve to illustrate a range of actions that the NPFMC and NOAA Fisheries have defined as their best illustration of the types of actions they intend to consider in applying its policy. The Programmatic SEIS action itself does not force the NPFMC or NOAA Fisheries to take the exact actions specified in the example FMPs. The example FMPs only illustrate a range of likely management measures from which the NPFMC and NOAA Fisheries may choose to enable implementation of the selected alternative. By design, the NPFMC and NOAA Fisheries attempted to make the example FMPs different in order to capture a meaningful range of future actions. Over time, the NPFMC will initiate FMP amendments and consider alternatives for specific actions. All of these future amendments will require analysis to satisfy NEPA, MSA, Regulatory Flexibility Act, and other applicable federal law. To the extent that the proposed actions fall within the range defined in the PA, the subsequent NEPA analysis can be tiered from this Programmatic SEIS and made more focused, thereby streamlining the regulatory process.

9. **What specific management measures will be set in motion for implementation by the adoption of the preferred alternative?**

   None. With the NPFMC's final recommendation of a PA, an FMP amendment will be submitted by the NPFMC to the Secretary and reviewed under Section 304 of the MSA. If approved, the amendment would replace the old policy with a new policy statement. Specific regulations implementing that policy are not planned to be submitted with the new policy statement. However, the NPFMC and NOAA Fisheries will modify, over a reasonable time frame, the current suite of management measures to better meet the goals and objectives of the new policy statement. If they so choose, the NPFMC and the Agency may simultaneously include in the ROD proposed regulatory changes to management measures with the adoption of the PA. It is not anticipated that this will occur, however, and it is not required. The policy statement will set the stage for future actions. These future actions will most often be accompanied by fishing regulations.

10. What is the baseline that you used as a reference point for analyzing the impacts of the alternatives?

For this revised 2003 Draft Programmatic SEIS, we used 2001 and 2002 data to develop the environmental baseline. NEPA requires that the affected environment and environmental baseline be defined (see Chapter 3). Our "snapshot" of the environment is the condition that existed in 2001 and 2002, to the extent that it can be described. For the socioeconomic and seabirds analyses in Chapter 4, 2001 data were used because 2002 were not available prior to the release of the 2003 Draft PSEIS. The regulatory baseline was the BSAI and GOA FMPs in effect following the June 2002 NPFMC meeting. The baseline characterization of current conditions is more, however, than simply a snapshot through time. It takes into account past human actions and natural events that have influenced resources in various ways, leading, for example, to population declines or increases, or changes in distribution. This baseline condition was then used as the reference point when analyzing the changes that could occur if one of the alternatives, or its example FMPs were approved. More detailed description of the baseline is included in Section 3.1.4. If the alternative resulted in no significant change to the baseline, it was concluded that the alternative or its example FMP resulted in insignificant changes to the environment. In instances where potential significant impacts could occur, we identify those impacts as being either conditionally significant, or significant (beneficial or adverse).

11. Why isn't there always a difference between Alternatives 1, 2, 3, 4 and the preferred alternative for some effects?

Sometimes the alternatives result in similar impacts on a particular resource. A Programmatic EIS is a big picture environmental assessment and the geographic scale and scope of analysis is very broad. For example, the analysis of population-level impacts to the current baseline for herring resulted in the same findings for all the alternatives. All alternatives resulted in insignificant impacts on herring mortality, reproductive success, prey availability, and herring habitat. All alternatives are different in terms of predicted bycatch of herring in the groundfish fisheries, which can result in serious allocation issues, but at the population level, none of these alternatives were determined to pose a serious threat to sustainability of herring populations.

12. What FMP components have the greatest influence on the total effects of a FMP?

The analysis contained in this Programmatic SEIS has revealed that three FMP components are the principle drivers behind an FMP and that the environmental consequences for the plan as a whole are influenced most by these FMP components. For every example FMP, the most influential components affecting the outcome and overall ratings were TAC-setting (how much fish, target and bycatch, is allowed), resource and community allocation (who can fish), and spatial closures (where can they fish). All other FMP components, while important for successful management of the fisheries, were found to have relatively minor influence on the overall rating of the FMP.

13. What is the difference between "overfished" and "overfishing"?

Overfishing is the act of fishing at a higher rate than that defined as the overfishing rate. In Alaska, groundfish overfishing rates are specified as the rate that would be expected to produce the MSY. Groundfish fishing at a higher rate would constitute overfishing.

Overfished means a stock has been fished to a point where the population is below a population size threshold (commonly taken to be about one-half of the target stock size or B_{MSY}) necessary to produce the MSY on a continuing basis.

14. Will any of the alternatives result in overfishing?

No. All of the alternatives prevent overfishing by design, although the risks of overfishing do vary among alternatives, with Alternative 2 posing the highest risk and Alternative 4 the lowest risk.

15. Is it true that fishing on a stock (Bering Sea pollock for example) can actually be beneficial to the population as a whole?

If the term "beneficial" means surplus production, then yes, fishing can improve a stock's ability to increase surplus production. If a stock is at its carrying capacity, then surplus production is zero. Principles of fisheries science tell us that by reducing the size of the population, the population turnover increases and over time will produce a surplus beyond what the stock needs to sustain its population.

16. Is there uncertainty and risk to the environment as a result of authorizing the groundfish fisheries in the BSAI and GOA?

Yes there is. We do not know the full effects of commercial fishing on the environment, nor do we understand the effects of fishing on the ecosystem and its processes. We have a choice as both managers and stewards of marine resources, and as a society. We can either move forward, cautiously and carefully in our management of fisheries, or we can reduce our harvests and perhaps even suspend some or all groundfish fisheries until we know more about our environment and the effects of fishing upon that environment.

17. How is uncertainty addressed across the alternatives?

Uncertainty is accounted for through regular development of stock assessment analyses. That is, as part of the regular review of stock assessments, robustness to model assumptions is continually evaluated. While this evaluation is objective, the risks of overfishing are treated differently than the risk of under exploiting stocks. These risks are presented annually to the NPFMC before they recommend ABC levels to NOAA Fisheries. For example, model alternatives that resulted in higher ABC's for Greenland turbot in the BSAI were rejected in 2002 over concerns about the change in recruitment pattern observed on the Eastern Bering Sea shelf from resource survey data. In this case, the more conservative model alternative was selected even though the fit to the data was better for the models that were less conservative.

More formal inclusion of risk-averse policies that relate to the uncertainties both in the observation error and in recruitment variability are taken into account under Alternative 3. These allow for a constant level of risk for all stocks. A different adjustment to the maximum permissible ABC level is used for Alternative 4 (based on the lower 90 percent confidence interval). This adjustment is more ad-hoc in that it fails to have a constant level of risk-aversion for all stocks.

18. Are there environmental trade-offs in groundfish fisheries management?

Yes. NEPA defines the human environment as being comprised of the natural and physical environments and the relationship of people with those environments. This Programmatic SEIS shows that with already established fisheries, continued use of fishery resources comes at a cost to the physical and natural environment. The challenge for society that falls on to the NPFMC and NOAA Fisheries is to balance environmental protection with resource use in a manner that achieves the best combination of benefits to the human environment as a whole.

19. How are these trade-offs considered and balanced?

The MSA, ESA, MMPA, and other applicable federal law, provide standards, objectives, and requirements with which the NPFMC and the Agency must comply. Balancing all of these values and mandates forces decision-makers to identify the action that achieves as many of these requirements as possible and violate none of them. Both the MSA and NEPA specify that a public process will be undertaken when making decisions so that the process is transparent and the public have the opportunity to be informed and to participate.

20. What are the cumulative effects of groundfish fishing over the last 25 years?

Over the last 25 years, management of the groundfish fishery has undergone a transition from a primarily foreign fishery, through a brief period of joint venture, to a completely domestic fishery. Areas fished, the nature and efficiency of gear types, utilization of catch, and rates of bycatch have changed significantly. The diversity of groundfish species fished, and the volume of catch increased through the early 1990's, and has since remained stable. The value of catch has continued to increase over time. Communities that participate in or support groundfish fishing have experienced cumulative beneficial effects, particularly in proportion to other state and federal fisheries. Alaska Natives that participate in the groundfish fisheries have experienced cumulative beneficial effects for themselves and their communities. There appear to be no adverse cumulative effects of groundfish fishing on target species. Management of the fishery has become more precautionary over time and developed extensive scientific knowledge regarding target species. Human activities over time have resulted in cumulative conditionally adverse effects on various components of the ecosystem including changes in species diversity, such as whales and harbor seals, western Alaska salmon, king and Tanner crab, and some types of benthic habitat. However, there is still uncertainty regarding the contribution of the domestic groundfish fishery to past cumulative effects on the North Pacific ecosystem. As more research has become available on other management issues such as ecosystem effects, fisheries management has incorporated measures to account for them, including temporal and spatial closures, and changes in fishing techniques and gear.

21. **Do the current management policy and FMPs incorporate ecosystem-based management principles?**

    Ecosystem-based management principles include the recognition that our ability to predict ecosystem behavior is limited and that diversity is important to ecosystem functioning. The current policy and FMPs incorporate ecosystem-based management principles primarily through management strategies that incorporate uncertainty, take into account the needs of other species, and those that promote participation, fairness, and equity in policy and management. Protection measures for dominant target species, ESA-listed species, prohibited species, and forage species ensure the protection of food web components that are more well-studied than others and those that are at critical population thresholds, but may not provide sufficient protection to others with less-complete information.

22. **What alternative best incorporates ecosystem-based management principles?**

    The ecosystem-based management principles recommended by the NOAA Fisheries ecosystem advisory panel and the National Resource Council include the recognition that our ability to predict ecosystem behavior is limited and that diversity is important to ecosystem functioning. Management policies that achieve those principles are policies that incorporate uncertainty, take the needs of other species into account, and promote participation, fairness, and equity in policy and management. Although Alternative 4 policies are strong in incorporating uncertainty and taking the needs of other species into account, these do so at the expense of fishers and communities dependent on these resources. Alternative 3 and the PA appear to provide the best balance of policies that take uncertainty and the needs of other species into account while still allowing participation and equity in its regulation of humans.

23. **Do the policy alternatives comply with MSA National Standards, MMPA, and ESA?**

    The policy alternatives have been designed to take into account the requirements of all applicable federal statutes and executive orders including the MSA, MMPA, ESA, NEPA, and RFA. However, analysis has shown that Alternatives 1 and 2 may not satisfy the MSA requirement that MSSTs be specified in the FMP or the National Standard Guidelines for determining whether a stock is currently overfished or approaching an overfished definition. Under Alternatives 1 and 2, MSSTs are operationally taken into account in the management of the fisheries, but MSSTs are specified in the Stock Assessment and Fishing Evaluation documents and not the FMPs.

    Alternative 2 may satisfy ESA at the policy level, but analysis of FMP 2.1 could result in the increase in harvest levels of prey species and the reopening of a number of closed areas. Such a FMP bookend may not comply with ESA without additional Steller sea lion protection measures. In addition, depending on the application of the policies, goals, and objectives in Alternative 2, bycatch measures may not necessarily satisfy the requirements of National Standard 9, which requires that bycatch and/or bycatch mortality be minimized.

24. Do any of the policy alternatives result in fisheries harvests on Steller sea lion prey species that could adversely effect their recovery?

Yes, the Alternative 2 policy. Under FMP 2.1, the combined harvest of all three key Steller sea lion prey species were determined to likely have a population-level effect on Steller sea lions and were found to be significantly adverse. The fishing mortality rate (F) over the next 5 years of EBS and GOA pollock is expected to increase by an average of 140 percent and 100 percent, respectively, relative to the comparative baseline of 2002. Although F of EBS pollock under baseline conditions has been qualified as being "artificially low" because TAC was capped by the OY, the EBS pollock F is expected to increase by 140 percent under FMP 2.1 relative to the comparative baseline (Baseline F = .22, 5 year average F from projections; under FMP 2.1 = .44). This projected increase in the harvest of this key prey species, relative to the comparative baseline, is expected to have significant adverse effects on Steller sea lion populations.

For other key species under FMP 2.1, the BSAI and GOA Pacific cod fishing mortality rate is expected to increase by 79 percent and 64 percent, respectively, and changes in AI Atka mackerel harvest are expected to increase by 124 percent, relative to the baseline. All of these increases are considered to be significantly adverse to Steller sea lion populations.

The combined harvest of Steller sea lion prey species under FMP 2.1 meets the criteria defined for a significant adverse determination for prey availability of Steller sea lions.

Under FMP 2.2, F of EBS pollock is expected to increase by an average 69 percent and the GOA pollock will decrease by 13 percent. BSAI and GOA Pacific cod fishing mortality rate is expected to increase by 28 percent and 19 percent, respectively. Changes in AI Atka mackerel harvest are expected to increase an average of 64 percent under FMP 2.2 relative to the baseline. The combined harvest of Steller sea lion prey species under FMP 2.2 is therefore expected to result in either insignificant or significantly adverse effects to Steller sea lions for individual prey species and is rated significant adverse, overall.

25. Could any of the policy alternatives result in fisheries harvests on forage fish species that could adversely effect the recovery of short-tailed albatross?

Under FMP 2.1, the ban on directed forage fish fisheries would be repealed. If a market developed so that substantial amounts of capelin and other forage fish were harvested (along with expected bycatch of squid and other pelagic invertebrates), there would be a potential for localized depletions of prey used by short-tailed albatross. However, since short-tailed albatross primarily feed on squid and forage over vast areas of ocean, the potential effects of localized depletions of forage fish are considered minimal for this species. In addition, since the near extinction of short-tailed albatross was caused by commercial hunting rather than habitat degradation, the carrying capacity of the environment, which once supported millions of these birds, should not limit their population recovery for a long time.

26. **Do any of the alternatives result in spatial or temporal concentrations of the catch? Could this concentration adversely impact Steller sea lions, seabirds, or EFH?**

It's possible. Under Alternative 1, the groundfish trawl fishery is compressed in time and fishing occurs in areas of historically high catch rates. Whether such spatial or temporal concentrations of catch significantly harm the stocks or the environment is unknown. Our analysis of the spatial and temporal closure schemes illustrated by example FMPs 3.2 and 4.1 indicate that fishing effort would be relocated to areas where little is known about the availability of the target species. The effects of such relocation of effort on bycatch and benthic habitat are also unknown. Due to this uncertainty, the risk of causing unintentional impacts by the closures is high. Past experience has shown that bycatch of certain species could increase if the fishing fleet is forced to operate in areas it would not normally fish. It is presumed that the fishing fleet currently deploys to those open areas where the catch-per-unit-effort (CPUE) for target species is the highest. Naturally, in instances where CPUE is high for target species, bycatch rates for non-targets species or prohibited species should be low in comparison. Since the entire GOA and BSAI are not fished continuously, we expect that there are seasonal differences in stock availability and catch rates across the continental shelf. Experimental fishing or test fishing would provide some insight as to whether the target species, and their respective TACs, could be harvested in the open areas illustrated by these FMPs.

Effects of fishing on benthic habitat is currently a major topic of research. Whether redistributed effort results in adverse impacts to benthic habitat can not be determined at this time. What can be answered is that the closure scheme illustrated by example FMP 3.2 and 4.1 do result in a greater separation of the commercial fishery from Steller sea lion haulouts and rookeries as well as known seabird colony sites. What is unknown is whether such separation provides any real benefits to these marine mammals and seabirds.

27. **How does the current gear specific closure scheme compare to past years? Are we being more protective of the environment now?**

Overall, it appears that more of the EEZ or fishable area is being afforded protection today than back in the late-1970s and early-1980s. More restrictions exist today on groundfish trawling compared to 1980. However, there are fewer area restrictions on fixed gear fisheries compared to 1980. As stated in this Programmatic SEIS, it is important to realize that benthic habitat is only fully protected from fishing impacts if a closure applies to all gear types and is in effect all year. Little area in the BSAI or GOA has been designated that meets this criteria. Partial closures that permit some bottom trawling to occur negates the benefits that accrue to that benthic habitat by restricting only certain fisheries. For example, the current closures surrounding Steller sea lion rookeries and haulout sites, apply only to those fisheries that target Steller sea lion prey (e.g. pollock, Pacific cod, and Atka mackerel). Trawl fisheries targeting flatfish are permitted within these closed areas. Concerns exists that such trawl impacts on certain types of benthic habitat may require a recovery period that is not satisfied by restricting only the pollock, cod, and mackerel fisheries. Little difference between the 1980 regime and the 2002 regime exist in terms of the amount of area that is fully protected from fishing. Alternatives 3 and 4 could increase the amount of area that is fully protected from fishing by 3 to 11 percent for the EEZ, or by 8 to 29 percent for the defined fishable area. Unfortunately, there is no information to conclusively show whether fishing impacts on the benthic environment are adverse and whether meaningful benefits to the environment would accrue as a result of a modified closure scheme.

28. Can any of the TACs be fully achieved in the more precautionary or extremely precautionary policy alternatives?

Maybe. It is uncertain whether the current TACs could be taken if the fishing fleet were not permitted to fish in areas where they currently operate. Current catch levels are unlikely to be possible under Alternative 4. This is primarily because the TACs will be set much lower as a precautionary measure until scientific information is collected that would support an increase in harvest levels. This alternative would also emphasize the use of no-take marine reserves where all commercial fishing would be prohibited. The combination of reduced TACs with closures of large areas would make achieving the current TAC level difficult.

29. Will any of the alternative closure schemes prevent TACs from being achieved? If so, why?

Alternatives 3 and 4 include management measures that lead to the creation of MPAs, or areas closed to particular gear types. It is possible that areas could be created that would preclude the attainment of TACs of certain species. Whether or not the closures will actually prevent achievement of the TACs depends on the TAC levels, on the location of the specific areas created, and on the level of abundance of the species outside the closed areas. To the extent that a closed area comprises the majority of the range of a particular species, then it is less likely the TAC for that species can be attained. If TACs are reduced significantly, as could happen under Alternative 4, then, even if a closure encompasses a large portion of the natural range of a species, it may still be possible to harvest the lower TAC.

30. What alternative best mitigates the effects of fishing on EFH?

It is difficult to say. The use of closures as a management tool is probably the most effective habitat protection measure. However, with so little information currently available on the different habitat types in the BSAI and GOA, and the affect of fishing on those habitats, it is difficult at this time to determine whether benefits of a closed area outweighs the social and economic cost. Alternatives 1, 3, and 4 all have the potential of providing protection to EFH. However, it is difficult to determine if all the current areas being closed or restricted provide measurable benefits to EFH. Similarly, while our analysis of Alternatives 3 and 4 indicate that they both have the potential of increasing protection to EFH, example FMPs 3.2 and 4.1 may not provide all the benefits to EFH as originally believed and therefore they highlight the importance of making sure that the areas closed are based on the best available science.

31. Are closures good for habitat?

They can be if they are established in the right place. However, if a closure is established in an area of historically high catches, the displaced effort will relocate and it could lead to higher levels of habitat disturbance in other areas which may negate the habitat benefits of the closure.

32. What is the impact of fishing offal and discards on seabirds?

Scavenging of fishery wastes can influence seabird population trends in either direction. Processing wastes may not be adequate foods for successfully rearing chicks but abundant scavenging during winter may improve survival of immature birds and increase populations of the large, competitive gull species. On the other hand, if populations of the larger gull species increase, local populations of other species (such as kittiwakes and murres) may be reduced through increased competition for nest sites and predation pressure on their young. Sudden withdrawal of discards might cause the predatory species to increase pressure on other species long before the predator populations decline to previous levels. Research on seabird populations in the North Sea has documented numerous instances of potential relationships between offal and discards and changes in breeding populations. However, no data are available on how important these supplemental food sources might be for various seabird species in Alaska or whether there are regional differences in offal use by seabirds.

33. What is the economic value of the Alaska groundfish fisheries to the Pacific Northwest and Alaska?

The socioeconomic data currently available to NOAA Fisheries does not include data on production costs. Without information on harvesting and processing costs it is not possible to determine whether businesses are profitable, much less the magnitude of the profit or how it has been affected by regulatory changes. However, economic theory would suggest that average costs are less than or equal to gross revenues. In 2001, total revenues from processing and harvesting groundfish were estimated to have exceeded $1.5 billion. The fishery supports thousands of regional jobs in both the fishing and support service industries. Revenues generated by commercial groundfish fishing are used by federal, state, and community governments to finance valued infrastructure and community services, and as such are important parts of the Alaska and Pacific Northwest economies. Measures to collect additional socioeconomic data needed to fully answer this question are included in the PA and in Alternatives 1, 3 and 4.

34. What happened to supply and demand? In example FMP 2.1 the amount of catch increases significantly but you assume there are no changes in prices. Similarly the amount of catch decreases significantly under example FMP 4.1 but again it does not appear that prices change. Shouldn't prices change as a function of supply and demand?

The analysis does not attempt to measure any price changes that may result from regulation of the groundfish fisheries. Evidence from the market for groundfish suggests that most groundfish products are shipped to foreign markets and markets in the "lower-48," where they compete with other seafood products and other sources of animal protein. As a result of the presence of a large number of substitutes for Alaska groundfish products, the demand curve for these products is relatively elastic. In other words, prices for groundfish products are unlikely to be significantly influenced by changes in groundfish harvests in Alaska. The absence of a price change would have a negative impact on participants in groundfish fisheries because little, if any, of their loss from harvest declines will be compensated for by a price rise.

35. Why do we prohibit harvesters that use specific gear types from retaining halibut and salmon, regardless of whether the fish are alive or dead? Can't we give the fish that would be discarded to food banks?

The purpose of PSC limits is to eliminate or substantially reduce the incentive for vessels to harvest certain non-groundfish species that are harvested in other domestic fisheries. At the same time, these restrictions recognize that some level of incidental catch of prohibited species can not be avoided without eliminating many groundfish fisheries. Amendment 28 to the BSAI FMP and Amendment 29 to the GOA FMP authorize a voluntary donation program for fish taken as bycatch in the groundfish trawl fisheries off Alaska. The seafood is distributed to economically disadvantaged individuals by tax-exempt organizations through a distributor authorized by NOAA Fisheries. Currently, the authorized distributor is Northwest Food Strategies (NFS), a 501 (c) 3 non-profit organization. NFS accesses seafood products for distribution to the America's Second Harvest network of 200 food banks and food-rescue organizations. Since it's inception in 1994, NFS has grown into the leading supplier of seafood to hunger-relief organizations in the country. The fish voluntarily donated by the groundfish fishing industry to NFS are salmon and halibut that are part of the groundfish fishery PSC. The salmon and halibut retained and donated under the NOAA Fisheries Prohibited Species Donation Program represent a small but significant portion of the seafood distributed by NFS. It is estimated that catcher processor companies donate one million seafood meals annually to provide hunger relief.

36. I live in Sandpoint, Alaska and I don't see anything in the Programmatic SEIS about the importance of groundfish to my community nor is there anything on the impact of the alternatives on my community. Will this shortcoming be addressed?

Because of the geographic scope of the Alaska groundfish fisheries, much of the social impact assessment information in the main body of the document is provided at the regional level. Community differences are highlighted in each discussion area, but much more detail on Sand Point itself and other fishing communities may be found in the *Interim Updates of Sector and Community Profiles*, on the NPFMC website at www.fakr.noaa.gov/npfmc. This document, incorporated by reference into the Programmatic SEIS, contains a detailed groundfish oriented profile of many of the fishery dependent communities including Sand Point. The profiles describe community engagement in, and dependence upon, the groundfish fishery. In terms of impacts of the alternatives to the community of Sand Point, quantitative information cannot be provided at the community level due to data confidentiality restrictions. However, the discussion of impacts to the Alaska Peninsula and Aleutian Islands region as a whole are applicable to Sand Point, and provide information on the nature, direction, and magnitude of the impacts that would be felt in the community.

37. I run a fuel supply business operating in Dutch Harbor and Bellingham, how can I tell what the impacts of the Programmatic SEIS will be on me?

As noted in the Chapter 4, the impact to support service sector businesses are likely to be somewhat different than the impacts to direct fishery sector businesses, depending on the specific alternative chosen. Both direct and support sector business activity is assumed to remain near to or exceed existing conditions levels under Alternatives 1 and 2, and both direct and support sectors are expected to decline under Alternative 4. Assuming your business varies with the volume of fishery activity in the region, you may be able to roughly gauge increases or decreases in demand by looking at the overall percentage change in regional indicators under those alternatives. Under Alternative 3, however, the outcomes for direct and support sectors may vary. As discussed in Chapter 4, support sector businesses (and some coastal communities that have large support sectors) that derive benefits from seasonal peaks (and the economic inefficiencies) of current race-for-fish fisheries could experience adverse impacts under rationalization conditions, at least in the short term during a transition to a lower if more stable level of employment.

Unalaska/Dutch Harbor has a relatively well developed support service sector that supports all major fishing industry segments, and this sector derives marked benefits from the current economic inefficiency within the fishery. It is relatively expensive to provide services in the community, but under conditions where it is important to minimize down time during a fishing season, services that cost more in Unalaska/Dutch Harbor than some other places (but are available on a more timely basis) are often deemed well worth the trade-off by fishery participants. Under a rationalized fishery, cost considerations become relatively more important (as the relative cost of time away from the fishing grounds decreases), giving service purchasers more options (to the possible detriment of providers in relatively remote locations). How your particular business changes as a result of fishery management changes depends, of course, to a large extent on the adaptability of the business to changed circumstances, which in turn depends on the relative economics of your business compared to other local providers of the same service.

38. In several of the alternatives, the concept of "rights-based management" appears. What is rights-based management?

A "rights-based management" approach to controlling harvesting and processing capacity in fisheries relies on incentive adjusting methods, such as the allocation of shares of the TAC to specific individuals or groups. With secure "rights" to specific quantities of fish, there is no incentive for fishermen to invest in ever more elaborate vessels or equipment—or, to be more precise, to select anything but the least cost combination and deployment of fishing inputs. In other words, rights-based management systems (in which rights are freely transferable) are "self-rationalizing" systems. Redundant capital is removed from the fishery as more efficient operations purchase the rights of less efficient operations. In economic theory, the less efficient operations, having sold their rights to participate, will exit the fishery and shift their labor and capital to some underutilized fishery or into an entirely different segment of the economy. The result is a net gain to society in the form of a reduction in costs and an increase in production. For more information on rights-based management in the groundfish fisheries, please see the QA paper on overcapacity in Appendix F-8.

39. Does "rights-based management" give an exclusive right to some individuals while keeping out others? Why are we giving away the public resource?

The MSA refers to an IFQ as an exclusive "fishing privilege," rather than a right. In specific reference to authorizing IFQs or other limited access systems, the MSA states that such an authorization, "(A) shall be considered a permit for the purposes of sections 307, 308 and 309; (B) may be revoked or limited at any time in accordance with this Act; (C) shall not confer any right of compensation to the holder of such IFQ or other such limited access system authorization if it is revoked or limited; and (D) shall not create, or be construed to create, any right, title, or interest in or to any fish before the fish is harvested" [Sec. 303(d)(3) 16 USC 1853(d)].

40. Won't "rights-based management" result in windfall gains (or the appearance of windfall gains) to permit holders from the reallocation of a public asset to private holdings?

First, it is important to recognize that our nation's fishery resources are given away at no charge when fisheries are managed through open access. Nevertheless, a potential and frequently anticipated effect of rights-based management is the provision of an apparent windfall profit (i.e., the ability to sell quota shares for which they did not have to pay) to the initial permit holders. Anyone receiving quota shares without explicit payment receives an increase in tangible wealth. The increased value of this wealth due to the efficiencies of the rationalization program is often seen as the source of windfall profits. Various mechanisms, such as the auctioning of quota shares or making them taxable, have been suggested to reduce or eliminate windfall profits and to recover for the nation the fair market value for private use of the natural resource. However, the MSA explicitly prohibits such mechanisms (as Sec. 304 (d) has been interpreted by NOAA Fisheries). There are differing viewpoints as to whether the MSA should be modified to allow an auction system or the imposition of taxes and, if so, how such authority should be utilized. Currently the sablefish IFQ cost-recovery program is authorized to collect up to two percent of the ex-vessel value of sablefish to pay for the costs of administering the program. Additionally, specific measures in PA and Alternative 3 would include a cost recovery program, and it is conceivable that if rights-based management measures were to be approved under Alternative 1, they would also include cost-recovery mechanisms.

41. Why not let the race for fish continue? If boats and processors can't make it, then they'll go out of business-that's the American way?

The "race for fish," in which each fisherman is motivated to be the first to capture fish, is undesirable because it usually leads to excess harvesting and processing capacity. The problems of excess capacity have been summarized by Kirkley and Squires (1999): *[Excess capacity] generates intense pressure to continue harvesting past the point of sustainability in order to keep as much of the fleet working as possible. With revenues spread among many vessels operating under little or no profits, reductions in fleet size become politically and socially more difficult. Vessels are more vulnerable to changes in the resource base and regulations when they are only marginally viable because of excess capacity. Excess capacity encourages inefficient allocation and constitutes a major waste of economic resources. Overcapitalization and excessive use of variable inputs follow. Excess capacity also complicates the fishery management process, particularly in open access, frequently leading to detailed and comprehensive regulation. Excess capacity substantially reinforces the increasing tendency for* *management decisions to become primarily allocation decisions, i.e. decisions about the gainers and losers of wealth and profits (or losses) from alternative management choices over an overfished or even declining resource stock.* For more information on the effects of the race for fish and the problem of excess capacity in the groundfish fisheries, please see the Qualitative Analysis paper on overcapacity (Appendix F-8).

42. What is the difference between bycatch, incidental catch, and discards?

The terms "bycatch" and "incidental catch" are often used interchangeably by fishermen and the public when referring to the catch of groundfish or other species that is taken incidentally when targeting other fish species and thrown away. However, legally, the two terms mean different things. The term "incidental catch" is defined by federal regulations (50 CFR 679.2) and refers to that catch that is taken while targeting some other species but is retained and used (e.g., cod taken in a pollock fishery). "Bycatch" is defined by the MSA as the portion of the catch that is not used and discarded. This discarded incidental catch may include regulatory discards defined by the MSA as fish harvested but are required by regulation to be discarded whenever caught (e.g., in Alaska these species are called "prohibited species"); and fish species that are undesirable and have no market, such as sculpins and skates. The MSA further defines economic discards as fish which are targeted in a fishery but are not retained because they are of an undesirable sex, size, or of poor quality.

43. Why does the analysis indicate that right-based management will lead to reductions in bycatch and incidental catches? What evidence exists that leads to this conclusion?

With a rights-based management program, as evaluated in the example FMP bookend 3.2, it is assumed that individual fishing vessels would be held accountable for their total catch of target species, prohibited species, and the non-specified species. For the target and prohibited species categories, each fishing vessel would receive species specific allocations which it could either use directly in its own fishing activities or transfer to another fishing operation. For the non-specified species category, there would not be allocations to individual fishing operations; however, the catch of these species would be counted against a fishing operation's total allocation of target species. Therefore, there would be an opportunity cost borne by the fishing operation for its catch of each of these three types of species. This management scenario would provide each fishing operation with an increased incentive to develop a fishing strategy that will decrease catch of species which would not be retained.

In addition, rights-based management will tend to decrease the cost of developing and using fishing strategies that decrease discards. This is the result of eliminating the "race for fish" as the allocation mechanism. The race for fish increases the opportunity cost of using fishing strategies that decrease the rate at which a vessel can harvest fish. For example, the time lost searching for areas with lower bycatch rates may be prohibitive in the very short season that can occur due to the "race for fish" style season. As experienced in the Alaska sablefish and halibut IFQ fisheries, elimination of the "race for fish" will result in an increase of the length of time a fishing vessel has to profitably retain catch that would otherwise be discarded.

One other benefit of rights-based management: fishermen are given better business "signals" from this type of management program; therefore, they tend to make better decisions that are more appropriate from society's perspective. This is the result of internalizing what had been external costs and benefits (i.e., costs and benefits that do not accrue to the fishing operation as a result of the fishing strategy it selects). The specifics of the rights-based system will determine the types of externalities that are addressed and the extent to which they are internalized. Such externalities are the source of a variety of fishery management problems, including excessive levels of discards. Therefore, example FMP 3.2 is expected to decrease discards by at least partially internalizing what are currently the external costs and benefits of decreasing discards.

44. Our community is completely dependent on the fishing and processing industry, however the regional impact analysis for the region I live in has lower income and employment multipliers than other regions that are less dependent on fishing. Are your multipliers correct?

The income and employment multipliers used in the regional effects analysis in this Programmatic SEIS are based on the most current information available from IMPLAN®, an input-output analysis software program that is generally regarded to provide accurate results. The multipliers indicate the additional income and employment that will be generated when industries produce and export their product outside the region. Multipliers will be higher in regions that produce a wide variety of potential inputs to the industry in question. If, for example, the fishing industry in a region purchased all of it vessels and engines from a local manufacturer the multiplier for the fishing industry would account for the additional jobs created in the vessel and engine manufacturing sectors. If instead, the industry purchases its vessels and engines from outside the region, jobs and income in some other region are affected rather than in the region itself. From this perspective, the more dependent a region is on a single industry, the lower its multipliers. Thus, the multipliers in Aleutian Islands are lower than the multipliers for southcentral Alaska.

45. How are environmental benefits such as viewing sea lions accounted for and compared to the benefits from the commercial harvesting and processing of fish?

The economic analysis contained in this Programmatic SEIS discusses the full range of benefits that the BSAI and GOA marine ecosystems and species associated with them (including sea lions) provide to the American public. Some of the goods and services these ecosystems produce are not exchanged in normal market transactions but have value nonetheless. While there are difficulties in estimating the value the public places on protecting ecological conditions, the analysis provides a qualitative discussion of possible benefits provided by the BSAI and GOA marine ecosystems. In addition to supporting commercial fisheries, these ecosystems support an array of recreational fishing and subsistence activities as well as non-consumptive activities such as wildlife viewing. Furthermore, some people may not directly interact with the BSAI and GOA marine ecosystems and the various species associated with them but derive satisfaction from knowing that the structure and function of these ecosystems are protected. For more information on the range of benefits these marine ecosystems provide, please see Section 3.9.7.

46. **In your assessment of non-market, recreational and tourism values, you indicate that the effects of FMP 1 are insignificant. I don't consider myself an environmentalist, but I am concerned about the effects of fishing on the endangered stock of Steller sea lions. If fishing has a negative effect on Steller sea lions how can the rating of FMP 1 be insignificant?**

    The significance ratings for each example FMP studied in this Programmatic SEIS are based on the question of whether there will be a significant change to the baseline at the population level as a result of the FMP. It does not mean that the NPFMC or the Agency is satisfied with the current state of the environmental baseline. For example, FMP 1 would continue the current suite of Steller sea lion protection measures to avoid jeopardy and adverse modification to their critical habitat. We have determined that FMP 1 would not significantly change the current management of the fisheries and so there would be no predicted beneficial or adverse change to the recovery plan currently in place. It is predicted that measures contained in example FMPs 3 and 4 would more likely result in changes believed positive to the recovery of Steller sea lions and so these FMPs received a conditionally significant beneficial rating.

47. **I operate a small 58 ft trawler. Although I favor the rationalization measures in Alternative 3, the closures that are also included are likely to make it impossible for me to operate. The impact analysis seems to underestimate the impacts of these closures. How come, and is there any way these shortcomings can be addressed?**

    Data necessary to make reliable quantitative projections of the impacts of closed areas were unavailable for use in the Programmatic SEIS. The illustrated closures used in this Programmatic SEIS are examples and only used for purposes of analysis. Adoption of a PA will not necessarily lead to implementation of these closures. The Programmatic SEIS analysis uses the illustrations to provide insight into the likely effects of closures. These effects can be used to highlight concerns and shape management policy. At such time in the future that specific closed areas are proposed following adoption of a PA, it is hoped that improved habitat data will allow for reliable quantitative estimates to be developed. Estimates of the percentage of catch by species that occurred in the proposed closed areas during the baseline period are shown in the habitat analysis of the alternatives. It is assumed that catch that is foregone in closed areas will be available to fishermen in areas that remain open because fish are mobile and generally widely dispersed. Our analysis shows that if this is true, smaller vessels could be affected to a greater degree compared to large vessels if the proposed closed areas are close to shore where small vessels often are forced to operate due to safety concerns.

48. **Can any of the policy alternatives adversely impact subsistence?**

    Yes. Groundfish fisheries managed under Alternative 2 could produce adverse indirect and cumulative effects on subsistence salmon harvests by increasing the bycatch of chinook and chum salmon in the BSAI, and by increasing the likelihood for fishery disturbance and competition for prey with Steller sea lions, a marine mammal used for subsistence. Alternatives 3 and 4, and the PA while potentially providing direct benefits to subsistence users by reducing salmon bycatch and reducing disturbance to Steller sea lions, are not enough to overcome the cumulative adverse effects of both human and natural events on Yukon-Kuskokwim River salmon stocks.

49. Do any of the alternatives adversely impact minority populations?

Yes, there are three potential effects of the groundfish fisheries on minority populations: adverse effects on Alaska Natives related to subsistence harvests; adverse affects on CDQ groups and other Alaska Natives participating in the groundfish fishery; and adverse effects on other minority populations participating in the groundfish fishery. Alternatives 2 and 4 appear to produce the most significant adverse effects on minority populations in Alaska. Alternative 2 will have potential adverse effects on subsistence harvests by Alaskan Natives of salmon (increasing salmon bycatch) and Steller sea lion (increasing disturbance and competition for prey). Alternative 4 , which could significantly reduce groundfish TACs will have adverse effects on Alaska Natives participating in groundfish fisheries and Alaska Native communities that are economically dependent on those fisheries by reducing or eliminating their participation on the groundfish fishery. The alternative would also have adverse effects on minority populations employed in fish processing as a result of reduced groundfish TACs.

50. Of the policy alternatives, which are most dependent on new research and scientific information?

All of the policy alternatives require some level of research and monitoring. However, Alternatives 3 and 4 and the PA each require increased levels of research and monitoring, beyond the current program, to fully achieve their respective policy goals and objectives. A description of ongoing, planned and recommendations for future research is provided in Chapter 5 of this Programmatic SEIS.

ES 11.0 Areas of Controversy and Issues to be Resolved

This Final Programmatic SEIS completes NOAA Fisheries' comprehensive review of the Alaska groundfish fisheries, its management regime, and its impact on the marine environment. It is the work product of countless meetings, scientific analysis, and thousands of public comments. NOAA Fisheries has attempted in every way, to listen, document, and consider all points of view and all sources of scientific information as well as local and Traditional Knowledge. The PA moves fishery management toward a more formalized ecosystem-based approach to management of the Alaska groundfish fisheries that is more precautionary when faced with uncertainty, as well as balanced, using the MSA National Standards as a guide, in ensuring sustainable fisheries for generations to come. Still, issues and controversy remain.

Section ES 5.1 (and Section 1.5 in the Final PSEIS) provides a list of ten issues that were identified as being the most important. These issues focus on the effects of commercial groundfish fishing on various components of the marine ecosystem. Each of these issues were addressed to the best of our ability in this Programmatic SEIS. However, it is clear that there is lack of consensus on our findings.

Throughout this document we have mentioned that our understanding of these issues and potential fishery-caused effects is made very difficult due to our lack of knowledge of how the marine ecosystem works and all of its internal processes. We have made few findings where we can conclude in a definitive manner, that the effects of fishing on a resource or ecosystem component is adverse (or beneficial). In many cases, we had to rely on qualitative analysis and the professional judgement of fishery scientists in reaching a finding. Until more environmental data are collected and until a number of information gaps are filled, analysts will always face controversy and differing opinions on these issues.

Two issues overlay all the environmental issues analyzed and still remain to be resolved. The first issue centers on the concept of environmental risk and uncertainty. How should managers respond to situations where the environmental impact of a proposed action is not known and where there is a great deal of uncertainty, both in the data collected as well as in our ability to predict future outcomes? How should managers apply the precautionary principle when making management decisions? The PA would reduce the risk of environmental harm by adopting measures that would mitigate against adverse impacts. Such measures would be monitored and if new data indicate they are not working as intended, the NPFMC and NOAA Fisheries would adapt the management regime accordingly. Controversy among various stakeholders is anticipated over the measures to be employed. We expect that the analysis of those proposed measures will be thorough and based on the best scientific information available. It is doubtful that a broad consensus among stakeholders can be reached on this issue until more environmental data are available.

The second issue focuses on the term ecosystem-based management. What does this truly mean? This issue is currently receiving national attention and scientific debate. How should resource managers apply ecosystem-based management principles? We have attempted, through this Programmatic SEIS, to inform the public on this subject. We anticipate that over the next few years, the American public will come to understand this concept more fully and we will begin to finds ways to incorporate this concept into our fishery management plans. The PA sets the stage for this debate and commits to its implementation once it is better defined and analyzed. NOAA Fisheries encourages the public to be full participants in the MSA-

NPFMC process by staying involved. This is accomplished by volunteering to serve on working groups and committees, by developing new ideas and management proposals consistent with the FMPs new policy goals and objectives, and by sharing in the responsibility for how these resources are to be managed.

ES 12.0 What Are the Next Steps in the Programmatic Supplemental Environmental Impact Statement Process?

This executive summary is a snapshot of the contents of the final Alaska Groundfish Fisheries Programmatic SEIS. Following release of the final PSEIS to the public in June 2004, the Agency will make its decision concerning the reauthorization of the Alaska groundfish fisheries. NOAA Fisheries will issue its Record of Decision no later than September 1, 2004. This decision document will conclude the NEPA process on the proposed action. For updates on the Programmatic SEIS and to obtain a copy of the Record of Decision, visit the NOAA Fisheries website at www.fakr.noaa.gov.

GLOSSARY

abiotic: not living.

acceptable biological catch (ABC): the range of allowable catch for a species or species group set by a scientific calculation of the sustainable harvest level of a fishery; a target reference point that management aims to achieve.

advection: horizontal or vertical movement of a mass of fluid, i.e. air or ocean current.

advisory panel (AP): a group of people appointed by a fisheries management agency to review information and give advice. Members are usually not scientists, but most are familiar with the fishing industry or a particular fishery.

alcids: small birds that fly with rapid wing beats and use their wings to swim underwater.

Alaska Coastal Current: a persistent flow of buoyant water circumscribing the inner shelf of the Gulf of Alaska shelf over 2000 km from its origin in the southeastern Gulf of Alaska to where it enters the Bering Sea in the southwestern gulf.

Alaska Current: the shallow, highly variable, eastern limb of the counterclockwise-flowing subpolar gyre in the North Pacific

Alaska Stream: the steady, swift current that flows westward approximately 150 km from the coast and reaches to the ocean floor.

albedo: the fraction of light radiation that is reflected by a body, as the moon or a cloud.

alkanes: any of numerous saturated, non-aromatic hydrocarbons; any of a series of open-chain hydrocarbons such as methane and butane.

American Fisheries Act (AFA): enacted 1998, this act requires the determination of whether vessels of 100 feet or greater in registered length comply with the new ownership, control and financing requirements imposed, thereby demonstrating eligibility to receive a fishing endorsement.

amphipods: small crustaceans with flat bodies.

GLOSSARY (Cont.)

anadromous: fish that migrate from saltwater to fresh water to spawn.

anal fin: the fin that lies behind the anus, usually on the back half of the fish.

annelids: long, segmented invertebrates that have a coelom. (e.g., earthworms, various marine worms, and leeches).

anomalous: inconsistent with or deviating from what is usual, normal, or expected.

anoxic: oxygen deficient.

anthropogenic: of or relating to the study of the origins and development of human beings.

anthozoans: sessile marine coelenterates including solitary and colonial polyps; the medusoid phase is entirely suppressed.

apex feeders: those who feed at the top of the food chain.

appendicularia: free-swimming tadpole-shaped tunicate resembling larvae of other tunicates.

aromatic hydrocarbons: a group of over 100 different chemicals that are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances.

arthropods: invertebrate animals such as crabs that have segmented bodies and jointed appendages, and an exoskeleton.

austral winter: winter in the southern hemisphere.

avian: pertaining to or characteristic of birds.

avifauna: the birds of a region or environment.

B: see *biomass*.

B_0: biomass at the starting point of a population at its original or pristine level.

B_{MSY}: the average biomass that would be achieved if fishing continued at a constant fishing mortality rate resulting in the maximum sustainable yield.

barnacle: a marine crustacean with feathery appendages for gathering food, free-swimming as larvae but permanently fixed (as to rocks, boat hulls, etc.) as an adult.

baroclinic: a state in which water surfaces of equal density are influenced by those of equal pressure.

barotropic: a water state in which surfaces of pressure and density coincide at all levels; depth-independent circulation due to changes in surface elevation.

basal metabolic rate: the rate at which heat is given off by an organism at complete rest.

bathyal: refers to organisms or phenomena at depths between 200 & 4000 meters, on the sea bottom; often coincident with the continental slope.

Bathylagidae: Family of fishes in the Class: Actinopterygii; distribution includes the Atlantic, Indian and Pacific Oceans. Physical characteristics include: Adipose fin may be present or absent.

bathylagids: deep-sea smelts.

bathymetric: water depth measurement.

benthic: portion of the marine environment inhabited by marine organisms that live permanently in or on the bottom.

benthic substrate: the base on which an organism lives.

benthypelagic: suspended in the water column near the bottom.

benthos: organisms that live on or in the bottom of a body of water.

Bering Sea Gyre: a barotropic, counterclockwise gyre of the Aleutian Basin.

Bering Slope Current: a counter-clockwise flow with an eastern boundary current at the shelf edge

biennial: occurring every second year.

bioaccumulation: an increase in the concentration of a chemical in a biological organism over time, compared to the chemical's concentration in the environment.

biogenic: produced by living organisms.

biomarker: a distinctive usually biochemical indicator of a biological or geochemical process or event.

biomass (*B*): amount of living matter per unit of water surface or volume expressed in unit weight .

biota: all the plant and animal life of a particular region.

biotic: living or related to living units.

biphenyls: a white crystalline hydrocarbon used especially as a heat-transfer medium ($C_6H_5 \cdot C_6H_5$.)

bivalve: having a shell composed of two valves.

boreal: of or located in northern regions.

brash ice: floating ice found between the year's first ice floes and made up of fragments from other ice forms.

bryozoan: one of a phylum of minute, mostly colonial aquatic animals, with body walls often hardened by calcium carbonate and growing attached to aquatic plants, rocks and other firm surfaces.

butyltins: organic tin compounds in either single, double, or triple forms and used to inhibit the growth of unwanted organism such as bacteria, algae, and barnacles.

bycatch: harvested species other than that for which the fishing gear was set. Also called *incidental catch*, bycatch is sometimes kept for sale (does not include fish released alive under a recreational catch-and-release program).

C: degrees Celsius.

calanoid (e.g., copepod): large copepod easily recognized by its longer-than-body antennae.

California Current: the eastern limb of the clockwise flowing subtropical gyre in the North Pacific.

cannibalistic: the eating of the flesh of an animal by another animal of the same kind.

caprellid: a species of amphipods commonly known as skeleton shrimp.

carapace: a bony case or shield covering the back or part of the back of an animal as a turtle or crab.

caridean: a group belonging to the crustaceans, commonly known as shrimp.

carrion: dead flesh that is unfit for food.

cartilaginous: composed of cartilage.

catch: the total number or poundage of fish captured from an area over some period of time, including fish that are caught but released or discarded instead of being landed.

catch per unit of effort (CPUE): the quantity of fish caught with one standard unit of fishing effort; e.g. the combination of gear type, gear size, and length of time gear is used. Also used as a measurement of relative abundance for a particular fish.

caudal: at the hind or tail end of the body.

GLOSSARY (Cont.)

caudal fin: the terminal fin, or tail, of a fish.

caveat: an explanation to prevent misinterpretation.

central Pacific Gyre: this gyre is bordered by the southern flowing, cold water California current which runs into the western moving, warm water North Equatorial Current. The North Equatorial Current moves north with the Philippines Current and then northeast into the Kuroshio Current. West winds push the North Pacific current east where it divides at the North American continental plate to form the Alaska Current to the north (part of the North Pacific gyre) and the California Current to the south. This is a clockwise moving gyre.

cessation: end, cease, stop.

cetaceans: aquatic, mostly marine, mammals including whales, dolphins, porpoises, and others that have a torpedo shaped, nearly hairless body, paddle-shaped forelimbs, no hind limbs, one or two nares opening externally at the top of the head, and a flat tail for locomotion.

chaetognath: small free-swimming marine worms with movable curved chaetae on either side of the mouth.

chlordane: a highly chlorinated viscous volatile liquid insecticide ($C_{10}H_6Cl_8$).

chrysene: one of the polycyclic aromatic hydrocarbon compounds formed when gasoline, garbage, or any animal or plant material burns. Usually found in smoke and soot, this chemical combines with dust particles in the air and is carried into water and soil and onto crops.

circumpolar: constantly visible above the horizon.

cladoceran: minute chiefly freshwater branchiopod crustaceans that includes the water fleas.

coastal lowland: a narrow strip of relatively low ground between the sea and the cliffs leading to the plateau with a climate wetter than that of the plateau; with fewer temperature extremes it is more subject to fog.

GLOSSARY (Cont.)

coastal runoff: land-based pollution, i.e., chemicals and other contaminants that make their way into coastal waters.

coccolithophorid: the unicellular marine plant plankton with a calcareous skeleton that form the base of the food chain.

community development quota (CDQ): a federal fisheries program that involves coalitions of communities who have formed six regional organizations. The program allocates a portion of the Bering Sea and Aleutian Island harvest amounts to groups.

concomitant: accompanying, especially in a subordinate or incidental way.

congener: a member of the same taxonomic genus as another plant or animal; something resembling another in nature or action.

continental shelf: a shallow submarine plain of varying width forming a border to a continent and typically ending in a steep slope to the ocean floor.

continental slope: the usually steep slope from a continental shelf to the ocean floor.

control rule: describes a variable over which management has some direct control as a function of some other variable(s) related to the status of the stock.

copepods: a group of small crustaceans, some free-swimming and some parasitic on fish gills or skin.

cottid: member of the family Cottidae, which includes sculpin and bullhead.

covariance: the expected value of the product of the deviations of two random variables from their respective means.

crangonid shrimp: commonly called bay shrimp; there are three species in the Family Crangonidae.

GLOSSARY (Cont.)

critical habitat: a specific area that is necessary for preservation of a threatened or endangered species that may require special protection or management.

crustacean: a group of freshwater and saltwater animals having no backbone, with jointed legs and a hard shell made of chitin.

ctenophore: marine animals superficially resembling jellyfishes but having biradial symmetry and swimming by means of eight meridional bands of transverse ciliated plates.

cumacea: an order of marine crustacea, mostly of small size.

cycloalkanes: alkanes in which at least one of the continuous carbon chains is linked back on to itself in the form of a ring.

davit: a crane that projects over the side of a ship or hatchway and is used for boats, anchors, or cargo.

decapod: crustaceans with five pairs of thoracic appendages one or more of which are modified into pincers, with stalked eyes, and with the head and thorax fused into a cephalothorax and covered by a carapace; cephalopod mollusks with 10 arms.

deep water basin: a collection of water so deep that surface waves are little affected by the ocean bottom; generally characterized as water deeper than one-half the surface wavelength.

demersal: living near the bottom of a water body.

density-dependent mortality: increased risk of death associated with increased population density.

denticulate: fine toothed or serrated.

depredation: to lay waste; to plunder.

depth strata: (also known as depth zone) any of one of the four oceanic environments: the littoral, neritic, bathyal and abyssal zones.

GLOSSARY (Cont.)

detritus: loose material (organic particles) resulting from disintegration.

diatoms: minute planktonic unicellular or colonial algae with silicified skeletons.

dibenzothiophenes: a polynuclear aromatic hydrocarbon; an environmental hazard.

dinoflagellate: chiefly marine phytoplanktonic, usually solitary unicellular flagellates that include luminescent forms and forms that cause red tide.

diurnal: having a daily cycle; occurring in the daytime.

domestic annual harvest (DAH): the domestic annual fishing capacity, modified by other factors (such as economic factors), which will determine estimates of what fishing fleets will harvest.

domestic annual processing (DAP): the amount that will be domestically processed, based not only on physical capacity but on a demonstrated intent and the effects of domestic harvesting, markets, and other fisheries.

donut hole: an area which encompasses approximately 48,000 square miles and comprises 19 percent of the Aleutian Basin or 10 percent of the entire Bering Sea area where the stocks being fished are suspected to straddle or move back and forth across the open area and an area of regulated national jurisdiction.

dorsal: the back of the body.

dorsal fin rays: cartilaginous structures within the dorsal fin.

downwelling: a circulation pattern in which warmer surface waters move down in the water column.

echinoderms: marine animals including starfishes, sea urchins, and related forms.

Echiuroid worm: marine worms that have sensitive but non-retractable proboscis above the mouth.

ecosystem: the community of living creatures occurring in an environment.

El Niño Southern Oscillation: an interannual disturbance of the climate system characterized by a periodic weakening of the tradewinds and warming of the surface layers in the equatorial Pacific Ocean every 4 to 7 years.

embayment: a small bay or semi-enclosed coastal water body whose opening to a larger water body is restricted.

endemic: native to a particular country; characteristic of or prevalent in a particular environment.

endocrine system: the system of glands/organs capable of secreting hormones which provide communication in the body

epibenthic: living on the surface of bottom sediments in a water body.

epifauna: invertebrates living on to of the sediment of the seafloor.

epipelagic: the zone of the ocean into which enough light penetrates for photosynthesis.

errantiate: form of the word "errant" meaning to move or wander, usually an irregular motion.

escarpment: a long cliff or steep slope separating two comparatively level or more gently sloping surfaces and resulting from erosion or faulting.

estuary(ies): a water passage where the tide meets a river current.

eunicid: a family belonging the to the Polychaetes, characterized by having up to five antennae and pincher-like jaw maxilla.

euphausiid: small, pelagic, shrimp-like crustaceans, e.g., krill.

euphotic: constituting the upper layers of a body of water where sufficient light penetrates to permit green plant growth.

ex-vessel: activities that occur when a commercial fishing boat lands or unloads a catch.

exclusive economic zone (EEZ): a zone under national jurisdiction (up to 200-nautical miles wide) within which the coastal State has the right to explore, and the responsibility to conserve and manage, the living and non-living resources.

exogenous: due to external causes; not arising within the organism.

extrapolate: to infer (values of a variable in an unobserved interval) from values within an already observed interval.

extrude: to force out.

$\boldsymbol{F}_{\mathbf{MSY}}$: a continuous fishing mortality rate that results in the maximum sustainable yield.

$\mathbf{F}_{\mathbf{\%SPR}}$: the fishing mortality rate associated with a stable spawning per recruit level equal to X% of the spawning per recruit level at equilibrium when no fishing has occurred.

faunal: being animal life.

fecundity: the measure of the egg-producing ability of a fish..

filter feeder: an animal that obtains food by filtering organic matter or minute organisms from a current of water passing through some part of its system.

fishery: as defined by the Magnuson-Stevens Fishery and Conservation Act, a fishery is one or more stocks of fish that can be treated as a unit for purposes of conservation and management and that are identified on the basis of geographic, scientific, technical, recreational, or economic characteristics.

fishery management plan (FMP): a plan developed by a regional fishery management council, or by the U.S. Secretary of Commerce, to manage a fishery resource to achieve specified management goals.

GLOSSARY (Cont.)

fishing mortality rate (F): a measurement of the rate of removal of fish from a population by fishing. Expressed as either "annual" or "instantaneous rates;" annual mortality if the percentage of fish dying in one year while instantaneous mortality is the percentage of fish dying at any one time.

fjord: a narrow inlet between cliffs or steep slopes.

fledge: to rear until ready for flight or independent activity.

foraminiferan: marine protozoans usually having calcareous shells that are perforated with minute holes for protrusion of slender locomotors or food gatherers.

forage fish: any fish eaten by larger predatory fish, seabirds, or marine mammals, usually swimming in large schools.

fossil fuel: a fuel (as coal, oil, or natural gas) that is formed in the earth from plant or animal remains.

fry: recently hatched or juvenile fish.

gadoid fish: resembling or related to the cods.

gammarid: a family belonging to the amphipods

gastropods: a large group of mollusks including the snails.

genus (plural, genera): a class or group marked by common characteristics.

gladius: the internal shell, or pen, of cephalopods like squid.

glaucous: of a pale yellow-green or a light bluish-gray or bluish-white color.

gorgonian: an anthozoan with a horny and branching axial skeleton.

GLOSSARY (Cont.)

gradient: the rate of regular or graded ascent or descent; part sloping upward or downward; change in the value of a quantity (temperature, pressure, or concentration) with change in a given variable.

greenhouse gases: gases that contribute to the greenhouse effect by trapping heat within the earth's atmosphere. The chief greenhouse gases are carbon dioxide and water vapor. Other potentially important trace gases are chlorofluorocarbons, methane, ozone, and nitrous oxide.

gregarious: tending to associate with others of one's kind.

groundfish: a species or group of fish that lives most of its life on or near the sea bottom.

guild: a group of species that utilize the same kinds of resources, such as food, nesting sites, or places to live, in a similar manner.

guild diversity: the variation in the number of species that share a common food source.

gyre: a giant circular oceanic surface current.

halocline: a usually vertical gradient in salinity.

harpacticoid copepods: minute crustaceans, often long and cylindrical in shape.

harvest: the total number or poundage of fish caught and kept from an area over a period of time.

holoplanktonic: living in the water column.

harpacticoid: a family belonging to the copepods.

haulout: a resting place.

hydroacoustic: sound waves bounced off the ocean floor.

GLOSSARY (Cont.)

hydrocarbon: an organic compound containing only carbon and hydrogen and often occurring in petroleum, natural gas, coal, and bitumens.

hydroid: of or relating to a hydrozoan; especially resembling a typical hydra.

hyperiid: a family belonging to the amphipods.

ichthyoplankton: fish eggs or larvae.

incidental catch: see *bycatch*.

indigenous: having originated or naturally occurring in a particular region or environment.

individual fishing quota (IFQ): a federal permit under a limited access system to harvest a quantity of fish, expressed by a unit or units representing a percentage of the total allowable catch of a fishery that may be received or held for exclusive use by a person.

infauna: invertebrates living in the sediment of the seafloor.

inflow: the flowing in [of air].

in situ: in the natural or original position or place.

instantaneous mortality: see *natural mortality*.

intertidal: relating to or being the part of the littoral zone above low-tide mark.

intra-annual: occurring during or within a year time span.

invertebrate: any animal lacking a spinal column.

isobath: a line of a map passing through all points of equal depth below water.

isomer: one of two or more compounds or ions that contain the same number of atoms of the same elements but differ in structural arrangement and properties.

isopod: a small crustacean with attached eyes and a body composed of seven free thoracic segments each bearing a pair of similar legs.

isotope: two or more species of atoms in a chemical element with the same atomic number and nearly identical chemical behavior but with differing atomic masses and different physical properties.

juvenile: a young fish or animal that has not reached sexual maturity.

kamaboke: white fish filleted and pounded into a paste.

Kamchatka Current: a current which brings water southward from the Bering Sea, where it is associated with the quasi-permanent anticyclonic eddies found close to the western shore.

kinetic energy: energy associated with motion.

kirimi: a fish processing style in which the head and tail are taken off and the guts are left in the fish.

landings: the number or poundage of fish unloaded at a dock by commercial fishermen or brought to shore by recreational fishermen for personal use.

larvaceans: small transparent animals found in marine plankton, e.g., tunicates

License Limitation Program (LLP): a limited access program intended to limit participation in the groundfish fisheries in the Gulf of Alaska and the Bering Sea and Aleutian Islands federal management areas and Bering Sea and Aleutian Islands crab fisheries based on past documented harvests made by each fishermen.

limit reference points: limits (e.g., OFL, MFMT) established by management to be avoided, constrains harvests so that the stock remains within safe biological limits.

littoral: of, relating to, or situated or growing on or near a shore. Or, a coastal region, especially the shore zone between high and low watermarks.

M: see *natural mortality*.

macrofauna: small to moderate sized invertebrates living on and in bottom sediments.

macrozooplankton: large, thick, or exceptionally prominent animal life of the plankton.

Magnuson-Stevens Fishery Conservation and Management Act: a federal law that created the regional councils and is the federal government's bases of fisheries management in the EEZ (U.S. Public Law 94-265, as amended through October 11, 1996).

marine mammal: animals that live in marine waters and breathe air directly, i.e., sea lions, porpoises, whales, and seals.

maximum fishing mortality threshold (MFMT): standard determination criteria for determining if overfishing is occurring within a stock; equivalent to OFL in the BSAI and GOA FMPs.

maximum sustainable yield (MSY): the largest average catch or yield that can continuously be taken from a stock under average environmental conditions.

medusae: jellyfish.

meiofauna: benthic animals that can fit a mesh size of 1 millimeter and be retained on a mesh size of 42 micrometers.

Meridional thermal gradient: the vertical (north-south) flow of water of which the surface is made up of warm waters underlain by deep cold waters.

mesopelagic region: relating to oceanic depths from about 600 feet to 3000 feet (200 to 1000 meters).

metabolite: substances which are required as basic raw materials for vital processes, such as glucose in respiration and other metabolic pathways.

GLOSSARY (Cont.)

meteorological regime: circulation air mass.

metric ton: 2,204.62 pounds.

microflora: minute plants not seeable with the naked eye.

micronekton: microscopic free-swimming aquatic animals that move independent of wave and current action.

millimeter (mm): ½5 of an inch.

milt: the sperm-containing fluid of a male fish.

minimum stock size threshold (MSST):a standard determination criteria used for determining when a stock is in a overfished condition; usually measured in terms of spawning biomass.

mollusk: an invertebrate animal with a soft unsegmented body usually with one or two hard shells made of calcium carbonate.

molt: to periodically shed hair, feathers, shell, horns, or other outer layer.

morphological: an organisms form and structure.

MSY control rule: a harvest strategy that results in a long-term average catch approximating MSY, enables the use of proxies.

multispecies perspective: a management theory that recognizes the interactions between organisms, for example: predator-prey relationships.

munid crabs: crustaceans belonging to the Family Galathoidae.

myctophids: members of the Family Myctophidae.

GLOSSARY (Cont.)

Myctophidae: deep sea fishes comprising the lantern fishes.

mysids: small, shrimp-like marine crustaceans, the females of which carry their eggs in a pouch beneath the thorax.

naphthalene: a crystalline aromatic hydrocarbon ($C_{10}H_8$) usually obtained by distillation of coal tar and used especially in organic synthesis.

natal area: area associated with birth.

National Standard Guidelines: seven FMP guidelines and standards required by MSFCMA to identify the nation's interest in fish management.

natural mortality rate (*M*): a measurement of fish deaths from all causes other than fishing such as predation, disease, starvation, and pollution.

nauplius (plural, nauplii): a crustacean larva usually in the first stage after leaving the egg and with three pairs of appendages, a median eye, and little or no segmentation.

nautical mile: 6,076.115 feet or 1,852 meters.

near-shore eddy(ies): inshore waters that run contrary to the current.

Near Strait Inflow: the primary source of inflow in the Bering Sea.

necropsy: an examination of an organism after death to determine the cause of death or the character and extent of changes caused by disease.

necrotic: localized death of living tissue.

nematode: elongated cylindrical worms parasitic in animals or plants or free-living in soil or water.

neoplasia: formation of tumors

GLOSSARY (Cont.)

neritic: region of shallow water adjoining the seacoast.

nocturnal: active at night.

nodal: being or located at or near a node. In a tide area, the point about which the tide oscillates and where there is little or no rise and fall of the tide.

Nor'eastern: a trawl constructed with polyethylene mesh and outfitted with other types of footropes for the Gulf of Alaska, the Aleutian Islands, and the Pacific West Coast shelf surveys, has a 27.2 meter headrope, and a 37.4 meter footrope; the body is 127 millimeter stretched mesh and the codend is 89 millimeter stretched mesh with a 32 millimeter stretched mesh codend liner; floats along the headrope hold the net open vertically.

North Pacific Index: the area-weighted sea level pressure over the North Pacific in the region 30°N to 65°N, 160°E to 140°W.

nuclide: species of atom characterized by the constitution of its nucleus and hence by the number of protons, the number of neutrons, and the energy content.

σ_t: a measure of the density of water, at its current pressure, if it were raised to the surface.

Ocean Current simulations model: ocean simulations models may input climate data, ocean circulation, sea-ice, temperature gradient, nutrient gradient, anthropogenic events and large climatic events (e.g. ENSO) among other information to better understand how the ocean works and predict weather events and possible human impacts on ocean systems (among other uses).

oceanographic: pertaining to the ocean.

offal: the waste or by-product of a process; debris, garbage, etc.

oikopleura: a small pelagic tunicate at the basis of the chordate phylum; larvaceans.

ommatidia: the structural elements forming the compound eye of arthropods, insects, etc.

omnivorous: feeding on both animals and vegetables.

ontogeny: the development or course of development of an individual organism.

onuphid: beachworm; a member of the family Onuphidae

optimum yield (OY): the harvest level for a species that achieves the greatest overall benefits, including economic, social, and biological considerations.

ostracods: very small, active, mostly freshwater crustaceans that have the body enclosed in a bivalve shell, the body segmentation hidden, the abdomen rudimentary, and only seven pairs of appendages.

overfished: a stock or stock complex whose size is sufficiently small that a change in management practices is required in order to achieve an appropriate level and rate of rebuilding; a stock is determined to be overfished when it is below the minimum stock size threshold.

overfishing: a rate or level of fishing greater than that which will meet the management goal and that jeopardizes the capacity of a fishery to produce the largest average catch or yield that can continuously be taken under average environmental conditions on a continuing basis.

overfishing level (OFL): a fishing rate that reduces the level of spawning biomass per recruit to some percentage of its original, pristine level; a limit reference point that management seeks to avoid.

overwintering: surviving the winter.

ovoviviparous: producing eggs that develop within the maternal body and hatch within or hatch immediately after being pushed out from the parent.

Pacific decadal oscillations: an El Niño-like pattern (see previous) of Pacific climate variability and persisting for 20 to 30 years with climatic fingerprints most visible in the North Pacific/North American sector.

panmictic: mating randomly.

GLOSSARY (Cont.)

parturition: the action of giving birth to offspring.

pelagic: refers to fish and animals who live in the open sea, away from the sea bottom.

per capita: per unit of population.

perylene: an organic molecule consisting of 20 carbon atoms and 12 hydrogen atoms arranged as five benzene-like rings connected to each other in a plane.

phenanthrenes: a crystalline aromatic hydrocarbon ($C_{14}H_{10}$) of coal tar isomeric with anthracene.

phyla: primary division of the animal kingdom.

phytoplankton: planktonic plant life.

pinniped: an aquatic carnivorous animal with all four limbs modified into flippers.

piscivorous: feeding on fishes.

planktivorus: feeding on plankton.

plankton: the passively floating or weak swimming animal and plant life of a body of water.

planktonic: of or relating to plankton

pleuronectid: pertaining to the flounder family.

polychaete: chiefly marine annelid worms, i.e., clam worms, usually with paired segmental appendages, separate sexes, and a free-swimming trochophore larva.

polychlorinated: PCB - any of several compounds that are produced by replacing hydrogen atoms in biphenyl with chlorine, have various industrial applications, and are poisonous environmental pollutants which tend to accumulate in animal tissues.

polycyclic: having more than one cyclic component, i.e. having two or more rings in the molecule.

polynias: see polynyas.

polynya(s): open water in sea ice.

population: fish of the same species inhabiting a specified area grouped together for management purposes.

predation: the act of preying or plundering; a mode of life in which food is primarily obtained by the killing and consuming of animals.

pre-neoplastic: pre-malignant.

probability density function: a statistical distribution; used in deriving overfishing limits and acceptable biological catch.

procellarid: one of a family of oceanic birds (Procellarid[ae]) including the petrels, fulmars, and shearwaters.

procellariiformes: tube-nosed swimmers, fulmars and albatrosses.

prohibited species catch (PSC): in applicable Bycatch Limitation Zones of the Bering Sea subarea - limits specified for red king crab, Chionoecetes bairdi Tanner crab, and C. opilio crab; throughout the BSAI - limits specified for Pacific halibut and Pacific herring. Regulations authorize the apportionment of each limit into allowances for specified fishery categories. Seven-and-a-half percent of each limit specified for halibut, crab, and salmon is reserved as a quota for use by the CDQ program.

protease: any of numerous enzymes that hydrolyze proteins.

GLOSSARY (Cont.)

protobranch: a gill structure occurring in bivalves in which gills are small and leaf like with the unmodified appearance occurring in primitive groups.

protozoan: minute cell-less or one-celled animals that often have complex life cycles and frequently are serious parasites to humans and other animals.

protracted spawning: a longer spawning period.

proxy: a substitution; something that is authorized to act in place of another.

pterpods: small mollusks that expand the front lobes of the foot into thin wing-like organs with which they swim.

pyrogenic: caused by or generating heat.

pteropod: holoplanktonic molluscs belonging to the orders of Thecosomata and Gymnosomata. The species have in common that the original foot has developed into a pair of 'wings' (parapodia), increasing the animals' buoyancy and locomotion capacity.

pycnocline: a layer in the water column separating two areas of different density.

quota: the maximum number of fish that can be legally landed in a time period.

radiolarian: spherical marine protozoans having radiating threadlike protrusions for locomotion or food gathering and often a siliceous skeleton of spicules.

radionuclide: a radioactive nuclide.

rebuilding plan: a plan that is designed to recover stocks when they are overfished.

recruit: an individual fish that has moved into a certain class, such as the spawning class or fishing-size class.

GLOSSARY (Cont.)

recruitment: a measure of the weight or number of fish that can enter a defined portion of stock, such as the fishable stock or the spawning stock, during some time period.

reef: a chain of rocks or coral or a ridge of sand at or near the surface of water or within a depth of 20 meters from the surface..

reference points: limits or values that are used to guide management decisions.

regime shift: a transition from one climactic state to another within a period substantially shorter than the lengths of the individual epochs of each of the two climatic states.

regulatory impact review (RIR): the part of a federal fishery management plan that describes the impacts resulting from the plan.

rip (also tide rip): agitation of water caused by the meeting of currents or by a rapid current setting over an irregular bottom. Termed tide rip when a tidal current is involved.

risk averse: avoiding risk.

roe: the eggs of a fish especially when still enclosed in the ovarian membrane.

rookery: the nest, haunt, or breeding ground of a colony, especially of gregarious birds or mammals.

salpa: a transparent barrel-shaped or fusiform free-swimming tunicate that is abundant in warm seas.

satiation: full or excessive satisfaction.

seamount: elevation rising 1000 meters or more from the sea floor and of limited extent across the summit.

sediment: matter that settles to the bottom; material deposited by water, wind, or glaciers.

GLOSSARY (Cont.)

serpulid: a small marine annelid worm which build limey tubes on stones and seaweed and extends a crown of tentacles to feed.

semidemersal: semi-bottom-dwelling.

sessile: permanently attached at the base or foot.

sideboard measures: constraints imposed on a directed fishery that restrict its participation in other directed fisheries.

sill fjord: natural rock barriers occurring at the mouth of a fjord and delineating the extent of the progress of the glacier that carved the fjord.

siphonophores: compound free-swimming or floating pelagic hydrozoans that are mostly delicate, transparent, and colored and have specialized zooids.

spatial dispersion: a movement over space or area.

spawning per recruit (SPR): amount of spawning biomass at a instantaneous fishing mortality rate, influenced by other values including growth, maturity, natural mortality and partial recruitment.

spermatheca: a sac for sperm storage in the female reproductive tract of many lower animals.

spermatophore: a capsule, packet, or mass enclosing spermatozoa extruded by the male and conveyed to the female in insemination.

standard determination criteria: criteria (e.g., MSST, MFMT) used to determine if a stock is in a overfished state, according to the National Standard Guidelines.

stalked ascidians: sea tulips.

steranes: organic molecules with 26 to 30 carbon atoms arranged in four rings.

stock or stock complex: a grouping of fish usually based on genetic relationship, geographic distribution, and movement patterns.

stock assessment: a means of estimating fish numbers and predicting how fish populations will respond to harvesting.

Stock Assessment and Fishery Evaluation Report (SAFE): a report that provides a summary of the most recent biological condition of a stock of fish as well as the economic and social condition of the recreational fishermen, commercial fishermen, and seafood processors who use the fish. It is used to determine harvest levels.

stratum: a sheet like mass of sedimentary rock or earth of one kind lying between beds of other kinds; a region of the sea or atmosphere that is analogous to a stratum of the earth.

subarctic: characteristic of, or being regions immediately outside of the arctic circle or regions similar to these in climate or conditions of life.

Subarctic Current: the current which flows eastward from the western Rim of the Pacific Ocean.

sublittoral: benthic region extending from mean low water to a depth of about 200 meters or to the edge of the continental shelf. Situated, occurring, or formed on the aquatic side of a shoreline or littoral zone.

subtidal: the zone that is permanently flooded by tidal water.

surimi: fish product made from inexpensive whitefish and often processed to resemble more expensive seafood (i.e., crabmeat).

Sustainable Fisheries Act (SFA): an amendment to the Magnuson-Stevens Fishery Conservation and Management Act which includes numerous provisions requiring science, management, and conservation action by NMFS.

target reference points: limits and benchmarks (e.g., ABC) to be achieved, but not exceeded, by management.

taxa: a category or group of related organisms.

taxonomic: classification of plants and animals according to their presumed natural relationships.

telemetry: the science of automatic data measurement and transmission of data.

teleost: a group consisting of fishes with bony skeletons and rayed fins.

temperate: marked by moderation; not extreme or excessive.

terrestrial: of or related to earth and its inhabitants.

terrigenous: relating to oceanic sediment derived directly from destruction of surface rock.

thermal stratification: horizontal layers of differing densities produced in a lake by temperature changes at different depths.

thermocline: the region in a thermally stratified body of water which separates warmer oxygen-rich surface water from colder oxygen-poor deep water and in which temperature decreases rapidly with depth.

thermoregulation: the maintenance or regulation of temperature, i.e., body temperature.

tide rip: see *rip*.

Tier: each stock or stock complex is categorized into a certain "tier" or level based on the amount of information available for the given stock or stock complex. From these tiers, certain limits are derived using mathematical equations.

tintinnid: marine plankton

topography: the configuration of an earth surface including its relief and the position of its natural and man-made features.

total allowable catch (TAC): the annual recommended catch for a species or species group. Set from the range of acceptable allowable catch.

Total Allowable Level of Foreign Fishing (TALFF): that portion of the optimum yield which will not be harvested by domestic vessels. The foreign allowable catch is determined by deducting the expected domestic annual harvest and reserve from the optimum yield (TALFF = OY- [DAH + reserve]).

triennial: occurring every three years.

triterpanes: pentacyclic biological marker hydrocarbons containing between 27 and 35 carbon atoms.

trophic: ecology of or involving the feeding habits or food relationship of different organisms in a food chain.

trophic level: a group of organisms that occupy the same position in a food chain.

trophic guild: a group of species which use similar resources (e.g. insectivorous birds are a trophic guild of birds that eat insects).

tunicate: marine chordate animals with a thick secreted covering layer, a greatly reduced nervous system, a heart able to reverse the direction of blood flow, and only in the larval stage a notochord.

turrid: a family of snails, now reclassified into several subfamilies.

ubiquitous: existing everywhere at the same time; constantly encountered.

µM: micrograms per liter.

uncertainty: a lack of perfect knowledge. Rosenberg and Restrepo (1994) identify five types of uncertainty: 1) measurement error, 2) process error, 3) model error, 4) estimation error, and 5) implementation error.

GLOSSARY (Cont.)

upwelling: the process by which water rises from a deeper to a shallower depth, usually as a result of offshore surface water flow; it is most prominent where persistent wind blows parallels to a coastline so that the resultant Ekman transport moves surface water away from the coast..

uterine cannibalism: while still in the mother's reproductive tract, the first hatchling eats either younger `hatchlings or unfertilized eggs to get nourishment.

vertebrate: having a spinal column.

vestigial: sign or evidence of some past thing.

viviparous: producing living young rather than eggs.

voracious: having a ravenous appetite.

vorticity: a swirling motion.

West Wind Drift: (also known as Antarctic Circumpolar Current) the ocean current from west to east through all the oceans around the Antarctic continent.

wind-stress curl: the plot of the energy transferred from the wind to the sea surface.

year-class: the fished spawned and hatched in a given year; a "generation" of fish.

young-of-the-year: fish or animals born in the past year, which have not yet reached one year of age.

zooplankton: plankton composed of animals.

Chapter 1

Chapter 1 Purpose and Need

This Programmatic Supplemental Environmental Impact Statement (Programmatic SEIS) constitutes the central environmental document supporting the Fishery Management Plan (FMP) for the groundfish Fishery of the Bering Sea and Aleutian Islands (BSAI) and the FMP for groundfish of the Gulf of Alaska (GOA). The historical and scientific information and analytical discussions contained herein are intended to provide a broad, comprehensive analysis of the general environmental consequences of fisheries management in the Exclusive Economic Zone (EEZ) off Alaska, and thus provide agency decision-makers and the public with information necessary for making informed decisions in managing the groundfish fisheries and for setting the stage for future policy decisions and management actions.

This introductory chapter establishes the purpose and need for the federal action supported by this Programmatic SEIS. It provides an overview of the National Environmental Policy Act (NEPA) of 1969 and its procedural requirements; a history of this document and how the National Marine Fisheries Service (National Oceanic and Atmospheric Administration [NOAA] Fisheries or NMFS) has conducted the NEPA scoping process and addressed public comments; and a review of the future steps that will be taken to finalize the Draft Programmatic SEIS. Finally, this introduction describes the overall organization of this document.

1.1 Purpose and Need for Federal Action

This section describes the purpose of and need for federal action. In this case, the federal action is a continuing activity: the ongoing management of the groundfish fisheries in the EEZ off Alaska, as authorized by the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and pursuant to NEPA and other applicable statutes and executive orders.

At a fundamental level, management of the groundfish fisheries has two interrelated purposes: to maximize the social and economic benefits of the groundfish resource to the people of the United States (U.S.) and to conserve the resource to ensure its sustained availability to current and future generations. The use and conservation of the fisheries need to be managed so that one objective—whether related to biological conservation or to socioeconomic well-being—does not take priority over the other, except when the resource itself is at risk of being depleted. To prevent such depletion of the resource, fisheries management strives to balance these two fundamental objectives.

The North Pacific Fishery Management Council (NPFMC) and NOAA Fisheries have managed the groundfish fisheries off Alaska for more than 20 years under the FMPs for the groundfish fisheries of the BSAI and GOA. These FMPs, subsequent FMP amendments, and related regulatory actions addressing changes in management measures have all been attended by NEPA documents, whether environmental impact statements (EISs), environmental assessments (EAs), or categorical exclusions that consider the environmental impact of those actions. At this juncture, however, the continuing effort to manage the groundfish fisheries requires a renewed evaluation of the overall environmental impacts of existing management policy and an analysis of alternative policies that will allow NPFMC and NOAA Fisheries to strike the most effective and efficient balance between the dual objectives of conservation and use.

1.2 Action Area

The subject groundfish fisheries take place in the Bering Sea and North Pacific Ocean within the U.S. EEZ from 50° North (N) to 65°N (Figure 1.2-1). The EEZ off Alaska extends seaward from 3 to 200 nautical miles (nm). The action area for the federally managed BSAI groundfish fisheries effectively covers all of the Bering Sea under U.S. jurisdiction, extending southward to include the waters south of the Aleutian Islands west of 170° West (W) longitude, to the border of the EEZ. The action area for the federally managed GOA groundfish fisheries includes the EEZ of the North Pacific Ocean, exclusive of the Bering Sea, between the eastern Aleutian Islands at 170°W longitude and Dixon Entrance at 132°40'W longitude. State waters and international waters adjacent to the action area are also affected by the federal groundfish fisheries. A review of areas fished by the groundfish fisheries (Fritz *et. al.* 1998) suggests that virtually the entire Bering Sea and GOA from the continental slope shoreward is utilized by one fishery or another.

The BSAI and GOA groundfish fisheries are divided into sub-areas for management purposes. The BSAI is divided into two sub-areas (eastern Bering Sea [EBS] and Aleutian Islands) and 19 reporting areas (Figure 1.2-2), and the GOA is divided into three sub-areas (western, central, and eastern) and eight reporting areas (Figure 1.2-3).

These regions constitute the areas that are potentially affected either directly or indirectly (or both) by the groundfish fisheries. A more detailed description of the action area is provided in Chapter 3, Affected Environment.

1.3 The Purpose and Need for the Programmatic Supplemental Environmental Impact Statement

The purpose of this Programmatic SEIS is to analyze comprehensive policy alternatives in support of the continuing management of the groundfish fisheries of the BSAI and GOA. A Programmatic SEIS such as this provides a broad, "big picture" environmental evaluation that examines a program on a large scale and may be used to evaluate an ongoing program and alternative directions that the program might take in the future (40 Code of Federal Regulations [CFR] 1502.4[b]). By providing up-to-date scientific information on the cumulative impacts of the groundfish fisheries on the physical, biological, and human environment of the action area, this Programmatic SEIS will serve as the environmental baseline for evaluating current and alternative management regimes and subsequent management actions.

As a comprehensive foundation for management of the BSAI and GOA groundfish fisheries, this Programmatic SEIS is intended to function as a "first tier" analysis for incorporation by reference into subsequent EAs and EISs that focus on specific federal actions. Rather, the federal action supported by this document is the continuing management of the groundfish fisheries in the EEZ off Alaska. This Programmatic SEIS sets forth four distinct management policies, including the current policy, from which NPFMC will choose a preferred management policy direction. Any specific FMP amendments or regulatory actions proposed in the future will be evaluated by subsequent EAs or EISs that are tiered from the Programmatic SEIS but stand as case-specific NEPA documents and offer more detailed analyses of the specific proposed actions. Any such amendments and actions will logically derive from the chosen policy direction set for the preferred alternative. To maintain this document's viability as the "first tier" reference for future analyses, NOAA Fisheries will periodically update this Programmatic SEIS as warranted by the availability of new information or the development of significant changes in the fisheries or their environment.

The need for a "Supplemental" EIS became apparent to NOAA Fisheries during the 1990s, when the agency was apprised of the legal and scientific insufficiency of the initial EISs prepared for the GOA and BSAI groundfish FMPs in 1979 and 1981, respectively. (For a more detailed discussion of the history of this document, see Section 1.5.) Regulations implementing NEPA require preparation of an EIS (or SEIS) when "there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts" (40 CFR 1502.9[c]). Significant changes have occurred in the resource and its environment over the past 20 years, and the initial EISs supporting the FMPs no longer adequately reflect the current state of the environment. While fishery management regulatory actions and FMP amendments have all been attended by environmental analyses, mainly EAs or EISs, none of those analyses attempted to examine the impact the FMPs in their entirety have had on the environment. Consequently, NOAA Fisheries announced its decision to prepare an SEIS that would, moreover, be a "programmatic" analysis based on the current state of the resource and its environment. In January 2001, NOAA Fisheries published the first draft Alaska Groundfish Fisheries Programmatic SEIS (hereinafter referred to as the 2001 Draft Programmatic SEIS).

The 2003 Draft Programmatic SEIS was released in August 2003 and substantially revised the 2001 Draft Programmatic SEIS. The 2003 Draft Programmatic SEIS public comment period began August 29, 2003 and ended November 6, 2003. This Final Programmatic SEIS responds to and integrates into the analysis, the substantive concerns raised by public comments on the 2003 Draft Programmatic SEIS.

1.4 National Environmental Policy Act of 1969

The Programmatic SEIS has been prepared to meet the requirements of NEPA (42 United States Code [USC] 4321-4347), the basic charter of the U.S. for protection of the environment. NEPA establishes the nationwide policy, goals, and legal authority for federal agencies regarding the environment (40 CFR 1500.1[a]). It requires federal agencies to study the environmental consequences of their actions and to use an interdisciplinary framework for environmental decision-making.

NEPA also requires federal agencies to make environmental information available to the public and to public officials, and to consider their comments, before making decisions that could affect the environment. Documents prepared by federal agencies in compliance with NEPA must focus on the issues that are truly significant to the action in question, rather than amassing needless detail, and present alternatives in a way that allows their potential environmental consequences to be clearly distinguished, along with "advice and information useful in restoring, maintaining, and enhancing the quality of the environment" (43 Federal Register [FR] 55990, November 28, 1978, and 40 CFR 1502.1, 1502.2, and 1502.14).

1.4.1 Provisions of National Environmental Policy Act

Title I of NEPA, "Congressional Declaration of National Environmental Policy," requires that a federal agency's study of environmental consequences be presented to the public in "a detailed statement" that must describe:

1. The environmental impact of the proposed action.
2. Any adverse environmental effects which cannot be avoided should the proposal be implemented.
3. Alternatives to the proposed action.
4. The relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity.
5. Any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented (42 USC 4332).

This requirement is based on the idea that if the potential effects of federal actions are publicly disclosed and considered before the actions are taken, the resulting decisions are more likely to be in the public interest (Bass, Herson, and Bogdan 2001).

Title II of NEPA, "Council on Environmental Quality," establishes and funds the President's Council on Environmental Quality (CEQ) to oversee the implementation of NEPA and, among other things, "to formulate and recommend national policies to promote the improvement of the quality of the environment" (42 USC 4342). In 1977, President Carter strengthened the CEQ's role in Executive Order (EO) 11991 (May 24, 1977), authorizing the CEQ to issue binding regulations to cover all of the procedural provisions of NEPA, which until that point had no formal guidance for implementation (Bass, Herson, and Bogdan 2001). A year later, the CEQ issued such regulations implementing NEPA (40 CFR 1500-1508). Among other provisions, the CEQ regulations set forth an orderly procedure that all federal agencies must follow to comply with NEPA, including the preparation of EISs. In accordance with these provisions, NOAA issued Administrative Order 216-6, the provides further guidance for implementing NEPA consistent with the agency's mission.

1.4.2 The National Environmental Policy Act Process for Environmental Impact Statements

The CEQ regulations provide a step-by-step procedure that federal agencies must follow when preparing EISs. (Figure 1.4-1 presents a diagram of how NOAA Fisheries has followed this procedure in preparing this Programmatic SEIS.) While the NEPA process is broad enough that agencies can tailor EISs to their individual missions and program needs, the preparation of an EIS must include the following five basic steps:

1. Scoping. Scoping, the first step in the NEPA process, provides an opportunity for the public, government agencies, and other interested groups to provide information and advice on issues that might be associated with the proposed project, so that the lead federal agency can decide whether and how to address them in the EIS. Scoping can also identify new alternatives to be considered in the EIS. This step is usually accomplished by publishing a Notice of Intent and through a combination of written communications, statements made at public meetings, and consultation with agency officials, interested individuals, organizations, and groups.

2. Draft Environmental Impact Statement. After scoping is completed, a draft EIS is prepared. The draft EIS describes and evaluates all reasonable alternative actions, including no action. If the lead agency has decided upon a preferred alternative by the time a draft EIS is prepared, it is identified. The draft EIS evaluates physical, biological, and socioeconomic environmental impacts that might result from the alternatives, and it identifies those impacts that are likely to be significant. It focuses on cause-and-effect relationships and provides sufficient evidence and analysis for determining the probable magnitude of predicted impacts. Finally, it identifies ways to mitigate the impacts–to avoid, minimize, rectify, reduce or eliminate those impacts over time, or to compensate for any potential harm to the environment that might be caused by any of the alternatives (40 CFR 1508.20).

3. Public Comment. Following publication of a draft EIS, a public notice of its availability for review is published in the FR, and a public comment period of no less than 45 days ensues. A public hearing may be conducted to provide an opportunity for interested parties to provide oral comments on the draft EIS. Following the public comment period, the lead agency considers all of the comments received and prepares a final EIS (FEIS) to incorporate responses to the comments. The responses to public comments can range from major document revisions to simple acknowledgments, depending on the nature of the comment, but the FEIS must address all of the comments received on the draft EIS–except when the public comments are particularly voluminous, in which case the federal agency may respond to comment summaries.

4. Final Environmental Impact Statement. The lead agency is required to address all substantive comments received on the draft EIS and include copies of the comments in the FEIS (40 CFR 1503). The FEIS must also identify the lead agency's preferred alternative and may identify the environmentally preferable alternative. These may be different: the preferred alternative is usually the one that the lead agency believes would best accomplish its mission and goals, whereas the environmentally preferable alternative is the one that would best promote NEPA's goals–that is, cause the least overall harm, on balance, to physical, biological, and socioeconomic resources. There

may be more than one environmentally preferable alternative; if so, they must each be identified and discussed. Once the FEIS is completed and published, agencies and the public may comment on the FEIS before a final decision is made by the lead agency (40 CFR 1503.1[6]). Public comments received on the FEIS are collected and considered by the lead agency prior to making a final decision regarding which of the alternatives to implement. No decision on the action may be made by the lead agency within the 30-day period following publication of the FEIS (40 CFR 1506.10[6]).

5. Record of Decision (ROD). Following completion of the FEIS process as described above, the lead agency prepares a ROD. The ROD must 1) state what the decision was, 2) identify all alternatives considered in reaching the decision and which were considered to be environmentally preferable, and 3) state whether all practicable means to avoid or minimize environmental harm have been adopted, and if not, why not (40 CFR 1505.2). If a monitoring and enforcement program is applicable for any mitigation, it must be adopted and summarized in the ROD (40 CFR 1505.2).

1.4.3 Supplemental and Programmatic Environmental Impact Statements

An SEIS is a document that is prepared after the issuance of an earlier EIS that pertains to the same federal action. The CEQ regulations require that an SEIS be prepared if a federal agency proposes substantial changes to an action that was the subject of a previous EIS, if those changes are relevant to environmental concerns, or if there are significant new circumstances or information bearing on the action or its impacts that are relevant to environmental concerns (40 CFR 1502.9[c]).

A Programmatic EIS is typically a broad-scale environmental evaluation that examines a program on a large scale. In keeping with CEQ regulations, agencies often prepare this type of EIS when considering new federal programs or regulations (40 CFR 1502.4[b]). However, a Programmatic EIS may also be used to evaluate an ongoing program and alternative directions that the program may take in the future. To streamline the NEPA process and avoid repetition, the CEQ regulations encourage federal agencies to develop a tiered approach to their analyses (40 CFR 1502.20). This allows broad, program-oriented issue analyses to be incorporated by reference into subsequent EAs or EISs that focus on specific proposed federal actions (40 CFR 1500.4[I]). NOAA, in its own NEPA guidelines (NOAA Administrative Order 216-6, Section 5.09a), states that “a programmatic environmental review should analyze the broad scope of actions within a policy or programmatic context by defining the various programs and analyzing the policy alternatives under consideration and the general environmental consequences of each.”

1.5 Historical Development of the Programmatic Supplemental Environmental Impact Statement

This section gives readers a brief overview of the history of this Programmatic SEIS and the key factors influencing its development.

Background

The present system of federal fisheries management in the EEZ was established by the MSA in 1976. In creating regional fishery management councils to manage fisheries, the MSA established NPFMC to develop FMPs and set fishery regulations for the marine waters off Alaska in conjunction with NOAA Fisheries, a federal regulatory agency.

The original EISs for the BSAI and GOA FMPs were finalized in 1981 and 1978, respectively. Although many EAs and several EISs have been prepared for FMP amendments and regulatory actions over the ensuing years, none examined the BSAI and GOA FMPs in their entirety or, in other words, at a programmatic level. Since the original EIS documents were developed, major changes have taken place in the technology of the fishing industry, in the allocation of the resources, in the environmental conditions, and in the FMPs themselves. The accumulation of these changes indicated a need for a revision of those initial EISs that would supplement the original analyses and would hence result in a Programmatic SEIS.

Among many other factors, the dramatic decline in the population of Steller sea lions since the 1970s has played a major role in shaping the supplemental analyses. NOAA Fisheries listed Steller sea lions as "threatened" under the Endangered Species Act (ESA) in 1990. Three years later, NOAA Fisheries designated "critical habitat areas" for sea lions around their major rookeries and haulouts. In 1997, NOAA Fisheries recognized two distinct populations of Steller sea lions and classified the western stock, including those animals living in the BSAI and GOA areas, as "endangered" under the ESA. Section 7 of the ESA required NOAA Fisheries to develop a Biological Opinion (BiOp) that analyzed the likelihood that the groundfish fishery would jeopardize the survival, recovery, or critical habitat of the endangered population. If a BiOp determines that a proposed action places the endangered species in jeopardy, ESA requires the agency to develop Reasonable and Prudent Alternatives (RPAs) for mitigating the impact of federal action and alleviating the condition of jeopardy.

In December 1998, NOAA Fisheries issued two documents to bring the federally managed fisheries into compliance with NEPA and ESA: the 1998 Final SEIS for the BSAI and GOA groundfish fisheries (NMFS 1998i) and a Steller sea lion BiOp (NMFS 1998j). Contrary to previous BiOps, the 1998 BiOp determined that the pollock fishery "jeopardized" the survival and recovery of the western stock of Steller sea lions and their critical habitat. In conjunction with this BiOp, NOAA Fisheries drafted a set of RPAs to mitigate the deleterious impacts of the pollock fisheries on sea lions (NMFS 1998k). These draft RPAs were used to implement emergency fishing rules by NPFMC. Since these RPAs constituted a separate federal action, they were also subject to the requirements of NEPA. NOAA Fisheries began work on a separate SEIS that would examine the impacts of the RPAs. At this point, NOAA Fisheries was responsible for developing a series of interrelated documents.

In 1999, the 1998 Final SEIS for the BSAI and GOA groundfish fisheries was challenged in court. In July of 1999, U.S. District Court Judge Thomas S. Zilly issued a ruling in *Greenpeace v. NOAA Fisheries* (Civ.No. C98-0492Z and 55F.Supp. 2d 1248 [W.D.Wash. 1999]) that the 1998 SEIS was legally inadequate and remanded the document back to NOAA Fisheries for additional analyses, directing the agency to produce a "programmatic" SEIS. Judge Zilly also upheld the conclusion of "jeopardy" in the pollock fisheries but remanded the 1998 BiOp back to NOAA Fisheries, directing them to revise the RPAs and explain how they will avoid the likelihood of jeopardy or adverse modification of critical habitat.

In October 1999, NOAA Fisheries published in the FR a Notice of Intent to prepare a Programmatic SEIS that would serve as a comprehensive foundation or "first tier" reference for future specific environmental analyses. NOAA Fisheries also issued a set of "Revised Final RPAs" (NMFS 1999d) in response to Judge Zilly's orders and which NPFMC implemented through emergency rules while litigation continued to challenge their sufficiency and legality.

In July of 2000, Judge Zilly ruled that NOAA Fisheries had not established sufficiently protective measures for Steller sea lions and ordered an injunction against all trawl fishing within designated critical habitat areas (*Greenpeace v. NOAA Fisheries*, 106 F.Supp.2d 1066 [W.D.Wash. 2000]). In November of 2000, NOAA Fisheries issued a new BiOp and an RPA (NMFS 2000a) that included further restrictions on the fishing industry. Judge Zilly lifted the injunction on trawl fishing at this point and attempted to get the litigants to settle their disputes through mediation. This effort was only partially successful. BiOp 2000 drew criticism from both sides. Environmental groups thought it sacrificed sea lion protection for industry profits and the fishing industry challenged the scientific basis for its conclusions of "jeopardy."

During this period of revising RPAs and legal challenges to the BiOps, NOAA Fisheries proceeded to develop a Programmatic SEIS for the groundfish fisheries and to incorporate government, industry, and public input at various stages through public hearings and comment periods. Then, in January 2001, NOAA Fisheries released the 2001 Draft Programmatic SEIS (NMFS 2001a). In November of the same year, NOAA Fisheries issued a Final SEIS for Steller sea lion protection measures (NMFS 2001b) that contained a great deal of similar information and analyses as the 2001 Draft Programmatic SEIS, but was more limited in scope and oriented toward compliance with the ESA. The 2001 BiOp and RPA (NMFS 2001c) concluded that the groundfish FMPs, as amended by the final RPA, did not jeopardize the survival or critical habitat of the western stock of Steller sea lions.

The 2001 Draft Programmatic SEIS

The 2001 Draft Programmatic SEIS was released for public review on January 26, 2001. This eight-volume report provided, for the first time, a comprehensive environmental review of the BSAI and GOA groundfish fisheries and their management over more than 20 years by NPFMC and NOAA Fisheries. In accordance with the requirements of NEPA, the 2001 Draft Programmatic SEIS was made available for public review. Given its significance as a precedent-setting analysis, and in light of on-going litigation and a number of environmental issues, extensive public comment was received on the 2001 Draft Programmatic SEIS.

Public Comment

The public comment period on the 2001 Draft Programmatic SEIS began on January 26, 2001 and was originally scheduled to end on April 26, 2001. Extended twice at the request of a number of public stakeholders, the public comment period closed on July 25, 2001. During the public comment period a number of public hearings were held on the 2001 Draft Programmatic SEIS in Anchorage, Kodiak, and Juneau, Alaska; Seattle, Washington; Washington, D.C.; and Portland, Oregon. In addition, two statewide teleconferences were held for the purpose of soliciting public comment from individuals living across Alaska, including Alaska Natives and tribal organizations, who were unable to attend any of the public hearings.

Approximately 21,000 comments were received during the comment period on the 2001 Draft Programmatic SEIS.One of the most substantive themes that emerged from the public comments was the concern that the alternatives analyzed in the 2001 Draft Programmatic SEIS focused too narrowly on specific issues, violated one pertinent law or another, and stood no realistic chance of being implemented. Many comments suggested that the document failed to present true alternative FMPs and, thus, simply reinforced the status quo and did nothing to promote ecosystem-based management policies. As a direct result of this input, NPFMC and NOAA Fisheries decided in December 2001 to revise the 2001 Draft Programmatic SEIS by restructuring the alternatives to better represent viable alternative FMPs.

The Restructured Alternatives

As described earlier, the programmatic alternatives put forward in the 2001 Draft Programmatic SEIS were based on different "primary objectives" that gave each alternative a distinct policy emphasis. For instance, Alternative 2 proposed the adoption of a fisheries management policy framework that emphasizes increased protection to marine mammals and seabirds, while Alternative 3 proposed adoption of a framework that emphasizes increased protection to target groundfish species; likewise, the remaining three alternatives proposed primary emphases, respectively, on protecting non-target and forage species, on protecting habitat, and on increasing the socioeconomic benefits of the fisheries.

The alternatives put forward in this revision replace the "primary-objective" approach with a more holistic approach that recognizes both the dynamic nature of the resource and its ecosystem and our imperfect understanding of their interactions. The restructured alternatives (now four in number) range from a relatively less environmentally precautionary approach to an approach that is relatively more precautionary. Toward this end, each policy alternative offers, to varying degrees, an integrated suite of comprehensive policy goals designed to meet the alternative's specific management or policy objective. To capture the breadth of each policy approach, each alternative (with the exception of the first, *status quo* alternative) contains two hypothetical FMPs that serve as "bookends" to illustrate a range of management actions and potential environmental effects consistent with that alternative policy framework (Section 2.6 provides a detailed description of the restructured alternatives and their development).

The 2003 Draft Programmatic SEIS

The 2003 Draft Programmatic SEIS was released for public review on August 29, 2003. This nine-volume report incorporated substantive public comments on the 2001 Draft document and was restructured substantially as described above.

Public Comment

The public comment period on the 2003 Draft Programmatic SEIS began on August 29, 2001 and was originally scheduled to end on October 15, 2001. However, at the request of a number of public stakeholders, the comment period was extended and finally closed on November 6, 2003 for a total comment period of 70 days. During the public comment period a number of public hearings were held on the 2003 Draft PSEIS in Anchorage, Kodiak, and Juneau, Alaska; in Seattle, Washington; and in Silver Spring, Maryland. All combined, only nine people provided oral testimony on the 2003 Draft PSEIS, however approximately 13,400 submissions were posted on the E-Comments website or mailed to NOAA Fisheries by the deadline.

The Comment Analysis Report (CAR) appended to this document (Appendix G) summarizes the public comments. As the primary response-to-comment document for this Programmatic SEIS, the CAR describes the methodology used by NOAA Fisheries in reviewing and sorting the comments and presents a synthesis of all comments that address a common theme. It also documents changes made in the revised Programmatic SEIS as a result of those comments. NOAA Fisheries undertook a careful and deliberate approach to ensure that all substantive public comments were treated equally and reviewed, considered, and responded to on the basis of the quality and substantive content of the comment, and not on the basis of who wrote the comment or how many other comments agree with it. Commenters can reference how and where their comments were responded to by using the cross-reference tables in the CAR.

1.6 The Final Programmatic Supplemental Environmental Impact Statement

The publication of this document begins the final stage of this NEPA process. CEQ regulations require that no decision be made until 30 days after publication of the Final Programmatic SEIS. Once that 30-day period has elapsed, NOAA Fisheries will issue its ROD in accordance with NEPA procedure.

The ROD will announce the selected policy alternative that will, in turn, be recommended by NPFMC for Secretarial review and approval in accordance with the MSA FMP amendment process. Subsequent to issuance of the ROD and upon Secretarial approval of an alternative, the NPFMC and NOAA Fisheries will likely need to prioritize the requisite amendments and regulatory actions required to effect the selected policy and identify those measures that may require additional data and analysis. The NPFMC and NOAA Fisheries will identify those priorities and set a realistic schedule for implementing the decision.

1.7 Document Organization

The management of the Alaska groundfish fisheries is a large, complex program that continues to evolve as more information is obtained on the fishery resources, the marine ecosystem, and those that derive benefits from both. The Programmatic SEIS provides a means for informing the public about Alaska groundfish management, the current regime, alternative regimes, known and unknown elements of the ecosystem, and the complex set of laws and regulations that apply to federal fisheries management. To meet its objectives, the document has been organized into a series of chapters and sections.

Chapter 1 establishes the purpose of and need for the federal action supported by this Programmatic SEIS. It provides an overview of NEPA and its procedural requirements, a history of this document including NOAA Fisheries' methods for conducting the NEPA scoping process and addressing public comments.

Chapter 2 presents the programmatic alternatives that are the focus of this document, beginning with a detailed explanation of the body of fisheries management policies, practices, tools, and methods that will give readers the foundation for a better understanding of the alternatives. This chapter also identifies the NPFMC's preferred alternative.

Chapter 3 describes the physical, biological, and socioeconomic resource components of the BSAI and GOA environments, and the eastern Bering Sea (EBS) and eastern North Pacific ecosystems. The objective of this chapter is to present a description of the relevant history and current status of the resources and environment that will serve as the baseline for the analyses of the alternatives. This chapter also includes a discussion of the past cumulative effects on the human environment, as they contribute to the existing baseline condition.

Chapter 4 discusses the effects of groundfish fishing on the environment under the different alternatives and their associated FMP bookends. The analyses examine the direct, indirect, and cumulative effects of each of the hypothetical FMPs that serve as bookends for the range of management actions appropriate to the particular policy alternative. This chapter then builds on these analyses and presents conclusions regarding the overall effects of the policy alternatives.

Section 4.1 provides a description of the methods used to determine the significance of potential consequences, the methods used to analyze the alternatives, and the application of the model output. The analysis of these model regimes and their contrast to the baseline condition established in Chapter 3 is intended to illustrate the general environmental effects of each programmatic policy alternative. In so doing, this Programmatic SEIS will provide the NPFMC and NOAA Fisheries, as well as the public, with information that can be used to guide future policy decisions.

Section 4.2 presents the analytical framework used to evaluate the alternatives. FMP bookends for each alternative were used as proxies for analyzing the policy alternatives. This section describes the FMP bookends and also presents maps that were developed to interpret the policy alternatives and depict some of the differences, such as closure areas, between the alternatives.

Section 4.3 presents abstracts of eleven Qualitative Analysis papers prepared to analyze the FMP components as they relate to the alternatives. These papers describe, in a qualitative manner, the effects of the alternative FMPs on key issues, such as fishing bycatch or overcapacity (the full text of these papers is included as Appendix F).

Section 4.4 provides a review of the comparative baseline statements carried forward for cumulative effects analysis for each key issue category.

Sections 4.5 through 4.9 present, by alternative, a detailed examination of the example FMP bookends and the likely environmental consequences of each alternative. Several key issues were identified through NOAA Fisheries' review of the scoping comments. A subset of ten key issues emerged as being mentioned more frequently and, we infer, most important to the public. The following list presents the ten key issues NOAA Fisheries used to develop the programmatic policy alternatives:

1. The effects of the alternatives on target groundfish species.

2. The effects of the alternatives on prohibited species.

3. The effects of the alternatives on other species.

4. The effects of the alternatives on forage species.

5. The effects of the alternatives on non-specified species.

6. The effects of the alternatives on essential fish habitat.

7. The effects of the alternatives on seabirds.

8. The effects of the alternatives on marine mammals.

9. The effects of the alternatives on the socioeconomics of the fishery.

10. The effects of the alternatives on the marine ecosystem.

Section 4.10 analyzes each alternative from a policy-level perspective, drawing on the results from the previous analyses, and Section 4.11 compares the alternatives at the policy-level, presenting the major conclusions of the findings on environmental and social issues.

Chapter 5 focuses on research and management, and provides a brief description of existing research priorities in fisheries management, as well as a list of data gaps and research needs for each policy alternative. This section also presents a discussion of management and enforcement considerations for each policy alternative.

Chapter 6 contains a list of preparers of the document while Chapter 7 presents the distribution list for the document. Chapter 8 contains the literature cited, and Chapter 9 provides an index.

The figures and tables of the document are included in Appendix A. Appendices B through E provide historical information on groundfish management. Appendix F contains the Qualitative Assurance papers, and Appendix G includes the comment analysis report (CAR) for the 2003 Draft Programmatic SEIS. Appendix H contains model output used to analyze the alternatives. Several appendices (I through L) provide copies of the Federal Register notices relating to the preparation of the Programmatic SEIS. Appendices M and N are informational NPFMC documents, and Appendix O is the Biological Assessment that presents the results from the informal Endangered Species Act consultation.

Chapter 2

Chapter 2 The Programmatic Alternatives

This chapter has two purposes. The first is to give readers a broad understanding of fisheries management policies and practices in the United States (U.S.) and, specifically, in the federally managed waters off Alaska. Beginning with a review of the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and the other applicable federal statutes and executive orders (EO), we discuss the development of fisheries policy, its assumptions and intentions, and how policy is conveyed and applied to the subject groundfish fisheries. This chapter explains how decisions are made and who makes them; how a Fishery Management Plan (FMP) operates; and how National Marine Fisheries Service (National Oceanic and Atmospheric Administration [NOAA] Fisheries or NMFS) uses the practical tools of fishery management to manage the groundfish fisheries on a daily basis. Knowing how the fisheries management system works will make the programmatic alternatives easier to understand.

This chapter's second purpose is to present the programmatic alternatives. Beginning with Section 2.6, we recount the history of the development of the alternatives and briefly discuss those alternatives that were considered but not carried forward in this document. We then present the programmatic alternatives and the methods used to evaluate them. The chapter concludes by identifying the North Pacific Fishery Management Council's (NPFMC) preferred alternative (PA).

2.1 Background Specific to Understanding this Federal Action

Chapter 1 discussed the general purpose and need for this federal action, the ongoing management of the federal groundfish fisheries off Alaska. Chapter 1 defined the purpose of a Programmatic Supplemental Environmental Impact Statement (SEIS) in terms of the procedural requirements of the National Environmental Policy Act (NEPA) and as defined by both the Council on Environmental Quality (CEQ) and NOAA in their respective guidelines. Chapter 1 also explained the specific purpose of this Programmatic SEIS in support of the continuing management of the subject groundfish fisheries. As a Programmatic SEIS, this document proposes to analyze the general environmental consequences of a broad scope of actions presented in the context of various policy alternatives.

The policy alternatives have been developed as alternative frameworks. A framework is a statement of particular goals and objectives that allows the NPFMC and NOAA Fisheries some latitude in proposing specific future actions necessary to manage the fishery and conserve the groundfish resource consistent with the goals and objectives that form the framework. Such frameworks, found in the existing FMPs for both the Bering Sea and Aleutian Islands (BSAI) and the Gulf of Alaska (GOA), provide the flexibility needed to manage dynamic fisheries that rely on a no less dynamic, complex, and changing ocean environment for their continued survival. A framework also allows the accommodation of changing public values regarding the nation's natural resources and how best to utilize and conserve those resources. Moreover, the frameworks allow decision-makers the latitude needed to balance sometimes competing objectives and priorities.

The current management policy for the groundfish fisheries, as identified in the current FMPs and presented herein as Alternative 1 (the no-action alternative), is also structured as a framework composed of a number of management goals and objectives. The policy frameworks of the FMPs, as shown later in this chapter, have allowed considerable latitude for action by the NPFMC and NOAA Fisheries; both FMPs have been amended more than 65 times over the last 25 years to respond to new information and new environmental issues and to improve the efficiency and effectiveness of fisheries management.

The alternatives to the status quo are also structured as policy frameworks. Other than this Programmatic SEIS process, no formal proposal is currently before the NPFMC or NOAA Fisheries that outlines a new or alternative management policy. However, NEPA requires that resource managers identify and evaluate alternatives to the status quo before promulgating new actions or, as in this case, to support continuing actions. Therefore, NOAA Fisheries developed the present policy alternatives that, in response to the values and objectives expressed through scoping and public comments on the 2001 Draft Programmatic SEIS and the 2003 Draft Programmatic SEIS, attempt to capture those values and objectives while remaining consistent with the MSA and other applicable federal law (see Section 2.3). A common theme that emerged from the public comments was the need to pursue a more precautionary approach to fisheries management when faced with the uncertainties associated with the effects of commercial fishing on the environment. With the assistance of the NPFMC and public stakeholders, NOAA Fisheries has designed alternative policy frameworks that, to varying degrees, capture the precautionary principle and elevate key ecosystem issues to the forefront of the fisheries decision-making process.

The main purpose of this chapter is to present the programmatic policy alternatives. To help readers understand and evaluate the programmatic alternatives, this chapter first provides a detailed discussion of the federal fishery management system in the Exclusive Economic Zone (EEZ) off Alaska.

2.2 Management Policies and Objectives

The survey of fishery management laws, policies, and practices begins with a review of federal policies regarding marine fishery conservation and management as those policies have evolved historically and as they are currently mandated by federal statute and EO. Throughout this general discussion, references are provided to more detailed discussions contained in the appendices.

2.2.1 Origins of United States Fisheries Policy

Fisheries management in the U.S. has historically been based on the principle of the public trust doctrine, a principle of common law that reflects certain political and cultural concepts pertaining to natural resources. Based first on Roman law and then on English common law, the principle asserts that certain resources, such as the air and the water in rivers and oceans, are incapable of private ownership and control. Fish swimming freely in rivers and oceans, by extension, are included in the principle. In medieval England, running water, the air, the sea, the shores of the sea, and the right to fish in the rivers and sea were considered common to all by "natural law." The Crown held these resources in trust for the benefit of the nation as its sovereign right and responsibility. When the U.S. colonies successfully defended their independence from England in the late eighteenth century, they assumed the trust authority of the Crown over navigable waterways within their borders, including the fish within these waters.

The public trust is held to be inalienable, and stewardship of natural resources cannot be transferred from the government that has responsibility for protecting those resources from overuse or habitat degradation for the benefit of its people (National Research Council [NRC] 1999). In the U.S., the public trust principle was further advanced under the presidency of Theodore Roosevelt, whose Chief Forester, Gifford Pinchot, asserted the government's right and duty to control the use of natural resources for the greater prosperity of the public (Mitchell 1997).

Regarding fisheries, a corollary to the public trust principle is that the principle applies to the resource in its natural state only; a fisherman acquires title to fish when he removes them from their natural state and takes them into his possession, i.e., when he catches them.

2.2.2 Current Federal Statutes and Mandates

The public trust doctrine stands as the basis for the Federal Government's responsibility to conserve and manage marine fisheries resources in the EEZ for the overall benefit of the people of the U.S. The principles of the doctrine are mandated by the body of federal statutes and EOs that guide the formulation and implementation of federal fishery management policies. Currently, these include 12 statutes and 7 EOs. Some of these laws speak directly to the conservation or management of fishery resources; others are directed at ensuring that fishery management measures and federal actions, in general, are fair and equitable and that potential environmental, economic, and social effects of federal actions are considered before they are adopted. For purposes of managing federal fisheries, the executive branch's responsibility for compliance with these mandates resides primarily with the Secretary of Commerce and has been delegated largely to NOAA Fisheries, one of the five NOAA agencies in the Department of Commerce.

In the following paragraphs, each of these federal statutes and EOs are discussed in turn as they apply to management and conservation of the groundfish fisheries.

Magnuson-Stevens Fishery Conservation and Management Act

The MSA (16 United States Code [USC] 1801, *et seq*.) is the principal federal statute providing for the management of U.S. marine fisheries. Originally enacted as the Fishery Conservation and Management Act in 1976 (Public Law 94-265), this law was arguably the most significant fisheries legislation in U.S. history. It has been amended periodically since 1976; most recently in 1996, by the Sustainable Fisheries Act (SFA) (Public Law 104-297). The basic concepts of that original Act, however, have not changed. They include the following:

1. Fisheries should be managed in a sustainable manner such that conservation and management measures achieve the optimum yield (OY) from each fishery on a continuing basis while preventing overfishing.

2. Conservation and management decision-making must be based on the best available scientific information, which should include social, economic, and ecological factors along with biological factors.

3. The needs of fishery resource users vary across the nation, and public participation in the policy-making process should be maximized.

The MSA (as amended in 1996 by the SFA) adds the following policy statement regarding the nation's fisheries (16 USC 1801(c)):

> *POLICY–It is further declared to be the policy of the Congress in this Act:*
>
> *To maintain without change the existing territorial or other ocean jurisdiction of the U.S. for all purposes other than the conservation and management of fishery resources, as provided for in this Act;*
>
> *To authorize no impediment to, or interference with, recognized legitimate uses of the high seas, except as necessary for the conservation and management of fishery resources, as provided for in this Act;*
>
> *To assure that the national fishery conservation and management program utilizes, and is based upon, the best scientific information available; involves, and is responsive to the needs of, interested and affected states and citizens; considers efficiency; draws upon federal, state, and academic capabilities in carrying out research, administration, management, and enforcement; considers the effects of fishing on immature fish and encourages development of practical measures that minimize bycatch and avoid unnecessary waste of fish; and is workable and effective;*
>
> *To permit foreign fishing consistent with the provisions of this Act;*

To support and encourage active U.S. efforts to obtain internationally acceptable agreements which provide for effective conservation and management of fishery resources, and to secure agreements to regulate fishing by vessels or persons beyond the exclusive economic zones of any nation;

To foster and maintain the diversity of fisheries in the U.S.; and

To ensure that the fishery resources adjacent to a Pacific Insular Area, including resident or migratory stocks within the exclusive economic zone adjacent to such areas, be explored, developed, conserved, and managed for the benefit of the people of such area and of the U.S.

The MSA also established 10 National Standards that serve as the overarching objectives for fishery conservation and management and the development of FMPs (16 USC 1851):

(a) IN GENERAL–Any Fishery Management Plan prepared, and any regulation promulgated to implement any such plan, pursuant to this title shall be consistent with the following National Standards for fishery conservation and management:

(1) Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the OY from each fishery for the U.S. fishing industry.

(2) Conservation and management measures shall be based upon the best scientific information available.

(3) To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

(4) Conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various U.S. fishermen, such allocation shall be (a) fair and equitable to all such fishermen; (b) reasonably calculated to promote conservation; and (c) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.

(5) Conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.

(6) Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

(7) Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

(8) *Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (a) provide for the sustained participation of such communities, and (b) to the extent practicable, minimize adverse economic impacts on such communities.*

(9) *Conservation and management measures shall, to the extent practicable, (a) minimize bycatch, and (b) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.*

(10) *Conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.*

The MSA also mandates the Secretary of Commerce to develop advisory guidelines to assist in FMP development. These guidelines serve primarily to interpret and aid compliance with the National Standards (codified at 50 Code of Federal Regulations [CFR] Part 600).

In recent years, amendments to the MSA have played a critical role in framing the regulatory regime within which the North Pacific groundfish fisheries operate. In particular, MSA amendments have addressed issues regarding overfishing, resource allocation among competing users, bycatch management, and conservation of essential fish habitat (EFH).

American Fisheries Act

Next to the MSA, the American Fisheries Act (AFA) (Public Law 105-277, division C, title II) is the only other fisheries-specific legislation affecting how groundfish fisheries in the BSAI and, to a lesser extent, the GOA are managed. Enacted in October 1998, the AFA represents the culmination of a decade-long struggle over the allocation of Alaska's most abundant fishery resource, pollock, in the BSAI. The AFA institutionalized a resource allocation scheme among competing onshore and offshore components of the fish processing industry.

Provisions mandated by the AFA, effective as of 1999, were implemented through the total allowable catch (TAC) specification process and emergency interim rule-making until the final regulations were published on December 30, 2002 (67 Federal Register [FR] 79692).

Major provisions of the AFA include the following:

- Requirement of a minimum of 75 percent U.S. ownership of fishing vessels (up from the majority ownership previously required) and maximum size and horsepower limits for replacement vessels.

- Specific allocation of the BSAI directed pollock fishery TAC among the inshore component (50 percent) catcher processor vessels in the offshore component (40 percent), and motherships in the offshore component (10 percent) after first deducting 10 percent of the TAC for the Community Development Quota (CDQ) Program and an incidental catch allowance.

- Buyout of nine catcher processor vessels' future fishing privileges, financed through a combination of a grant and direct loan obligations, to be paid back by a tax of $0.006 per pound of pollock harvested by the inshore sector.

- Specific naming of 20 catcher processor vessels that may participate in the (offshore) pollock fishery, seven catcher vessels that may deliver pollock to those catcher processors, and 19 catcher vessels that may deliver pollock to motherships.

- Criteria for catcher vessels to participate in harvesting BSAI pollock in the inshore sector, and criteria for limiting the participation of onshore processing plants in the BSAI pollock fishery.

- The ability to form fishery cooperatives (with limitations on their structure and the participation of catcher vessels and the inshore sector processing plants).

- Directions for the NPFMC to develop or improve on limitations (sideboards) on the activities of AFA vessels and processors in non-pollock fisheries to prevent negative spillover effects of fishery cooperatives.

Beginning January 1, 2000, all vessels and processors wishing to participate in the non-CDQ BSAI pollock fishery are required to have valid AFA permits on board the vessel or at the processing plant. AFA permits are required even for vessels and processors specifically named in the AFA and are required in addition to any other federal or state permits. AFA permits also may limit the take of non-pollock groundfish, crab, and prohibited species as governed by AFA "sideboard" provisions.

With the exceptions of applications for inshore vessel cooperatives and for replacement vessels, the AFA permit program had a one-time application deadline of December 1, 2000, for AFA vessel and processor permits. Applications for AFA vessel or processor permits were not accepted after this date, and any vessels or processors for which an application had not been received by this date became permanently ineligible to receive AFA permits.

National Environmental Policy Act

The first chapter explained the provisions of NEPA (42 USC 4331, *et seq*.), the U.S.'s basic national charter for environmental responsibility. To briefly recount those provisions: NEPA establishes the national environmental policy, provides an interdisciplinary framework for environmental planning by federal agencies, and contains action-forcing procedures to ensure that federal decision-makers take environmental factors into account. NEPA does not require that the most environmentally desirable alternative be chosen, but does require that the environmental effects of all the alternatives be analyzed equally for the benefit of decision-makers and the public.

NEPA has two principal purposes:

1. To require federal agencies to evaluate the potential environmental effects of any major planned federal action to ensure that public officials make well-informed decisions about the potential impacts.

2. To promote public awareness of potential impacts at the earliest planning stages of major federal actions by requiring federal agencies to prepare a detailed environmental evaluation for any major federal action significantly affecting the quality of the human environment.

As with the MSA, NEPA requires an assessment of both the biological and the social and economic consequences of fisheries management alternatives and provides that members of the public have an opportunity to be involved in and to influence decision-making on federal actions. In short, NEPA ensures that environmental information is available to government officials and the public before decisions are made and actions taken.

Title II, Section 202 of NEPA (42 USC 4332) created the CEQ. The duties of CEQ include, among other things, advising and assisting the President in preparing an annual environmental quality report, which is submitted to Congress. This report gathers information concerning trends in the quality of the environment, and developing policies to promote the goals of NEPA (42 USC 4344). The CEQ is also responsible for the development and oversight of regulations and procedures implementing NEPA. The CEQ regulations provide guidance for federal agencies regarding NEPA's requirements (40 CFR Part 1500) and require agencies to identify processes for issue scoping, for the consideration of alternatives, for developing evaluation procedures, for involving the public and reviewing public input, and for coordinating with other agencies—all of which are applicable to the NPFMC's development of the groundfish FMPs.

NOAA has also prepared environmental review procedures for implementing NEPA (NOAA Administrative Order 216-6). This Administrative Order describes NOAA's policies, requirements, and procedures for complying with NEPA and the implementing regulations issued by the CEQ. A 1999 revision and update to the Administrative Order includes specific guidance regarding categorical exclusions, especially as they relate to endangered species, marine mammals, fisheries, and habitat restoration. The Administrative Order also expands on guidance for consideration of cumulative impacts and "tiering" in the environmental review of NOAA actions. This Administrative Order provides comprehensive and specific procedural guidance to NOAA Fisheries and the NPFMC for preparing and adopting groundfish FMPs.

Federal fishery management actions subject to NEPA requirements include the approval of FMPs, FMP amendments, and regulations implementing FMPs. Such approval requires preparation of an environmental assessment (EA). The purpose of an EA is to determine if the proposed action is a major federal action significantly affecting the environment and thereby requiring an environmental impact statement (EIS) or whether the action does not significantly affect the environment, in which case a finding of no significant impact may be issued.

NEPA and the MSA requirements for schedule, format, and public participation are compatible and allow one process to fulfill both obligations. If an EIS or SEIS is prepared, however, the notice of availability (NOA) of a final EIS (or SEIS) must be published at least 30 days before the Secretary of Commerce approves, disapproves, or partially approves an FMP or FMP amendment.

Endangered Species Act

The Endangered Species Act (ESA) (16 USC 1531 *et seq.*), passed in 1973 and reauthorized in 1988, provides broad protection for fish and wildlife species that are listed as threatened or endangered. The ESA establishes procedures for the formal listing of a species, for the development of recovery plans, and for designation of critical habitats. It also outlines procedures for federal agencies to follow when taking actions that may jeopardize the continued existence of a species or that may adversely modify its critical habitat. Responsibilities for implementing the ESA are shared by the U.S. Fish and Wildlife Service (USFWS) and NOAA Fisheries. With some exceptions, the USFWS oversees freshwater fish, birds, terrestrial mammals, and plants, and NOAA Fisheries oversees anadromous and marine fish, marine mammals, and sea grasses. NOAA Fisheries is therefore tasked both with managing the groundfish harvest through FMPs and with ensuring that identified threatened and endangered species (e.g., the Steller sea lion) receive appropriate consideration and protection during the planning and implementation of groundfish management measures. It should be noted that compliance with ESA provisions is not subject to modification based on economic hardship. Recovery plans required under the ESA give priority to those listed species that may be affected by different economic activities.

Sections 2(c)(1) and 7(a)(1) of the ESA require federal agencies to conserve endangered and threatened species; however, conservation is broadly defined. Section 7(a)(2) of the ESA requires federal agencies to ensure that any action authorized, funded, or carried out by such agencies is not likely to jeopardize or result in the destruction or adverse modification of the critical habitat of endangered or threatened species.

Under an FMP, all fishing activities must be considered; not just the specific fisheries for which management measures are under consideration. NOAA Fisheries must conduct a formal Section 7 consultation that results in a biological opinion if a proposed action "may affect" or "is likely to adversely affect" endangered or threatened species or their critical habitat. If the biological opinion concludes that the proposed action "is likely to jeopardize the continued existence of" threatened or endangered species, then reasonable and prudent alternatives must be developed to minimize or mitigate the effect of the action. The fishery management action in question must then be revised to implement the reasonable and prudent measures.

The Marine Mammal Protection Act

The Marine Mammal Protection Act (MMPA) of 1972 (16 USC 1361, *et seq.*), as amended, establishes a federal responsibility to conserve marine mammals. Congress declared that marine mammals are resources of great international significance and that they should be protected and their development promoted to the greatest extent feasible, commensurate with sound resource management policies. Finding that certain species and populations of marine mammals are or may be in danger of extinction or depletion due to human activities, Congress vested NOAA Fisheries with management responsibility for cetaceans (whales) and pinnipeds other than walrus (seals). (All other marine mammals found in Alaska, such as the sea otter, walrus, and polar bear, fall under the auspices of the USFWS.)

The MMPA's primary management objective is to maintain the health and stability of the marine ecosystem, with a goal of obtaining an optimum sustainable population of marine mammals within the carrying capacity of the habitat. The MMPA is intended to work in concert with the provisions of the ESA. The Secretary of Commerce is required to give full consideration to all factors regarding regulations applicable to the "take" of marine mammals. (The MMPA defines "take" broadly to mean "to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal.") Such factors include the conservation, development, and utilization of fishery resources, and the economic and technological feasibility of implementing the regulations. If a fishery affects a marine mammal population, then the potential impacts of the fishery must be analyzed in the appropriate EA or EIS, and the pertinent regional council or NOAA Fisheries may be requested to consider regulations to mitigate adverse impacts.

The Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (FWCA) authorizes collection of fisheries data and coordination with other agencies for environmental decisions affecting living marine resources. Both formal and informal consultations, cooperative research, and data-gathering programs are routinely pursued.

The Federal Power Act

The Federal Power Act (FPA) provides for concurrent responsibilities with the USFWS in protecting aquatic habitat. The original statute was enacted in 1920; however, only the 1935 and 1986 amendments added new requirements to incorporate fish and wildlife concerns in licensing, relicensing, and exemption procedures for power projects.

Coastal Zone Management Act

The Coastal Zone Management Act (CZMA) (16 USC 1451, *et seq.*) is designed to encourage and assist states in developing coastal management programs, to coordinate federal and state activities, and to safeguard regional and national interests in the coastal zone. Section 307(c) (16 USC 1456(c)) of the CZMA requires that any federal activity affecting the land or water uses or natural resources of a state's coastal zone be consistent with the state's approved coastal management program to the maximum extent practicable.

A proposed fishery management action that requires an FMP amendment or implementing regulations must be assessed to determine whether it directly affects the coastal zone of a state with an approved coastal zone management program. If so, NOAA Fisheries must provide the state agency having CZMA responsibility with a consistency determination for review at least 90 days before final NOAA Fisheries action.

Administrative Procedure Act

The Administrative Procedure Act (APA) (5 USC 551, *et seq.*) requires federal agencies to give the public prior notice of rule-making and an opportunity to comment on proposed rules. General notice of proposed rule-making must be published in the FR, unless persons subject to the rule have actual notice of the rule. Proposed rules published in the FR must include reference to the legal authority under which the rule is proposed and explain the nature of the proposed action, its intended effect, and any relevant regulatory history that provides the public with a well-informed basis for understanding and commenting on the proposed action. The APA also specifies conditions that allow an agency to implement regulations on an emergency or interim basis without requiring public comment periods. These emergency conditions can be of an ecological, economic, social, or public health nature.

Except for the emergency or interim rule provisions, a proposed rule is designed to give interested or affected persons opportunity to submit written data, views, or arguments for or against the proposed action. After the end of a public comment period, the APA requires comments received to be summarized and responded to in the final rule notice. Further, the APA requires the effective date of a final rule to be no less than 30 days after publication of the final notice in the FR. This delayed effectiveness or "cooling off" period is intended to allow the affected public to become aware of and be prepared to comply with the requirements of the rule. For fishery management regulations, the primary effect of the APA, in combination with the MSA, NEPA, and other statutes, is to provide for public participation and input into the development of FMPs, FMP amendments, and regulations implementing FMPs.

Regulatory Flexibility Act

The Regulatory Flexibility Act (RFA) (5 USC 601, *et seq*.) requires federal agencies to assess the impacts of their proposed regulations on small entities and to seek ways to minimize economic effects on small entities that would be disproportionately or unnecessarily adverse. The RFA defines small entities as (1) small businesses which, for commercial fishing or fish processing, are firms with receipts of up to $3 million annually or up to 500 employees, respectively, (2) small non-profit organizations, and (3) small governmental jurisdictions with a population of up to 50,000 persons. For Alaska fisheries, these criteria include most fishing firms except for the large catcher processor vessels and most coastal communities except for Anchorage. NOAA Fisheries has published revised guidelines dated August 16, 2000, for RFA analysis; they include criteria for determining if the action would have a significant impact on a substantial number of small entities. Those guidelines may be viewed online at www.nmfs.noaa.gov/sfa/prorules.

Although the RFA allows agencies to certify that a proposed rule will not have significant impacts on a substantial number of small entities, an initial regulatory flexibility analysis (IRFA) is routinely prepared for most proposed Alaska groundfish fishery management measures. The IRFA is usually combined with the EA or EIS document required by NEPA. If, following public comments on the proposed rule, the action is still considered to meet the criteria for requiring RFA analysis, then a final regulatory flexibility analysis (FRFA) must be prepared. The FRFA contains most of the same information presented in the IRFA, but also must include (1) a summary of significant issues raised in public comment on the IRFA and the agency's response to those comments, and (2) a description of the steps the agency has taken to minimize the significant economic impacts on small entities, including a statement of factual, policy, and legal reasons for selecting the alternative adopted in the final rule and why all other alternatives considered were rejected. Finally, the FRFA or a summary of it must be published in the FR with the final rule.

Paperwork Reduction Act

The Paperwork Reduction Act (PRA) of 1995 (44 USC 3501 *et seq*., and 5 CFR part 1320) is designed "to minimize the paperwork burden for individuals, small businesses, educational and nonprofit institutions, federal contractors, state, local and tribal governments, and other persons resulting from the collection of information by or for the Federal Government." In brief, this law is intended to ensure that the government is not overly burdening the public with requests for information. Procedurally, the PRA requirements constrain what, how, and how frequently information will be collected from the public affected by a rule that requires reporting (e.g., the amount of fish caught during a fishing trip).

Data Quality Act

Section 515 of the Treasury and General Government Appropriations Act for Fiscal Year 2001 (Public Law 106-554) directed the Office of Management and Budget (OMB) to issue government-wide guidelines that provide policy and procedural guidance for ensuring and maximizing the quality, objectivity, utility, and integrity of information (including statistical information) disseminated by federal agencies. This bill is known as the Data Quality Act. The OMB's guidelines require all federal agencies to develop their own guidelines for ensuring and maximizing the quality, objectivity, utility, and integrity of information disseminated by the agency. NOAA published its guidelines in February 2002 (available online at http://www.commerce.gov).

Executive Order 12630: Takings

This EO on Government Actions and Interference with Constitutionally Protected Property Rights was signed by the President on March 15, 1988, and published on March 18, 1988 (53 FR 8859). This EO requires that each federal agency prepare a "takings implications assessment" for any of its administrative, regulatory, and legislative policies and actions that affect, or may affect, the use of any real or personal property. Fishery management measures that limit fishing seasons, areas, catch quotas, the size of harvested fish, and bag limits have received a categorical exclusion from a takings analysis. However, takings issues are raised frequently in the context of limited access systems, which confer a harvesting privilege on a fisherman in the form of a permit to catch a specific amount of fish or a license to enter and participate in a fishery. Although such permits and licenses may be transferrable, and therefore increase (or decrease) in market value, they do not convey any property rights in the fishery resource (i.e., the fish).

Executive Order 12898: Environmental Justice

EO 12898, signed by the President on February 11, 1994, and published February 16, 1994 (59 FR 7629), requires that federal agencies make achieving "environmental justice" part of their mission by identifying and addressing disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low income populations in the U.S. A growing number of Alaska Natives participate in the groundfish fisheries as a result of the federal CDQ Program. As a result, coastal Native communities participating in the CDQ Program derive substantial economic benefits from the federal groundfish fisheries. The effects of the federal action on minority populations are described in Chapter 4.

Executive Order 13175: Consultation and Coordination with Indian Tribal Governments

This EO, signed by the President on November 6, 2000, and published November 9, 2000 (65 FR 67249), is intended to establish regular and meaningful consultation and collaboration between federal agencies and Native tribal governments in the development of federal regulatory practices that significantly or uniquely affect their communities. This EO prohibits regulations that impose substantial direct compliance costs on

Native tribal communities. In preparing this Programmatic SEIS, NOAA Fisheries has initiated a government-to-government consultation process with affected Native communities.

Executive Order 13158: Marine Protected Areas

This EO, signed by the President on May 26, 2000, and published on May 31, 2000 (65 FR 34909), directs the Departments of Commerce and the Interior to jointly develop a national system of marine protected areas (MPAs). The purpose of the system is to strengthen the management, protection, and conservation of existing protected areas and establish new or expanded MPAs. The MPA system is to be scientifically based, representing diverse U.S. marine ecosystems and the nation's natural and cultural resources. Establishing such a system is intended to reduce the likelihood that MPAs are harmed by federally approved or funded activities. Alternatives 1(b), 3, and 4 of this Programmatic SEIS specifically address this EO in their respective policy frameworks.

Executive Order 12114: Environmental Effects Abroad

This EO, signed by the President on January 4, 1979, and published on January 9, 1979 (44 FR 1957), directs agencies to consider the effects of major federal actions upon the environment of foreign nations or of "global commons" such as the oceans. These actions include those major federal actions that result in significant environmental effects that extend outside of the geographic borders of the U.S. In some cases, an EIS may be required. This EO encourages international agreements and an exchange of information between the affected nations and the U.S. This EO may pertain to the groundfish fisheries in the EEZ off Alaska to the extent that those fisheries impact the ocean environment beyond the EEZ.

Executive Order 12866: Regulatory Planning and Review

EO 12866, signed by the President on September 30, 1993, and published October 4, 1993 (58 FR 51735), replaced EOs 12291 and 12498. Its purpose, among other things, is to enhance planning and coordination with respect to new and existing regulations, and to make the regulatory process more accessible and open to the public. In addition, EO 12866 requires agencies to take a deliberative, analytical approach to rule-making, including assessment of costs and benefits of the intended regulations. For fisheries management purposes, it requires NOAA Fisheries (1) to prepare a regulatory impact review (RIR) for all regulatory actions, (2) to prepare a unified regulatory agenda twice a year to inform the public of the agency's expected regulatory actions, and (3) to conduct a periodic review of existing regulations.

The purpose of an RIR is to assess the potential economic impacts of a proposed regulatory action. As such, it can be used to satisfy NEPA requirements and to serve as a basis for determining whether a proposed rule will have a significant impact on a substantial number of small entities which would trigger the completion of an IRFA under the RFA. For this reason, the RIR is frequently combined with an EA and an IRFA in a single EA/RIR/IRFA document that satisfies the analytical requirements of NEPA, RFA, and EO 12866. Criteria for determining "significance" for EO 12866 purposes, however, are different than those for determining significance for RFA purposes. A significant rule under EO 12866 is one that is likely to (1) have an annual effect on the economy (of the nation) of $100 million or more; (2) create serious inconsistency or otherwise interfere with an action taken or planned by another agency; (3) materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or (4) raise novel legal or policy issues.

Although fisheries management actions rarely have an annual effect on the national economy of $100 million or more or trigger any of the other criteria, OMB makes the ultimate determination of significance under this EO, based in large measure on the analysis in the RIR. A recent example of a fishery management action determined to be "significant" under this EO is the regulatory action to implement provisions of the AFA. The significance determination is in part because, at least initially, the AFA rule-making raises novel legal or policy issues arising out of legal mandates. An action determined to be significant is subject to OMB review and clearance before its publication and implementation.

Executive Order 13132: Federalism

The "Federalism" EO, signed by the President on August 4, 1999, and published on August 10, 1999 (64 FR 43255), supercedes earlier federalism EOs (12612 and 13083), and supplements EOs 12372 ("Intergovernmental Review of Federal Programs"), 12866, and 12988 ("Civil Justice Reform"). This EO is intended to guide federal agencies in the formulation and implementation of "policies that have federalism implications," such as regulations, legislative comments or proposed legislation, and other policy statements or actions that have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government. This EO requires federal agencies to have a process to ensure meaningful and timely input from state and local officials in the development of regulatory policies that have federalism implications. A federalism summary impact statement is also required for rules that have federalism implications.

To preclude conflict between state and federal law on fishery management issues, the MSA (16 USC 1856) explicitly establishes conditions for federal preemption of state regulations (and of any extension of state fishery management authority into the EEZ). Furthermore, close consultation between the state and federal governments on Alaska groundfish fishery measures is provided by the NPFMC process (see Section 2.4).

Summary

These federal statutes and EOs constitute the legal foundation for all fishery management actions in the EEZ. As we have shown, some, such as the MSA and AFA, provide direct statutory direction for fisheries management, while others, such as the Administrative Procedure and PRAs, pertain to more general issues that impact all federal actions, including fisheries management. Together they require the NPFMC and NOAA Fisheries to create management policies and practices that are environmentally, socially, and economically responsible to the people of the U.S.

In the following section, we continue our discussion of how federal fisheries are managed by examining the components and functions of those FMPs and how they are developed by the NPFMC under the regional council process.

2.3 Components of a Fishery Management Plan

The MSA mandates the creation of FMPs as the primary fisheries management tools to be developed by the regional councils. Sections 303(a) and (b) of the MSA (16 USC 1853(a) and (b)) mandate that each FMP will contain 14 mandatory provisions and may contain 12 additional, discretionary provisions. The provisions are statements of policy and, in some cases, reflect competing objectives which must be balanced in the course of decision-making. These provisions are summarized below.

Required Provisions

FMPs must:

1. Contain conservation and management measures to prevent overfishing, rebuild overfished stocks, and promote the long-term health and stability of the fishery.

2. Contain a description of the fishery, including, but not limited to, the number of vessels involved, the type and quantity of fishing gear used, the species of fish involved and their location, the cost likely to be incurred in management, actual and potential revenues from the fishery, any recreational interest in the fishery, and the nature and extent of foreign fishing and Indian treaty fishing rights, if any.

3. Assess and specify the maximum sustainable yield and OY from the fishery and include a summary of calculations used to specify the maximum sustainable yield.

4. Assess and specify the proportion of OY that can be harvested and processed by U.S. interests.

5. Specify the fishing industry data that will be submitted to the Secretary of Commerce.

6. Consider and provide for temporary adjustments of fishing efforts that were curtailed for safety reasons.

7. Describe and identify EFH and protect such habitats from adverse fishing impacts.

8. Assess and specify the nature and extent of the scientific data needed for effective implementation of the plan.

9. Include a fishery impact statement that describes the likely effects of conservation and management measures, if any, on participants in the fisheries and fishing communities.

10. Specify objective and measurable criteria for identifying when the fishery is overfished with an analysis of how the criteria were determined.

11. Establish a standardized reporting methodology to assess the amount and type of bycatch occurring in the fishery, and include measures to minimize bycatch and minimize the mortality of bycatch that cannot be avoided.

12. Assess the efficacy of catch-and-release fishery management programs.

13. Describe the participation of the recreational and charter fishing sectors.

14. Allocate any harvest restrictions or recovery benefits fairly and equitably among the commercial, recreational, and charter fishing sectors in the fishery.

Discretionary Provisions

FMPs may:

1. Require permits and fees from any fishing vessel or fish processor who receives fish that are subject to the plan.

2. Establish time, area, and gear restrictions to limit fishing effort as necessary.

3. Establish catch, sale, or transportation limits based on area, species, size, number, weight, sex, bycatch, total biomass, or other factors consistent with any applicable federal and state safety and quality requirements.

4. Prohibit, limit, condition, or require the use of specified types and quantities of fishing gear, fishing vessels, or equipment for such vessels, including devices which may be required to facilitate enforcement provisions.

5. Incorporate (consistent with other applicable laws) the relevant fishery conservation and management measures of the coastal states nearest to the fishery.

6. Establish a limited access system for the fishery in order to achieve OY.

7. Require fish processors to submit data necessary for the conservation and management of the fishery.

8. Require observers to be carried aboard a vessel for the purpose of collecting data necessary for the conservation and management of the fishery.

9. Assess and specify the impact of the plan on the naturally spawning anadromous fish stocks of the region.

10. Include incentives to minimize bycatch and decrease bycatch mortality.

11. Reserve portions of the allowable catch for use in scientific research.

12. Prescribe other measures, requirements, conditions, and restrictions necessary for the conservation and management of the fishery.

The First BSAI and GOA FMPs

An FMP thus comprises a set of coherent, specific policy statements that define a particular fishery. The role of the NPFMC and its regulatory partners is to apply a long list of general fishery policy objectives—the FMP requirements and standards listed above—to the particulars of the Alaska groundfish fishery. Competing interests within the fishing industry and competing policy objectives make this deliberative process a continual balancing act.

Both the BSAI and GOA groundfish FMPs state the NPFMC's goals and objectives for managing the fisheries (see Section 2.6.1). These goals and objectives and their accompanying policy statements are intended to clarify the basis for the NPFMC's decisions and recommendations to the Secretary of Commerce. They are also intended to provide the public and the stakeholders of the resource a clear sense of the management direction for the fisheries. It is important to recognize that at the time the original FMPs were prepared, the Alaska groundfish fisheries were going through a remarkable transition, changing from a foreign-dominated fishery to a purely domestic fishery. The goals and objectives developed during this period reflect the issues and needs of the time, and do not necessarily represent today's perspective and our current understanding of the fisheries and the marine ecosystem. (In Appendices C and D, readers may review a summary of the original FMPs and the numerous amendments that have been adopted since that time to see how changes in policy emphasis have reflected changing conditions in the fishery and environment.)

The GOA groundfish FMP, published in 1979, was the first FMP adopted by the NPFMC. Following implementation of the MSA in 1976, preliminary management plans were prepared for the GOA and BSAI to establish a management regime to control the foreign fisheries. The management of domestic harvests of groundfish requires an FMP. The NPFMC chose to prepare an FMP for the GOA first because at the time it was the only area with an existing domestic groundfish fishery. As a result, the GOA FMP was a simple document and limited in scope, compared to the regime in place today. In 1985, a general omnibus amendment (Appendix D; Amendment 14) overhauled the GOA FMP by addressing a number of administrative weaknesses. It also updated the plan's policy statement to better reflect the thinking at that time.

The BSAI groundfish FMP, implemented in 1981, set new standards for fisheries management. The FMP introduced a "framework" approach to decision-making. This plan authorized certain management tools, the subsequent application of which would not require a lengthy plan amendment process. Rather, such tools—already authorized by the FMP—could be implemented by regulatory amendment, a more efficient and expeditious means of implementing actual management measures than by FMP amendment. The BSAI FMP was also based on ecosystem principles, reflected in a statement of policy goals and objectives that has not been changed since 1981.

Subtle differences exist between the BSAI and GOA FMPs in terms of policy. Prepared by different authors, the FMPs exhibit differences in wording that can be attributed to the respective authors' different writing styles. Partially conflicting policy goals and objectives listed in both FMPs require that the NPFMC balance conflicting goals (e.g., stimulating the development of domestic fisheries versus rebuilding depressed stocks). Both policy statements reference the National Standards of the MSA as the overarching principles for managing the groundfish fisheries. The GOA FMP policy places primary emphasis on maximizing positive economic benefits to the U.S., consistent with resource stewardship responsibilities for the continuing welfare of the GOA's living marine resources. The BSAI FMPs policy is more neutral. The BSAI policy recognizes the dynamics of the Bering Sea ecosystem and the need for a flexible management regime to accommodate new information as more is learned about the ecosystem. Among other secondary objectives, the BSAI FMP also highlights the importance both of designing fishing strategies that have minimal impact on the environment and of taking a precautionary approach when data on the stock or the ecosystem is lacking. The differences in wording of the BSAI policy goals and objectives reflect a broader ecosystem view of the fisheries. Even though the policy statements in the two FMPs are worded differently, both areas are managed using the same principles. The NPFMC has always managed the BSAI and GOA groundfish fisheries as a whole, recognizing the close inter-relationships that exist between the fisheries and the two geographical areas.

The specificity of FMPs has changed over time. Early FMPs contained very specific management measures and harvest levels that could only be changed through a lengthy plan amendment process, which could require 18 to 24 months from problem identification to a change in management. Because of this process delay, changes in harvest limits often lagged behind changes in stock abundance. In addition, federal regulations often lagged behind changes in regulations for adjacent state waters, causing conflicts and confusion where stocks had to be managed as a unit throughout their range. This process has been streamlined by incorporating "framework" management tools into the FMP that allow for management changes within prescribed boundaries. For instance, harvest levels are now adjusted through a relatively brief specifications process, implemented by notice in the FR, rather than by the FMP amendment process (see Section 2.4).

2.4 Decision-Making Process for Fishery Management Plans

In addition to establishing the requirements for FMPs, the MSA also created a system of regional councils to manage the nation's marine fisheries. Unlike management of the nation's timber, mineral, grazing, and water resources, for which policy is determined by a federal agency, management responsibility for the nation's marine fisheries is assigned by the MSA to eight regional councils, which are charged with overseeing fisheries in their respective regions. For the federal waters off Alaska, the MSA thus created the NPFMC to be charged with responsibility for making fisheries management policy in the Alaska region of the EEZ.

The North Pacific Fishery Management Council

The NPFMC is composed of 15 members: 11 voting and four non-voting. Seven of the voting members are appointed by the Secretary of Commerce upon the recommendation of the governors of Alaska and Washington. The Governor of Alaska nominates candidates for five seats, the Governor of Washington two seats. Each member is appointed to a three-year term and may be reappointed, but may not exceed three consecutive terms. Four mandatory voting members are the leading fisheries officials from the states of Alaska, Washington, and Oregon, as well as the Alaska Regional Administrator for NOAA Fisheries. The four non-voting members are the Executive Director of the Pacific States Marine Fisheries Commission, the Area Director for the USFWS, the Commander of the 17th Coast Guard District, and a representative from the U.S. State Department. From the voting membership, the NPFMC elects a Chairman and Vice-Chairman to serve one-year terms. The NPFMC's current members are identified on the NPFMC website (http://www.fakr.noaa.gov/npfmc/).

The NPFMC has five regularly scheduled meetings each year, four in communities in Alaska, and one in Washington or Oregon. The NPFMC may also schedule additional meetings if the need arises. At each of these meetings, the NPFMC receives advice from its 22-member Advisory Panel, representing fishing industry groups, environmentalists, and consumer groups, and from its 12-member Scientific and Statistical Committee, made up of highly respected scientists who review all information brought to the NPFMC. In addition, the NPFMC works collaboratively with NOAA Fisheries, the federal regulatory agency charged with implementing and enforcing the management decisions of the NPFMC and running the day-to-day operations of fishery management. NOAA Fisheries scientists also conduct research and provide analysis for the NPFMC.

North Pacific Fisheries Management Council Action

The NPFMC uses a formal public process to solicit proposals on how the fisheries should be managed. Through this deliberative public process, and in consultation with several federal and state agencies, the NPFMC develops and amends the FMPs (with the approval of the Secretary of Commerce). FMP amendments may be inspired by a variety of events, including new laws, statutory requirements, and operational problems. Most FMP amendments, however, are generated by public recommendation through an open process (Figure 2.4-1).

The NPFMC annually solicits proposals for FMP amendments or regulatory changes from the public. These proposals are reviewed and qualitatively ranked in terms of analytical difficulty by the NPFMC's Plan Development Team for each FMP. Unfortunately, the number of proposals that merit serious policy consideration far exceed the number of policy analyses that the NPFMC can reasonably accomplish in any one year, so amendments that are needed to address critical issues, such as overfishing, take precedence. All of the amendment proposals are reviewed by the NPFMC's Advisory Panel, which makes recommendations on which proposals should be considered. After hearing the recommendations and public testimony on them (usually at the NPFMC's October meeting), the NPFMC selects the proposals—those it considers most urgent—that it will consider during the coming year.

Selected proposals are then analyzed in compliance with the laws and statutory requirements outlined in Section 2.2.2. Amendment analyses are usually drafted by NPFMC staff biologists and economists, with whatever assistance and collaboration may be needed from scientists and managers of NOAA Fisheries and the Alaska Department of Fish and Game (ADF&G). Sometimes the NPFMC contracts with private consultants to prepare all or part of an analysis. Any proposals made by NOAA Fisheries or ADF&G to improve the implementation of existing management policies frequently are analyzed by staff of the proposing agency.

No specific time limit is imposed by law for completing the draft analysis. Generally, for any particular amendment proposal, the NPFMC staff attempts to complete its analysis before the NPFMC's April meeting following the year in which the NPFMC decided to address the proposal. This is not always possible, however. Controversial proposals, or those that have a large number of alternatives and options for analysis, may require more time than the four months typically allocated for the analytical task. In addition, a proposal that, if implemented, could have a significant impact on the human environment is required by NEPA to have an EIS or SEIS instead of an EA. In this event, NEPA requires "scoping": "an early and open process for determining the scope of issues to be addressed and for identifying the significant issues related to a proposed action" (40 CFR 1501.7). Formal scoping officially begins with publication in the FR of a notice of intent to prepare an EIS or SEIS. Depending on the nature of the proposed action, it may be a lengthy period, involving numerous public hearings, or it may be fairly brief and involve no hearings and only a brief public comment period. At a minimum, however, the public comment period on the scope of issues to be addressed in the analysis should be at least 30 days (NAO 216-6). This additional public process, which occurs at the beginning of the analysis period, plus the greater depth of analysis in a draft EIS or SEIS, adds substantially to the overall time to plan and draft the analysis.

The next step is for the NPFMC to review a draft analysis and decide whether to release it officially for public review and comment. In making this decision, the NPFMC relies heavily on the advice it receives from its Advisory Panel and Scientific and Statistical Committee. The NPFMC also receives public testimony before making this decision, as the public too is given access to the initial draft analysis in advance of the formal public comment period. This "public release" decision also considers whether the analysis adequately addresses a reasonable range of alternatives and options, and adequately responds to the requirements of the MSA and other applicable laws. The NPFMC may decide at this point to release the initial draft analysis "as is" for formal public review; to instruct staff to make certain minor revisions before release; to request major revisions and another NPFMC review before release; or to suspend further action on the analysis, which would, at least temporarily, stop further development of the proposal. If the NPFMC decides to release the initial draft analysis for public review, the comment period is normally scheduled to begin at least four weeks before the NPFMC's next meeting. Complicated proposals are often granted longer public comment periods.

The NPFMC's next action on a management proposal is to decide on its PA. The NPFMC's PA at this point may be entirely different from the preference of the person or constituency group that originally proposed the action, or the NPFMC may decide to abandon the proposal. Normally, however, the NPFMC selects a PA from those in the analysis or one that is reasonably within the range of alternatives analyzed. The NPFMC takes this action after hearing again from its Advisory Panel, Scientific and Statistical Committee, and the public. If the NPFMC chooses a policy alternative that is not explicitly assessed in the analysis as its PA, the analysis is revised to include the PA.

The NPFMC's choice of a PA is frequently referred to as the "final action of the NPFMC to adopt an FMP/amendment for recommendation to the Secretary of Commerce," or simply as the NPFMC's "final action." Although the analysis frequently needs to be revised to specify the PA and rule-making documents that need to be drafted, the NPFMC rarely reviews the decision-making documents and analyses following a final vote. Instead, the NPFMC relies on the work of its staff and the NOAA Fisheries staff in the Alaska Regional Office and NOAA General Counsel, Alaska region, to prepare the necessary documents in final form. This cooperation among professional staffs is necessary to ensure that the proposed regulatory language accurately reflects the intent of the PA, results in an administratively efficient and enforceable program, and meets all the applicable laws. When all the necessary documents are complete, the NPFMC then transmits the necessary legal documents to the Secretary of Commerce for official review.

Secretarial Review

Section 304(a)(1) of the MSA (16 USC 1854(a)(1)) requires the Secretary of Commerce, "upon transmittal by the NPFMC to the Secretary of a Fishery Management Plan or plan amendment," to "immediately commence a review" of the FMP/amendment and to "immediately publish" a NOA in the FR soliciting public comment on the proposed plan/amendment for a 60-day period beginning on the date of publication. NOAA Fisheries, by delegation of the Secretary's authority, is required to review the documents and determine if they comply with the MSA and other applicable laws and if the policy proposal is structurally complete.

The decision to approve or disapprove a proposal is prescribed by the MSA (16 USC 1854(a) and (b)). For an FMP/amendment, NOAA Fisheries must approve, disapprove, or partially approve the FMP/amendment within 30 days of the end of the comment period published in the NOA. If Secretarial action is not taken within this 30-day period, then the FMP/amendment takes effect as if it were fully approved. The MSA clearly gives NOAA Fisheries only the power to approve, disapprove, or partially approve a NPFMC-recommended FMP/amendment and does not allow NOAA Fisheries to substitute its judgment for that of the NPFMC's or to attach conditions for approval. If an FMP/amendment is disapproved or partially approved, NOAA Fisheries must give written notice to the NPFMC specifying the applicable law with which the FMP/amendment is inconsistent, the nature of the inconsistency, and recommendations on how the NPFMC could correct the inconsistency. A similar process is required for proposed regulatory amendments. If NOAA Fisheries determines that the proposed regulatory amendment is consistent with the FMP/amendment and applicable laws, then it is published in the FR for a 15- to 60-day public comment period. If the determination is negative, NOAA Fisheries must notify the NPFMC in writing, specifying the inconsistencies and providing recommendations for revision that would make the proposed regulation consistent. A schematic representation of the procedural steps involved from NPFMC transmittal to an approval/disapproval decision is presented in Figure 2.4-2.

An approved FMP/amendment is implemented by publication of the final rule in the FR. The preamble to a final rule must summarize and respond to comments received on the proposed FMP/amendment or proposed rule. The MSA requires that a final rule be published within 30 days of the end of the comment period on the proposed rule. The rule normally is not effective for an additional 30 days after it is published as required under the APA. Regulations governing federal marine fisheries off the coast of Alaska are codified in the CFR at 50 CFR Part 679.

2.5 Fishery Management Practices

To govern a fishery, policy statements must be translated into the regulatory language of management rules. In the Alaska region, this is the responsibility of NOAA Fisheries. These fishery regulations must not only accurately reflect the intent of the NPFMC's policy; they must be consistent with national policy as expressed by the laws and EOs described in Section 2.2.

Although an FMP is technically a set of policy statements and does not implement any specific regulatory language, the proposed plan amendment must be analyzed in a manner that satisfies both MSA and NEPA requirements. In order to accomplish this analysis at a meaningful level of detail and specificity, managers and researchers must analyze sets of particular management tools as alternatives to the existing management tools used in the FMP (e.g., the status quo FMP). These alternatives must address the proposed action. Since the NPFMC could elect to use a different set of tools, or more likely, different configurations of the same tools, it is important for the reader to have a basic understanding of the nature of these management tools and how they might be used to achieve particular results. It is also useful to have an understanding of what types of information, or data, are available to guide and monitor the effectiveness of different management measures. The following sections will provide a brief summary of the management practices and tools currently used in the Alaska groundfish fisheries. Technical descriptions and stock assessment models are included in Appendix F-1.

2.5.1 Management Tools

Management measures and management tools are the means by which managers control the fishery. The two terms, "management measures" and "management tools" (often used interchangeably by fishery managers), refer to all the rules, regulations, conditions, and methods that are required to rebuild, restore, or maintain any fishery resource and the marine environment. For each management issue or problem, managers review the available tools to determine the best way to address the issue or solve the problem. Some management tools are designed to be manipulated within the broadly authorized regulatory framework of the FMPs. Others require a lengthy process of amending the FMP to be implemented.

Most fisheries management regulations limit the power of individuals and corporations to catch fish. These regulations govern who can fish, what species they can catch, when they can fish, where they can fish, and what gear they can use. Some fishery regulations are more administrative in nature and require those fishing to keep records of and report certain data to fishery managers. This data is used by fishery managers and biologists to monitor the biological and economic health of the fishery, develop conservative harvest strategies and assess their potential impacts, and to enforce regulations. In addition, the regulations sometimes define measures that ensure fairness for all participants in a fishery. For example, some regulations require fishermen to apply for a license, file a particular report, or pay certain fees. Such fairness rules may also apply to the regulatory agency itself by requiring the agency to issue certain reports, specify catch limits, or make certain determinations by a certain date.

The following paragraphs discuss each of the management measures or tools that fishery managers use to manage and conserve the resource: who can participate in a fishery; what species may be harvested; when and where harvesting may occur; and what restrictions may be placed on fishing gear.

Who May Participate

Until the MSA was implemented in 1976, the only restrictions on who could participate in offshore fisheries were imposed by bilateral or multilateral agreements with foreign countries (see Appendix B). Fishery resources beyond the territorial jurisdiction (which at that time extended to only 3 nautical miles [nm] from shore) of any nation were considered common property and open to access by fishermen from all nations. Freedom to fish on the high seas was considered a basic principle of international law of the sea. (Koers 1973). The MSA established, for the first time at the national level, an access priority for U.S. domestic fishermen over foreign fishermen in the U.S. EEZ (3 nm to 200 nm from shore off the coast of Alaska). Although this change was made primarily to support a growing U.S. industry, it was also justified on the grounds of addressing environmental conservation concerns. While the MSA began to limit participation in the fisheries in the EEZ to domestic fishermen, it nonetheless continued to allow an "open access" fishery with few limitations on fishing activities.

The problem with such an open access fishery has been summarized as follows:

If no control exists over access in fisheries and if demand for a stock (or stocks) of fish increases, then:

- Overcapitalization is inevitable and will become worse as prices for the product increase.
- Measures to prevent depletion will either impose or lead to increased costs of fishing to the fishermen, and these costs will become greater as prices for the product increase.
- The costs of management, research, and enforcement will be borne entirely by the taxpayer (Christy 1978).

Theoretically, the problem of an open-access resource may easily be solved by limiting access or establishing a system of property rights in the resource. Once a policy decision is made to limit access to a fishery, the first question is raised: to whom should exclusive harvesting privileges be granted? Typically, fishermen who have traditionally and regularly participated in a fishery in the past are included (i.e., licensed or permitted) in a limited-access fishery, and those who have never participated or have had insignificant involvement are not included. Early limited-access programs had problems in defining these categories of participants (Ginter and Rettig 1978). Fair and defensible implementation of a limited-access system requires precise and politically acceptable definitions of traditional, regular, and insignificant participation. Not surprisingly, most of the political controversies and legal challenges attending limited-access systems have focused on the questions, "Who is in?" "Who is out?" and "Why?"

Although limiting the number of vessels that can fish in a given area is a powerful tool for protecting limited stocks, modern fishing technologies (such as computerized fish detectors and global positioning systems, as well as gear improvements) often allow fishermen to harvest a large amount of fish in a short period of time. If the TAC for a given area can be caught in a matter of days, fishermen wishing to participate in that particular fishery are forced into a "race-for-fish," where the fishermen who catch the most fish in the shortest amount of time "win" the race. This is one indication that, even with limited entry, a given fishery may have an over-harvesting capacity. While the race-for-fish system is "fair" in the sense that everyone has the same opportunity to enter the race, such a system leads to needlessly dangerous fishing conditions by compelling fishermen to work with very little sleep and heedless of weather or sea conditions. Another argument against the race-for-fish is that it tends to swamp the capacity of fish processors when all the fish come in at the same time and leads to wasteful and inefficient use of the resource and increased bycatch and discards.

One way that fishery managers have responded to this situation is by developing so-called “rationalized” or “rights-based” fisheries. These controversial programs give specific individuals or communities the right to harvest a given percentage of the TAC, thus eliminating the race-for-fish because each individual’s (or community’s) share is protected from harvest by another individual or community. These programs can be designed to allow individuals to catch their quota of fish over a relatively long time period. The intent is that quota holders would fish when it is safe or convenient to do so, given all other fishing restrictions. If designed properly, this individual flexibility could reduce the race-for-fish, increase the temporal and spatial distribution of fishing effort, allow fishermen the time to minimize bycatch, and distribute the fishery’s demands on the processing/marketing sectors more evenly. The controversy arises over the contention that these programs grant private access to public resources, with all the economic benefits that accrue, to the exclusion of other citizens. Some people feel that rationalization plans have little to do with conservation or safety concerns and are really designed to preserve profitability for the select few who receive the fishing rights.

Under the MSA, limited-access systems are discretionary, but the law provides some guidance and standards in developing them. The NPFMC has exercised this discretionary limited-access authority on several occasions.

In December 1991, in response to overcapacity conditions, the NPFMC adopted a limited-access system in the form of an Individual Fishing Quota (IFQs) Program for the halibut and sablefish fixed-gear fisheries. An IFQ is essentially a federal permit that gives the person holding the IFQ an exclusive harvesting privilege to catch a specified percentage of the TAC of a fishery (i.e., a certain amount of fish). A novel feature of the IFQ Program is that it includes a separate allocation of halibut and sablefish for a CDQ Program. A CDQ is an allocation of a specific amount of fish that may be harvested by a particular type of coastal community or group of communities.

(It should be noted here that while sablefish are a target species defined under the BSAI and GOA groundfish FMPs and governed under the MSA, Pacific halibut are governed under the Northern Pacific Halibut Act of 1982, which authorizes the NPFMC to recommend allocation measures for the halibut fishery to the Secretary of Commerce.)

In the early 1990s, the NPFMC became increasingly aware of excess harvesting capacity also in the groundfish and crab fisheries under its jurisdiction. In June 1992, the NPFMC again exercised its discretion to recommend a limited-access policy by adopting a moratorium on the entry of new vessels into the groundfish and Bering Sea crab fisheries. The Vessel Monitoring Program (VMP) was designed to be an interim measure until a comprehensive “rationalization” plan could be developed and implemented. The VMP limited the ability of new participants to enter these fisheries until it was replaced by the License Limitation Program (LLP) in October 1998. The LLP was adopted together with a multi-species CDQ Program that included all other groundfish and crab species for which there were no CDQ allocations at that time. Under the LLP, qualified fishing vessels receive a license that authorizes fishing operations. The LLP, in and of itself, does not eliminate the race-for-fish situation; although the use of qualifying criteria has reduced the number of vessels, the race-for-fish can still occur even though the fleet size is smaller than it once was. This realization has led managers to consider other types of programs for rationalizing fisheries.

Currently, participation in all fisheries for which the NPFMC has an FMP is managed under a limited-access program. The federal regulations that implement such programs for the IFQ, CDQ, LLP, and AFA programs for the groundfish fisheries are published primarily at 50 CFR 679.4, 679.30–32, 679.40–45, and 679.60–64, which list the qualification criteria for receiving and transferring harvesting privileges (permits or licenses) under these limited-access systems and other management considerations. The Restricted Access Management division of NOAA Fisheries, Alaska Region administers these programs (http://www.fakr.noaa.gov/ram/).

What May Be Harvested

To manage the species of groundfish likely to be taken in the groundfish fisheries, the FMPs divide those species into four categories.

1. Target Species–Those species that are commercially important and for which a sufficient database exists that allows each to be managed on its own biological merits. Accordingly, a specific determination of the total amount of fish that can be taken (the TAC) is established annually for each target species. Catch of each species must be recorded and reported.

2.. Other Species–Species that are currently of slight economic value and not generally targeted. This category contains species with economic potential or those that are important ecosystem components, but for which there is insufficient stock assessment data to manage each separately. Accordingly, a single TAC applies to this category as a whole. Catch of this category as a whole must be recorded and reported.

3. Nonspecified Species–Those species and species groups of no current economic value but that are taken by the groundfish fishery only as incidental catch in the target fisheries. Virtually no data exist that would allow population assessments. No record of catch is required. The TAC for this category is the amount that is taken incidentally while fishing for target species, whether retained or discarded.

4. Prohibited Species–Those species and species groups that must be returned to the sea with a minimum of injury, except when their retention is authorized by other applicable law. Groundfish species and species groups for which the annual TAC has already been taken are treated in the same manner as prohibited species.

Restrictions on what species of fish and, more specifically, how much of a particular species of fish may be harvested represent the most basic form of fisheries management in the EEZ off Alaska. Such restrictions focus on either numbers of animals, volume, or weight of the regulated species and are commonly referred to as *quotas*, *catch limits*, or *bag limits*. A catch limit is designed to balance the natural reproductive growth of the stock and the desire to harvest fish. Theoretically, at the "right" catch limit, the stock can continue to reproduce itself and sustain being harvested over time. A corollary control that is frequently integrated in a catch limit rule is a size limit. Minimum size limits are designed to allow fish to grow to sexual maturity and spawn at least once before becoming vulnerable to fishing gear or "recruited to the fishery." Maximum size limits may also be used to protect the largest animals from harvest because, in some species, the largest animals are the best reproducers.

A TAC is specified for each target groundfish species. The FMP implementing regulations require NOAA Fisheries, through formal consultation with the NPFMC, to establish TACs annually for each groundfish species, based on the biological condition of the stocks and on socioeconomic considerations (50 CFR 679.20(a)). The analytical basis for the NPFMC's TAC recommendations is the annual Stock Assessment and Fishery Evaluation (SAFE) report, produced by NOAA Fisheries biologists and economists and reviewed by the NPFMC's Plan Teams, Scientific and Statistical Committee, and Advisory Panel.

The sum of the TACs for all groundfish species is restricted to an established range of OY for the groundfish complex as a whole. OY represents a calculation of the amount of harvest that provides the greatest overall benefit to the nation with particular reference to food production and the protection of marine ecosystems. The OY range represents the lower and upper limits within which the yield is "optimum" for both the fishery and the resource. In the BSAI, the lower limit of that range is 1.4 million metric tons (mt), and the upper limit is 2 million mt (50 CFR 679.20(a)(1)(I)). In the GOA, the OY range is between 116,000 mt and 800,000 mt (50 CFR 679.20(a)(1)(ii)).

The annual TAC-setting process is similar to the public rule-making process for FMP amendments. The process begins in September with the NPFMC Plan Teams' review of preliminary stock assessment data. The NPFMC deliberates on TAC limits and some prohibited species catch (PSC) limits, and decides how the TACs should be apportioned and allocated among various fishing industry components. In October, the NPFMC selects proposed TACs and allocations that are published by NOAA Fisheries in the FR for public comment. With public input and further committee reviews of updated stock assessments, the NPFMC selects final TACs for the following year at its December meeting. Ultimately, when approved by NOAA Fisheries, the final TAC amounts and their apportionments and allocations among areas, gear types, or sectors are published in the FR. Fishery closures are made by the agency during that fishing year to avoid exceeding the amounts of fish authorized for harvest, as specified by the TACs. See Section 2.3 and Appendix F-1 for more details on how TACs are calculated.

Another major fishery management issue is the regulation of incidentally caught species, or "bycatch." Bycatch is inevitable in almost all fisheries that use nets, hooks, or traps of any kind. Bycatch may not always be a species different from that being targeted. For example, individual fish of the target species that are too small, too large, or of the wrong gender may be worthless in the fisherman's market; any fish that is discarded because it has little or no value to the fisherman is often referred to as "economic bycatch." Another form of bycatch occurs when fishermen catch fish that are commercially valuable but, if retained, would violate various fishing regulations designed to conserve or allocate the resource. Fishing vessels are usually required to discard these fish at sea, and this is called "regulatory bycatch."

Fishery managers can implement regulatory incentives and gear restrictions to minimize economic bycatch. Bycatch limits may be imposed that, when reached, cause closure of the targeted fishery or closure of certain high bycatch areas. Alternatively, fishery managers may require fishermen to retain bycatch onboard rather than discard it at sea. This imposes an economic cost in the time it takes fishermen to handle the bycatch and in the hold space it takes up. These management measures in Alaska are called Improved Retention/Improved Utilization programs (IR/IU). Gear restrictions include minimum mesh sizes for trawls, biodegradable panels and halibut excluder devices on pot gear, and careful release mechanisms for longline gear. Certain gear types, like seine and gillnets, have been prohibited in the groundfish fishery because of their indiscriminate bycatch. Efforts to measure and improve the effectiveness of bycatch measures receive a great deal of attention from the fishing industry, conservation organizations, and fishery managers alike.

The groundfish fisheries are prohibited from harvesting some species because other fisheries depend on them. Prohibited species (crab, Pacific halibut, Pacific salmon, and Pacific herring) are identified in the FMPs and must be discarded if caught (with certain exceptions). Management efforts to minimize this regulatory bycatch include PSC limits that, when reached, cause closure of the targeted fishery or closure of certain high bycatch areas. As mentioned above, gear restrictions also help minimize catch of prohibited species.

When, Where, and How Harvesting May Occur

In the U.S., fishing has historically been allowed unless regulations specifically close or limit the harvesting of fish. In other words, if there are no regulations prohibiting or constraining a fishery, gear type, or catch level, then a fishing activity can legally proceed without any constraints. Typically, such constraints are specified in terms of the area and time period during which they apply. Hence, regulations governing when and where fish may be harvested are nearly always linked. For example, a rule usually specifies an area in which certain restrictions apply for a specified time period or season. An area may be closed all the time, only for certain periods, or it may be open at the beginning of a fishing year and remain open unless certain criteria are triggered during the year that cause it to close. The reasons for restricting fishing in a certain area are as varied as the types of restrictions that apply. An area may be closed to fishing to protect spawning stocks, to protect sensitive habitat, to control the bycatch of a non-target species, or to prevent competition between the fishery and marine mammals protected under the ESA. Fishing in certain areas may also be restricted for allocation purposes or to eliminate conflicts between different gear types. Fishing effort may be dispersed over a larger area by selectively closing smaller areas.

For the groundfish fisheries in the EEZ off Alaska, rules restricting where and when fishing can occur generally appear at 50 CFR 679.22–23. In addition, regulations at 50 CFR 679.20–21 provide for certain area closures when specified TAC and PSC limits are reached.

Management Areas and Area Closures

Sectioning areas of ocean along the Alaska coastline into discrete management areas has been a fundamental fishery management tool beginning with the declaration of the EEZ by the MSA in 1976. With further division of the EEZ into the GOA and BSAI in 1978 and 1981, respectively, the NPFMC and NOAA Fisheries have used area designations to more effectively gather data, prevent overharvest of the TACs, reduce bycatch, allocate harvesting and processing privileges, promote rebuilding of depressed crab stocks, and protect areas containing sensitive marine habitat. For more than 25 years, a complex grid of management areas and area closures has been used to provide strict control over the GOA and BSAI groundfish fisheries and to achieve the policy objectives of the FMPs. Groundfish management areas and area closures are implemented by regulations at 50 CFR 679.21-24. See Figure 4.2-1 for a map of these areas as defined in the 2002 regulations. See also Appendix F-3 for a qualitative discussion paper on the current closed areas and an environmental impact assessment of potential amendments to this regulatory scheme.

Fishing Gear Restrictions

Many species of fish can be caught with a variety of fishing techniques. Although some types of fishing gear are more selective than others for the species targeted, there are many logistical and traditional reasons that certain gear types are preferred in different areas. For fishery managers, restrictions on the types of fishing gear that may be used represent another basic management tool. Such restrictions usually prescribe what types of fishing gear may or may not be used to harvest certain species and are often linked to specific areas and time frames.

Gear restrictions may be imposed for various reasons, including biological conservation of target or non-target species, habitat protection, or socioeconomic management. Also, gear restrictions may be necessary to resolve gear conflicts or to protect the interests of fishermen who have traditionally used a particular gear type. For example, GOA FMP Amendment 14, adopted by the NPFMC in 1985, prohibited the use of pot gear in the eastern GOA in the sablefish fishery because pots conflicted with the retrieval of hook-and-line gear, which was traditionally used in that fishery. In addition, gear restrictions are commonly used in an open-access fishery to impose constraints on the harvesting efficiency of the fleet. Efficiency restrictions effectively allow for more participation in the fishery rather than less, which may be desirable to slow the pace of harvesting or to distribute the social and economic benefits of the harvest among more participants.

Until recently, any fishing gear could be used to harvest fish in the EEZ unless it was specifically prohibited or regulated. The 1996 amendments to Section 305(a) of the MSA (Section 305(a)) changed this approach by requiring the Secretary of Commerce to publish a list of authorized fisheries and fishing gear. Under this change, a fish, regardless of whether it was targeted for capture, may be retained only if it is taken within a listed fishery, is taken with gear authorized for that fishery, and is taken in conformance with all other applicable regulations. A final rule that lists authorized fisheries and gear types was published December 2, 1999 (64 FR 67511). Authorized gear types for the BSAI and GOA groundfish fisheries include bottom and pelagic trawls, pots, and hook-and-line. Groundfish gear limitations are implemented by regulations at 50 CFR 679.24. See Appendix F-7 for the distribution of gear types used to catch different groundfish species. (The reader can learn more about the current Federal Observer Program and potential changes being considered by NOAA Fisheries in Appendix F-10). See Appendix F-7 for a qualitative discussion paper on the rationale behind the current gear restrictions and gear allocations in the Alaska groundfish fisheries and on the environmental tradeoffs of potential amendments to these regulations.

Summary

These management tools—restrictions on who may fish what, when, where, and how—allow NOAA Fisheries and the NPFMC to maintain the control necessary to maximize the benefit of the fisheries while conserving the resource to ensure its sustained availability. The success of these tools requires that managers have access to up-to-date information, sometimes on a daily basis, about the fisheries and their harvests and about the state of the resource and its environment. To gather that information, NOAA Fisheries has developed an elaborate system for monitoring the fisheries, the resource, and the environment. The sources and methods for gathering data on the fisheries are the subject of the following section.

2.5.2 Sources of Fisheries Management Data

Fisheries managers use several different sources of information to design, implement, and monitor the specific goals and effects of FMPs. These include catcher vessel and processor logbook records, data collected by trained observers, detailed location data collected with automated Vessel Monitoring System (VMS) units, and independent research carried out by government agencies and academia. This section summarizes the collection and importance of those data for fisheries management.

Record-Keeping and Reporting Requirements

Reporting requirements include maintaining logbooks at sea and on shore, as well as submitting certain forms to NOAA Fisheries. Catcher vessels and buying stations (tender vessels and land-based buying stations) are required to record fishery information in logbooks daily. Processors (motherships, catcher processors, shoreside processors, and stationary floating processors) are required to record fishery information in logbooks daily and summarize the information on production reports that are submitted weekly to NOAA Fisheries.

To assist NOAA Fisheries in determining fishing effort by species, processors also report the start and end of their participation in fishing operations (called check-in/check-out reports). To allow NOAA Fisheries to develop a catch history for catcher vessels delivering to motherships, each mothership must issue ADF&G fish tickets for each groundfish delivery. Information common to all the logbooks includes participant identification; amount and species of harvest, discard, and product; gear type used to harvest the groundfish; area where fish were harvested; and observer information. The reader can learn more about the current data and reporting requirements and the cost and benefits of potential changes in Appendix F-11.

Participation in the BSAI and GOA groundfish fisheries in any manner (i.e., as catcher, processor, or transporter of fish) requires one or more federal permits. All permit holders are required to comply with record-keeping and reporting requirements to report groundfish harvest, discard, receipt, and production (50 CFR 679.5).

Since 1992, NOAA Fisheries has based all estimates of catch in the groundfish fisheries on a combination of observer data and Weekly Production Report (WPR) data. The WPR summarizes the Daily Cumulative Production Logbook (DCPL) on a weekly basis. The operator of a catcher processor or mothership or the manager of a shoreside processor must submit a WPR for any week the mothership, catcher processor, or shoreside processor is checked in. A Shoreside Processor Electronic Logbook Report (SPELR) is required instead of a DCPL and WPR for shoreside processors or stationary floating processors receiving groundfish from AFA catcher vessels or receiving pollock harvested in a directed pollock fishery.

The blend data processing system developed by NOAA Fisheries combines data from industry and observer reports to estimate groundfish harvest in North Pacific groundfish fisheries. The systems blends the best available data from different sectors of the fishery to generate what, NOAA Fisheries believes, is the most accurate estimate of total groundfish harvest possible with the existing data.

WPRs for shoreside processors report landed weight of catch. These WPRs are the best source of data for retained groundfish landings. All fish delivered to shoreside processors are weighed on scales, and these weights are used to account for retained catch. Observers on catcher vessels report groundfish species composition, total catch, and estimates of retention and discard on a weekly basis. Observer information on groundfish discards is used in conjunction with total retained groundfish catch from shoreside weekly production reports to estimate total at-sea discards from all catcher vessels, including observed and unobserved vessels. All observer data for a month, gear, and target fishery are combined to compute discard rates for each groundfish species observed to be discarded. The discard rates are expressed as a ratio of the weight of the discarded species to the total retained groundfish weight. The discard rates are multiplied by the retained landings for each shoreside processor to estimate total at-sea discards of groundfish associated with the groundfish landed to the processor.

Total catch for shoreside processors is obtained by adding the landed catch weights reported on shoreside processor WPRs to the estimates of at-sea discards. WPRs for catcher processors and motherships report weights of processed product and round weights of discards. Product weights are converted to equivalent round weights using product recovery rates (PRRs). Total catch may be estimated using cod-end or bin volumetrics, scales, or conversion from production data. Species composition of the catch is obtained by sampling the catch, and the total catch is apportioned by species based on that sampling.

Total groundfish catch for all species combined is computed each week for each processor vessel from the WPR and the observer report. If either report is missing, the available report is selected. If both reports are available, the blend compares the two numbers: if the WPR and observer total catch numbers are within 5 percent, the WPR is selected as the data source; if the WPR is more than 30 percent higher than the observer total catch (for pollock target fisheries) or more than 20 percent higher (for all other target fisheries), the WPR is selected as the data source. In all other cases, the observer report is selected as the data source. The blend program then returns to the source data (WPR or observer) and copies the detailed records, showing gear type, area and species, to the blend. Records from WPRs are identified in the blend by a source field value of "W," observer records are identified by a source field value of "O."

As noted above, the blend process combines data from industry production reports and observer reports to make the best possible, comprehensive accounting of groundfish catch. These data are used to manage quotas for groundfish in the GOA and BSAI . The blend data are also used as the basis for computing estimates of prohibited species bycatch and for numerous regional and national reports, fishery stock assessments, and analysis of FMPs.

In 2003, NOAA Fisheries, Alaska Region implemented a new groundfish accounting system. This new groundfish catch accounting system utilizes the same data sources as the blend—observer data, shoreside processor landings data, and processor weekly production report data, but where the blend aggregated all data to the level of processor and week, the new system accounts for data at the haul (observer) and delivery (shoreside landings) level and can track all the current quotas. The new system is also more adaptable for anticipated future changes. More information on the new accounting system is online at http://www.fakr.noaa.gov/sustainablefisheries/catchaccounting.htm.

The reader can learn more about the current data and reporting requirements and the cost and benefits of potential changes in Appendix F-11.

Observer Program

The North Pacific Groundfish Observer Program offers an important check on the validity of data reported by catcher vessels and processors and provides some data that would not otherwise be available. Observers are trained by NOAA Fisheries (through contract with the University of Alaska's North Pacific Observer Training Center in Anchorage) and hired by private contractors who provide observer services to catcher vessels and processors. NOAA Fisheries requires that observers have a minimum of a bachelor's degree in biology, zoology, wildlife management, fisheries, or a related area of study; and one course each in math and statistics. Some contractors also require employees to have additional coursework or experience, especially with computers.

As a condition of their fishing permits (see 50 CFR 679.50), fishing vessels and processors are required to provide various levels of observer coverage for their operations. Vessels 125 feet (ft) or greater in length overall (LOA) are required to carry observers for 100 percent of their fishing days. Vessels that are 60 ft LOA or greater but less than 125 ft LOA are required to carry observers for 30 percent of their fishing days. (Vessels under 60 ft LOA are not required to carry observers.) Observers are also required at shoreside and floating processing plants according to processing rate, with 100 percent observer coverage of plants processing 1,000 mt or more per month, and 30 percent observer coverage of plants processing 500 to 1,000 mt per month.

Groundfish observers collect catch and other biological data throughout the groundfish fishing season. Information is recorded on catch composition of targeted, bycatch, and prohibited species; total groundfish catch, location of fishing, and fishing effort; length and weight frequency measurements, collection of age structures (scales/otoliths), and retrieval of tags from tagged fish. Observers also record the species, number, and condition of marine mammals and seabirds observed in the area or interacting with the fishing gear.

The catch-estimation methods used by observers vary among the vessel types, due to differences in available equipment and fishery operations. For individual hauls at sea, observers aboard catcher vessels using trawl gear make volumetric estimates of catch weight (by making either measurements of the trawl net as it is hauled aboard or measurements of fish in the holding bins multiplied by a density factor). When the vessel delivers to a shoreside processor, the catch is weighed on scales. The observer then uses the at-sea volumetric estimates and discard information to calculate the proportional weight of individual hauls. If an observer is unable to make volumetric estimates at sea (for a variety of logistical reasons), the vessel operators estimate individual haul weights using a variety of methods. The accuracy or precision of vessel estimates is unknown.

The trawl catcher processors that fish under the AFA or the CDQ regulations are required to weigh their catches using NOAA Fisheries-inspected, in-line motion-compensated scale systems that provide very accurate individual haul weights. All fish coming aboard these vessels are weighed, and these weights are reported to NOAA Fisheries by the observer. The observer also has a role in monitoring the daily testing of the scale to ensure its accuracy.

Aboard hook-and-line vessels, observers count or estimate the total number of hooks in each set, tally the number and species caught in sampled sections of the set, estimate the average weight of individuals of each species sampled, and multiply these average species weights and numbers by the number of hooks in the entire set. Observers are instructed not to use vessel estimates of total catch aboard hook-and-line vessels because they usually do not include bycatch and fish that drop off hooks before being hauled aboard. Consequently, observer catch estimates for unsampled sets are extrapolated from similar sampled sets. Observers aboard boats using pot gear count and weigh the catch in sampled pots and estimate the total catch in a set by multiplying the sampled species' numbers and average weights by the number of pots in the set. Weekly summary reports of observer data are sent to the NOAA Fisheries, Alaska Region for use in groundfish and prohibited species accounting. Daily reports are sent as needed to monitor specific fisheries. The reader can learn more about the current federal observer program and potential changes being considered by NOAA Fisheries in Appendix F-10.

Vessel Monitoring System

Beginning in 2002, all fishing vessels participating in the directed fisheries for pollock, Pacific cod, or Atka mackerel using pot, hook-and-line, or trawl gear are required to have aboard an operable VMS, which provides regular vessel location data to NOAA Fisheries via satellite (40 CFR 679.7(a)(18)). This requirement is necessary to monitor fishing restrictions in Steller sea lion protection and forage areas. A VMS consists of a Global Positioning System unit that is integrated with a satellite communication device in a tamper-proof system. The VMS determines vessel location in latitude and longitude and transmits this data, along with a vessel identifier number and the time of transmission, to NOAA Fisheries. VMS data are used to monitor compliance with closed areas and to verify the location of catch when separate quotas are established inside small or irregularly shaped areas that do not correspond with the standard reporting or statistical areas.

Independent Resource Surveys

Measuring fish stock abundance or biomass in the ocean is not easy. Unlike trees, and even unlike fish that have been harvested, fish below the water surface cannot simply be individually counted. Assessing stock abundance and biomass is further complicated because fish move around and may migrate extensively over relatively short time periods. This means that the abundance of oceanic fish stocks can only be estimated, and the only feasible way to estimate fish abundance independent of commercial harvests is by survey sampling methods. The Alaska Fisheries Science Center (AFSC), the research arm of NOAA Fisheries in Alaska, and specifically, the AFSC's Resource Conservation Assessment Engineering (RACE) Division have primary responsibility for conducting sampling surveys and have made some of the most significant contributions to the science of fishery resource surveys as it has developed over the past 40 years (Gunderson 1993).

Several different surveys have been developed for the BSAI and GOA areas, including bottom trawl surveys, acoustic echo-integration/trawl surveys, and longline surveys. Each survey has unique strengths and weaknesses for estimating abundance depending on the species' social behavior, preferred habitat, location in the water column or proximity to the sea floor, swimming ability, and attraction to bait, among other variables. For example, the bottom trawl survey can do a good job of estimating the biomass of rock sole, which inhabit the seafloor, but will be less effective at estimating the biomass of midwater or pelagic fishes, such as herring and squid. Conversely, fish without air bladders or that live on the sea floor are very difficult to detect by acoustic survey systems. For estimating abundance and distribution of Alaska's groundfish resources, the AFSC's primary methods include area-swept bottom trawl surveys for shellfish and bottomfish stocks; echo-integration/trawl surveys (acoustic surveys) for the dominant semipelagic stocks, such as pollock; and longline surveys for measuring relative abundance of valuable bottom species that inhabit the deeper waters of the upper portion of the continental slope.

The AFSC's comprehensive survey strategy consists of a suite of annual and triennial bottom trawl and acoustic surveys alternating among the eastern Bering Sea (EBS), Aleutian Islands, GOA, and the West Coast regions. Annual surveys have been conducted for the crab and groundfish stocks in the Bering Sea, spawning pollock in Shelikof Strait of the GOA, and Bogoslof Island area of the Bering Sea, and sablefish in the GOA. In recent years, NOAA Fisheries bottom trawl surveys have annually sampled an area of approximately 600,000 square kilometers (km^2), an area that includes as many as 1,400 sampling stations. The winter and summer acoustic surveys cover about 15,000 km of tracklines annually. The annual Alaska sablefish longline survey covers about 95,000 km^2 and fishes 16 km (7,200 hooks) of longline per station over a depth range of about 660 to 3,960 ft at about 90 sampling stations.

Survey gear is generally designed to catch fish over a wide range of sizes. Hence, surveys provide a consistent sample of fish from year to year, and provide information on prerecruit-size fish (fish smaller than those "recruited" to the fishery, i.e., available for legal harvest) that would otherwise not be available for stock assessment. Survey stations are either laid out in a systematic pattern over the fishing grounds or in a stratified random pattern. Table 2.5-1 summarizes the survey strategy for the BSAI and GOA fisheries for the 1999-2000 period. See Appendix B for maps and tables summarizing the historic survey efforts. For further information on the AFSC, RACE, and the surveys, visit the AFSC website at www.afsc.noaa.gov.

In summary, the groundfish surveys conducted off Alaska represent probably the most extensive survey effort implemented by a single government agency anywhere in the world. The survey strategy is currently being expanded to an annual/biennial cycle, which will greatly increase the pollock stock monitoring in the groundfish stocks. The increased age composition data from expanded surveys will also improve stock assessments and forecasts, particularly for the younger incoming year-classes (all fish born in a particular year). Data collection management from the observer program and resource surveys has been enhanced by modern computer technology, which expedites the availability of fishery catch data to allow in-season management of harvest quotas. Both survey and catch data now become available in time to be incorporated into annual stock assessment updates used to set TACs for the upcoming fishing season. These surveys also provide the best database for identifying EFH, interspecific interactions (interactions between different species), and biodiversity of marine ecosystems.

Summary

This section has outlined the systems and methods that the NPFMC and NOAA Fisheries use to gather information about the fisheries, the resource, and the environment. Yet, however elaborate and sophisticated these systems and methods may be, the fact remains that fishery scientists and managers cannot simply count the individual fish below the surface, and for this reason, the fisheries must necessarily be managed in the face of some degree of uncertainty. The following sections discuss the strategies fisheries biologists and managers have developed for accounting for uncertainty and integrating it into fisheries management.

2.5.3 Establishing Limits in the Face of Uncertainty

Fishery managers face the daunting task of controlling the large-scale manipulation of a complex system, the marine environment, without causing unacceptable changes in that system. The traditional scientific approach to this task is to reduce the complex problem into simpler components, analyze these components separately, and then try to synthesize the different pieces and extrapolate the effects on the whole. Fishery managers have followed this tradition by reducing the complex ecosystem problem to a series of single-species management problems, analyzing the impacts of fishing on one species at a time, and then trying to synthesize the impacts at a broader management level.

While single-species management analyses try to incorporate a wide variety of environmental information into their stock assessment models and the NPFMC has established principles of ecosystem-based management, the reality is that the larger system is far too dynamic and complex for even the best minds with the fastest computers to fully understand. Of course, managers of other natural resource systems struggle with the same issue, namely, how do you do your job in the face of continual uncertainty about how the system really works and how it responds to various human activities?

The short answer is that fishery managers do the best they can with the available information, however imperfect and uncertain. At the same time, they try to eliminate as much uncertainty as possible by expanding and improving the types of information available to them and improving the integration of that information into the decision-making process. That is one of the major goals of this Alaska Groundfish Fisheries Programmatic SEIS.

This section will provide brief descriptions of the complicated processes required to establish the goals and limits of the groundfish fisheries and, at the same time, to account for uncertainty at every level in order to manage the system in a "precautionary" manner, as required by the NPFMC policy. Discussion of these processes is simplified for readers. Details of the calculations and methodology discussed here can be found in Appendix B.

Stock Assessments for Alaska Groundfish Stocks

Passage of the MSA in 1976 marked the beginning of the collection by NOAA Fisheries of fisheries data in an effort to generate stock assessments of major groundfish resources. The AFSC, responsible for BSAI and GOA groundfish assessments, updates the stock assessments annually in the SAFE reports. These SAFE reports are prepared and reviewed by the NPFMC's BSAI and GOA groundfish plan teams, which are comprised of scientists from NOAA Fisheries, ADF&G, USFWS, several universities, and NPFMC staff.

Spearheading each of these plan teams are NOAA Fisheries scientists from the AFSC Resource Evaluation and Fishery Ecology Division. These scientists incorporate the biomass estimates generated by the RACE division's stock assessment surveys into statistical models to provide insight into the effects of different harvesting strategies, to test analytical assumptions, and to learn more about how the marine ecosystem works and the effects of fishing on that ecosystem. For further information on the AFSC, Resource Evaluation and Fishery Ecology Division, and the methods and analyses used in making stock assessment projections, visit the AFSC website at www.afsc.noaa.gov.

Stock assessment analysis is a way to estimate how many fish are in a specific geographic ocean area or fishing grounds and to predict how these fish stocks or populations will respond to a particular harvest rate. Scientists use resource survey and fishery information in mathematical calculations to estimate how many fish are in a specific management area of the ocean (abundance or biomass). Life history information (growth, maturity, fecundity) is combined with estimates of natural mortality, including removals by predators, and used to estimate how many fish can be caught in a fishing season without impacting future stocks. While the NPFMC weighs economic and social considerations along with biological and ecological concerns to establish OY, stock assessments are primarily concerned with biological limits and stock production variability.

Three analytical assessment methods are typically used for Alaska groundfish: index methods, stock synthesis, and an Automatic Differentiation (AD) model builder. (For a review of current stock assessment methodology used in the TAC-setting process, see Section 4.3.1 and Appendix F-1.) A brief discussion of these three assessment methods, beginning with the simplest follows below.

Index Methods

The simplest way to assess a fish stock is to create an index of population size or biomass based primarily on resource surveys (see Section 2.3). A survey method is selected that targets one or more stocks in a specific area. By multiplying the average catch rate (the rate at which the survey caught fish) by the size of the area fished, scientists can estimate the abundance of fish or the biomass for that survey area. The results can be expressed either as an index of abundance or as an estimate of stock biomass in metric tons. There are several sources of sampling and statistical uncertainty inherent in these surveys that cannot be eliminated merely by increasing the frequency or intensity of the surveys. Ideally, the amount of uncertainty at each step in the process is incorporated into a "confidence interval" for each estimate. For example, the stock assessment could say there is a 95 percent chance that the actual biomass of the stock in the given area is between a range of high and low values. Given a particular data set, the narrower the range of points between those high and low values, the less confidence one may have that a point between that range is an accurate estimate of biomass.

Stock Synthesis and Automatic Differentiation Model Builder

Stock synthesis and AD model builder are computer programs that create statistical models of complex fish population dynamics. Without going into the details of statistical analysis and model-building here, we can say that, as the name suggests, model builder software allows us to create models: statistical replicas of a fish population that, while not as accurate as, say, a photograph, nevertheless provide scientists with a statistically reasonable facsimile of what a population looks like and what it will look like at a given time in the near future. Basically, this software allows us to input what we do know about the fish stocks to find out some of what we do not know (again, because we can not count the fish) and to predict short-term trends in biomass with some certainty.

The survival and growth of eggs, larvae, and juvenile fish are highly variable over time due to natural fluctuations in the marine environment. The appearance of small, younger fish in resource survey and observer data provides a means to forecast the strength of various year-classes. However, variability in recruitment (the number of fish that survive and grow large enough to be targeted by the fishery) from one year to the next impairs our ability to project stock trends with much certainty. The ability to determine changes over time in the age-structure of a fish population (how many fish of each year-class make up the total population) is critical to assessing a stock accurately—particularly if the population has undergone extreme changes in abundance. With a time series of age composition data, scientists can use stock synthesis and AD model builder software to generate complex population models.

For most Alaska groundfish, spawning is highly seasonal, so that all fish in a particular year-class will have been born within a month or two of each other. Stock synthesis and AD model builder keep track of each year- class as it ages, enters the fishery, and eventually dies out. Recruitment occurs when a year-class begins to be captured by fishing gear. For example, the relatively strong 1994 year-class of pollock in the GOA "recruited" to the fishery in 1996 at age two; in 1999, at age five, it constituted 36 percent of the total pollock catch. Being able to keep track of year-classes in this way improves abundance estimates and allows scientists to better predict short-term trends.

One of NOAA Fisheries's primary long-term objectives is to reduce uncertainty in stock assessments. Moving from an assessment based on a biomass index, or an aggregate biomass model, to an age-structured assessment is a positive step towards achieving this objective. In 1990, four Alaska groundfish assessments were based on age-structured models. By 2004, 19 assessments were based on age-structured models, and 19 were based on a survey index (Table 2.5-2).

Further refinements, such as the development of AD model builder applications specific for Alaska groundfish, may further reduce uncertainty, but only moderate gains can be expected. The real strength of these modern assessment methods lies in their ability to realistically integrate into the model the uncertainty inherent in the assessment processes. Using AD model builder, it is possible to obtain confidence limits for current stock size that reflect the uncertainty in the input parameters and in how well the model fits the data. These confidence limits may be rather large for many groundfish stocks.

Setting Fishery Targets and Limits

Fishery managers have developed a series of targets and limits for each fishery. They are all abbreviated in common usage among scientists and managers, and can be quite confusing at first. Readers new to the science should refer to the Acronyms and Abbreviations located in the beginning of this document. This section will introduce the terms, their relationships to each other, and how they are used in fishery management. Details on the mathematical derivations of each term are listed in Appendix B. The Appendix also includes a qualitative discussion paper on the TAC-setting process currently being used and provides an EA of potential amendments to that process (see Appendix F-1).

The National Standards established in the MSA (see Section 2.2.2) establish guidelines for the management of fishery resources based on the concept of Maximum Sustainable Yield (MSY). According to these FMP guidelines, a stock is defined to be overfished if the harvest exceeds MSY for a year or more. Overfishing is, by definition, a rate of fishing that is not sustainable over time. Thus, MSY and the overfishing level (OFL) are examples of a fishery *limit*, an amount of fishing that management is trying to avoid. The FMP guidelines distinguish such a limit from a fishery *target*, an amount of fishing that management is trying to achieve. Historically, NPFMC policy has been to use a precautionary approach in setting target levels so that they are well below the appropriate limits. Furthermore, NPFMC policy holds that the criteria used to set target catch levels should be explicitly risk-averse, so that the caution used in setting target levels is commensurate with the uncertainty about the status or productivity of a stock.

The National Standards require that each FMP specify, to the maximum extent possible, objective and measurable criteria for determining the status of each stock or stock complex covered by the FMP. The FMP must also provide an analysis of how those criteria were chosen, and describe how they relate to the reproductive potential of a stock. One such criterion is the maximum fishing mortality threshold: in other words, the maximum allowable number of fish killed through fishing. In the BSAI and GOA groundfish FMPs, the maximum fishing mortality threshold is equivalent to the OFL. The OFL is the most basic fishery limit and is defined as any amount of fishing in excess of a prescribed maximum allowable rate. Exceeding the maximum fishing mortality threshold for a period of one year or more constitutes *overfishing*. The maximum allowable rate of fishing varies depending on the amount of information available from the stock assessment. The BSAI and GOA groundfish stocks are managed within a system of six tiers corresponding to a descending order of the availability of reliable information. Stocks managed under Tier 1 have the most reliable stock assessment data, and those managed under Tier 6 have the least reliable data. The NPFMC's Scientific and Statistical Committee has the final authority for determining whether a given item of information is "reliable" for the purpose of assigning a stock to a certain tier, and may use either objective or subjective criteria in making such determinations.

The second status determination criterion of the National Standards is the minimum stock size threshold (MSST). Although MSSTs are not specified by the BSAI and GOA groundfish FMPs, the fact that their use is required by the National Standards resulted in their becoming a standard component of the SAFE Reports beginning in 1999. It is currently considered impossible to evaluate the status of stocks in Tiers 4-6 with respect to their MSSTs because stocks qualify for management under these tiers only if reference stock levels (such as MSST) cannot be reliably estimated. Derivation and values of MSST for Tier 1-3 species are included in Appendix B.

The stock-specific TAC has been the basic target or goal for a fishery and is set by the NPFMC for different categories of groundfish species and species groups every year after taking into account other uses and needs of the ecosystem. The decision to manage a species individually or as part of a species group depends on the commercial importance and the amount of biological information that is available for each species. *Target species* are commercially valuable and are managed individually with separate TACs. *Other species* have some economic potential but are not generally targeted and are managed as a group with a single TAC that applies to the whole category. *Nonspecified species* have no commercial value, and the single TAC for the group is whatever amount is caught incidentally. *Prohibited species* have, by definition, no allowable catch limit and must be released with a minimum of injury. The NPFMC has the discretion to create or change subgroups of species within a management category, but an FMP amendment is required to move a species into the target category.

The TAC specifications define upper harvest limits, or fishery removals, for the next fishing year. The sum of the TAC specifications is important because the FMPs specify the upper and lower ceilings for total TAC in each management area. As noted earlier, those upper and lower ceilings define the OY for each management area. In the BSAI, the lower limit is 1.4 million mt and the upper limit is 2 million mt (50 CFR 679.20(a)(1)(I)). In the GOA, the lower limit is 116,000 mt and the upper limit is 800,000 mt (50 CFR 679.20(a)(1)(ii)).

Sub-allocations of TAC are made for biological and socioeconomic reasons according to percentage formulas established through FMP amendments. For particular target fisheries, TAC specifications are further allocated within management areas (Eastern, Central, Western Aleutian Islands; Bering Sea; Western, Central, and Eastern GOA), among management programs (open access or CDQ Program), processing components (inshore or offshore), specific gear types (trawl, nontrawl, hook-and-line, pot, jig), and seasons according to regulations at 50 CFR 679.20, 50 CFR 679.23, and 50 CFR 679.31.

There are certain notice and comment rule-making requirements that NOAA Fisheries must meet, particularly those of the APA, concerning prior public review and comment regarding regulatory actions. To satisfy these requirements, NOAA Fisheries uses a three-part process for publishing the TAC specifications and allocations in the FR. Proposed, interim, and final TAC specifications and allocations are published in sequence by NOAA Fisheries.

NOAA Fisheries first publishes *proposed specifications* based on the NPFMC's recommendations from its October meeting. These recommendations are typically based on the previous year's fishing data, as contained in the SAFE reports. All Plan Team and NPFMC meetings leading up to the proposed specifications are open to the public with opportunities for public comment. It then takes NOAA Fisheries about two months to draft, review, get internal clearance, and publish the proposed regulations after receiving the NPFMC's recommendations in October. The proposed regulations are typically published in December. In 2002, for example, the NPFMC met and recommended proposed year 2003 specifications on October 6, 2002, and the proposed specifications were published December 13, 2002. After the publication date, NOAA Fisheries must then provide a 30-day public comment period before publishing *final specifications*.

However, because the fishing year in both the GOA and BSAI begins on January 1, and because the final specifications and allocations cannot be published by this date, NOAA Fisheries publishes *interim specifications* which are effective from January 1 until implementation of the final specifications. The interim TAC specifications are prescribed as 25 percent of the proposed TACs. Final TAC specifications are recommended by the NPFMC at its December meeting. These recommendations are based on the final SAFE reports that incorporate much of the data from the most recent fishing season and so represent an updated picture of the fishery. Again, it takes NOAA Fisheries about two months to prepare and approve the final regulations based on these new recommendations from the NPFMC. For the 2003 fishing year, the NPFMC met December 4–9, 2002, and recommended final TAC specifications that were published in the FR on February 18, 2003.

Since 1991, an EA has been prepared on each year's TAC specifications to comply with both MSA and NEPA requirements. These EAs are used in the decision-making process and accompany the specification rules through regulatory review and filing with the FR.

The TAC-setting process is known to have flaws. The proposed specifications are outdated by the time they are published and the public has a formal opportunity to comment on them. Compounding the problem is that the initial specifications are not based on the best scientific information. The scientific information obtained from the surveys, observer program, and other sources is usually not available until November. Stock assessment biologists need some time to review the data, correct errors, and run their population dynamics models. The NPFMC recommended a revision of the TAC-setting process in 1996 (BSAI/GOA FMP Amendments 48/48), but technical difficulties pertaining to the timing and completion of analyses have delayed a regulatory amendment. A new draft analysis to revise the process was presented to the NPFMC in September 2002. If approved, a revised TAC-setting process would be in effect in time for setting the TACs for the 2004 fishing year. See www.fakr.noaa.gov for updates on this analysis and schedule for decision-making.

Target Species Limits

Target species are those groundfish species or species groups that are actively pursued by the fishing industry. As described above, an annual process has been established for setting TAC for each of these target species. The annual TAC for each species of groundfish is allocated or apportioned to industry components based on gear type, vessel size category, processing sector, and quota recipient class (such as CDQ group or AFA cooperative or IFQ holders).

The CDQ Program receives an allocation of a percentage of each groundfish species or species group that are managed under the BSAI FMP and that have an annual TAC. The overall CDQ allocation for each species is further allocated to the six CDQ groups. NOAA Fisheries requires each CDQ group to submit catch reports for all vessels fishing for it. Observer data are used to monitor groundfish CDQ harvests by all catcher processors and motherships. Trawl catcher vessels are required to retain and deliver groundfish CDQ harvest to a shoreside processor, where they must be sorted by species, weighed (or, as in the case of salmon, counted), and reported by the processor on a CDQ delivery report. Observer data are used to verify the species reported on the CDQ delivery report and to check the species weights. For hook-and-line and pot catcher vessels, they may either deliver their fish to shoreside processors and use their delivery reports or use on-board observer data.

TACs are further subdivided for the GOA and BSAI sablefish fixed gear fisheries, which are managed under the IFQ Program (see 50 CFR 679.40 to 679.45). Once all of the CDQ and or trawl allocations have been subtracted, the remaining sablefish TAC is allocated to the fixed gear sablefish fishery. Permits are issued to qualified IFQ Program participants, allocating them a specific amount of sablefish quota by area and vessel size category. Individual accounts are established for each permit in the NOAA Fisheries database. Fishermen must report landed weights of sablefish using a real-time transaction processing system. A computer system subtracts the amount from the IFQ account and prints a receipt for the fisherman showing the transaction amount and remaining account balance. For more details on the sablefish IFQ program, see the NOAA Fisheries webpage at www.fakr.noaa.gov.

The pollock fishery in the BSAI is managed under the AFA. The annual pollock TAC, after subtracting the CDQ percentage and an incidental catch allowance, is allocated among the catcher processor, mothership, and inshore sectors that have formed cooperatives. Currently, one catcher processor cooperative, one mothership cooperative, and eight inshore cooperatives have formed, each of which receives an allocation of pollock based on the historic harvest percentages of each catcher vessel in the cooperative. The history of catcher vessels not in cooperatives forms the basis of an open-access quota, available to vessels not in cooperatives. Pollock caught in the directed pollock fishery count against the cooperative allocations. NOAA Fisheries considers all pollock caught by vessels using pelagic trawl gear to be directed fishing. Pollock caught with non-pelagic (bottom) trawl gear is counted against the incidental catch allowance. Regulations at 50 CFR 679.24(b)(4) prohibit directed fishing for pollock with nonpelagic trawl gear. The pollock cooperatives actively monitor their pollock harvest and cease fishing activity when their catch equals their allocation. NOAA Fisheries also monitors the pollock harvest and can close a cooperative fishery if needed.

For the general groundfish fishery—all groundfish fishing not managed under either the CDQ, IFQ, or AFA Cooperative Programs—NOAA Fisheries monitors the catch and issues regulatory notices to open and close specific fisheries. In some cases, catch is monitored from daily or weekly reports, and a closure date is projected by extrapolating catch rates. If fishing effort is high relative to the available quota, NOAA Fisheries will estimate the length of the fishery using historic effort and catch rates, and open the fishery for a specific length of time, ranging from as little as six hours to several days.

If NOAA Fisheries determines that a groundfish allocation or apportionment (quota) will be reached, the agency establishes a directed fishing allowance (DFA) under regulations at 50 CFR 679.20(d)(1)(I). The DFA is an amount less than the quota, leaving a portion to support incidental catch of the species in other fisheries. When the DFA is reached, NOAA Fisheries prohibits directed fishing for that species under 50 CFR 679(d)(1)(iii). When directed fishing is closed, fishermen may retain incidental catch of the species up to specified percentage limits (50 CFR 679.20(e)), which allows limited retention of the species but greatly reduces the catch rate compared to the directed fishery.

When a groundfish TAC is reached, NOAA Fisheries prohibits further retention of the species under 50 CFR 679.20(d)(2). If catch amounts reach the level defined as overfishing for the species, the agency can take actions to restrict other fisheries to prevent overfishing the species, under 50 CFR 679.20(d)(3).

Most groundfish quotas are for areas that correspond with federal statistical areas or FMP management areas. For these quotas, the location of catch is determined by the reported catch location or the observed haul location. However, when catch quotas are established for small areas (for example, the Atka mackerel TAC in the Aleutian Island Steller sea lion critical habitat area), the agency cannot accurately monitor the quotas based on the reporting areas or observer data alone. Fishing vessels typically haul their nets for at least several hours; so, in a small enough area, a vessel's initial setting of the net could occur inside the area, while the haul-back of the net occurs outside the area. NOAA Fisheries has adopted two strategies to address this type of problem.

One strategy is to treat the critical habitat quota as a limit within the overall area quota. NOAA Fisheries monitors the overall area catch, and when an amount equal to the critical habitat quota is reached, the agency closes critical habitat. This method is very effective in controlling the catch inside critical habitat. Because all catch from the larger area is initially counted against the critical habitat quota, it tends to encourage vessels to fish inside critical habitat first, which may cause concerns about temporal concentration of the catch in critical habitat, even though the catch amount is well-controlled.

The other strategy, which has become popular, is to utilize VMS data in conjunction with observer data to monitor vessel location during the time between gear set and retrieval. This method allows assignment of catch from a specific haul or set as inside or outside critical habitat. If any portion of the haul or set occurs inside critical habitat, the catch for that haul or set is counted as coming from inside critical habitat.

Prohibited Species Catch Limits

Bycatch—defined as fishery discards (e.g., fish not kept for sale or personal use) and unobserved mortalities resulting from direct encounter with fishing gear—has become a central concern of commercial and recreational fisheries, resource managers, scientists, and the public, both nationally and globally. Bycatch concerns arise from the apparent waste that discarded fish represent when so many of the world's marine resources are either fully utilized or overexploited. These issues apply to fishery resources as well as to marine mammals, seabirds, sea turtles, and other components of the marine ecosystem even though they may not technically be included in the bycatch definition. There are allocative issues related to bycatch as well.

The U.S. Congress, NOAA Fisheries, and the NPFMC have responded to these concerns by modifying the groundfish management program in ways that result in lower bycatch and waste. Bycatch limits, specified in regulations, provide a popular management tool that serves as an economic disincentive to those fisheries that experience high bycatch levels. When specified for a particular species, bycatch limits close all further groundfish fishing in an area once the limit is reached. The disincentive, then, is for fishermen to find ways through improved gear technology, improved communication among the fleet, and changed fishing behavior, to reduce their bycatch and not reach the bycatch limit. In doing so, the fishermen can continue to harvest groundfish up to the TAC. The lower their bycatch rate, the more fish they catch, and the more profitable the fleet.

In order to eliminate any incentive for the groundfish fleet to target commercially exploited species that already support their own commercial fishery off Alaska, the BSAI and GOA FMPs prohibit the groundfish fisheries from retaining all species of salmon, king and Tanner crabs, Pacific halibut, and Pacific herring taken as bycatch. Annual PSC are specified each year based on a review of the fishery and the policy goals for bycatch reduction. These prohibited species must be returned to the sea as soon as possible after they are caught. One exception to the mandatory discard rule is the Prohibited Species Donation Program. Under this program, groundfish fishermen who incidentally harvest salmon or halibut can donate them to a foodbank for the poor. Retaining them for donation is a legal alternative that does not "waste" the resource, yet maintains the disincentive to target salmon or halibut.

The North Pacific Groundfish Observer Program collects data on the numbers and weights of each prohibited species caught and sorts them by vessel, gear type, season, and fishing area. NOAA Fisheries combines this information with the catch rate of targeted species and calculates the rates at which prohibited species are caught per unit of groundfish caught for each fishing sector. Bycatch rates of prohibited species for unobserved vessels are extrapolated from similar observed vessel data. Observer data also provides estimates for the proportion of each prohibited species that is effectively killed before it is released under different fishing regimes.

PSC limits for each species are expressed in terms of mortality. Annual PSC limits for some species are specified under 50 CFR 679.21, or through the annual specification process. The PSC limits may be further allocated to fishery categories, gear groups, or seasons to create PSC quotas. The rules for whether particular prohibited species count against a PSC quota are specific to different fisheries, areas, gear types, and seasons (see Appendix B, Table B.4-3). When NOAA Fisheries projects that a PSC quota will be reached in a given fishery, the agency publishes a notice in the FR closing the area or season for the fishery, even if groundfish quota remains unharvested.

Other management tools have been used to directly control and meet bycatch reduction objectives. These include gear restrictions, season delays, and mandatory retention and utilization regulations. For information pertaining to these FMP management tools, see Chapter 4. The reader is also directed to the Appendix which also includes a qualitative discussion paper on bycatch and incidental catch restrictions currently being used and provides an environmental impact assessment of potential amendments (see Appendix F-5).

In-Season Monitoring and Control of Catch Limits

The annual TAC for each species of groundfish is allocated or apportioned to industry components based on gear type, vessel size category, processing sector, and quota recipient class such as CDQ group or AFA Cooperative. These allocations and apportionments result in a set of quotas that NOAA Fisheries must monitor. The procedures for monitoring and management of each quota depend on the regulatory program that established the quota. All of these systems rely heavily on catch reports from observers on catcher vessels and in processing facilities. Reports of catch from unobserved vessels and processors are combined with observer reports from similar operations. NOAA Fisheries accounting systems are quite complicated and require consistent and standardized input from the fishing industry. Changes in management rules, especially those triggered by certain catch limits, can happen very quickly. Communication channels between NOAA Fisheries and the industry, including where catch data and stock assessments are published, are spelled out in the regulations governing each program. The reader can read more about in-season management by reviewing Appendix F-11, which provides a qualitative discussion paper on the data and reporting program and the federal fishery observer program.

Summary of Sections 2.1 through 2.5

The preceding sections of this chapter have outlined the laws and policies governing fisheries management in the EEZ off Alaska; described the tools and practices that the NPFMC and NOAA Fisheries use to manage the groundfish fisheries in conformance with those laws and policies; and presented some of the complexities of groundfish management—all in an effort to provide readers with a basic context for understanding and evaluating the programmatic alternatives.

2.6 The Programmatic Alternatives

National Environmental Policy Act Guidance for Alternatives

In keeping with CEQ requirements for implementing NEPA, the Programmatic SEIS offers a range of alternatives, in addition to the no-action, or status quo, alternative, and a discussion of the environmental impacts of activities that flow from each. The alternatives, four in number, represent alternative policies for the continuing management of the federal groundfish fisheries off Alaska and range from an aggressive harvest strategy to a more environmentally precautionary harvest strategy. These alternatives are intended to serve as options for an overarching framework for managing the groundfish fisheries off the coast of Alaska. Each is based on a different philosophy and management approach and, to varying degrees, contains the principles of ecosystem-based management. Each alternative contains a policy statement, a set of goals and objectives for that policy, and, with the exception of the status quo alternative, a pair of example FMPs that would achieve the goals and objectives of the policy statement. The selection of one of these policy alternatives will set the stage for subsequent FMP amendments that will alter the FMP and its implementing regulations to achieve a particular policy goal or objective. In providing such policy options, these alternatives are action-forcing and binding.

The impacts of the four alternatives presented in this section are evaluated from information and analysis summarized in Chapter 3 (Affected Environment) and Chapter 4 (Environmental and Economic Consequences). Chapter 4 presents the issues (and their potential impacts) as defined by the public scoping and comment process. Our findings in these chapters provide the basis for the public's assessment of the relative merits of the alternatives and, ultimately, for the NPFMC's and NOAA Fisheries' choice of a PA.

Recent History of the Development of the Alternatives

The alternatives presented here are the product of two-and-a-half years of public process. As noted in the review of the history of the development of this Programmatic SEIS in Chapter 1, NOAA Fisheries announced its decision to revise the January 2001 draft Programmatic SEIS (2001 Draft Programmatic SEIS) after reviewing public comments and determining that, as those comments suggested, the alternatives could be improved by 1) being restructured from single-focus to multi-component alternatives; 2) expanding the cumulative effects analysis; and 3) making the document more concise and easier to read. In January 2002, the agency placed these new alternatives on its website and solicited public comment. In February of the same year, following review of the public comment, the NPFMC developed a range of eight policy alternatives and case studies ranging from the original FMPs to a "No Fishing" FMP. The NPFMC requested that NOAA Fisheries continue to work with these alternatives to make them more specific and differentiable, to address problems of combining specific management tools with the policy objectives in each alternative's set of goals and policies, and to consolidate the alternatives if possible.

Between the February and April, 2002 NPFMC meetings, NOAA Fisheries, including the AFSC, consulted with public stakeholders and legal counsel to determine the best way to restructure the alternatives to provide the specificity needed to differentiate between the policy alternatives, as well as to provide the detail necessary to conduct a meaningful scientific analysis. At the April 15, 2002 NPFMC meeting, NOAA Fisheries recommended that the eight more specific objective alternatives be consolidated into four broad-band policy alternatives (Figure 2.6-1). Each alternative to the status quo would include two FMP-like examples that would serve as bookends to an FMP framework, within which future project-level management decisions could be made. Under this scenario, the bookends do not reflect the actual specific measures that will be chosen in the future. Rather, they represent the outer bounds of the range of management decisions and measures specific to any policy alternative and serve, also, to provide the basis for a solid scientific analysis of the effects of each specific policy alternative.

This approach to developing the programmatic alternatives sets a distinct course for decision-making. At the same time, it maintains flexibility in decision-making by providing a range of policy goals and objectives that form a framework within which the NPFMC and NOAA Fisheries can work as they seek to satisfy their statutory obligations under the MSA, the MMPA, and other federal statutes. These alternatives also provide the NPFMC with flexibility in selecting those policy goals, objectives, and foreseeable actions that it intends to pursue as FMP amendments in the near future. This approach allows the alternatives to capture the full range of policy options and actions approved by the NPFMC at the February 2002 meeting. This approach also will provide the specificity needed to satisfy the legal and analytical requirements of this Programmatic SEIS.

This approach does, however, constitute a departure from the 2001 Draft Programmatic SEIS. In adopting the current approach, the NPFMC recognized that to satisfy the legal requirements of this Programmatic SEIS by examining alternative FMPs that are comparable in scope to the current FMPs, the NPFMC and NOAA Fisheries needed to commit to a review of different policy objectives as well as the "means" of achieving a change in policy direction. Developing an example FMP range for each alternative to status quo will allow the NPFMC to consider potential FMP management measures and a preliminary assessment of their environmental impacts. These measures will subsequently be further developed and implemented by the NPFMC as follow-on amendments through its normal FMP decision-making process. The time schedule for developing any follow-on amendments will be determined after the NPFMC has constructed its PA, reviewed data requirements and public comment, and prioritized its policy objectives.

During its June 4-12, 2002 meeting, the NPFMC received a report from NOAA Fisheries staff on the refinements made to the April 2002 suite of programmatic alternatives and the results of several meetings held with public stakeholder groups. The NPFMC also reviewed written comments from the public and received oral testimony from a number of representatives of fishing industry and environmental organizations. Following a review of all this information, the NPFMC modified, through a series of motions, the wording of alternative policy language as well as details of the alternatives' associated FMP examples. The NPFMC completed its June action by adopting the present suite of alternatives for analysis. [At its June 2003 meeting the Council adopted a PA based on a preliminary review of the findings contained in the 2003 Draft Programmatic SEIS. This PA is based on a variation of Alternative 3 where the Council incorporated a number of policy elements from the other alternatives. For more information on the PA, see Section 2.6.9.]

This Final Programmatic SEIS identifies the PA. The NPFMC revisited the preliminary PA (PPA) after reviewing all the public comments on the 2003 Draft Programmatic SEIS and has recommended a final PA (PA) that contains FMP policy goals and objectives that are different from the policy goals and objectives contained in the current FMPs. The NPFMC will formally move to amend the BSAI and GOA groundfish FMPs to incorporate any change in policy. NOAA Fisheries will announce the PA in the Record of Decision document, which will also contain a time schedule for implementing FMP amendments and regulatory changes necessary for implementing the selected policy. Following publication of the Record of Decision, the NPFMC will submit the proposed FMP policy amendment for approval by the Secretary of Commerce and, upon Secretarial approval, NOAA Fisheries will publish the new policy in the FR.

Overview of the Programmatic Alternatives

The four policy alternatives range from a harvest policy that is more aggressive than the status quo to two different harvest policies that are more environmentally precautionary. Each policy alternative is comprised of a set of FMP policy goal and objective statements. Additionally, except for Alternative 1 (the no-action or status quo alternative), each new policy alternative includes two illustrative FMPs that serve as bookends to a management framework consistent with that policy. Each FMP bookend will be analyzed separately and will serve as a proxy for a range of future management actions. As explained above, the bookend approach will illustrate the range of environmental effects of that policy. The bookends are not intended to be self-sufficient alternatives. Rather, the bookends establish the likely range of management actions the NPFMC will examine when implementing the selected policy alternative and predict the range of potential environmental effects from the use of those management tools. Once the NPFMC and NOAA Fisheries choose a policy-level alternative (and accompanying bookends), it will be committing, to the extent practicable, to devise and implement FMPs and management actions consistent with the goals and objectives of that chosen alternative.

This alternative structure recognizes that the resource being managed and the marine ecosystem are quite dynamic in nature and only partially understood. By providing a range of management tools and their potential effects for each policy alternative, attempts were made to take into account the dynamic nature of the fisheries as a whole and to provide enough flexibility in each alternative management regime to allow decision-makers to base decisions on the best available science.

Each of the alternatives is informed by ecosystem-based policies. The NOAA Fisheries Ecosystem Principles Advisory Panel (NMFS Ecosystem Principles Advisory Panel 1999) describes ecosystem-based management for marine fisheries as follows:

> *Ecosystem-based management can be an important complement to existing fisheries management approaches. When fishery managers understand the complex ecological and socioeconomic environments in which fish and fisheries exist, they may be able to anticipate the effects that fishery management will have on the ecosystem and the effects that ecosystem change will have on fisheries. However ecosystem-based management cannot resolve all of the underlying problems of the existing fisheries management regimes. Absent the political will to stop overfishing, protect habitat, and support expanded research and monitoring programs, an ecosystem-based approach cannot be effective.*
>
> *A comprehensive ecosystem-based fisheries management approach would require managers to consider all interactions that a target fish stock has with predators, competitors, and prey species; the effects of weather and climate on fisheries biology and ecology; the complex interactions between fishes and their habitat; and the effects of fishing on fish stocks and their habitat. However, the approach need not be endlessly complicated. An initial step may require only that managers consider how the harvesting of one species might impact other*

species in the ecosystem. Fishery management decisions made at this level of understanding can prevent significant and potentially irreversible changes in marine ecosystems caused by fishing.

While the alternatives are all ecosystem-based and conform to federal law, they differ in the number and specificity of the policy objectives contained within each policy statement. The alternatives provide vision. They set the stage for future decision-making. They capture a range of philosophical differences and varying degrees of precautionary management when faced with uncertainty about the effects of fishing on the environment and the lack of understanding of the ecological processes exhibited by a dynamic ever-changing marine ecosystem. They capture a range of values and needs from a diverse and educated group of public stakeholders. The goals and objectives are grouped around the key principles and issues identified by the public as being very important in the management of the Alaska groundfish fisheries. These principles and issues led to the list of key FMP components that would need to be addressed in an Alaska groundfish FMP.

The policy issues associated with management of the fisheries and reflected in this analysis arise from a number of questions faced by the NPFMC and NOAA Fisheries. In what direction should the NPFMC and NOAA Fisheries go with regard to managing the fishery resources off Alaska? How successful has past management policy been in meeting the goals and objectives of national fisheries policy, while conserving marine fish resources and providing protection to marine mammals and endangered species? Do we need to change our current policy, and if so, in what ways? How can we achieve the broadly supported goals of sustainable fisheries while still generating the social and economic benefits of a diverse population of citizens? The information and analyses needed to answer these questions are contained in this Programmatic SEIS. Whether past management policy has been in the best interest of the U.S., or whether a change in policy is needed, is ultimately a decision that will be made by the NPFMC and NOAA Fisheries. With public comment, the NPFMC and NOAA Fisheries will make what they believe to be the wisest policy decision for managing the Alaska groundfish fisheries in the future. Once a policy alternative is adopted and made a part of the BSAI and GOA groundfish FMPs, the preferred policy will establish a path for managers and stakeholders to follow. Future management actions taken by the NPFMC and implemented by NOAA Fisheries, through FMP amendments and regulatory changes, will each aim to achieve the goals and objectives of the policy in a balanced fashion.

2.6.1 Alternative 1(a) – Continue Under the Current Risk-Averse Management Policy (the no-action, status quo alternative)

The GOA and BSAI groundfish FMPs, first implemented in 1978 and 1981, respectively, contained management policy statements that incorporated the MSA's National Standards (there were seven then; now there are 10) and reflect the management issues and priorities of that period. Because the two FMPs were prepared by different writers, their respective policy statements differ in wording. They differ also because, in 1985, the GOA FMP policy was updated. Since 1985, there have been no formal amendments to either the GOA or the BSAI FMP policy statement. Adoption of this alternative would leave these sections of the FMPs unchanged.

Current Policy Statement for Managing the BSAI Groundfish Fisheries (FMP 3.2)

Goals for Management Plan

The NPFMC has determined that all its FMPs should, in order to meet the requirements of its constituency, the resources, and the MSA, achieve the following goals:

1. Promote conservation while providing for the OY from the region's groundfish resource in terms of providing the greatest overall benefit to the nation with particular reference to food production and recreational opportunities; avoiding irreversible or long-term adverse effects on the fishery resources and the marine environment; and ensuring availability of a multiplicity of options with respect to the future uses of these resources.

2. Promote, where possible, efficient use of the fishery resources but not solely for economic purposes.

3. Promote fair and equitable allocation of identified available resources in a manner such that no particular group acquires an excessive share of the privileges.

4. Base the plan on the best scientific information available.

In accomplishing these broad objectives a number of secondary objectives have been considered:

1. Conservation and management measures have taken into account the unpredictable characteristics of future resource availability and socioeconomic factors influencing the viability of the industry.

2. Where possible, individual stocks of fish are managed as a unit throughout their range, but such management is in due consideration of other impacted resources.

3. In such instances when stocks have declined to a level below that capable of producing MSY, management measures promote rebuilding the stocks. In considering the rate of rebuilding, factors other than biological considerations have been taken into account.

4. Management measures, while promoting efficiency where practicable, are designed to avoid disruption of existing social and economic structures where fisheries appear to be operating in reasonable conformance with the MSA and have evolved over a period of years as reflected in community characteristics, processing capability, fleet size and distribution. These systems and the resources upon which they are based are not static, but change in the existing regulatory regime should be the result of considered action based on data and public input.

5. Management measures should contain a margin of safety in recommending allowable biological catches when the quality of information concerning the resource and ecosystem is questionable. Management plans should provide for accessing biological and socioeconomic data in such instances where the information base is inadequate to effectively establish the biological parameters of the resource or to reasonably establish OY. This plan has identified information and research required for further plan development.

6. Fishing strategy has been designed in such a manner as to have minimal impact on other fisheries and the environment.

Current Policy Statement for Managing the GOA Groundfish Fisheries (FMP 2.1)

Goals and Objectives for Management of GOA Groundfish Fisheries

The NPFMC is committed to developing long-range plans for managing the GOA groundfish fisheries that will promote a stable planning environment for the seafood industry and will maintain the health of the resource and the environment. In developing allocations and harvesting systems, the NPFMC will give overriding considerations to maximizing economic benefits to the U.S. Such management will:

- Conform to the National Standards and to the NPFMCs' Comprehensive Fishery Management Goals.

- Be designed to assure that to the extent possible:
  – Commercial, recreational, and subsistence benefits may be obtained on a continuing basis
  – Chances of irreversible or long-term adverse effects on fishery resources and the marine environment are minimized
  – A multiplicity of options will be available with respect to future use of the resources
  – Regulations will be long-term and stable with changes kept to a minimum

Principal Management Goal. Groundfish resources of the GOA will be managed to maximize positive economic benefits to the U.S., consistent with resource stewardship responsibilities for the continuing welfare of the GOA living marine resources. Economic benefits include, but are not limited to, profits, benefits to consumers, income and employment.

To accomplish this goal, a number of objectives will be considered:

Objective 1: The NPFMC will establish annual harvest guidelines, within biological constraints, for each groundfish fishery and mix of species taken in that fishery.

Objective 2: In its management process, including the setting of annual harvest guidelines, the NPFMC will account for all fishery-related removals by all gear types for each groundfish species, sport fishery, and subsistence catches, as well as by directed fisheries.

Objective 3: The NPFMC will manage fisheries to minimize waste by:

– Developing approaches to treating bycatches other than as a prohibited species. Any system adopted must address the problems of covert targeting and enforcement.
– Developing management measures that encourage the use of gear and fishing techniques that minimize discards.

Objective 4: The NPFMC will manage groundfish resources of the GOA to stimulate development of fully domestic fishery operations.

Objective 5: The NPFMC will develop measures to control effort in a fishery, including systems to convert the common property resource to private property, but only when requested to do so by industry.

Objective 6: Rebuilding stocks to commercial or historic levels will be undertaken only if the benefits to the U.S. can be predicted after evaluating the associated costs and benefits and the impacts on related fisheries.

Objective 7: Population thresholds will be established for economically viable species complexes under NPFMC management on the basis of the best scientific information, and acceptable biological catches (ABCs) will be established as defined in this document. If population estimates drop below these thresholds, ABCs will be set to reflect necessary rebuilding as determined in Objective 6.

2.6.2 Alternative 1(b) – Update and Reformat the Current Policy Statement for both the Bering Sea and Aleutian Islands and Gulf of Alaska Groundfish Fishery Management Plans

This variation of Alternative 1 would update the old policy by modifying its format and incorporating the new National Standards and ecosystem-based management principles. Adoption of this variation of Alternative 1 would lead to a plan amendment that would replace the current BSAI and GOA policy statements with the new statement below.

Management Approach

Continue to work toward the goals of maintaining sustainable fisheries, protecting threatened and endangered species, and protecting, conserving, and restoring living marine resource habitat through existing institutions and processes. Continue to manage the groundfish fisheries through the current risk-averse conservation and management program that is based on a conservative harvest strategy. Under this management strategy, fishery impacts to the environment are mitigated as scientific evidence indicates that the fishery is adversely impacting the ecosystem. Management decisions will utilize the best scientific information available; the management process will be able to adapt to new information and respond to new environmental issues. Management will incorporate and apply ecosystem-based management principles; consider the impact of fishing on predator-prey, habitat, and other important ecological relationships; maintain the statute-mandated programs to reduce excess capacity and the race-for-fish; draw upon federal, state, and academic capabilities in carrying out research, administration, management, and enforcement; and consider the effects of fishing and encourage the development of practical measures that minimize bycatch and adverse effects to EFH. This strategy is based on the assumption that fishing produces some adverse impact on the environment and that as these impacts become known, mitigation measures will be developed and FMP amendments implemented. Issues will be addressed as they ripen and are identified through NPFMC staff tasking and research priorities. The NPFMC will continue to use the National Standards and other applicable law as its guide in practicing adaptive management and responsible decision-making and will amend the FMPs consistently and accordingly. To meet the goal of this overall program, the NPFMC and NOAA Fisheries will seek to achieve the following management objectives:

Prevent Overfishing

1. Adopt conservative harvest levels for single-species fisheries and specify OY.

2. Continue to use existing OY cap for BSAI and GOA groundfish fisheries.

3. Provide for adaptive management by continuing to specify OY as a range.

Preserve Food Web

4. Incorporate ecosystem considerations into fishery management decisions.

5. Continue to protect the integrity of the food web through limits on harvest of forage species.

6. Develop a conceptual model of the food web.

Reduce and Avoid Bycatch

7. Continue current incidental catch and bycatch management program.

8. Continue to manage incidental catch and bycatch through seasonal distribution of TAC and geographical gear restrictions.

9. Continue to account for bycatch mortality in monitoring annual TACs.

10. Control the bycatch of prohibited species through PSC limits.

11. Continue program to require full utilization of target species.

12. Continue to respond to evidence of population declines by closing areas and implementing gear and seasonal restrictions in affected areas.

Avoid Impacts to Seabirds and Marine Mammals

13. Continue to cooperate with USFWS to protect ESA-listed and other seabird species.

14. Maintain current protection measures in order to avoid jeopardy to ESA-listed Steller sea lions and adverse modification of their critical habitat.

Reduce and Avoid Impacts to Habitat

15. Respond to new scientific information regarding areas of critical habitat by closing those regions to all fishing (i.e., no-take marine reserves such as Sitka Pinnacles).

16. Evaluate the impacts of trawl gear on habitat through the stepwise implementation of a comprehensive research plan, to determine appropriate habitat protection measures.

17. Continue to evaluate candidate areas for MPAs.

Allocation Issues

18. Continue to reduce excess fishing capacity, overcapitalization and the adverse effects of the race for fish.

19. Provide economic and community stability by maintaining current allocation percentages to harvesting and processing sectors.

Increase Alaska Native Consultation

20. Continue to incorporate Traditional Knowledge in fishery management.

21. Continue current levels of Alaska Native participation and consultation in fishery management.

Data Quality, Monitoring, and Enforcement

22. Continue the existing reporting requirements and Observer Program to provide catch estimates and biological information.

23. Continue on-going effort to improve community and regional economic impact assessments.

24. Increase the quality of monitoring data through improved technological means.

2.6.3 Alternative 2 – Adopt a More Aggressive Management Policy

This policy alternative, while still meeting the minimum requirements of the MSA, MMPA, ESA, and other federal law, would result in a more aggressive management approach when faced with uncertainty as compared to Alternative 1. Adoption of Alternative 2 would lead to a plan amendment that would replace the current BSAI and GOA policy statements with the new statement below.

Management Approach

Amend the current FMPs to establish a more aggressive harvest strategy while still preventing overfishing of target groundfish stocks. The goal would be to maximize biological and economic yield from the resource. Such a management approach will be based on the best scientific information available, take into account individual stock and ecosystem variability; involve and be responsive to the needs and interests of affected states and citizens; continue to work with state and federal agencies to protect threatened and endangered species; maintain the statutorily mandated programs to reduce excess capacity and the race-for-fish; draw upon federal, state, and academic capabilities in carrying out research, administration, management, and enforcement; and consider the effects of fishing and encourage the development of practical measures that minimize bycatch and adverse effects of fishing on EFH. This strategy is based on the assumption that fishing does not have an adverse impact on the environment except in specific cases as noted. To meet the goal of this overall program, the NPFMC and NOAA Fisheries will seek to achieve the following management objectives:

Prevent Overfishing

1. Prevent overfishing by setting an OY cap at the sum of OFL or the sum of the ABCs for each species.

2. Provide for adaptive management by continuing to specify OY as a range.

Preserve Food Web

- (none)

Reduce and Avoid Bycatch

3. Monitor the bycatch of prohibited species and adjust or eliminate PSC limits.

4. Manage incidental catch and bycatch through closure areas for selected gear types.

Avoid Impacts to Seabirds and Marine Mammals

5. Maintain current protection measures to protect ESA-listed seabird species.

6. Maintain current protection measures to avoid jeopardy to ESA-listed Steller sea lions and adverse modification of their critical habitat.

Reduce and Avoid Impacts to Habitat

7. Evaluate the impacts of trawl gear on habitat through the implementation of the existing research plan, identify EFH, and determine appropriate habitat protection measures.

8. Continue to evaluate candidate areas for MPAs.

Allocation Issues

9. Maintain AFA and CDQ program as authorized by MSA.

Increase Alaska Native Consultation

10. Continue to incorporate Traditional Knowledge in fishery management.

11. Continue current levels of Alaska Native participation and consultation in fishery management.

Data Quality, Monitoring, and Enforcement

12. Continue the existing reporting requirements to provide catch estimates and biological information.

13. Continue on-going effort to improve community and regional economic impact assessments.

14. Consider repealing the Observer Program.

2.6.4 Alternative 3 – Adopt a More Precautionary Management Policy

This policy alternative, while still meeting the requirements of the MSA, MMPA, ESA, and other federal law, would result in a more precautionary management approach when faced with uncertainty as compared to Alternative 1. Adoption of Alternative 3 would lead to a plan amendment that would replace the current BSAI and GOA policy statements with the new statement below.

Management Approach

Accelerate precautionary management measures through community or rights-based management, ecosystem-based management principles, and where appropriate and practicable, increased habitat protection and additional bycatch constraints. This policy objective seeks to provide sound conservation of the living marine resources; provide socially and economically viable fisheries and fishing communities, minimize human-caused threats to protected species; maintain a healthy marine resource habitat; and incorporate ecosystem-based considerations into management decisions. This policy recognizes the need to balance many competing uses of marine resources and different social and economic goals for fishery management. This policy will utilize and improve upon existing processes to involve a broad range of the public in decision-making. Further, these objectives seek to maintain the balanced goals of the National Standards and other provisions of the MSA as well as the requirements of other applicable law, all as based on the best scientific information available. This policy takes into account the National Academy of Sciences Policies Recommendations for Sustainable Fisheries (NAS SF). Under this approach, additional conservation and management measures will be taken as necessary to respond to social, economic or conservation needs, or if scientific evidence indicates that the fishery is negatively impacting the environment. To meet the goal of this overall program the NPFMC and NOAA Fisheries will seek to achieve the following management objectives.

Prevent Overfishing

1. Adopt conservative harvest levels for multi-species and single-species fisheries.

2. Provide for adaptive management by continuing to specify OY as a range or a formula.

3. Initiate a scientific review of the adequacy of F_{40} and implement improvements accordingly.

4. Continue to collect scientific information and improve upon MSSTs including obtaining biological information necessary to move Tier 4 species into Tiers 1-3 in order to obtain MSSTs.

Preserve Food Web

5. Incorporate ecosystem-based considerations into fishery management decisions.

6. Develop indices of ecosystem health as targets for management.

7. Improve the procedure to adjust ABCs as necessary to account for uncertainty and ecosystem factors such as predator-prey relationships and regime shifts.

8. Initiate a research program to identify the habitat needs of different species that represent the significant food web.

Reduce and Avoid Bycatch

9. Continue and improve current incidental catch and bycatch management programs.

10. Developing incentive programs for incidental catch and bycatch reduction including the development of mechanisms to facilitate the formulation of bycatch pools, vessel bycatch accountings, or other bycatch rationalization programs.

11. Encourage research programs to evaluate current population estimates for non-target species with a view to setting appropriate bycatch limits as information becomes available.

12. Continue program to reduce discards by developing management measures that encourage the use of gear and fishing techniques that reduce discards.

Avoid Impacts to Seabirds and Marine Mammals

13. Continue to cooperate with USFWS to protect ESA-listed and other seabird species.

14. Initiate joint research program with USFWS to evaluate current population estimates for all seabird species that interact with the groundfish fisheries.

15. Maintain or adjust current protection measures as appropriate in order to avoid jeopardy to ESA-listed Steller sea lions and adverse modification of their critical habitat.

16. Encourage programs to review status of other marine mammal stocks and fishing interactions (e.g., right whales, sea otters) and develop fishery management measures as appropriate.

Reduce and Avoid Impacts to Habitat

17. Develop goals, objectives, and criteria to evaluate the efficacy of MPAs and no-take marine reserves as tools to maintain abundance, diversity, and productivity of marine organisms. Consider implementation of MPAs if and where appropriate, giving due consideration to areas already closed to various types of fishing operations.

18. Develop a research program to identify regional baseline habitat information and mapping.

19. Evaluate the impacts of all gear on habitat through the implementation of a comprehensive research plan, to determine habitat protection measures as necessary and appropriate.

20. Identify and designate EFH and habitat areas of particular concern.

Allocation Issues

21. Provide economic and community stability to harvesting and processing sectors through fair allocation of fishery resources.

22. Maintain LLP program and further decrease excess fishing capacity and other adverse effects of the race-for-fish by eliminating latent licences and extending programs such as community- or rights-based management to some or all groundfish fisheries.

23. Provide for adaptive management by periodically evaluating the effectiveness of rationalization programs and the allocation of property rights based on performance.

24. To support fishery management, extend the cost recovery program to all groundfish fisheries.

Increase Alaska Native Consultation

25. Continue to incorporate Traditional Knowledge in fishery management.

26. Consider ways to enhance collection of Traditional Knowledge from communities, and incorporate such knowledge in fishery management where appropriate.

27. Increase Alaska Native participation and consultation in fishery management.

Data Quality, Monitoring, and Enforcement

28. Increase the utility of groundfish fishery observer data for the conservation and management of living marine resources.

29. Improve the Groundfish Observer Program, and consider ways to address the disproportionate costs associated with the current funding mechanism.

30. Improve community and regional economic impact assessments through increased data reporting requirements.

31. Increase the quality of monitoring data through improved technological means.

32. Establish a coordinated, long-term ecosystem monitoring program to collect baseline information and compile existing information from a variety of ongoing research initiatives.

33. Adopt the recommended research plan included in this document.

34. Cooperate with research institutions such as the North Pacific Research Board in identifying research priorities to address pressing fishery issues.

2.6.5 Alternative 4 – Adopt a Highly Precautionary Management Policy

This policy alternative, while still meeting the requirements of the MSA, MMPA, ESA, and other federal law, would result in a highly precautionary management approach when faced with uncertainty as compared to Alternative 1. Adoption of Alternative 4 would lead to a plan amendment that would replace the current BSAI and GOA policy statements with the new statement that follows.

Management Approach

Adopt a highly precautionary approach to managing fisheries under scientific uncertainty in which the burden of proof is shifted to the user of the resource to demonstrate that the intended use will not have a detrimental effect on the environment. Modify restrictive conservation and management measures as additional, reliable scientific information becomes available. Establish a fishery conservation and management program to maintain ecological relationships among exploited, dependent, and related species, as well as the ecosystem processes that sustain them. Management decisions assume that science cannot eliminate uncertainty and that action must be taken in the face of large uncertainties, guided by policy priorities and the strict interpretation of the precautionary principle. Management decisions will involve and be responsive to the public but decrease emphasis on industry and community concerns; incorporate and apply strict ecosystem principles; address the impact of fishing on predator-prey, habitat, and other important ecological relationships in the marine environment; implement measures that avoid or minimize bycatch; include the use of explicit allocative or cooperative programs to reduce excess capacity and allocate fish to particular gear types and fisheries; identify and incorporate non-consumptive use values; and draw upon federal, state, academic, and other capabilities in carrying out research, administration, management, and enforcement. This strategy is based on the assumption that fishing produces adverse impacts on the environment but due to lack of information and uncertainty, little is known about these impacts. This strategy would result in a number of significant changes to the FMPs that would significantly curtail the groundfish fisheries until more information is known about the frequency and intensity of fishery impacts upon the environment. Expanded research and monitoring programs will fill critical data gaps. Once more is known about fishery effects on the ecosystem, precautionary measures initially adopted will be modified or relaxed when scientific information warrants such a change. To meet the goals of this overall program, the NPFMC and NOAA Fisheries will seek to achieve the following management objectives:

<u>Prevent Overfishing</u>

1. Prevent overfishing by transitioning from single-species to ecosystem-oriented management of fishing activities.

2. Close an additional 20 to 50 percent of known spawning areas of target species across the range of the stock to protect the productivity and genetic diversity.

Preserve Food Web

3. Develop and implement a Fishery Ecosystem Plan through the modification or amendment of current FMPs.

4. Conserve native species and biological diversity at all relevant scales of genetic, species, and community interactions.

5. Reduce the ABC to account for uncertainty and ecological considerations for all exploited stocks, including genetic, life history, food web, and habitat considerations.

6. Set fishing levels in a highly precautionary manner to preserve ecological relationships between exploited, dependent, and related species.

Reduce and Avoid Bycatch

7. Include bycatch mortality in TAC accounting and improve the accuracy of mortality assessments for target, non-target, and PSC bycatch, including unobserved mortality.

8. Reduce incidental catch, bycatch, and PSC limits (e.g., by 10 percent/year for 5 years).

9. Phase out fisheries with >25 percent incidental catch and bycatch rates.

10. Establish PSC limits for salmon, crab, and herring in the GOA.

11. Set stringent bycatch limits for vulnerable non-target species based on best available information.

Avoid Impacts to Seabirds and Marine Mammals

12. Set protection measures immediately for all seabird species and cooperate with USFWS to develop fishing methods that reduce incidental takes to levels approaching zero for all threatened or endangered species and for USFWS's list of species of management concern.

13. Initiate joint research program with USFWS to evaluate current population estimates for all seabird species that interact with the groundfish fisheries and modify protection measures based on research findings.

14. Increase existing protection measures for ESA-listed Steller sea lions by further restricting gear in critical habitat and setting more conservative harvest levels for prey base species.

Reduce and Avoid Impacts to Habitat

15. Zone and delimit fishing gear use in the action area and establish no-take marine reserves (both pelagic and nearshore) encompassing 20 to 50 percent of management areas to conserve EFH, provide refuges from fishing, serve as experimental controls to test the effects of fisheries, protect genetic and biological diversity, and foster regeneration of depleted stocks in fished areas.

16. To protect habitat and reduce bycatch, prohibit trawling in fisheries that can be prosecuted with more selective gear types and establish trawl closure areas.

17. Manage fisheries in an explicitly adaptive manner to facilitate learning (including large no-take marine reserves that provide experimental controls).

18. Protect marine habitats, including EFH, habitat areas of particular concern, ESA-designated critical habitats and other identified habitat types.

19. Commit to funding a comprehensive research plan in order to provide a baseline habitat atlas.

Allocation Issues

20. Reduce excess fishing capacity and employ equitable allocative or cooperative programs to end the race-for-fish, reduce waste, increase safety, and promote long-term stability and benefits to fishing communities.

21. Consider non-consumptive use values.

Increase Alaska Native Consultation

22. Utilize Traditional Knowledge in fishery management, including monitoring and data-gathering capabilities, through co-management and cooperative research programs.

23. Increase participation of and consultation with Alaska Native subsistence users and explicitly address the direct, indirect and cumulative fishery impacts on traditional subsistence uses and cultural values of living marine resources.

Data Quality, Monitoring, and Enforcement

24. Increase the precision of observer data through increased observer coverage and enhanced sampling protocols, and address the shortcomings of the current funding mechanism by implementing either a federally funded or equitable fee-based system for a revamped Observer Program Research Plan.

25. Improve enforcement and in-season management through improved technological means.

26. Establish a coordinated, long-term monitoring program to collect baseline information and better utilize existing research information to improve implementation of the Fishery Ecosystem Plan.

27. Adopt the recommended research plan included in this Programmatic SEIS.

2.6.6 Management Tools for Achieving Policy Goals and Objectives

A description of the principle management tools used to make up an FMP is provided in Section 2.5.1. This section briefly describes the combination of management tools used to achieve each goal and objective set forth in the alternatives.

Prevent Overfishing

Fishery managers can achieve this policy goal in a number of ways. Most commonly, managers establish quotas, or TACs to limit commercial, recreational, and subsistence catch. Setting conservative TAC levels are intended to reduce the probability of overfishing a particular fish species, fish population, or fish stock. Resource managers in some parts of the U.S. and the world have chosen not to use quotas but instead attempt to control fishing effort through use of seasons, vessel days, gear restrictions, and restrictions on the number of fishing vessels. In Alaska, the NPFMC and NOAA Fisheries have chosen to use TACs in combination with other measures such as defined fishing seasons, IFQs, and PSC limits. The components of the BSAI and GOA groundfish FMPs must therefore contain such basic elements as a TAC-setting process, bycatch reduction measures, PSC limits, marine mammal and seabird protection measures, habitat protection measures, and data collection and information reporting programs.

Preserve Food Web

Efforts to explicitly preserve the ecological food web of marine ecosystems and maintain biodiversity in fishery management programs have only recently begun as public consciousness has become more aware of the importance of marine ecosystems in the overall environmental health of a region. Such increased awareness has led to new and expanded research programs that are designed to teach us how marine ecosystem processes function and how fishing affects those processes. There is much to learn about marine ecosystems. Currently, fishery managers in Alaska rely heavily on government and academic research programs and attempt to incorporate ecosystem considerations into their decision-making through synthesis of ongoing research into the annual TAC-setting process, as well as when taking actions intended to protect endangered Steller sea lions and short-tailed albatrosses. Information on marine ecosystems is increasingly being used by the NPFMC when considering management actions such as bycatch reduction measures, closures to protect EFH, and the effects of fishing on non-target groundfish species.

Reduce and Avoid Bycatch

The reduction of bycatch and the minimization of waste have become important management goals for the NPFMC and NOAA Fisheries. Management tools used to achieve these goals include direct measures, such as PSC limits to control the mortality of prohibited species, gear restrictions to minimize bycatch, and regulations requiring that certain target species be kept and utilized, regardless of their size or condition. Management tools that indirectly reduce bycatch include area closures, allocations of TAC spread out over time, and programs designed to address overcapacity by slowing the rate of harvest and reducing the number of fishing vessels. Overcapacity programs like the sablefish IFQ program or the pollock cooperative program are proving to be significantly beneficial indirect management approaches to reduce bycatch.

Avoid Impacts to Seabirds and Marine Mammals

Management tools used to achieve the goal of minimizing adverse impacts to seabirds and marine mammals include required gear modifications and fishing techniques in the hook and longline fisheries, reduced TAC of bird and mammal prey species, use of closure areas to minimize any disturbance to rookeries and haul-out sites from commercial fishing operations, and specific take limits.

Reduce and Avoid Impacts to Essential Fish Habitat

Marine habitat determined to be important to the life history of groundfish species and the ecology of the marine ecosystem can be afforded some protection by the use of closed areas, gear restrictions, and some combination of the two management tools. Such tools can also be used to restore damaged habitats that have been identified as important and warrant recovery.

Allocation Issues

The allocation of fish resources among users usually takes the form of a specific quota. The groundfish TAC can be allocated to different harvesting and processing sectors of the fishing industry, to specific communities, and to individual users or groups of users. Other allocation-based management tools include area registration requirements (where fishermen can register for no more than one area at a time, thereby spreading out the effort over a broad area), and allocations of fishing effort (e.g., vessel days or trip limits).

Increase Native Consultation and Participation

Management tools used to address Alaska Native issues and satisfy federal requirements for public outreach, NEPA, and government-to-government consultation, typically take the form of informal and formal discussions. These discussions are enhanced by special meetings, newsletters, webpage bulletins, and e-mail. Public hearings and NPFMC meetings provide a frequent venue for public stakeholders to provide comments and any information that may improve the management of fisheries off Alaska as well as opportunities to learn more about the effects of management on subsistence fishing and minority populations. Opportunities for cooperative research may also serve as a management tool to increase Native involvement in the management of fisheries, as well as to foster transfer of Traditional Ecological Knowledge.

Data Quality, Monitoring, and Enforcement

The success of any fishery management policy is dependent on the ability of the manager to collect biological, economic, and social information on the fishery. The management tools typically used to accomplish this collection of data include requirements to submit fishing logbooks, written harvest and processing summary reports, and observer information. Monitoring objectives are accomplished through electronic location devices placed on vessels, radio check-in and check-out reports, onboard fishery observers, and enforcement overflights. These management tools are designed to provide the information needed to measure the success of the various components of the FMPs. Fishery management plans are routinely amended to address subject areas where fishing effects are unacceptable.

2.6.7 The Alternatives Considered but Not Carried Forward

A No-Fishing Policy

People have fished from waters off North America for thousands of years. The traditional uses of fish for food and commerce were recognized as a common practice during formation of the republic. Citizens of the U.S. have since continued to harvest fishery resources from waters off the coasts and as a matter of policy and custom place high value on fish and fishing.

A permanent "no-fishing" policy would end all commercial groundfish fishing in the EEZ off Alaska. Adoption of such a policy would be inconsistent with one stated purpose of the MSA: "to promote domestic commercial and recreational fishing under sound conservation and management principles." Through its 10 National Standards and other mandates (see Section 2.2.2), the MSA directs the NPFMC and NOAA Fisheries to authorize fisheries—no matter how large or small—as long as those fisheries are managed in way that is consistent with the 10 National Standards.

When the NPFMC first prepared its GOA and BSAI groundfish FMPs, it considered a no-fishing policy. In its analysis of this alternative, the NPFMC found that adopting this policy would result in the economic ruin of the fishing industry and place great hardship on fishing communities economically and socially dependent upon the BSAI and GOA groundfish resources. This policy was believed by the NPFMC to violate the MSA by preventing the U.S. from exploiting the social and economic benefits of groundfish of the BSAI and GOA in the nation's interest (NPFMC 1981).

NOAA Fisheries subsequently reviewed and prepared a detailed analysis of the effects of a no-fishing policy in its 1998 final SEIS (NMFS 1998i). Such a policy would reduce EEZ fishing mortality to zero for all target groundfish and non-target species, resulting in no commercial catch except for harvests within the State of Alaska's jurisdiction and beyond 200 miles. The primary impact of this action would be to eliminate the impact of fishing on stock trends and conditions. For example, a pollock TAC of zero would eliminate the directed fishery for pollock and eliminate the risk of overfishing and localized stock depletion (provided that harvests within Alaska waters remain low). A zero TAC for pollock and other directed fisheries would eliminate any bycatch of pollock caught in this fishery. A zero TAC of pollock and other groundfish would impact the amounts of groundfish available to the ecosystem. More commercial-sized fish would be available as prey and predators in the ecosystem. Additionally, zero TACs on the predators of pollock would increase the predation on pollock and other forage fish.

A no-fishing policy could have positive benefits for the western stock of Steller sea lions if it eliminates fisheries harvest from a list of factors causing or contributing to Steller sea lion population decline. Direct takes from federally managed groundfish fisheries would be zero. Benthic habitat communities would eventually move toward a prefished condition.

However, closing the fisheries would likely result in alterations to existing predator–prey relationships, which over time could influence the population dynamics of a particular resource. Fish stocks could decline below current levels. A no-fishing policy would also eliminate thousands of jobs in the groundfish harvesting, processing, and support sectors. It would idle over $1 billion of harvesting and processing capital, decrease the income of groundfish fishermen and processing plant employees by several $100 million, and decrease the value of U.S. seafood exports by more than $500 million. Few opportunities appear to offset these losses to the fishing industry, to the communities in which they are based, and to the nation. In short, implementation of such a policy would have widespread effects to the human environment.

NOAA Fisheries concluded that such a policy was not a reasonable choice among the alternatives considered in its 1998 SEIS. NOAA Fisheries again considered "no fishing" as a policy alternative during the development of the 2001 Draft Programmatic SEIS and again in this Programmatic SEIS but rejected full consideration of such a policy alternative. NOAA Fisheries rejected the no-fishing policy alternative because such an alternative would be based on the premise that no fishing could occur in the Alaska groundfish fisheries regardless of the level of scientific data demonstrating the sustainability of such a fishery. Such a policy runs counter to the MSA requirement that conservation and management measures prevent overfishing while achieving on a continuing basis OY from each fishery for the U.S. fishing industry (16 USC 1851(a)(1)). In contrast, Alternative 4 establishes an extremely precautionary policy to fisheries management that permits fishing when it can be demonstrated that the fishery will not have a detrimental effect on the environment and that relieves restrictions on fishing when new scientific data support such a change.

Alternatives that Result in Specific Fishery Regulations

A number of public comments received during the scoping process or on the 2001 and 2003 Draft Programmatic SEISs requested that alternatives be developed that go beyond policy and actually include regulatory changes to the fisheries. NOAA Fisheries rejected these requests as being beyond the scope and purpose of a Programmatic EIS. As explained previously in this document, NOAA Fisheries is preparing this programmatic document of the Alaska groundfish fisheries and their management in compliance with a court order and with CEQ and NOAA regulations.

A Programmatic SEIS on the Alaska groundfish fisheries that included specific regulatory changes would require an intricate level of detailed alternatives and a commensurately detailed analysis. However, neither NEPA nor the court require NOAA Fisheries to prepare such a document. NOAA's own NEPA guidelines (NAO 216-6 Section 5.09a) state that "a programmatic environmental review should analyze the broad scope of actions within a policy or programmatic context by defining the various programs and analyzing the policy alternatives under consideration and the general environmental consequences of each" (emphasis added). Furthermore, the court stated that ". . . a programmatic analysis would not require consideration of detailed alternatives with respect to each aspect of the plan—otherwise a programmatic analysis would be impossible to prepare and would merely be a vast series of site-specific analyses. See Robertson, 35 F3d at 1306 ('specific analysis is better done when a specific development action is to be taken, at the programmatic level.')" *Greenpeace v. National Marine Fisheries Service*, 55 F. Supp. 2d 1248, 1276 (W.D. Wash. 1999).

NOAA Fisheries has determined that a Programmatic SEIS for the Alaska groundfish fisheries should essentially be a broad environmental review of the GOA and BSAI groundfish FMPs and alternatives to them. The Programmatic SEIS includes a cumulative impact analysis of management actions as a whole, and examines policies and potential future actions from a variety of environmental perspectives. The Programmatic SEIS therefore provides a broad look at the alternatives and the issues and is somewhat qualitative in nature.

Findings contained within this analysis could result in FMP amendments that, in turn, could lead to formal rule-making and implementation of changes to the current management regime governing the groundfish fisheries off Alaska. Such specific proposed regulatory changes can be expected in the future, and will be attended by case-specific, detailed analyses in subsequent second-level tiered EAs or EISs. In this Programmatic SEIS, however, NOAA Fisheries intends to provide the public with insight into the environmental effects that result from the current management regime as well as from alternative management regimes.

2.6.8 The Environmentally Preferred Alternative

The environmentally PA [40 CFR 1505.2(b)] will promote the national environmental policy as expressed in Section 101 of NEPA. Ordinarily, this means that the alternative causes the least damage to the physical and biological environment and is the alternative that best protects, preserves, and enhances historic, cultural, and natural resources. In this case, the environmentally PA is Alternative 4, the alternative that represents a highly precautionary management policy. As stated in this Programmatic SEIS, Alternative 4 is the only policy alternative that explicitly shifts the burden of proof from the resource to the managers and users of the Alaska groundfish resource. This alternative, as illustrated by its FMPs, would substantially reduce the harvest levels in the fisheries, establish a system of marine reserves where a large portion of the continental shelf would be closed to all commercial fishing, phase out bottom trawl gear, and establish lower bycatch limits. As a result, this alternative would produce the lowest amount of fish harvest, the least amount of bycatch, the least adverse impact to marine mammals, seabirds, and species listed under the ESA, and the least adverse impact to benthic habitat.

2.6.9 The Preferred Alternative

2.6.9.1 Development of the Preferred Alternative

The PA for the management policy to govern the BSAI and GOA groundfish fisheries was recommended by the NPFMC after careful consideration of public comments and the analyses of the alternatives in the PSEIS. The analyses in the PSEIS were based on the best scientific information available. The PA is based on the policy goals and objectives described under Alternative 3, with refinements incorporated from both Alternatives 1 and 4 as well as suggestions taken from public comments. NOAA Fisheries has reviewed the NPFMC recommendation, and has endorsed it as the Agency’s PA.

The management approach and the objectives in the PA reflect a conservative, precautionary approach to ecosystem-based fisheries management, and communicate a policy direction for the future. The PA is a realistic and responsible approach that addresses and complies with the various goals, objectives and requirements of the MSA and other applicable law. The policy elements contained in the PA are consistent with, and also achieve a reasonable balance between the competing interests reflected in, the National Standards. The PA continues the commitment by the NPFMC and NOAA Fisheries to prevent overfishing, reduce bycatch and habitat impacts, and to the extent practicable, protect seabirds and marine mammals. The PA incorporates ecosystem-based management principles into a management approach that recognizes the need to both promote sustainable fisheries and protect fishery-dependent communities. It also retains the strong role of science in fishery management, and fosters a transparent and effective regulatory process where all stakeholders have a meaningful role. The PA is an adaptive management policy which will guide and inform fisheries management decisions made by the NPFMC and NOAA Fisheries. The adaptive nature of the PA also gives the NPFMC and NOAA Fisheries the flexibility to modify policy elements in response to new information or changing circumstances in order to continue to adequately manage the fisheries.

The example FMP bookends PA.1 and PA.2 serve to illustrate management concepts and future actions that logically flow from the PA policy and provide sufficient detail to allow for focused analysis of their environmental consequences. The NPFMC and NOAA Fisheries believe that this final Programmatic SEIS provides the public and decision-makers with the information they need to understand the challenges in managing a complex fishery, the uncertainties being faced and how managers are addressing those uncertainties, and the value of the Alaska groundfish fisheries to the residents of Alaska, the Pacific Northwest, and the nation.

2.6.9.2 The Preferred Alternative

The following has been identified as the NPFMC's and NOAA Fisheries' PA. The management approach and the objectives in the PA reflect a conservative, precautionary approach to fisheries management.

Management Approach

The productivity of the North Pacific ecosystem is acknowledged to be among the highest in the world. For the past 25 years, the NPFMC's adopted management approach has incorporated forward looking conservation measures that address differing levels of uncertainty. This management approach has, in recent years, been labeled the precautionary approach. The NPFMC's precautionary approach is about applying judicious and responsible fisheries management practices, based on sound scientific research and analysis, proactively rather than reactively, to ensure the sustainability of fishery resources and associated ecosystems for the benefit of future and current generations. Recognizing that potential changes in productivity may be caused by fluctuations in natural oceanographic conditions, fisheries, and other, non-fishing activities, the NPFMC intends to continue to recommend appropriate measures to ensure the continued sustainability of the managed species. It will carry out this objective by considering reasonable, adaptive management measures as described in the MSA and in conformance with the National Standards, the ESA, the NEPA and other applicable law. This management approach takes into account the NAS' recommendations on SF Policy.

As part of its policy, the NPFMC intends to consider and recommend, as appropriate, measures that accelerate the NPFMC's precautionary, adaptive management approach through community- or rights-based management, ecosystem-based management principles that protect managed species from overfishing, and where appropriate and practicable, increase habitat protection and bycatch constraints. All management measures will be based on the best scientific information available. Given this intent, the fishery management goal is to provide sound conservation of the living marine resources; provide socially and economically viable fisheries and fishing communities; minimize human-caused threats to protected species; maintain a healthy marine resource habitat; and incorporate ecosystem-based considerations into management decisions.

This management approach recognizes the need to balance many competing uses of marine resources and different social and economic goals for sustainable fishery management including protection of the long-term health of the resource and the optimization of yield. This policy will utilize and improve upon the NPFMC's existing open and transparent process to involve the public in decision-making.

Adaptive management requires regular and periodic review. Objectives identified in this policy statement will be reviewed annually by the NPFMC. The NPFMC will also review, modify, eliminate, or consider new issues as appropriate to best carry out the goals and objectives of this management policy.

To meet the goals of this overall management approach, the NPFMC and NOAA Fisheries will use the Programmatic SEIS as a planning document. To help focus its consideration of potential management measures, it will use the following objectives as guideposts to be re-evaluated as amendments to the FMP are considered over the life of the Programmatic SEIS.

Prevent Overfishing

1. Adopt conservative harvest levels for multi-species and single-species fisheries and specify OY.
2. Continue to use existing OY cap for BSAI (as stated in current law) and GOA groundfish fisheries.
3. Provide for adaptive management by continuing to specify OY as a range.
4. Initiate a scientific review of the adequacy of F_{40} and adopt improvements as appropriate (refer to Appendix B).
5. Continue to improve the management of species through species categories.

Promote Sustainable Fisheries and Communities

6. Promote conservation while providing for OY in terms of providing the greatest overall benefit to the nation with particular reference to food production, and sustainable opportunities for recreational, subsistence and commercial fishing participants and fishing communities.
7. Promote management measures that, while meeting conservation objectives, are also designed to avoid significant disruption of existing social and economic structures.

8. Promote fair and equitable allocation of identified available resources in a manner such that no particular sector, group, or entity acquires an excessive share of the privileges.

9. Promote increased safety at sea.

Preserve Food Web

10. Develop indices of ecosystem health as targets for management.

11. Improve the procedure to adjust ABCs as necessary to account for uncertainty and ecosystem factors.

12. Continue to protect the integrity of the food web through limits on harvest of forage species.

13. Incorporate ecosystem-based considerations into fishery management decisions as appropriate.

Manage Incidental Catch, and Reduce Bycatch and Waste

14. Continue and improve current incidental catch and bycatch management programs.

15. Develop incentive programs for bycatch reduction including the development of mechanisms to facilitate the formation of bycatch pools, vessel bycatch allowances, or other bycatch incentive systems.

16. Encourage research programs to evaluate current population estimates for non-target species with a view to setting appropriate bycatch limits as information becomes available.

17. Continue program to reduce discards by developing management measures that encourage the use of gear and fishing techniques that reduce bycatch, which includes economic discards.

18. Continue to manage incidental catch and bycatch through seasonal distribution of TAC and geographical gear restrictions.

19. Continue to account for bycatch mortality in TAC accounting and improve the accuracy of mortality assessments for target, PSC bycatch, and non-commercial species.

20. Control the bycatch of prohibited species through PSC limits or other appropriate measures.

21. Reduce waste to biologically and socially acceptable levels.

Avoid Impacts to Seabirds and Marine Mammals

22. Continue to cooperate with USFWS to protect ESA-listed species, and if appropriate practicable, other seabird species.

23. Maintain or adjust current protection measures as appropriate to avoid jeopardy to ESA-listed Steller sea lions.

24. Encourage programs to review status of endangered or threatened marine mammal stocks and fishing interactions and develop fishery management measures as appropriate.

25. Continue to cooperate with NMFS and USFWS to protect ESA-listed marine mammal species, and if appropriate and practicable, other marine mammal species.

Reduce and Avoid Impacts to Habitat

26. Review and evaluate efficacy of existing habitat protection measures for managed species.

27. Identify and designate EFH and habitat area of particular concern (HAPC) pursuant to MSA rules, and mitigate fishery impacts as necessary and practicable to continue the sustainability of managed species.

28. Develop an MPA policy in coordination with national and state policies..

29. Encourage development of a research program to identify regional baseline habitat information and mapping, subject to funding and staff availability.

30. Develop goals, objectives, and criteria to evaluate the efficacy and suitable design of MPAs and no-take marine reserves as tools to maintain abundance, diversity, and productivity, and implement MPAs if and where appropriate.

Promote Equitable and Efficient Use of Fishery Resources

31. Provide economic and community stability to harvesting and processing sectors through fair allocation of fishery resources.

32. Maintain LLP program and modify as necessary and further decrease excess fishing capacity and overcapitalization by eliminating latent licences and extending programs such as community or rights-based management to some or all groundfish fisheries.

33. Provide for adaptive management by periodically evaluating the effectiveness of rationalization programs and the allocation of access rights based on performance.

34. Develop management measures that, when practicable, consider the efficient use of fishery resources and account for the interest of harvesters, processors, and communities.

Increase Alaska Native Consultation

35. Continue to incorporate local and Traditional Knowledge in fishery management.

36. Consider ways to enhance collection of local and Traditional Knowledge from communities, and incorporate such knowledge in fishery management where appropriate.

37. Increase Alaska Native participation and consultation in fishery management.

Improve Data Quality, Monitoring, and Enforcement

38. Increase the utility of Groundfish Fishery Observer data for the conservation and management of living marine resources.

39. Improve the Groundfish Observer Program, and consider ways to address the disproportionate costs associated with the current funding mechanism.

40. Improve community and regional economic impact costs and benefits through increased data reporting requirements.

41. Increase the quality of monitoring and enforcement data through improved technological means.

42. Encourage a coordinated, long-term ecosystem monitoring program to collect baseline information and compile existing information from a variety of ongoing research initiatives, subject to funding and staff availability.

43. Cooperate with research institutions such as the North Pacific Research Board (NPRB) in identifying research needs to address pressing fishery issues.

44. Promote enhanced enforceability.

45. Continue to cooperate and coordinate management and enforcement programs with the Alaska Board of Fish, Department of Fish and Game, and Alaska Fish and Wildlife Protection, the USCG, NMFS Enforcement, IPHC, federal agencies, and other organizations to meet conservation requirements, promote economically healthy and sustainable fisheries and fishing communities, and to maximize efficiencies in management and enforcement programs through continued consultation, coordination, and cooperation.

Chapter 3

This page intentionally left blank

Chapter 3 Affected Environment

This chapter describes the physical, biological, and socioeconomic resources of the Bering Sea/Aleutian Islands (BSAI) and Gulf of Alaska (GOA) and the ecosystems of the eastern Bering Sea (EBS) and northeastern North Pacific Ocean. These descriptions present the relevant history, natural history, and current status of the groundfish resources and their environments and are intended to establish an environmental baseline that will serve as a starting point for the direct, indirect, and cumulative effects analysis to come in Chapter 4.

We begin the chapter by explaining the approach and methods that have been used in gathering and presenting this information and by discussing the methodology used to analyze the environmental and socioeconomic effects of past amendments to the current BSAI and GOA groundfish Fishery Management Plans (FMPs).

This page intentionally left blank.

3.1 Approach and Methods

The current status of any given resource is the result of the interplay between many natural events and human actions and influences over time. An analysis of cumulative effects on a resource must necessarily begin by identifying the events and actions that have affected the resource in the past and continue to exert an influence in the present. To this end, the present chapter describes each resource, reviews historical trends, and conducts a past/present effects analysis of the actions and events that have altered the resource from its original, pre-development condition. These descriptions, reviews, and analyses combine to form a baseline that represents current conditions of the resources and environment of the groundfish fisheries in the Exclusive Economic Zone (EEZ) off Alaska. This baseline will serve as the starting point for the direct, indirect, and cumulative effects analyses to come in Chapter 4.

The methods described below comply with Council on Environmental Quality (CEQ) guidance for scoping and organizing processes associated with cumulative effects analyses (CEQ 1997), as well as United States (U.S.) Environmental Protection Act (EPA) guidance for the consideration of cumulative effects (EPA 1999). The reader should refer to Section 4.1.4 for a comprehensive description of how the past/present effects analyses feed into the direct, indirect, and cumulative effects analyses in Chapter 4.

3.1.1 Scoping

Scoping defines the issues, actions, and geographic and chronological boundaries for the past/present effects analyses. The scoping process for the analyses of this chapter has entailed the following:

- Reviewing public and agency comments;
- Identifying the issues and events connected with the groundfish fisheries since their implementation;
- Identifying internal Magnuson-Stevens Fishery Conservation and Management Act (MSA) management actions and their potential effects (see Section 3.2 for a discussion of this analysis)
- Identifying issues and events (natural and human-influenced) external to the groundfish fisheries; and
- Identifying management actions external to the MSA process and their potential effects.

The overall geographic scope of the analyses has been broadly defined as the Bering Sea and North Pacific Ocean. This broad geographic scope was necessitated by the transboundary movements of a number of fish species. Such a broad area, however, is not relevant to all resource categories discussed in this section. When the overall geographic scope is not applicable to a given resource, a relevant geographic sub-area in the analysis of that particular resource is defined. Likewise, when events outside the overall geographic scope have strongly influenced the baseline condition for a given resource, such as with some migratory seabirds and marine mammals, we define an extended geographic scope for analysis of effects on that resource.

EPA guidance (1999) recommends establishing a chronological reference point to mark the beginning of a historical review, or past effects analysis. For our present purposes, that environmental reference point in time is defined as 1740, one year prior to first contact of non-indigenous people. This assumes that at that time the BSAI and GOA ecosystems existed in an ecologically sustainable condition; hence, the environmental reference point of 1740 is a logical starting point for the ecosystem discussion. The overall time frame for the past/present effects analyses thus spans the period from 1740 to 2002. For many of the resources under consideration here, however, the lack of data requires that the discussion use a later point in time as a starting point. In these cases, we define the relevant environmental reference point in each particular analysis.

3.1.2 Organizing

The organizing step characterizes and consolidates the issues and actions defined during the scoping process. The following steps have been taken to organize the information of this chapter accordingly:

- Identifying the relevant physical, biological, and socioeconomic resources;
- Reviewing the literature, personal communications with resource specialists, and documentation of available information on identified resources (i.e., descriptive, trend, and impact information);
- Identifying indicators for direct/indirect effects that could cause population and/or ecosystem level effects to occur;
- Conducting a past/present effects analysis; and
- Defining a baseline condition for identified resources.

3.1.3 Identifying Effects, Events, and Actions

A cumulative effects analysis takes into account the incremental impact of the proposed action when added to other past, present, and reasonably foreseeable future actions (40 Code of Federal Regulations [CFR] 1508.7). For the purposes of this Programmatic Supplemental Environmental Impact Statement (SEIS), the definition of other actions includes human-controlled, natural, and climatic events.

To identify direct/indirect effect indicators and external events and management actions, we have produced a comprehensive checklist for each resource category. Information presented in the checklists was obtained from reviewing environmental impact statements (EIS), reports and resource studies, peer-reviewed literature, and from conferring with expert contributors to the Programmatic SEIS. The checklists have been entered into the administrative record.

Direct/Indirect Effect Indicators

Direct/indirect effect indicators are specific to each resource category and are presented in the past/present effects analysis for each resource.

Past/Present External Events and Actions

The detailed checklists identify the following human-controlled external event and action categories and natural and climatic events relevant to the past/present effects analysis:

- Past and present foreign fisheries (inside the U.S. EEZ prior to the MSA and, after passage of the MSA in 1976, outside the EEZ). Appendix B of this document provides a detailed discussion of the historical foreign fisheries and pertinent management actions;

- Fisheries managed by the International Pacific Halibut Commission (IPHC).
- Fisheries managed by the State of Alaska.
- Native subsistence fisheries.
- Commercial harvesting of marine mammals and seabirds.
- Subsistence hunting of marine mammals and seabirds.
- Pollution and toxic contamination, including the *Exxon Valdez* Oil Spill (EVOS).
- Introduction of mammalian predators to seabird colonies.
- Natural events and phenomena.
- Long- and short-term climatic events.

Internal Events and Actions

These include post-MSA foreign fisheries inside the U.S. EEZ, Joint Venture (JV) fisheries, and domestic fisheries. Management actions include the BSAI and GOA FMPs and associated amendments. Also included are the Endangered Species Act (ESA) Section 7 consultations (Biological Opinions [BiOps]) of National Marine Fishery Service (NMFS or National Oceanic and Atmospheric Administration [NOAA] Fisheries) and the U.S. Fish and Wildlife Service (USFWS), and the resulting Reasonable and Prudent Alternatives (RPAs) that have been implemented to protect endangered or threatened species. Appendix B of this document provides a detailed discussion of the evolution of the fisheries management plans in use today and an analysis of FMP amendment actions.

3.1.4 Past/Present Effects Analysis

There are two reasons for describing and evaluating past and present effects on the environment. First, this process is necessary to build the picture of the baseline–the status as of 2001 or 2002–for each resource component (for example, walleye pollock, Steller sea lion, the ecosystem, per capita income). In other words, *it helps to explain how the baseline got to be the way it is.* And second, the past/present effects analysis identifies past effects of human actions and natural events that may persist in the present *and continue to exert an influence in the future*.

To evaluate the significance of potential impacts, it is necessary to establish a baseline, or benchmark, against which the predicted direct, indirect, and cumulative effects of the alternatives can be compared. For comparative purposes, the baseline is a slice through time, a snapshot, that represents the affected environment at a fixed point in time. The description of the comparative baseline was prepared utilizing data available through 2001 or 2002, depending on the type of data. With the exception of socioeconomics and seabirds, the comparative baseline for environmental factors utilize data through 2002. For the socioeconomic comparative baseline and socioeconomic model used for analysis in Chapter 4, 2001 data were used because 2002 were not available prior to the release of the 2003 Draft PSEIS. These years were chosen because they were the most recent years for which a wide range of fishery-related and other resource data were available to the analysts preparing the draft document. The National Environmental Policy Act (NEPA) does not contain a standard rule that prescribes how the baseline should be defined, but the standard practice is to select the most recent year for which nearly complete environmental data are available when starting the analyses. In Chapter 4, the authors have updated some impact analyses between the draft and final documents in cases where new data that might affect the significance determinations were available. As a practical matter, the document preparation and review process makes it infeasible to move the baseline continuously forward in time, and the use of 2001 and 2002 as the baseline remains relevant and appropriate to the baseline characterization and impact assessments as of 2004.

The baseline characterization of current conditions is more, however, than simply a snapshot through time. It takes into account past human actions and natural events that have influenced resources in various ways, leading, for example, to population declines or increases, or changes in distribution. To characterize such dynamic processes, it is necessary to identify trends that began in the past and have continued to affect resources through the years leading up to the baseline. This allows the baseline description to distinguish features that are continuously changing from those that are static, an important factor in assessing the potential environmental impacts of the alternatives. In addition, the identification of trends is necessary to make future projections regarding a particular resource component, because trends from the past and present may continue into the future. This aspect is especially relevant to the cumulative effects analyses in Chapter 4, because those assessments must take into account past, present, and reasonably foreseeable future human actions and natural events that might add to or interact with the predicted direct and indirect effects of the alternatives (CEQ 1997).

Accordingly, the text descriptions of the affected environment for each of the resource components described in this chapter take past effects and trends into account. A two-tier table structure is used for summarizing the written discussions and for organizing the information used in the cumulative effects analyses. For each resource, a first table organizes the information from the past/present effects analysis used in defining baseline conditions for a resource. This baseline information then feeds into a second table, which is the cumulative effects table. Chapter 4 provides a detailed discussion of the cumulative effects tables. The first-tier, past/present effects tables are explained below.

The main column headings in the past/present effects analysis table are as follows:

Direct/Indirect Effects: Effects identified for each resource that have the potential to cause population and/or ecosystem level effects are listed, as follows.

- **Past/Present Events:** Events that produce or have the potential to produce the identified direct/indirect effects, listed in relation to direct/indirect effects listed in the first column. This column heading is further divided into two sub-columns:
  - External: Natural, climatic, and human controlled events and actions not directly associated with management of the groundfish fisheries.
  - Internal: Events and actions directly associated with management of the groundfish fisheries.

- **Past/Present Management Actions:** Management actions that regulate the events, listed in relation to the direct/indirect effects listed in the first column. This column heading is further divided into two sub-columns:

- External: actions self-imposed by management and industry related to the direct/indirect effects listed in the first column and not directly associated with management of the groundfish fisheries)
- Internal: Management actions related to the direct/indirect effects listed in the first column and directly associated with groundfish fisheries management

In addition, a text box is provided with each past/present effects table that summarizes the comparative baseline of a resource. All of the information in the past/present effects tables is also discussed in each resource category sub-section.

By using this approach the Programmatic SEIS provides two ways of viewing the analyses, in text and tabular formats. The information in the tables is supported by the text, so that the reader can refer to the text description to get more information on any aspect of a table. Conversely, the reader can use the tables to gain a quick summary of the conclusions in the text. To facilitate this, the text discussions and related tables are cross-referenced.

3.2 Assessment of the Fishery Management Plan Amendments

The BSAI and GOA FMPs were implemented in 1979 and 1981, respectively. Since that time, the BSAI FMP has been amended 65 times, and the GOA FMP has been amended 55 times. Each FMP amendment was supported by the required level of analysis under NEPA, Executive Order (EO) 12866, and the Regulatory Flexibility Analysis. As part of the programmatic review, it is necessary to analyze the cumulative impacts of the groundfish fisheries on the human environment. This includes reviewing the incremental impacts of the FMP amendments, the impact of groundfish fishery management, and the impact of other past external events, in order to establish a baseline condition against which to compare the Programmatic SEIS alternatives for direct, indirect and cumulative effects.

Appendix B provides a description and detailed discussion of the nature of the fisheries and the lingering influences of pre-MSA fisheries in the North Pacific. Later sections of Chapter 3 discuss other ongoing external influences on the human environment that may be impacting synergistically with the groundfish fisheries. Appendix E summarizes the regulatory amendments that regulate the fisheries within the guidelines of the amended FMPs. This section deals specifically with the incremental amendments to groundfish fishery management. Section 3.2.1 describes the management actions contained within the BSAI and GOA amendments. Section 3.2.2 provides a description of the FMP amendments, objectives, implementing regulations, and results. Section 3.2.3 assesses the cumulative past effects of similar management actions in order to determine whether an impact occurred, and if so, whether it was adverse or beneficial. This evaluation is an important element in assessing the baseline condition for the groundfish fisheries.

3.2.1 Fishery Management Plan Amendments

The management measures implemented through the BSAI and GOA FMPs, and their amendments, are categorized and summarized in Tables 3.2-1 and 3.2-2 for the BSAI and GOA, respectively. The management actions have been grouped into six categories: management and monitoring, groundfish yield/sustainability, bycatch and incidental catch, habitat conservation, seabird and marine mammal conservation, and socioeconomic issues. Many of the amendments initiate multiple management changes, and the amendment number may appear in more than one category. However, each specific measure only appears once in the table. The categorization is based on the primary objective of the management action. For example, although a particular management action may have achieved a secondary objective of providing incidental benefits for habitat conservation, if the primary intent of the action (as stated in the supporting analysis) was to control bycatch, the management action is listed in the 'Bycatch and Incidental Catch' category.

The six categories of management actions and their concomitant objectives are as follows:

- Management and Monitoring
  - To continue authorization of the groundfish fisheries
  - To establish a structured process for administering groundfish fisheries
  - To correct inefficiency in administration of the fishery management process
  - To make the management process more understandable to users
  - To facilitate enforcement of fishery regulations
  - To enhance data collection and record keeping
  - To improve reporting
  - To clarify the intent of past regulations

- Groundfish Yield/Sustainability
  - To protect target groundfish stocks
  - To ensure productivity of groundfish stocks
  - To control the rate of groundfish harvest
  - To maintain long-term yield from groundfish stocks
  - To improve the quality of groundfish products
  - To protect groundfish habitat

- Bycatch and Incidental Catch
  - To reduce discards to the extent practicable
  - To minimize the incidental catch of non-target groundfish species, undersized target groundfish, and prohibited species
  - To avoid waste of marine resources
  - To facilitate full utilization of catches taken in groundfish fisheries
  - To avoid gear loss and subsequent "ghost fishing" of lost gear

- Habitat, Seabird and Marine Mammal Conservation
  - To reduce fishing gear effects on the marine environment
  - To avoid fishing effects on marine mammals, birds, or habitat areas of critical concern
  - To avoid disturbance, injury, or mortality to marine mammals or seabirds
  - To protect marine mammal and seabird food sources

- Socioeconomic Issues
  - To manage effort in groundfish fisheries
  - To make prosecution of groundfish fisheries more fair to user groups
  - To avoid gear conflicts, gear entanglement, or gear damage
  - To enhance safety at sea

3.2.2 Description of Fishery Management Plan Amendments, Objectives, Implementing Regulations, and Results

A detailed summary of the amendments to the BSAI and GOA FMPs may be found in Appendix C and Appendix D respectively. The amendments are listed numerically, and for each, the following information is included: the dates of decision-making and implementation, the purpose and need of each amendment, a summary of implementing regulations, a description of the supporting analysis, and a statement of the results of the amendment.

3.2.3 Cumulative Past Effects of Fishery Management Plan Amendments

The following section summarizes the results of the historical review of the North Pacific fishery management incremental decision-making process. The FMP amendments are assessed below. Section 3.2.3.1 examines the FMP amendment actions by determining the degree to which they were effective at resolving the stated management objective. Section 3.2.3.2 summarizes the impact of the FMP amendments on particular resources or resource categories. It directs the reader to the more detailed analysis of the contribution that groundfish fishery management has made to the comparative baseline condition of the resources in question.

3.2.3.1 Fishery Management Plan Amendments Assessed by Management Objective

As described in Section 3.2.1, the historical FMP amendments have been organized into six categories based on the objective of the management action: management and monitoring actions, groundfish yield and sustainability actions, bycatch and incidental catch actions, habitat actions, seabird and marine mammal actions, and socioeconomic actions. The BSAI and GOA FMP amendments are assessed below in terms of their efficacy in achieving the management objective and mitigating adverse effects of groundfish fishery prosecution.

Management and Monitoring Actions

Various GOA and BSAI FMP amendments implemented administrative changes. FMP amendments are denoted in the following manner: GOA FMP Amendment 1 is listed as GOA 1. GOA 1, 7, and 8 extended the GOA FMP and eliminating the expiration date. GOA 16 and 34 corrected previous FMP language. GOA 14, 15, and 18 and BSAI 1, 11, 12, 13, and 21 added framework measures to remove the setting of target quotas, incidental catch and prohibited species catch (PSC) limits, and fishing season dates from the FMP amendment process, and to conform the GOA FMP with the BSAI FMP. GOA 21 and BSAI 16 established procedures for setting interim total allowable catch (TACs), so that the fisheries could open on January 1. Since these actions provided for more effective fishery management, they are considered to have had a non-conditional beneficial effect on the groundfish fisheries.

Clarifications and definitions of terms and standards are management actions that form part of the FMP amendments. Target and prohibited species are defined in GOA 16 and 21 to be consistent with the BSAI FMP. GOA 14, 16, 21 and 24 and BSAI 9, 16, and 19 also specify and define legal gear and clarify directed fishing definitions. GOA 21, 44 and 56, and BSAI 16, 44 and 56 define overfishing levels for the groundfish fishery resources, allowing for improved conservation of target groundfish stocks. Additionally, GOA 15 revised the goals and objectives for the GOA FMP. Unambiguous standards, definitions and policies assist the efficient prosecution of the groundfish fisheries and are considered to have had a beneficial effect.

The GOA and BSAI FMPs, GOA 4, 11, 14, 15, 16, 17, and 18 and BSAI 9, 10, 11a, 12, and 13 established and revised recordkeeping and reporting requirements for vessels participating in the groundfish fisheries. The GOA and BSAI FMPs included provisions for observers on foreign fishing boats, while GOA 18 and 30 and BSAI 10, 13, 27, and 37 initiated and redefined the domestic fisheries observer program. Data from catch and observer reports are important components of the fisheries management processes. Therefore, we consider the establishment of these programs and their continuing implementation to have had a non-conditional beneficial effect on the groundfish fisheries.

Various GOA and BSAI FMP amendments were intended for conservation purposes or to increase the ability of managers to respond quickly to situations to resolve gear conflict issues. The GOA FMP, GOA 8 and 15 and BSAI 1, 10, 16a, 19, 21 and 24 all authorize the NOAA Fisheries Regional Administrator to use inseason management measures to react responsively to fishery issues. The intent of these actions, the issuance of rapid field orders in response to newly developing issues, has not necessarily been fulfilled; however, to the extent that it has allowed flexibility in management, these actions are considered beneficial.

The original GOA FMP, GOA 22, and BSAI 17 allowed the issuing of experimental fishing permits for the purpose of testing gear efficiency, fishing techniques, bycatch mortality reduction techniques, and other methodologies. It is inferred that information gained from activities conducted under experimental fishing permits leads to gains in the effectiveness of the groundfish fisheries. Therefore, these actions are considered to have had a conditionally beneficial effect on the groundfish fisheries.

Groundfish Yield and Sustainability Actions

The BSAI and GOA FMPs establish annual harvest levels for groundfish species. For foreign fishermen, exceeding a nation's allocation in a management area or district triggered closure of that area to fishermen from that nation. These actions are considered beneficial as they prevented overfishing of the stocks by foreign fishermen.

The GOA FMP establishes optimum yield (OY) levels for each groundfish species, with revisions to squid, Atka mackerel, Pacific cod, pollock, sablefish, 'other rockfish', and 'other species' determinations made in GOA 4, 7, 10, 11, 13, 14. Available data on stock biomass indicated that the given target groundfish stocks were appropriate. Therefore, these actions are considered to have had a neutral to beneficial effect on the given target groundfish stocks. As discussed in the Management and Monitoring Actions above, GOA 15 revised the process for setting target species quotas, resulting in the establishment of an OY range, and an annual TAC-setting process implemented by regulatory amendment. Harvest levels were established in the BSAI FMP also; however BSAI 1 established a multi-year, multi-species OY (a range from 1.4-2.0 million metric tons [mt]) for the BSAI groundfish complex as a whole. Prior to the implementation of this amendment, BSAI 4 adjusted the Pacific cod harvest levels from the harvest levels set in the BSAI FMP. The TAC framework has had a beneficial impact due to the increased management flexibility, and the incorporation of an annual status of stock review that sets catch quotas based on the best available science.

The GOA and BSAI FMPs managed specific species targeted by the groundfish fisheries, and identified requirements for some incidentally caught species (see prohibited species discussions in the following section). Various FMP amendments made alterations to the management categories identified in the FMPs. GOA 5, 7, and 8 established new management categories for grenadiers, and for idiot rockfish, and non-specified species. GOA 14 gave the Secretary of Commerce the authority to split or combine species within the target species category. GOA 31 established Atka mackerel as a separate target species category. BSAI 12 established a separate rock sole target species category separate from the 'other flatfish' category. Since these actions provided for more species-specific management and thus reduced the risk of overfishing the stocks, they are considered to have had a beneficial effect.

The GOA FMP apportioned quota over five subareas, which were reduced to three by GOA 4, GOA 8, 11, and 22. They divided and modified the eastern GOA districts for sablefish management. GOA 13 combined the western and central management areas for pollock allocations. GOA 14 created a new regulatory district for 'other rockfish', and recognized the State of Alaska management areas for demersal shelf rockfish. GOA 18 and BSAI 17 established the Shelikof District in the GOA (which was rescinded in favor of other measures in GOA 25 as part of Steller sea lion protection measures) and the Bogoslof district in the Bering Sea, respectively, in order to manage the fisheries' catch of spawning pollock. GOA 4, 8, and 22 modified the GOA regulatory districts. BSAI 28 divided the Aleutian Islands subarea into three management districts for the immediate purpose of spatially allocating Atka mackerel in order to address localized depletion. The creation of subareas and species-specific districts has allowed managers to control for uneven exploitation and is considered beneficial.

GOA 21 and 46 deferred demersal shelf, blue, and black rockfish management to the State of Alaska. The management shift is considered to have had a conditionally beneficial effect, since state management has allowed more consistent management of these species throughout federal and state waters, minimizing the risk of localized depletion and the possibility of exceeding TAC.

GOA 19 and BSAI 14 allocated the pollock TAC seasonally, over four seasons in the GOA and two in the BSAI, in order to reduce the potential for fishing on spawning aggregations to adversely impact the sustainability of the stock. Limiting the amount of quota available during spawning seasons is effective at reducing fishing on spawning populations, although it also decreases the value of the fishery.

GOA 10, 32, and 38 were conservation measures taken to rebuild depressed Pacific ocean perch stocks. These measures were implemented specifically to conserve stocks, and have succeeded at rebuilding the Pacific ocean perch stocks. They are considered to be beneficial.

Bycatch and Incidental Catch Actions

Species that must be discarded at sea are specified in the GOA and BSAI FMPs, and limits on the catch of these prohibited species are established in the FMP amendments as a way to minimize the bycatch and encourage the use of more selective gear. Once a limit is achieved, a closure is triggered either of a fishery, fisheries, or a specified fishing area. GOA 14, 15, 18, and 21 specify halibut PSC limits for the GOA groundfish fisheries, and apportion them by season and gear. BSAI 1a, 3, 8, 12, 12a, 16, 19, 25, 37, 40, 41, 57 and 58 all establish or modify PSC limits in the BSAI for halibut, crab, salmon and herring, by sector and fishery. PSC limits have been consistently used as a bycatch management tool, have been extended from applying to halibut to most prohibited species in the BSAI, and have consistently decreased over the years. It is inferred from this that PSC limits are successful in decreasing the bycatch of these species in the groundfish fisheries. As a result, these actions are considered beneficial in minimizing the impact of the groundfish fisheries.

Many measures identify gear specific closure areas to reduce bycatch. The GOA and BSAI FMPs, GOA 9 and 10 and BSAI 4, 7, and 10 specified foreign bottom trawl and trawl closures to reduce crab and halibut bycatch. Although GOA 4 and BSAI 1 exempted the domestic fleet from some of the domestic bottom trawl restrictions in the GOA and BSAI FMPs, GOA 15, 18, 26, and 60 reinstituted specific non-pelagic trawl prohibitions around Kodiak and in Cook Inlet to lower bycatch of crab species. BSAI 10, 12a , 21a, 35, 37, 40, and 57 established restricted seasonal, year-round or PSC limit-triggered areas to decrease crab bycatch. BSAI 10, 12a, 16a, and 57 established protections to lower the bycatch of halibut. BSAI 1a, 3, and 8 were early measures to reduce salmon PSC limits over time, as referred to above, whereas BSAI 21b, 35, and 58 attempted to address salmon bycatch using trigger amounts and area closures. BSAI 16 established herring savings areas. It is inferred that these measures improved the efficiency of groundfish harvest, and decreased the incidental take of species in bottom trawls. Therefore, these measures are considered to have had a conditionally beneficial effect.

Various other measures were adopted to control bycatch and incidental catch. GOA 24 and BSAI 19 delayed the start of the groundfish trawl fisheries in order to avoid excessive bycatch. Also, GOA 45 adjusted the seasonal pollock allowance schedule in order to avoid high salmon bycatch in the summer months. Bycatch reduction was also encouraged through gear modifications. GOA 21 and 16 required halibut excluder devices on pots, and FMP amendment actions were specifically implemented to reduce ghost fishing by lost gear. GOA 8 and 21 and BSAI 16 required biodegradable panels on sablefish pots. Any reduction in ghost fishing or increase in gear selectivity is considered to have a conditionally beneficial effect.

Additionally, incentive programs were introduced in GOA 21 and 24 and BSAI 16 and 19 to penalize vessels with excessive bycatch. Vessel sanctions under the incentive programs have proved very difficult to enforce, and these actions have not achieved bycatch reductions in the groundfish fisheries.

Another goal of bycatch-related measures is the minimization of waste. BSAI 11 minimized waste by splitting the annual JV pollock quota into two seasons, and GOA 19 and BSAI 14 prohibited roe stripping of pollock in the groundfish fisheries. Both amendments encouraged greater utilization of fish fit for human consumption and mitigated the potential for overharvest of spawning stocks to affect the sustainability of the pollock resource. BSAI 26 and 50 and GOA 29 and 50 were implemented to reduce post-harvest waste of incidentally-caught Pacific halibut and salmon in specified groundfish fisheries by donating the bycatch to social service food banks. Since Pacific halibut and salmon bycatch would typically be discarded in federal waters, these actions help provide for the needy and have a non-conditional beneficial effect. The retention of Pacific halibut and salmon bycatch also provides an additional opportunity to collect biological samples and scientific data to support long-term solutions to bycatch of these species. Therefore, these actions are also considered to have had a beneficial effect on groundfish fisheries.

GOA 49 and BSAI 49 were implemented to reduce discards in the groundfish fisheries, and encourage full utilization. The amendments required 100 percent retention of pollock and Pacific cod and, as of January 1, 2003, for rock sole and yellowfin sole as well, regardless of how or where the fish were caught unless the fish were unfit for human consumption. These measures, beginning in 1998, have dramatically reduced the discard rates of pollock and Pacific cod. Therefore, they are considered to have had a conditionally beneficial effect on groundfish fisheries. BSAI 75 repealed the implementation of Improved Retention/Improved Utilization (IR/IU) for flatfish due to the excessive cost it would have imposed on flatfish fishermen. Because IR/IU was never implemented for flatfish, this action has had no effect.

Habitat Actions

GOA 14 and 55 and BSAI 9 and 55 defined and established habitat protection policies for the future conservation of groundfish stocks. GOA 55 and BSAI 55 identified and described essential fish habitat (EFH) for species managed under the FMPs. Habitat areas of particular concern were identified as living substrates in shallow and deep waters, and freshwater habitats used by anadromous fish. To the extent that such policies increase awareness of sensitive habitat and influence other management decisions, they have provided a conditionally beneficial effect to marine habitat. However, no concrete measures were proposed in conjunction with these FMP amendments to mitigate adverse habitat impacts from fishing activities.

GOA 59 established the Sitka Pinnacles Marine Reserve encompassing a 2.5 square nautical miles (nm^2) area off the Cape Edgecumbe pinnacles as a protected area for rockfish and lingcod habitat. This action is anticipated to be beneficial to these long-lived, vulnerable species.

Seabirds and Marine Mammal Actions

Forage fish (e.g., capelin, eulachon, and sand lance) are an important food source for seabirds and marine mammals. GOA 39 and BSAI 36 prohibited the establishment of a commercial fishery targeting forage fish, thereby preserving the food resource. These FMP amendments are considered to have had a conditionally beneficial effect on seabirds and marine mammals.

Several FMP amendments have been implemented specifically for the direct protection and conservation of marine mammals. No-fishing buffer zones were established around rookeries and haulouts deemed critical to walrus (BSAI 13 and 17) and Steller sea lions (BSAI 20 and GOA 25). GOA 25 also modified pollock management districts in the western/central GOA, to reduce the effects of prey competition from the groundfish fisheries. While the impact of the fisheries on walrus has not reasserted itself as a problem, the population levels of the western stock of Steller sea lions continued to decline even after the protection measures adopted in GOA 25. Further protection measures have been implemented by emergency rules and regulatory amendments since 1999; however, the degree to which the Steller sea lion population levels are impacted by the groundfish fisheries is still a matter of scientific controversy. As such, the effect of the FMP amendments relating to Steller sea lion protection measures cannot be determined.

Socioeconomic Actions

The establishment of groundfish quotas and spatial and seasonal allocation was discussed previously in the groundfish yield and sustainability actions section.

The GOA and BSAI FMPs established specific allocations for foreign and domestic fisheries, with reserves providing for growth of the domestic fisheries. The program was modified in GOA 7, 8, and 11; and GOA 2 and 6, BSAI 2 and 4 increased domestic groundfish quota and correspondingly decreased foreign allocations. To the extent that the MSA called for domestication of the fisheries, the amendments were beneficial in promoting domestic groundfish harvests. The establishment of foreign closure areas, particularly in areas likely to be utilized by domestic fishermen (such as the Aleutian Islands and southeast Alaska) under the FMPs, was also effective in preventing gear conflict between domestic and foreign fishermen and promoting domestic fisheries (although certain foreign and domestic restrictions were relaxed in GOA 4 after they were found to be unnecessary).

The GOA and BSAI FMPs specified allocations between gear types for foreign fishermen. Management measures favoring foreign longliners were adopted in GOA 3, which modified restrictions on foreign Pacific cod quota in the Chirikof District in order to allow the foreign longline fleet to take a higher percentage of the allocated foreign quota, and GOA 4, which separated longliners from trawlers for quota closures. The greater selectivity of longline gear over trawl gear resulted in beneficial impacts on bycatch rates and habitat.

Allocation by gear type was first adopted for the domestic fisheries in GOA 14. In order to address excess capacity in the sablefish fishery, fixed allocations were assigned over a four-year adjustment period, to longline, trawl, and pot fisheries, with pot fisheries being phased out of the GOA sablefish fishery by the end of that time. Additionally, the amendment delayed the sablefish fishery start date to allow smaller vessels more opportunity to participate in the fishery. The FMP amendment slowed the growth in capacity and diminished the possibility of gear conflicts and grounds preemption, but did not solve the problem of overcapacity in the fishery.

The sablefish fishery was further modified by GOA 20 and BSAI 15, which implemented the sablefish Individual Fishing Quota (IFQ) program and eliminated the derby-style fishing associated with these fisheries. While the framework of the IFQ program was set out in GOA 20 and BSAI 15, modifications were made to ownership, transfer, and processing restrictions in GOA 35, 36, 37, 42, 43, 54, and 64 and BSAI 31, 32, 33, 42, 43, 54, and 72. The sablefish IFQ program has been successful in diminishing the number of participants in the sablefish fishery, and has succeeded at reducing bycatch (particularly of Pacific halibut), improving safety, reducing gear conflicts and fishing mortality due to lost gear, and increasing the economic value of the fishery.

Quota allocation between gear types continued to be used to address socioeconomic issues in the groundfish fisheries. BSAI 34 allocated two percent Atka mackerel TAC in the eastern Aleutian Islands to jig gear, in order to promote a local, small vessel fishery without direct competition from the large, high-capacity trawl fleet. Although the amendment was successful in creating a quota allocation for the jig gear fishery, the fishery has not taken advantage of the quota to harvest Atka mackerel. Therefore the amendment has had no appreciable effect. BSAI 53 allocated shortraker/rougheye rockfish between trawl and non-trawl gear in the Aleutian Islands, as the potential overfishing of shortraker/rougheye by the trawl fleet was also threatening to close non-trawl fisheries, resulting in loss of economic opportunity. The gear allocation was successful in limiting the scope of the problem.

In the pollock fishery, allocation of quota was further divided between processing sectors, namely trawl catcher processors and trawl catcher vessels delivering to catcher processors (the offshore sector), and trawl catcher vessels delivering to inshore processors. BSAI 18 established a 35/65 percent allocation of pollock between the inshore and offshore sectors, which was extended through 1998 in BSAI 38. BSAI 18, 38, and 51 established, adjusted, and extended the catcher vessel operational area, to a designated area off of Dutch Harbor to which the offshore sector was allowed only minimal access. GOA 23 allocated 100 percent of GOA pollock to inshore processors, which allocation was extended in GOA 40, 51, and 61. The amendments were successful in preventing the grounds preemption that occurred in 1991 and prompted development of the inshore/offshore allocations.

BSAI 61 implemented the provisions of the American Fisheries Act (AFA), establishing sector and cooperative allocations of pollock. The amendment defined specific vessel and processor cooperative linkages, and defined 'sideboards' that limited the participation of AFA pollock vessels in other fisheries in the BSAI and the GOA (implemented in the GOA in GOA 61). BSAI 69 further modified the BSAI pollock cooperative program. The establishment of cooperatives, and the buyout of nine vessels participating in the pollock fishery, was considered beneficial as it served to reduce excess capacity in the BSAI pollock fishery, resulting in increased economic efficiencies.

In conjunction with the BSAI and GOA pollock inshore/offshore allocations, Pacific cod was identified in GOA 23 with 90 percent allocated to inshore processors and 10 percent to offshore processors. This allocation was extended through 2004 in GOA 40, 51, and 61. In the BSAI, Pacific cod was initially allocated by gear type in BSAI 24 between trawl, hook-and-line, pot, and jig gear. BSAI 46 modified the percentage allocation between trawl and fixed gear, and extended the two percent jig allocation. The specific allocation to jig gear was beneficial in that it gave coastal communities a way to compete in the valuable fishery. However, the allocation is not fully utilized by the jig fleet. BSAI 64 further divided the fixed gear allocation between hook-and-line catcher processors, and hook-and-line catcher vessels, pot vessels, and vessels less than 60 feet (ft) length overall (LOA). In order to avoid a substantial number of new entrants into the Pacific cod fishery, BSAI 67 specified eligibility requirements and required a limited entry permit Pacific cod species and gear endorsement for participation in the Pacific cod fishery. To the extent that the amendment avoided excess capacity in the fishery, it is considered beneficial.

GOA 28 and BSAI 23 established a vessel moratorium on new vessels entering into the groundfish fisheries, and was supplemented in GOA 41 and BSAI 39 with a License Limitation Program (LLP) for participating groundfish vessels. This program was modified and extended in GOA 57 and 58 and BSAI 59 and 60. The moratorium and LLP have reduced excess capacity in the groundfish fisheries, and prevented further growth, resulting in a beneficial impact.

The Community Development Quota (CDQ) program was established in conjunction with the sablefish and Pacific halibut IFQ programs in BSAI 15; however, due to delays in the implementation of that program, the CDQ program was first actualized in the pollock fishery as a result of BSAI 18. The CDQ quota for sablefish was increased in BSAI 30. BSAI 38 and 45 extended the pollock CDQ allocation, and BSAI 39 established a multi-species CDQ program for all groundfish species managed under the BSAI FMP. This was subsequently modified in BSAI 66 which removed squid from the CDQ program in order to allow more efficient use of the small squid quota allocation. The CDQ program was created in order to provide fishermen who reside in western Alaska communities a fair and reasonable opportunity to participate in the groundfish fisheries, to expand their participation in nearshore fisheries, and to help alleviate the growing social economic crisis in these communities. The FMP amendments are considered beneficial in their impact on western Alaska communities, as they have created revenues and employment in many of the communities.

GOA 27 and BSAI 22 established gear test areas in the Bering Sea that could be used to ensure that gear was in working order prior to season opening dates. It is inferred that this action likely resulted in reduced gear loss and entanglement on the fishing grounds, which would increase economic efficiency and reduce adverse habitat and mortality impacts due to ghost fishing.

Vessel safety was addressed in the GOA FMP in GOA 16, which formally incorporated safety considerations in accordance with the MSA. The amendment had little effect, other than to reinforce fishery managers' awareness of vessel safety considerations in decision-making.

3.2.3.2 Fishery Management Plan Amendments – Assessed by Impact to Resource Category

Although adopted to achieve a particular management objective, the FMP amendments have had secondary and indirect impacts as a result of their implementation. The impacts of the FMP amendments on the resources or resource categories that are components of the human environment affected by the groundfish fisheries, are discussed in detail in the remainder of Chapter 3. Specifically, the contribution of internal groundfish fishery management and the amended FMPs is assessed as part of the analysis of the cumulative past effects influencing the baseline condition of each resource. This section provides a brief summary of the FMP amendment impacts, and includes a reference to the relevant section later in Chapter 3 for more detailed discussion.

Target Species

Since the implementation of TAC frameworking removed the adjustments and modification of OY from the need for an FMP amendment, the amendments relating directly to target species have primarily been allocative (allocating TAC among seasons, areas or gear types, or implementing rationalization programs for target species). These amendments result primarily in socioeconomic impacts, rather than affecting the sustainability of the stocks. Some amendments have directly impacted the stocks. For example, BSAI 14 and GOA 19 dispersed directed fishing on pollock spawning aggregations, and GOA 59 established a protection area for rockfish and lingcod habitat. Other amendments have had ancillary impacts on target stocks. These impacts are discussed in further detail in the species subsections in Section 3.5.1, under internal effects from foreign, JV and domestic groundfish fisheries from 1976 to the present.

Prohibited Species and Non-Target Species

Many amendments have been implemented since the original FMPs to minimize bycatch of target and non-target species. PSC limits, with triggered closures upon exceeding the limits, have been the most popular and effective method for addressing prohibited species concerns.

Other measures that were implemented for other reasons have had incidental benefits for non-target species. BSAI 13, 15, and 46 and GOA 3 and 20 increased apportionment of target groundfish quotas to the longline fleet, which equated to a decrease in bottom trawl quotas. It is inferred that these measures improved the efficiency of groundfish harvest and as a consequence decreased the incidental take of species in bottom trawls. Therefore, these measures are considered to have had a conditionally beneficial effect.

BSAI 13, 15, and 46 and GOA 3 and 20 increased apportionment of target groundfish quotas to the longline fleet, which equated to a decrease in bottom trawl quotas. GOA 12 prohibited the use of longline pot gear for the harvest of sablefish in favor of hook-and-line gear. It is inferred that these measures may have had offsetting results such as decreased grenadier bycatch from bottom trawls, and increased grenadier and skate bycatch in the longline fishery. Therefore, these measures are considered to have had a conditionally insignificant effect on grenadier and skate stocks.

The impact of the FMP amendments on prohibited species is discussed in detail in Section 3.5.2, under the individual species headings. The impact on non-target species is discussed in the species subsections in Sections 3.5.3, 3.5.4, and 3.5.5, under internal effects from foreign, JV and domestic groundfish fisheries from 1976 to the present (also referred to as post-MSA fisheries).

Habitat

Many FMP amendments whose purpose was primarily to reduce bycatch or incidental take or to address allocation issues have also mitigated fishing impacts on habitat. GOA 3 and 20 and BSAI 15 increased apportionment of target fish quotas to the longline fleet, equating to a decrease in bottom trawl quotas. BSAI 10 and 21a and GOA 9, 15, 18, and 26 closed specific geographic areas to bottom trawling, primarily for the protection of prohibited species. The reduction of bottom trawling due to these measures could provide conditionally beneficial effects to benthic habitat in localized areas.

In contrast, BSAI 4 allowed fishing within 3 to 12 nautical miles (nm) of the Aleutian Islands on the narrow margin of the continental shelf. The potential offsetting effects would be increased benthic damage around the Aleutian Islands and less damage in other areas. With BSAI 4, it is inferred that since more productive fishing grounds were being accessed, fewer trawls would be required to reach harvest quotas resulting in less overall trawl damage to the marine habitat. However, trawl damage tends to be most severe in areas of highly localized fishing where the benthos is repeatedly disrupted. Decreased, but more localized fishing effort might actually be more damaging. The net habitat effect resulting from BSAI 4 could not be determined.

Further discussion of the impact of past amendment and management actions on habitat is contained in Section 3.6.5.

Seabirds and Marine Mammals

Interactions of the groundfish fisheries with seabirds and marine mammals may involve direct injury or mortality of these animals, or may result from prey competition where the groundfish fisheries catch species that form the prey base for marine mammals or seabirds. Efforts have been made to minimize the interaction in both of these areas. BSAI 36 and GOA 39 banned a directed fishery on forage fish, which are preyed upon by seabirds, marine mammals, and commercially important groundfish species. Forage fish are the principal diet of more than two thirds of Alaskan seabirds.

Other efforts to avert prey competition with the Steller sea lion are amendments dispersing Steller sea lion prey species, pollock, Pacific cod and Atka mackerel, in space and time. These actions were precipitated by the rapid decline in the western stock of Steller sea lions. Although scientific evidence of the relationship between the groundfish fisheries and Steller sea lion decline is a matter of controversy, measures were put in place in various FMP amendments to disperse the fishery and to prevent disturbance of the animals at rookeries and haulouts.

For further discussion of the effect of FMP amendments on seabirds and marine mammals, refer to Section 3.7.1 for seabirds, and to individual marine mammals species subsections in Section 3.8, under the headings relating internal effects from the MSA groundfish fisheries).

Socioeconomic Factors

Section 3.9.1 contains a historical overview of the fisheries that includes changes since the implementation of the FMPs. Impacts of the FMP amendments on harvesting and processing sectors are discussed in detail in Section 3.9.2.2.

Impacts of other amendments on communities are discussed in Section 3.9.3. Impacts of the CDQ program are discussed in detail in Section 3.9.4.3.

Ecosystem

Section 3.10.1.4 discusses the FMP management changes since the implementation of the FMPs, and the impact of the amendments on the ecosystem.

3.2.4 Significant Changes to Bering Sea and Aleutian Islands and Gulf of Alaska Groundfish Fishery Management

Since the implementation of the BSAI and GOA FMPs in 1978 and 1981 respectively, the manner in which the groundfish fisheries have been managed has adapted and changed. These changes have been incrementally analyzed in terms of the specific actions implemented by the individual FMP amendments, and their impacts, as summarized above. When these changes are viewed cumulatively, however, it is apparent that the current fishery management philosophy is built upon the incremental responses of the last twenty years.

This section attempts to identify the significant changes to the way the groundfish fisheries are managed, since the implementation of the FMPs. The changes identified in this section have been deemed significant by NOAA Fisheries analysts; however, due to the qualitative nature of this discussion, the list may not be exhaustive. Additionally, the discussion of the amendments is primarily based on the NEPA documents that analyzed the action (Environmental Assessments [EAs] or EIS). While these documents do address the purpose and need for proposing a change to existing management conditions, and often include a rationale for selecting a preferred alternative, the full debate regarding the implementation of a particular amendment is not always apparent in the NEPA analysis, particularly if changes are made as a result of Secretarial disapproval. To the degree that the analysis below is based in large part on the analysis of the NEPA documentation, the discussion of significant changes may also be lacking.

The significant management changes since 1978 (GOA) and 1981 (BSAI) that have been identified by NOAA Fisheries analysts are changes to: 1) the OY framework and to the apportionment of quota; 2) methods to minimize bycatch particularly of prohibited species; 3) tools to deal with excess capacity; 4) means for protecting communities dependent on fishing; 5) monitoring and reporting programs; and 6) frameworking and flexible management.

The establishment of a multi-species groundfish OY range in the BSAI and GOA FMPs represented a significant shift in groundfish fishery management. Although the implementation of the BSAI OY range was Amendment 1 to the BSAI FMP, it was analyzed as part of the FMP EIS. The OY range in the GOA was established in GOA 15. This change allowed considerably more flexibility of management, as the annual quota for an individual species was no longer defined in the FMP and would be set annually, based on best available science and in accordance with the TAC frameworking procedures in the FMP, using the more streamlined regulatory amendment process. GOA 15 was implemented in 1987. In the eight years prior to its implementation, OY adjustments had been made in eight of the thirteen amendments.

The implementation of the OY range in the BSAI has had other impacts because the maximum limit of the FMP-defined OY range constrains the sum of groundfish acceptable biological catch (ABC). The sum of groundfish ABC for 2003 was approximately 3.5 million mt, while the maximum limit of the OY range is set at 2 million mt. As a result, the North Pacific Fishery Management Council (NPFMC) has leeway in making recommendations for TAC settings in the BSAI, and in determining which species should be fished to the level of their ABC and which should not. The cap on OY is believed by NPFMC to be an effective conservation measure that mitigates uncertainty, particularly in the BSAI. The use of the existing OY ranges has been reaffirmed by NPFMC in the Preferred Alternative (PA).

Another significant change since the implementation of the FMPs is to the apportionment of annual quota. In the original FMPs, the domestic fishery received a species-specific catch quota for the managed groundfish species that, in the GOA was spatially divided among five statistical areas. The foreign catch quota in the GOA was spatially distributed and had seasonal restrictions. Although not specified in the FMPs, the foreign catch quota was allocated among nations. Since the implementation of the original FMPs, the spatial, seasonal, directed fishery, and gear-specific subdivision of species quota allocation has increasingly become a management tool that is used to address a variety of problems. In the GOA FMP, quota was divided among the statistical areas to “reduce the likelihood of uneven exploitation on localized stocks or concentrations” (NMFS 1978). This issue was echoed in BSAI 28, where the ability to apportion the Atka mackerel TAC over subdivided BSAI districts allowed for a higher Atka mackerel ABC than would otherwise be recommended if the directed fishery were allowed to take the quota all from one spatially concentrated portion of the subarea (NMFS 1993b). Seasonal quota allocations (BSAI 14 and GOA 19) and the creation of species-specific management districts (BSAI 17 and GOA 18) were also used as tools to protect the pollock stock against intensive fishing on spawning aggregations.

The subdivision of allocation by gear type has also been used to resolve socioeconomic issues such as gear conflicts and grounds preemption disputes. Further discussion may be found under Socioeconomic Actions in Section 3.2.3.1. Due to the difference in selectivity and bycatch rates among different gear types, excessive groundfish bycatch by a particular gear-type may result in a target fishery being closed before the quota is reached, when that quota could safely be harvested by vessels of a different gear type without triggering a bycatch concern. To the extent that species allocation by gear type allows the fishery to achieve the optimum harvest levels and avoids gear conflict, it is a useful tool that will continue to be recommended by the NPFMC. The downside of subdividing allocations is that it requires increased attention from NOAA Fisheries managers in terms of the potential need to close fisheries, to reallocate incidental catch amounts, or to investigate overages. In 2003 in BSAI, there were 152 non-CDQ TAC allocations, and 29 TAC allocations for each of the six CDQ groups. This represents a 23-fold increase from 1995.

The use of PSC limits has also been a significant change in fisheries management since the implementation of the original FMPs. Although prohibited species, which must be discarded at sea, were specified in the original FMPs, limits on their catch were not formally included in the FMPs. Subsequent amendments first specified catch limits on foreign catch of halibut in the GOA, and chinook salmon, halibut and crab in the BSAI. Once its PSC limit was reached, the nation was prohibited from fishing in the management area or subarea. The application of PSC limits as a tool for reducing prohibited species bycatch was subsequently applied to the domestic fleet trawl sectors, and then to the fixed gear sectors, and apportioned by area or season. The NPFMC continues to find PSC limits to be an effective method for reducing bycatch, and the establishment of PSC limits for salmon, crab and herring in the GOA are included in the PA. Analysis to address salmon bycatch, and suggested PSC limits for the GOA, have already been initiated.

PSC limits have been implemented in response to increased concern as to the rate of prohibited species bycatch in the groundfish fisheries. Prior to the full domestication of the groundfish fisheries, domestic catch of prohibited species was not a matter of concern. Once the issue was raised at the NPFMC level, however, PSC limits have been demonstrably effective in reducing PSC in the groundfish fisheries. For details on the specific reductions in prohibited species bycatch, see Appendix C BSAI Amendment description for BSAI 21b, 25, 35, 37, 40, and 41.

Since the domestication of the groundfish fisheries, excess capacity has increasingly become an issue for the NPFMC. Programs such as the vessel monitoring program (VMP), the LLP, the IFQ program for sablefish, and the AFA cooperatives for BSAI pollock have all changed the nature of groundfish fisheries from their state as described in the original FMPs. The impact of these programs is described in detail in Section 3.9 of this document. The NPFMC has identified comprehensive rationalization as a policy goal since 1992. In the PA of this document, the NPFMC has reaffirmed its intention to further decrease excess capacity and overcapitalization through eliminating latent licenses and extending programs such as community or rights-based management to some or all groundfish fisheries.

The NPFMC has also specifically recommended prioritizing the implementation of management measures that provide stable economic opportunities for fishery-dependent coastal communities. This includes management measures that provide allocations to small vessels or particular gear types, such as allocations to jig gear (BSAI 24 and 34). Additionally, consideration for coastal communities is important during the development of area restrictions such as closure areas so that they still allow access for local vessels. The inshore-offshore issue in the pollock fleet included coastal community consideration, as communities hosting a processor were more likely to benefit from inshore allocations (BSAI 18, 38, and 61 and GOA 23, 40, and 51). The establishment of the CDQ program for western Alaska coastal communities illustrates a well-developed program for community protection, where a percentage of the TAC for each BSAI groundfish and crab species is allocated among six CDQ groups. The economic impacts of the CDQ program are discussed in detail in Section 3.9.4.3. The NPFMC is currently developing a program in the GOA for eligible communities to purchase sablefish quota share (GOA 66). The shift in emphasis to provide for sustainable fisheries-dependent communities influences all groundfish fishery management actions, and in particular is a major criterion in the development of future rationalization programs.

The original FMPs established specific monitoring and reporting requirements for the foreign fisheries, and minimal reporting requirements for the domestic fisheries. As the domestic fleet began to increase their proportion of the North Pacific TAC, however, the need for more timely and comprehensive domestic fishery data became apparent. Management and Monitoring Actions of Section 3.2.3.1 provides a summary of the various FMP amendments that increased observer coverage for domestic fishery operations and expanded recordkeeping and reporting requirements. These programs, in combination with NOAA Fisheries independent resource surveys, are part of one of the most comprehensive fishery data collection systems in the world (Appendix F-11). Acknowledged deficiencies of the system are the non-random observer coverage in the 60 ft to 125 ft sector of the groundfish fleet, and the lack of observer coverage on vessels smaller than 60 ft. Additionally, the economic data collected is mostly limited to price and revenue data. In order for fishery managers to assess the full economic impact of their decisions, it is necessary to expand the range of economic data collected to include, for example, expenditure, employment and earnings data. These deficiencies are addressed in policy objectives in the PA.

Since the implementation of the FMPs, a major management emphasis has been on frameworking of management measures. The process for implementing FMP amendments is time-consuming, and does not allow for quick responsiveness to new conservation or management issues. In contrast, the nature of fisheries management is variable, with stock sizes fluctuating naturally from year to year. As a result, when rapid reaction to a conservation issue is required, the immediate management response must often be implemented by NOAA Fisheries' emergency rule, and after the fact be supported by an FMP amendment and requisite analyses. As a result of the bureaucracy of this latter procedure, the NPFMC has attempted to framework those management measures that are reviewed and adjusted on a regular basis, so that their change does not trigger the procedure of an FMP amendment. Instead, the procedure for regular review and modification is outlined in the FMP, along with the NPFMC intent and authorization, and as a result, the actions can subsequently be implemented through regulatory amendments rather than FMP amendments. Various management measures have been frameworked in this manner, including the TAC-setting process as discussed above. Additionally, setting annual PSC limits for some prohibited species, setting season start dates, inseason management measures, and granting experimental fishing permits are all actions that are authorized in the FMPs, often with specific criteria and procedural requirements, but are implemented through regulatory amendments.

Another example of a framework procedure is the hot spot authority granted to NOAA Fisheries. The NPFMC has frequently recommended that the FMPs be amended to allow the NOAA Fisheries Regional Administrator the field authority to implement temporary time or area closures to specific areas for conservation reasons (known as hot spot authority), such as if a particular fishing ground seems to be producing high bycatch rates (BSAI 1, 4, 10, 16a, 19; GOA 15, 24). Although numerous efforts were made between 1983 and 1992 to refine the authorization language and enable temporary fishery closures by regulatory amendment, the original rapid reaction intent has not been met. The standards of evidence and public comment periods required for inseason management to close an area to fishing do not permit for flexible, temporary closures of the type envisioned by the NPFMC. The principle of hot spot closures has been used voluntarily in the BSAI pollock cooperatives to reportedly good effect. A review of the effectiveness of bycatch reduction in the BSAI pollock fishery is currently initiated in the PA.

3.3 Physical Oceanography of the Fisheries Management Units

3.3.1 The Northeast Pacific Ocean

3.3.1.1 Description

Bounded on the north and east by the North America land mass, and essentially open to the west and south, the northeast "quadrant" of the Pacific Ocean includes the GOA and the Bering Sea (Figure 3.3-1). Although separated from the main ocean body by the Aleutian Islands, the Bering Sea is considered to be a northern extension of the northeast Pacific Ocean by virtue of hydraulic communication through the numerous passes and channels between the islands. On the west and south, the bounds of the northeast Pacific Ocean are generally considered to be the International Dateline and the northern 30th parallel, respectively.

Although dotted by numerous seamounts rising to within 1,000 meters (m) of the surface, seabed depths over most of the northeast Pacific Ocean tend to be greater than 4,000 m. Maximum depths of more than 7,000 m occur in the Aleutian Trench, which parallels and marks the southern base of the Aleutian Island chain (Figure 3.3-1). Along the land boundary, the continental shelf (depth less than or equal to [$\leq$] 200 m) is relatively narrow (less than [<] 50 kilometers [km]) along the British Columbia and southeast Alaska coasts, and then broadens to 100 km or more along southcentral Alaska coast. Along portions of the Kenai and Alaska Peninsulas, the continental shelf attains a width of nearly 200 km.

3.3.1.2 Circulation

Surface currents in the Pacific Ocean are driven by the trade winds and westerlies, such that surface flows are predominantly westward in low latitudes (10° - 30°North [N]) and eastward in high latitudes (35° - 50°N). When these flows encounter the continents they are diverted both north and south to form coastal currents, which further serve to establish rotating water masses (gyres) that characterize the overall circulation patterns of the ocean (Figure 3.3-1).

The seaward "boundaries" of the northeast Pacific Ocean are arbitrarily, if not practically, determined by large-scale circulation features that result from these planetary driving forces. On the south, the North Pacific Drift transports surface waters eastward along (approximately) the 45th parallel. Upon reaching the North American continent, this flow splits into northbound and southbound branches known, respectively, as the Alaska Current and the California Current. As the Alaska Current tracks anti-clockwise along the continental margin, portions of it are known as the Alaska Coastal Current (ACC) and the Alaskan Stream (Figure 3.3-1). The anti-clockwise loop is closed by the Aleutian Current, which is a south-to-southeasterly extension of the Alaska Current (Figure 3.3-2). The resulting anti-clockwise circulation pattern is known as the Alaskan Gyre.

Winter intensification of the Aleutian Low leads to strong southeasterly winds along the southeast Alaska coast, which produce onshore Ekman transport and downwelling of coastal waters (Royer 1975). During summer, the North Pacific High tends to dominate the region such that lighter, more variable winds result in a relaxation of the coastal convergence. The overall anti-clockwise circulation is maintained by the introduction of fresh water along the coastline, as described in the following section.

3.3.1.3 Water Mass Characteristics

In the North Pacific high latitudes, surface waters have relatively low salinities because of the excess of precipitation and runoff over evaporation. Cooling these surface waters even to the freezing point does not make them sufficiently dense to cause them to descend any deeper than 200 m in the water column. Consequently, the deeper water in the North Pacific must originate elsewhere, and must flow in through the South Pacific because the connection with the Arctic Ocean, through the Bering Strait, is too narrow and shallow to be of consequence.

These deeper waters of the North Pacific originate in the southern (i.e. Antarctic) and North Atlantic Oceans, where the combination of surface temperatures and salinities produces very dense waters that subsequently sink to the sea floor. The Pacific Ocean has been described as a vast estuary, with low-salinity surface outflow from the North Pacific mixing with deeper, more saline water flowing in at depth through the south Pacific. Ultimately, the increasingly dense North Pacific water returns to the areas of sinking in the North Atlantic to complete the circuit, which is estimated to take centuries to complete.

Nutrients are distributed throughout the world's oceans by this system of deep circulation. For example, inorganic phosphates are consumed by plant growth at the surface and are regenerated at greater depths as the plants die, sink, and decay. Consequently, nutrients are in greater concentrations at depths of one to two km than at the surface. Inflow of the deeper water into the Pacific Ocean brings in water that is high in phosphate compared to the average concentration in the Atlantic Ocean. As a result, the accumulated phosphate in the Pacific Ocean has a concentration about twice that of the Atlantic.

The next two subsections describe in greater detail the physical oceanography of the two federal fisheries management units (FMUs) of the northeast Pacific Ocean. A final subsection addresses the sources and magnitude of variability in oceanic parameters.

3.3.2 Gulf of Alaska Fishery Management Unit

3.3.2.1 Description

The GOA FMU includes all waters within the EEZ along the southeastern, southcentral, and southwestern coasts of Alaska from Dixon Entrance to Unimak Pass, a distance along the Alaskan coastline of more than 2,500 km (Figure 1.2-3). Greatest depths within the GOA FMU range from 3,000 m off southeast Alaska, to 4,000 m off southcentral, and to 7,000 m at the west end of the FMU, where the Aleutian Trench begins. However, the continental shelf areas (depths < 200 m) are of greatest importance in the context of fishery management issues.

As noted previously, the continental shelf within the GOA FMU is narrowest in southeast Alaska, ranging in width from less than 50 km between Dixon Entrance and Cape Spencer, and then broadening to 100 km or more along the southcentral coast to Seward. South of the Kenai Peninsula and west of Kodiak Island, the continental shelf is broadest, about 200 km, on Portlock Bank. Proceeding westward from Kodiak along the Alaska Peninsula, the shelf narrows gradually from 150 km to about 50 km at Unimak Pass. The progressive broadening and narrowing of the continental shelf from east to west plays an important role in the circulation of waters through the GOA FMU.

3.3.2.2 Circulation

Water movements within the GOA FMU are dominated by the ACC which changes character and direction three times and is joined by other narrower currents as it is forced by the coastline to change direction from northwestward to westward to southwestward as it flows through the unit (Figure 3.3-1). Starting off southeast Alaska like a wide river with imbedded eddies the main flow turns westward with the coastline and becomes two currents as it is joined by the faster ACC close to shore. As the coastline turns southwestward the flow seaward of the shelf break accelerates taking on the dynamics of a western boundary current, the Alaskan Stream, which reaches speeds of 60 to 100 centimeters per second (cm/sec) staying in a narrow jet over the continental slope to the end of the unit. This broad southwestward flow is now in four bands; the weak offshore portion, the swift Alaskan Stream, a weak tidally and bathymetry influenced flow on the outer shelf, and the moderate ACC inshore. Some of the offshore flow recirculates to the south then east forming the western branch of the GOA Gyre. This coastal circulation is driven in winter by the persistent anti-clockwise wind stress over the GOA and in summer by the immense fresh water input from coastal sources in British Columbia and southeast Alaska.

During the winter, when coastal runoff is minimal, anti-clockwise atmospheric circulation is most intense over the GOA, and wind stress maintains the coastal circulation with strong onshore convergence or downwelling. During summer when winds over the GOA slacken considerably, coastal runoff increases dramatically and creates a density gradient in nearshore waters that serves to maintain the anti-clockwise coastal circulation. Thus seasonal variations in wind stress and coastal runoff are balanced so that together they serve to maintain the generally steady westward movement of water through the GOA FMU.

Circulation near the continental shelf break (approximately [~] 200 m depth) generally follows the isobaths, with frequent eddies and meanders. Closer to shore the flow is more stable with fewer eddies and is more closely aligned with the coastline. Within the broader Alaska Current, the narrow and intense coastal current ACC extends from southeast Alaska to Kodiak Island. The ACC results from the density gradient produced by prodigious amounts of freshwater runoff that varies with the annual hydrologic cycle (Royer 1979 and 1983). The width of the ACC varies from only 5 to 10 km wide to as much as 40 to 50 km, depending on the rate of freshwater input. Current speeds within the ACC occasionally exceed 100 cm/sec, which has caused occasional reference to it as a coastal jet. The dilutional effects of the freshwater input are generally confined to the top layers (50 to 100 m) of the water column. The western segment of the ACC has been called the Kenai Current (Schumacher 1980).

West of Kodiak Island, where freshwater input is much reduced, the Alaska Current is driven more by prevailing winds. Accordingly, in winter a westward flow is maintained by wind stress, but in summer this driving force is somewhat lessened so current reversals and eddies occasionally occur (Schumacher and Reed 1986).

3.3.2.3 Water Column

The density structure of the water column is determined by its physical properties, most notably its temperature and salinity, as they vary with depth. At the temperatures typical of the northern GOA water (i.e., < 10 degrees Celsius [° C]), salinity is the dominant determinant of water density. Because of the plentiful coastal runoff and the excess of precipitation over evaporation, coastal waters of the GOA have salinities that are significantly lower than those of the North Pacific, which are already low relative to the world's oceans. Salinities at depths less than about 10 m in the GOA FMU are typically 25 to 30 practical salinity units (psu).

Salinity and density increase with depth, but the greatest rate of increase occurs within the pycnocline, which extends from about 30 m to 200 m depth. Above the pycnocline is the surface mixed-layer, in which the salinity is 32 to 33 psu. Below the pycnocline, salinity increases slowly to about 34.4 psu at a depth of 1,500 m. Temperatures in the mixed layer vary from 3° to 12°C seasonally. Below the pycnocline the temperature decreases slowly from 3° to 2.5°C near 1,500 m. These are relatively permanent features so significant changes occur only rarely, and then only as a result of large-scale changes in circulation. Ranges of physical properties of GOA waters are listed in Table 3.3-1.

Small horizontal changes in water properties occur as the flow proceeds westward, but mainly in the mixed layer. Nearshore salinities in the eastern and northern GOA can be as low as 26.0 psu in the ACC in the fall, when precipitation is at its maximum. Along the edge of the shelf in the Alaskan Stream a low-salinity (<32.0 psu) tongue like feature protrudes westward. In Shelikof Strait and to the east, the range of temperatures (0° to 15°C) can be substantially greater than those farther west. Whereas surface salinity increases toward the west as sources of fresh water from the land diminish, salinity values at 1,500 m decrease very slightly. Temperatures at all depths tend to decrease toward the west.

Some chemical properties of GOA water make it unique in the world ocean. Compared to other ocean waters at similar latitudes, the deep water of the GOA has higher concentrations of silicate, phosphate, and nitrate and its well-developed oxygen minimum. The oxygen and phosphate distributions result from the decomposition of particulate organic matter sinking from the surface, as elsewhere, but the higher concentrations arise because of accumulation resulting from poor circulation of the deep water. Reeburgh and Kipphut (1986) examined GOA chemical profiles for dissolved oxygen, silicate, phosphate, and nitrate, and summarized available historical data in three distinct oceanographic domains: 1) the deep sea, 2) the continental shelf, and 3) fjords and estuaries. Of the three, the shelf domain has the least data.

Deep sea profiles show temperature decreasing continuously with depth, first in the main thermocline from 10°C at the surface to 6°C at 100 m, then gradually to 4°C at 350 m and even more slowly to 1.8°C at 2,500 m (Reeburgh and Kipphut 1986). Dissolved oxygen decreases from about 300 micromoles (μM) oxygen/kilogram (kg) at the surface to less than 50 μM oxygen/kg at 400 m, followed by a minimum near 900 m then a gradual rise to about 120 μM oxygen/kg at 4,000 m. Phosphate increases from 0.5 μM phosphoric acid-phosphorus/kg at the surface to a maximum of almost 3 μM phosphoric acid-phosphorus/kg from 500 to 1,500 m, then decreasing slightly to about 2.6 μM phosphoric acid-phosphorus/kg near 2,500 m. Nitrate increases from about 0.3 μM nitrate-nitrogen/kg at the surface to a maximum of about 40 μM nitrate-nitrogen/kg from 500 to 1,500 m, then decreases only slightly to about 35 μM nitrate-nitrogen/kg near 2,500 m. Silicate increases from about 5 μM dissolved silica-silica/kg to 150 μM dissolved silica-silica/kg at 500 m, then continues to increase slightly to 175 μM dissolved silica-silica/kg at 2,500 m. The dissolved oxygen minimum and the phosphate and nitrate maxima occupy similar depth zones. Some studies have investigated long-term variability in the deep sea using Ocean Station P data. Surface nitrate was never less than 10 μM, even during peak uptake. Hokkaido University (1981) confirmed measurable nitrate was always present and probably does not limit surface productivity. A well-established population of pelagic grazers appears to be responsible for the relatively high surface-nutrient concentrations (Miller *et al.* 1984).

The nutrients in the shelf waters interact horizontally and thus have similar properties to the shallow (< 250 m) range of the oceanic water described above. Seasonal changes depend upon the seasonal variations in the meteorological regime (Royer 1975). In the winter, southeasterly winds bring convergence and downwelling (Royer 1981) along with the winter cooling and replacement of warm, high-saline bottom waters. In the summer, the wind field reverses, bringing relatively warm, high-saline, low-oxygen, high-nutrient waters from the central GOA back onto the shelf at depths of 100 to 200 m. Nitrate profiles from near the mouth of Resurrection Bay show values 20 to 40 µM between 0 and 250 m depth during winter, and summer values of 1 to 30 µM over the same depth range.

Few nutrient studies have been done in fjords and estuaries, but exchange with the shelf water has been determined from a few localized intensive studies to be a function of sill depth. No anoxic conditions were observed in Alaskan fjords, indicating at least annual bottom water renewal (Muench and Heggie 1978). Shallow-silled (< 50 m) fjords renewed between February and April when surface waters were most dense. Intermediate sill depth (120 to 160 m) fjords followed shelf water density changes and led to fairly continuous flushing. Deep or unrestricted sill (greater than [>] 180 m) fjords are flushed between July and October, when warm, saline, higher-nutrient water returns to the shelf after the relaxation of convergence.

3.3.3 Bering Sea and Aleutian Islands Fishery Management Unit

3.3.3.1 Description

The Bering Sea is a semi-enclosed, high-latitude, subarctic sea and is considered to be a northern extension of the North Pacific Ocean. Shaped somewhat like a sector of a circle with its apex at the Bering Strait, the Bering Sea has a total area of 2.3 million square kilometers (km^2). Forty-four percent is continental shelf (depth < 200 m), 13 percent is continental slope, and 43 percent is deepwater basin where depths reach as much as 3800 m along the western margin of the sea. The broad continental shelf on the east side of the Bering Sea is one of the most biologically productive areas of the world. The BSAI FMU comprises most of the continental shelf and consists of the entire EBS from the Alaskan coastline westward to the international boundary. Also, those waters within the EEZ south of the Aleutian Islands from Unimak Pass to the international boundary are included in the BSAI FMU (Figure 1.2-2).

3.3.3.2 Circulation

Numerous straits and passes through the 2,000-km arc-shaped Aleutian-Komandorski archipelago connect the Bering Sea to the North Pacific Ocean. The amount of water exchanged between the North Pacific Ocean and the Bering Sea through passes between the various Aleutian Islands is uncertain. Waters from the Alaska Current enter the Bering Sea at Unimak Pass and, to a lesser extent, through other passes between Aleutian Islands. Major exchanges of water occur at the west end of the Aleutian-Komandorski archipelago, with large inflow to the Bering Sea through Near Strait and outflow through Kamchatka Strait. Some additional leakage into the Bering Sea occurs through passes between the islands just east of Near Strait.

As the warm Alaska Stream water enters the Bering Sea and is cooled and transported through the anti-clockwise Bering Sea Gyre, large upwellings occur bringing cold deep waters to the surface (Ohtani 1970). Eddies, ranging in diameter from 10 to 200 km, can be found throughout the Bering Sea and contribute to the vertical mixing of waters. These eddies are thought to be caused by instabilities, wind forcing, strong flow through passes in the U.S., and topography (Schumacher and Stabeno 1998).

To the north, the Bering Sea is connected with the Chukchi Sea and Arctic Ocean through the Bering Strait which separates the Seward Peninsula (Alaska) from the Chukotka Peninsula (Russia). At the Bering Strait, there is a relatively small net annual outflow of water (Coachman and Aagaard 1988), although this flow can be reversed by relatively rare combinations of meteorological conditions (Coachman and Aagaard 1981).

Patterns of circulation in the Bering Sea have been inferred mostly from distributions of water properties, but some knowledge has also been obtained from drifter studies (Stabeno and Reed 1994). The overall circulation pattern is generally anti-clockwise within the basin, with the most prominent feature on the east side being a weak and variable northwestward flow over the broad continental shelf adjacent to Alaska. Along the edge of this shelf the Bering Slope Current transports water northwest at speeds of 10 to 20 cm/sec (Kinder *et al.* 1975, 1986), although Royer and Emery (1984) found this flow to be somewhat slower in winter. The Bering Slope Current intensifies as it approaches the Asian continent, bifurcating into a northerly flow through the Gulf of Anadyr and a southwesterly flow that is the origin of the Kamchatka Current. The Kamchatka Current is an intense western boundary current that continues southwestward along the Russian coast (Figure 3.3-2).

Flow over the North Aleutian Shelf (adjacent to Alaska) is characterized by Schumacher and Reed (1992) as weak and variable, with low current speeds (< 5 cm/sec). Mean speeds observed in the central shelf area are less than 1.0 cm/sec and reveal no organized circulation (Kinder and Schumacher 1981). Within Bristol Bay the *mean* flow is weak and shows an anti-clockwise tendency along the perimeter of the bay. Maximum speeds (~ 3.5 cm/sec) occur near the 50-m isobath and near the coast. However, the vast majority of the velocity variance within the bay is tidal, with tidal currents an order of magnitude larger than the mean flow. For example, on the north Aleutian shelf, where net currents are 1-5 cm/sec and the typical wind-driven currents are approximately 10 cm/sec at 5-m depth, the tidal currents are 40-80 cm/sec or more (Thorsteinson 1984). Turbulence resulting from these tidal currents causes mixing of the water column from the seabed to about 50 m above it.

3.3.3.3 Hydrography

Hydrographic structure over the U.S. is well-defined and consists of three domains that are separated by physical fronts (Kinder and Coachman 1978, Schumacher *et al.* 1979, Kinder and Schumacher 1981). The inner front is aligned approximately with the 50-m isobath, the middle with the 100-m isobath, and the outer at the shelf break (~ 200 m). The associated oceanographic domains are referred to as the coastal domain, middle domain, and outer domain. Two other distinct domains exist off the shelf: a narrow, energetic shelf break domain and the deep-ocean domain. The Pribilof Islands and the Unimak Islands provide distinct separate habitats within the Bering Sea. These domains will be referred to repeatedly in the following sections that describe the characteristics of the Bering Sea.

Circulation over the shelf is related to domain structure (Coachman 1986). In the outer domain (100 to 200 m), tidal currents account for about 80 percent of the flow, with a mean of about 5 cm/sec along shore to the northwest, and an onshore-offshore flow of 1 to 5 cm/sec that is quite variable. Tidal mixing is very important in the outer domain. In the middle domain (50 to 100 m) the important flow is due to tides and inertial currents. There is little net motion, and vertical mixing due to tides is important here. Tidal currents account for about 95 percent of the flow energy in the coastal domain (< 50 m), but as already noted, the mean flow has a speed of 1 to 5 cm/sec in a generally northwest direction. In contrast to circulation of the GOA, the circulation of the Bering Sea shelf has relatively small net flows and relatively large tidal forcing.

There are two main water masses on the shelf: Alaska Coastal water and central Bering water. Coastal water is found shoreward of the 50-m isobath in the south U.S., while central Bering water is found in the middle domain, from the inner front (~ 50 m) to the middle front (~ 100 m). Alaska Coastal water is a combination of coastal freshwater discharge and more saline water from the deep basin, and is generally well-mixed by winds and tides. The central Bering water in the middle domain has a lower layer that is isolated from seasonal heating and thus has temperatures that reflect prior winter conditions. Water of the outer domain

(100 to 200 m) is not really an identifiable water mass, but instead is a mixture of central shelf and deep Bering Sea water. Because of greater tidal and advective energy, it is less strongly stratified than the middle domain, but exhibits considerable small-scale vertical variation in properties that originate in the middle domain. These vertical variations, known as vertical "fine structure," are important to the flux of water properties horizontally and vertically through the water column.

Hattori and Goering (1986) summarized the available data on the distribution of salinity, temperature, phosphate-phosphorous, nitrate-nitrogen and ammonia-nitrogen, and silicic acid (Table 3.3-2) and characterized the four domains according to nutrients. Because the fronts inhibit lateral fluxes of water and dissolved materials between the four domains, nutrient zones are consistent with the physical domains. The vertical physical system also regulates the biological processes that lead to separate cycles of nutrient regeneration. The source of nutrients for the outer domain is the deep oceanic water, and for the middle domain, it is the shelf-bottom water. Starting in winter, surface waters across the shelf are high in nutrients. Spring surface heating stabilizes the water column, then the spring bloom commences and consumes the nutrients. Steep seasonal thermoclines over the deep Bering Sea at depth of 30 to 50 m, the outer domain at 20 to 50 m, and the middle domain at 10 to 50 m restrict vertical mixing of water between the upper and lower layers. Below these seasonal thermoclines nutrient concentrations in the outer domain are invariably higher than those in the deep Bering Sea water with the same salinity. Winter values for nitrate-nitrogen/phosphate-phosphorous ratios are similar to the summer ratios which suggests that, even in winter, the mixing of water between the middle and outer domains is substantially restricted (Hattori and Goering 1986).

Spring and summer storms can increase the total seasonal productivity by mixing to depths sufficient to resupply nutrients to the euphotic zone, but by the end of summer, nutrient depletion in the euphotic zone is common all across the shelf. Year-to-year consistency of trends between summer nutrient distributions in 1975 and 1978 was shown by Hattori (1979).

3.3.3.4 Effects of Sea Ice

Oceanic conditions, both physical and biological, can be profoundly influenced by the presence of sea ice. During extreme winter conditions, sea ice covers the entire eastern shelf of the Bering Sea; however, interannual variability of coverage can be as great as 40 percent (Niebauer 1988). The growth of ice over deep water is limited by relatively warm water in the central basin, so the maximum extent of the ice is restricted to the shelf.

The ice generally begins its seasonal southward formation in November. It is estimated that about 97 percent of the ice in the Bering Sea is formed within the Bering Sea itself (Leonov 1960). Very little ice is transported south through the Bering Strait (Tabata 1974). The ice apparently forms like a giant conveyor belt, being generated along the south-facing coasts in the Bering Sea and moving southward at as much as 0.5 meters per second before finally melting at its southern limit (Pease 1981). On average, seasonal ice formation progresses at an average rate of 12 to 13 percent per month over the area of the eastern shelf, reaching 60-65 percent coverage by late March (Niebauer 1981). The ice advance generally consists of a short, rapid advance (approximately 24 percent per month) in November-December, before slowing to approximately 6 to 7 percent in December-March. With the exception of the rapid advance in November and part of December, the ice appears to dissipate faster than it forms, at about 18-20 percent per month in late March to early July. Lisitsyn (1966) reported that, during the period of ice retreat, 63 percent of the ice melts within the Bering Sea basin. The remainder leaves the Bering Sea by way of various straits and passes.

The sea ice affects exchanges with the atmosphere and inhibits the transfer of freshwater (salt) and heat. It changes the coupling of the oceanic and atmospheric momentum exchanges by altering the surface roughness. The creation and melting of the sea ice alters the horizontal and vertical density gradients in the water column. Increases or decreases in the vertical density gradient affect the mixing and transport of nutrients and organisms in the euphotic zone. The ice edge also serves as both a source and sink of freshwater that can affect productivity. In fall during freeze-up, freshwater is extracted from the seawater, while during the spring, melting supplies freshwater to the ice edge.

One might reasonably assume that primary productivity in a winter ocean covered to a large extent by ice would be low and uncomplicated. However, McRoy and Goering (1974) reported on studies that revealed a complex productivity system in the water column and ice that makes a measurable contribution to the total annual production of the Bering Sea. The annual increase in production in the Bering Sea begins in late February with the development of the algal community in the sea ice. The production of this community increases with the passing of winter and probably reaches a maximum just before the ice melts completely. The ice algae comprise the first spring bloom that occurs in the Bering Sea, preceding the bloom that occurs in the open water farther south.

In April, as the ice melts, a second spring bloom develops in the wake of the receding ice. This begins along the southern ice front, coinciding approximately with the edge of the continental shelf. This bloom is promoted by the stability associated with the low-density water around the melting ice. As a result of the seasonal ice cover, the annual primary production of the Bering Sea is actually increased. Furthermore, the annual spring increase in algal standing stock begins in the middle and northern Bering Sea rather than the expected southern waters. Niebauer *et al.* (1990) subsequently estimated that the ice edge bloom of phytoplankton accounts for between ten percent and 65 percent of the total annual primary production.

Sea ice also influences bottom temperatures, and hence influences many species on the shelf. In winter, there is little stratification, and the sea is cold from top to bottom. In colder years there is more sea ice than in warmer years. The ice helps to cause and maintain density stratification when it melts. After the ice has melted, solar heating causes further stratification, and thus bottom temperature changes very slowly. Consequently, in cold years—years with extensive sea ice—the colder-than-normal bottom temperature is even more persistent than usual (Coachman 1986). Thus, the distribution and abundance of temperature-sensitive bottom-dwelling species and some nearshore species are related to the extent of sea ice. Variability (1972-1998) of sea ice arriving and departing the southern middle shelf is discussed by Stabeno *et al.* (2001).

3.3.4 Sources and Magnitude of Oceanic Variability

3.3.4.1 Atmosphere-Ocean Time Scales and Forcing Mechanisms

Atmospheric and oceanic parameters in the North Pacific and Bering Sea have variability that exists on several time scales and is due to many different forcing mechanisms (Table 3.3-3). Short-term (daily to annual) fluctuations in atmospheric and oceanic conditions are familiar and generally well-understood, to the extent that cause-and-effect relationships are well established. Fluctuations having longer (interannual) time scales are becoming better documented, due to extensive environmental monitoring activities, but definition of causal relationships for most remains an elusive challenge. The focus of this section is on atmosphere-ocean interactions that occur on time scales of several months to several years, or even decades. No attempt is made to catalogue all possible sources of variability. Rather, only the few that are well-known are identified and their possible influences are described.

3.3.4.2 Mesoscale Eddies

Eddies are rotating masses of water that are formed when an ocean current is deflected or pinched off by a topographic feature on the seabed or at the continental margin. Eddies can also form as a result of velocity shear on the fluid boundary between a relatively swift current and a much slower moving water mass. Rotating around generally vertical axes, mesoscale eddies have diameters of tens to hundreds of kilometers and, depending on their size, have rotational periods measured in days, or even weeks. Because they dissipate their energy only very slowly, these eddies can have lives measured in months to years, and their trajectories can be traced by the persistence of water properties in their cores. Movement of an eddy past a fixed current meter is evidenced by a cycle of flow acceleration, deceleration, and then acceleration back to the mean flow speed (or vice versa).

Mesoscale eddies are ubiquitous features of oceanic circulation and occur frequently on continental shelves and slopes. Kinder and Coachman (1977) described observations of an isolated eddy of high-salinity water nestled in the outer reaches of the Pribilof Canyon and partially in water depths greater than 1,000 m. The temperature-salinity characteristics of the eddy were those of the Bering Slope Current. The authors attribute its formation as evolving from a pinching off of a meander of this current in a manner similar to that which occurs when the Gulf Stream (Atlantic Ocean) forms warm eddies that travel northward along the U.S. east coast. Similar eddy events have been observed in the northern GOA and reported by Royer *et al.* (1979). They describe a persistent clockwise 100-km feature lying off the continental shelf and attribute its formation to instabilities of the Alaska Current.

The role of mesoscale eddies in the ocean and, more specifically, in the GOA and Bering Sea, is not determined. However, eddies could play an important role in controlling exchange of water between the North Pacific and Bering Sea (Okkonen 1993). Eddies have an important role in mixing water masses, so they might be providing microclimates that enhance or deter productivity. The interaction of eddies with other longer-term oceanic processes can serve to confound further comprehension of the overall circulation and its ecosystem-level effects. Accordingly, mesoscale eddies are essentially noise that is superimposed over the combined signal of longer-term quasi-periodic processes that are evident in the overall picture of oceanic variability.

3.3.4.3 Interannual Variability

The phenomenon known as El Niño – Southern Oscillation (ENSO), as described by Philander (1990), has long been recognized as a significant factor in the interannual variability of atmospheric-oceanic response. ENSO events radiate from the equatorial regions at irregular intervals, but ranging most commonly from three to seven years between events. ENSO events account for approximately one-third of the ice and sea surface temperature variability in the Bering Sea (Niebauer and Day 1989). ENSO forcing in the oceans at high latitudes is primarily through poleward propagation of Kelvin waves (Jacobs *et al.* 1994). This conclusion is supported by data of Enfield and Allen (1980) who found poleward-propagating, coastal-trapped disturbances along the west coast of North America that were correlated with equatorial disturbances. Royer (1994) reported that ocean temperature fluctuations at depth at GAK 1 (an oceanographic observation station near Seward) are well-correlated with ENSO events.

In addition to fluctuations associated with ENSO forcing, the water temperature variations at GAK 1 have been found to be associated with the lunar nodal tide component, which has a period of 18.6 years (Royer 1994). This tide component is the twelfth largest of all tidal components and is related to the 18.6-year periodicity of the lunar declination. Equilibrium tide theory predicts that this tidal component will vary with latitude, with amplitudes increasing with latitude (Parker *et al.* 1995). Because the interdecadal sea surface variability seems to occur simultaneously in the GOA and Bering Sea, it is expected that this component forces Bering Sea parameters in a similar fashion as in the GOA. Temperature anomaly patterns are similar with no phase shift, which suggests that the forcing is simultaneous.

3.3.4.4 Interdecadal Variability

A chronology of interdecadal climatic changes affecting the North Pacific Ocean was compiled from available measured atmospheric pressure data by Minobe (1997) for the period 1899-1997. A climatic regime shift was defined as a transition from one climatic state to another within a period substantially shorter than the lengths of the individual epochs of each of the (two) climatic states. Data used included the North Pacific index (NPI). The NPI is the area- and time-averaged sea level pressure anomalies in the region of 160°East (E) to 140°West (W) by 30° to 60°N for winter to spring (December to May), which illustrated rapid strength changes in the Aleutian low in the winter and spring seasons. Bidecadal pressure averages during 1899-1924 showed that the Aleutian low was about one millibar (mb) weaker than average, then strengthened to one mb below normal during 1925-1947. Similar behavior occurred in the later part of the Twentieth century as the Aleutian low shifted back to one mb above normal from 1948 to 1976, then strengthened back to one mb below normal during 1977-1997.

Using late-nineteenth century data for spring air temperature in western North America, Minobe (1997) identified 1890 to be the first regime shift. This extended the length of the first period to 34 years in comparison to the 22-, 26-, and 20+-year regimes to follow. The 50- to 70-year interdecadal variability, a two-regime cycle, has been prevalent from the nineteenth century to the present in North America. Minobe (1997) speculated that the likely cause of this variability is an internal oscillation in the coupled atmosphere-ocean system. This suggests that the next climatic regime shift is likely to occur between 2000 and 2007.

Long-term changes in fish populations around the North Pacific Ocean have apparently been influenced by climatic change of the same 50- to 70-year variability. Alaska salmon decreased in the 1940s and increased in the 1970s. Larger Japanese sardine catch amounts occurred in the regimes with the deepened Aleutian low. Baumgartner *et al.* (1992) found evidence of an approximately 60-year variability in sardine and northern anchovy populations in the eastern North Pacific from sediments in the Santa Barbara basin dating back to A.D. 270.

3.3.4.5 Regime Shifts

An update of evidence for regime shifts in the North Pacific Ocean in the 1920s, the 1940s, a major one in the winter of 1976/1977, and a minor one in 1988/1989 was presented recently at the North Pacific Marine Science Organization (PICES) symposium (Hare *et al.*, Hare and Mantua, McFarlane *et al.*, Zhang *et al.*, Park and Oh, Kang *et al.*, Suga *et al.*, Yasuda *et al.*, Savelieva *et al.*, Rogachev, Overland *et al.*, Miller and Schneider, and Minobe 2000). Coincidentally, the beginnings of another large change in 1998/1999 were mentioned at the symposium; these are discussed in more recent papers by Minobe (2002), Conners *et al.* (2002), Mantua and Hare (2002), and Schwing *et al.* (2002).

In the late 1970s a step change in climate, referred to as a regime shift, occurred in the North Pacific Ocean. While there is evidence to suggest that there have been previous regime shifts, as noted in the previous section, it was the 1970s regime shift that stimulated extensive research on the topic, and especially how oceanic ecosystems were responding to these phenomena. Although more than a decade was required to recognize the pattern, the regime shift of 1976/1977 is now widely acknowledged, as well as its associated far-reaching consequences for the large marine ecosystems of the North Pacific Ocean. The 1989 regime shift has been studied extensively by Hare and Mantua (2000) who assembled and examined 100 environmental time series of indices (31 climatic and 69 biological) to obtain evidence of regime shift signals. A few examples of these illustrate that such signals are evident in the BSAI and GOA data.

Sea surface temperature anomalies, relative to long-term averages, around the Pribilof Islands indicate that the BSAI environmental regime appears to have shifted. The dominance of positive anomalies (warmer than average) from 1977 to 1988 switched abruptly to negative anomalies (colder than average) in 1989, which prevailed at least through 1997. Further evidence of a regime shift is seen in the time series of the southern extent of sea ice in the Bering Sea.

Niebauer (1998) reports that prior to the late 1970s ENSO regime shift below-normal sea ice cover in the Bering Sea was typically associated with ENSO conditions. These conditions caused the Aleutian Low atmospheric pressure center to move east of its average or normal position, with the result that warm Pacific air was directed over the Bering Sea. Conversely, above-normal sea ice cover was associated with La Niña conditions, during which the Aleutian Low moves west of its normal position, allowing higher pressure and colder weather in the Bering Sea. However, since the1970s regime shift, ENSO conditions are causing the Aleutian Low to move even farther east, causing winds to blow from the east and north off Alaska, and resulting in above-normal ice cover in the Bering Sea.

Before the regime shift, ENSO and La Niña conditions occurred with about the same frequency. Since the regime shift, ENSO conditions are about three times more prevalent. Both Mantua *et al.* (1997) and Minobe (1997) present evidence that this regime shift is the latest in a series of climate shifts that date back at least to the late 1800s and might be attributable to a 50- to 70-year oscillation in a North Pacific atmospheric-ocean coupled system.

Abundant evidence suggests that the coupled atmospheric-oceanic system of the North Pacific is subject to multiple forcing factors, each having characteristic behaviors and different frequencies of occurrence. The evidence also indicates that, rather than there being a single average or normal condition, the overall system appears to stabilize periodically around two or more normal states, changing from one to another abruptly in what has been termed a regime shift. These are the characteristics of systems whose dynamics are addressed by chaos theory, which is a body of mathematical theory that focuses on systems that have multiple states of equilibrium. Chaos theory attempts to define the mechanisms that cause the systems to change from one equilibrium state to another and to predict all such equilibrium conditions.

Using available sea level pressure and sea surface temperature data, along with coastal air temperature data from Sitka, Overland *et al.* (2000) formulated a conceptual chaotic model for the North Pacific. They were able to determine that the energy content of North Pacific time series of these parameters is broad-banded (i.e. over a broad frequency range) and temporally irregular (i.e. non-steady with respect to time). They reported that their conceptual model reflects the observed irregular behavior and suggests that the transitions from one equilibrium state to another are rapid rather than gradual.

Use of the word chaos in this context is not to imply the more common definition of great confusion or disorder. Rather, its use invokes the mathematical implication that there is order behind the irregularity of the system. A chaotic model may lead to a better understanding of the low-frequency relationship between the physical and biological systems in the North Pacific. One characteristic of a chaotic system is that , near the time of major interdecadal transition, there could be several years of extreme, and perhaps opposite, anomalies in the physical system. These extremes provide opportunities for change in the biological system. Recent experience with North Pacific fisheries may provide examples of such transition periods.

Although the Bering Sea is not discussed, a new review paper summarizes many details and the big picture of multidecadal (about 50 years) change in the Pacific Ocean (Chavez *et al.* 2003) characterized by about 25-year boom and 25-year bust cycles in the opposing anchovy-sardine populations. In the mid-1970s the change was from a cool anchovy regime to the warm sardine regime. Satellites have recently confirmed an increase in basin-wide sea-level slope after the 1997/1998 ENSO coincident with a dramatic increase in chlorophyl off California, indicating a shift back to a cool anchovy regime that occurred in the middle to late 1990s. The effects of ENSO in the tropics which radiate north on a shorter cycle of three to seven years and some unmeasured anthropogenic effects may tend to mask some of the synchronicity of changes in the physical and biological systems.

3.4 Threatened and Endangered Species

The ESA of 1973 as amended (16 United States Code [USC] 1531 et seq.), provides for the conservation of endangered and threatened species of fish, wildlife, and plants. The program is administered jointly by the NOAA Fisheries for most marine mammal species, marine and anadromous fish species, and marine plants species and by the USFWS for bird species, and terrestrial and freshwater wildlife and plant species.

The designation of an ESA-listed species is based on the biological health of that species. The status determination is either threatened or endangered. Threatened species are those likely to become endangered in the foreseeable future (16 USC 1532(20)). Endangered species are those in danger of becoming extinct throughout all or a significant portion of their range (16 USC 1532(20)). Species can be listed as endangered without first being listed as threatened. The Secretary of Commerce, acting through NOAA Fisheries, is authorized to list marine and anadromous fish species, plants, and mammals (except for walrus and sea otter). The Secretary of the Interior, acting through the USFWS, is authorized to list walrus and sea otter, seabirds, terrestrial plants and wildlife, and freshwater fishes and plants.

In addition to listing species under the ESA, the critical habitat of a newly listed species must be designated concurrent with its listing to the "maximum extent prudent and determinable" (16 USC 1533(b)(1)(a)). The ESA defines critical habitat as those specific areas that are essential to the conservation of a listed species and that may be in need of special consideration. Federal agencies are prohibited from undertaking actions that destroy or adversely modify designated critical habitat. Some species, primarily the cetaceans, which were listed in 1969 under the Endangered Species Conservation Act and carried forward as endangered under the ESA, have not received critical habitat designations.

Federal agencies have an affirmative mandate to conserve listed species (Rohlf 1989). One assurance of this is federal actions, activities or authorizations (hereafter referred to as federal action) must be in compliance with the provisions of the ESA. Section 7 of the ESA provides a mechanism for consultation by the federal action agency with the appropriate expert agency, NOAA Fisheries or USFWS. Informal consultations, resulting in letters of concurrence, are conducted for federal actions that have no adverse affects on the listed species. Formal consultations, resulting in BiOps, are conducted for federal actions that may have an adverse affect on the listed species. Through the BiOps, a determination is made as to whether the proposed action poses jeopardy or no jeopardy of extinction to the listed species. If the determination is that the action proposed, or ongoing, will cause jeopardy, RPAs may be suggested that, if implemented, would modify the action to no longer pose the jeopardy of extinction to the listed species. The RPAs must be incorporated into the federal action if it is to proceed. A BiOp with the conclusion of no jeopardy may contain a series of management measures intended to further reduce negative impacts to the listed species. These management alternatives are advisory to the action agency (50 CFR 402.24(j)). If a likelihood exists of any taking occurring during promulgation of the action, an incidental take statement may be appended to a BiOp to provide for the amount of take that is expected to occur from normal promulgation of the action. An incidental take statement is not the equivalent of a permit to take. The term take under the ESA means "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or attempt to engage in any such conduct" (16 USC 1538(a)(1)(B)).

Twenty-five species occurring in the BSAI and/or GOA groundfish management areas are currently listed as endangered or threatened under the ESA (Table 3.4-1): seven great whales, one pinniped, 13 Pacific salmon, three birds, and one turtle.

In summary, species listed under the ESA are present within the management area. Some may be negatively affected by groundfish fishing, the subject of this Programmatic SEIS federal activity. NOAA Fisheries is the expert agency for ESA-listed marine mammals. The USFWS is the expert agency for ESA-listed seabirds. The proposed action, continuation of the federal groundfish fisheries in the 200-mile EEZ off Alaska, must be in compliance with the ESA.

The material presented in the subsections that follow further explains the ESA and ESA Section 7 consultations that have occurred prior to preparation of this Programmatic SEIS. Sections 3.4.1 and 3.4.2 describe certain listed species present in the management (e.g., action) area. All other ESA-listed species are described in their own independent sections (e.g., marine mammals, seabirds, etc.) in Chapters 3 and 4 of this document.

Section 7 Consultations

Because groundfish fisheries are federally regulated, any negative effects of the fisheries on ESA-listed species or critical habitat, and any takings that may occur are subject to ESA Section 7 consultation. NOAA Fisheries initiates the consultation with itself for marine mammals and anadromous fish and with the USFWS for birds. The resulting letters of concurrence and BiOps are issued to NOAA Fisheries. NPFMC may be invited to participate in the compilation, review, and analysis of data used in the consultations. The determination of whether the action "is likely to jeopardize the continued existence of" endangered or threatened species, or to result in the destruction or modification of critical habitat, however, is the responsibility of either NOAA Fisheries or USFWS. If the action is determined to result in jeopardy, the opinion includes reasonable and prudent measures that are necessary to alter the action to avoid jeopardy. If an incidental take of a listed species is expected to occur under normal promulgation of the action, an incidental take statement is appended to the BiOp.

For all ESA-listed species, Section 7 consultation must be reinitiated if the amount or extent of taking specified in the incidental take statement is exceeded; new information reveals effects of the action that may affect listed species in a way not previously considered; the action is subsequently modified in a manner that causes an effect to listed species that was not considered in the BiOp; or a new species is listed or critical habitat is designated that may be affected by the action.

Section 7 consultations have been done for all the listed species in Table 3.4-1— some individually and some as groups. Below are summaries of species that are not described in their own independent section (e.g., marine mammals, seabirds, etc.), and Section 7 consultations have been included in the descriptions.

3.4.1 Leatherback Turtle (*Dermochelys coriacea)*

Life History and Distribution

Leatherback turtles are the largest sea turtles in the world, reaching a shell length of 1.6 m and a mass of 700 kg. They reach sexual maturity at an estimated age of 13 to 14 years for females and live for more than 30 years (Zug and Parham 1996). Leatherbacks must surface to breathe air, but can stay submerged for 2 hours and dive to 1,000 m. Males do not leave the ocean, but females come ashore on open, sandy beaches to dig nests and lay eggs. Nestlings emerge from the sand at night and attempt to make their way to the sea. Very little is known about the distribution and natural history of these young turtles after they leave their natal beaches.

Leatherback turtles are widely distributed throughout the world's oceans (Ernst and Barbour 1989). In the Pacific Ocean, they range as far north as Alaska and as far south as Chile and New Zealand. In Alaska, leatherback turtles are found as far north as 60°34'N, 145°38'W (Copper River delta) and as far west as the Aleutian Islands (Hodge 1979, Stinson 1984). Leatherback turtles have also been found in the Bering Sea along the coast of Russia (Bannikov *et al.* 1971). The Pacific coast of Mexico is generally regarded as the most important breeding ground for nesting leatherback turtles in the world. No nesting is known to occur in U.S. waters of the Pacific. Nesting is widely reported from the western Pacific, including China, southeast Asia, Indonesia, and Australia.

Leatherback turtles undertake the longest migrations and exhibit the broadest thermal tolerances among sea turtles (NMFS and USFWS 1992). Leatherback turtles have been found in waters ranging from 7° to 27° C in temperature (Shoop and Kenney 1992). They are typically associated with continental shelf habitats and pelagic environments and are sighted regularly in offshore waters at depths greater than 328 ft.

Estimating the population size of this species is especially difficult because individuals are widely dispersed and males never come ashore. Population estimates are usually based on the number of females seen on nesting beaches. These counts are problematic because females frequently change beaches. In spite of the difficulty in censussing their numbers, it is clear that the population of leatherback turtles is declining significantly. The global leatherback turtle population was estimated to number approximately 115,000 adult females in 1980 (Pritchard 1982), but only 34,500 in 1995 (Spotila *et al.* 1996). The Pacific leatherback population appears to be in a critical state of decline. The eastern Pacific leatherback population was estimated to be over 91,000 adults in 1980 (Spotila *et al.* 1996), but is now estimated to number less than 3,000 total adult and subadult animals (Spotila *et al.* 2000). Leatherback turtles have experienced major declines at all major Pacific basin rookeries (Sarti *et al.* 1996, Spotila *et al.* 2000). In the western Pacific, the decline is equally severe. Current nestings at Terengganu, Malaysia, represent one percent of the levels recorded in the 1950s (Chan and Liew 1996).

Trophic Interactions

Leatherback turtles feed predominately on jellyfish and other large planktonic species (siphonophores and salpae) in temperate and boreal latitudes (NMFS and USFWS 1998). There is little information available on their diet in subarctic waters. To a large extent, the oceanic distribution of leatherback turtles may reflect the distribution and abundance of their planktonic prey. Adult leatherbacks do not have many natural predators although killer whales are known to eat adult leatherbacks off the coast of Mexico (Sarti *et al.* 1996). Nestling and juvenile turtles fall prey to a host of bird, mammal, and fish species throughout their range, especially coastal and pelagic sharks.

Wildlife Management Responsibility

NOAA Fisheries and the USFWS share responsibilities at the federal level for the research, management, and recovery of Pacific sea turtle populations under U.S. jurisdiction. The leatherback turtle was listed as endangered under the ESA in June of 1970. NOAA Fisheries and USFWS have created a joint Pacific Sea Turtle Recovery team to develop a recovery plan for the species (NMFS and USFWS 1998). Under the requirements of the ESA, these agencies are responsible for issuing Section 7 consultations (BiOps) for federal actions that may impact the species, such as the BSAI and GOA groundfish FMPs.

Leatherback turtles are classified as Critically Endangered in the International Union for Conservation of Nature's (IUCN) *Red List of Threatened Species* (IUCN 2000), where taxa so classified are considered to be "facing an extremely high risk of extinction in the wild in the immediate future ." In October of 2000, the U.S. ratified the Inter-American Convention for the Protection and Conservation of Sea Turtles. This treaty is the first international agreement dedicated solely to raising standards for the protection of sea turtles.

Past/Present Effects and Management Actions

Direct Mortality: Harvest and Other Intentional Take

Nesting on open, sandy beaches, leatherback turtles are susceptible to a number of human activities including beachfront development that results in habitat loss. In some areas, adults are taken for meat and oil. The poaching of eggs from nests continues in many areas including the U.S. Virgin Islands and Puerto Rico. On some beaches, nearly 100 percent of the eggs laid have been harvested (Eckert 1996). Many of these eggs end up on the black market for sale as aphrodisiacs.

The setting of large mesh nets suitable for turtling is common in the waters off Puerto Rico. Although the practice was outlawed in 1984, it still continues illegally. The nets are intended for hawksbills and green turtles, but leatherbacks occasionally become entangled (NMFS and USFWS 1998).

Direct and Indirect Effects of External Fisheries

Leatherback turtles have been strongly impacted by commercial fisheries. The primary threats are entanglement in fishing gear (e.g., driftnets, longlines, lobster pots, weirs), boat collisions, contamination by oil spills, and ingestion of marine debris (Eckert 1996, Spotila *et al.* 1996, NMFS and USFWS 1998). Although some driftnet fisheries, particularly shrimp trawlers, are required to use Turtle Exclusion Devices, leatherbacks are too big for most commercially available devices and are drowned in nets even if they are equipped with these devices. Spotila *et al.* (2000) state that a conservative estimate of annual leatherback fishery-related mortality (from longlines, trawls, and gillnets) in the Pacific during the 1990s was 1,500 animals. They estimate that this represented about a 23 percent mortality rate (or 33 percent if mortality was focused on the east Pacific population). Based on recent modeling efforts, the leatherback turtle population cannot withstand more than a one percent human-related mortality level, which translates to 150 nesting females (Spotila *et al.* 1996; Spotila, personal communication). The model simulations indicated that leatherbacks could maintain a stable population if both juvenile and adult survivorship remained high, and other life history stages (i.e., egg, hatchling, and juvenile) remained static. Characterizations of this population suggest that it has a very low likelihood of survival and recovery in the wild under current conditions.

Direct and Indirect Effects of the BSAI/GOA groundfish Fisheries

NOAA Fisheries Protected Resources Division (PRD) issued a BiOp in November 2000 on the interaction of leatherback turtles and the BSAI and GOA groundfish fishery (NMFS 2000a). In that document, NOAA Fisheries noted that the GOA groundfish FMP area is at the extreme edge of the leatherback turtle's historic range. They occur generally as stranded animals along the coastlines of southeast Alaska and are not considered to be frequent visitors to the GOA fishing grounds or found in the BSAI FMP area at all. According to NOAA Fisheries, there have been no direct takes of leatherbacks in the commercial fisheries in the BSAI and GOA. No information is available to help NOAA Fisheries assess the potential competition or cascade effects of the fisheries on the trophic level of leatherbacks, either positively or negatively. There is no fishery that is targeting the prey of this species. NOAA Fisheries concludes that the direct and indirect effects of commercial fisheries in the BSAI and GOA on leatherback turtles is negligible and not likely to jeopardize its survival or recovery.

Comparative Baseline

Leatherback turtle populations are in serious decline around the world, largely due to many human-related sources of mortality. All of them must be addressed, if this species is to recover from the brink of extinction (NMFS and USFWS 1998). Although some commercial fisheries have played a major role in the decline of this species, NOAA Fisheries has concluded that the BSAI and GOA groundfish fisheries have negligible effects, if any, on the species (NMFS 2000a).

Status for Cumulative Effects Analysis

Leatherback turtles rarely enter the waters fished by the BSAI/GOA groundfish fisheries and do not appear to be affected in any direct or indirect manner by the fisheries. Since the groundfish fisheries do not contribute to the cumulative effects on the species, leatherback turtles will not be carried forward for analysis in Chapter 4.

3.4.2 Pacific Northwest Salmon

Five species of Pacific salmon, pink (*Oncorhynchus gorbuscha*), chum (*O. keta*), sockeye (*O. nerka*), coho (*O. kisutch*) and chinook salmon (*O. tshawytscha*), as well as steelhead trout (*O. mykiss*) occur in Alaska.

Refer to Section 3.5.2.2 for Pacific salmon life history and trophic interaction information. This section will explain the relationship between the BSAI and GOA groundfish fisheries and Pacific Northwest salmon. For a thorough description of Pacific Northwest salmon distribution, management and past/present effects within its habitat of origin, refer to the NOAA Fisheries Final Programmatic EIS for Pacific Salmon Fisheries Management off the Coasts of southeast Alaska, Washington, Oregon, and California and in the Columbia River Basin (NOAA Fisheries 2003).

Pacific Northwest Salmon Management

Pacific salmon off the Alaska coast are managed under a complex mixture of domestic and international bodies, treaties, regulations, and other agreements. Federal and state agencies cooperate in managing salmon fisheries. The Alaska Department of Fish & Game (ADF&G) manages salmon fisheries within jurisdictional waters where the majority of harvest occurs. Management in the EEZ is the responsibility of the NPFMC. Under Amendment 4 of the Federal Salmon FMP, regulation of the directed salmon fishery occurring in the EEZ off southeast Alaska is deferred to the State of Alaska (NPFMC 1990). Management of Alaska salmon fisheries is based primarily on regional stock groups of each species and on time and area harvesting by specific types of fishing gear. Over 25 different commercial salmon fisheries in Alaska are managed with a special limited-entry permit system that specifies when and what type of fishing gear can be used in each area. These fisheries, extending from Dixon Entrance in southeast Alaska to Norton Sound in the Bering Sea, are allowed to catch salmon in different fisheries, either with drift gillnets, set gillnets, beach seines, purse seines, hand troll, power troll, or fish wheel harvest gear. Sport fishing is limited to hook-and-line, while subsistence fishermen may use gillnets, dip nets, or hook-and-line. Some subsistence harvesting of salmon is also regulated by special permits.

The southeast Alaska salmon fisheries have the largest impact on the Pacific Northwest salmon, relative to other Alaska salmon fisheries. Only southeastern Area A is open to commercial salmon fishing, although there are three minor fisheries in the Yakutat Area D. These salmon fisheries are regulated by ADF&G and adhere to the FMP for the Salmon Fisheries off the Coast of Alaska (NPFMC 1990), the MSA, the Pacific Salmon Treaty (see below), and the ESA when applicable, along with other federal laws. Sport fisheries also occur in southeast Alaska, and are managed by ADF&G. Anglers are required to obtain a fishing license, restrictions vary for each salmon species. ADF&G also monitors subsistence and personal use permits in southeast Alaska.

Salmon fisheries are managed to meet an escapement goal of a certain number of spawners for each river system. Meeting escapement goals is considered equivalent to maintaining healthy stocks. In general, spawners are counted on their way upstream, after their numbers have already been reduced by natural mortality at sea, bycatch at sea, and directed fisheries downstream.

<u>International Management</u>

Some fisheries, including the southeast Alaska chinook, coho, and sockeye fisheries, have harvest limits that are subject to negotiations between the U.S. and Canada under the Pacific Salmon Treaty. This treaty originally signed in 1983 also covers salmon that are intercepted in fisheries that are returning to Idaho, Oregon, and Washington. In recent years, the treaty process was stalled due to disagreements between the two countries on allocations for certain fisheries and species. In 1999, a new harvest agreement was signed. The new treaty specified new harvest limits for both countries. In recent years, the treaty process was stalled due to disagreements between the two countries on allocations for certain fisheries and species. The new agreement provides stability to the fisheries of both countries. The agreements are complex and require continuous coordination between both countries to be successful. The new treaty will expire, unless renewed, in 2008.

On a broader international scope, the management of salmon harvest in the high seas of the North Pacific Ocean from 1957 to 1992 was authorized by the International North Pacific Fisheries Commission (INPFC), and via bilateral and multilateral agreements and negotiations with Taiwan and the Republic of Korea (South Korea). In 1993, the North Pacific Anadromous Fish Commission (NPAFC) was formed to replace the International North Pacific Fisheries Commission. This four-country commission (Canada, Japan, the Russian Federation, and the U.S.) now provides a framework for international cooperation in salmon management and research in the North Pacific Ocean. The NPAFC Convention prohibits high seas salmon fishing and trafficking of illegally caught salmon. Coupled with United Nations General Assembly Resolution 46/215, which bans large-scale pelagic driftnet fishing in the world's oceans, harvesting of Pacific salmon on the high seas, except for illegal fishing, no longer occurs. This allows for effective management control to fully return to the salmon-producing nations.

<u>NOAA Management</u>

There are no GOA FMP amendments that directly address salmon bycatch. However, while PSC limits have not been established for salmon, the timing of seasonal openings for the pollock fisheries in the central and western GOA have been adjusted to avoid periods of high chinook and chum salmon bycatch.

Endangered Species Act

No stocks of Pacific salmon originating from freshwater habitat in Alaska are listed under the ESA. The ESA-listed species or evolutionary significant units (ESUs) that migrate into marine waters off Alaska, originate in freshwater habitat in Washington, Oregon, Idaho, and California. In the marine waters off Alaska, the ESA-listed salmon stocks are mixed with hundreds to thousands of other stocks originating from the Columbia and Willamette Rivers, British Columbia, Alaska, and Asia. The ESA-listed fish are not visually distinguishable from the other, unlisted, stocks. Minimal take of them in the salmon bycatch portion of the fisheries is assumed based on limited abundance, timing, and migration pattern information gleaned from recovery locations of coded-wire-tagged (CWT) surrogate stocks (closely related hatchery stocks that are tagged with CWT). For information on PSC limits and commercial salmon fishery catch limits set in Alaska waters by NOAA Fisheries and ADF&G, see Section 3.5.2.2.

Pacific Northwest Salmonid Past/Present Effects Analysis

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document.

The following direct and indirect effect indicators were identified as potentially having population level effects on Pacific Northwest salmon:

- Catch/bycatch of Pacific Northwest salmon (direct effect).
- Reduced/increased recruitment due to hatchery programs (indirect effect).
- Reduced recruitment due to habitat degradation (indirect effect).
- Reduced/increased recruitment due to climate changes and regime shifts (indirect effect).

The past/present events determined to be applicable to the Pacific Northwest salmon past/present effects analysis include the following:

- Past/Present External Events:
  - State of Alaska directed salmon fisheries (commercial and sport fisheries)
  - Washington, Oregon, California Coast groundfish fisheries (NMFS 1999b)
  - Washington, Oregon and California state salmon fisheries (NMFS 1999b)
  - Alaska subsistence fisheries
  - Foreign fisheries (pre-MSA)
  - Hatchery programs (NMFS 1999b)
  - Habitat degradation (NMFS 1999b)
  - Hydro-development (NMFS 1999b)
  - Climate changes and regime shifts
- Past/Present Internal Events:
  - BSAI and GOA groundfish fisheries

- Past/Present Management Actions:
  - ADF&G management
  - Washington, Oregon, and California state management
  - International agreements
  - Endangered Species Act (Section 7 consultation)
  - Federal, state and local agencies associated with salmon habitat
  - Foreign fisheries management
  - Industry self-imposed management
  - FMP groundfish fisheries management

Washington, Oregon and California State salmon fisheries and groundfish fisheries and salmon hatchery programs have not been brought forward for past/present effects analysis. For a thorough description of these fisheries and their impacts on the salmon, see the November 1999 Endangered Species Act - Reinitiated Section 7 Consultation, BiOp (NMFS 1999b). According to the 1999 BiOp, open Pacific Ocean habitat was not considered a critical habitat to ESA-listed salmon species and special management considerations were not discussed further (58 CFR 68547).

The quality of salmon spawning habitat is influenced by land management practices (e.g., forestry practices, agricultural practices and urbanization) and climatic events (e.g., flooding that scours streams). Several agencies, entities, and groups exert control over watersheds used by spawning salmon. NOAA Fisheries designated critical habitat in 1993 (57 Federal Register [FR] 57051) for the Snake River sockeye, Snake River spring/summer chinook, and Snake River fall chinook salmon. The designations did not include any marine waters, and therefore, does not include any habitat where Alaska groundfish fisheries are promulgated. For a thorough analysis of habitat degradation and hydro-development impacts on Pacific Northwest salmon, see the November 1999 Endangered Species Act - Reinitiated Section 7 Consultation, BiOp (NMFS 1999b).

<u>External Mortality: Catch/bycatch by State of Alaska Directed Salmon Fisheries</u>

The commercial salmon fisheries in southeast Alaska began in the late 1870s, primarily targeting sockeye salmon. Pink salmon began to dominate in early 1900s and has continued to dominate into recent years. Salmon catch has increased since the mid-1970s with more diverse catches of salmon including pink, chum, coho and sockeye salmon. Catches of chinook salmon have been limited in recent years due to harvest limits imposed by the Pacific Salmon Treaty. Trawlers take a majority of the salmon catch in southeast; drift and set gillnet and purse seine fishermen only operate within state waters.

The list of ESA-listed salmon stocks as of 2002 is in Table 3.4-2. Those stocks that are likely to migrate into marine waters off Alaska are highlighted: they include six ESUs of chinook salmon, one ESU of chum salmon, and five ESUs of steelhead (i.e., Snake River fall chinook, Snake River spring/summer chinook, Puget Sound chinook, Upper Columbia River spring chinook, Upper Willamette River chinook, Upper Columbia River spring chinook, Columbia River chum, Upper Columbia River steelhead, Upper Willamette River steelhead, Middle Columbia River steelhead, Lower Columbia River steelhead, and Snake River basin steelhead).

Incidental take of listed salmon species likely to range into Alaskan waters in the southeast Alaskan fisheries are limited by the Pacific Salmon Treaty. Bycatch varies from year to year and is dependent upon abundance of salmon stock and established catch limits. The November 1999 BiOp (NMFS 1999b) determined southeast Alaskan fishery bycatch is not at a level that is likely to jeopardize any of the Pacific Northwest salmon

ESUs. However, ADF&G is still required to implement reasonable and prudent measures under the ESA as follows:

- Management objectives (pre-season and inseason) established for the southeast Alaska fisheries must be consistent with the provision established by the Pacific Salmon Treaty.

- ADF&G must monitor catch and implementation of management measures in the southeast Alaska fisheries.

- ADF&G with NOAA Fisheries Alaska Region and NPFMC chair must sample the southeast Alaska fishery catch to determine stock composition and gather biological information intended to determine fishery-related impacts on listed ESUs.

External Mortality: Alaska Subsistence Fisheries

Harvest of Pacific Northwest salmon by Alaskan and Pacific Northwest subsistence groups probably occurs, although their impacts on the ESA-listed salmon stocks is likely to be minimal.

External Mortality: BSAI and GOA Foreign Groundfish Fisheries (pre-MSA) Bycatch

Although it is impossible to determine the number of Pacific Northwest salmon taken by the BSAI and GOA foreign groundfish fisheries prior to the MSA, it is assumed that bycatch of salmon per region per year was substantially higher than what occurs currently.

Internal Mortality: BSAI and GOA Groundfish Fisheries (post-MSA) Bycatch

Pacific Northwest chinook salmon stocks may compose a larger proportion of GOA bycatch than they do of BSAI bycatch (personal communication with Kate Myers, NOAA Fisheries Auke Bay, 2003). While some Pacific Northwest stocks are listed as endangered or threatened under the ESA (Table 3.4-2), none of the catches observed in Alaska would exceed the incidental take limit of 40,000 fish accepted under ESA Section 7 consultation.

The effects of the BSAI and GOA groundfish fisheries on listed salmon were considered through informal consultations with NOAA Fisheries (February 20, 1992; April 21, 1993; June 7, 1993; and September 22, 1993) and by formal consultations (NMFS 1994, 1995a, and 1999a). Each consultation is summarized below, beginning with the informals and moving through the formals in order of issuance. Informal consultations were done on fishing years 1992 and 1993 (February 20, 1992 and April 21, 1993, respectively), and on BSAI Amendment 28 (June 7, 1993) and GOA Amendment 31 (September 22, 1993).

In the latter two informal consultation memorandums, NOAA Fisheries stated that it was essential that monitoring efforts be continued and that NOAA Fisheries continue to seek additional information regarding potential impacts to listed fish.

The 1994 BiOp was the first formal consultation considering whether continuation of the groundfish fisheries in the BSAI and GOA in 1994 and beyond was likely to jeopardize the continued existence of Snake River sockeye salmon, Snake River spring/summer chinook salmon, or Snake River fall chinook salmon. Assessment of impacts in the BiOp established approaches for evaluating the proposed actions. Using those approaches, effects of the proposed action on the listed species were evaluated. Effects are expressed in terms of numerical catch assessment, base period analysis (1986 to 1990), cumulative effects analysis, and combined effects analysis. For purposes of the analysis, it was assumed that annual bycatch of chinook salmon in 1994 and for the foreseeable future would be 40,000 or fewer fish in each of the BSAI and GOA groundfish fisheries. Relative to the base period analysis question, the assumed maximum bycatch of 40,000 chinook salmon per region per year is substantially less than that which occurred in the foreign and JV fisheries in earlier years. No cumulative effects accruing to the listed species of activities occurring within the action areas are thought to exist (NMFS 1994).

In the BiOp, NOAA Fisheries "determined that it is highly unlikely that any Snake River sockeye salmon are taken in the groundfish fisheries." Based on that, "NOAA Fisheries concluded that the groundfish fisheries are not likely to adversely affect Snake River sockeye salmon and thus will not jeopardize their continued existence." For listed chinook salmon, "NOAA Fisheries concluded that the catch of Snake river spring/summer chinook salmon is unlikely to average more than one fish per year in each region, and that it is highly unlikely than any Snake River fall chinook salmon are taken in the BSAI groundfish fisheries." NOAA Fisheries concluded that the catch of Snake River fall chinook in the GOA groundfish fisheries "is unlikely to average more than five fish per year and may be substantially less." Based on available information, NOAA Fisheries concluded "the groundfish fisheries are not likely to jeopardize the continued existence of any of the ESA-listed salmon" (NMFS 1994). The 1994 BiOp contained four conservation recommendations:

- NPFMC and NOAA Fisheries, Alaska Region should monitor the bycatch of chinook salmon in the groundfish fisheries and take necessary actions to ensure that the bycatch is minimized to the extent possible and in any case does not exceed 40,000 chinook salmon per year in either the BSAI or GOA groundfish fisheries.

- NPFMC and NOAA Fisheries, Alaska Region should improve estimates of the region-of-origin and stock composition of the chinook salmon bycatch by increasing CWT sampling rates as part of the mandatory salmon retention program, collecting and analyzing scale samples, and employing additional stock identification techniques applicable to the problem.

- NPFMC and NOAA Fisheries, Alaska Region should use information collected during the observer monitoring program to identify times and areas of high salmon abundance that could be used to reduce salmon bycatch through regulatory action.

- NPFMC and NOAA Fisheries, Alaska Region should encourage development of incentive programs designed to reduce the bycatch of salmon in the BSAI and GOA groundfish fisheries.

The incidental take statement appended to the BiOp allowed for take of five Snake River fall chinook in the GOA, zero in the BSAI, one take of Snake River spring/summer chinook in the BSAI and GOA fisheries, and zero take of Snake River sockeye in either fishery, per year. As explained above, it is not technically possible to know if any have been taken. Compliance with the BiOp was stated in terms of limiting salmon bycatch per year to under 40,000 fish per year for chinook salmon, and 200 and 100 fish per year for sockeye salmon in the BSAI and GOA fisheries, respectively (NMFS 1994). Keeping salmon bycatch within these limits is presumed to reduce the probability of incidental catch of listed salmon to near-zero.

Three terms and conditions were to be implemented by NOAA Fisheries, Alaska Region to carry out the reasonable and prudent measures established under the incidental take statement.

- NOAA Fisheries, Alaska Region shall continue to implement the current observer program for the BSAI and GOA groundfish fisheries. Mothership processor vessels or shoreside processing facilities that process 1,000 mt per day or more must have a NOAA Fisheries certified observer on board the vessel or at the facility each day it receives or processes groundfish. Motherships or shoreside processing facilities that process 500 to 1,000 mt per day must have a NOAA Fisheries certified observer for at least 30 percent of the days it receives or processes fish. Catcher processor or catcher vessels 125 ft LOA or longer are required to have a groundfish observer onboard for 100 percent of their fishing days. Vessels from 60 to 124 ft LOA are required to have a groundfish observer aboard for 30 percent of their fishing days. Vessels under 50 ft LOA are not required to carry groundfish observers.

- NOAA Fisheries, Alaska Region shall monitor the year-to-date bycatch estimates of chinook salmon on a weekly basis. If it is anticipated inseason that the annual total bycatch of chinook salmon will exceed 40,000 fish in either the BSAI or GOA fisheries, NPFMC and NOAA Fisheries, Alaska Region should reinitiate consultation.

- NOAA Fisheries, Alaska Region shall estimate and report the bycatch of sockeye salmon annually as part of the post season analysis. If the annual bycatch of sockeye exceeds 200 fish in the BSAI or 100 fish in the GOA fishery, consultation shall be reinitiated (NMFS 1994).

A second BiOp was issued in 1995 (NMFS 1995a), to reflect new information pertinent to the assumption that the bycatch of chinook salmon in the BSAI and GOA would not exceed 40,000 fish per year in either region. The estimated bycatch of chinook in the BSAI area was 44,487 in 1994, and revised estimates for the number of chinook salmon taken in the years 1991-1993 were greater than 40,000 fish per year (in 1993, 46,014; 1992, 41,955; and 1991, 48,880), thus exceeding the terms of the incidental take statement. The purpose of the reinitiated consultation was to consider whether this new information affected the previous conclusion that the BSAI groundfish fisheries were not likely to jeopardize the continued existence of Snake River spring/summer or fall chinook salmon. Conclusions regarding impacts to sockeye salmon the BSAI and GOA groundfish fisheries and chinook salmon in the GOA were not reviewed because the new information did not pertain to those species or areas.

In the 1995 BiOp conclusions, NOAA Fisheries reiterated its previous conclusions that NPFMC regulated groundfish fisheries were not likely to adversely affect Snake River sockeye salmon and thus could not jeopardize their continued existence. Based on the available information, NOAA Fisheries also concluded that the groundfish fisheries were not likely to jeopardize the continued existence of Snake River spring/summer chinook salmon or Snake River fall chinook salmon (NMFS 1995a).

The first conservation recommendation contained in the January 19, 1994, BiOp was revised (as reproduced below). The remaining conservation recommendations (numbers 2 through 4) remain in effect.

1. NPFMC and NOAA Fisheries, Alaska Region should monitor the bycatch of chinook salmon in the groundfish fisheries and take necessary actions to ensure that the bycatch is minimized to the extent possible and in any case does not exceed 55,000 chinook per year in the BSAI fisheries or 40,000 chinook salmon per year in the GOA fisheries. (NMFS 1995a).

The second of the three terms and conditions to the incidental take statement was modified (as follows) to reflect the increase in the estimate of chinook bycatch in the BSAI.

2. NOAA Fisheries, Alaska Region shall monitor the year-to-date bycatch estimates of chinook salmon on a weekly basis. If it is anticipated inseason that the annual total bycatch of chinook salmon will exceed 55,000 fish in the BSAI fisheries or 40,000 fish in the GOA fisheries, NPFMC and NOAA Fisheries, Alaska Region should reinitiate consultation. (NMFS 1995a).

A third BiOp was issued on December 22, 1999 (NMFS 1999a). The reasons for reinitiation of consultation were the new (1997 and 1999) listings of a number of salmon ESUs under the ESA (Table 3.4- 2). NOAA reviewed the status of Snake River fall chinook, Snake River spring/summer chinook, Puget Sound chinook, Upper Columbia River spring chinook, Upper Willamette River chinook, Lower Columbia River chinook, Upper Columbia River steelhead, Upper Willamette River steelhead, Middle Columbia River steelhead, Lower Columbia River steelhead, and Snake River basin steelhead; the environmental baseline for the action area; the effects of the proposed fishery; and the cumulative effects. After the review, NOAA Fisheries determined that the BSAI and GOA groundfish fisheries subject to the BSAI FMP groundfish fishery and the GOA groundfish FMP, as proposed, was not likely to jeopardize their continued existence.

The incidental take statement appended to the BiOp allowed for take of 55,000 chinook salmon in the BSAI and 40,000 chinook salmon in the GOA. No take of Hood Canal summer run chum or Lower Columbia River chum was expected in BSAI or GOA groundfish fisheries. NOAA Fisheries does not anticipate that the proposed fisheries will take any coho from the southern Oregon/northern California coast or central California ESUs, any Snake River or Lake Ozette sockeye salmon, or any steelhead ESUs (NMFS 1999a).

Two reasonable and prudent measures were provided to minimize and reduce the anticipated level of incidental take associated with NPFMC-regulated groundfish fisheries:

1. NPFMC and NOAA Fisheries, Alaska Region shall ensure there is sufficient NOAA Fisheries-certified observer coverage such that the bycatch of chinook salmon and other salmon in the BSAI and GOA groundfish fisheries can be monitored on an in season basis.

2. NPFMC and NOAA Fisheries, Alaska Region shall monitor bycatch reports inseason to ensure that the bycatch of chinook salmon does not exceed 55,000 fish per year in the BSAI fisheries and 40,000 fish per year in the GOA fisheries (NMFS 1999a).

In order to be exempt from the prohibitions of Section 7 of the ESA, the specified agencies must comply with the following terms and conditions, which implement the reasonable and prudent measures described above. These terms and conditions are non-discretionary.

- NOAA Fisheries, Division of Sustainable Fisheries (Alaska Region) shall provide an annual report to the PRD (Alaska Region) that details the results of its monitoring of bycatch reports during each fishing season. These reports shall be submitted in writing within one month of the new fishing year (February 1) and will summarize all statistical information based on a January 1 through December 31 fishing year (NMFS 1999a).

The reasonable and prudent measures, with their implementing terms and conditions, are designed to minimize the impact of incidental take that might result from the proposed action. If during the course of the groundfish fishery this level of incidental take is exceeded, the additional level of take would represent new information requiring reinitiation of consultation and review of the reasonable and prudent measures provided above.

Section 7(a)(1) of the ESA directs federal agencies to utilize their authorities to further its purposes by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary measures suggested to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to develop additional information, or to assist federal agencies in complying with their obligations under ESA Section 7(a)(1). NOAA Fisheries believes the following conservation recommendations are consistent with these obligations, and therefore should be implemented by NPFMC and NOAA Fisheries:

- NPFMC and NOAA Fisheries, Alaska Region should improve estimates of the region-of-origin and stock composition of the chinook salmon bycatch by increasing CWT sampling rates as part of the mandatory salmon retention program, collecting and analyzing scale samples, and employing additional stock identification techniques applicable to the problem.

- NPFMC and NOAA Fisheries, Alaska Region should use information collected during the observer monitoring program to identify times and areas of high salmon abundance that could be used to reduce salmon bycatch through regulatory action.

- NPFMC and NOAA Fisheries, Alaska Region should encourage development of incentive programs designed to reduce the bycatch of salmon in NPFMC groundfish fisheries (NMFS 1999a).

In order for NOAA Fisheries to be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, NOAA Fisheries requested notification of the implementation of any conservation recommendations.

External Reduced Recruitment: Commercial Seal Harvesting and Commercial Whaling

Currently, the effects of rebounding seal and whale populations on salmon mortality, especially chinook salmon, are not well understood. Commercial whale and seal harvest were banned in 1972 with the passing of the Marine Mammal Protection Act (MMPA). Presently, foreign and subsistence whale harvests are monitored by the International Whaling Commission (IWC) (NMFS 1999b).

External Increased/Reduced Recruitment: Climate Changes and Regime Shifts

Various climate factors, including ENSO, have had different affects on the Pacific Northwest salmon populations. Included climate factors are severe flooding, droughts, and change in ocean productivity. In the Pacific Northwest, researchers have found that salmon may be responding to the Pacific Decadal Oscillation, a 20- to 30-year cycle of climate conditions and ocean productivity (Mantua *et al.* 1997). Response to these climate changes depends upon the stock and its timing and distribution. Overall, it appears that Pacific Northwest salmon may have been negatively affected in this phase of the cycle. One example is the Puget Sound chinook stocks which dropped to half of their 1974 to 1977 broods in 1979 (Cramer *et al.* 1999).

Pacific Northwest Salmon Comparative Baseline

Southeast salmon stocks reached their highest levels in the 1980s and 1990s (Rogers *et al.* 1987, Wertheimer 1997); spawning escapement has increased since the 1970s and have reached escapement objectives in recent years. Of the 407 chinook stocks harvested in the southeast, 81 percent are classified as not threatened, and 15 percent are special concern or at risk (Slaney *et al.* 1996). Large portions of the southeast chinook harvest originate from the Columbia River upriver bright chinook, Middle Columbia River bright chinook, and north-migrating Oregon coastal chinook; these stocks are considered stable (NMFS 2002b). Chinook stocks listed under the ESA make up a small portion of the southeast harvest, and nearly all coho salmon harvested originate from Alaskan streams (Weitkamp *et al.* 1995).

For current status information on West Pacific Coast and Columbia River Basin salmon stocks, refer to the Final Programmatic EIS for Pacific Salmon Fisheries Management off the Coasts of southeast Alaska, Washington, Oregon, and California, and in the Columbia River Basin, Chapter 3 – Affected Environment, Section 3.4 and 3.5 (NOAA Fisheries 2003).

Pacific Northwest Salmon Cumulative Effects Analysis Status

Due to the limited impacts of the BSAI and GOA groundfish fisheries on Pacific Northwest salmon, these stocks will not be brought forward for cumulative effects analysis. For up-to-date information on the status of these stocks and their habitat, visit the NOAA Fisheries Northwest Region website at http://www.nwr.noaa.gov. Comments on the Northwest Region Draft Programmatic EIS for Pacific Salmon Fisheries Management off the Coasts of southeast Alaska, Washington, Oregon, and California, and in the Columbia River Basin were due November 22, 2002. BiOps, FMPs, EISs, and other informative documents involving these stocks are also available on the Northwest Region website.

3.5 Target Groundfish Species

3.5.1 Target Groundfish Species

Bering Sea and Aleutian Islands Target Groundfish Species

This section presents descriptions of major target species, summarizing important life history traits, their habitat environment, prey base, past effects, stock management, stock assessment, and current status and trends of the stocks. Additional information on life history and habitat features for each major groundfish species can be found in the following three documents: 1) EA of the EFH (NPFMC 1998a), 2) EFH assessment report for the groundfish resources of the BSAI region (NPFMC 1998b), and 3) EFH assessment report for the groundfish resources of the GOA region (NPFMC 1998c).

3.5.1.1 BSAI Walleye Pollock

Life History and Distribution

Walleye pollock (*Theragra chalcogramma)* is the most abundant groundfish species within the EBS. It is widely distributed throughout the NPO in temperate and subarctic waters (Wolotira *et al.* 1993). Pollock is a semidemersal schooling fish, which becomes increasingly demersal with age. Approximately 50 percent of female pollock reach maturity at age 4 years, at a length of approximately 40 centimeters (cm). Pollock spawning is pelagic and takes place in the early spring on the outer continental shelf. In the EBS, the largest concentrations occur in the southeast, north of Unimak Pass (Kendall *et al.* 1996). Pollock are comparatively short-lived (Hollowed *et al.* 1997, Wespestad and Terry 1984), with a maximum recorded age of around 22 years. Table 3.5-1 summarizes the biological and reproductive traits and habitat associations of pollock at its different life stages.

Trophic Interactions

The diet of pollock in the EBS and GOA has been studied extensively (Dwyer 1984, Lang and Livingston 1996, Livingston 1991b, Livingston and deReynier 1996, Livingston *et al.* 1993, Yang and Nelson 2000). These studies have shown that pollock feed on euphausiids and calanoid copepods and other crustaceans. As the pollock increase in size, their diet begins to include juvenile pollock and other teleosts. Other fish consumed by pollock include juveniles of Pacific herring, Pacific cod, arrowtooth flounder, flathead sole, rock sole, yellowfin sole, Greenland turbot, Pacific halibut, and Alaska plaice. On the shelf area, the contribution of these other fish prey to the diet of pollock tends to be very low, (i.e., usually less than 2 percent by weight of the diet) (Livingston 1991b, Livingston and deReynier 1996, Livingston *et al.* 1993). However, in the deeper slope waters, deep-sea fish (myctophids and bathylagids) are a relatively important diet component (12 percent by weight), along with euphausiids, pollock, pandalid shrimp, and squid (Lang and Livingston 1996).

The cannibalistic nature of pollock, particularly adults feeding on juveniles, is well documented by field studies in the EBS (Bailey 1989, Dwyer *et al.* 1987, Livingston 1989b, 1991b, Livingston and deReynier 1996, Livingston and Lang 1997, Livingston *et al.* 1993). Cannibalism rates in the EBS vary depending on year, season, area, and predator size (Dwyer *et al.* 1987, Livingston 1989b, Livingston and Lang 1997). Rates are highest in autumn, next highest in summer, and lowest in spring. Cannibalism rates by pollock larger than 40 cm are higher than those by pollock smaller than 40 cm. Most pollock cannibalized are age-0 and age-1 fish, with most age-1 pollock being consumed northwest of the Pribilof Islands where most age-1 pollock are found. Pollock larger than 50 cm tend to consume most of the age-1 fish. Smaller pollock consume mostly age-0 fish. Although age-2 and age-3 pollock are sometimes cannibalized, the frequency of occurrence of these age groups in stomach contents is quite low. Laboratory studies have shown the possibility of cannibalism among age-0 pollock (Sogard and Olla 1993a). Field samples have confirmed this interaction, but so far this interaction appears not to be very important. Cannibalism by pollock in the Aleutian Islands region has not yet been documented (Yang 1996).

Field and laboratory studies on juvenile pollock have examined behavioral and physical factors that may influence vulnerability of juveniles to cannibalism (Bailey 1989, Olla *et al.* 1995, Sogard and Olla 1993a and 1993b). Although it had previously been hypothesized that cannibalism occurred only in areas with no thermal stratification, these recent studies indicate that age-0 pollock can move below the thermocline into waters inhabited by adults. All age-0 fish tend to inhabit surface waters for feeding at night, but larger age-0 fish tend to move below the thermocline during the day. Most cannibalism may occur during the day. If food availability is high, all sizes tend to stay above the thermocline, but when food resources are low, even small age-0 fish move toward the colder waters as an energy-conserving mechanism. Thus, prediction of cannibalism rates may require knowledge of the thermal gradient and food availability to juveniles in an area.

Other groundfish predators of pollock include Greenland turbot, arrowtooth flounder, Pacific cod, Pacific halibut, and flathead sole (Livingston 1991a, Livingston and deReynier 1996, Livingston *et al.* 1993). These species are some of the more abundant groundfish in the EBS, and pollock constitute a large proportion of the diet for many of them. Other less abundant species that consume pollock include Alaska skate, sablefish, Pacific sandfish, and various sculpins (Livingston 1989a, Livingston and deReynier 1996). Small amounts of juvenile pollock are even eaten by small-mouthed flounders such as yellowfin sole and rock sole (Livingston 1991a, Livingston and deReynier 1996, Livingston *et al.* 1993). Age-0 and age-1 pollock are the targets of most of these groundfish predators, with the exception of Pacific cod, Pacific halibut, and Alaska skate, which may consume pollock ranging in age from age-0 to greater than age-6, depending on predator size.

Pollock is a significant prey item of marine mammals and birds in the EBS and has been the focus of many studies. Studies suggest that pollock is a primary prey item of northern fur seals when feeding on the shelf during summer (Sinclair *et al.* 1994 and 1997). The main sizes of pollock consumed by fur seals range from 3 to 20 cm for age-0 and age-1 fish. Older age groups of pollock may appear in the diet, during years of lower abundances of young pollock (Sinclair *et al.* 1997). Pollock has been noted as a prey item for other marine mammals including northern fur seals, harbor seals, fin whales, minke whales, and humpback whales. The importance of pollock in these species' diets has not been well-defined due to the limited number of collected stomach samples from the EBS (Kajimura and Fowler 1984). Pollock are among the most common prey in the diet of spotted seals and ribbon seals which feed on pollock in the winter and spring in the areas of drifting ice (Lowry *et al.* 1997).

Pollock can be the dominant component in the diets of northern fulmars, black-legged kittiwakes, common murres, and thick-billed murres, while red-legged kittiwakes tend to rely more heavily on myctophids (Hunt *et al.* 1981a, Kajimura and Fowler 1984, Shuntov 1993, Springer *et al.* 1986). Age-0 and age-1 pollock are consumed by these bird species, and the dominance of a particular pollock age-group in the diet varies by year and season.

Aydin *et al.* (2002) have conducted a mass-balance food-web model comparing the western and eastern Bering Sea (EBS) ecosystems. These researchers have found that on a per-unit-area measure, the western Bering Sea is more productive than the EBS. Pollock is a keystone species in both ecosystems, although the pathways of energy flow differ (Figure 3.5-1).

BSAI Pollock Management

Although stock structure of Bering Sea pollock is not well defined (Wespestad 1993), the U.S. portion of Bering Sea pollock is considered to form three stocks for management purposes: the EBS stock found on the EBS shelf from Unimak Pass to the U.S.-Russia Convention line; the Aleutian Islands region stock found on the Aleutian Islands shelf region from 170°W to the U.S.-Russia Convention line; and the central Bering Sea-Bogoslof Island pollock stock, which is a mixture of pollock that migrate from the U.S. and Russian shelves to the Aleutian Basin. In the Russian EEZ, the pollock population forms two stocks, one centered in the Gulf of Olyutorski (western Bering Sea stock) and the other, northern stock located along the Navarian shelf from 171°E to the U.S.-Russian Convention line. Researchers are currently investigating Bering Sea pollock stock structure using genetic analyses (Ianelli *et al.* 2001b).

Under current management, the general impacts of fishing mortality within BSAI FMP Amendment 56/GOA FMP Amendment 56 (Amendment 56/56) ABC and overfishing level (OFL) definitions discussed in Appendix B, apply to pollock in the BSAI. Pollock in the EBS fall within Tier 1a of the ABC/OFL definitions, and the Aleutian Islands and central Bering Sea-Bogoslof Island regions fall within Tier 5. In the Aleutian Islands region, no directed pollock fishing is allowed under current management, a strategy that eliminates the risk of overfishing the stock (Ianelli *et al.* 2001b).

In the EBS, based on Tier 1a, reliable estimates of biomass ($B_{40\%}$) and fishing mortality ($F_{40\%}$) are required to determine OFL and ABC values, respectively. Under the definitions and current stock conditions, the OFL value equals 3,530,000 mt for 2003 and the ABC for EBS pollock equals of 2,330,000 mt. The TAC will be set below this ABC value (Ianelli *et al.* 2002b).

The central Bering Sea-Bogoslof region stock is managed under Tier 5, and requires that the maximum permissible ABC is 75 percent of the product of the natural mortality rate (0.30) and biomass. Therefore, the ABC value for 2003 is 34,000 mt. The OFL is the product of the natural mortality rate and biomass, equating to 45,300 mt in 2003. However, following Alaska Fisheries Science Center (AFSC) recommendations, the 2003 ABC value is reduced to 4,074 mt (Ianelli *et al.* 2002b).

The Aleutian Island region stock is also managed under Tier 5. The 2002 Aleutian Islands bottom trawl survey yielded an estimated biomass of 175,280 mt, leading to an ABC of 39,438 mt. The OFL based on the 2002 biomass estimates is 52,585 mt (Ianelli *et al.* 2002b). See Table 3.5-2 for status and catch specifications (mt) of walleye pollock in the BSAI in recent years

In the EBS, pollock are assessed with an age-structured model incorporating fishery data and two types of survey catch data and age compositions. Bottom trawl surveys are conducted annually from June through August and provide a consistent time series of adult population abundance from 1982 to 2002. Echo-integrated-trawl (EIT) surveys are run every three years (typically) and provide an abundance index on more pelagic (typically younger) stock segments. Both surveys separate their catches into their relative age compositions prior to analyses. Fishery data include estimates of the total catch by area/time strata and the average body weight-at-age and relative age composition of the catch within each stratum. The results of the statistical model applied to these data are updated annually and presented in the BSAI pollock chapter of NPFMC's BSAI Stock Assessment and Fishery Evaluation (SAFE) report. Also included are separate analyses on pollock stocks in the Aleutian Islands and central Bering Sea-Bogoslof Island areas. In the Aleutian Islands, information comes from observer data and triennial bottom trawl surveys. The bottom trawl data may not provide an accurate view of pollock distribution, because a significant portion of the pollock biomass may be pelagic and not available to bottom trawls and much of the Aleutian Islands shelf is untrawlable due to rough bottom. These analyses are constrained by data limitations and are presented relative to the status of the EBS stock. This analysis focuses specifically on the EBS stock with the view that extensions to these other areas are equally applicable. The stock assessment is reviewed by both the BSAI Groundfish Plan Team and NPFMC's Scientific and Statistical Committee (SSC) before being presented to NPFMC.

The trend in more recent modeling efforts (Honkalehto 1989, Livingston 1993, 1994a and 1994b) has been to examine cannibalism using more standard stock assessment procedures such as virtual population analysis or integrated catch-age models such as Methot's (1990) synthesis model. The purpose is to obtain better estimates of juvenile pollock abundance and mortality rates, which can improve our knowledge of factors affecting recruitment of pollock into the commercial fishery at age-3 years. Effects of variable temperatures on pollock abundance and distribution have also been taken into account by modeling efforts in recent years (Ianelli *et al.* 2002b).

Past/Present Effects Analysis

The geographic scope for the BSAI pollock past/present effects analysis is the same as the BSAI FMP management area (Figure 1.2-2). The temporal scope for this effects analysis begins in 1958 with the start of intensive foreign fishing of pollock in the Bering Sea and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-3 provides a summary of the pollock past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on pollock:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to removal of predators, cannibalism, spatial/temporal concentration of fishery catch/bycatch, roe stripping, fishery selectivity of juveniles, and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, marine pollution and oil spills, introduction of exotic species, and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, marine pollutants and oil spills, introduction of exotic species, and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and oil spills was not brought forward for analysis. The NOAA National Status and Trends (NS&T) program has produced a summary of Alaska marine environmental quality through its research and sampling projects, including the Mussel Watch Project and the Benthic Surveillance Project. This report is available on the NOAA website at: <http://ccmaserver.nos.noaa.gov/NSandT/BrochurePDFs/Alaska.pdf>. This report was produced in 1999 and will be updated periodically. The document reports that the source of major and trace elements in sediments are likely from local mineralogy rather than human contaminants. The presence of chemicals such as *para*-dichlorodephenyltrichloroethane (DDTs) and metabolites found in fish liver and mussel tissue has shown a decreasing trend over time (1986-1995), probably due to the ban on those chemicals. No obvious trend in contaminant concentrations could be determined from the mussel tissue program over the duration of the monitoring program (Cantillo *et al.* 1999). Furthermore, international, federal and state laws and enforcement agencies are in place to monitor marine pollution.

Change in important habitat and prey availability due to the introduction of exotic species by way of ballast water and climate changes and regime shifts has not been brought forward since the impacts on pollock in the Bering Sea as a result of these events have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation on the occurrences of unusual species in the BSAI.

The past/present events determined to be applicable to the pollock past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1958-1976)
  - Russian pollock fishery (1976-present)
  - State of Alaska groundfish fisheries
  - State of Alaska herring fisheries
  - Subsistence and personal use fisheries
  - Commercial whaling
  - Seal harvests
  - Cannibalism
  - Climate changes and regime shifts
  - Marine pollution and oil spills

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1991)
  - JV groundfish fisheries (1980-1991)
  - Domestic groundfish fisheries (1988-1991)

- Past/Present Management Actions
  - Bilateral agreements
  - IWC management
  - MMPA of 1972
  - Convention of the Conservation and Management of the Pollock Resources
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions

- Steller sea lion protection measures
- Preliminary groundfish FMPs (pre-MSA)
- FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1958-1976)

The earliest documented exploratory pollock fishery ran from 1933-1937 with a Japanese fleet fishing off Bristol Bay. Foreign groundfish fishing in the EBS did not resume until 1954 after the signing of the peace treaty between the U.S. and Japan in 1952. Following the overfishing of yellowfin sole in 1958, the Japanese pollock fishery developed, making up approximately 80 percent of the total Japanese catch by 1970 (Forrester *et al.* 1974).

The Russian fishery that would later develop into the Russian pollock fishery started in the EBS in 1967 along the outer continental shelf from Unimak Pass to northwest of the Pribilof Islands. This fishery focused on pollock by 1971 and has remained predominantly the same to the present. Russia has also trawled for pollock along the Aleutian Islands in recent years, although the effort has been relatively low (Chitwood 1969, Forrester *et al.* 1974, Office of Enforcement and Surveillance 1965, 1967-1970, and Law Enforcement Division 1974, 1975, and 1977).

A fleet from the Republic of Korea targeting pollock around the eastern Aleutian Islands, west of the Pribilof Islands, and the EBS began exploratory fishing in 1968, reaching its peak in 1976. A small Taiwanese fishery focusing on pollock and flounder and consisting of one or two independent stern trawlers began in 1974 along the continental shelf edge west and southwest of the Pribilof Islands (Office of Enforcement and Surveillance 1967-1970, Law Enforcement and Surveillance Division 1971, 1973, 1974, 1975, and 1977).

By 1972, foreign catch of pollock in the EBS had peaked at over 1.8 million mt. In 1973, a bilateral agreement between the U.S. and Japan and the then U.S.S.R. (Soviet Union) included annual catch quotas, which reduced the catch of pollock to 1.2 million by 1976. However, each country was still responsible for monitoring its catch quotas, the only internationally acceptable arrangement at the time. With the passing of the MSA and the increase of U.S. and JV groundfish fisheries, foreign groundfish catch in the Bering Sea had dropped below 1 million mt by 1985 (NPFMC 2002a).

Although large removals of pollock occurred during the foreign fisheries, there does not appear to be a lingering effect on the BSAI pollock populations.

External Russian Pollock Fishery (1967-present)

Harvests by Russian fishing vessels and Russia-licensed vessels from third countries of pollock originating from the EBS pollock stock are considered insufficient in magnitude to push the fishing effort close to the overfishing level threshold. Evidence that this may be occurring stems from the research showing that the pollock of the EBS range westward beyond the U.S. EEZ into waters under the jurisdiction of the Russian Federation and mix with Russian pollock stocks before returning to U.S. waters (Wespestad *et al.* 1996). Moreover, a Russian and a Russia-licensed fishery occurs on the U.S.-Russian Convention Line of 1867 targeting pollock stocks that straddle the boundary line (Pautzke 1997).

Internal Foreign, JV and Domestic Groundfish Fisheries (1976-present)

The U.S. began fishing for pollock in 1980 in the EBS in conjunction with foreign fisheries called JV groundfish fisheries. The U.S. fisheries worked with over 28 different countries, including Japan, South Korea, Poland, the Soviet Union, Portugal, and Iceland. The catch history of pollock in the EBS and Aleutian Islands from 1979-2002 is detailed in Ianelli *et al.* 2002b.

BSAI FMP Amendments 1, 2, 4, 6, and 11 were proposed partially in response to concerns that the domestic annual harvest (DAH) was being dominated by the foreign and JV groundfish fisheries. Since 1977, the pollock fishery in the BSAI evolved from an entirely foreign-harvested fishery to a predominantly domestic-harvested fishery. Yet the volume of fish delivered to foreign groundfish processors continued to largely exceed the amount delivered to domestic groundfish shore-based processors. In 1986, nearly 95 percent of the total 886,000 mt DAH was taken in JV groundfish operations.

Instead of relegating JV groundfish operations to specific areas and prohibiting roe-stripping, BSAI FMP Amendment 11 adopted a split-season proposal to reduce the amount of pollock harvested by the JV groundfish fisheries during the spawning season. This action was designed to prevent the further development of a pollock roe fishery, as well as allow for the expansion of the domestic groundfish processing fishery. Although there have been large removals of pollock by the JV and past domestic fisheries, there does not appear to be a lingering effect on the BSAI pollock populations.

By 1991, foreign groundfish fishing had been phased out of the EEZ and in that year the entire BSAI groundfish harvest (2,126,000 mt) was taken by 391 U.S. vessels. NPFMC has since prohibited the practice of roe-stripping of pollock. With the advent of the U.S. EEZ, DAH levels have ranged between 0.9 million to 1.5 million mt annually, with an average harvest of 1.2 million mt annually (Ianelli *et al.* 2001b).

Change in Reproductive Success

External Foreign Groundfish Fisheries (1958-1976)

Bycatch in the foreign groundfish fisheries has not been well documented; however, it is assumed that bycatch of pollock consisted mainly of juveniles. Few observers were allowed on Soviet vessels under the bilateral agreements, and the Soviets were well-known for under-reporting their catches of target species and, presumably, bycatch as well.

The fisheries could potentially have had a positive effect on the pollock recruitment by reducing the adult pollock biomass. Since mature pollock are known to cannibalize on juvenile pollock, a reduction of mature pollock biomass could actually increase juvenile recruitment.

Internal Foreign Groundfish Fisheries (1976-1991)

Foreign groundfish vessels began fishing the "Donut Hole," the international fishing zone of the Bering Sea, in the mid-1980s. Foreign groundfish vessels from Japan, South Korea, Poland, and China moved into the Donut Hole to fish pollock because they were displaced from U.S. waters by the growth of U.S. domestic groundfish fisheries. Pollock catch increased rapidly, peaking in 1989 at 1.45 million mt, and then declined more rapidly. A moratorium on fishing since 1993 has been observed by all countries including the U.S. and

Russia. The Convention on the Conservation and Management of the Pollock Resources in the central Bering Sea, which outlines the fishing moratorium and establishes an approach for future fishing operations if the stock is to become sustainable, was signed on June 16, 1994, by representatives of the People's Republic of China, and the Republic of Korea, and the Russian Federation (Colson 1994 as referenced by Pautzke 1997). The past foreign fisheries are considered to have overfished the Donut Hole and Bogoslof region pollock populations. Furthermore, these fisheries have changed the spatial/temporal distribution of those pollock populations through the spatial/temporal concentration of the fisheries.

In 1992, NPFMC passed BSAI FMP Amendment 17, establishing the Bogoslof District which was intended to protect the Aleutian Basin pollock stock associated with the Donut Hole. This amendment allowed for a separate TAC for pollock in this subarea, thereby providing regulatory protection of Aleutian Basin pollock during spawning to help rebuild the stock.

The fisheries could potentially have had a positive effect on the pollock recruitment by reducing the adult pollock biomass. Since mature pollock are known to cannibalize on juvenile pollock, a reduction of mature pollock biomass could actually increase juvenile recruitment.

External Russian Pollock Fishery (1967-present)

Scientists and managers are presently concerned that strong to moderate year-classes may reside in the Russian EEZ adjacent to the U.S. EEZ as juveniles. It has been acknowledged that potential large catches and discards of juvenile pollock may be occurring in the Russian EEZ and may effect the EBS stocks that migrate to that area, possibly requiring the reduction of U.S. TACs (Wespestad *et al.* 1996).

Internal Foreign, JV and Domestic Groundfish Fisheries (1976-present)

Fishery Selectivity

BSAI pollock are caught as bycatch in other directed fisheries (e.g., mostly trawl Pacific cod, rock sole and yellowfin sole fisheries). However, because they occur primarily in well-defined aggregations, the impact of this bycatch is typically minimal. The directed pollock fishery has a very low bycatch rate with discards of 10 percent or less since 1992. Most of the discards in the pollock fishery are juvenile pollock, or pollock too large to fit filleting machines. In the pelagic trawl fishery, the catch is almost exclusively pollock, but in the past bottom trawl pollock fishery the bycatch of other species has been higher. Bycatch in the directed fisheries has decreased in recent years due to regulatory amendments and self-imposed actions taken by the fishing industry (Ianelli *et al.* 2002b).

The EBS pollock fishery primarily harvests mature pollock. The 50 percent selectivity corresponds to the age of 50 percent maturity, age-4 years. Fishery selectivity increases to a maximum around age 7 to 8 and then declines. The reduced selectivity for older ages is due to pollock becoming increasingly demersal with age. Younger pollock form large schools and are semi-demersal, thereby being easier to locate by fishing vessels. Immature fish (ages-2 and -3) are usually caught in low numbers. Generally the catch of immature pollock increases when strong year-classes occur and the abundance of juveniles increases sharply. This occurred with the 1989 year-class, the second largest year-class on record. Juvenile bycatch increased sharply in 1991 and 1992 when this year-class was age-2 and -3 (Ianelli *et al.* 2001b).

BSAI FMP Amendment 13 established the Observer Program in the BSAI partially in an effort to reduce bycatch on non-target species. BSAI FMP Amendments 9, 11a, and others established reporting requirements to better track the catch and bycatch of target and non-target species in the BSAI.

BSAI FMP Amendment 49, passed in 1998, requires fishermen to land all pollock harvested, including juveniles and other unmarketable fractions. Because there is little value in small fish, it is hoped that fishermen will avoid areas where juveniles are caught in large concentrations, thus avoiding the economic costs of landing an unmarketable part of the resource. The overall intent of the program is to reduce bycatch and discarding of juveniles, and thus help the stocks remain robust. This measure has dramatically reduced overall discards of groundfish.

In both the BSAI and GOA, cumulative impacts of fishing mortality on age composition are influenced by the selectivity of the fishery. The current age composition of the stocks reflects a fished population with a long catch history. In any given year, the age composition of the stock is influenced by previous year-class strength. The reproductive potential of the stock in a given year depends on the biomass of spawners, as modified by abiotic and biotic conditions. Thus, the average age of unfished populations is likely to have varied interannually due to oceanic and climate conditions. The NOAA Fisheries' Fisheries Oceanography Coordinated Investigations (FOCI) (discussed below in GOA) and Coastal Ocean Program's southeast Bering Sea Carrying Capacity (SEBSCC) regional study focus research on improving understanding of mechanisms underlying annual production of pollock stocks in the GOA and EBS. NOAA's long-term goal is to improve the ability to assess quantitatively the long-term impact of commercial removals of adult pollock on future recruitment by combining the findings of process-oriented research programs such as FOCI and SEBSCC with NOAA Fisheries' ongoing studies of species interactions, fish distributions, and abundance trends. This Programmatic SEIS does not seek to evaluate the range of mean ages that could have occurred in the absence of fishing.

The fishery effects on age-at-maturity and fecundity of pollock stocks are a potential concern; investigations regarding this issue began with a new study in 2002 (Ianelli *et al.* 2002b).

Roe Fishery

BSAI Amendment 14 was passed in 1991 to address the pollock roe fishery and the following issues:

1. Roe stripping is a wasteful use of the pollock resource;

2. Roe stripping causes unintended allocation of pollock TAC among seasons and industry sectors;

3. Roe stripping may adversely affect the ecosystem;

4. Roe stripping may adversely affect the future productivity of the stock; and,

5. Roe stripping increases the difficulty of accurately monitoring the pollock TAC for inseason management.

In 1993, regulations were further tightened to close loopholes that could have potential undermined the intent of the roe stripping regulations (58 FR 57752).

The fisheries could potentially have a positive effect on the pollock recruitment by reducing the adult pollock biomass. Since mature pollock are known to cannibalize on juvenile pollock, a reduction of mature pollock biomass could actually increase juvenile recruitment.

Spatial/Temporal Concentration of Catch

The directed fishery for the BSAI pollock is conducted by catcher processors and catcher vessels using pelagic trawl gear, although bottom trawl gear was used prior to 1996. The season has traditionally been broken into two parts; a roe season during early winter, and a surimi (imitation crab) and filet season during the second half of the year. The pollock "A season" fishery, which historically focused on roe-bearing females, is concentrated mainly north and west of Unimak Island (Ianelli *et al.* 1998) and along the 100 m contour between Unimak and the Pribilof Islands. Following the closures of the Donut Hole and Bogoslof District in 1993, the fishing effort was further shifted eastward toward the southeast fishing grounds (Area 51). The 1999-2002 fishing seasons have seen a more equal take of males and females, with only slightly more females taken in this fishery in recent years. The pollock "B season" takes place west of 170°W (northwest fishing grounds, Area 52). Catches in this area have declined since 1990, although there has been a slight increase in recent years (2000-2001). Furthermore, there has been a decline in catch within the Steller sea lion conservation areas, except for the 2002 fishing season (Ianelli *et al.* 2002b).

The past JV and past domestic fisheries have overfished the Donut Hole and Bogoslof region pollock populations. Furthermore, these fisheries are found to have changed the spatial/temporal distribution of those populations through the spatial/temporal concentration of the fisheries.

Management of the pollock fishery has changed recently as NOAA Fisheries and NPFMC have taken measures to reduce the possibility of competitive interactions with Steller sea lions. In 1999, this led to further closures of critical habitat to pollock fisheries in the Aleutian Islands region, the EBS, and the GOA. A total of 210,350 km^2 (54 percent) of critical habitat was closed to the pollock fishery. Following 1998, catches of pollock and the proportion of seasonal TAC caught in the Steller Sea Lion Conservation Area and Steller sea lion critical habitat have been reduced. In the Aleutian Island region, directed fishery removals of pollock have been prohibited. Management has also attempted to disperse the fisheries temporally and spatially by means of seasonal TAC releases to further reduce fishery related impacts on the sea lion population of the EBS shelf (Ianelli *et al.* 2001b).

<u>External Commercial Whaling and Seal Harvests</u>

Whaling is identified as having a past beneficial effect on the recruitment of BSAI pollock stocks. Pollock has been noted as a prey item for fin whales, minke whales, and humpback whales (see Sections 3.8.12, 3.8.14, and 3.8.15). By removing the large predators, pollock recruitment is favored. In the EBS, past seal harvests are identified common prey in the diet of spotted seals and ribbon seals, which feed on pollock in the winter and spring in the areas of drifting ice (Lowry *et al.* 1997, see Section 3.8.5 and 3.8.8). The whale and seal harvests are no longer of concern with the banning of commercial whaling by the IWC and protection of marine mammals through the MMPA passed in 1972 (see Section 3.8). The continued harvest of marine mammals by subsistence users is unlikely to have a significant impact on the BSAI pollock population.

External Cannibalism

Adult pollock are known to cannibalize on juvenile pollock, especially on age-0 and age-1 pollock, the age classes in which cannibalism appears to be the most important source of predation mortality. Predation mortality rates for juvenile pollock are not constant, as assumed in most population assessment models, but vary across time mainly due to changes in predator abundance, but perhaps also because predators feed more heavily on more abundant year-classes. The decline in pollock recruitment observed at high pollock spawning biomasses appears to be due to cannibalism. There also appears to be an environmental component to juvenile pollock survival (Wespestad and Dawson 1992), wherein surface currents during the first three months of life may transport larvae to areas more favorable to survival (e.g., away from adult predators or in areas more favorable for feeding). Estimates of total amount of pollock consumed by important groundfish predators show that cannibalism is the largest source of removal of juvenile pollock by groundfish predation (Livingston 1991a, Livingston and deReynier 1996, Livingston *et al.* 1993).

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of pollock. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of the species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an in-depth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions, because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries.

Change in Prey Availability

External Foreign Groundfish Fisheries (1958 - 1976) and Internal Foreign, JV, and Domestic Groundfish Fisheries (1976 - present)

The fisheries bycatch of forage species consumed by pollock is unlikely to have a population-level effect. BSAI FMP Amendment 13 established the Observer Program in the BSAI partially in an effort to reduce bycatch on non-target species. BSAI FMP Amendments 9, 11a, and others established reporting requirements to better track the catch and bycatch of target and non-target species in the BSAI, and Amendment 36 was established to protect forage species from being marketed, thereby protecting the availability of pollock prey species.

External State of Alaska Groundfish Fisheries and Herring Fisheries

Bycatch of forage species in the BSAI State of Alaska groundfish fisheries is minimal and is unlikely to have population-level effects on the BSAI pollock stocks. Since pollock prey on a number of different species in addition to herring, it is unlikely that State of Alaska herring fisheries would have a significantly adverse impact on pollock prey availability.

External Subsistence and Personal Use Fisheries

Subsistence and personal use fishermen are known to fish a number of different species, including Pacific herring, Pacific cod, Pacific halibut, and many other target species. However, due to the small extent and localization of these users, it is unlikely that these fisheries would have a significantly adverse impact on pollock prey availability.

External Climate Change and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the prey availability of pollock. In general, a shift toward warmer waters favors recruitment and survival of pollock. In 1998/1999, the Pacific Decadal Oscillation shifted to negative, with cooler-than-average northeastern Pacific surface temperatures and warmer-than-average central Pacific surface temperatures. The Ocean Surface Current Simulations (OSCURS) model has also shown stronger on-shelf drift in the EBS from April-June in 1998, 1999, and 2002 (Ianelli *et al.* 2002b); indicating favorable conditions for pollock.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect they have on the important prey species of pollock.

Change in Important Habitat

External Foreign and JV Groundfish Fisheries (1958 - 1991)

Bottom trawl gear is the focus of most of the concerns regarding spawning habitat disruption in the NPO. Beginning in about 1960, the Bering Sea experienced rapid and intensive development of commercial bottom trawl fisheries. Between 1973 and 1997, a total of 412,040 records of observed bottom trawls were obtained from the NOAA Fisheries Observer Database (NORPAC). Note that the number of recorded observed bottom trawls is only a small portion of the total number of bottom trawls during that time period. Because gear information is not available, bottom trawls by the JV groundfish (1980–1990; 101,376 trawls) and foreign groundfish (1973–1989; 127,959 trawls) fleets were selected based on the presence of benthic organisms (e.g., crab, snails, and seastars) in the catch (see Section 3.6 for more information).

Due to intensive bottom trawling by the foreign groundfish and JV groundfish fisheries, a bottom trawling ban was initiated in pollock spawning habitats by the 1977 BSAI Preliminary FMP. Several of the foreign groundfish fisheries also imposed restrictions on themselves to reduce potential adverse effects on pollock spawning habitats.

External Climate Change and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the habitat suitability of pollock. In general, a shift toward warmer waters favors recruitment and survival of pollock. In 1998/1999, the Pacific Decadal Oscillation shifted to negative, with cooler-than-average northeastern Pacific surface temperature and warmer-than-average central Pacific surface temperatures. The OSCURS model has also shown stronger on-shelf drift in the EBS from April-June in 1998, 1999, and 2002 (Ianelli *et al.* 2002b); indicating favorable conditions for pollock.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of pollock.

Internal Domestic Groundfish Fisheries (1976 - present)

Bottom trawls by the domestic groundfish trawl fleet from 1986 to 1997 resulted in 182,705 records of observed bottom trawls obtained from the NORPAC. Note that the actual total number of unrecorded bottom trawls is much larger.

To minimize the potential interaction with other groundfish species and to reduce the magnitude of bottom disturbance, the domestic pollock fishery converted to mainly pelagic gear by 1996. Several industry-imposed restrictions also reduced bottom disturbance through modification of fishing gear. The BSAI FMP Amendment 57 went into effect in the 1999 and 2000 seasons, prohibiting the pollock fishery from using non-pelagic gear. Pelagic trawl gear, when used in mid-water, has no known direct effects on the substrate. Pelagic trawl gear can also be fished on the bottom, and sometimes is; however, the pelagic trawls used off Alaska are generally designed to fish downward from the depth of the doors, which are not designed for contact with the seafloor, although the footropes can come in contact with, and affect the bottom (see Section 3.6).

The 1991–1995 period saw broad implementation of closures to further protect Steller sea lions. For example, NOAA Fisheries closed areas year-round to trawling within 10 nm of 37 Steller sea lion rookeries, and to within 20 nm during the pollock A season (January 20 to April 15) around five rookeries in the BSAI. There were comparable closures in the GOA. These trawl closures indirectly protect pollock habitat, as well as protecting Steller sea lion habitat (Ianelli *et al.* 2001b).

BSAI FMP Amendments 55 and 65 were proposed in order to identify EFH, minimize practicable adverse effects on habitat from the fishery, and encourage conservation of Habitats of Particular Concern (HAPC) for all target species.

BSAI Pollock Comparative Baseline

The EBS bottom trawl surveys show an increasing trend in pollock abundance during the 1980s, due to strong 1978, 1982, and 1984 year-class recruitment. The population remained at a high and stable level from 1991 to 1995. As these strong year-classes were replaced by weaker year-classes, a sharp decrease in population resulted (1996), followed by an increase to the present. Most recently, there appears to be a higher-than-average year-class for 1995 and 1996; prior to that, the 1992 year-class was very high. The abundance of these year-classes is evident from the EIT and bottom trawl surveys, in addition to the extensive fishery age composition data that have been collected. The selectivity of the fishery has cumulative impacts on the age composition due to fishing mortality. The fishery has tended to exhibit variable selectivity over time, but generally targets fish age-5 years and older (Ianelli *et al.* 2001b). The estimated 2002 age composition of EBS pollock from the stock assessment model is shown in Figure 3.5-2.

The statistical catch-age model exhibits a high level of exploitable biomass (age-3+) from 1982 to 1988, with a peak occurring in 1985, followed by a decline until 1991. Since then, exploitable biomass has varied around 10 million mt (Ianelli *et al.* 2002b).

The EBS pollock stock is neither overfished, nor approaching an overfished condition. The stock assessment model indicates that the 2003 age-3+ biomass is 11,100,000 mt, higher than the previous year's assessment. The 2002 bottom trawl and EIT surveys both show an increase in pollock biomass from the 2001 estimates, with 16 and 18 percent increases, respectively (Ianelli *et al.* 2002b).

Since the Aleutian Island and central Bering Sea-Bogoslof Island regions are managed under Tier 5, it is not possible to determine whether those stocks are overfished or approaching an overfished condition. However, the 2002 bottom trawl survey estimates indicate a 65 percent increase in biomass compared to the 2000 survey in the Aleutian Island region. Note that the increase in the 2002 survey biomass may be also be attributed to survey techniques and timing. The 2002 hydroacoustic survey of the Bogoslof Island region reported a biomass estimate of 227,000 mt (Ianelli *et al.* 2002b).

BSAI Pollock Cumulative Effects Analysis Status

The BSAI pollock will be brought forward for cumulative effects analysis.

3.5.1.2 BSAI Pacific Cod

Life History and Distribution

Pacific cod (*Gadus macrocephalus*) is a demersal species that occurs on the continental shelf and upper slope from Santa Monica Bay, California through the GOA, Aleutian Islands, and EBS to Norton Sound (Bakkala 1984). The Bering Sea represents the center of greatest abundance, although Pacific cod are also abundant in the GOA and Aleutian Islands. GOA, EBS, and Aleutian Island cod stocks are genetically indistinguishable (Grant *et al.* 1987), and tagging studies show that cod migrate seasonally over large areas (Shimada and Kimura 1994).

In the late winter, Pacific cod converge in large spawning masses over relatively small areas. Major aggregations occur between Unalaska and Unimak Islands, southwest of the Pribilof Islands, and near the Shumagin group in the western GOA (Shimada and Kimura 1994). Spawning takes place in the sublittoral–bathyal zone near the bottom, the area of the continental shelf and slope about 40 to 290 m deep. The eggs sink to the bottom and are somewhat adhesive (Hirschberger and Smith 1983). Table 3.5-4 summarizes the biological and reproductive traits and habitat associations of Pacific cod at its different life stages.

Pacific cod reach a maximum recorded age of 19 years. In the BSAI, 50 percent of Pacific cod is estimated to reach maturity by the time they reach 67 cm in length, or an age of about 5 years (Thompson and Dorn 1999). The same length in the GOA stock corresponds to an age of about 7 years (Thompson *et al.* 1999).

Trophic Interactions

Pacific cod is an opportunistic feeder that feeds both in the water column and in benthic areas (Yang and Nelson 2000). In the BSAI and GOA, in terms of percent occurrence in stomach contents, the most important items were polychaetes, amphipods, and crangonid shrimp. In terms of numbers of individual organisms consumed, the most important items were euphausiids, miscellaneous fish, and amphipods. In terms of weight of organisms consumed, the most important items were pollock, fishery offal, and yellowfin sole. Small Pacific cod were found to feed mostly on invertebrates, while large Pacific cod are mainly piscivorus (Livingston 1991b). In studies conducted on GOA Pacific cod, polychaetes and cephalopods were the most frequently found invertebrates in stomach contents. However, pandalid shrimp were more important in terms of percentage of total stomach contents weight. GOA Pacific cod also consumed large amounts of tanner crabs (Yang and Nelson 2000). Predators of Pacific cod include Pacific halibut, salmon shark, northern fur seals, Steller sea lions, harbor porpoises, various whale species, and tufted puffins (Westrheim 1996).

Pacific Cod Management

Pacific cod in the BSAI is currently managed under Tier 3a of NPFMC's ABC and OFL definitions (Appendix B). Management under Tier 3a requires reliable estimates of projected biomass, $B_{40\%}$, $F_{40\%}$ (for ABC), and $F_{35\%}$ (for OFL). Under Tier 3a, the maximum permissible ABC depends on the relationship of projected female spawning biomass to $B_{40\%}$. The 2002 assessment projected a 2003 female spawning biomass of 423,000 mt, essentially unchanged from the 2001 assessment's projection for 2002 corresponding to a maximum permissible 2003 ABC of 278,000 mt. NPFMC adopted a 2003 ABC of 223,000 mt, identical to the 2002 ABC and about 20 percent below the maximum permissible value. The 2003 OFL for the BSAI stock is 324,000 mt, up 10 percent from the 2002 OFL (Thompson and Dorn 2002) (Table 3.5-2).

Beginning with the 1993 BSAI SAFE report (Thompson and Methot 1993), a length-structured synthesis model (Methot 1990) has formed the primary analytical tool used to assess Pacific cod. No formal assessment model exists for the Aleutian Islands portion of the BSAI stock. Instead, results from the EBS assessment are inflated proportionally to account for the Aleutian Islands region fish.

Annual trawl surveys in the EBS and triennial (recently, biennial) trawl surveys in the Aleutian Islands are the primary fishery-independent sources of data for Pacific cod stock assessments (Thompson and Dorn 2002, Thompson *et al.* 2002). Other available data include catch size compositions and biomass by gear, for the years 1978 through the early part of 2002. Within each year, catches are divided according to three time periods: January-May, June-August, and September-December. This particular division, which was suggested by participants in the EBS fishery, is intended to reflect actual intra-annual differences in fleet operation (e.g., fishing operations during the spawning period may be different than at other times of year). Four fishery size composition components were included in the likelihood functions used to estimate model parameters: the January-May (early) trawl fishery, June-December (late) trawl fishery, the longline fishery, and the pot fishery. In order to account for differences in selectivity between mostly foreign, mostly domestic, and very recent fisheries, the fisheries data were split into pre-1989, 1989-1999, and post-1999 eras in the EBS. In addition to the fishery size composition components, likelihood components for the size composition and biomass trend from the bottom trawl surveys were included in the model. All components were weighted equally.

Quantities estimated in the most recent stock assessments include parameters governing the selectivity schedules for each fishery and survey in each portion of the time series, parameters governing the length-at-age relationship, population numbers at age for the initial year in the time series, and recruitments in each year of the time series. Given these quantities, plus parameters governing natural mortality, survey catchability, the maturity schedule, the weight-at-length relationship, and the amount of spread surrounding the length-at-age relationship, the stock assessments reconstruct the time series of numbers at age and the population biomass trends (measured in terms of both total and spawning biomass).

The model around which the Pacific cod assessments are structured uses an assumed survey catchability of 1.0 and an assumed natural mortality rate of 0.37 (see Appendix B). Several previous assessments included statistical analyses of the uncertainty surrounding the true values of the survey catchability and natural mortality rate. These analyses of uncertainty led to a risk-averse adjustment factor of 0.87 which is multiplied by the maximum permissible F_{ABC} to obtain the recommended F_{ABC}. Other outputs of the assessments include projections of biomass and harvest under a variety of reference fishing mortality rates.

BSAI Pacific Cod Past/Present Effects Analysis

The geographic scope for the BSAI Pacific cod past/present effects analysis is the same as the BSAI FMP management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1864 when the BSAI domestic fishery begins and ends in 2002, the most recent year for which a stock assessment is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-5 provides a summary of the BSAI Pacific cod past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on BSAI Pacific cod:

- Mortality due to catch/bycatch and marine pollutants and oil spills (direct effect).

- Change in reproductive success due to fishery selectivity of juveniles, spatial/temporal concentration of catch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, introduction of exotic species, marine pollution and oil spills, and climate changes and regime shifts (indirect effect).

- Change in important habitat due to impacts of fishery gear, marine pollutants and oil spills, introduction of exotic species and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species by way of ballast water and climate changes and regime shifts has not been brought forward since the impacts on Pacific cod in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the Pacific cod past effects analysis include the following:

- Past/Present External Events
  - Subsistence and personal use
  - Foreign groundfish fisheries (1964-1976)
  - State of Alaska crab bait fishery
  - IPHC longline bait fishery
  - Marine pollution and oils spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1988-1991)
  - Domestic groundfish fisheries (1864-1950; 1981 - present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the Pacific cod fishery. Amendments discussed in Section 3.2 which impact the target fisheries as a whole are not repeated here.

Mortality

External Subsistence and Personal Use

The earliest fisheries for groundfish in the EBS and Aleutian Islands were the Native subsistence fisheries. They are an important part of the life of Native people, and dependence on demersal species of fish may have been critical to their survival in periods of the year when other sources of food were scarce or lacking. Fishing often takes place in near-shore waters utilizing such species as Pacific cod, Pacific halibut, rockfish, and other species. These small-scale subsistence fisheries have continued through to the present time, although there is likely no impact on Pacific cod at a population-level (NPFMC 2002a).

External Foreign Groundfish Fisheries (1964-1976)

During the early 1960s, a Japanese longline fishery harvested BSAI Pacific cod for the frozen fish market. Beginning in 1964, the Japanese trawl fishery for pollock expanded and Pacific cod became an important bycatch and an occasional target species when concentrations were detected during pollock operations (NPFMC 2002a).

The Soviet groundfish fishery that would later develop into the Soviet pollock fishery targeted Pacific cod, rockfish, pollock and various flatfish species north of Dutch Harbor beginning in 1968. In 1969, the fishery became a year-round operation peaking in late winter when fishing vessels from the herring and flounder fishery joined the fleet. The emphasis of the fishery shifted mainly to pollock in 1971 (NPFMC 2002a).

Catches of Pacific cod in the EBS increased steadily in the earlier years of the fishery to reach levels of more than 50,000 mt by 1968. Annual catches remained relatively stable for several years thereafter, ranging around 50,000 mt with the largest catch of 70,000 mt taken in 1970. Catches in the Aleutian Island region were not recorded until the late 1960s, followed by a slight increase, probably due to better identification of Pacific cod in bycatch, although catch remained relatively low throughout the foreign engagement there (NPFMC 2002a).

The foreign fisheries contributed to fishing mortality in the BSAI. However, the foreign fisheries are thought to have had no observable effect on the BSAI Pacific cod populations.

<u>External State of Alaska Crab Bait Fisheries and IPHC Longline Bait Fisheries</u>

The State of Alaska crab bait fisheries and the IPHC longline bait fisheries contributed to fishing mortality in the BSAI through removal of Pacific cod as bycatch and removal to be used in the fisheries as bait. The influence of these removals is noted as adverse.

<u>Internal JV and Domestic Groundfish Fisheries (1864-present)</u>

The first commercial venture for bottomfish occurred in 1864 when a single schooner fished for Pacific cod in the Bering Sea (Cobb 1927). The cod fishery did not commence on a regular annual basis until 1882. This domestic groundfish fishery continued until 1950 when demand for cod declined and economic conditions caused the fishery to be discontinued (Alverson *et al.* 1964). Fishing areas in the EBS were from north of Unimak Island and the Alaska Peninsula to Bristol Bay (Cobb 1927). Vessels operated from home ports in Washington and California and from shore stations in the eastern Aleutian Islands. Canadian vessels also participated in the cod fishery to a limited extent.

The early domestic cod fishery reached its peak during World War I when the demand for cod was high. Numbers of schooners operating in the fishery ranged from 1-16 prior to 1915 and increased to 13-24 in the period from 1915 to 1920. Estimated catches during the peak of the fishery ranged annually from 12,000-14,000 mt (Pereyra *et al.* 1976). Numbers of vessels in the fishery declined following 1920 until the fishery was terminated in 1950. From 1930-1958, annual catch was less than 200 mt, then rose sharply to about 4,900 mt in 1963, and back down to 450 mt in 1977. The decline in catch since 1963 resulted from reduced abundance and restrictions on the fishery. In years of high production, the catch was split about evenly between Canadian and U.S. vessels up until 1972, after which the U.S. share was larger. There was no catch reported in the Aleutian area before 1960 (NPFMC 2002a). The catch history of Pacific cod in the EBS and Aleutian Islands regions is detailed in Thompson and Dorn 2002.

By 1981, a U.S. domestic groundfish trawl fishery and several JV groundfish fisheries had again begun operations in the BSAI. The foreign and JV sectors dominated catches through 1988, but by 1989 the domestic groundfish sector was dominant. The foreign and JV sectors had been displaced entirely by 1991.

Presently, the Pacific cod stock is exploited by a multiple-gear fishery, including trawl, longline, pot, and jig components (Thompson and Dorn 2001).

Allocation of the BSAI Pacific cod TAC among gear types began in 1993. Amendment 24 to the BSAI FMP established an explicit allocation of the Pacific cod TAC between gear types. The percentage allocations for the 1994, 1995, and 1996 fishing seasons were: trawl gear 54 percent, fixed gear 44 percent, and jig gear 2 percent. At that time, NPFMC was in the initial stages of developing its Comprehensive Rationalization Plan, which emphasized the allocation as a stabilizing mechanism and bridge to overall comprehensive rationalization (NPFMC 2002a).

Because FMP Amendment 24 Pacific cod allocations were scheduled to expire at the end of 1996, NPFMC placed discussion of this issue on the December 1995 meeting agenda, with the intent that an amendment be prepared to allow an allocation beyond 1996. At the December 1995 meeting, NPFMC identified changes which had taken place in the Pacific cod fishery since Amendment 24 went into effect on January 1, 1994. These changes were viewed as biological, economic, and regulatory in nature. Problems identified by NPFMC included compressed fishing seasons, periods of high bycatch, waste of resource, and new entrants competing for the resource due to crossovers allowed under NPFMC's Moratorium Program. NPFMC identified the need for management measures to ensure that the cod TAC was harvested in a manner which reduced discards in the target fisheries, reduced PSC mortality, reduced non-target bycatch of cod and other groundfish species, took into account the social and economic aspects of variable allocations, and addressed impacts of the fishery on habitat. In addition, the amendment would continue to promote stability in the fishery as NPFMC continues on the path towards comprehensive rationalization (NPFMC 2002a).

Beginning in 1997, Amendment 46 to the BSAI groundfish FMP allocated the TAC for BSAI Pacific cod among jig gear, trawl gear, and fixed gear (hook-and-line and pot). It reserved two percent of the TAC for jig gear, 51 percent for fixed gear, and 47 percent for trawl gear. The amendment also split the trawl apportionment between catcher vessels and catcher processors 50/50, but it did not split the fixed gear allocation between hook-and-line and pot vessels.

In October 1999, NPFMC approved BSAI FMP Amendment 64, which split the fixed gear allocation of Pacific cod between the hook-and-line catcher processors, hook-and-line catcher vessels, and pot sectors in the BSAI. NPFMC allocated 80 percent of the fixed gear share of the Pacific cod TAC to hook-and-line catcher processors, 0.3 percent to hook-and-line catcher vessels, 1.4 percent to pot and hook-and-line catcher vessels less than 60-foot length overall, and 18.3 percent to pot vessels. The amendment was approved by the Secretary of Commerce in July 2000, and implemented by final rule on August 24, 2000 (65 FR 51553) (NPFMC 2002a).

Amendment 64 became effective on September 1, 2000. At the time NPFMC approved Amendment 64, it acknowledged that a further split among the pot sector may be necessary to ensure the historical harvest distribution among pot catcher processors and pot catcher vessels in the BSAI Pacific cod fishery. Concern was expressed that the pot sector needed the stability of a direct gear allocation, as had been implemented for the hook-and-line catcher processors and catcher vessels under Amendment 64. However, because the public had not been given notice that this action might be taken under Amendment 64, NPFMC decided to delay action specific to the pot sector and include the proposal in a follow-up amendment (BSAI FMP Amendment 68) (NPFMC 2002a).

Further changes to the BSAI cod fishery occurred in April 2000 when NPFMC approved BSAI FMP Amendment 67. Amendment 67 requires that vessels fishing with hook-and-line and pot gear that are participating in the BSAI Pacific cod fishery must qualify for a Pacific cod endorsement, which would be part of the participant's license under the LLP. Eligibility for a cod endorsement is based on past participation in the BSAI fixed gear fisheries during specific combinations of the years 1995-1999. Amendment 67 effectively granted exclusive access to longtime participants in the BSAI fixed gear cod fishery, and thus reduced the number of allowable participants, including the number of eligible pot vessels. This amendment was approved by the Secretary on November 14, 2001, and the implementing regulations were in place for the 2003 fishing season (NPFMC 2002a).

An analysis of Amendment 68 (further allocation of Pacific cod among pot gear sectors) was initially reviewed by NPFMC in February 2001 and then was made available for public review with recommended revisions by NPFMC. However, because of the potential implications of Amendment 67 and the uncertainty of implications related to management measures being developed to protect the Steller sea lion, NPFMC decided to delay final action on Amendment 68 pending resolution of these issues. With both Secretarial approval of Amendment 67 and completion of the Steller Sea Lion Protection Measures Final SEIS in November 2001, NPFMC scheduled final action for Amendment 68 in June 2002. A draft EA/Regulatory Impact Review (RIR)/Initial Regulatory Flexibility Analysis (IRFA) was released for public review on May 14, 2002 (NPFMC 2002a). However, at its June 2002 meeting, NPFMC voted to take no action on BSAI FMP Amendment 68 partly due to the potential implications of the Pacific cod endorsement required under BSAI Amendment 67 and partly because BSAI Amendment 64 was scheduled to expire after the 2003 fishery anyway, meaning that continuation or modification of Pacific cod allocations among the hook-and-line and pot gear sectors in the BSAI would require a new amendment.

Past JV and pre- and post- MSA domestic fisheries contributed to the fishing mortality in the BSAI, however there are no observable lingering effects on the Pacific cod populations.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1964-1976)

Fishery Selectivity

In 1969 and 1970, the Soviet groundfish fishery targeted on arrowtooth flounder, sablefish, and pollock with bycatches of Pacific cod, rockfish, and other bottomfish. Data regarding the amount of bycatch and the age of the fish caught is not available; however, it is assumed that bycatch of juvenile Pacific cod took place. Whether fishery bycatch of juveniles has had an effect on the Pacific cod population is unknown, although it does not appear to have had a lingering adverse effect on the present Pacific cod population.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of Pacific cod. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin

(1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries.

<u>Internal JV and Domestic Groundfish Fisheries (1864-present)</u>

Fishery Selectivity

Pacific cod are caught as bycatch and discarded in the Pacific cod fishery and other domestic groundfish trawl fisheries, including the fisheries for pollock, yellowfin sole, and rock sole in the EBS and in the shallow water flatfish, arrowtooth flounder, and flathead sole fisheries in the Aleutian Island trawl fisheries. Since 1998 (BSAI FMP Amendment 49), discarding of Pacific cod has been prohibited except for fisheries in which Pacific cod has a bycatch only status. BSAI FMP Amendments 9, 11a, 13 and others have been designed to limit bycatch and improve reporting of target and non-target species in the BSAI.

Spatial/Temporal Concentration of Catch/Bycatch

The Pacific cod fishery has changed recently due to management measures instituted to reduce possible adverse impacts on the western population of Steller sea lions. Some of these measures attempted to distribute catch more evenly throughout the year. On average during the period 1998-2000, 81 percent of annual trawl catch, 60 percent of annual longline catch, and 82 percent of annual pot catch was taken from January to May in the Bering Sea, while 89 percent of the annual trawl catch, 69 percent of annual longline catch and 89 percent of the annual pot catch was taken from January to May in the Aleutian Islands. The attempted redistribution of Bering Sea catch appears to have been at least somewhat successful, with January to May trawl, longline, and pot catches reduced to 64 percent, 43 percent and 71 percent of their respective year-end totals in 2001. Correspondingly, fishery activity increased during the remainder of the year in the Bering Sea. The Aleutian Islands fisheries saw comparatively little change in temporal distribution, with the most significant change taking place in the pot fishery, where the January to May catch decreased from 89 percent of the year-end total in 1998-2000 to 73 percent in 2001 (Thompson and Dorn 2002).

Change in Prey Availability

<u>External Foreign Groundfish Fisheries (1964-1976)</u>

Foreign past fisheries in the BSAI have had an adverse impact on prey availability for large Pacific cod. Large Pacific cod are mainly piscivorus consuming pollock ranging in age from age-0 to greater than age-6 depending on predator size. However, due to the opportunistic nature of Pacific cod, it is unlikely that the fisheries would have had a population-level effect. No observable lingering negative effects are apparent in the present Pacific cod populations.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse with respect to prey availability. In general, a shift toward warmer waters appears to favor recruitment and survival of Pacific cod. As described in Section 3.10.1.5 of the Programmatic SEIS, when the Aleutian Low was weak, resulting in colder water, shrimp dominated the catches. When the Aleutian Low was strong, water temperatures were higher, and the catches were dominated by Pacific cod, pollock, and flatfishes.

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of small Pacific cod.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of Pacific cod.

Internal JV and Domestic Groundfish Fisheries (1864-present)

Past JV fisheries in the BSAI have also had a negative impact on prey availability. However, as stated above, due to the opportunistic nature of Pacific cod, it is unlikely that these past fisheries have had a population-level effect on these stocks. There is no observable lingering negative impacts on the present Pacific cod population.

Change in Important Habitat

External Foreign Groundfish Fisheries (1964-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability has been negatively affected by the intensity of the past foreign fisheries; however, the effects are not considered to have had a lingering influence on Pacific cod populations.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse with respect to habitat suitability. In general, a shift toward warmer waters appears to favor recruitment and survival of Pacific cod. As described in Section 3.10.1.5 of this Programmatic SEIS, when the Aleutian Low was weak, resulting in colder water, shrimp dominated the catches. When the Aleutian Low was strong, water temperatures were higher, and the catches were dominated by Pacific cod, pollock, and flatfishes.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the habitat suitability of Pacific cod.

Internal JV and Domestic Groundfish Fisheries (1864-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability has been adversely affected by the intensity of the past JV fisheries; however, the effects are not considered to have had a lingering influence on Pacific cod populations. BSAI FMP Amendments 55 and 65 are designed to identify EFHs, minimize practicable adverse effects on habitat, and encourage conservation. Furthermore, domestic (post-MSA) bottom trawl fisheries have been limited by regulations and FMP amendments (BSAI FMP Amendments 20, 55, 57, 65 and Steller sea lion conservation measures).

BSAI Pacific Cod Comparative Baseline

The EBS shelf trawl surveys indicate that the Pacific cod biomass increased steadily from 1978 to 1983 and remained at relatively constant levels from 1983 to 1989. Biomass estimates peaked in 1994 and decreased steadily through 1998. Biomass estimates remained steady in the 520,000 to 620,000 mt range from 1998-2000, and increased by 57 percent in 2001 to 830,479 mt, which is very likely overestimated. The 2002 estimate is 616,923 mt. The 2002 Aleutian Islands survey shows a decline from the 2000 biomass estimates at 82,853 mt (Thompson and Dorn 2002).

The stock assessment model indicates a relatively steady decline in age-3+ biomass from 1987 to the present, with the lowest estimate since 1980 occurring in 2001. The female spawning biomass estimates also show a steady decline from 1987 to 2000 with a slight increase in 2001 and 2002, although recent years' estimates are still the lowest since 1981. Regardless, model projections indicate that the BSAI stock is neither overfished, nor approaching an overfished condition (Thompson and Dorn 2002).

BSAI Pacific Cod Cumulative Effects Analysis Status

BSAI and GOA Pacific cod will be brought forward for cumulative effects analysis.

3.5.1.3 BSAI Sablefish

Life History and Distribution

Sablefish (*Anoploma fimbria*) are found from northern Mexico to the GOA, westward to the Aleutian Islands, and into the Bering Sea (Wolotira *et al.* 1993). They are often found in gullies and deep fjords generally at depths greater than 200 m. Sablefish observed from a manned submersible were found on or within 1 m of the bottom (Krieger 1997). There appear to be two populations of sablefish: the Alaska population which inhabits waters near Alaska and northern British Columbia and the southern or west coast population which inhabits waters off of southern British Columbia, and Washington, Oregon, and California. Mixing of these populations occurs off southwest Vancouver Island and northwest Washington (McDevitt 1990, Saunders *et al.* 1996, Kimura *et al.* 1998). Studies have shown sablefish to be highly migratory for at least part of their life cycle (Heifetz and Fujioka 1991, Maloney and Heifetz 1997), and substantial movement between the BSAI and the GOA has been documented (Heifetz and Fujioka 1991). Thus, sablefish in Alaskan waters are assessed as a single stock (Sigler *et al.* 2001a).

Spawning is pelagic at depths of 300 to 500 m near the edges of the continental slope (McFarlane and Nagata 1988). Juveniles are pelagic and appear to move into comparatively shallow nearshore areas where they spend the first 1 to 2 years (Rutecki and Varosi 1997). After their second summer, juveniles begin moving offshore, eventually reaching the upper continental slope as adults. Sablefish reach maturity at 4 to 5 years (McFarlane and Beamish 1990). Sablefish are long-lived, with a maximum recorded age in Alaska of 94 years (Kimura *et al.* 1998). Table 3.5-6 summarizes the biological and reproductive traits and habitat associations of sablefish through its different life stages.

Trophic Interactions

Larval sablefish feed on a variety of small zooplankton, ranging from copepod nauplii to small amphipods. Young-of-the-year sablefish are epipelagic and feed primarily on macrozooplankton and micronekton (e.g., euphausiids) (Sigler *et al.* 2001b). Juveniles less than 60 cm feed primarily on euphausiids, shrimp, and cephlapods (Yang and Nelson 2000), while sablefish greater than 60 cm feed more on fish. Both juvenile and adult sablefish are considered opportunistic feeders. Fish most important to the sablefish diet include pollock, eulachon, capelin, Pacific herring, Pacific cod, Pacific sandlance, and some flatfish, with pollock being the most predominant (10 to 26 percent of prey weight, depending on year). Squid, euphasiids, and jellyfish were also found, squid being the most important of the invertebrates (Yang and Nelson 2000). Feeding studies conducted in Oregon and California found that fish made up 76 percent of the sablefish diet (Laidig *et al.* 1997). Off the southwest coast of Vancouver Island, euphausiids dominated (Tanasichuk 1997).

Adult coho and chinook salmon feed on young-of-the-year sablefish, the fourth most common reported species in the salmon troll logbook program from 1977 to 1984 (Wing 1985). Pacific halibut also feed on juvenile and adult sablefish, although sablefish make up less than one percent of the stomach contents (M.S. Yang, AFSC, personal communication, 14 October 1999).

Management Tier/Stock Assessment

Sablefish are managed under Tier 3b in the BSAI and GOA. The fishing mortality rate of 0.13 (Appendix B) leads to a maximum permissible ABC of 25,400 mt. In 2002, a decision analysis was conducted to determine what catch levels will likely avoid the historic low abundance of 1979; this is in contrast to past year's assessments which evaluated catch rates that would result in a stable or increasing spawning biomass. The switch in methodology came about due to an increase in sablefish abundance. The BSAI and GOA sablefish stock abundance is considered moderate and has increased from recent lows. The 2003 recommended ABC is 20,900 mt, a yield that has a 0.6 probability of reducing the 2007 spawning biomass below the historic low. This ABC is the 5-year average of catches under the $F_{40\%}$ policy. This ABC has been apportioned separately in the EBS, Aleutian Islands, and GOA at 2,900 mt, 3,110 mt, and 14,890 mt, respectively. The 2003 OFL is 4,290 mt, 4,590 mt, and 22,020 mt for the EBS, Aleutian Islands, and GOA for a total of 30,900 mt. GOA ABC and OFL are further allocated into management areas; western, central, west Yakutat, and east Yakutat/southeast outside (SEO) (eastern = west Yakutat + east Yakutat/southeast outside) (Sigler *et al.* 2002) (Tables 3.5-2 and 3.5-28).

Several studies have shown sablefish to be highly migratory for at least part of their life cycle (Heifetz and Fujioka 1991, Maloney and Heifetz 1997), and substantial movement between the BSAI and the GOA has been documented (Heifetz and Fujioka 1991). Thus, Alaskan sablefish are considered a single stock and assessed in a combined area (BSAI and GOA) with an age-structured model incorporating fishery and survey catch data and age and length compositions. Survey data come from annual sablefish longline surveys in the GOA, and biennial longline surveys in the BSAI. Sablefish are more abundant and easier to catch in the GOA. Longline survey catch rates in the EBS and Aleutian Islands from 1990-1999 average only about one-fifth of those in the GOA.

Sablefish Past/Present Effects Analysis

The geographic scope for the BSAI and GOA sablefish past/present effects analysis is the same as for the BSAI and GOA FMP management areas (Figure 1.2-2 and 1.2-3). The temporal scope for this analysis begins in 1906 when the North American sablefish fishery begins and ends in 2002, the most recent year of which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-7 provides a summary of the BSAI and GOA sablefish past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on BSAI and GOA sablefish:

- Mortality due to catch/bycatch and the EVOS (direct effect).
- Change in reproductive success due to fishery selectivity, spatial/temporal concentration of catch/bycatch, the EVOS, and climate changes and regime shifts (indirect effect).
- Change in prey availability due to fishery catch/bycatch of prey species, introduction of exotic species, the EVOS and climate changes and regime shifts (indirect effect).
- Change in important habitat due to fishery gear impacts, the EVOS, introduction of exotic species and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on sablefish in the BSAI and GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI and GOA.

The past/present event determined to be applicable to the sablefish past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (BSAI: 1958-1976, GOA: 1963-1976)
  - State of Alaska groundfish fisheries
  - IPHC halibut longline fishery
  - EVOS
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (BSAI: 1980-1991, GOA: 1976-1985)
  - JV groundfish fisheries (BSAI: 1980-1991, GOA: 1979-1991)
  - Domestic groundfish fisheries (BSAI: 1980-present, GOA: 1979-present)
  - GOA domestic U.S. National Pacific cod fisheries (1800s-1976)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the sablefish fishery. Amendments discussed in Section 3.2 which have an impact on the target fisheries as a whole are not repeated here.

Mortality

External BSAI Foreign Groundfish Fisheries (1958-1976)

Japanese longline vessels began fishing in the Bering Sea in 1958, with peak catch in 1962 at 25,989 mt. Aleutian Island sablefish catch remained relatively low during the foreign fisheries. The bilateral agreement between the U.S., Japan and the Soviet Union began to include catch quotas in the EBS and Aleutian Islands regions beginning in 1973. Evidence of decline in sablefish abundance led to fishery restrictions starting in 1978, reducing total catches to about 12,200 mt by 1985 (NPFMC 2002a).

The Soviet Union caught sablefish from 1967 to 1973 in the EBS (McDevitt 1986) and the Republic of Korea from 1974 to 1983. The Republic of Poland, Taiwan, Mexico, Bulgaria, Federal Republic of Germany, and Portugal have all reported small catches of sablefish, as well (Low *et al.* 1976).

External GOA Foreign Groundfish Fisheries (1963-1976)

Already having started a sablefish fishery in the EBS, Japanese longline vessels began fishing in the GOA in 1963, which led to a rapid increase in annual harvests of sablefish. Harvests peaked in 1972 at 36,776 mt in the GOA. Sablefish were also caught by trawl vessels in the GOA, where sablefish were bycatch in the Japanese Pacific ocean perch fishery until 1972, when some vessels started targeting sablefish (Sasaki 1973).

The sablefish population was overexploited by foreign fisheries. However there is no lingering impact. The population recovered from overfishing starting in the late 1970s due to strong year-classes during 1977-1981.

External BSAI and GOA IPHC Longline Fishery and State of Alaska Directed Sablefish Fishery

Minor state fisheries were established in Alaska in 1995 primarily to provide open-access fisheries to fishermen who could not participate in the federal sablefish IFQ fishery. These fisheries occur in the northern GOA and in the Aleutian Island region, and averaged 180 mt from 1995-1998, with catches predominantly from the Aleutian Island region (ADF&G 2000b, Sigler *et al.* 2001a). In addition, three major state fisheries targeting sablefish operate in Prince William Sound (PWS), Chatham Strait, and Clarence Strait (Sigler *et al.* 2001a).

The past State of Alaska directed fishery and the IPHC longline fishery are found to have no lingering adverse effects on the sablefish population. Although mortality rates likely were higher in some state fisheries than the federal fishery during the 1990s, the effect on the population was low because catches in the state fisheries are small compared to the federal fishery.

Internal GOA Domestic Groundfish Fisheries (late 1800s -1976)

The North American fishery consisting of both the U.S. and Canada began as a secondary activity of the halibut fishery in the late 1800s. The first fishing grounds were off the coasts of Washington and British Columbia and had spread to Oregon, California, and Alaska by the 1920s. The fishery was exclusively North American from 1906 to 1957, taking place from northern California to Kodiak Island in the GOA. Annual catches of sablefish in Alaska averaged about 1,700 mt from 1930 to 1957 and generally were limited to areas near fishing ports (Low *et al.* 1976). The catch history of sablefish in the BSAI and GOA is detailed in Sigler *et al.* 2002.

The sablefish population in Canada was overexploited by foreign fisheries. However there is no lingering impact. The population recovered from overfishing starting in the late 1970s due to strong year-classes during 1977-1981.

Internal BSAI JV and Domestic Groundfish Fisheries (1980 - present)

In the late 1980s, a substantial increase in abundance in sablefish population and the expansion of the domestic fishery increased catches, peaking in 1987 at 8,012 mt (domestic only). Annual catch declined throughout the 1990s to the present at about 1,600 mt. Some catches were not reported during the late 1980s (Kinoshita *et al.* 1995).

BSAI FMP Amendments 1, 2, 4, 6, and 11 all worked to phase-out foreign and JV fisheries and encourage the growth of the domestic fishery.

NPFMC identified concerns regarding sablefish bycatch and the unrelated 50 percent decline in the number of observed walrus hauled out on Round Island. In addition to the changes described in Section 3.5.1.1, BSAI FMP Amendment 13 also 1) allocated sablefish by gear, 2) closed areas to groundfish fishing to protect walrus, 3) deleted fishing season dates from the FMPs but retained them in regulations, and 4) clarified the authority to recommend TACs for additional or fewer target species within the target species category.

Amendment 15 established an IFQ program for sablefish fixed gear fisheries in 1995, and allocated 20 percent of the fixed gear allocation of sablefish to a CDQ reserve for the BSAI. This program was designed to promote the conservation and management of sablefish fisheries by assigning a percentage of the sablefish harvest to certain individuals who have had a history of harvest in that fishery. Over time, this program has decreased the total number of quota shareholders, reduced the amount of bycatch, increased safety, reduced gear conflicts, reduced fishing mortality due to lost gear, increased product quality, and reduced the competition for fishing grounds. Management under the IFQ program also has increased the fishery catch rate 1.8 times, decreased harvest of immature fish so that spawning biomass per recruit increased nine percent, and decreased variable costs of catching the quota from eight to five percent of landed value (Sigler and Lunsford 2001).

A regulatory amendment was passed in the BSAI (57 CFR 37906) banning the use of longline pot gear for fishing of sablefish in 1992. This prohibition was later removed except from June 1 to June 30 to prevent gear conflicts with trawlers, effective September 12, 1996.

Past JV fisheries and domestic fisheries in the BSAI may have had a lingering adverse impact on fishing mortality. Catches were under reported during the late 1980s (Kinoshita *et al.* 1995), and this may have contributed to the substantial abundance decline in the 1990s.

Internal GOA JV and Domestic Groundfish Fisheries (1979 - present)

JV fisheries began in the GOA in 1979, peaking in 1984 at 411 mt (NPFMC 2002b). In 1983, GOA FMP Amendment 11 lowered the sablefish quota due to reduced abundance of sablefish, and also to encourage growth of the domestic fisheries. By 1986, the sablefish resource had recovered and the quota was again increased to 15,000 mt for the domestic fishery. GOA domestic harvests peaked in 1989 at 29,900 mt and have since declined to the 2002 harvest of 13,570 mt.

In 1980, GOA FMP Amendment 8 created four species management categories (target, other species, unallocated, and non-specified) and three regulatory districts for sablefish in southeast Alaska. Its purpose was to make the GOA FMP conform to the newly adopted BSAI FMP, to enhance target species management, and to protect incidentally caught species. Information on squid, rockfish, and several other species was found insufficient to warrant OYs for the three main regulatory areas in the GOA; therefore, their management was changed to a gulfwide management strategy. Changes in sablefish management were also needed because the growing U.S. fishery tended to fish in too localized an area off southeast Alaska. The eastern regulatory area thus was divided into three smaller areas to spread the fishery out, and biodegradable panels were required to reduce ghost fishing by lost pots. Lastly, the timing of reserve releases was modified to allow for increased catches by domestic fisheries.

Amendment 14 to the GOA FMP allocated sablefish quota by gear type, effective in 1985. This FMP amendment also banned the use of pots for fishing for sablefish in the GOA, effective November 18, 1985. Amendment 20 to the GOA FMP established an IFQ management for sablefish beginning in 1995 with the same benefits as described for BSAI in the previous section. In 1997, maximum retainable bycatch percentages for groundfish were revised. The percentage is dependent on the basis species: pollock one percent, Pacific cod one percent, deep flatfish 7 percent, rex sole 7 percent, flathead sole 7 percent, shallow flatfish one percent, arrowtooth flounder 0 percent, Pacific ocean perch 7 percent, shortraker and rougheye rockfish 7 percent, other rockfish 7 percent, northern rockfish 7 percent, pelagic shelf rockfish (PSR)7 percent, demersal shelf rockfish (DSR) in the SEO 7 percent, thornyhead rockfish 7 percent, Atka mackerel one percent, other species one percent, and aggregated amount of non-groundfish species one percent.

A draft EA/RIR/IRFA document was released for public review for Amendment 66 to the GOA groundfish FMP in May of 2002. This amendment would allow for the purchase of commercial halibut and sablefish catcher vessel quota share for lease by eligible persons. This amendment is designed to help reduce unemployment and related social and economic issues in rural GOA fishing communities by allowing a few of those communities to participate in the sablefish and halibut fisheries (Hiatt *et al.* 2002).

Past JV and domestic fisheries in the GOA may have had a lingering adverse impact on the sablefish population. Catches were under reported during the late 1980s (Kinoshita *et al.* 1995), and this under reporting may have contributed to the substantial abundance declines in the 1990s.

Change in Reproductive Success

External BSAI and GOA Foreign Groundfish Fisheries (1958-1976)

Fishery Selectivity

Japanese trawlers targeting pollock, rockfishes, Greenland turbot, and Pacific cod also caught large sablefish as bycatch. From 1964-1972, the bycatch averaged nearly 12,000 mt for the Japanese trawl fisheries (Sasaki 1973). In 1968, sablefish bycatch by longline or otter trawl was allowed to be retained up to 10 percent by weight of each landing; this amount was increased to 20 percent in 1972. Bycatch of sablefish in the foreign fisheries was monitored by the foreign Observer Program, and several gear regulations were passed in an attempt to reduce bycatch (NPFMC 2002a).

In 1960, 1961, and 1967, legal gear for the taking of sablefish in directed and bait fishery was defined. Pots were allowed in 1970 and modifications required in 1976, including an untreated cotton escape which would deteriorate and allow for the escapement of bycatch if the pot were lost at sea (NPFMC 2002a).

External State of Alaska Directed Sablefish Fisheries

Spatial/Temporal Concentration of Catch/Bycatch

1999 ADF&G data show that the state sablefish fishery is somewhat concentrated; in the PWS, catch was dominated by a few statistical areas; in the Cook Inlet region, catches came from the outer coast; and in the south Alaska Peninsula fishery, catches came predominately from the areas southwest of Unimak Island. The fishery in the PWS is also concentrated temporally, lasting only a few days, whereas the Cook Inlet and south Alaska Peninsula fisheries last a few months (ADF&G 2000b).

The state fishery is found to have had an adverse effect on the spatial/temporal distribution of the sablefish stock due to the spatial/temporal concentration of the catch. However, there are no observable lingering negative effects on the sablefish population.

External Exxon Valdez Oil Spill

The effects of the EVOS on sablefish recruitment in the GOA are unknown.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of sablefish. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

The regime shift of 1976/1977 had a beneficial effect of recruitment of sablefish and other groundfish species (Sigler *et al.* 2002, Wooster and Hollowed 1995). Sablefish recruitment was high during 1977-1981, associated with the regime shift of 1976/1977. The effects of these strong year-classes lasted about two decades.

Internal JV and Domestic Fisheries (1979 - present)

Fishery Selectivity

The percent of sablefish catch discarded during 1995-2000 averaged 2.8 percent in the directed Alaska-wide sablefish longline fishery. Discards also took place in the BSAI Greenland turbot fishery (31 percent), the BSAI Pacific cod longline fishery (41.4 percent), Alaska-wide rockfish trawl fishery (17.4 percent) and Alaska-wide flatfish trawl fishery (42.1 percent) (Sigler *et al.* 2001a). BSAI FMP Amendment 13 and 15/GOA Amendment 20 helped reduce sablefish bycatch and discards by establishing the domestic Observer Program and the sablefish IFQ program, respectively.

Longline catches are typically of mature, larger sized fish, whereas trawl fisheries tend to target small to medium sized sablefish. The trawl fisheries occur within juvenile sablefish habitat, along the continental shelf. The trawl fisheries make up only 12 percent of the total catch, but may reduce sablefish recruitment by a larger amount because the fish caught are often younger, smaller fish that have not reached their full size (Sigler *et al.* 2002).

The dominating factor determining the age composition is the magnitude of the recruiting year-classes. The selectivity of the fishery has cumulative impacts on the age composition due to fishing mortality, and the current composition is also the result of a fished population with a several-decades catch history. How the current age composition of the population compares with the unfished population is unknown. In the short-term, however, the impact of the current fishing mortality levels is overshadowed by the magnitude of incoming year-classes, which in turn are highly dependent on environmental conditions (Sigler *et al.* 2001a).

The IFQ program (BSAI FMP Amendment 15/GOA FMP Amendment 20) has increased fishery catch rates while decreasing the harvest of immature fish (Sigler and Lunsford 2001). Catching efficiency increased 1.8 times with the change from an open-access to an IFQ fishery. Decreased harvest of immature fish improved the chance that individual fish will reproduce at least once. Spawning potential of sablefish, expressed as spawning biomass per recruit, increased nine percent under the IFQ fishery (Sigler *et al.* 2001a).

Spatial/Temporal Concentration of Catch/Bycatch

In 1980, GOA FMP Amendment 8 allowed for changes in sablefish management that were needed because the growing U.S. fishery tended to fish in too localized an area off southeast Alaska. This amendment divided the eastern regulatory area into two smaller areas to spread the fishery out. Biodegradable panels were also required to reduce ghost fishing by lost pots.

Change in Prey Availability

External BSAI and GOA Foreign Groundfish Fisheries (1958-1976)

The past foreign fisheries are unlikely to have had an impact on sablefish prey availability since sablefish are opportunistic feeders as described under the trophic interactions of this section. Larval sablefish feed on a variety of small zooplankton ranging from copepod nauplii to small amphipods. The epipelagic juveniles feed primarily on macrozooplankton and micronekton (i.e. euphausiids). The older demersal juveniles and adults appear to be opportunistic feeders, with food ranging from variety of benthic invertebrates, benthic fishes, as well as squid, mesopelagic fishes, jellyfish, and fishery discards. Fish comprise a large part of the adult sablefish diet. Nearshore residence during their second year provides the opportunity to feed on salmon fry and smolts during the summer months.

External State of Alaska Directed Sablefish Fisheries

As with the foreign fisheries, the State of Alaska directed sablefish fishery is unlikely to have an impact on the prey availability of sablefish due to the opportunistic nature of the species.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

As described under trophic interactions, larval sablefish feed mostly on copepods, young-of-the-year sablefish feed mostly on euphausiids and juvenile and adult sablefish are opportunistic feeders. Larvae and young-of-the-year sablefish are more susceptible than juvenile and adult sablefish to large shifts in ecosystem productivity due to their dependence on a few species. However, time-series data are not available to link fluctuations in copepod and euphausiid abundance with larvae and young-of-the-year sablefish abundance (Sigler *et al.* 2002).

External Exxon Valdez Oil Spill

The effects of the EVOS on the abundance of sablefish prey species and on the sablefish population are unknown.

Internal JV and Domestic Fisheries (1979 - present)

Again, as with the foreign fisheries and State of Alaska directed sablefish fisheries, it is unlikely that the past JV and domestic fisheries have had an impact on the prey availability of sablefish due to the opportunistic nature of the species.

Change in Important Habitat

External BSAI and GOA Foreign Groundfish Fisheries (1958-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability has been adversely affected by the intensity of the past foreign fisheries in the BSAI and GOA. The effects of fishery gear on important sablefish habitat are lingering at the population-level.

External State of Alaska Directed Sablefish Fisheries

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability has been adversely affected by the intensity of the state fisheries. The effects of fishery gear on important sablefish habitat are lingering at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

Sablefish recruitment appears to be influenced by water mass movements and temperature (Sigler *et al.* 2001a). Data suggest that sablefish recruitment increases with above average temperature as well as the growth rate of young-of-the-year sablefish (Sigler *et al.* 2002).

External Exxon Valdez Oil Spill

The effects of the EVOS on sablefish habitat suitability are unknown.

Internal JV and Domestic Fisheries (1979-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability has been adversely affected by the intensity of the past JV and domestic fisheries. The effects of fishery gear on important sablefish habitat are lingering at the population-level. BSAI FMP Amendment 13 closed waters seaward of 3 nm out to 12 nm surrounding the Walrus Islands and Cape Pierce from April 1 through September 30 to all groundfish fishing. Amendments 55 and 65 were proposed to identify EFH, minimize practicable adverse effects on habitat, and encourage conservation.

BSAI/GOA Sablefish Comparative Baseline

Longline surveys were conducted annually in the GOA by the Japan-U.S. cooperative longline survey from 1978 to 1994, and added the Aleutian Islands region in 1980 and the EBS in 1982 (Sasaki 1985, Sigler and Fujioka 1988). The AFSC began conducting annual longline surveys in the upper continental slope in 1987 to continue the U.S.-Japan cooperative survey time series (Sigler and Zenger 1989). The AFSC survey began annual sampling in the GOA in 1987, biennial sampling in the Aleutian Islands region in 1996, and biennial sampling in the EBS in 1997 (Rutecki *et al.* 1997).

Killer whale depredation of the survey's sablefish catches has occurred in the Bering Sea since the beginning of the survey and has been adjusted for by excluding portions of the gear affected (Sasaki 1987). However, sperm whale depredation has not been adjusted for because researchers are uncertain when the depredation began. If depredation began recently, the current survey estimates would underestimate the biomass. However, if adjustments were made and depredation occurred consistently over time, then the biomass would be overestimated. Sperm whale depredation will continue to be monitored; however, no plans have been made to adjust survey estimates (Sigler *et al.* 2001a).

Relative abundance of sablefish has cycled through three major declines and two significant increases between 1970 and 1985. The post-1970 decline has been attributed to heavy fishing, and the 1985 peak has been attributed to high recruitment of late 1970s year-classes. Following 1988, sablefish abundance has decreased significantly, declining faster in the EBS, Aleutian Islands region, and western GOA and slower in the central and eastern GOA (Sigler *et al.* 2002). Geographic differences are probably due to the migration of small sablefish westward, while large sablefish migrate eastward (Heifetz and Fujioka 1991).

Recent important year-classes are 1980-1981, 1984, 1990, 1995, and 1997. Abundance has fallen in recent years because recent recruitment is insufficient to replace strong year-classes from the later 1970s, which are dying off (Sigler *et al.* 2001a).

BSAI Sablefish Cumulative Effects Analysis Status

BSAI sablefish will be brought forward for cumulative effects analysis.

3.5.1.4 BSAI Atka Mackerel

Life History and Distribution

Atka mackerel (*Pleurogrammus monopterygius*) are distributed from the east coast of the Kamchatka Peninsula, Russia, throughout the Aleutian Islands and the EBS, and eastward through the GOA to southeast Alaska (Wolotira *et al.* 1993). Their current center of abundance is in the Aleutian Islands, with marginal distributions extending into the southern Bering Sea and into the western GOA (Lowe *et al.* 2001, Lowe and Fritz 2001).

Atka mackerel are one of the most abundant groundfish species in the Aleutian Islands, where they are the target of a directed trawl fishery (Lowe and Fritz 2001). Adults are semipelagic and spend most of the year over the continental shelf in depths generally less than 200 m. Adults migrate annually to shallow coastal waters during spawning, forming dense aggregations near the bottom (Morris 1981, Musienko 1970). In Russian waters, spawning peaks in mid-June (Zolotov 1993) and in Alaskan waters in July through October (McDermott and Lowe 1997). Females deposit adhesive eggs in nests or rocky crevices. The nests are guarded by brightly colored males until hatching occurs (Zolotov 1993). The first *in situ* observations of spawning habitat in Seguam Pass were documented in August 1999 and 2000 (Robert Lauth, NOAA Fisheries AFSC, personal communication). Atka mackerel nests, nest-guarding males, and spawning females were observed and verified with underwater video and SCUBA diving operations. Nichol and Somerton (2002) examined the diurnal vertical migrations of Atka mackerel using archival tags, and related these movements to light intensity and current velocity. Atka mackerel displayed strong diel behavior, with vertical movements away from the bottom occurring almost exclusively during daylight hours and little to no movement at night. A morphological and merisitic study suggests that there may be separate populations of Atka mackerel in the GOA and the Aleutian Islands (Levada 1979). Data from another morphological study conducted in the BSAI and GOA showed some differences between samples, although the differences were not consistent by area for each characteristic analyzed, suggesting a certain degree of reproductive isolation (Lee 1985). More recent genetic analyses show no evidence of discrete stocks in Alaskan waters (Lowe *et al.* 1998). However, the growth rates have been shown to vary extensively among different areas, and the two Aleutian Islands and GOA populations differ significantly in the size, distribution, and recruitment patterns (Kimura and Ronholt 1988, Lowe *et al.* 1998, Lowe and Fritz 2001). Age and size at 50 percent maturity has been estimated at 3.6 years and 33-38 cm, respectively (McDermott and Lowe 1997). Atka mackerel are a relatively short-lived groundfish species. A maximum age of 15 years has been noted; however, most of the population is probably less than 10 years old. Natural mortality estimates vary extensively, as determined by various methods. The current assumed value of natural mortality is 0.30, which is consistent with values of natural mortality derived from methods which do not rely on growth parameters which vary according to area. Table 3.5-8 summarizes biological and reproductive attributes and habitat associations of Atka mackerel in the BSAI and GOA.

Trophic Interactions

The diets of commercially important groundfish species in the Aleutian Islands during the summer of 1991 were analyzed by Yang (1996 and 1999). More than 90 percent of the total stomach content (by weight) of Atka mackerel in the study was made up of invertebrates, with less than 10 percent made up of fish. Euphausiids (mainly *Thysanoessa inermis* and *T.rachii*) were the most important prey items, followed by calanoid copepods. The two species of euphausiids comprised 55 percent of the total stomach contents, and copepods comprised 17 percent. Larvaceans and hyperiid amphipods had high frequencies of occurrence (81 percent and 68 percent, respectively), but comprised less than 8 percent of the total stomach content weight. Squid was another item in the diet of Atka mackerel; it had a frequency of occurrence of 31 percent, but comprised only 8 percent of total stomach content. Atka mackerel are known to eat their own eggs. Yang (1996 and 1999) found that Atka mackerel eggs comprised 3 percent of the total stomach content and occurred in 9 percent of the analyzed Atka mackerel stomachs. Pollock were the second most important prey fish of Atka mackerel, comprising about 2 percent of the total stomach content. Myctophids, bathylagids, zoarcids, cottids, stichaeids, and pleuronectids were minor components of the Atka mackerel diet; each category comprised less than one percent of the total stomach content.

Yang (1996 and 1999) found some differences between the diet composition of male versus female Atka mackerel; females were found to cannibalize on eggs more often and preferred calanoids when cannibalism occurred, whereas males preferred euphasiids. Yang (1999) hypothesizes that this difference is due to the egg-guarding behavior of males which deters the males from feeding on their own eggs. The location of the cannibalism (Kiska Island) suggests that this area may be a spawning ground for Atka mackerel.

Atka mackerel are an important component in the diet of other commercial groundfish, mainly arrowtooth flounder, Pacific halibut, and Pacific cod; seabirds, mainly tufted puffins; and marine mammals, mainly northern fur seals and Steller sea lions (Byrd *et al.* 1992, Livingston *et al.* 1993, Fritz *et al.* 1995; as referenced by Yang 1996 and 1999). Atka mackerel are also components in the diets of the following marine mammals and seabirds: harbor seals, Dall's porpoise, thick-billed murres, and horned puffins (as referenced by Yang 1996 and 1999).

BSAI Atka Mackerel Management

In the 2002 assessment for the 2003 fishery, Atka mackerel fell into Tier 3a of the ABC and OFL definitions. According to the definitions of Amendment 56 and current stock conditions, the OFL fishing mortality rate at $F_{35\%}$ is estimated to be 0.84 for Atka mackerel (see Appendix B), which equates to a yield of 99,700 mt. The maximum allowable fishing mortality rate for ABC at $F_{40\%,}$ is estimated to be 0.66 for Atka mackerel in 2003, which translates to a yield of 82,800 mt. A recommendation of 63,000 mt, lower than the maximum permissible ABC, was performed by NPFMC (Lowe *et al.* 2002) (Table 3.5-2).

The BSAI Atka mackerel stock is above its minimum stock size threshold (MSST) and is not overfished or approaching an overfished condition. Under current management, the status determination of Atka mackerel relative to its MSST is made under the auspices of NOAA Fisheries' National Standards Guideline, rather than the groundfish FMPs.

Atka mackerel are a difficult species to survey because they do not have a swim bladder and are therefore poor targets for hydroacoustic surveys. They prefer rough and rocky bottoms that are difficult to sample with the current survey gear, and their schooling behavior and patchy distribution result in survey estimates with large variances. The stock assessment in the Aleutian Islands is based on the NOAA Fisheries trawl surveys, as well as total catch and catch-at-age data from the commercial fishery.

In 2002, the BSAI Atka mackerel were assessed using a Stock Assessment Toolbox. This new stock assessment model is designed to better evaluate and estimate assessment uncertainty; to explore alternative models for fishery and to survey selectivities, natural mortality and survey catchability; and to report on abundance and recruitment trends (Lowe *et al.* 2002).

Past/Present Effects Analysis

The geographic scope for the BSAI Atka mackerel past/present effects analysis is the same as the BSAI management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1970 when the foreign fishery started and ends in 2002, the most recent year for which stock assessment information exists.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-9 provides a summary of the BSAI Atka mackerel past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on BSAI Atka mackerel:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to fishery selectivity, spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to commercial whaling, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, marine pollution and oil spills, introduction to exotic species, and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on Atka mackerel in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the Atka mackerel past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1970-1976)
  - Commercial whaling

- Marine pollution and oil spills
- Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1991)
  - Domestic groundfish fisheries (1981-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - IWC regulations
  - MMPA of 1972
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the Atka mackerel fishery. Amendments discussed in Section 3.2 which impact on the target fisheries as a whole and Atka mackerel as a component of the fishery, are not repeated here.

Mortality

External Foreign Groundfish Fisheries (1970-1976)

From 1970 to 1979, the Atka mackerel catch was taken exclusively by foreign fleets, including the Soviet Union, Japan, and the Republic of Korea. Catches of Atka mackerel peaked during the 1970s at over 24,000 mt in 1978 (Lowe *et al.* 2001). The Atka mackerel foreign fisheries had been phased out by 1984.

Although large removals of Atka mackerel occurred during the time of the foreign fisheries, there are no observable lingering negative effects on the Atka mackerel population.

Internal Foreign, JV and Domestic Groundfish Fisheries (1976-present)

The U.S. JV fishery began in 1980, and dominated the Atka mackerel catch from 1982-1988. Catches of Atka mackerel declined from their 1970s numbers from 1980-1983, largely due to changes in management and allocations. From 1985-1987, catches again increased, reaching their highest level at 34,000 mt annually. The domestic Atka mackerel fishery began in 1988 and was fully domesticated by 1990. TACs steadily increased from 1992 on in response to evidence of a large exploitable Atka mackerel population in the central and western Aleutian Islands (Lowe *et al.* 2002).

In June of 1997, BSAI FMP Amendment 34 was passed, allocating Atka mackerel catch to jig gear. This amendment was intended to provide an opportunity for local, small-vessel jig gear fleets to fish for Atka mackerel without direct competition from the large, high-capacity trawl fleets. Since that time, little of the jig gear fishery TAC has been harvested.

Although large removals of Atka mackerel have occurred in the past JV and domestic fisheries, there are no observable lingering adverse effects on the population.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1970-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The Atka mackerel fishery is characteristically a highly localized fishery that occurs in the same few locations every year. Foreign catches were made predominantly in the western Aleutian Islands (west of 180°W longitude) during the early 1970s and moved east during the late 1970s and early 1980s. Past foreign fisheries are found to have had an adverse impact on the spatial/temporal distribution of Atka mackerel due to the spatial/temporal concentration of the fishery in the BSAI.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of Atka mackerel. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries.

Internal Foreign, JV and Domestic Groundfish Fisheries (1976-present)

Spatial/Temporal Concentration of Catch/Bycatch

The Atka mackerel fishery is a spatially and temporally concentrated fishery, and occurs primarily in depths less than 200 m. As stated above, the fisheries moved eastward from 180° W longitude in the early 1980s, near Seguam and Amlia Islands. The 1984 and 1985 catches took place primarily from a single 1/2° latitude by 1° longitude block in Seguam Pass. Atka mackerel are not commonly caught as bycatch in other directed fisheries, although the largest amounts occur in the trawl Pacific cod and rockfish fisheries (Lowe *et al.* 2000). Prior to 1998, the highest recorded discard rates were recorded in the western Aleutian Islands (543) and the lowest have been recorded in the eastern (541) (Lowe *et al.* 2002). The JV and past domestic groundfish fisheries have had an adverse impact on the spatial/temporal distribution of Atka mackerel due to the spatial/temporal concentration of the fishery in the BSAI.

Prior to 1993, no mechanism existed to spatially allocate TACs in the Aleutians to minimize the likelihood of localized depletion of Atka mackerel. In mid-1993, however, Amendment 28 to the BSAI FMP became effective, dividing the Aleutian subarea into three districts at 177° W and 177° E longitudes for the purposes of spatially apportioning TACs. Amendment 28 created the western (543), central (542), and eastern (541) Aleutian Districts. The BSAI Atka mackerel ABCs and TACs have been apportioned among areas based on weighted average distribution of biomass from the Aleutian Islands bottom trawl surveys.

Studies on Steller sea lion food habits indicate that Atka mackerel is the most common food item of adult and juvenile Steller sea lions in the summer (NMFS 1995b) and winter (Sinclair and Zeppelin 2002). A 10 nm year-round trawl exclusion zone was established around all rookeries west of 150°W in 1991-1992; and a 20 nm trawl exclusion zone was established around 6 rookeries in 1992-93, two of which included Seguam and Agligadak Islands. In 1993, a 20 nm aquatic zone was established around all rookeries and major haulouts west of 144°W and around three foraging areas, including one located near Seguam Pass.

Due to concerns that the spatial/temporal concentration of Atka mackerel catch could be high enough to affect prey availability for Steller sea lions, NPFMC passed a fishery regulatory amendment in June of 1998 which further dispersed the fishery spatially and temporally and reduced the level of fishing within Steller sea lion critical habitat in the BSAI. These regulations have been superceded by Amendment 70 to the BSAI and GOA FMPs which enacted the current Sea Lion Protection Measures in 2002 (Section 12.2.2 of Lowe and Fritz 1997).

Change in Prey Availability

External Commercial Whaling

Whaling is identified as having a past beneficial effect on prey availability for the Atka mackerel stocks. Atka mackerel have been documented as a prey of certain whale species; therefore, by removing large predators, Atka mackerel recruitment is favored.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. In general, a shift toward colder waters favors recruitment and survival of Atka mackerel. When the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of Atka mackerel.

Change in Important Habitat

External Foreign Groundfish Fisheries (1970-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Due to the schooling, semi-demersal nature of Atka mackerel, this species is readily caught by bottom trawl gear (Lowe *et al.* 2001). Therefore Atka mackerel habitat is also subject to fishery gear impacts associated with bottom trawling. However, data on how fishery gear has specifically affected Atka mackerel habitat is unavailable; therefore, the effects of the past foreign fisheries on habitat suitability for the BSAI stock are unknown.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability in both stocks. In general, a shift toward colder waters favors recruitment and survival of Atka mackerel. When the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of Atka mackerel.

Internal Foreign, JV and Domestic Groundfish Fisheries (1976-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

As stated in the external foreign fisheries section above, data regarding fishery gear impacts specific to Atka mackerel habitat are unavailable; therefore, the effects of the post-MSA foreign, JV, and domestic fisheries on the important habitat of Atka mackerel are unknown.

BSAI FMP Amendment 28, discussed above, helped to guard against reduced habitat suitability by reducing the concentration of Atka mackerel fishing effort spatially and temporally. The June 1998 regulation discussed above also contributed to guarding against reduced habitat suitability by banning trawl fishing within Steller sea lion critical habitat, which is habitat shared by Atka mackerel. Amendment 70, which supercedes the previous Steller sea lion regulations, closes Atka mackerel fishing in the Seguam foraging areas in all critical habitat areas east of 178°W longitude, and within 10 nm of rookeries west of 178°W longitude except Buldir which is closed within 15 nm. Atka mackerel fishing is also prohibited within 3 nm of all haulouts. Further closures have also been initiated in the Bering Sea, although the closures are more complex dependent on the type of fishery, gear used, location, and timing of the fishery. BSAI FMP Amendments 55 and 65 were both designed to identify and conserve EFH and HAPC (see Appendix C).

BSAI Atka Mackerel Comparative Baseline

Survey biomass estimates for Atka mackerel come from the 1986 U.S.-Japan cooperative trawl survey and from domestic trawl surveys in 1991, 1994, 1997, 2000, and 2002. The biomass estimate from 2002 is 772,798 mt, a 51 percent increase from the 2000 survey estimate. Atka mackerel biomass tends to be highly variable over depth (between 1 and 200 m) and area. Virtually all the biomass in the trawl surveys was found between 1 and 200 m. In the 2002 survey, areas with large catches were located north of Akun Island, Seguam Pass, Tanaga Pass, south of Amchitka Island, Kiska Island, Buldir Island, and Stalemate Bank (Lowe *et al.* 2002).

Factors that may affect Atka mackerel distribution, and thus availability to surveys, include bottom water temperatures and tidal cycles. Low bottom temperatures could impact the distribution of Atka mackerel and/or their food source. In 2000, the lowest bottom temperatures were recorded relative to past surveys and the fish during the 2000 survey were also found to weigh less than in the 1994 and 1997 surveys, suggesting a food-related impact. Atka mackerel are also thought to be responsive to tidal cycles; during high tide Atka mackerel may not be as accessible to surveys.

The 2000 survey age composition of Atka mackerel from the fishery is shown in Figure 3.5-4. The age composition is dominated by a strong 1992 and 1995 year-class and a very strong 1998 year-class (2 year-olds). The estimated mean age of the 2000 survey age composition is 5 years (Lowe *et al.* 2001). The current fishery tends to select fish aged 3 to 12 years old (Lowe and Fritz 2001). The 2001 fishery age composition data were dominated by the 1995 and 1998 year-classes (Lowe *et al.* 2002). It is not known how the age composition of the population would look in an unfished population.

BSAI Atka Mackerel Cumulative Effects Analysis Status

The BSAI Atka mackerel will be brought forward for cumulative effects analysis.

3.5.1.5 BSAI Yellowfin Sole

Life History and Distribution

Yellowfin sole (*Limanda aspera*) are distributed from British Columbia to the Chukchi Sea (Hart 1973). In the Bering Sea, they are presently the most abundant flatfish species and are the target of the largest flatfish groundfish fishery in the U.S. While also found in the Aleutian Islands and GOA, the stock is of much smaller size in those areas and is less likely to be commercially exploited there. Adults are benthic and occupy separate winter and spring/summer spawning and feeding grounds. Adults overwinter near the shelf-slope break at approximately 200 m and move into nearshore spawning areas as the shelf ice recedes (Nichol 1997). Spawning is protracted and variable, beginning as early as May and continuing through August, occurring primarily in shallow water at depths less than 30 m (Wilderbuer *et al.* 1992). Eggs, larvae, and juveniles are pelagic and usually are found in shallow areas. The estimated age at 50 percent maturity is 10.5 years at a length of approximately 29 cm (Nichol 1994). The maximum recorded age of a yellowfin sole is 34 years. Table 3.5-10 summarizes biological and reproductive attributes and habitat associations of yellowfin sole in the BSAI and GOA.

Trophic Interactions

Major prey items include bivalves, polychaete and echiuroid worms, euphausiids, and crangon shrimp (Livingston and deReynier 1996). Hafflinger and McRoy (1983) also showed that yellowfin sole will consume bairdi and opilio Tanner crabs and red king crabs at certain areas and times in the EBS. Livingston (1991b) found that yellowfin sole consume small quantities of juvenile bairdi and opilio Tanner crab, and blue king crab.

Groundfish predators of yellowfin sole include Pacific cod, skates, and Pacific halibut, which consume fish ranging from 7 to 25 cm standard length (Livingston and deReynier 1996).

BSAI Yellowfin Sole Management

In the Bering Sea, yellowfin sole are considered one stock for management purposes. The reference fishing mortality rate and ABC for yellowfin sole are determined by the amount of population information available (see Appendix B). Yellowfin sole are currently managed under Tier 3a of NPFMC's ABC and OFL definitions (Appendix C; Amendment 56). Management under Tier 3a requires reliable estimates of projected biomass, $B_{40\%}$, $F_{40\%}$ (for ABC), and $F_{35\%}$ (for OFL). The projected yellowfin sole female spawning biomass for 2003 is greater than $B_{40\%}$ (452,800 mt >385,000 mt), leading to an ABC value of 114,000 mt for 2003. The OFL was determined from the Tier 3a formula, equating to a value of 135,000 mt. Model projections indicate that the yellowfin sole stock is neither overfished nor approaching an overfished condition, according to the BSAI groundfish FMP Amendment 56 definitions, although the yellowfin sole stock continues to decline, mainly due to poor recruitment in the last decade (Wilderbuer and Nichol 2002) (Table 3.5-2).

Information on yellowfin sole stock conditions in the BSAI comes primarily from the annual EBS trawl survey. Estimates of yellowfin sole biomass derived from these surveys have been more variable than would be expected for a comparatively long-lived and lightly exploited species (Wilderbuer 1997). The reason for this variability is not known. Recent stock assessment analyses indicate a positive linear relationship between annual estimates of trawl survey biomass and bottom water temperature. This may be due to the decline in activity at low temperatures of the influence of water temperature on the timing of spawning migrations. As indicated by the 2000 survey, a significant portion of the yellowfin sole biomass appears to lie outside this survey border (Wilderbuer and Nichol 2002).

The time-series of fishery and survey age compositions allows the use of an age-based stock assessment model (Wilderbuer 1997). The outputs include estimates of abundance, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass. The model also estimates reference fishing mortality rates in terms of the ratio of female spawning biomass to unfished levels, which, when considered with projected future biomass, are used to calculate ABC. The stock assessment is updated annually at the conclusion of the summer trawl survey and is incorporated into the BSAI SAFE report.

BSAI Past/Present Effects Analysis

The geographic scope for the yellowfin sole past/present effects analysis is the same as the BSAI management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1954 when the foreign fishery for flounders started and ends in 2002, the most recent year for which a stock assessment is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-11 provides a summary of the yellowfin sole past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on yellowfin sole:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to fishery selectivity, spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, marine pollution and oil spills, introduction of exotic species and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on yellowfin sole in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the northwest Pacific to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the yellowfin sole past/present effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1954-1976)
  - State of Alaska crab fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1991)
  - Domestic groundfish fisheries (1987-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the yellowfin sole fishery. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality

External Foreign Groundfish Fisheries (1954-1976)

The first EBS foreign yellowfin sole fishery was conducted by Japan from 1940 to 1941. The catches for these years totaled 9,600 and 12,200 mt, respectively. Japan was not allowed back into Alaska waters until the signing of the peace treaty between the U.S. and Japan in 1952 (NPFMC 2002a).

In 1954, the Japanese again began targeting flounders (primarily yellowfin sole) in the mothership fishery. Fishing occurred mostly off of Bristol Bay. From 1958 to 1963, the Japanese mothership fleet expanded in the Bering Sea. The foreign fisheries overexploited the yellowfin sole stock from 1959 to 1962, with catches averaging 400,000 mt annually, including the Soviet catch. The Soviet flounder fishery did not begin until about 1959, and occurred in areas where the yellowfin sole formed their winter aggregations. The Soviet portion of the flounder catch (made up mostly of yellowfin sole) from 1959 to 1963 ranged between 60,000 and 155,000 mt. Reduced abundance caused a decline in catches to about 100,000 mt annually from 1963 to 1971. By 1973, the Soviet flounder fishery failed to develop and was limited to a two-week period by four trawlers. A small Taiwanese fishery occurred in December of 1974, and was believed to have been targeting pollock and flounders. Yellowfin sole harvests continued to decline to 50,000 mt from 1972 to 1977. However, with an increase in abundance, the foreign and JV harvest increased in the 1980s. Foreign fisheries dominated the yellowfin sole harvest until 1984, and were completely phased-out of the BSAI in 1987 when the domestic and JV fisheries began rapid development (NPFMC 2002a).

Flounders have made up a relatively minor fishery in the Aleutian Islands, and consist of yellowfin sole, Alaska plaice, rock sole and flathead sole. Annual catch remained well under 5,000 mt from 1962 to 1971, increased to about 10,000 mt in 1972, and decreased to previous levels (5,000 mt) by 1976 (NPFMC 2002a).

Although large removals of yellowfin sole occurred during the past foreign fisheries, there are no observable lingering adverse effects on the BSAI yellowfin sole population.

Internal JV and Domestic Groundfish Fisheries (1980-present)

JV fisheries began in 1980 and ended in 1991 when the fishery became fully domesticated. The domestic yellowfin sole fishery began in 1987. Since that time, catches have not exceeded 150,000 mt annually, except for the 1997 harvest at 181,389 mt. In more recent years, the catch has been below 100,000 mt. The fishery is generally limited by Pacific halibut and crab bycatch limits, and market limitations (Wilderbuer and Nichol 2002).

Although large removals of yellowfin sole occurred during the JV and past domestic fisheries, there are no observable lingering adverse effects on the BSAI yellowfin sole population.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1954-1976)

The fishing mortality imposed on the yellowfin sole population by the foreign fisheries operating in the Bering Sea prior to 1976 has had no effect on the reproductive capabilities of the present population. Large removals of yellowfin sole in the early 1960s were followed by sustained above-average recruitment for over a decade in the period from 1966-1976. This level of productivity resulted in high levels of female spawning biomass. Furthermore, the age classes exploited during those years are no longer present in the current population due to natural mortality.

External Climate Changes and Regime Shifts

Patterns of yellowfin sole recruitment do not directly correspond with changes in the climate and the known regime shifts in 1977 and 1989. Following more than a decade of sustained above-average recruitment, the regime shift in 1977 ushered in a period of more variable recruitment success with very large year-classes in 1981 and 1983 interspersed with years of below average recruitment. The 1990s appear to be a less productive decade for recruitment. Because yellowfin sole are late spring/summertime spawners, it is unknown what physical mechanisms influence recruitment success.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The exploitation fraction of the fisheries on yellowfin sole since the MSA has averaged 0.06 and is thus unlikely to have had much effect on the reproductive success of the stock. The fisheries are also characterized as having been spread out over time and space which has caused minimal disruption to spawning concentrations.

Change in Prey Availability

External Foreign Groundfish Fisheries (1954-1976)

The foreign fisheries in the BSAI are unlikely to have directly impacted prey availability for the yellowfin sole stock since these fish eat infaunal and epifaunal invertebrates. The lingering effect in the BSAI yellowfin sole stock is likely due to the natural events related to climate change.

External State of Alaska Crab Fisheries Bycatch of Juvenile Crabs

The bycatch of juvenile crabs (the size consumed by yellowfin sole) is relatively minor in State of Alaska crab fisheries. It is unknown what effect this removal of juvenile crab has on the foraging capabilities of yellowfin sole as juvenile crabs are only one component of yellowfin sole diet. Also the summertime feeding distribution of yellowfin sole is quite extensive over the Bering Sea shelf, whereas these fisheries are quite limited in space.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. Although flatfishes tend to dominate catch during strong Aleutian Lows, on a microclimate scale, community structures changed in some nearshore areas with decreasing populations of shrimps and small forage fish, and increasing populations of the large, fish-eating species, such as Pacific cod, and other flatfishes (see Section 3.10.1.5). Pacific cod, skates, and Pacific halibut are all predators of yellowfin sole.

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of yellowfin sole.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of yellowfin sole.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The bycatch of juvenile crabs occurs in small numbers in domestic trawl fisheries. Crabs less than 25 mm in carapace width are estimated to have a selectivity of 0.001 in domestic fisheries from the snow crab assessment model. Combined with the fact that juvenile crab are only one component of the diet of yellowfin sole, these fisheries are not expected to impact the foraging capabilities of yellowfin sole.

Change in Important Habitat

External Foreign Groundfish Fisheries (1954-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of past foreign fisheries on habitat suitability is either beneficial or adverse; the effects are found to have had a lingering influence in yellowfin sole stocks, and the overall effect is beneficial in the BSAI yellowfin sole assemblage, probably due to climatological effects.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability; depending if habitat suitability is evaluated on a macro- or microscale. In general, when the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Survey biomass estimates of yellowfin sole over the past 15 years show a positive correlation with shelf bottom temperatures (Nichol 1998); estimates have been low during cold years.

(Wilderbuer and Nichol 2001). The lingering beneficial influence in the BSAI yellowfin sole stock is likely due to the natural events related to climate change.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of yellowfin sole.

Internal JV and Domestic Groundfish Fisheries (1980-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Recent research by the Resource Conservation Assessment Engineering (RACE) Division of the AFSC has investigated the consequences of lost habitat on juvenile flatfishes. The researchers found that juvenile flatfishes, including Pacific halibut and rock sole, prefer structured habitat (sand with sponges, bryozoans, bivalve shells, and waves). Furthermore, it was found that these structured habitats provide for reduced mortality rates by reducing their encounter rate with predators. Invertebrate bycatch from trawled and untrawled areas northeast of the Crab and Halibut Protection Zone 1 in the EBS inspired this research; invertebrates were more abundant in the non-fished zone versus the fished zone (Stone 2002).

The effect of past JV fisheries on habitat suitability is either beneficial or adverse; the effects are found to have had a lingering influence in yellowfin sole stocks, and the overall effect is beneficial in the BSAI yellowfin sole assemblage, probably largely due to climatological effects.

BSAI Yellowfin Sole Comparative Baseline

AFSC surveys conducted in waters 20-200 m from the Alaska Peninsula north to St. Matthew and Nunivak Islands show a doubling of biomass between 1975 and 1979, with a continued increase till 1981 at 2.3 million mt for fish age-7+ (exploitable biomass). Biomass estimates varied from 1981 to 1990, but levels between 1990 and 1999 have shown an even trend at high levels. 1999 and 2000 biomass estimates are at lower levels, while there is a slight increase in the 2001 and 2002 survey estimates (Wilderbuer and Nichol 2002).

Variations in survey results can be attributed to the availability of the yellowfin sole population in a survey area. Yellowfin sole are known to migrate from wintering areas off the shelf-slope break to spawn in nearshore waters that are not sampled by the AFSC survey (Nichol 1995, Wakabayashi 1989, Wilderbuer *et al.* 1992). Some variability can also be attributed to shelf bottom temperatures; biomass estimates over the past 15 years have shown a positive correlation with shelf bottom temperature: the colder the year, the lower the estimate. This may further reduce the availability of the yellowfin sole population to the survey area (Wilderbuer and Nichol 2001).

Model results suggest that the age-2+ biomass was at low levels during most of the 1960s and 1970s. A peak of 2.5 million mt occurred in 1985 due to sustained above average recruitment from 1967-1976 combined with low exploitation. Since 1985, the population of age-2+ yellowfin sole and female spawning biomass has been in slow decline. Above average recruitment from the 1991 year-class is expected to maintain the abundance of yellowfin sole above the $B_{40\%}$ level in the near future (Wilderbuer and Nichol 2001).

BSAI Yellowfin Sole Cumulative Effects Analysis Status

BSAI yellowfin sole will be brought forward for cumulative effects analysis.

3.5.1.6 BSAI Rock Sole

Life History and Distribution

Rock sole are distributed from southern California northward through Alaska (Wolotira *et al.* 1993). Two species of rock sole occur in the NPO, the northern rock sole (*Lepidopsetta polyxystran* sp.), and the southern rock sole (*L. bilineata*). These species have an overlapping distribution in the GOA, but the northern species primarily comprise the BSAI populations (Wilderbuer and Walters 1997). Their center of abundance occurs off the Kamchatka Peninsula, Russia (Shubnikov and Lisovenko 1964), off British Columbia (Forrester 1969), in the central GOA, and in the southern EBS (Alton and Sample 1976). Adults are benthic and, in the EBS, occupy separate winter (spawning) and summertime feeding distributions on the continental shelf. Spawning takes place during the late winter and early spring, near the edge of the continental shelf at depths of 125 to 250 m. Eggs are demersal and adhesive (Forrester 1964). The estimated age at 50 percent maturity for female rock sole is 9-10 years at a length of 35 cm (Wilderbuer and Walters 1997). Table 3.5-12 summarizes biological and reproductive attributes of rock sole in the BSAI and GOA.

Trophic Interactions

Major prey items include polychaete and miscellaneous worms, amphipods, and miscellaneous fish. Groundfish predators on rock sole include Pacific cod, skates, pollock, yellowfin sole, and Pacific halibut, which primarily consume fish ranging from 5-15 cm standard length. (Livingston and deReynier 1996).

BSAI Rock Sole Management

Northern and southern rock sole are managed as a single unit in the BSAI, and are currently managed under Tier 3a of NPFMC's ABC and OFL definitions. Management under Tier 3a requires reliable estimates of projected biomass, $B_{40\%}$, $F_{40\%}$ (for ABC) and $F_{35\%}$ (for OFL). Since the projected rock sole spawning biomass for 2003 is greater than $B_{40\%}$ (303,000 > 158,000), $F_{40\%}$ (the upper limit on ABC) is recommended as the F_{ABC} harvest reference point for 2003. This equates to a 2003 ABC of 110,000 mt and an OFL of 132,000 mt. Rock sole are abundant on the EBS shelf and also occur in the Aleutian Islands. This species represents a relatively data-rich case (Wilderbuer and Walters 2002) (Table 3.5-2).

Information on the rock sole stock conditions in the BSAI comes primarily from AFSC surveys. The time-series of fishery and survey age compositions allows the use of an age-based stock assessment model as the primary analytical tool. The outputs include estimates of abundance, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass. The model also estimates reference fishing mortality rates in terms of the ratio of female spawning biomass to unfished levels, which, when considered with projected future biomass, are used to calculate ABC. The stock assessment is updated annually at the conclusion of the summer trawl survey and is incorporated into the BSAI SAFE report (Wilderbuer and Walters 2001).

BSAI Rock Sole Past/Present Effects Analysis

The geographic scope for the BSAI rock sole past/present effects analysis is the same as the BSAI management units (Figure 1.2-2). The temporal scope for this analysis begins in 1954 when the foreign flounder fishery began and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-13 provides a summary of the rock sole past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on rock sole:

- Mortality due to catch/bycatch and marine pollution and oils spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch, the rock sole roe fishery, fishery selectivity and climate changes and regime shifts (indirect effect).
- Change in prey availability due to introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the rock sole fishery. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here. For the BSAI, there are no amendments that specifically mention rock sole.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species by way of ballast water and climate changes and regime shifts has not been brought forward since the impacts on rock sole in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regimes shifts.

The past/present events determined to be applicable to the rock sole past/present effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1954-1976)
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1990)
  - Domestic groundfish fisheries (1987-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1954-1976)

Rock sole were first targeted in the Japanese mothership fishery which began in 1954. The rock sole fisheries are the same as the flounder fisheries described in Section 3.5.1.5 that primarily targeted yellowfin sole and include the Japanese and Soviet fisheries. Rock sole were not always identified in catches prior to about 1970. Rock sole catch appears to have remained steady at about 7,000 mt from 1963-1969 and then increased to about 30,000 mt annually between 1970 and 1975. The end of the Soviet flounder fishery in 1973 (due to political reasons) is thought to have had a beneficial effect on the flatfish of the BSAI (NPFMC 2002a).

Flounders have made up a relatively minor fishery in the Aleutian Islands, and consist of yellowfin sole, Alaska plaice, rock sole and flathead sole. Annual catch remained well under 5,000 mt from 1962-1971, increased to about 10,000 mt in 1972 and decreased back down to about 5,000 mt by 1976 (NPFMC 2002a, Wilderbuer and Walters 2002).

Although removals of rock sole occurred during the foreign fisheries, there are no observable lingering adverse effects on the BSAI rock sole populations.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The JV fishery began in 1980 and was phased out of the BSAI by 1990. The JV fisheries averaged 2,000 to 9,000 mt annually from 1980-1983, increasing to nearly 30,000 mt in 1984. Peak harvest occurred in 1988 at about 40,000 mt. The domestic rock sole fishery began in 1987. The domestic harvest ranges from about 25,000 to 63,000 mt annually, with a peak in 1997 at 67,564. The average annual harvest from 1987-2000 is 54,960 mt. Rock sole are also a target of a high value roe fishery in February and March which takes the majority of the annual catch. The rock sole directed fishery tends to be limited due to bycatch of prohibited species (i.e. Pacific halibut and crab) (Wilderbuer and Walters 2001).

Although large removals of rock sole occurred during the JV and past domestic fisheries, there are no observable lingering adverse effects on the BSAI rock sole population.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1954-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effects of the foreign fisheries on the spatial/temporal distribution of BSAI rock sole due to the spatial/temporal concentration of the fishery is unknown. However, any effects would not have had lingering population effects in the population.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of rock sole. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries

Spatial/Temporal Concentration of Catch/Bycatch

The JV and past domestic fisheries effects on the spatial/temporal distribution of the BSAI rock sole due to the spatial/temporal concentration of the fishery is unknown. However, any effects would not have had lingering population effects in the population.

Fishery Selectivity

Large amounts of rock sole are discarded overboard in various Bering Sea trawl target fisheries. Fisheries with the highest discard rates include the rock sole, yellowfin sole, Pacific cod, and the bottom pollock fisheries. Rock sole discard rates have exceeded the amount of rock sole retained since 1987, ranging from 33-45 percent retention from 1990-2000. Recently, percent discards have increased to 66 and 57 percent, respectively, for 2001 and 2002, and the amount discarded was 9,956 mt and 17,291 mt, respectively. Peak discard occurred in 1993 at 45,669 mt, but has generally ranged from 12,000 to 40,000 mt annually based on 1987-2002 (Wildebuer and Walters 2002).

Roe Fishery

The rock sole roe fishery takes a majority of the annual catch of rock sole, although the total catch in recent years has only been 21 percent of the ABC (2000).

Change in Prey Availability

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on and prey availability depending on the frame of reference. In general, when the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of rock sole.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of rock sole.

Change in Important Habitat

External Foreign Groundfish Fisheries (1954-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Recent research by the RACE division of the AFSC has investigated the consequences of lost habitat on juvenile flatfishes. The researchers found that juvenile flatfishes, including Pacific halibut and rock sole, prefer structured habitat (sand with sponges, bryozoans, bivalve shells, and waves). Furthermore, it was found that these structured habitats provide for reduced mortality rates by reducing the flatfish encounter rate with predators. Invertebrate bycatch from trawled and untrawled areas northeast of the Crab and Halibut Protection Zone 1 in the EBS inspired the research; invertebrates were more abundant in the non-fished zone than in the fished zone (Stone 2002).

The effect of these fisheries is either beneficial or adverse; they are found to have had a lingering beneficial influence in the BSAI, probably mostly due to climatological effects.

External Climate Changes and Regime Shifts

The effect of climate changes on habitat suitability is either beneficial or adverse depending on the frame of reference; they are found to have had a lingering beneficial influence in the BSAI. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of rock sole.

Internal JV and Domestic Groundfish Fisheries

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of past JV fisheries on habitat suitability is either beneficial or adverse; they are found to have had a lingering beneficial influence in the BSAI, probably mostly due to climatological effects.

BSAI Rock Sole Comparative Baseline

The AFSC stratified area-swept bottom trawl surveys indicate that rock sole biomass remained stable through 1979, with a substantial increase in abundance to 799,300 mt in 1984. A slight decrease occurred in 1985, but estimates rose again to over 1 million in 1986 and continued to increase throughout the 1990s. The survey estimates peaked in 1994 and thereafter show the stock at a high level with a 2002 estimate of 1.9 million mt (Wilderbuer and Walters 2001).

The stock assessment model abundance estimates indicate that rock sole were at low levels during the mid-1970s through 1982. The population increased from 1982 to 1995, during a period of above-average recruitment and low exploitation, peaking in 1995 at over 1.5 million mt. Current population-levels are 38 percent lower than the peak estimate of 1995, attributable to below-average recruitment of the adult portion of the population during the 1990s, and is projected to decline further in 2003. The female spawning biomass is estimated at a high level, but slightly declining in 2002. Model projections indicate that this stock is neither overfished nor approaching an overfished condition (Wilderbuer and Walters 2002).

Currently, rock sole spawning stock has contributions from a wide range of ages and is well above the $B_{40\%}$ level. Projections for the near future indicate a decline in female spawning biomass due to a lack of good recruitment during the 1990s (Wilderbuer and Walters 2001).

BSAI Rock Sole Cumulative Effects Analysis Status

The BSAI rock sole will be brought forward for cumulative effects analysis.

3.5.1.7 BSAI Flathead Sole

Life History and Distribution

Flathead sole (*Hippoglossus elassodon*) are distributed from northern California northward throughout Alaska. In the northern part of its range, the species overlaps with the related and very similar Bering flounder (*Hippoglossoides robustus*) (Wolotira *et al.* 1993, Hart 1973). Adults are benthic and occupy separate winter spawning and summer feeding distributions. From overwintering grounds near the continental shelf margin, adults begin a migration onto the mid- and outer continental shelf in April or May. The spawning period occurs in late winter/early spring, primarily in deeper waters near the margins of the continental shelf (Walters and Wilderbuer 1997). Eggs are large and pelagic. Upon hatching, the larvae are planktonic and usually inhabit shallow areas (Waldron and Vinter 1978). Age and size at maturity are unknown, but recruitment to the fishery begins at age 3 (Figure 3.5-5). The maximum age from fishery age samples is 28 years. Flathead sole are taken in bottom trawls both as a directed fishery and in pursuit of other bottom dwelling species. Table 3.5-14 summarizes biological and reproductive attributes and habitat associations of flathead sole in the BSAI and GOA.

Trophic Interactions

Flathead sole feed primarily on invertebrates such as ophiuroids, tanner crab, bivalves and polychaetes. Their diet has been shown to include commercially important species such as pollock and tanner crabs. In the EBS, other fish species represented 5 to 25 percent of the diet (Livingston *et al.* 1993). Groundfish predators include Pacific cod, Pacific halibut, arrowtooth flounder, and also cannibalism by large flathead sole, mostly on fish less than 20 cm standard length.

BSAI Flathead Sole Management

Since it is difficult to separate flathead sole and Bering flounder at sea, they are currently managed as a single stock (Walters and Wilderbuer 1997) under Tier 3a of NPFMC's ABC and OFL definitions. Management under Tier 3a requires reliable estimates of projected biomass, $B_{40\%}$, $F_{40\%}$ (for ABC), and $F_{35\%}$ (for OFL). Since the projected flathead sole female spawning biomass for 2003 (225,000 mt) is greater than $B_{40\%}$, the maximum F_{ABC} is recommended as the harvest reference point for 2003, equating to an ABC of 66,000 mt (Table 3.5-2). The $F_{35\%}$ value (0.37) gives an OFL value of 81,000 mt.

Annual trawl survey biomass results have been the primary data component used to assess stock level since 1982. The assessment model has a length-based formulation, which is underlaid by an age-based model. The outputs include estimates of abundance, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass. The model also estimates reference fishing mortality rates in terms of the ratio of female spawning biomass to unfished levels which, when considered with projected future biomass, are used to calculate ABC. The stock assessment is updated annually at the conclusion of the summer trawl survey and is incorporated into the BSAI SAFE report (Spencer *et al.* 2001a).

BSAI Flathead Sole Past/Present Effects

The geographic scope for the BSAI flathead sole past/present effects analysis is the same as the BSAI management units (Figure 1.2-2). The temporal scope for this analysis begins in 1954 when the foreign flounder fishery started and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-15 provides a summary of the flathead sole past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on flathead sole:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch, fishery selectivity, and climate changes and regime shifts (indirect effect).

- Change in prey availability due to climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, marine pollution and oil spills, introduction of exotic species and climate changes and regime shifts (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the rock sole fishery. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here. For the BSAI, no amendments specifically mention flathead sole.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on flathead sole in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the flathead sole past/present effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1954-1976)
  - State of Alaska crab fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1990)
  - Domestic groundfish fisheries (1987-present)

- Past/Present Management Actions
  - Bilateral agreement
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1954-1976)

Flathead sole were first targeted with other flatfish species in the Japanese mothership fishery which began in 1954. The flathead sole fisheries are the same as the flounder fisheries described in Section 3.5.1.5 that primarily targeted yellowfin sole and include the Japanese and Soviet fisheries. Flathead sole were not always identified in catches prior to about 1970, and were combined into the "other species" category. Flathead sole catch declined from approximately 30,000 mt to under 10,000 mt annually from 1963-1965 and then increased steadily to about 25,000 mt in 1969. A significant increase in catch occurred after 1969, peaking in 1971 at about 51,000 mt. Catches again decreased following 1971 to about 20,000 mt annually and remained relatively stable through 1976. The discontinuation of the Soviet flounder fishery (1973) is thought to have had a beneficial effect on the flatfish of the BSAI (NPFMC 2002a, Spencer *et al.* 2002a).

Flounders have made up a relatively minor fishery in the Aleutian Islands, which consists of yellowfin sole, Alaska plaice, rock sole and flathead sole. Annual catch remained well under 5,000 mt from 1962-1971, increased to about 10,000 mt in 1972 and decreased back down to about 5,000 mt by 1976 (NPFMC 2002a).

Although large removals of flathead sole have occurred in the foreign fisheries, there are no observable lingering negative effects in the BSAI flathead sole population.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The JV fishery began in 1980 and was phased out of the BSAI by 1990. From 1977 to 1989, flathead sole harvests were under 10,000 mt annually, with an average annual catch of 5,286 mt. Catches increased in 1990-2000 to an average of 17,946 mt annually. Flathead sole have remained lightly harvested largely due to prohibited species bycatch restrictions, including halibut and crab limits.

Due to the small removals of flathead sole by the JV and past domestic fisheries, there are no observable lingering adverse effects on the BSAI flathead sole populations.

Prior to 1994, flathead sole and Bering flounder were managed as unit stock *Hippoglossoides sp.* under the "other flatfish" assemblage in the BSAI. At that time NPFMC requested the BSAI Groundfish Plan Team to assign a separate ABC for flathead sole in the BSAI, rather than combining it with the other flatfish assemblage. This request was made to protect the less abundant species of the "other flatfish" category at a time of increased targeting on flathead sole since individual species catch are not distinguished when managing as an assemblage, but rather the ABC is prescribed as a composite of all species.

Recent studies have described the growth and distribution differences between the flathead sole and Bering flounder and have illustrated the possible ramifications of combining the two species as a unit stock (Walters and Wilderbuer 1997). This may lead to separate management in the future.

Change in Reproductive Success

External Foreign Groundfish Fisheries

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the foreign fisheries on spatial/temporal distribution of the BSAI flathead sole stocks is unknown. These fisheries are determined not to have had lingering population effects in the BSAI population. Winter time-area closures in the south EBS, designed pre-MSA for the protection of halibut, also benefitted flathead sole because they form winter concentrations in this area as well. Furthermore, the absence of a directed Soviet fishery on flathead sole after 1972 may have additionally benefitted the stocks (NPFMC 2002a).

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of flathead sole. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries (1980-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the JV fisheries on the spatial/temporal distribution of the BSAI flathead sole stock is unknown. These effects are determined not to have had lingering population effects in the BSAI population.

Fishery Selectivity

Significant amounts of flathead sole bycatch occur in the Pacific cod, pollock and rock sole fisheries, although the percentage of retention has increased in recent years from 51 percent in 1995 to 82 percent in 2001. Actual amounts of flathead sole discard have declined from 7,189 mt in 1998 to 3,231 mt in 2001; there has been a slight increase in 2002 at 3,646 mt as of September 21, 2002 (Spencer *et al.* 2002a).

Change in Prey Availability

<u>External Foreign Groundfish Fisheries (1954-1976)</u>

It is unlikely that the foreign fisheries had an effect on the prey availability of flathead sole. Flathead sole are characterized as having both a mixed fish and invertebrate diet. They receive this characterization due to the presence of pollock, brittle stars, crangon shrimp, mysids, and bivalves in their diet. Fish are a relatively small portion (less than 20 cm) of the flathead sole diets, but are increasingly important with size (Livingston and deReynier 1996). Records of past foreign fishery juvenile crab bycatch are unavailable; however, the impacts of these fisheries on flathead sole prey availability are also considered to be minimal.

<u>External State of Alaska Crab Fisheries</u>

The bycatch of juvenile crabs (the size consumed by flathead sole) is relatively minor in the State of Alaska crab fisheries. It is unknown what effect this removal of juvenile crab has on the foraging capabilities of flathead sole as crabs are only one component of their diet and these fisheries are quite limited in space.

<u>External Climate Changes and Regime Shifts</u>

Environmental conditions, such as changes in the Aleutian Low pressure system, may affect flathead sole stock recruitment (Hare and Mantua 2000). Future flathead sole research will take environmental variability into account when performing stock-recruitment analyses. Currently, Wilderbuer *et al.* (in press) are investigating a shift in wind patterns that coincided with below average recruitment of flathead sole in the 1990s.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability depending on the frame of reference. In general, when the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of flathead sole.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of flathead sole.

Internal JV and Domestic Groundfish Fisheries (1980-present)

It is unlikely that the JV and domestic fisheries have had an effect on the prey availability of flathead sole due to the mixed fish and invertebrate diet of flathead sole. Fish make up a relatively small portion of flathead sole diet, although the importance of fish increases with size. The bycatch of juvenile crabs occurs in small numbers in domestic trawl fisheries. Crabs less than 25 mm in carapace width are estimated to have selectivity of 0.001 in domestic fisheries from the snow crab assessment model. Combined with the fact that juvenile crab are only one component of the diet of flathead sole, these fisheries are not expected to impact their forage capabilities.

Change in Important Habitat

External Foreign Groundfish Fisheries (1954-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the foreign fisheries on habitat suitability is either beneficial or adverse; the effects are found to have had a lingering beneficial influence in the BSAI, probably due to climatological effects.

External IPHC Longline and State of Alaska Crab Fisheries

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the IPHC longline and State of Alaska crab fisheries on BSAI flathead sole habitat suitability is expected to be adverse, however, the magnitude of these effects are unknown. The lingering beneficial influence on habitat suitability in the BSAI in likely due to climatological effects.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability depending on the frame of reference. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in the same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of flathead sole.

Internal JV and Domestic Groundfish Fisheries (1980-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6 for a discussion of the potential impacts of fishery gear on habitat.

Recent research by the RACE division of the AFSC has investigated the consequences of lost habitat on juvenile flatfishes. The researchers found that juvenile flatfishes, including Pacific halibut and rock sole, prefer structured habitat (sand with sponges, bryozoans, bivalve shells, and waves). Furthermore, it was found that these structured habitats provide for reduced mortality rates by reducing the encounter rate between flatfish and predators. Invertebrate bycatch from trawled and untrawled areas northeast of the Crab and Halibut Protection Zone 1 in the EBS inspired the research; invertebrates were more abundant in the non-fished zone than in the fished zone (Stone 2002).

The effect of the JV fisheries on habitat suitability is either beneficial or adverse; the effects are found to have had a lingering beneficial influence in the BSAI, probably due to climatological effects.

BSAI Flathead Sole Comparative Baseline

Survey biomass estimates indicate that flathead sole increased from low levels in the early 1980s to a high stable level in the mid-1990s. However, values for 1999-2000 were nearly half of the peak value estimated in 1997, with a slight increase in the 2001 and 2002 surveys (Spencer *et al.* 2002a).

Model estimates indicate an increase in age-3+ total biomass from 1977 to a peak in 1991, followed by a steady decline through 2001. Female spawning biomass increased from 1977 to a peak in 1995, also followed by a steady decline through 2001. Model estimates fit the survey biomass estimate data well, except for 1994, 1997, and 1998 estimates. Model projections indicate that this stock is neither overfished nor approaching an overfished condition.

BSAI Flathead Sole Cumulative Effects Analysis Status

The BSAI flathead sole will be brought forward for cumulative effects analysis.

3.5.1.8 BSAI Arrowtooth Flounder

Life History and Distribution

Arrowtooth flounder (*Atheresthes stomias*) occur from central California to the Bering Sea, in waters from about 20-800 m (Zimmerman and Goddard 1996). Spawning is protracted and variable and probably occurs from September through March (Zimmermann 1997). For female arrowtooth flounder collected off the Washington coast, the estimated age at 50 percent maturity was 5 years, with an average length of 37 cm.

Males matured at 4 years and 28 cm (Rickey 1995). The maximum reported ages are 16 years in the Bering Sea, 18 years in the Aleutian Islands, and 23 years in the GOA (Turnock *et al.* 1997a, Wilderbuer and Sample 1997). Arrowtooth flounder is currently the most abundant groundfish species in the GOA; however, they are currently considered of low value and mostly discarded.

In the Bering Sea, the arrowtooth flounder inhabits the continental shelf waters almost exclusively until age-4, but older ages occupy both shelf and slope waters, with greatest concentrations at depths between 100 and 200 m (Martin and Clausen 1995). The very similar Kamchatka flounder (*Atheresthes evermanni*) also occurs in the Bering Sea. Values of 50 percent maturity for the Bering Sea stock are 42.2 cm and 46.9 cm for males and females, respectively (Zimmerman 1997). Table 3.5-16 summarizes biological and reproductive attributes and habitat associations of arrowtooth flounder in the BSAI and GOA.

Trophic Interactions

Arrowtooth flounder play an important role in the Bering Sea and GOA ecosystems because they are large, aggressive, and abundant predators of other groundfish species (Hollowed *et al.* 1995, Livingston 1991b, Yang 1993). The majority of prey by weight of arrowtooth flounders larger than 40 cm is pollock, the remainder consisting of herring, capelin, euphausiids, shrimp, and cephlapods (Yang 1993). These fish also consumed salmonids and Pacific cod in the GOA (Yang and Nelson 2000). The percent of pollock in the diet of arrowtooth flounder increases for sizes greater than 40 cm. Arrowtooth flounder 15-30 cm consume mostly shrimp, capelin, euphausiids and herring, with small amounts of pollock and other miscellaneous fish (DiCosimo 1998). Groundfish predators on arrowtooth include Pacific cod and pollock, which feed mostly on small fish (Livingston and deReynier 1996).

BSAI Arrowtooth Flounder Management

Since the Kamchatka flounder is not usually distinguished from arrowtooth flounder in commercial catches, both species are managed as a group. These species are managed under Tier 3a of the ABC/OFL definitions since equilibrium recruitment can be approximated by the average recruitment from the time-series estimated in the stock assessment, and $B_{40\%}$, $F_{40\%}$, and $F_{35\%}$ can be estimated. The spawning biomass is above $B_{40\%}$ (436,000 mt >206,000 mt), which leads to an ABC value of 112,000 mt. The 2003 OFL has been established at 139,000 mt (Table 3.5-2). The BSAI Arrowtooth flounder stock is neither overfished nor approaching an overfished condition (Wilderbuer and Sample 2002).

Information on arrowtooth flounder stock conditions in the BSAI comes primarily from the AFSC annual continental shelf trawl survey, the U.S.-Japan cooperative trawl surveys conducted triennially on the continental slope from 1979-1991 (and 1981), and triennial surveys in the Aleutian Island region. The 2002 BSAI SAFE report introduced a new split-sex model for arrowtooth flounder. This model takes into account the high ratio of females to males and estimates a separate natural mortality rate for males. In turn, separate selectivities are calculated for males and females. The abundance, mortality, and recruitment are also evaluated with this model. The outputs include estimates of sex-specific abundance, year-class strengths, length-at-age relationship, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass. The model also estimates reference fishing mortality rates in terms of the ratio of female spawning biomass to unfished levels, which, when considered with projected future biomass, are used to calculate ABC. The stock assessment is updated annually at the conclusion of the summer trawl survey and is incorporated into the BSAI SAFE report. The reference fishing mortality rate and ABC for arrowtooth flounder are determined by the amount of population information available (see Appendix B) (Wilderbuer and Sample 2002).

BSAI Past/Present Effects Analysis

The geographic scope for the arrowtooth flounder past/present effects analysis is the same as the BSAI management units (Figure 1.2-2). The temporal scope for this analysis begins in 1954 when the foreign fishery for arrowtooth flounder began and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-17 provides a summary of the arrowtooth flounder past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on arrowtooth flounder:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to the spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery bycatch of prey species, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, introduction of exotic species, marine pollution and oil spills, and climate changes and regime shifts (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explains any management actions specific to the arrowtooth flounder. Amendments discussed in Section 3.2 which impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on arrowtooth flounder in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate change or regime shifts.

The past/present events determined to be applicable to the arrowtooth flounder past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1954-1976)
  - State of Alaska groundfish fisheries
  - State of Alaska herring fisheries

- Marine pollution and oil spills
- Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1990)
  - Domestic groundfish fisheries (1986-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1954-1976)

The foreign flatfish fishery began in 1954, mainly targeting yellowfin sole (see Section 3.5.1.5). Catches of Greenland turbot (arrowtooth flounder and Greenland turbot) were relatively high in early years of the EBS fishery ranging over 50,000 mt in 1961 and 1962. Japanese fisheries targeted on arrowtooth flounder from 1961 to 1962 for the production of fishmeal (Takahashi 1976). Catches dropped below 40,000 mt in 1963-1970 as these species were only taken as bycatch in the pollock and other directed fisheries. Annual harvest of arrowtooth flounder reached peak rates between 1974-1976 at levels between 19,000 and 25,000 mt (NPFMC 2002a).

Flounders have formed a relatively small proportion of the total catches in the Aleutian Islands dominated by the Japanese fisheries, although Greenland turbot and arrowtooth flounder have been the main flounder species taken. Reported catches of arrowtooth flounder and Greenland turbot were low until 1970, after which they increased sharply, with Greenland turbot as the primary species taken (NPFMC 2002a).

Although large removals of arrowtooth flounder have occurred during the foreign fisheries, there are no observable lingering adverse effects in the BSAI arrowtooth flounder populations.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The JV arrowtooth flounder fisheries began in 1980 and were phased-out by 1990, when the fishery became fully domesticated. The domestic fisheries began in 1986. With the phasing-out of the foreign fisheries and restrictions placed on Greenland turbot fisheries, harvest rates decreased from the foreign exploitation harvest rates and have remained lightly harvested since that time, averaging 13,500 mt from 1977-2000. Total catch for 2001 (as of September 15, 2001) was 11,230 mt, well below the ABC. Arrowtooth flounder are typically caught in the pursuit of high-value fish and are not a target species in the BSAI (Wilderbuer and Sample 2002).

Prior to 1985, arrowtooth flounder were managed with Greenland turbot as a species complex due to similarities in their life history characteristics, distribution, and exploitation. Greenland turbot were the target species of the fisheries, whereas arrowtooth flounder were caught as bycatch. Because the stock condition of the two species have differed markedly in recent years, management since 1986 has been by individual species.

Discard rates of arrowtooth flounder have been high, ranging from 72 mt in 1985 to 18,841 mt in 1991. Percent retention from 1985-1998 ranged from 4 to 19 percent; however, retention has risen in recent years to 62 percent in 2001. Substantial amounts of discard take place in the BSAI trawl and longline target fisheries, mostly in the Pacific cod, rock sole, "other flatfish," and Greenland turbot fisheries. A developing arrowtooth flounder market is expected to increase retention in coming years (Wilderbuer and Sample 2001).

Although large removals of arrowtooth flounder have occurred in the JV and past domestic fisheries, there are no observable lingering adverse effects in the arrowtooth flounder populations.

Currently, arrowtooth flounder have a low perceived commercial value because the flesh softens soon after capture due to protease enzyme activity (Greene and Babbitt 1990). Enzyme inhibitors such as beef plasma have been found to counteract this flesh-softening activity, but suitable markets have not been established to support increased harvests. Thus, arrowtooth flounder are primarily caught by bottom trawls as bycatch in high value fisheries. Stocks are lightly exploited and appear to be increasing in both the GOA and the BSAI.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1954-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the direct foreign fisheries on the spatial/temporal distribution of the BSAI arrowtooth flounder is unknown. However, these effects are determined to not have had lingering population effects on the stock.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of arrowtooth flounder. The combination of climate effects and regime shifts on prey availability and habitat suitability influence the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an in-depth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries.

Internal JV and Domestic Groundfish Fisheries (1980-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the JV and past domestic fisheries on the spatial/temporal distribution of the BSAI arrowtooth flounder is unknown. However, these effects are determined to not have had lingering population effects in either stock.

Change in Prey Availability

External Foreign Groundfish Fisheries (1954-1976)

The past foreign fisheries in the BSAI have had either an adverse or beneficial lingering impact on prey availability. Arrowtooth flounder from 15-30 cm feed mostly on shrimp, euphausiids, capelin, and herring (DiCosimo 1998). Arrowtooth flounder are important as a large and abundant predator of other groundfish species. Adults (fish over 40 cm) are almost exclusively piscivorus and over half their diet can consist of pollock (Hollowed *et al.* 1995, Livingston 1991b, Yang 1993). In turn, the effects of the fisheries could have been beneficial or adverse since pollock also prey on arrowtooth flounder.

Bycatch of forage species in the past foreign BSAI groundfish fisheries is also likely to have been minimal. Furthermore, since arrowtooth flounder feed on a number of different prey species, it is also unlikely that the groundfish fisheries would have had a significantly adverse impact on prey availability.

External State of Alaska Groundfish Fisheries and Herring Fisheries

Bycatch of forage species and juvenile pollock in the BSAI State of Alaska groundfish fisheries is minimal and is unlikely to reduce the prey availability of arrowtooth flounder. Furthermore, since arrowtooth flounder feed on a number of different prey species, it is also unlikely that State of Alaska herring fisheries would have a significantly adverse impact on prey availability.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of arrowtooth flounder.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The past JV fisheries in the BSAI have had either an adverse or beneficial lingering impact on prey availability. However, there are no indications that harvest conditions resulting from arrowtooth flounder management would alter the genetic structure of the populations, the available prey, or the suitability of nursery and/or spawning habitat in a manner that would impede long-term suitability of the stock.

Bycatch of forage species in the BSAI groundfish fisheries is minimal. Furthermore, since arrowtooth flounder feed on a number of different prey species, it is also unlikely that the groundfish fisheries would have a significantly adverse impact on prey availability. BSAI/GOA Amendment 36/36 was established to protect forage fish species from developing in to a fishery market, and limiting the forage fish bycatch.

Change in Important Habitat

External Foreign Groundfish Fisheries (1954-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability for both stocks has been either adversely or beneficially affected by the intensity of the past foreign fisheries, and these effects are considered to have lingering influence at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of arrowtooth flounder.

Internal JV and Domestic Groundfish Fisheries (1980-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability for both stocks has been either adversely or beneficially affected by the intensity of the past JV fisheries, and these effects are considered to have lingering influence at the population-level.

There are no indications that harvest conditions resulting from arrowtooth flounder management would alter the genetic structure of the populations, the available prey, or the suitability of nursery and/or spawning habitat in a manner that would impede long-term suitability of the stock.

BSAI Arrowtooth Flounder Comparative Baseline

Estimated biomass from the AFSC surveys on the continental shelf showed a consistent increasing trend from 1975-1995. These estimates remained at high levels from 1992-1997, but declined from 1997-2000 to levels 60 percent below the peak 1994 biomass estimate. 2001 survey biomass estimates are slightly higher than the 2000 estimate; however, the 2002 biomass estimates are down from 2001 (Wilderbuer and Sample 2002).

Continental slope surveys show an increase in biomass estimates between 1982 and 1985. Estimates for 1988 and 1991 are lower; however, the surveys in these years were not as deep as in previous years (200-800 m versus 200-1000 m in previous years). Survey estimates from 1979-1985 indicate that 27-51 percent of the arrowtooth flounder biomass are found in slope waters. The 2002 EBS continental slope survey found over 90 percent of arrowtooth flounder biomass at less than 800 m. Biomass estimates in the Aleutian Island region have remained stable at relatively high values since 1994 (Wilderbuer and Sample 2002).

Stock assessment model estimates indicate a five-fold increase in total biomass from 1980 to 1996, attributed to five strong year-classes. Biomass has since declined 22 percent from the peak of 817,700 mt to the 2002 biomass estimate of 638,000 mt. The decline in abundance can be attributed to a below average recruitment during the late 1990s. Currently the arrowtooth flounder spawning stock has contributions from a wide range of ages, and the stock is considered at a high level but declining. Model projections indicate that this stock is neither overfished nor approaching an overfished condition (Wilderbuer and Sample 2002).

BSAI Arrowtooth Flounder Cumulative Effects Analysis Status

The BSAI arrowtooth flounder will be brought forward for cumulative effects analysis.

3.5.1.9 BSAI Greenland Turbot

Life History and Distribution

Greenland turbot (*Reinhardtius hippoglossoides*) are distributed from Baja California northward throughout Alaska and the Arctic, although they are rare south of Alaska and primarily distributed in the EBS and Aleutian Islands region (Hubbs and Wilimovsky 1964). Juveniles are believed to spend the first three or four years of life on the continental shelf, then move to the continental slope as adults (Alton *et al.* 1988, Templeman 1973). Greenland turbot are demersal to semipelagic. Unlike most flatfish, the Greenland turbot's migrating eye does not move completely to one side, but stops at the top of the head, which presumably results in a greater field of vision and helps to explain this species' tendency to feed off the sea bottom (de Groot 1970). Spawning occurs in winter and may be protracted, starting as early as September and continuing until March (Bulatov 1983). The eggs are benthypelagic (D'yakov 1982). Juveniles are absent in the Aleutian Islands, suggesting that populations in that area originate from elsewhere (Alton *et al.* 1988). Greenland turbot are a moderately long-lived species, with a maximum recorded age of 21 years (Ianelli and Wilderbuer 1995). Table 3.5-18 summarizes biological and reproductive attributes and habitat associations of Greenland turbot in the BSAI and GOA.

Trophic Interactions

Pelagic fish are the main prey of Greenland turbot, with pollock often a major species in the diet. Other prey items include squid, euphasiids, shrimp, and other fish species inhabiting deepwater, such as Bathylagidae and Myctophidae (Livingston 1991b).

Groundfish predators include Pacific cod, pollock, and yellowfin sole, which feed mostly on fish ranging from 2-5 cm standard length (Livingston and deReynier 1996).

BSAI Greenland Turbot Management

Greenland turbot are currently managed as a single stock in the BSAI under Tier 3a of NPFMC's ABC and OFL definitions (Amendment 44 to the FMP). Management under Tier 3a requires reliable estimates of projected biomass, $B_{40\%}$, $F_{40\%}$ (for ABC), and $F_{35\%}$ (for OFL). The addition of new slope survey estimates indicate a lower female spawning biomass for 2003 than predicted in the previous year (67,800 mt), which leads to a more conservative ABC. The recommended ABC for 2003 is 5,800 mt based on the recent 5-year average fishing mortality. This conservative ABC value is intended to protect the Greenland turbot stock in light of low recruitment and continued decline in stock abundance. The corresponding OFL is 17,800 mt (Table 3.5-2). Additional slope trawl surveys are necessary to reduce uncertainty in this stock (Ianelli *et al.* 2002a).

Abundance of juvenile and adult Greenland turbot on the EBS shelf is estimated by an annual trawl survey and in the Aleutian Islands by a triennial trawl survey. Abundance of adults and older juveniles were surveyed every three years on the slope cooperatively by the U.S. and Japan from 1979-1991. In the 2002, a biennial bottom trawl survey began in the upper continental slope of the EBS by the AFSC. Data collected provides information on abundance trends and trends in the biological condition of the groundfish and invertebrate resources in that region. As mentioned above, a new continental slope survey also began in the BSAI in 2002 (Ianelli *et al.* 2002a).

The time-series of fishery and survey length compositions allows the use of a length-based stock assessment model (Ianelli *et al.* 1997). The outputs include estimates of abundance, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass. The model also estimates reference fishing mortality rates in terms of the ratio of female spawning biomass to unfished levels, which, when considered with projected future biomass, are used to calculate ABC. The stock assessment is updated annually at the conclusion of the summer trawl survey and is incorporated into the BSAI SAFE report. Recent efforts simplify the model used for Greenland turbot through a two-fishery combined-sexes model. However, further model specification issues will need to be addressed before the model is used extensively (Ianelli *et al.* 2001a).

BSAI Greenland Turbot Past/Present Effects Analysis

The geographic scope for the BSAI Greenland turbot past/present effects analysis is the same as the BSAI management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1954 when the foreign flounder fishery began and ends in 2002, the most recent year for which stock assessment information exists.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-19 provides a summary of the BSAI Greenland turbot past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on BSAI Greenland turbot.

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect)
- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).
- Change in prey availability due to fishery catch/bycatch of prey species, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).
- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explains any management actions specific to the Greenland turbot. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on Greenland turbot in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the Greenland turbot past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1954-1976)
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1968-1990)

- Domestic groundfish fisheries (1968-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1954-1976)

The flounder foreign fishery began in 1954 and primarily targeted yellowfin sole (see Section 3.5.1.5). Catches of Greenland turbot (combined arrowtooth flounder and Greenland turbot) were high, ranging over 50,000 mt in 1961 and 1962, during which time the Japanese fisheries were targeting arrowtooth flounder for fishmeal (Takahashi 1976). From 1963 to 1970, catches dropped below 40,000 mt as Greenland turbot and arrowtooth flounder were only taken as bycatch in the pollock and other target fisheries. After 1970, Greenland turbot catch increased in both the Japanese and Soviet fisheries, reaching 70,000 mt in 1974 (NPFMC 2002a).

Flounders formed only a minor fishery in the Aleutian Islands region. Combined catches of arrowtooth flounder and Greenland turbot were low until 1970, after which there was a sharp increase in catch dominated by Greenland turbot. Catches from 1972-1975 ranged from 12,000 to 14,000 mt, taken mostly by the Japanese fisheries (NPFMC 2002a).

The large removals of Greenland turbot by the foreign fisheries are determined to have had an adverse effect on the BSAI Greenland turbot population. However, partly due to the longevity of the species, these effects are determined not to have had any observable lingering adverse effects in the population. The current low levels of BSAI Greenland turbot abundance is not attributed to foreign fishery removals.

Internal JV and Domestic Groundfish Fisheries (1968-present)

Following implementation of the MSA in 1976, catches still remained high, ranging from 48,000 to 57,000 mt annually. Catch restrictions placed on the Greenland turbot due to signs of declining abundance caused a decline in annual harvest rates from 1984 to the present. During these years, catches ranged from a high of 23,120 mt in 1984 to a low of 2,689 mt in 1992. Concerns over low recruitment led to a TAC setting at 7,000 mt between 1992-1997 and has resulted in a primarily bycatch-only fishery (Ianelli *et al.* 2001a).

Prior to 1985, Greenland turbot was managed with arrowtooth flounder as a species complex due to similarities in their life history characteristics, distribution, and exploitation. Greenland turbot were the target species of the fisheries, whereas arrowtooth flounder were caught as bycatch. Because the respective stock conditions of the two species have differed markedly in recent years, management since 1986 has been by individual species (Ianelli *et al.* 2002a).

Discard rates of Greenland turbot are significant, ranging from 2,711 mt in 1994 to a low of 729 mt in 1999. Bycatch occurs primarily in the Greenland turbot, sablefish, flathead sole, Pacific cod, and arrowtooth flounder fisheries. The sablefish fishery has the highest discard rate, increasing from 17 percent in 1999 to about 40 percent in 2001 (Ianelli *et al.* 2001a).

The large removals of Greenland turbot by the JV and past domestic fisheries are found to have had an adverse effect on the BSAI Greenland turbot population However, partly due to the longevity and turnover of the species, these effects are determined not to have had lingering population effects in the population. The current low level of BSAI Greenland turbot abundance is not attributed to the JV and past domestic fisheries removals.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1954-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the past foreign fisheries on spatial/temporal distribution of the BSAI Greenland turbot populations is unknown. However, there are no observable lingering adverse effects on the BSAI stock of Greenland turbot.

External Climate Changes and Regime Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of Greenland turbot. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Dramatic declines in the number of immature Greenland turbot on the EBS shelf relative to 1970s abundance information have inspired research into possible causes of this decline. One hypothesis is that increased abundance of predators (e.g., Pacific cod, Pacific halibut) in the mid-1980s (possibly due to climatological effects) reduced the survival of juvenile Greenland turbot (Ianelli *et al.* 2001a).

Internal JV and Domestic Groundfish Fisheries (1968-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the past JV fisheries on spatial/temporal distribution of the BSAI Greenland turbot stock is unknown. However, there are no observable lingering adverse effects in the BSAI Greenland turbot population.

Change in Prey Availability

External Foreign Groundfish Fisheries (1954-1976)

The foreign fisheries in Bering Sea could have had lingering adverse or beneficial effects on the availability of prey for Greenland turbot. Pelagic fish are the main prey of Greenland turbot, with pollock often a major species in the diet (Livingston 1991b). Greenland turbot also feed on squid, euphausiids, and shrimp.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. For example when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes such as Greenland turbot. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes. Greenland turbot and Pacific halibut responded more strongly to longer-term events (such as decadal-scale climate regime patterns). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor in the population.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of Greenland turbot.

Internal JV and Domestic Groundfish Fisheries (1968-present)

The JV fisheries in the Bering Sea could have had lingering adverse or beneficial effects on the availability of prey for Greenland turbot. Pelagic fish are the main prey of Greenland turbot, with pollock often a major species in the diet (Livingston 1991b). Greenland turbot also feed on squid, euphausiids, and shrimp. However, there are no indications that harvest conditions under current management would alter the population genetic structure, the available prey, or the suitability of nursery and/or spawning habitat in a manner that would impede long-term sustainability of the stock in both the BSAI and GOA.

Change in Important Habitat

External Foreign Groundfish Fisheries (1954-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the past foreign fisheries on habitat suitability is either beneficial or adverse; overall, a lingering influence on the population is found in both stocks probably mostly due to climatological effects.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. Another hypothesis to explain the decreased abundance of immature Greenland turbot is that the environmental regime shift that occurred in the late 1970s affected the abundance or shifted the location of Greenland turbot at different life stages due to the changing oceanographic conditions. A Greenland turbot tagging study is being currently being conducted by the NOAA Fisheries Auke Bay Laboratory in an effort to better understand Greenland turbot life history and to develop a multi-species ecosystem model (Ianelli *et al.* 2001a).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of Greenland turbot.

Internal JV and Domestic Groundfish Fisheries (1968-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of these fisheries on habitat suitability is either beneficial or adverse; overall, a lingering influence on the population is found in both stocks, probably mostly due to climatological effects. In 1998, no halibut PSC was apportioned to the Greenland turbot trawl fishery; therefore, no directed trawl fishing occurred, which may decrease the intensity of the fishery on Greenland turbot habitat.

There are no indications that harvest conditions under current management would alter the population genetic structure, the available prey, or the suitability of nursery and/or spawning habitat in a manner that would impede long-term sustainability of the stock in both the BSAI and GOA.

BSAI Greenland Turbot Comparative Baseline

Combined shelf and slope surveys indicate a decline in Greenland turbot abundance between 1979 and 1985. Following 1985, slope and Aleutian Island biomass results are not comparable since surveys were conducted at different depths. However, there is an indication that biomass estimates declined between 1985 and 1991.

The average shelf survey biomass estimate during 1993 and 2001 is 29,968 mt with a declining trend during this period. In the Aleutian Island region, U.S.-Japan cooperative longline surveys suggest an increasing trend from 1980 to 1986, possibly due to the migration of older fish from the EBS (Ianelli *et al.* 2002a).

The stock assessment model estimates biomass in the early 1960s are nearly half of those estimated during the 1970s. Subsequent poor recruitment of young juvenile Greenland turbot led to a decrease in abundance of exploitable stock in the 1980s. However, these biomass estimates may be biased towards low values since the Aleutian Island survey biomass estimates are not included. The Aleutian Island survey biomass estimates typically average about one fourth to one third of the total trawl survey population biomass estimate for the BSAI.

BSAI Greenland Turbot Cumulative Effects Analysis Status

BSAI Greenland turbot will be brought forward for cumulative effects analysis.

3.5.1.10 BSAI Alaska Plaice and Other Flatfish

Life History and Distribution

In the Bering Sea, fifteen flatfish species are managed under the "other flatfish" assemblage: Arctic flounder (*Liopsetta glacialis*), butter sole (*Isopsetta isolepis*), curlfin sole (*Pleuronectes decurrens*), deep-sea sole (*Embassichthys bathybus*), Dover sole (*Microstomus pacificus*), English sole (*Parophrys vetulus*), longhead dab (*Limanda proboscidea*), Pacific sanddab (*Citharichthys sordidus*), petrale sole (*Eopsetta jordani*), rex sole (*Glyptocephalus zachirus*), roughscale sole (*Clidodoerma asperrimum*), sand sole (*Psettichthys melanostictus*), slender sole (*Lyopsetta exilis*), starry flounder (*Platichthys stellatus*), and Sakhalin sole (*Pleuronectes sakhalinensis*). Until 2002, Alaska plaice (*Pleuronectes quadriterculatus*) was also a part of the other flatfish assemblage but has since been broken out and managed separately (Spencer *et al.* 2002c).

The species of the "other flatfish" complex are generally found on the EBS continental shelf, with small populations in the Aleutian Islands region. The distribution of many of the flatfish species extends down to Baja California, Mexico (Eschmeyer *et al.* 1983). Arctic flounder has a larger distribution, and can be found in the northeastern Atlantic, Arctic, and North Pacific oceans. In the North Pacific, the Arctic flounder can be found in the Chukchi and Bering seas and northern Okhotsk Sea. Both Arctic flounder and starry flounder are known to enter rivers (Nielsen 1986, Morrow 1980). Flatfish species tend to prefer sandy and/or muddy bottoms. Adults overwinter in deeper water and move into nearshore spawning areas in the late winter and spring. Spawning takes place as early as November for Dover sole (Hagerman 1952) but occurs from February through April for most species (Hart 1973). All flatfish eggs are pelagic and sink to the bottom shortly before hatching (Alderdice and Forrester 1968, Hagerman 1952, Orcutt 1950, Zhang 1987), except for butter sole, which has demersal eggs (Levings 1968). Little is known of the spawning, growth characteristics, or seasonal movements and population age and size structure of the species in the flatfish complex.

Dover sole produce large amounts of slime which may cover other fishes when caught in trawls (Clemens and Wilby 1961). Dover sole can hybridize with starry flounder producing *Inopsetta ischyra*, which can be found in the Bering Sea south to San Francisco, California. Starry flounder also hybridizes with the stone flounder (*Kareius bicoloratus)* (Morrow 1980).

Of the other flatfish species in the Bering Sea, Alaska plaice is the most abundant and commercially important. It is a comparatively long-lived species, and has frequently been aged as high as 25 years. This species is found at depths less than 110 m in the summer, with small juveniles frequenting in the shallower coastal waters and adults in deeper waters.

The other flatfish species complex in the GOA is currently managed as four categories: shallow water flatfish, deepwater flatfish, flathead sole, and rex sole (*Errex zachirus*). In 2002, flathead sole (*Hippoglossoides elassodon*) (see Section 3.5.1.7) was broken out of the flatfish assemblage and managed independently in the GOA. The shallow water flatfish consist of Alaska plaice (*Pleuronectes quadrituberculatus*), starry flounder (*Platichthys stellatus*), yellowfin sole (*Pleuronectes asper*) (see Section 3.5.1.5), English sole (*Pleuronectes vetulus*), butter sole (*Pleuronectes isolepis*), sand sole (*Psettichthys melanostictus*), northern rock sole (*Lepidopsetta perarcuata*) (see Section 3.5.1.6), and southern rock sole (*Pleuronectes bilineatus*) (see Section 3.5.1.6). Deepwater flatfish include Dover sole (*Microstomus pacificus*), Greenland turbot (*Reinhardtius hippoglossoides*) (see Section 3.5.1.9), and deep-sea sole (*Embassichthys bathbius*). Life history and distribution for these benthic species are as described above as in the BSAI or in the individual sections as indicated. Table 3.5-20 summarizes biological and reproductive attributes and habitat associations of selected flatfish in the BSAI and GOA

Trophic Interactions

The information provided below applies for both BSAI and GOA species not previously discussed in other sections.

Alaska plaice appear to feed primarily on polychaetes, marine worms, and other benthic invertebrates (Livingston and deReynier 1996, Livingston *et al.* 1993, Zhang 1988). Although little is known on the feeding habitats of the remaining flatfish species, most seem to prefer benthic invertebrates including small crustaceans, marine worms, mollusks, echinoderms, and small fishes (Hart 1973, Brodeur and Livingston 1988, Pearcy and Hancock 1978, Lamb and Edgell 1986, Nielsen 1986).

A common documented predator of many of the flatfish, including the Dover and English sole and the Pacific sanddab, is the California sea lion (Lowry *et al.* 1990). Other predators of various flatfish species include the Pacific halibut (on Dover sole) (Yang and Nelson 2000), the Pacific staghorn sculpin (on English sole) (Armstrong *et al.* 1995), the Pacific bonito (on Pacific sanddab) (Oliphant 1962), and the blue shark in California waters (on Pacific sanddab) (Harvey 1989). The hydromedusa water jellyfish may also prey upon the larvae and eggs of the English sole and the sand sole as found in a study in British Columbia (Purcell 1989). Predators of Alaska plaice include Pacific halibut, yellowfin sole, beluga whales, and fur seals.

BSAI Alaska Plaice and Other Flatfish Management

Beginning in 2002, Alaska plaice was broken out of the other flatfish assemblage and managed independently (Table 3.5-2). In the past, Alaska plaice dominated the other flatfish assemblage, constituting 87 percent of the 2000-2001 other flatfish catch. Alaska plaice is evaluated under Tier 3a of Amendment 56. Model projections indicate that Alaska plaice stocks are not overfished or approaching an overfished condition. (Spencer *et al.* 2002c).

The time series of fishery and survey age compositions allows the use of an age-based stock assessment model for the Alaska plaice stock. The outputs include estimates of abundance, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass (Spencer *et al.* 2002c).

Although there are fifteen species considered as part of the "other flatfish" complex, only seven species comprise the majority of catch. These species include English sole, Sakhalin sole, Dover sole, butter sole, longhead dab, rex sole and starry flounder. According to 2001 EBS survey results, English sole, Sakhalin sole, and Dover sole constitute less than one percent of the remaining total flatfish biomass (minus Alaska plaice biomass), butter sole constitutes one percent, longhead dab 16 percent, rex sole 28 percent, and starry flounder 55 percent. The other flatfish assemblage is assessed under Tier 5 for 2002, although it has been managed under Tier 4 and 3a in the past. An ABC value for the other flatfish complex is determined at the 0.75 M level, equating to an ABC of 16,000 mt. The 2003 OFL value is 21,400 mt, based on the Tier 5 formula $F = M$ (Table 3.5-2). It is not possible to determine if the other flatfish assemblage is overfished or approaching an overfished condition (Spencer *et al.* 2002b).

Because other flatfish are generally not targeted in the BSAI, commercial catch data are of limited use for stock assessment purposes. The principal source of information for evaluating the condition of other flatfish stocks in the BSAI is the annual EBS shelf trawl survey. Thus, the annual trawl survey biomass estimates are considered the best information available to determine the stock biomass. Model assessments are not conducted for this group due to lack of sufficient information. The stock assessment is updated annually at the conclusion of the summer trawl survey and is incorporated into the BSAI SAFE report (Spencer *et al.* 2001b).

BSAI Alaska Plaice and Other Flatfish Past/Present Effects Analysis

The geographic scope for the Alaska plaice and other flatfish assemblage past/present effects analysis is the same as the BSAI management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1954 when the foreign flounder fishery begins and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-21 provides a summary of the BSAI Alaska plaice and other flatfish assemblage past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on the BSAI Alaska plaice and other flatfish assemblage:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shift (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, climate changes and regime shifts, introduction of exotic species, and marine pollution and oil spills (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, introduction of exotic species, and marine pollution and oil spills (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explains any management actions specific to the other flatfish assemblage. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on the Alaska plaice and the other flatfish assemblage in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the other flatfish assemblage past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1954-1976)
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1988-1991)
  - Domestic groundfish fisheries (1988-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1954-1976)

The flounder foreign fishery began in 1954 and primarily targeted yellowfin sole (see Section 3.5.1.5). Catches of the other flatfish species, including flathead sole increased from 25,000 mt in the 1960s to 52,000 mt in 1971, mostly due to better identification and better reporting of catches during the 1970s (NPFMC 2002a).

Alaska plaice, which has made up the largest portion of catch of the other species assemblage prior to 2002, were probably taken as bycatch in the yellowfin sole fishery (Zhang *et al.* 1998). Following the peak in 1971, annual catch fell below 20,000 mt throughout the rest of the 1970s (Spencer *et al.* 2001b).

Although large removals of Alaska plaice and other flatfish occurred during the foreign fisheries, they are determined not have had any observable lingering adverse effects on the BSAI Alaska plaice and other flatfish populations.

Internal JV and Domestic Groundfish Fisheries (1988-present)

The other flatfish JV fishery began in 1988 and produced the largest catch of Alaska plaice since 1963 at 67,425 mt (Zhang *et al.* 1998). Harvest was drastically reduced in the remaining years of the JV fisheries to below 20,000 mt annually. The JV fisheries were phased-out and the fishery completely domesticated by 1991. The domestic fishery has taken under 20,000 mt in most years, except 1994 and 1997 which were still under 25,000 mt of annual catch. As of November 2, 2002, the Alaska plaice catch has exceeded the OFL of 11,400 mt. In recent years, the other flatfish fishery has been restricted by PSC limits for Pacific halibut and crab (Spencer *et al.* 2002b, Spencer *et al.* 2002c).

Alaska plaice and other flatfish are taken in directed bottom trawl fisheries in the EBS. The discard rates for the other flatfish fishery are significant, ranging from 11,000-19,000 mt from 1993-2000 (discard rates prior to 1995 also include flathead sole). Percent retention is low, with an average retention rate of 27 percent from 1993-2001. Discard occurs primarily in the yellowfin sole, flathead sole, and rock sole fisheries in 2000 (Spencer *et al.* 2002b, 2002c).

Although large removals of Alaska plaice and other flatfish have occurred in the JV and past domestic fisheries, they are determined not to have had any observable lingering adverse effects on the BSAI Alaska plaice and other flatfish populations.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1954-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the foreign fisheries on the spatial/temporal distribution of the BSAI Alaska plaice and other flatfish populations in the BSAI is unknown. However, these fisheries are determined not to have had any observable lingering adverse effects on the BSAI populations.

External Climate Changes and Regime Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of the Alaska plaice and other flatfish assemblage. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries (1988-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the JV and past domestic fisheries on the spatial/temporal distribution of the BSAI Alaska plaice and other flatfish populations in the BSAI is unknown. However, these fisheries are determined not to have had any observable lingering adverse effects on the BSAI populations.

Change in Prey Availability

External Foreign Groundfish Fisheries (1954-1976)

The foreign fisheries BSAI are unlikely to have directly impacted prey availability for the other flatfish since these fish eat infaunal invertebrates. The lingering beneficial influence in the BSAI flatfish stock is likely due to the natural events related to climate changes.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of Alaska plaice and other flatfish.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of the other flatfish group.

Internal JV and Domestic Groundfish Fisheries (1988-present)

The JV fisheries in the BSAI are unlikely to have directly impacted prey availability for the other flatfish since these fish eat infaunal invertebrates. The lingering beneficial influence in the BSAI flatfish stock is likely due to the natural events related to climate changes.

Change in Important Habitat

External Foreign Groundfish Fisheries (1954-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the foreign fisheries on habitat suitability is either beneficial or adverse; they are found to have had a lingering influence in the BSAI stock, and the overall lingering effect is beneficial on the BSAI other flatfish assemblage, probably mostly due to climatological effects.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of the other flatfish group.

Internal JV and Domestic Groundfish Fisheries (1988-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the JV fisheries on habitat suitability is either beneficial or adverse; they are found to have had a lingering influence in the BSAI stock, and the overall lingering effect is beneficial in the BSAI other flatfish assemblage, probably mostly due to climatological effects.

BSAI Alaska Plaice and Other Flatfish Comparative Baseline

Trawl survey biomass estimates indicate that the abundance of Alaska plaice increased on the EBS continental shelf from 1975 through 1984. A slight decline in the Alaska plaice biomass occurred between 1984 and 1985 and remained relatively stable until an increase in abundance in 1994 and 1997. The 2002 estimate of 424,971 mt is a 27 percent decrease relative to the 2001 biomass estimate, and is very close to the 2000 biomass estimate. It should be noted that there is uncertainty associated with the area-swept method of trawl surveying. Furthermore, there have been changes in gear over time during which the survey has been conducted (Spencer *et al.* 2002c).

Miscellaneous other species in the other flatfish category have shown relatively stable biomass estimates from trawl surveys from 1983-1995. Biomass estimates increased from 1996-2001 with a substantial increase in the 2002 biomass estimate at 97,938 mt in the EBS. The Aleutian Island region generally shows smaller populations of other flatfish, showing slight increases during each survey year since 1991. (Spencer *et al.* 2002b)

BSAI Alaska Plaice and Other Flatfish Cumulative Effects Analysis Status

The BSAI Alaska plaice and the other flatfish assemblage will be brought forward for cumulative effects analysis.

3.5.1.11 BSAI Pacific Ocean Perch

Life History and Distribution

Pacific ocean perch (*Sebastes alutus)* is primarily a demersal species that inhabits the outer continental shelf and slope regions of the NPO and the Bering Sea from southern California to Japan (Allen and Smith 1988). As adults, they live on or near the seafloor, generally in areas with smooth bottoms (Krieger 1993) and generally at depths ranging from 180-420 m. Though more is known about the life history of Pacific ocean perch than about other rockfish species (Kendall and Lenarz 1986), much uncertainty still exists about its life history. Pacific ocean perch are viviparous, with internal fertilization and the release of live young (Hart 1973). Insemination occurs in the fall, and release of larvae occurs in April or May. Pacific ocean perch larvae are thought to be pelagic and drift with the current. Juveniles seem to inhabit rockier, higher relief areas than adults (Carlson and Straty 1981, Krieger 1993). The maximum recorded age of Pacific ocean perch is 100 years (Frimodt 1995). Table 3.5-22 summarizes biological and reproductive attributes and habitat associations of Pacific ocean perch in the BSAI and GOA.

The Pacific ocean perch were found to be genetically similar throughout their range based on allozyme variation (Seeb and Gunderson 1988); however, preliminary analysis using microsatellite deoxyribonucleic acid (DNA) techniques suggests that genetically distinct populations of Pacific ocean perch exist (A.J. Gharrett personal communication, University of Alaska Fairbanks).

Trophic Interactions

During the summer of 1990, the diets of commercially important groundfish species in the GOA were analyzed by Yang (1993). About 98 percent of the total stomach content weight of Pacific ocean perch in the study was made up of invertebrates and 2 percent of fish. Euphausiids (mainly *Thysanoessa inermis*) were the most important prey item. Euphausiids comprised 87 percent, by weight, of the total stomach contents. Calanoid copepods, amphipods, arrow worms, and shrimp were frequently eaten by Pacific ocean perch (Brodeur and Percy 1984, Yang 1996).

Documented predators of Pacific ocean perch include Pacific halibut and sablefish, and it is likely that Pacific cod and arrowtooth flounder also prey on Pacific ocean perch. Pelagic juveniles are consumed by salmon, and benthic juveniles are eaten by lingcod and other demersal fish (NMFS 1997).

BSAI Pacific Ocean Perch Management

Pacific ocean perch is the most commercially important rockfish in Alaska's fisheries and is taken mostly with bottom trawls. Reliable estimates of $B_{40\%}$, $F_{40\%}$, and $F_{35\%}$ exist for this stock, therefore qualifying the stock for management under Tier 3. The projected spawning biomass for 2003 is 135,000 mt, placing it into sub-tier "b" of Tier 3. The recommended ABC value for 2003 is 15,100 mt, apportioned between four areas: BS = 2,410 mt; Area 541 = 3,495 mt; Area 542 = 3,330 mt; Area 543 = 5,835 mt. The OFL value of 17,900 mt has been established for the BSAI in 2003 (Table 3.5-2). Model projections indicate that the Pacific ocean perch stock is neither overfished nor approaching an overfished condition.

Previous to 2001, Pacific ocean perch were assessed separately using a model for the EBS and the Aleutian Island region. Beginning with the 2001 stock assessment, the Pacific ocean perch were assessed as one stock, and a single model for the BSAI was used, incorporating the Aleutian Islands trawl survey and the BSAI-wide catches. Pacific ocean perch are assessed with an age-structured model incorporating fishery and survey catch data and length and age compositions. Survey data are from the NOAA Fisheries triennial trawl groundfish surveys, and the fishery data comes from the Observer Program. The age-structured population model is used to obtain estimates of recruitment, numbers at age, and catch at age. Natural mortality and individual weight-at-age are estimated independent of the model (Spencer and Ianelli 2001).

BSAI Pacific Ocean Perch Past/Present Effects Analysis

The geographic scope for the Pacific ocean perch past/present effects analysis is the same as the BSAI management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1960 when the foreign Pacific ocean perch fishery begins and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-23 provides a summary of BSAI Pacific ocean perch past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on BSAI Pacific ocean perch:

- Mortality due to catch/bycatch, and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes, and regime shifts (indirect effect).

- Change in prey availability due to commercial whaling, climate changes and regime shifts, marine pollution and oil spills, and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, marine pollution and oil spills, and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explain any management actions specific to Pacific ocean perch. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on the Pacific ocean perch in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to Pacific ocean perch past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1960-1976)
  - Commercial whaling
  - IPHC longline fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1990)
  - JV groundfish fisheries (1980-1990)
  - Domestic groundfish fisheries (1982-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1960-1976)

The Japanese Pacific ocean perch fishery began in 1960 when a mothership operation began fishing for Pacific ocean perch along the continental slope between the Pribilof Islands and Cape Navarin. This fishery expanded in 1963 to Bowers Banks off the Aleutian Islands. Japanese fleets involved in the yellowfin sole fishery also extended their operations to include Pacific ocean perch in 1961-1962 due to the reduced abundance of yellowfin sole. This fishery lengthened the fishing season from one to between four and nine months and began winter fishing. The main target fish of the foreign fisheries was Pacific ocean perch in the Aleutian Islands region. Japanese trawls for Pacific ocean perch concentrated along the shelf edge in the central and western part of the chain, and the fishery took place mostly in the summer or early fall (NPFMC 2002a).

The Soviet Pacific ocean perch fishery also began in 1960 with 25-30 trawlers along the edge of the continental shelf in the eastern and central Bering Sea. Effort shifted to the Aleutian Islands and GOA by 1963, and the directed EBS effort was completely eliminated. However, bycatch of Pacific ocean perch did occur in Soviet pollock fisheries in subsequent years. Soviet harvests of Pacific ocean perch peaked in 1974 and 1975 at 61,000 and 71,000 mt, respectively. In the following years, fishing effort become more sporadic due to reduced abundance of rockfish. Catches in 1973 and 1974 had been reduced to 3,000 and 800 mt, respectively (NPFMC 2002a).

Overall, foreign fishery harvest of Pacific ocean perch and other rockfish species peaked in 1965 in the Aleutian Islands region at 109,100 mt. Apparently, stocks were not productive enough to support the large removals that took place, and they declined throughout the 1960s and 1970s, reaching their lowest levels in the early 1980s. Since that time, stocks have stabilized in the EBS and have increased in the Aleutian Islands and GOA (NPFMC 2002a).

Past foreign fisheries are found to have overfished the BSAI Pacific ocean perch populations; these effects are lingering at the population-level.

Internal JV and Domestic Groundfish Fisheries (1980-present)

A small JV fishery began in 1980 with catches generally under 1,000 mt annually (except in 1988). This fishery was replaced by the domestic fishery in 1990. Domestic Pacific ocean perch fisheries began in 1982 in the EBS and in 1984 in the Aleutian Islands. The EBS fisheries developed rapidly with over 1,000 mt of catch taken by 1984. The Aleutian Islands domestic fishery did not take over 1,000 mt until 1989. Overall, the BSAI Pacific ocean perch domestic fishery reached its peak removal in 1990 at 18,182 mt and has since declined with catches in recent years. The majority of catches take place in the Aleutian Islands region (Spencer and Ianelli 2002).

Discard rates in the Pacific ocean perch fisheries are relatively low, averaging 24.5 percent discard rate in the Bering Sea and a 16.7 percent discard rate in the Aleutian Islands from 1990-1999.

Pacific ocean perch were managed as a complex in association with northern rockfish, rougheye rockfish, shortraker rockfish, and sharpchin rockfish in two distinct areas in the BSAI from 1979-1990. In 1991, NPFMC enacted new regulations that divided the Pacific ocean perch complex into three subgroups in the EBS and two sub-groups in the Aleutian Islands region; Pacific ocean perch, shortraker/rougheye rockfishes, and sharpchin/northern rockfishes in the EBS and shortraker/rougheye and sharpchin/northern rockfishes in the Aleutian Islands region. These groups were established to protect Pacific ocean perch, shortraker rockfish, and rougheye rockfish from possible overfishing. Each group was assigned an individual TAC. Beginning in 1996, the Pacific ocean perch TAC was further subdivided in the Aleutian Islands region. A portion of the Pacific ocean perch TAC (7.5 percent) is allocated to the CDQ group, as well.

The large removals of Pacific ocean perch that occurred in the JV and past domestic fisheries have had an adverse effect on the BSAI Pacific ocean perch population; these effects are lingering at the population-level.

Change in Reproductive Success

<u>External Foreign Groundfish Fisheries (1960-1976)</u>

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the foreign fisheries on spatial/temporal distribution of the BSAI Pacific ocean perch populations due to the spatial/temporal concentration of the fishery is unknown. However, any possible effects are not expected to have any lingering adverse effects in the populations. Forty-nine percent of the foreign and JV fisheries Pacific ocean perch harvest from 1977-1988 was between 200 and 299 m. Forty-six percent of the past foreign and JV fisheries Pacific ocean perch catch took place in management area 541 (Figure 1.2-2). In the late 1970s, management area 543 contributed a large share of the catch; however, the proportions of total Pacific ocean perch caught by foreign fisheries that were sampled by the observers were quite low prior to 1984 (Megrey and Wespestad 1990).

<u>External Climate Changes and Regime Shifts</u>

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of Pacific ocean perch. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

<u>Internal JV and Domestic Groundfish Fisheries (1980-present)</u>

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the JV and past domestic fisheries on spatial/temporal distribution of the BSAI Pacific ocean perch populations is unknown. However, any possible effects are not expected to have any lingering adverse effects in the populations. Forty-nine percent of the foreign and JV fisheries observed fishing depth was from 200-299 m between 1977 and 1988 and forty-six percent of the past foreign and JV fisheries Pacific ocean perch catch took place in management area 541 (Figure 1.2-2). Sixty-six percent of the observed domestic catch took place between 200-299 between 1990-2000; and forty-two percent of the domestic catch came from management area 541. Area 543 contributed a large share of the catch in the mid-1990s to the present.

Change in Prey Availability

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. Populations of Pacific ocean perch have rebounded from low population-levels. The controlling factor for these increases appears to be environmental, with changes in the species composition in nearshore areas linked to an increase in advection in the Alaska current. Increased flow around the GOA may enhance the supply of nutrients and plankton on the shelf and upper slope areas, resulting in an increase in productivity.

External Commercial Whaling

Whaling is identified as having a past beneficial effect on prey availability for all Pacific ocean perch stocks, since the diet of Pacific ocean perch appears to consist primarily of plankton (Brodeur and Percy 1984); euphausiids are the single most important prey item (Yang 1996). A reduction in baleen whale populations could mean that more euphausiids would be available for use by Pacific ocean perch. Documented predators of Pacific ocean perch include Pacific halibut and sablefish, and it likely that Pacific cod and arrowtooth flounder also prey on Pacific ocean perch. Pelagic juveniles are consumed by salmon, and benthic juveniles are eaten by lingcod and other demersal fish (NMFS 1997).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of Pacific ocean perch.

Change in Important Habitat

External Foreign Groundfish Fisheries (1960-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effects of the past foreign fisheries on habitat suitability are adverse for the BSAI stock and are found to have had a lingering adverse influence in the stocks. The intense trawling of the foreign, JV and past domestic fisheries is the likely cause of this lingering effect.

External IPHC Longline Fisheries

The impacts of IPHC longline gear on Pacific ocean perch habitat have been identified as adverse effects. Longline fishing is likely to have caused Pacific ocean perch habitat degradation and disruption of Pacific ocean perch spawning and/or rearing grounds. This effect is still lingering at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of Pacific ocean perch.

Internal JV and Domestic Groundfish Fisheries (1980-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effects of past JV fisheries on habitat suitability are adverse for the BSAI stock; the effects, in combination with climatic changes, are found to have had a lingering adverse influence in the stock. The intense trawling of the foreign, JV and past domestic fisheries is the likely cause of this lingering effect.

BSAI Pacific Ocean Perch Comparative Baseline

The Aleutian Islands survey covers the Aleutian Islands management area, and a portion of the EBS management area; the entire survey biomass is used as an index of Pacific ocean perch abundance in the BSAI. The EBS slope survey is not used in modeling due to its high variability and relatively small population sizes compared to the Aleutian Islands biomass estimates (Spencer and Ianelli 2002).

Survey biomass estimates in the entire survey area show a steady increase from 1980-1997, followed by a decline to the 2000 and 2002 estimates. The portion of the Aleutian Islands survey that occurs in the EBS has produced variable biomass estimates, from 1,501 mt in 1991 to 18,870 mt in 2000. In the Aleutian Islands region, the biomass estimates are less variable (Spencer and Ianelli 2002).

Surveys produce large amounts of biological data, including age determination, length-weight relationships, sex ratio information, and information for estimating the length distribution of the population. Improved age determination methods have determined the maximum age of Pacific ocean perch to be 90 years (Chilton and Beamish 1982).

Modeling results show that estimated survey biomass declined from 1960 to 1978 and increased to 500,933 mt in 2002. Total biomass results show a similar trend as the survey biomass with a 2002 total biomass estimate of 374,809 mt. Recruitment in the EBS and Aleutian Islands tends to be highly variable, although the 1962 year-class appears to be the largest, more than twice as large as any other estimated recruitment (Spencer and Ianelli 2002).

BSAI Pacific Ocean Perch Cumulative Effects Analysis Status

BSAI Pacific ocean perch will be brought forward for cumulative effects analysis.

3.5.1.12 BSAI Rockfish

Life History and Distribution

Northern Rockfish

Northern rockfish (*Sebastes polyspinis*) inhabit the outer continental shelf from the EBS, throughout the Aleutian Islands and the GOA (Kramer and O'Connell 1988). This species is semidemersal and is usually found in comparatively shallower waters off the outer continental slope (from 50-600 m). Little is known about the biology and life history of northern rockfish. However, they appear to be long-lived, with late maturation and slow growth. Like other members of the genus *Sebastes*, they bear live young, and birth occurs in the early spring through summer (McDermott 1994).

Shortrater/Rougheye Rockfish

Shortraker (*Sebastes borealis*) and rougheye rockfish (*S. aleutianus*) inhabit the outer continental shelf of the NPO from the EBS as far south as southern California (Kramer and O'Connell 1988). Adults of both species are semidemersal and are usually found in deeper waters (from 50 m to 800 m) and over rougher bottoms than Pacific ocean perch (Krieger and Ito 1999). Little is known about the biology and life history of these species, but they appear to be long-lived, with late maturation and slow growth. Shortraker rockfish have been estimated to reach ages in excess of 120 years, and rougheye rockfish in excess of 140 years. Like other members of the genus *Sebastes*, they are viviparous (bear live young), and birth occurs in the early spring through summer (McDermott 1994).

Both species are associated with a variety of habitats, from soft to rocky bottoms, although boulders and sloping terrain appear also to be desirable habitat (Krieger and Ito 1999). Length at 50 percent sexual maturity is about 45 cm for shortraker rockfish and about 44 cm for rougheye rockfish (McDermott 1994). Shortraker and rougheye rockfish are managed as part of the slope rockfish assemblage in the GOA and as part of the other red rockfish assemblage in the BSAI.

Two genetically distinct populations of rougheye rockfish with partially overlapping geographic ranges were found by Hawkins *et al.* (1997) and Gharrett and Gray (1998), and confirmed with recent mitochondrial and microsatellite analyses (A.J. Gharrett, University of Alaska Fairbanks, personal communication).

Other Rockfish

The 'other rockfish' management category includes 28 of the *Sebastes* and *Sebastolobus* species. Of these, only eight have ever been confirmed or tentatively identified in fishery catches in the BSAI, and so these eight species only are managed. The two most abundant species are light dusky rockfish (*Sebastes ciliatus* *sp cf*) and shortspine thornyheads (*Sebastolobus alascanus*). Red banded rockfish (*Sebastes babcocki*), dark dusky rockfish (*Sebastes ciliatus*), redstripe rockfish (*Sebastes proriger*), yelloweye rockfish (*Sebastes ruberrimus*), harlequin rockfish (*Sebastes variegatus*), and sharpchin rockfish (*Sebastes zacentrus*) have been identified by U.S. fishery observers and are also included in this group.

Thornyheads in Alaskan waters are comprised of two species, the shortspine thornyhead (*Sebastolobus alascanus*) and the longspine thornyhead (*S. altivelis*). Only the shortspine thornyhead is of commercial importance and it is now one of the most commercially valuable rockfish species. Thornyheads are a demersal species found in deepwater, from 94 m to 1,460 m, from the Bering Sea and GOA to Baja California (Gaichas and Ianelli 2001). Little is known about thornyhead life history. Like other rockfish, they are long-lived and slow-growing. The maximum recorded age is in excess of 50 years, and females do not become sexually mature until an average age of 12 to 13 years and a length of about 21 cm. Thornyheads spawn large masses of buoyant eggs during the late winter and early spring (Pearcy 1962). Juveniles are pelagic for the first year. The shortspine thornyhead is managed as a single stock in its own management group in the GOA; however, this species and the longspine thornyhead are managed as part of the other rockfish assemblage in the BSAI. Table 3.5-26 summarizes biological and reproductive attributes and habitat associations of thornyhead rockfish in the BSAI and GOA.

Light dusky rockfish are only occasionally observed in surveys and are caught as bycatch in other target fisheries. This species is generally caught between 125-200 m, and largely in the Aleutian Islands region. In recent years, bycatch has been highest near Seguam Pass and Petrel Bank; survey catch has been highest at the western tip of Amchitka Island. Light dusky rockfish are rarely found in the EBS, although some bycatch has occurred along the EBS slope, north of Unalaska Island and Akutan Island, the southern part of the EBS and the southern tip of Zhemchung Canyon in the northern EBS. EBS surveys found light dusky rockfish largely near Unalaska Island and Akutan Island (Reuter and Spencer 2003).

Table 3.5-27 summarizes biological and reproductive attributes and habitat associations for selected rockfish species in the BSAI and GOA.

Trophic Interactions

<u>Northern Rockfish</u>

Northern rockfish are generally planktivorous (feed on plankton) with euphausiids being the predominant prey item (Yang 1993). Copepods, hermit crabs, and shrimp have also been noted as prey items in much smaller quantities. Predators of northern rockfish are not well documented, but likely include larger fish such as Pacific halibut that are known to prey on other rockfish species.

<u>Shortraker/Rougheye Rockfish</u>

Food habit studies conducted by Yang (1993) indicate that the diet of rougheye rockfish is dominated by shrimp. The diet of shortraker rockfish is not well known; however, based on a small number of samples, the diet appears to be dominated by squid. Because shortraker rockfish have large mouths and short gill rakers, it is possible that they are potential predators of other fish species (Yang 1993).

Other Rockfish

Yang (1993 and 1996) and Yang and Nelson (2000) showed that shrimp, mainly pandalids, were the most important food of the thornyhead. Tanner crabs comprised less than 7 percent by weight of stomach contents, and fish such as pollock, capelin, and sculpins comprised about 15 percent. Other prey items for thornyheads included polychaetes, mysids, amphipods, and other crabs. California sea lion (Lowry *et al.* 1990) and sablefish (Orlov 1997) have both been documented as predators of shortspine thornyhead.

Trophic interactions of dusky rockfish are not well known. Food habits information is available from just one study, with a relatively small sample size for dusky rockfish (Yang 1993). This study indicated that adult dusky rockfish consume primarily euphausiids, followed by larvaceans, cephalopods, and pandalid shrimp. Predators of dusky rockfish have not been documented, but likely include species that are known to consume rockfish in Alaska, such as Pacific halibut, sablefish, Pacific cod, and arrowtooth founder.

The diet of the other rockfish species (BSAI) for which dietary information exists seems to consist primarily of planktonic invertebrates (Yang 1993 and 1996). Predators of other rockfish are also not well documented, but likely include larger fish, such as Pacific halibut, which are known to prey on other rockfish species.

Management of Rockfish

Northern Rockfish

In 2003, northern rockfish were split out from the BSAI other red rockfish group, which originally included northern, rougheye, and shortraker rockfish. Northern rockfish is now managed under Tier 3 of Amendment 56 to the BSAI groundfish management plan. The projected spawning biomass for 2003 is 43,700 mt, which is greater than the $B_{40\%}$ value, placing it into subtier "a". The recommended ABC value for 2004 is 6,800 mt, apportioned between two areas: EBS = 19 mt and the Aleutian Islands = 6,861 mt. The OFL value of 8,140 mt has been established for the BSAI for 2004 (Table 3.5-2). Model projections indicate that the northern rockfish stock is neither overfished nor approaching an overfished condition (Spencer and Ianelli 2003).

Shortraker/Rougheye Rockfish

Shortraker/rougheye rockfish are now managed as their own group and are managed under Tier 5 of Amendment 56 to the BSAI groundfish management plan, relying on survey biomass estimates for information on population size and to determine ABC and OFL values. ABC values for the BSAI were calculated by 0.75 M = F_{ABC}. It is not possible to determine whether these species are overfished or approaching an overfished condition because they are managed under Tier 5.

It has been recommended that shortraker and rougheye be assigned separate TACs in future evaluations to prevent overfishing of one of the species. However, due to poor identification of shortraker and rougheye as separate species, the SSC was unable to establish separate TACs. Although shortraker/rougheye will remain as a single TAC for 2003, changes have been implemented in the Observer Program to improve species identifications and implement separate TACs beginning in 2004 (Spencer and Reuter 2003).

Though shortraker and rougheye rockfish are highly valued, amounts available to the commercial fisheries are limited by relatively small TAC and ABC amounts, which are to support bycatch needs in other groundfish fisheries. As a result, the directed fishery for these species is typically closed at the beginning of the fishing year. The primary methods of harvest for shortraker and rougheye rockfishes are bottom trawls and longline gear. The bulk of the commercial harvest usually occurs at depths between 200 m and 500 m along the upper continental slope.

Other Rockfish

None of the species in the other rockfish assemblage are subject of a directed fishery, but are mainly caught as bycatch in the other BSAI target fisheries. Two species are predominant in both the catch and survey data: light dusky rockfish and shortspine thornyheads. In 2002, sharpchin rockfish were removed from the other red rockfish assemblage to the other rockfish assemblage in the BSAI. Currently, the other species complex is assumed to be two separate stocks in the EBS and Aleutian Islands regions and is assessed as such.

The other rockfish assemblage falls under Tier 5 of Amendment 56 of the BSAI groundfish FMP, relying on biomass estimates to determine ABC and OFL values. ABC is calculated by multiplying 0.75 M by the best estimate of complex-wide biomass. This equates to a 2003 ABC value of 960 mt in the EBS and 634 mt in the Aleutian Islands (Table 3.5-2). The OFL value is determined by setting F_{OFL} = M, equating to a 2003 OFL value of 1,280 mt in EBS and 846 mt in the Aleutian Islands (Reuter and Spencer 2002).

Reuter and Spencer (2002) recommended in the BSAI SAFE that light dusky rockfish be split out of the other rockfish group and assigned a separate ABC due to findings that indicate that light dusky rockfish make up a large amount of the other rockfish catch in the Aleutian Islands and may be disproportionally exploited. Furthermore, Reuter and Spencer (2002) have recommended that EBS and Aleutian Islands biomass estimate for light dusky rockfish be combined for the BSAI. This recommendation comes in light of new catch and survey distribution maps which show continuous spatial distribution of light dusky rockfish along the Aleutian Islands and EBS slope.

Rockfish Past/Present Effects Analysis

This past/present effects analysis discusses northern, shortraker/rougheye and other rockfish groups managed within the BSAI. These species have been discussed together since they have only recently been broken out for management reasons. Refer to Table 3.5-24 for a list of the rockfish occurring in the BSAI and GOA and their associated management groups.

The geographic scope for the BSAI rockfish past/present effects analysis is the same as the BSAI management areas (Figure 1.2-2). The temporal scope for this analysis begins in 1960 when the foreign rockfish fisheries began and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-25 provides a summary of BSAI rockfish past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on BSAI rockfish:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to commercial whaling, climate changes and regime shifts, marine pollution and oil spills and introduction to exotic species (indirect effect).

- Change in important habitat due to climate changes and regime shifts, fishery gear impacts, marine pollution and oil spills and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explains any management actions specific to rockfish. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on other rockfish in the BSAI have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the BSAI as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to rockfish past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1960-1976)
  - IPHC longline fisheries
  - State of Alaska shrimp fisheries
  - Commercial whaling
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1990)
  - Domestic groundfish fisheries (1986-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

External Foreign Groundfish Fisheries (1960-1976)

Foreign fisheries for rockfish began in 1960, with the Soviet and Japanese fisheries. These fisheries are the same as were targeting Pacific ocean perch. See Section 3.5.1.11 for more information.

Large removals of rockfish have occurred in the foreign fisheries, although the proportion of removals per species is unavailable due to poor species identification. These removals are identified as having had an adverse effect on the rockfish populations. Moreover, due to the longevity of these species, these fisheries are determined to have had a lingering influence on the these BSAI populations.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The JV fisheries began targeting rockfish in 1980 and were phased-out of the BSAI by 1990 when the fishery became fully domesticated. The domestic rockfish fisheries began in 1986. Removals of rockfish by the JV and past domestic fisheries are determined to have had an adverse effect on the rockfish population, although data regarding the proportion of removals per species is unavailable due to poor species identification. Moreover, due to the longevity of these species, these fisheries are determined to have had a lingering influence on these BSAI rockfish populations.

Northern, Shortraker and Rougheye Rockfish

Catches of rockfish from the EBS and Aleutian Islands are dominated by northern rockfish and shortraker rockfish. The largest catches in the northern rockfish times series have occurred since 1993. Catches of shortraker and rougheye rockfish appear low in the mid-1980s, when the foreign fishery was reduced; however, catches of shortraker rockfish have been relatively high since 1995 (Spencer and Reuter 2002).

Other red rockfish were managed as part of the Pacific ocean perch complex from 1979-1990. In 1991, Pacific ocean perch were separated into two management subgroups; the Pacific ocean perch and the other red rockfish group in the EBS, and into the Pacific ocean perch, shortraker/rougheye rockfishes and sharpchin/northern rockfishes group in the Aleutian Islands region. In 2000, the EBS other red rockfish group was furthered divided into the rougheye/shortraker and sharpchin/northern rockfish groups, as was done in the Aleutian Islands region. Each group was assigned a separate TAC to protect these species from overfishing. In 2002, sharpchin rockfish were removed from the other red rockfish assemblage to the other rockfish assemblage in the BSAI. Finally, in 2003, northern rockfish and shortraker/rougheye rockfish were separated and are now managed as their own group with separate TACs; the other red rockfish assemblage no longer exists.

There are concerns that assigning a TAC for two or more species may allow one of those species to be overfished while still remaining under the group TAC. Separate TACs for each individual species were recommended in the 2002 BSAI SAFE report; however, efforts to establish these levels were hindered by limited observer identification of shortraker and rougheye species (Spencer and Reuter 2001).

Other Rockfish

Prior to 1979, the other rockfish category included northern, rougheye, and shortraker rockfish. Catches prior to 1990 are assumed to include discards, whereas catches from 1999-2000 explicitly account for discards based on Observer Program information. The peak catch of other rockfish occurred in the EBS in 1978 with a removal of 941 mt, and in the Aleutian Islands region, the peak occurred in 1982 with a harvest of 2,114 mt. The bulk of the catch comprises shortspine thornyheads in the EBS and light dusky rockfish in the Aleutian Islands, according to Observer Program data (Spencer and Reuter 2002).

Change in Reproductive Success

External Foreign Groundfish Fisheries (1960-1976)

Spatial/Temporal Concentration of Catch/Bycatch

Effects of the foreign fisheries on spatial/temporal distribution of the BSAI rockfish populations due to the spatial/temporal concentration are identified as either adverse or unknown. When the past effect of the fishery is unknown, it is also unknown whether the effect could be lingering.

External Climate Changes and Regimes Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as a potentially beneficial or adverse on the reproductive success of other rockfish. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Change in Prey Availability

External State of Alaska Shrimp Fisheries

Effects of State of Alaska shrimp fisheries on the prey availability of BSAI rockfish are potentially adverse, however, due to the localized nature of these fisheries, they are unlikely to have a population-level effect.

External Commercial Whaling

The effects of commercial whaling increased the availability of euphausiid prey for northern rockfish and some of the other rockfish species and is therefore noted as a potential beneficial effect.

External Climate Changes and Regimes Shifts

The effects of climate changes and regime shifts are identified as a potentially beneficial or adverse influence on prey availability depending on the frame of reference. Lingering population effects are identified in the these stocks for this category. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important prey species of rockfish.

Change in Important Habitat

External Foreign Groundfish Fisheries (1960-1976)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas, and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The impacts of foreign groundfish fishery gear on rockfish and habitat have been identified as adverse effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

External IPHC Longline Fishery

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas, and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The impacts of IPHC longline gear on rockfish habitat have been identified as adverse effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

External Climate Changes and Regimes Shifts

The effects of climate changes and regime shifts are identified as a potentially beneficial or adverse influence on habitat suitability depending on the frame of reference. Lingering population effects are identified in the stocks for this category. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the BSAI and what effect these have on the important habitat of rockfish.

Internal JV and Domestic Groundfish Fisheries (1980-present)

See Section 3.5.1.1 (BSAI walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas, and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The impacts of JV and domestic groundfish fishery gear on rockfish habitat have been identified as adverse effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

Rockfish Comparative Baseline

Data for determining exploitable biomass estimates come from a number of surveys, including the U.S.-Japan cooperative survey in the EBS on the continental shelf and slope from 1979-1985, and from 1980-1986 in the Aleutian Islands, and domestic trawl surveys in the EBS slope in 1988 and 1991 and in the Aleutian Islands region in 1991, 1994, 1997, 2000, and 2002. In the Aleutian Islands, the exploitable biomass estimate is the average of the most recent surveys; in the 2002 stock assessment those are the 1991, 1994, 1997, 2000, and 2002 Aleutian Islands surveys. The EBS is divided into two areas when determining the biomass of the other red rockfish category. These two areas are: the shelf/slope area and the area that is labeled the Aleutian Islands portion of the EBS, whose 2002 biomass is determined by averaging the three most recent Aleutian Islands surveys.

Surveys from 1991-2002 indicate that the majority of northern rockfish biomass is found in the western Aleutian Islands (72%). Survey biomass estimates show a steady trend in northern rockfish biomass from 1977 at 131,684 mt to 161,984 mt in 1992. The 2003 survey estimate is 137,564 mt. Modeling results estimate total and spawning biomass for 2003 at 143,604 mt and 46,390 mt, respectively (Spencer and Ianelli 2003).

Surveys estimates indicate that rougheye rockfish biomass has declined since the 1980s from approximately 26,277 mt (1980) to 10,379 mt in 2004. Shortraker rockfish biomass estimates have also indicate a decline from the 1980 value of 38,299 mt to 23,379 mt in 2004. Modeling results estimate rougheye rockfish biomass to be 1,503 mt in the EBS and 11,480 mt in the Aleutian Islands for 2004. Shortraker rockfish biomass is estimated at 6,535 mt in the EBS and 27,317 mt in Aleutian Islands for 2004 (Spencer and Reuter 2003).

The recent surveys indicate that shortspine thornyhead, light dusky rockfish, and harlequin rockfish comprise most of the total other rockfish estimated biomass, approximately 90 percent of which is shortspine thornyheads. The discrepancy between the amount of light dusky rockfish catch in the fishery and the light dusky rockfish catch in the survey is attributed to the unequal survey sampling of differing depth zones. For instance, the majority of the light dusky rockfish fishery catch is at depths less than 200 m, whereas the trawl survey targets waters deeper than 200 m. Based on the best available information, the estimated 2003 exploitable biomass for other rockfish is 6,884 mt in the EBS and 12,087 mt in the Aleutian Islands (Reuter and Spencer 2002).

Gulf of Alaska Target Groundfish Species

This section presents descriptions of major target species, summarizing important life history traits, their habitat environment, prey base, past effects, stock management, stock assessment, and current trends of the stocks. Additional information on life history and habitat features for each major groundfish species can be found in the following three documents 1) EA of the EFH (NPFMC 1998a), 2) EFH assessment report for the groundfish resources of the BSAI region (NPFMC 1998b), and 3) EFH assessment report for the groundfish resources of the GOA region (NPFMC 1998c).

Rockfish Cumulative Effects Analysis Status

BSAI northern rockfish, shortraker/rougheye rockfish, and other rockfish will be brought forward separately for cumulative effects analysis.

3.5.1.13 GOA Walleye Pollock

Life History and Distribution

Walleye pollock is the second most abundant groundfish stock, after arrowtooth flounder, in the GOA. In the GOA, the largest spawning concentrations occur in Shelikof Strait and the Shumagin Islands (Kendall *et al.* 1996). Life history of the GOA pollock is similar to those that inhabit the BSAI (refer to Section 3.1.1.1). Olsen *et al.* (2002) found two major spawning areas in the GOA, one occurring in the Shumagin Island area between February 15 and March 1 and the other occurring in the Shelikof Strait between March 15 and April 1.

<u>Trophic Interactions</u>

Larvae, 5 to 20 millimeters (mm) in length, consume larval and juvenile copepods and copepod eggs (Canino 1994, Kendall *et al.* 1987). Early juveniles (25 to 100 mm) of pollock in the GOA primarily eat juvenile and adult copepods, larvaceans, and euphausiids; late juveniles (100 to 150 mm) eat mostly euphausiids, chaetognaths, amphipods, and mysids (Brodeur and Wilson 1996, Grover 1990, Krieger 1985, Livingston 1985, Merati and Brodeur 1997, Walline 1983). Juvenile and adult pollock in southeast Alaska rely heavily on euphausiids, mysids, shrimp, and fish as prey (Clausen 1983). Euphausiids and mysids are important to smaller pollock; and shrimp and fish are more important to larger pollock in that area. Copepods are not a dominant prey item of pollock in the embayments of southeast Alaska but appear mostly in the summer diet. Similarly, the summer diet of pollock in the central and western GOA does not include as many copepods (Yang 1993). Euphausiids are the dominant prey, constituting a relatively constant proportion of the diet by weight across pollock size groups.

In the GOA, fish prey becomes an increasing fraction of the pollock diet with increasing pollock size. Over 20 different fish species have been identified in the stomach contents of pollock from this area, but the dominant fish consumed is capelin (Yang 1993). A high diversity of prey fish were also found in pollock stomachs. Commercially important fish prey included Pacific cod, pollock, arrowtooth flounder, flathead sole, Dover sole, Pacific halibut, and Greenland turbot. Forage fish such as capelin, eulachon, and Pacific sand lance were also found in pollock stomach contents. However, over the period 1993-1996, Yang and Nelson (2000) found that consumption of capelin declined to non-existent as did the consumption of pandalid shrimp. It appears that because of declining pandalid shrimp and capelin populations, pollock in the GOA consumed more euphausiids and copepods in 1996 as compared to 1993.

Dominant groundfish populations in the GOA that prey on pollock include arrowtooth flounder, sablefish, Pacific cod, and Pacific halibut (Albers and Anderson 1985, Best and St-Pierre 1986, Jewett 1978, Yang 1993). Pollock is one of the top five prey items (by weight) for Pacific cod, arrowtooth flounder, and Pacific halibut. Other predators of pollock include great sculpins (Carlson 1995) and shortspined thornyheads (Yang 1993) (Figure 3.5-3). As in the EBS, Pacific halibut and Pacific cod tend to consume larger pollock, while arrowtooth flounder consume pollock that are mostly under age 3 years. Unlike the EBS, however, the main source of predation mortality on pollock at present appears to be from the arrowtooth flounder (Livingston 1994a and 1994b). Stock assessment scientists have attempted to incorporate predation mortality by arrowtooth flounder, Pacific halibut, and sea lions in the stock assessment for pollock in the GOA (Hollowed *et al.* 1997).

Research on the diets of marine mammals and birds in the GOA has recently been greatly accelerated (Brodeur and Wilson 1996, Calkins 1987, DeGange and Sanger 1986, Hatch and Sanger 1992, Lowry *et al.* 1989, Merrick and Calkins 1996, Pitcher 1980a, 1980b, and 1981) (see Sections 3.7 and 3.8). Brodeur and Wilson's review (1996) summarized both bird and mammal predation on juvenile pollock. The main piscivorus birds that consume pollock in the GOA are black-legged kittiwakes, common murres, thick-billed murres, tufted puffins, horned puffins, and probably marbled murrelets. The diets of common murres have been shown to contain around 5 percent to 15 percent age-0 pollock by weight, depending on the season. Both horned puffins and tufted puffins consume age-0 pollock. The tufted puffin diet is more diverse and tends to contain more pollock than that of the horned puffin (Hatch and Sanger 1992).

Pollock is a major prey of Steller sea lions and harbor seals in the GOA (Merrick and Calkins 1996; Pitcher 1980a, 1980b, and 1981). Pollock is a major prey of both juvenile and adult Steller sea lions in the GOA. It appears that the proportion of animals consuming pollock increased from the 1970s to the 1980s, and this increase was most pronounced for juvenile Steller sea lions. Sizes of pollock consumed by Steller sea lions range from 5 to 56 cm, and the size composition of pollock consumed appears to be related to the size composition of the pollock population. However, juvenile Steller sea lions consume smaller pollock on average than adults. Age-1 pollock was dominant in the diet of juvenile Steller sea lions in 1985, possibly a reflection of the abundant 1984 year-class of pollock available to Steller sea lions in that year. Harbor seals tend to have a more diverse diet, and the occurrence of pollock in their diet is lower than in the diet of sea lions.

GOA Pollock Management

Pollock in the GOA are thought to be a single stock (Alton and Megrey 1986) originating from springtime spawning in Shelikof Strait (Brodeur and Wilson 1996). Separation of GOA pollock from the BSAI pollock stocks is supported by analysis of larval drift patterns from spawning locations and microsatellite allele variability (Bailey *et al.* 1997), genetic studies (Grant and Utter 1980), and mitochondrial DNA variability (Mulligan *et al.* 1992, Dorn *et al.* 2001).

Studies conducted by Olsen *et al.* (2002) indicate that there may be two genetically distinct pollock stocks in the GOA: the northern GOA stock that includes PWS and Middleton Island, and the Shelikof Strait stock. Large interannual genetic variations in the PWS stock between 1997 and 1998 were found; however, Olsen *et al.* (2002) suggest that this variation may be caused by variable reproductive success, adult philopatry, source-sink population structure, or utilization of the same spawning areas by genetically distinct stocks with different spawning times (as referenced in Dorn *et al.* 2002).

Under current management, the general impacts of fishing mortality within Amendment 56/56 ABC and OFL definitions discussed in Appendix B, apply to pollock in the GOA (Table 3.5-28). GOA pollock are managed under Tier 3b of the ABC/OFL definitions, which requires reliable estimates of biomass, $B_{40\%}$ and fishing mortality rates $F_{30\%}$ and $F_{40\%}$. Under the definitions and current stock conditions, the overfishing rate is the fishing mortality rate that reduces the spawning stock biomass per recruit to 35 percent of its unfished level (the $F_{35\%}$ rate). In the GOA region west of 140°W, the 2003 ABC value of 49,590 mt is recommended, with an OFL of 69,410 mt. This year's ABC value was 35 percent lower than the 2002 ABC, partly due to a reported decrease in the female spawning biomass. In the western, central, and west Yakutat areas, the ABC value has been reduced by 1,720 mt to accommodate the Prince William Sound state pollock fishery (see the past/present effects analysis section for a description of the state pollock fishery). The west Yakutat area receives a 1,078 mt allocation, leaving 46,812 mt ABC for the western and central areas. In the east Yakutat and SEO areas, the 2003 ABC and OFL values are the same as the 2002 ABC and OFL values of 6,460 and 8,610 mt, respectively, due to the lack of new survey data. In southeast Alaska (Area 650), a ban on trawling prevents directed harvest of pollock (Figure 1.2-3; Table 3.5-28).

GOA pollock are assessed with an age-structured model incorporating fishery and survey data. The data used in this analysis consist of estimates of total catch biomass, bottom trawl biomass estimates, EIT survey estimates of the spawning biomass in Shelikof Strait, egg production estimates of spawning biomass in Shelikof Strait, and fisheries catch-at-age and survey size compositions. The bottom trawl data may not provide an accurate view of pollock distribution, because a significant portion of the pollock biomass may be pelagic and not available to bottom trawls and because much of the GOA shelf is untrawlable due to the rough bottom. Fishery catch statistics (including discards) are estimated by the NOAA Fisheries, Alaska Regional Office. These estimates are based on the best blend of observer reported catch and weekly production reports. Age composition data are obtained from several sources, including catch-at-age aggregated over all seasons, nations, vessel classes, and INPFC statistical areas for the years, and catch-at-age from the spring EIT survey and the bottom trawl surveys. Historical information on pollock size composition was obtained from the Japanese Pacific ocean perch fishery from the period 1964–1975 (Hollowed *et al.* 1991). Recent assessments have explored the impact of predation mortality by arrowtooth flounder, Pacific halibut, and Steller sea lions by incorporating time series of estimated predator biomass, the age composition of pollock consumed by predators, and estimated consumption rates (Hollowed *et al.* 1997).

Past/Present Effects Analysis

The geographic scope for the GOA pollock past/present effects analysis is the same as the GOA FMP management areas (Figure 1.2-3). The temporal scope for this analysis begins in 1964 when the GOA foreign groundfish fishery begins and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4. Table 3.5-29 provides a summary of the GOA pollock past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA pollock:

- Mortality due to catch/bycatch and the EVOS (direct effect).

- Change in reproductive success due to removal of predators, fishery selectivity of juveniles, roe stripping, spatial/temporal concentration of catch/bycatch, and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, introduction of exotic species, the EVOS, and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, the EVOS, introduction of exotic species, and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution was not brought forward for analysis. The NOAA NS&T program has produced a summary of Alaska marine environmental quality through its research and sampling projects, including the Mussel Watch Project and the Benthic Surveillance Project. This report is available on the NOAA website at: http://ccmaserver.nos.noaa.gov/NSandT/BrochurePDFs/Alaska.pdf. Furthermore, international, federal and state laws and enforcement agencies are in place to monitor marine pollution.

Change in prey availability and in important habitat due the introduction of exotic species by way of ballast water and climate changes and regime shifts has not been brought forward since the impacts on pollock in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998) Also, see Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA.

The past/present events determined to be applicable to the pollock past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1964-1976)
  - State of Alaska shrimp fisheries
  - State of Alaska crab fisheries
  - State of Alaska groundfish fisheries
  - IPHC halibut fishery
  - Commercial whaling

- Seal harvests
- EVOS
- Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1979-1991)
  - Domestic groundfish fisheries (1976-present)

- Past/Present Management Actions
  - Bilateral agreements
  - IWC management
  - MMPA of 1972
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - Steller sea lion protection measures
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1964-1976)

Pollock began being targeted in 1964 by the foreign groundfish fisheries, predominately by Japan, the Soviet Union and the Republic of Korea. Most of these foreign groundfish fisheries had started in the GOA targeting Pacific ocean perch and switched to other target species during the late 1960s and early 1970s when Pacific ocean perch was reduced in abundance (NPFMC 2002b).

The Soviet fishing vessels first began in the GOA in 1962 and principally targeted Pacific ocean perch. Following decline of the Pacific ocean perch stock, the Soviet fisheries shifted to pollock, Atka mackerel, and flounders. All fishing by the Soviet fisheries in the GOA has been done by trawls (NPFMC 2002b).

The Japanese fishery began exploratory fishing in 1960, although their full-scale groundfish fishery in the GOA did not start until 1963, possibly precipitated by the start of the Soviet fishery. Like the Soviets, the Japanese targeted Pacific ocean perch and did not focus on other targets, including pollock, Pacific cod, and flounder, until the decline of Pacific ocean perch (NPFMC 2002b).

The Republic of Korea fishery began fishing in the GOA in 1972 and targeted pollock, Pacific cod, flounder, sablefish and Atka mackerel. By 1978, the Republic of Korea relied almost exclusively on trawl gear with pollock being the primary target species. As a result of the expansion of the domestic groundfish fisheries, the Republic of Korea has not received a directed fishing allocation in the GOA since 1985 (NPFMC 2002b).

Smaller scale foreign groundfish fisheries, including Poland, Taiwan, and Mexico, have also been conducted in the GOA. Poland arrived in 1973 and began targeting pollock in 1977. From 1978 to 1981, harvest averaged 39,900 mt per year. Poland has not received a directed fishing allocation since 1985. Taiwan began fishing in the GOA in 1975, but Taiwanese vessels were apprehended for violating the U.S. contiguous fishing zone soon thereafter. By 1977, Taiwan had discontinued fishing within the GOA. Mexico harvested about 10,400 mt of groundfish from the GOA in 1979, of which pollock made up 84 percent (NPFMC 2002b).

In 1973, a bilateral agreement between the U.S. and Japan and the U.S. and the Soviet Union included annual catch quotas, which reduced the catch of pollock in the GOA. However, each country was still responsible for monitoring its catch quotas, the only internationally acceptable arrangement at the time. With the passing of the MSA and the increase of U.S. and JV fisheries, foreign groundfish catch in the GOA was further reduced (NPFMC 2002b).

Although large removals of pollock occurred during the foreign fisheries, there appears to be no lingering effect on the GOA pollock populations.

External State of Alaska Groundfish Fisheries

The directed state pollock fishery began in 1995 and is located in PWS. This fishery is broken into three management sections by ADF&G. These sections are the Port Bainbridge Section (waters west of 148°W), the Knight Island Section (waters between 148°W and 147°20'W) and the Hinchinbrook Section (waters east of 147°20'W). Forty percent of the Guideline Harvest Level (GHL) for the year is allocated to each management area. The GHL is accounted for by the federal ABC limits and is allocated to these state fisheries starting at 1,420 mt in 2000 and increasing to 1,720 mt in 2001 and 2002. The fishery is managed to allow closures due to bycatch, exceeding the GHL, or due to emergency orders to protect Steller sea lions. Furthermore, the fisheries are subject to federal observer coverage and are required to maintain a federal logbook and bycatch data. The state fisheries are also subject to IR/IU (5 Alaska Administrative Code [AAC] 29.079 & 5 AAC 28.075), requiring that all pollock be retained during an open directed pollock fishery and up to the maximum retainable bycatch limits when the directed pollock fishery is closed (ADF&G 2002b).

The Cook Inlet Area pollock fishery is a bycatch only fishery, although opportunities are available for directed pollock fisheries through permitting. These directed fisheries are constrained by the same requirements as the PWS directed pollock fisheries (ADF&G 2002a).

External State of Alaska Crab and Shrimp Fisheries and the IPHC Halibut Fisheries

The GOA bait fishery arose due to the need for bait in the crab and halibut fisheries. The bait fishery occurred from PWS west to the Aleutians, with two-thirds of the catch occurring in Kodiak. The catch consisted largely of pollock, Pacific cod, and various flounder species. Groundfish for bait was taken primarily as bycatch in the Kodiak shrimp fishery during the early to mid-1970s. The bait fishery was later characterized by trawlers and longline vessels which targeted groundfish species. Prior to 1972, unrecorded catch of bait may have equaled or exceeded the recorded groundfish catch since bait was transferred to crab and halibut vessels on the fishing grounds. From 1972 to 1976, the catch of groundfish for bait increased from 96 mt to 303 mt. Catches continued to increase through the late 1970s and by 1982 accounted for 1,059 mt. (NPFMC 2002b). In 1983, GOA FMP Amendment 11 eliminated the bait and personal consumption component of the domestic groundfish fishery. Although past bycatch of pollock has occurred in the shrimp fishery, it does not appear to have had a lingering effect on the GOA pollock populations .

External Exxon Valdez Oil Spill

The number of pollock that suffered direct mortality as a result of the EVOS is unknown, but such mortality has not resulted in population-level effects on GOA pollock.

Internal JV and Domestic Groundfish Fisheries (1976-present)

The domestic pollock fishery began in the GOA in 1976 when a fleet of three trawlers from Petersburg, Alaska trawled for pollock during the winter months. Approximately 60 mt of pollock were landed to shoreside processors. During winter, the fishing effort is targeted primarily on pre-spawning aggregations in the Shelikof Strait and near the Shumagin Islands. Fishing in the summer is more variable, but typically occurs on the east side of Kodiak Island and near-shore waters along the Alaska Peninsula. Kodiak, Sand Point, and Dutch Harbor are all major ports for the GOA pollock fishery, with 53 percent of the 1995-2000 landings occurring in Kodiak. The pollock fishery in the GOA was fully domestic by 1988 (NPFMC 2002b).

The development of JV groundfish fisheries occurred rapidly since their beginning in 1979. GOA FMP Amendment 6 regulations adjusted the DAH and the foreign fishery allocations to reflect the best information available from the observers and domestic processors and to allow for a fully utilized groundfish fishery in the GOA. Pollock became the principle target species of the JV groundfish fisheries in 1980, comprising 99 percent of the total catch. In 1980, GOA Amendment 8 modified the timing of reserve releases to allow for increased catches by domestic groundfish fisheries. However, further FMP amendments were needed to make changes in allocations of fish to domestic groundfish and JV groundfish fishermen, and flexibility was needed for the NOAA Fisheries Regional Administrator to reapportion reserves and domestic allocations to foreign groundfish fishermen if it were projected that domestic groundfish fishermen could not harvest them. The Regional Administrator also needed flexibility to impose on foreign groundfish fisheries such closures for conservation reasons as were in place for domestic groundfish fisheries (NPFMC 2002b).

In response, GOA FMP Amendment 11 in 1983: 1) increased the pollock OY in the central GOA from 95,200 to 143,000 mt, 2) established a framework procedure to annually determine domestic groundfish and JV groundfish processing components of the DAH for each species OY, 3) eliminated the bait and personal consumption component of the DAH, 4) increased the flexibility of the Regional Administrator to reapportion reserves and surplus DAH to foreign groundfish fishing, 5) authorized the Regional Administrator to impose time/area closures on foreign nations to conserve resources, and 6) imposed radio/telephone catch reporting requirements on domestic groundfish vessels leaving state waters to land fish outside Alaska beginning in 1983, thus ensuring that all catches were reported.

In 1984, GOA FMP Amendment 13 combined the western and central GOA pollock OYs into a single OY and increased it from 200,000 to 400,000 mt. It was intended to provide optimum harvest of the pollock resource, to allow the pollock resource in the western and central GOA to be managed as one stock, and to prevent undue restriction and economic hardship on the domestic groundfish fishery, by allowing both the harvest of the increased surplus and the distribution of fishing effort to be based on pollock availability.

In 1985, GOA FMP Amendment 14 modified the management of a number of target species. Under this amendment, OYs were changed for pollock, Pacific ocean perch, other rockfish, Atka mackerel, and other species. A mechanism was also established for timely reporting of catches by domestic groundfish catcher processors that stayed at sea for long periods, and NOAA Fisheries habitat policy was implemented.

The 1992 inshore/offshore amendment (GOA FMP Amendment 23) required that 100 percent of the pollock catch be processed at shoreside plants, completing the phase-out of foreign groundfish and JV fisheries in the GOA. This amendment also moved the fishery from bottom to pelagic trawls to avoid bycatch of prohibited species (i.e., halibut) and closed the factory trawling fisheries of the GOA.

Although large removals have occurred in the JV and domestic fisheries, these fisheries have not had a lingering effect on the GOA pollock population.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1964-1976)

Bycatch in the foreign groundfish fisheries has not been well documented; however, it is assumed that bycatch of pollock consisted mainly of juveniles. Few observers were allowed on Soviet vessels under the bilateral agreements, and the Soviets were well-known for under-reporting their catches of target species and, presumably, bycatch as well.

Foreign groundfish fisheries in the GOA also tended to target younger pollock, with a maximization selection of 5 to 6 years versus the current domestic groundfish fishery which selects fish age-7 to -8 years (Dorn *et al.* 2001).

The effect of the foreign fisheries GOA pollock recruitment due to the foreign fisheries selectivity and bycatch of juvenile pollock is unknown.

External Climate Changes and Regime Shifts

Recruitment of GOA pollock is more variable than EBS pollock. Evidence suggests that spawner productivity is higher at low spawning biomass compared to high spawning biomass. The density-dependence of the survival of eggs corresponds with decadal trends in spawner productivity and have produced a pattern in the GOA pollock population (Dorn *et al.* 2002). Environmental conditions have likely influenced spawner biomass, thus influencing GOA pollock recruitment.

FOCI is used by the SSC to make predictions on the strength of year-classes. These predictions are based on precipitation, wind mixing energy, advection of ocean water, pollock larvae counts, and pollock abundance estimates. Precipitation, wind-mixing and advection are all important factors in the survival and success of pollock larvae.

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of pollock. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an in depth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries.

Internal JV and Domestic Groundfish Fisheries (1976-present)

Fishery Selectivity

GOA pollock are caught as bycatch in other directed fisheries. However, because they occur primarily in well-defined aggregations, the impact of this bycatch is typically minimal. Most of the discards in the pollock fishery are juvenile pollock, or pollock too large to fit filleting machines. In the pelagic trawl fishery the catch is almost exclusively pollock; however in the past bottom trawl pollock fishery the bycatch of other species was higher.

To improve reporting of catch and bycatch, reporting requirements were established for the domestic groundfish fisheries under GOA FMP Amendment 7 in 1979. This amendment created the first domestic groundfish reporting requirements to facilitate better estimates of DAH and processing capabilities, along with other management actions. It also initiated area closures to the JV groundfish fisheries to encourage the growth of the domestic groundfish fishery. GOA FMP Amendment 18 established the domestic Observer Program, designed to estimate bycatch and discard rates, among other things. Additional GOA FMP amendments addressing data collection needs (Amendments 11, 14, 15, 16, 17, 18, 30, and 47) were subsequently approved.

GOA FMP Amendment 49 initiated the IR/IU program to reduce discards of all groundfish target fisheries. This amendment required vessels fishing for groundfish in the GOA to retain all pollock beginning January 1, 1998.

Selectivity in the GOA pollock fishery has changed as the fishery has evolved from a foreign groundfish fishery occurring along the shelf break to a domestic groundfish fishery on spawning aggregations and in nearshore waters. Since 1992, GOA pollock have been managed with time and area restrictions, and selectivity has been fairly stable. As in the BSAI, fishery selectivity increases to a maximum around age 7-8 and then declines.

Like the BSAI, cumulative impacts of fishing mortality on age composition are influenced by the selectivity of the fishery. The current age composition of the stock reflects a fished population with a long catch history under low exploitation rates. The NOAA Fisheries FOCI and Coastal Ocean Programs' SEBSCC regional study focuses research on improving understanding of mechanisms underlying annual production of pollock stocks in the GOA and EBS.

Roe Stripping

Large spawning aggregations of pollock were discovered in the Shelikof Strait in 1981, which initiated the development of the GOA pollock roe fishery (Megrey 1989). By 1990, the growth of the domestic pollock fishery had created competition for the pollock TAC. GOA FMP Amendment 19 was implemented in 1991 to address the following roe stripping issues:

- Roe stripping is a wasteful use of the pollock resource.

- Roe stripping causes an unintended allocation of pollock TAC among seasons and industry sectors.
- Roe stripping may adversely affect the ecosystem.
- Roe stripping may adversely affect the future productivity of the stock.
- Roe stripping increases the difficulty of accurately monitoring the pollock TAC for inseason management.

In 1993, regulations were further tightened to close loopholes that could have potentially undermined the intent of the roe stripping regulations (58 FR 57752).

Spatial/Temporal Concentration of Catch/Bycatch

GOA pollock tend to concentrate along the shelf break at intermediate depths of about 150-200 m and pollock fisheries generally occur from 100-200 m (Hollowed *et al.* 1997). Fisheries concentrate on large concentrations of pollock in the central and western GOA management areas (147°W-170°W), mainly in Shelikof Strait, the trough or gully regions of the east side of Kodiak Island, and Shumagin area. Studies show that the GOA pollock, unlike the BSAI pollock, do not show strong seasonal differences in distribution. Spatial patterns remained consistent from 1984-1996, and shifts in the spatial distribution of pollock reflect the seasonal migrations to spawning locations. In general, the fishery for pollock in the GOA has remained fairly constant in time and space, if not in the amount of biomass removed. Therefore, it is suggested that recent levels of fishing in the GOA may not have had a strong impact on these distributions (Meuter and Norcross 2002).

Management of the pollock fishery has changed recently as NOAA Fisheries and NPFMC have taken measures to reduce the possibility of competitive interactions with Steller sea lions. In 1999, this led to further closures of critical habitat to pollock fisheries in the Aleutian Islands region, the EBS, and the GOA. A total of 210,350 km^2 (54 percent) of critical habitat was closed to the pollock fishery. Following 1998, catches of pollock and the proportion of seasonal TAC caught in the Steller Sea Lion Conservation Area and Steller Sea Lion critical habitat have been reduced (Ianelli *et al.* 2001b).

<u>External Commercial Whaling and Seal Harvests</u>

Whaling is identified as having a past beneficial effect on GOA pollock recruitment. Pollock has been noted as a prey item for fin whales, minke whales, and humpback whales (see Sections 3.8.12, 3.8.14 and 3.8.15). By removing the large predators, pollock recruitment is favored. Whale and seal harvests are no longer of concern. Subsistence and personal use of marine mammals is at such a small scale that it is unlikely to have a population-level effect on the GOA pollock stock.

Change in Prey Availability

External Foreign Pacific Ocean Perch and Pollock Fisheries (1964-1976) and Internal JV and Domestic Pacific Ocean Perch and Pollock Fisheries (1976-present)

Research by Somerton (1979) and Alton *et al.* (1987) has explored the possibility that the rise of pollock in the GOA in the early 1970s was in response to the large biomass removals of Pacific ocean perch, a potential predator for euphausiid prey (Dorn *et al.* 2001). The foreign fishery for Pacific ocean perch started in the GOA in 1962 and peaked in 1966. By 1985, only sufficient quantities for bycatch purposes were allocated by NPFMC. A series of GOA FMP amendments (10, 32, and 38) closed Pacific ocean perch areas to the fisheries and laid out a rebuilding plan.

External Exxon Valdez Oil Spill

The effects of pollution have been found to have reduced pollock prey availability, although it is unlikely that pollution has had a population-level effect on the GOA pollock stocks.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the prey availability of pollock. In general, a shift toward warmer waters favors recruitment and survival of pollock. In 1998/1999, the Pacific Decadal Oscillation shifted to negative, with cooler-than-average northeastern Pacific surface temperature, and warmer-than-average central Pacific surface temperatures.

Changes in Important Habitat

External Foreign Groundfish Fisheries (1964-1976)

Information of the number of trawls that occurred during the pre-MSA GOA foreign fisheries is unavailable. The effects of fishery gear on pollock habitat is potentially adverse, although if so, this does not appear to have had a lingering adverse effect on the GOA pollock populations. See Section 3.6.4 for a discussion of the potential effects of fishery gear on habitat.

A bottom trawling ban was initiated in pollock spawning habitats in pre-MSA fishery management regulations. This initiative reduced the bycatch of juvenile pollock while indirectly reducing the intensity of trawling on pollock spawning habitat. Several of the foreign groundfish fisheries also imposed restrictions on themselves to reduce their effects on pollock spawning habitats.

External Exxon Valdez Oil Spill

This event has been identified as resulting in an adverse effect on pollock spawning habitat; however, this effect has not shown population-level impacts on GOA pollock.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as having potentially beneficial or adverse effects on habitat suitability. In general, a shift toward warmer waters favors recruitment and survival of pollock. As described in Section 3.10.1.5, when the Aleutian Low was weak, resulting in colder water, shrimp dominated the catches. When the Aleutian Low was strong, water temperatures were higher, and the catches were dominated by cod, pollock, and flatfishes.

Large fluctuations in pollock abundance without large changes in the direct fishing suggest that the GOA pollock may be strongly influenced by environmental controls and indirect ecosystem effects. This implies a need for conservative management, since adverse population effects by the fisheries may be difficult or impossible to reverse through management measures (Dorn *et al.* 2002).

Internal JV and Domestic Groundfish Fisheries (1976-present)

Very little research regarding the effects of trawling activities in the GOA has been conducted. The greatest bottom trawl effort in the GOA has taken place in the Kodiak Island region, where directed fisheries have targeted Pacific ocean perch, Pacific cod, and flatfish. Over nine years (1990-1998), a total of 57,948 tows were observed in the GOA. If expanded to include unobserved tows, the total number of trawl tows were estimated at 116,288 tows. The total bottom trawl effort measured in 24-hour days was estimated at 11,829 trawl-days. The highest estimated number of bottom trawls in both the GOA and Aleutian Islands occurred on the continental shelf at a depth of 101-200 m. The density value of trawling for the GOA overall was calculated at 0.35/km^2, the highest density in the Kodiak Island region at 1.43/km^2 in an area of 4,657 km^2 at a depth of 301-500 m. The highest bottom trawl duration in the GOA was at a depth of 101-200 m, with the highest number of days trawled per km^2 in the Chirikof Island area at 0.74 days/km^2 at 301-500 m (see Section 3.6 for more information).

For the period 1990-2000, 64,948 bottom trawls were observed in the GOA. The spatial pattern of this effort is much more dispersed than in the Bering Sea region. During 2000 the amount of trawl effort was 3,443 sets. Areas of high fishing effort are dispersed along the shelf edge with high pockets of effort near Chirikof Island, Cape Barnabus, Cape Chiniak and Marmot Flats. Catch in these areas was composed primarily of pollock, Pacific cod, flatfish and rockfish. A larger portion of the trawl fleet in the Kodiak Island area is composed of smaller catcher vessels that require 30 percent observer coverage (see Section 3.6 for more information).

In April 1987, GOA FMP Amendment 15 closed two areas around Kodiak Island to bottom trawling and scallop dredging. These areas were designated as important rearing habitat and migratory corridors for juvenile and molting crabs. The closures are intended to assist rebuilding severely depressed Tanner and red king crab stocks. In addition to crab resources, the closed areas and areas immediately adjacent to them have rich stocks of groundfish including flathead sole, butter sole, Pacific halibut, arrowtooth flounder, Pacific cod, pollock, and several species of rockfish.

GOA FMP Amendment 18 enhanced the protection of target species beginning in 1990. It established the Shelikof Strait area as a management district because the area was found to contain spawning populations of pollock. The amendment also extended the closed areas around Kodiak Island to bottom trawl gear because those closure areas were scheduled to expire at the end of the year.

As mentioned above, GOA FMP Amendment 23 eliminated the domestic bottom trawl fishery for pollock to avoid bycatch of prohibited species and to further reduce the fisheries impacts on benthic habitats. The fishing industry also initiated self-imposed gear modifications to further protect pollock spawning habitat and other benthic habitats.

GOA FMP Amendment 25 established Steller sea lion buffer zones in the GOA. Regulations authorized by this amendment implemented the following measures:

1. Areas are closed year-round to fishing by trawl vessel within 10 nm of key Steller sea lion rookeries.

2. Areas within 20 nm of five sea lion rookeries are closed to directed pollock fisheries during the “A” season.

3. The specified TAC for pollock in the combined western/central area is further divided among three pollock management districts: Area 61, Area 62, and Area 63. The Shelikof Strait District was eliminated. To prevent excessive accumulation of unharvested portions and quarterly allowance of the pollock TAC, a limit of 150 percent of the initial quarterly allowance in each pollock management district was established.

In 1993, NOAA Fisheries extended the no-trawl zone around Ugamak Island out to 20 nm during the pollock roe fishery (58 FR 13561). GOA Amendment 45 further subdivided the areas for pollock fishing; these areas were further modified in June of 1998 (63 FR 31939).

GOA FMP Amendments 55 and 65 were recently passed in order to identify EFH, minimize practicable adverse effects on habitat, and encourage conservation of HAPC.

GOA Pollock Comparative Baseline

AFSC bottom trawl surveys are conducted every three years in the GOA. Starting in 2001, these surveys have been conducted every two years. In 2001, the AFSC survey covered the western and central GOA, which typically accounts for 97 percent of the GOA pollock. The 2001 biomass estimate (216,761 mt) indicates a 65 percent decline in biomass compared to the 1999 biomass survey estimate (Dorn *et al.* 2001).

The Shelikof Strait EIT survey has been conducted annually since 1981 and is used to assess the biomass of pollock in the Shelikof Strait area. Age-2+ abundance estimates were estimated at 229,100 mt, a 38 percent decrease from the 2001 biomass estimates. However, the 2002 age-3 estimated abundance was the third largest on record. EIT surveys were also conducted in the Shumagin Islands spawning areas and the area along the shelf east of the entrance to the Shelikof sea valley in winter of 2002. The 2002 survey results indicate that there may not be a constant ratio of stock spawning in the Shelikof Strait for the total pollock biomass, an assumption used in the modeling of GOA pollock. The GOA pollock stock modeling will be reevaluated in light of these new results (Dorn *et al.* 2002).

The ADF&G crab/groundfish trawl survey is conducted at a fixed number of stations, mostly nearshore from Kodiak Island to Unimak Pass. These surveys have been conducted since 1987. The 2002 biomass estimate (96,237 mt) indicates an increase of 11 percent from the 2001 biomass, in contrast to the steep decline suggested by the Shelikof Strait EIT survey. The ADF&G survey also shows a predominance of older fish (greater than 45 cm) which may be attributed to selectivity of the gear (Dorn *et al.* 2002). The survey biomass estimates from the AFSC, Shelikof Strait EIT and ADF&G trawl surveys for GOA pollock are listed in Dorn *et al.* 2002.

In order to estimate pollock biomass from 1961-1982, a generalized linear model (GLM) was fit to pre-1984 trawl data and post-1984 triennial trawl survey data. This model indicates low biomass estimates between 1961 and 1971, an increase by a factor of 10 in 1974 and 1975, and declining to 900,000 mt in 1978. No consistent trends are noticeable in the GLM following 1978. The coefficients of variation for the GLM-based biomass estimates range between 0.24 and 0.64, larger than the triennial survey biomass estimates (Dorn *et al.* 2001).

Over the last 15 years, NOAA Fisheries' FOCI targeted much of their research on understanding processes influencing recruitment of pollock in the GOA. These investigations led to the development of a conceptual model of factors influencing pollock recruitment (Kendall *et al.* 1996). Bailey *et al.* (1996) reviewed 10 years of data for evidence of density-dependent mortality at early life stages. Their study revealed evidence of density-dependent mortality only at the late larval to early juvenile stages of development. Bailey *et al.* (1996) hypothesize that pollock recruitment levels can be established at any early life stage (egg, larval, or juvenile) depending on sufficient supply from prior stages. They labeled this hypothesis the *supply dependent multiple life stage control model*. In a parallel study, Megrey *et al.* (1996) reviewed data from FOCI studies and identified several events that are important to pollock survival during the early life history. These events are climatic events (Hollowed and Wooster 1995, Stabeno *et al.* 1995); preconditioning of the environment prior to spawning (Hermann *et al.* 1996), the ability of the physical environment to retain the planktonic life stages of pollock on the continental shelf (Bograd *et al.* 1994, Schumacher *et al.* 1993), and the abundance and distribution of prey and predators on the shelf (Bailey and Macklin 1994, Canino 1994, Theilacker *et al.* 1996). Thus, the best available data suggest that pollock year-class strength is controlled by sequences of biotic and abiotic events and that population density is only one of several factors influencing pollock production.

The 2002 FOCI predictions were based on information from: 1) observed 2002 Kodiak monthly precipitation, 2) wind mixing energy at 57°N, 156°W, 3) advection of ocean water in the vicinity of Shelikof Strait, 4) rough counts of pollock larvae from May 2002, and 5) estimates of age-2 pollock abundance. By weighting these elements, FOCI forecasted that the 2001 year-class is strong and 2002 year-class is average (Dorn *et al.* 2002).

GOA Pollock Cumulative Effects Analysis Status

GOA pollock will be brought forward for cumulative effects analysis.

3.5.1.14 GOA Pacific Cod

Life History and Distribution

Pacific cod (*Gadus macrocephalus*) is a demersal species that occurs on the continental shelf and upper slope from Santa Monica Bay, California through the GOA, Aleutian Islands, and EBS to Norton Sound (Bakkala 1984). The Bering Sea represents the center of greatest abundance, although Pacific cod are also abundant in the GOA and Aleutian Islands. GOA, EBS, and Aleutian Island cod stocks are genetically indistinguishable (Grant *et al.* 1987), and tagging studies show that cod migrate seasonally over large areas (Shimada and Kimura 1994).

In the late winter, Pacific cod converge in large spawning masses over relatively small areas. Major aggregations occur between Unalaska and Unimak Islands, southwest of the Pribilof Islands, and near the Shumagin group in the western GOA (Shimada and Kimura 1994). Spawning takes place in the sublittoral–bathyal zone near the bottom, the area of the continental shelf and slope about 40 to 290 m deep. The eggs sink to the bottom and are somewhat adhesive (Hirschberger and Smith 1983). Table 3.5-4 summarizes the biological and reproductive traits and habitat associations of Pacific cod at its different life stages.

Pacific cod reach a maximum recorded age of 19 years. In the BSAI, 50 percent of Pacific cod is estimated to reach maturity by the time they reach 67 cm in length, or an age of about 5 years (Thompson and Dorn 1999). The same length in the GOA stock corresponds to an age of about 7 years (Thompson *et al.* 1999).

Trophic Interactions

Pacific cod is an opportunistic feeder that feeds both in the water column and in benthic areas (Yang and Nelson 2000). In the BSAI and GOA, in terms of percent occurrence in stomach contents, the most important items were polychaetes, amphipods, and crangonid shrimp. In terms of numbers of individual organisms consumed, the most important items were euphausiids, miscellaneous fish, and amphipods. In terms of weight of organisms consumed, the most important items were pollock, fishery offal, and yellowfin sole. Small Pacific cod were found to feed mostly on invertebrates, while large Pacific cod are mainly piscivorus (Livingston 1991b). In studies conducted on GOA Pacific cod, polychaetes and cephalopods were the most frequently found invertebrates in stomach contents. However, pandalid shrimp were more important in terms of percentage of total stomach contents weight. GOA Pacific cod also consumed large amounts of tanner crabs (Yang and Nelson 2000). Predators of Pacific cod include Pacific halibut, salmon shark, northern fur seals, Steller sea lions, harbor porpoises, various whale species, and tufted puffins (Westrheim 1996).

GOA Pacific Cod Management

Pacific cod in the GOA is managed under Tier 3a. The 2002 assessment projected a 2003 female spawning biomass of 88,300 mt, about 8 percent above 2001 assessment's projection for 2002 and corresponding to a maximum permissible 2003 ABC of 59,900 mt. NPFMC adopted a 2003 ABC of 52,800 mt, down about 8 percent from the 2002 ABC and about 12 percent below the maximum permissible value. The 2003 OFL for the GOA stock is 70,100 mt, down about 9 percent from the 2002 OFL. The 2003 ABC is intended to include all harvest mortality, including catches taken in the State of Alaska Pacific cod fisheries (Table 3.5-28). ABC is allocated among regulatory areas according to the average proportion of trawl survey biomass in each area: western, 39 percent; central, 55 percent; and eastern, 6 percent (Thompson *et al.* 2002) .

Beginning with the 1994 GOA SAFE report (Thompson and Zenger 1994), a length-structured synthesis model (Methot 1990) has formed the primary analytical tool used to assess Pacific cod.

Annual trawl surveys in the EBS and triennial (recently, biennial) trawl surveys in the Aleutian Islands and GOA are the primary fishery-independent sources of data for Pacific cod stock assessments (Thompson and

Dorn 2002, Thompson *et al.* 2002). Other available data include catch size compositions and biomass by gear, for the years 1978 through the early part of 2002. Within each year, catches are divided according to three time periods: January-May, June-August, and September-December. This particular division, which was suggested by participants in the EBS fishery, is intended to reflect actual intra-annual differences in fleet operation (e.g., fishing operations during the spawning period may be different than at other times of year). Four fishery size composition components were included in the likelihood functions used to estimate model parameters: the January-May (early) trawl fishery, June-December (late) trawl fishery, the longline fishery, and the pot fishery. In order to account for differences in selectivity between mostly foreign, mostly domestic, and very recent fisheries, the fisheries data were split into pre-1987, 1987-1999, and post-1999 eras in the GOA and pre-1989, 1989-1999, and post-1999 eras in the EBS. In addition to the fishery size composition components, likelihood components for the size composition and biomass trend from the bottom trawl surveys were included in the model. All components were weighted equally.

Quantities estimated in the most recent stock assessments include parameters governing the selectivity schedules for each fishery and survey in each portion of the time series, parameters governing the length-at-age relationship, population numbers at age for the initial year in the time series, and recruitments in each year of the time series. Given these quantities, plus parameters governing natural mortality, survey catchability, the maturity schedule, the weight-at-length relationship, and the amount of spread surrounding the length-at-age relationship, the stock assessments reconstruct the time series of numbers at age and the population biomass trends (measured in terms of both total and spawning biomass).

The model around which the Pacific cod assessments are structured uses an assumed survey catchability of 1.0 and an assumed natural mortality rate of 0.37 (see Appendix B). Several previous assessments included statistical analyses of the uncertainty surrounding the true values of the survey catchability and natural mortality rate. These analyses of uncertainty led to a risk-averse adjustment factor of 0.87 which is multiplied by the maximum permissible F_{ABC} to obtain the recommended F_{ABC}. Other outputs of the assessments include projections of biomass and harvest under a variety of reference fishing mortality rates.

GOA Pacific Cod Past/Present Effects Analysis

The geographic scope for the GOA Pacific cod past/present effects analysis is the same as the GOA FMP management areas (Figure 1.2-3). The temporal scope for this analysis begins in 1867 when the GOA domestic fishery begins and ends in 2002, the most recent year for which a stock assessment is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-30 provides a summary of the GOA Pacific cod past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA Pacific cod:

- Mortality due to catch/bycatch and marine pollutants and oil spills (direct effect).

- Change in reproductive success due to fishery selectivity of juveniles, spatial/temporal concentration of catch, and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to impacts of fishery gear, marine pollutants and oil spills, introduction of exotic species and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due the introduction of exotic species by way of ballast water and climate changes and regime shifts has not been brought forward since the impacts on Pacific cod in the GOA has not been directly observed or documented. See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the Pacific cod past effects analysis include the following:

- Past/Present External Events
  - Subsistence and personal use
  - Foreign groundfish fisheries (1962-1976)
  - State of Alaska crab fisheries
  - IPHC longline fisheries
  - State of Alaska groundfish fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1987)
  - JV groundfish fisheries (1978-1988)
  - Domestic groundfish fisheries (1867-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Subsistence and Personal Use

The earliest fisheries for groundfish in the GOA were the Native subsistence fisheries. Catches were traded or sold to the Russians and later to the Americans after the purchase of Alaska by the U.S. in 1867. Groundfish and herring are still important sources of food to many groups of Alaska Natives, although these subsistence harvests are now dwarfed by commercial operations (NPFMC 2002b). Since the overall Pacific cod catch by these groups is relatively small and localized, it is unlikely that these users would have an adverse effect on the GOA Pacific cod populations.

External Foreign Groundfish Fisheries (1962-1976)

The foreign trawl fisheries began in the GOA in 1962 with a Soviet fleet targeting Pacific ocean perch. Japan began fishing the following year, focusing on Pacific ocean perch and sablefish. These fisheries expanded rapidly in the late 1960s, and began targeting other groundfish species, although Pacific cod was not targeted until 1972 by Japan and the Soviet Union, and 1978 by the Republic of Korea. Prior to 1976, the majority of Pacific cod catch was bycatch. Pacific cod became the primary target of Japanese longline vessels in 1978 following the phase-out of foreign fisheries in the sablefish fishery and the expansion of domestic utilization (GOA FMP Amendments 2, 3, and 6). The foreign Pacific cod fishery peaked in 1981 at about 35,000 mt. Foreign fisheries dominated groundfish catch until 1985, when they were limited to only pollock and Pacific cod due to the rapid expansion of domestic fisheries capable of harvesting other species. By 1987, foreign fisheries were eliminated from the GOA (NPFMC 2002b). The past foreign fisheries contributed to fishing mortality in the GOA. Due to the short duration and moderate catch of the past Pacific cod foreign fisheries, there are no observable lingering adverse effects on the GOA Pacific cod populations.

External State of Alaska Groundfish Fisheries

The state-managed Pacific cod fishery began in 1997. Pacific cod fisheries are located in PWS, Cook Inlet, Chignik, Kodiak and the south Alaska Peninsula; each unit is regulated by a state FMP. A portion of the federal ABC is allocated to Pacific cod fisheries as a GHL, similar to the pollock fisheries. The GHLs are then allocated according the location of the fishery and gear type (pot and jig gear) within state waters. In 1999, approximately 14,044 mt of Pacific cod were harvested in the state-managed fisheries (ADF&G 2000b).

The State of Alaska contributed to the fishing mortality of Pacific cod in the GOA. These removals do not appear to have a significantly adverse effect on the GOA Pacific cod populations.

External State of Alaska Crab Bait Fisheries and IPHC Longline Bait Fisheries

The GOA bait fishery arose mainly in response to the need for bait in the growing crab fisheries of Alaska. The halibut fishery also required substantial amount of groundfish for bait. The bait fishery occurred from PWS west to the Aleutians, but some two-thirds of the catch was landed in Kodiak. The catch consisted mainly of pollock, Pacific cod, and various flounder species. The ability to measure the catch of groundfish for bait has been limited due to utilization of large amounts of Pacific cod on board halibut vessels. Therefore, unrecorded catch of bait may equal or exceed the recorded catch of bait. Bait has also been transferred to crab and halibut vessels on the fishing grounds. From 1972 to 1976 the catch of groundfish for bait increased from 96 mt to 303 mt. Catches continued to increase through the late 1970s and by 1982 accounted for 1,059 mt (NPFMC 2002b).

The State of Alaska crab fisheries and the IPHC longline fisheries contributed to fishing mortality in the GOA. The effect of these fisheries consisted of both removals of the fish as bycatch and removals of Pacific cod to be used in the fishery as bait. These past removals may have exerted impacts to the Pacific cod resource, resulting in adverse effects to overall mortality. GOA Amendment 11 was passed in order to eliminate the non-processed portion (bait and personal component) of the domestic fishery.

Internal JV and Domestic Groundfish Fisheries (1867 - present)

The first commercial groundfish fishery in the GOA was a setline fishery for Pacific cod by U.S. Nationals in 1867. Canadians were involved in the groundfish fisheries in the GOA since the beginning of the 20th century, although most of their efforts were focused on Pacific halibut and ended in 1981 as a result of extended jurisdiction (NPFMC 2002b).

Pacific cod have been landed domestically since the late 1950s and early 1960s, although the fishery did not really begin to develop until 1978. In 1985, the foreign fisheries were limited to pollock and Pacific cod in an effort to build the domestic fishery, and by 1987 the GOA had become completely domesticated. A small Pacific cod JV fishery existed through 1988, with a small average catch of approximately 1,400 mt per year. GOA FMP Amendment 8 was proposed to phase out the JV and foreign fisheries. The past JV and pre- and post-MSA domestic fisheries have contributed to the fishing mortality of GOA Pacific cod. There are no observable lingering effects in the GOA Pacific cod populations from these fisheries.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1962-1976)

Fishery Selectivity

In 1969 and 1970, the Soviet groundfish fishery targeted on arrowtooth flounder, sablefish, and pollock with bycatches of Pacific cod, rockfish, and other bottomfish. Data regarding the amount of Pacific cod bycatch and the age of the catch are unavailable; however, it is assumed that the bycatch of juvenile Pacific cod took place. Regardless, there are no observable lingering effects on the GOA Pacific cod population due to past foreign fishery selectivity.

External State of Alaska Groundfish Fisheries

Spatial/Temporal Concentration of Catch/Bycatch

State of Alaska Pacific cod fisheries tend to be spatially concentrated in the separate management areas. In the PWS, a majority of catches occur west of Montague Island and the western part of PWS. In Cook Inlet, catches came predominately from Kachemak Bay. The south Alaska Peninsula fisheries focus on the Sanak and Shumagin Islands area. The Kodiak and Chignik areas are more broadly distributed in space than the other fisheries. Overall, all of the state-managed Pacific cod fisheries tend to be broadly distributed in time, although there is some concentration during the late summer and early fall in certain regions (ADF&G 2000b).

Due to its localized nature, the State of Alaska directed Pacific cod fishery has been noted to have an adverse effect on the spatial distribution of the GOA Pacific cod stock. This effect is determined to have had lingering population effects in that stock.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of Pacific cod. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5 for more details).

Internal JV and Domestic Groundfish Fisheries (1867-present)

Fishery Selectivity

Pacific cod are caught as bycatch and discarded in the Pacific cod fishery and other domestic groundfish trawl fisheries. GOA FMP Amendment 18 established the Observer Program partially in an attempt to reduce target and non-target species bycatch. Since 1998 (GOA FMP Amendment 49), discarding of Pacific cod has been prohibited except for fisheries in which Pacific cod has a bycatch-only status.

Spatial/Temporal Concentration of Catch/Bycatch

The Pacific cod fishery has changed recently due to management measures instituted to reduce possible adverse impacts on the western population of Steller sea lions. Some of these measures attempted to distribute catch more evenly throughout the year. On average during the period 1998-2000, 84 percent of the annual trawl catch, 97 percent of the annual longline catch, and 90 percent of the annual pot catch was taken from January to May. The attempted redistribution of trawl catches appears to have been the most successful, as the proportion taken during January to May was reduced to 63 percent in 2001. Correspondingly, the proportion of trawl catch taken during June to August increased by one percent and the proportion taken during September to December and increased by 20 percent. The longline and pot fisheries saw little change in temporal distribution; although pot gear saw a slight decline in the proportion of the catch taken during January to May with a slight corresponding increase from September to December (Thompson *et al.* 2002).

Change in Prey Availability

External Foreign Groundfish Fisheries (1962-1976)

Past foreign fisheries in the GOA have had an adverse impact on prey availability for large Pacific cod due to large removals of pollock. Large Pacific cod are mainly piscivorus consuming pollock ranging in age from age-0 to greater than age-6 depending on predator size. However, due to the opportunistic nature of Pacific cod, it is unlikely that the fisheries would have had a population-level effect of these populations. No observable lingering effects are apparent in the present GOA Pacific cod populations .

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of Pacific cod.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse with respect to prey availability. In general, a shift toward warmer waters appears to favor recruitment and survival of Pacific cod. As described in Section 3.10.1.5 of this Programmatic SEIS, when the Aleutian Low was weak, resulting in colder water, shrimp dominated the catches. When the Aleutian Low was strong, water temperatures were higher, and the catches were dominated by Pacific cod, pollock, and flatfishes.

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of small Pacific cod.

Internal JV and Domestic Groundfish Fisheries (1867-present)

JV and domestic fisheries in the GOA have had an adverse impact on prey availability for large Pacific cod due to large removals of pollock. Large Pacific cod are mainly piscivorus consuming pollock ranging in age from age-0 to greater than age-6 depending on predator size. However, due to the opportunistic nature of Pacific cod, it is unlikely that the fisheries would have had a population-level effect of these populations. No observable lingering effects are apparent in the present GOA Pacific cod populations .

Change in Important Habitat

External Foreign Groundfish Fisheries (1962-1976)

The statistics on the effects of bottom trawling in the GOA pre-MSA is generally unavailable. It is assumbed that habitat suitability has been negatively affected by the intensity of the past foreign fisheries; however, the effects have not shown a lingering influence at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse with respect to habitat suitability. In general, a shift toward warmer waters appears to favor recruitment and survival of Pacific cod. As described in Section 3.10.1.5 of this Programmatic SEIS, when the Aleutian Low was weak, resulting in colder water, shrimp dominated the catches. When the Aleutian Low was strong, water temperatures were higher, and the catches were dominated by Pacific cod, pollock, and flatfishes.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of Pacific cod.

Internal JV and Domestic Groundfish Fisheries (1867-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability has been adversely affected by the intensity of the past JV and domestic trawl fisheries; however, the effects are not considered to have a lingering influence at the population-level. GOA FMP Amendments 15, 18, 23, 25 and Steller sea lion protection measures have all contributed to reducing the intensity of bottom trawling by the domestic fishery. GOA FMP Amendments 55 and 65 were proposed to identify EFH, minimize practicable adverse effects on habitat from the fishery, and encourage conservation of HAPC.

GOA Pacific Cod Comparative Baseline

The highest biomass estimate recorded was in the 1984 survey at 571,188 mt and the lowest during the 2001 survey. However, the 2001 survey did not cover the eastern portion of the GOA. The highest number of fish was observed in 1996 with a population estimate of over 315 million fish. Pacific cod distributed throughout the GOA, with 47 percent of the biomass in the western GOA, 45 percent of the biomass in the central GOA, and 8 percent of the biomass in the eastern GOA according to the 2001 survey, using the 1999 eastern GOA survey estimate to approximate the 2001 eastern GOA biomass (Thompson *et al.* 2001).

Modeling indicates an increase in the age-3+ biomass during the early 1980s followed by a period of sustained high abundance through the rest of that decade. A steady decline in survey biomass has occurred from the early 1990s through the present. Female spawning and survey biomass trends also show declines throughout the past decade. Recruitment of age-3 Pacific cod appears to be average for the 1995 year-class and below average for 1998 year-class. Model estimates of age-1 recruitments closely parallel the age-3 recruitment, with the addition of a below average 1999 year-class and an average 2000 year-class (Thompson *et al.* 2002).

GOA Pacific Cod Cumulative Effects Analysis Status

GOA Pacific cod will be brought forward for cumulative effects analysis.

3.5.1.15 GOA Sablefish

Sablefish in the BSAI and GOA are managed as a single stock. Thus, the direct/indirect effects summary and cumulative effects analysis status of BSAI and GOA stocks is presented in Section 3.5.1.3.

3.5.1.16 GOA Atka Mackerel

Life History and Distribution

Atka mackerel existed in the GOA throughout the early 1980s and supported a large foreign fishery. By the mid-1980s, the population had nearly disappeared. This suggests that the Atka mackerel population in the GOA may be the edge of its distribution and that the GOA be populated only during periods of strong recruitment from the Aleutian Islands region. No reliable estimate exists of current Atka mackerel biomass in the GOA. Atka mackerel have not been commonly caught in the GOA triennial trawl surveys and, recently, have been detected by the summer trawl surveys only in the Shumagin (western) area of the GOA (Lowe and Fritz 2001).

Trophic Interactions

The diets of commercially important groundfish species in the GOA during the summer of 1990 were analyzed by Yang (1993). Atka mackerel were not sampled as a predator species. However, it is a reasonable assumption that the major prey items of GOA Atka mackerel would likely be euphausiids and copepods, as was found in Aleutian Islands Atka mackerel (Yang 1996).

The abundance of Atka mackerel in the GOA is much lower compared to the Aleutian Islands. Predators of the GOA Atka mackerel are similar to those encountered in the BSAI, although Atka mackerel appeared only as a minor component in the diet of arrowtooth flounder in the GOA (Yang 1993).

GOA Atka Mackerel Management

GOA Atka mackerel fall into Tier 6 of the ABC and OFL definitions, which define the OFL level as average catch from 1978 to 1995 and ABC as not exceeding 75 percent of OFL. The average annual catch from 1978 to 1995 is 6,200 mt; thus ABC cannot exceed 4,700 mt. The current ABC recommendation from the stock assessment is below the maximum prescribed under Tier 6, to provide a very conservative harvest strategy given the uncertainty about GOA Atka mackerel abundance. The 2002 stock assessment for the 2003 fishery recommended an ABC of 600 mt, with the intention of precluding a directed fishery, while providing for bycatch needs in other trawl fisheries (Table 3.5-28). An ABC lower than the maximum prescribed under Tier 6 was recommended since the fishery may have created localized depletions of Atka mackerel. Catch-per-unit-effort (CPUE) data indicate declines in the Atka mackerel population from 1992-1994 and since data indicated that the GOA population is vulnerable to fishing pressure (Lowe 2002).

Atka mackerel have not been commonly caught in the GOA triennial trawl surveys. It has been determined that the general GOA groundfish bottom trawl survey does not assess the GOA portion of the Atka mackerel stock well, and resulting biomass estimates have little value as absolute estimates of abundance or as indices of trend (Lowe and Fritz 2001). Because of this lack of fundamental abundance information, GOA Atka mackerel are not assessed with an age-structured model. The stock assessment, which does not utilize abundance estimates from the trawl survey, consists of descriptions of catch history, length and age distributions from the fishery (1990-1994), and length distributions from the trawl surveys (1996, 1999, and 2001). This information is presented in the GOA Atka mackerel stock assessment, which is incorporated into the GOA SAFE report.

Complicating the difficulty in surveying Atka mackerel is the low probability of encountering schools in the GOA, where the abundance is lower and their distribution is patchier relative to the BSAI. Because of this, it has not been possible to estimate population trends for the species in the GOA.

Past/Present Effects Analysis

The geographic scope for the GOA Atka mackerel past/present effects analysis is the same as the GOA management areas (Figure 1.2-3). The temporal scope for this analysis begins in 1973 when the foreign fishery started and ends in 2002, the most recent year for which stock assessment information exists.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-31 provides a summary of the GOA Atka mackerel past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA Atka mackerel:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to the spatial/temporal concentration of catch/bycatch, fishery selectivity and climate changes and regime shifts (indirect effect).

- Change in prey availability due to commercial whaling, the introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, introduction of exotic species and marine pollution and oil spills (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on Atka mackerel in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the Atka mackerel past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1973-1976)
  - Commercial whaling
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1986)
  - JV groundfish fisheries (1979-1985)
  - Domestic groundfish fisheries (1979-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - IWC management
  - MMPA of 1972
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the Atka mackerel fishery. Amendments discussed in Section 3.2, which impact on the target fisheries as a whole and Atka mackerel as a component of the fishery, are not repeated here.

Mortality

External Foreign Groundfish Fishery (1973-1976)

Atka mackerel was an important target species of the foreign fishery in the GOA. The past foreign Atka mackerel fisheries participated in the GOA from about 1973 to 1986. Harvests peaked in 1975 at 27,777 mt, and were taken mainly by the Soviet fishery, largely due to a decrease in Pacific ocean perch abundance (NPFMC 2002b). The large removals of Atka mackerel by the foreign fisheries are found to have had a lingering adverse effect on the GOA Atka mackerel population.

Internal JV and Domestic Groundfish Fisheries

The past JV Atka mackerel fishery participated for a short time in the GOA, from 1979 to 1985, although significant catches were not made until 1983. Since 1985, all Atka mackerel landings have been by domestic fleets. The domestic fishery began in 1979 but, like the JV fishery, did not begin catching significant amounts of Atka mackerel until 1983 (NPFMC 2002b). By 1992, catches increased to 14,000 mt (Lowe and Fritz 2001). The Atka mackerel fishery is currently a bycatch only fishery. The large removals of Atka mackerel by the JV and past domestic fisheries (see catch history in Lowe 2002) are found to have had a lingering adverse effect on the GOA population.

An Atka mackerel population existed in the GOA primarily in the Kodiak, Chirikof, and Shumagin areas and supported a large foreign fishery through the early 1980s. By the end of the mid-1980s, this fishery, and presumably the population, had all but disappeared. Atka mackerel were combined with the "other species" category in 1988 (GOA FMP Amendment 16). This regulatory category resulted in the mandatory discard of species of minor commercial importance such as sculpin, skate, squid, smelt, etc. In 1990, a directed fishery resumed when a closure of the Atka mackerel fishery in the BSAI resulted in the movement of vessels into the western regulatory area to continue targeting this species. The fishery had expanded significantly by 1992, and the expansion resulted in the listing of the "other species" category as bycatch only. This closure caused the discard of minor species such as octopus. In 1993, Atka mackerel were again targeted in the GOA, accounting for almost the entire TAC of other species in the western regulatory area. As a result, the "other species" category was closed to directed fishery in the western regulatory area. Since Atka mackerel no longer met the definition of other species (of slight economic importance or containing economically valuable species but insufficient data to allow separate management), Atka mackerel were established as a target species in its own right in the GOA by Amendment 31, and harvest levels were then based on biological stock assessments. Such an action reduced the potential for overfishing Atka mackerel, while allowing for increased harvest of the other species complex, and reduced user conflicts within the western regulatory area of the GOA. Steller sea lion conservation measures in 1991-1993 further restricted the amount of Atka mackerel that could be taken in certain areas. GOA Amendment 44 provided a more conservative OFL definition for Atka mackerel, based on Tier 6, which set the OFL equal to the average catch from 1978 to 1995. However, since 1997, the Atka mackerel has been managed as a bycatch only fishery, with a sufficient level to provide for bycatch in other target fisheries (600 mt annually).

Change in Reproductive Success

External Foreign Groundfish Fishery (1973-1976)

Spatial/Temporal Concentration of Catch/Bycatch

As in the BSAI, the foreign GOA Atka mackerel fishery was a highly localized fishery, occurring in the same locations every year at depths less than 200 m. The past foreign fisheries are found to have had an adverse impact on the spatial/temporal distribution of the GOA Atka mackerel stock due to the spatial/temporal concentration of the fishery. This effect is determined to have a lingering population effect in the GOA stock.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of Atka mackerel. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fishery (1979-present)

Fishery Selectivity

The 1991 to 1994 data show that during certain months on the Davidson Bank and near the Shumagin Islands, more females than males are caught. The presumption is that there is a natural segregation of the population during spawning periods. The Umnak Island fishery ground (1991-1994) represents a more even distribution of males to females in the catch (Lowe and Fritz 2001).

Spatial/Temporal Concentration of Catch/Bycatch

In 1990, the localized Atka mackerel fishery took place near the edge of the continental shelf on Davidson Bank south of Unimak and Sanak Islands, and moved off the southern coast of Umnak Island from 1991-1994. In 1993 and 1994, fishing also took place off the south and east coasts of the Shumagin Islands (Lowe and Fritz 2001).

In 1994, small amounts of Atka mackerel bycatch were caught in the pollock, Pacific cod, and rockfish trawl fisheries in GOA management areas 610 and 620. Bycatch calculations are difficult to obtain for the rockfish fisheries since some vessels "top-off"their hauls with Atka mackerel rather than catch them strictly as bycatch. The 1994 discard rate for the GOA Atka mackerel fishery was about 8 percent (Lowe and Fritz 2001). GOA FMP Amendment 18 (1990) established the Observer Program which was designed to help decrease bycatch and discard rates, among other things.

The past JV fisheries are found to have had an adverse impact on the spatial/temporal distribution of the GOA Atka mackerel stock due to the spatial/temporal concentration of the fishery. This effect has resulted in a lingering population effect.

Change in Prey Availability

External Commercial Whaling

Whaling is identified as having a past beneficial effect on prey availability for the Atka mackerel stocks. Atka mackerel have been recorded as a prey species of certain whales; therefore, by removing large predators, Atka mackerel recruitment is favored.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability in both stocks. In general, a shift toward colder waters favors recruitment and survival of Atka mackerel. When the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of Atka mackerel.

Change in Important Habitat

External Foreign Groundfish Fishery (1973-1976)

Statistics on the number of bottom trawls and the effects of bottom trawling on habitat within the GOA is generally unknown. Due to the schooling, semi-demersal nature of Atka mackerel, this species is readily caught by bottom trawl gear (Lowe and Fritz 2001). The effect of the past foreign fisheries on habitat suitability for the GOA stock is unknown.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability in both stocks. In general, a shift toward colder waters favors recruitment and survival of Atka mackerel. When the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of Atka mackerel.

Internal JV and Domestic Groundfish Fishery (1979-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas, and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat. Sex ratio data (1991-1994) suggest that the fisheries frequent habitats inhabited by Atka mackerel, including possible spawning and nesting habitats (Lowe and Fritz 2001). The effects of the JV and past domestic fisheries gear on Atka mackerel habitat are unknown.

Steller sea lion no-trawl or limited trawl zones were established in the BSAI and GOA in 1991, 1992 and 1993. This included a 20 nm aquatic zone around the Shelikof Strait foraging area. From 1991 to 1993, 82 to 89 percent of Atka mackerel were caught between 10-20 nm of Steller sea lion rookeries on islands near Umnak and in the Shumagin Islands. Concerns were raised regarding the localized reduction of food availability to Steller sea lions in those areas. GOA FMP Amendments 55 and 65 were designed to identify, conserve, and mitigate impacts on EFH and HAPC. The effect of the JV fishery on habitat suitability for the GOA stock is unknown.

GOA Atka Mackerel Comparative Baseline

Biomass estimates by survey data are considered unreliable due to high variability in the Atka mackerel distribution and anomalously high single catches. CPUE analyses of Atka mackerel fisheries are the only indicator of recent trends in abundance. These analyses suggest that the Atka mackerel population declined 81 percent between 1992 and 1994 near Umnak Island and declined 58 percent near Shumagin Island in the GOA (Lowe and Fritz 2001).

Fishery age composition data suggests that in 1990, 1992 and 1994, most Atka mackerel were between 3 and 4 years old (1988 year-class). The oldest fish from the 1994 sample was 11 years old from Shumagin Bank (Lowe and Fritz 2001).

GOA Atka Mackerel Cumulative Effects Analysis Status

The GOA Atka mackerel will be brought forward for cumulative effects analysis.

3.5.1.17 GOA Shallow Water Flatfish

Life History and Distribution and Trophic Interactions

Eight flatfish species inhabit shallow waters and are managed in the shallow water flatfish assemblage in the GOA. They include: northern and southern rock sole, yellowfin sole, starry flounder, butter sole, English sole, Alaska plaice and sand sole. The life history, distribution and trophic interactions of these species have been described under the BSAI in Section 3.5.1.5 for yellowfin sole, 3.5.1.6 for rock sole and 3.5.1.10 for the remaining flatfish species.

GOA Shallow Water Flatfish Management

Survey results from 2001 indicate that over half of the estimated biomass (54 percent) of this assemblage are northern and southern rock sole. Rock sole, for which maturity information is deemed adequate, are managed in Tier 4 of the ABC and OFL definitions where $F_{ABC} = F_{40\%}$ (0.17) and $F_{OFL} = F_{30\%}$ (0.209). This equates to on ABC value of 28,351 mt (9,571 mt for northern rock sole and 18,780 mt for southern rock sole) and to an OFL value of 34,214 mt for both species of rock sole; 11,550 mt for northern rock sole and 22,664 mt for southern rock sole (Table 3.5-28) (Turnock 2002b). The rest of the shallow water group is managed as a Tier 5 species in the GOA where ABCs are calculated using F_{ABC} = 0.75 M (0.15) and F_{OFL} = M (0.2). The group is managed this way because maturity information for the GOA stock is unavailable (Turnock *et al.* 2001b).

Stock assessment models are not used for any of the shallow water flatfish in the GOA due to the lack of available information (Turnock *et al.* 2001b). Triennial trawl survey biomass estimates from 1984, 1987, 1990, 1993, 1996, 1999, and 2001 are considered the best information available to determine stock biomass for all of the flatfish species in the GOA. The 2001 GOA survey effort did not encompass the eastern GOA and resulted in the eastern GOA biomass being approximated using the average of the 1993-1999 GOA biomass estimates. Beginning with the 1996 trawl survey, rock sole was further divided into northern rock sole (*Lepidopsetta sp. cf. bilineata*) and a southern rock sole (*L. bilineata*) Overlapping distributions may lead to separate management in the future (Turnock *et al.* 2001b).

GOA Shallow Water Flatfish Past/Present Effects Analysis

The geographic scope for the GOA shallow water flatfish assemblage past/present effects analysis is the same as the GOA FMP management areas (Figure 1.2-3). The temporal scope for this analysis begins in the 1960s when the GOA shallow water flatfish assemblage foreign fishery began and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-32 provides a summary of the GOA shallow water flatfish assemblage past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA shallow water flatfish assemblage:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch, fishery selectivity and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery prey bycatch, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery impacts, scallop dredging, introduction of exotic species, marine pollutants and oil spills and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on the shallow water flatfish in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the shallow water flatfish assemblage past/present effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1960s-1976)
  - State of Alaska scallop fishery
  - State of Alaska crab bait fisheries
  - IPHC longline bait fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1968-1988)
  - Domestic groundfish fisheries (1968-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the shallow water flatfish assemblage fishery. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality

External Foreign Groundfish Fisheries (1960s-1976)

The Japanese and Soviet flounder fisheries both started as Pacific ocean perch fisheries in the early 1960s and switched to other target Groundfish following the decline of Pacific ocean perch. Annual harvests were about 15,000 mt taken mostly by Japanese trawlers. By 1981, the Soviet fleets were no longer allowed in the GOA due to political reasons and Japanese catch was minimal. By 1988, only domestic fleets were harvesting flatfish (NPFMC 2002b).

Although removals of shallow water flatfish occurred during the past foreign fisheries, there are no observable adverse lingering effects on the GOA shallow water flatfish population.

External State of Alaska Crab Bait and IPHC Longline Bait Fisheries

The GOA bait fishery targeted pollock, Pacific cod, and various flounder species in order to provide needed bait for the crab and halibut fisheries. Bait fisheries occurred from PWS west to the Aleutians, although the majority of the bait has been landed in the Kodiak area (NPFMC 2002b). Although these fisheries contributed to flatfish mortality, there are no observable lingering effects on the population.

Internal JV and Domestic Groundfish Fishery (1968-present)

The domestic and JV flounder fisheries began in 1968, although catches were minimal until 1986. The JV fisheries were responsible for a large amount of the increase in flatfish catch in 1986-1987, with a four-fold increase in the 1987 catch. JV fisheries were phased-out of the flatfish fishery by 1988; however, the catch continued to increase with the domestic fishery to a high of 43,107 mt in 1996. Flatfish declined in 1998 to 23,237 mt, increased to 37,303 mt in 2000, and declined again in 2001 to 31,734 mt. Shallow water flatfish remained lightly harvested in 2001 at 6,173 mt, a decrease from 6,928 mt in 2000. The flatfish fishery is likely to be limited by the potential for exceeding the Pacific halibut PSC limits in the future (Turnock *et al.* 2002b).

In the GOA, yellowfin sole is managed as part of the flatfish assemblage. In 1990, NPFMC divided the flatfish assemblage into four categories; shallow flatfish, deep flatfish, flathead sole and arrowtooth flounder. Yellowfin sole fell into the shallow flatfish category. This classification was made because of the significant difference in halibut bycatch rates in directed fisheries targeting on shallow water and deepwater flatfish species. Arrowtooth flounder was separated from the other categories due to its high abundance and low commercial value. Flathead sole were separated due to an overlap in depth distribution with the shallow water and deepwater groups.

Rex sole was split out of the deepwater management category in 1993 due the relatively large amounts of Pacific ocean perch bycatch occurring in the rex sole target fishery. Beginning in 1996, rock sole was split into two species, a northern (*Lepidopsetta sp. cf. bilineata*) and a southern rock sole (*Lepidopsetta bilineata*) (personal communication, Jay Orr) due to overlapping distributions.

The large removals of shallow water flatfish by the JV and past domestic fisheries are found to have had a lingering adverse effect on the GOA shallow water flatfish populations.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1960s-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the past foreign fisheries on the spatial/temporal distribution of the GOA shallow water flatfish assemblage stock is unknown. However, any effects on the spatial/temporal distribution are not expected to have had a lingering population effect.

External Climate Changes and Regime Shifts

Climate changes and regime shifts are identified as having potentially beneficial or adverse effects on the reproductive success of GOA shallow water flatfish. The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fishery (1968-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the past JV fisheries on the spatial/temporal distribution of the GOA shallow water flatfish assemblage is unknown. However, any effects on the spatial/temporal distribution are not expected to have had lingering population effects.

Change in Prey Availability

External Foreign Groundfish Fisheries (1960s-1976)

The foreign fisheries in the GOA are unlikely to have directly impacted the prey availability for the shallow water flatfish assemblage since these fish eat infaunal and epifaunal invertebrates. The lingering effect in the GOA shallow water flatfish stock is likely due to the natural events related to climate change.

External Climate Changes and Regime Shifts

The lingering adverse effect in the GOA shallow water flatfish stock is likely due to the natural events related to climate change. Although flatfishes tend to dominate catch during strong Aleutian Lows, on a microclimate scale, community structures changed in some nearshore areas with decreasing populations of shrimps and small forage fish, and increasing populations of the large fish-eating species, such as Pacific cod, and other flatfishes. Pacific cod, skates, and Pacific halibut are predators of the species of the shallow water flatfish assemblage.

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of the shallow water flatfish.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of the shallow water flatfish group.

Internal JV and Domestic Groundfish Fishery (1968-present)

The bycatch of juvenile crabs occurs in small numbers in domestic trawl fisheries. Crabs less than 25 mm in carapace width are estimated to have a selectivity of 0.001 in domestic fisheries from the snow crab assessment model. Combined with the fact that juvenile crab are only one component of the diet of yellowfin sole, these fisheries are not expected to impact the foraging capabilities of yellowfin sole.

Change in Important Habitat

External Foreign Groundfish Fisheries (1960s-1976)

The statistics on the number of bottom trawls occurring in the GOA, and their effects on habitat are generally unknown. It is assumed that the effect of the foreign fisheries on habitat suitability is either beneficial or adverse; and the effects are found to have had a lingering influence in shallow water flatfish assemblage stocks.

External State of Alaska Scallop Fishery

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The State of Alaska scallop fishery has a history of being sporadic due to exploitation of limited stocks, market conditions, and availability of more lucrative fisheries. In 1999, only three boats fished for scallops (B. Bechtol, ADF&G, personal communication). While the effects of dredging on benthic habitat are intense, the magnitude of the overall impact of this fishery is likely to be small.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability in both stocks. When the Aleutian Low was strong, water temperatures were higher, and biomass in the catches was dominated by cod, pollock, and flatfishes. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of the shallow water flatfish group.

Internal JV and Domestic Groundfish Fishery (1968-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of these past fisheries on habitat suitability is either beneficial or adverse; and the effects are found to have had a lingering influence in the shallow water flatfish assemblage. The 1998 bottom trawl prohibition in the eastern area of 140°W may have had a beneficial effect on habitat suitability for flatfish in that area.

GOA Shallow Water Flatfish Assemblage Comparative Baseline

The 2001 biomass survey took place only in the central and western Gulf; therefore, the eastern GOA biomass has been estimated using the average of the 1993 through 1999 eastern GOA biomass estimates for all flatfish species except butter sole and English sole. Since the trends for butter sole in the central GOA are similar to their trends in the eastern GOA, the 2001 biomass estimates were obtained by applying the declining trend in biomass from 1999 to 2001 in the central GOA to the 1999 biomass in the eastern GOA. For English sole, the biomass estimate from 1999 was used without adjustment for the 2001 biomass.

Northern rock sole and butter sole have all decreased in 2001 relative to 1990s biomass estimates. Alaska plaice experienced an increase in biomass from 1993-1999; however, 2001 estimates show a decline in biomass. In contrast, southern rockfish and yellowfin sole both showed declines in years previous to 1999 with an increase in 2001 biomass estimates. Starry flounder has shown a continuous increase in biomass since 1990, while English sole increased from 1993-1999 and stabilized from 1999-2001. Sand sole has been variable over the years but has shown a slight increase between 1999 and 2001. Exploitable biomass estimates are assumed to be the same as the 2001 survey biomass results (Turnock *et al.* 2002b). Some experimental evidence indicates that flatfish biomass may be under estimated by the northeastern trawl (Weinberg 2003). Experiments are being conducted to estimate the herding component of catchability.

GOA Shallow Water Flatfish Assemblage Cumulative Effects Analysis Status

The GOA shallow water flatfish assemblage will be brought forward and examined as a group in the cumulative effects analysis.

3.5.1.18 GOA Flathead Sole

Life History and Distribution

Flathead sole (*Hippoglossus elassodon*) are distributed from northern California northward throughout Alaska. In the northern part of its range, the species overlaps with the related and very similar Bering flounder (*Hippoglossoides robustus*) (Wolotira *et al.* 1993, Hart 1973). Adults are benthic and occupy separate winter spawning and summer feeding distributions. From overwintering grounds near the continental shelf margin, adults begin a migration onto the mid- and outer continental shelf in April or May. The spawning period occurs in late winter/early spring, primarily in deeper waters near the margins of the continental shelf (Walters and Wilderbuer 1997). Eggs are large and pelagic. Upon hatching, the larvae are planktonic and usually inhabit shallow areas (Waldron and Vinter 1978). Age and size at maturity are unknown, but recruitment to the fishery begins at age 3 (Figure 3.5-5). The maximum age from fishery age samples is 28 years. Flathead sole are taken in bottom trawls both as a directed fishery and in pursuit of other bottom dwelling species. Table 3.5-14 summarizes biological and reproductive attributes and habitat associations of flathead sole in the BSAI and GOA.

Trophic Interactions

Flathead sole feed primarily on invertebrates such as ophiuroids, tanner crab, bivalves and polychaetes. Their diet has been shown to include commercially important species such as pollock and tanner crabs. In the EBS, other fish species represented 5 to 25 percent of the diet (Livingston *et al.* 1993). Groundfish predators include Pacific cod, Pacific halibut, arrowtooth flounder, and also cannibalism by large flathead sole, mostly on fish less than 20 cm standard length.

GOA Flathead Sole Management

Beginning in 2002, flathead sole were managed independent of the other flatfish complex in the GOA. The projected spawning biomass for flathead sole is estimated above the $B_{40\%}$ biomass (38,163 mt), and is therefore evaluated under Tier 3a. The 2003 ABC equates to 41,390 mt, and the OFL equates to 51,556 mt (Table 3.5-28). The ABC and OFL are further apportioned to western, central, and west and east Yakutat GOA regions (Turnock *et al.* 2002c).

An age-structured model was developed for flathead sole in the 2002 GOA SAFE Report. This model includes age and biomass estimates from the 1984, 1993 and 1996 trawl surveys and length and biomass estimates from the 1987, 1990, 1999, and 2001 trawl surveys. CPUE data from the commercial fisheries was also used from 1985-2002 (Turnock *et al.* 2002c).

GOA Flathead Sole Past/Present Effects Analysis

The geographic scope for the GOA flathead sole past/present effects analysis is the same as the GOA management units (Figure 1.2-3). The temporal scope for this analysis begins in 1960s when the foreign flounder fishery started and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. The following direct and indirect effects were identified as potentially having population-level effects on GOA flathead sole:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery bycatch of prey species, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

- Change in important habitat due to fishery gear impacts, marine pollution and oil spills, introduction of exotic species and climate changes and regime shifts (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following section explains any amendments specific to the flathead sole fishery. Amendments discussed in Section 3.2 which impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on flathead sole in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the flathead sole past/present effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (1960s-1976)
  - IPHC longline fisheries
  - State of Alaska scallop fisheries
  - State of Alaska crab fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1968-1988)
  - Domestic groundfish fisheries (1968-present)

- Past/Present Management Actions
  - Bilateral agreements

- Industry initiated actions
- Foreign groundfish fishery initiated actions
- Preliminary groundfish FMPs (pre-MSA)
- FMP groundfish fisheries management

For a discussion of the past/present effects on the flathead sole, see the GOA shallow water flatfish past/present effects analysis (Section 3.5.1.5).

GOA Flathead Sole Comparative Baseline

Previous to 1981, flatfish were taken primarily by the foreign fisheries at about 15,000 mt annually. After the passage of the MSA in 1977, catches decreased to a low of 2,441 mt in 1986 and then steadily increased to a high of 43,107 mt in 1996. Flatfish declined in 1998 to 23,237 mt, increased to 37,303 mt in 2000, and declined again in 2001 to 31,734 mt. Flathead sole remain lightly harvested in 2002 at 2,029 mt as of October 5, 2002, a slight increase from 2001. The flatfish fishery is likely to be limited by the potential for high catches of Pacific halibut in the future (Turnock *et al.* 2002c).

Many flatfish species exhibited an increasing biomass trend in the 1980s and an decreasing trend in the 1990s. Flathead sole declined from 247,247 mt in 1990 to 170,915 mt in 2001. Exploitable biomass estimates are assumed to be the same as the 2001 survey biomass results (Turnock *et al.* 2002b). Some experimental evidence indicates that flatfish biomass may be underestimated by the northeastern trawl (Weinberg 2003), experiments are being conducted to estimate the herding component of catchability.

GOA Flathead Sole Cumulative Effects Analysis Status

GOA flathead sole will be brought forward for cumulative effects analysis.

3.5.1.19 GOA Arrowtooth Flounder

Life History and Distribution

Arrowtooth flounder (*Atheresthes stomias*) occur from central California to the Bering Sea, in waters from about 20-800 m (Zimmerman and Goddard 1996). Spawning is protracted and variable and probably occurs from September through March (Zimmermann 1997). For female arrowtooth flounder collected off the Washington coast, the estimated age at 50 percent maturity was 5 years, with an average length of 37 cm. Males matured at 4 years and 28 cm (Rickey 1995). The maximum reported ages are 16 years in the Bering Sea, 18 years in the Aleutian Islands, and 23 years in the GOA (Turnock *et al.* 1997a, Wilderbuer and Sample 1997). Arrowtooth flounder is currently the most abundant groundfish species in the GOA; however, they are currently considered of low value and mostly discarded.

In the Bering Sea, the arrowtooth flounder inhabits the continental shelf waters almost exclusively until age-4, but at older ages occupies both shelf and slope waters, with greatest concentrations at depths between 100 and 200 m (Martin and Clausen 1995). The very similar Kamchatka flounder (*Atheresthes evermanni*) also occurs in the Bering Sea. Values of 50 percent maturity for the Bering Sea stock are 42.2 cm and 46.9 cm for males and females, respectively (Zimmerman 1997). Table 3.5-16 summarizes biological and reproductive attributes and habitat associations of arrowtooth flounder in the BSAI and GOA.

Trophic Interactions

Arrowtooth flounder play an important role in the Bering Sea and GOA ecosystems because they are large, aggressive, and abundant predators of other groundfish species (Hollowed *et al.* 1995, Livingston 1991b, Yang 1993). The majority of prey by weight of arrowtooth flounders larger than 40 cm is pollock, the remainder consisting of herring, capelin, euphausiids, shrimp, and cephlapods (Yang 1993). These fish also consumed salmonids and Pacific cod in the GOA (Yang and Nelson 2000). The percent of pollock in the diet of arrowtooth flounder increases for sizes greater than 40 cm. Arrowtooth flounder 15-30 cm consume mostly shrimp, capelin, euphausiids and herring, with small amounts of pollock and other miscellaneous fish (DiCosimo 1998). Groundfish predators on arrowtooth include Pacific cod and pollock, which feed mostly on small fish (Livingston and deReynier 1996).

GOA Arrowtooth Flounder Management

For the GOA, arrowtooth flounder are also defined in Tier 3a of the ABC and OFL definitions. The 2003 stock assessment ABC (155,140 mt) was based on the $F_{40\%}$ fishing mortality rate because reliable estimates of F_{MSY} and B_{MSY} are unavailable. The 2003 ABC is further apportioned between the western, central, and west and east Yakutat/southeast outside GOA management units. The 2003 OFL value is based on the $F_{35\%}$ value and equates to 181,390 mt (Turnock *et al.* 2002a) (Table 3.5-28).

The stock assessment model used in the arrowtooth flounder assessment uses abundance estimates from IPHC trawl surveys, NOAA Fisheries groundfish surveys, and NOAA Fisheries triennial surveys. Fishery catch and size compositions were also used in the model. Current abundance estimates indicate that arrowtooth flounder have the largest biomass of the groundfish species inhabiting the GOA. The time-series of fishery and survey size compositions allows the use of an age-based stock assessment model. The outputs include estimates of sex-specific abundance, spawning biomass, fishery and survey selectivity, exploitation trends, and projections of future biomass. The model also estimates reference fishing mortality rates in terms of the ratio of female spawning biomass to unfished levels, which are used to calculate ABC. The assessment for 2002 adjusted the population sex ratio so that females were 70 percent of the population. Length frequency data were also incorporated to the 2002 assessment. The stock assessment is updated annually and incorporated into the GOA SAFE report (Turnock *et al.* 2001a).

GOA Arrowtooth Flounder Past/Present Effects Analysis

The geographic scope for the GOA arrowtooth flounder past/present effects analysis is the same as the GOA management units (Figure 1.2-3). The temporal scope for this analysis begins in the 1960s when the foreign fishery for flounders began, and ended in 2002, the most recent year for which stock assessment information exists.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-33 provides a summary of the arrowtooth flounder past effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on arrowtooth flounder:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery bycatch of prey species, marine pollution and oil spills, climate changes and regime shifts and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, introduction of exotic species and marine pollution and oil spills (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explains any management actions specific to the arrowtooth flounder. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on arrowtooth flounder in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the arrowtooth flounder past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1960s-1976)
  - IPHC longline fisheries
  - State of Alaska crab fisheries
  - State of Alaska groundfish fisheries
  - State of Alaska herring fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1968-1990)
  - Domestic groundfish fisheries (1968-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1960s-1976)

The Japanese and Soviet flounder fisheries both started as Pacific ocean perch fisheries in the early 1960s and switched to other target groundfish following the decline of Pacific ocean perch (NPFMC 2002b). Catch of arrowtooth flounder remained low from 1964 to 1973, when harvest peaked at 10,007 mt. Catch decreased to between 2,500 and 5,000 mt annually between 1974 and 1976 (Turnock *et al.* 2001a).

Although removals of arrowtooth flounder occurred during the foreign fisheries, there are no observable lingering adverse effects in the GOA arrowtooth flounder populations.

External IPHC Halibut Longline Fisheries and State of Alaska Crab Fisheries

The GOA bait fishery targeted pollock, Pacific cod, and various flounder species in order to provide needed bait for the crab and halibut fisheries. These fisheries took place from PWS west to the Aleutians, although most were landed in the Kodiak area (NPFMC 2002b). The amount of arrowtooth flounder caught in these fisheries is unknown.

Although removal of arrowtooth flounder occurred during the IPHC and crab bait fisheries, there are no observable lingering adverse effects in the GOA arrowtooth flounder populations.

Internal JV and Domestic Groundfish Fisheries (1968-present)

The domestic and JV flounder fisheries began in 1968, although catches of arrowtooth flounder were minimal throughout their duration (catches were dominated by foreign fisheries). From 1980-1990, annual harvest rates remained under 10,000 mt. JV fisheries were phased-out of the arrowtooth flounder fishery by 1990; however, the catch increased with the domestic fishery to a high of 24,252 mt in 2000. The average annual catch from 1990-2001 is approximately 18,000 mt. In 2000, the arrowtooth flounder trawl fishery was limited to bycatch only due to PSC limits for Pacific halibut in the central GOA management region (Turnock *et al.* 2001a).

Arrowtooth flounder is of low value and is typically caught as bycatch in the pursuit of more highly valued target species. Thus, arrowtooth flounder discard rates are high and corresponding percentages of retention are low. From 1991-2000, discard rates averaged 17,000 mt annually, with percent retention ranging from 10 to 43.2 percent. Retention has improved in recent years; 1999 and 2000 percent retention were 26.3 and 43.2 percent, respectively. Marketing efforts for arrowtooth flounder are expected to increase retention rates in coming years (Turnock *et al.* 2001a).

Although removals of arrowtooth flounder have occurred in the JV and past domestic fisheries, there are no observable lingering adverse effects on the GOA arrowtooth flounder populations.

Prior to 1990, arrowtooth flounder was reported as an aggregate of flatfish species. In 1990, NPFMC divided the flatfish assemblage into four categories; shallow water flatfish, deepwater flatfish, flathead sole and arrowtooth flounder. This classification was made because of the significant difference in halibut bycatch rates in directed fisheries targeting on shallow water and deepwater flatfish species. Flathead sole was separated due to an overlap in depth distribution with the shallow water and deepwater groups. Arrowtooth flounder was separated from the other categories due to its high abundance and low commercial value.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1960s-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the foreign fisheries on the spatial/temporal distribution of arrowtooth flounder in the GOA is unknown. However, these effects are determined to not have had lingering population effects on the stock.

External Climate Change and Regime Shift

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of arrowtooth flounder. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries (1968-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the direct JV fisheries on the spatial/temporal distribution of arrowtooth flounder in the GOA is unknown. However, these effects are determined to not have had lingering population effects in the stock.

Change in Prey Availability

External Foreign Groundfish Fisheries (1960s-1976)

Past foreign fisheries in the GOA have had either an adverse or beneficial lingering impact on prey availability. Arrowtooth flounder from 15-30 cm feed mostly on shrimp, euphausiids, capelin, and herring (DiCosimo 1998). Adults (fish over 40 cm) are almost exclusively piscivorus and over half their diet can consist of pollock (Hollowed *et al.* 1995, Livingston 1991b, Yang 1993). Therefore, arrowtooth flounder are important as a large and abundant predator of other groundfish species. In turn, the effects of the fisheries could have been beneficial or adverse since pollock prey on arrowtooth flounder.

Bycatch of forage species in the foreign GOA groundfish fisheries is likely to have been minimal. Furthermore, since arrowtooth flounder feed on a number of different prey species, it is also unlikely that the groundfish fisheries would have had a significantly adverse impact on prey availability.

External State of Alaska Groundfish Fisheries and Herring Fisheries

Bycatch of forage species and juvenile pollock in the GOA State of Alaska groundfish fisheries is minimal and is unlikely to reduce the prey availability of arrowtooth flounder. Furthermore, since arrowtooth flounder feed on a number of different prey species, it is also unlikely that State of Alaska herring fisheries would have a significantly adverse impact on prey availability.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. Arrowtooth flounder and other flatfishes increased with an increase in advection in the Alaska current. The controlling factor for these increases appears to be environmental, with changes seen in the species composition in nearshore areas. Increased flow around the GOA may enhance the supply of nutrients and plankton on the shelf and upper slope areas, resulting in an increase in productivity.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species arrowtooth flounder.

Internal JV and Domestic Groundfish Fisheries (1968-present)

Bycatch of forage species and juvenile pollock in the GOA groundfish fisheries is minimal. Furthermore, since arrowtooth flounder feed on a number of different prey species, it is also unlikely that the groundfish fisheries would have a significantly adverse impact on prey availability. BSAI/GOA Amendment 56/56 was established to protect forage fish species from developing into a fishery market, and to limit the forage fish bycatch.

Change in Important Habitat

External Foreign Groundfish Fisheries (1960s-1976)

The statistics on the number of bottom trawls and their effects on habitat in the GOA pre-MSA are generally unknown. It is assumed that habitat suitability for the GOA stock has been either beneficially or adversely affected by the intensity of the past foreign fisheries, and these effects are considered to have lingering influence at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak

Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of arrowtooth flounder.

Internal JV and Domestic Groundfish Fisheries (1968-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Habitat suitability for the GOA stock has been either adversely or beneficially affected by the intensity of the past JV fisheries, and these effects are considered to have lingering influence at the population-level.

There are no indications that harvest conditions resulting from arrowtooth flounder management would alter the available prey in a manner that would impede long-term suitability of the stock.

GOA Arrowtooth Flounder Comparative Baseline

Small scale, nearshore surveys indicate that arrowtooth flounder may have been at low levels in the 1960s and 1970s. The AFSC gulfwide triennial surveys estimate that biomass increased to about 1,640,000 mt in 1996, declined to 1,262,797 mt in 1999, and is now at a very high and stable level. Since the eastern GOA was not surveyed in 2001, the average biomass in the eastern GOA for 1993-1999 was used to estimate the biomass for 2001 (Turnock *et al.* 2001a).

Age-3+ biomass increased from a low in 1961 to a high of 1,815,500 mt in 2002. The 2001 survey biomass estimate of 1,621,890 mt is slightly higher than the 1999 estimate. There is not enough information available to estimate recruitment of age-3 arrowtooth flounder for 1999-2001; however, model estimates show an increase of age-3 recruits in the 1970s and 1980s with a decrease in the 1990s (Turnock *et al.* 2002a).

GOA Arrowtooth Flounder Cumulative Effects Analysis Status

The GOA arrowtooth flounder will be brought forward for cumulative effects analysis.

3.5.1.20 GOA Deepwater Flatfish

GOA Deepwater Flatfish Assemblage

Greenland turbot, Dover sole, and deep-sea sole are members of the GOA deepwater flatfish assemblage. Section 3.5.1.9 discusses the life history, distribution, and trophic interactions for Greenland turbot in the

BSAI and GOA. Refer to Section 3.5.1.10 for a description of the life history, distribution, and trophic interactions of Dover sole and deep-sea sole, both members of the BSAI other flatfish assemblage.

GOA Deepwater Flatfish Management

The reference fishing mortality rate and ABC for the flatfish management groups are determined by the amount of population information available. ABCs for Dover sole were calculated using F_{ABC} = 0.75 M and F_{OFL} = M (Tier 5), because maturity information was not available. Natural mortality was assumed to be 0.1 for Dover sole. Greenland turbot and deepsea sole are in Tier 6 because no reliable biomass estimates exist, where ABC = 0.75 OFL and the OFL = the average catch from 1978 to 1995 (238 mt) (Table 3.5-28). ABC is further apportioned among western, central, west and east Yakutat/southeast outside GOA management areas (Turnock *et al.* 2002b).

Stock assessment models are not used for the deepwater flatfish in the GOA due to the lack of available information. Triennial trawl survey biomass estimates from 1984, 1987, 1990, 1993, 1996, 1999, and 2001 are considered the best information available to determine stock biomass for all of the flatfish species in the GOA. The 2001 GOA survey effort did not encompass the eastern GOA and resulted in biomass in the eastern GOA being approximated using the average of the 1993-1999 GOA biomass estimates (Turnock *et al.* 2001b).

GOA Deepwater Flatfish Past/Present Effects Analysis

The geographic scope for the GOA the deepwater flatfish assemblage past/present effects analysis is the same as the GOA management areas (Figure 1.2-3). The temporal scope for this analysis begins in the 1960s when the foreign flounder fishery began and ends in 2002, the most recent year for which stock assessment information exists.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-34 provides a summary of the GOA the deepwater flatfish assemblage past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA the deepwater flatfish assemblage:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).
- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate change and regime shifts (indirect effect).
- Changes in prey availability due to fishery catch/bycatch of prey species, climate changes and regime shifts, introduction of exotic species and marine pollution and oil spills (indirect effect).
- Changes in important habitat due to fishery gear impacts, climate changes and regime shifts, introduction of exotic species, and marine pollution and oil spills (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explain any management actions specific to the deepwater flatfish assemblage. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on the deepwater flatfish in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the deepwater flatfish assemblage past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1960s-1976)
  - State of Alaska scallop fisheries
  - State of Alaska crab bait fisheries
  - IPHC longline bait fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1968-1988)
  - Domestic groundfish fisheries (1968-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

<u>External Foreign Groundfish Fisheries (1960s-1976)</u>

The Japanese and Soviet flounder fisheries both started as Pacific ocean perch fisheries in the early 1960s and switched to other target groundfish following the decline of Pacific ocean perch abundance (NPFMC 2002b). Previous to 1981, catches were about 15,000 mt annually for the entire flatfish assemblage, including arrowtooth flounder, (Turnock *et al.* 2001b).

Removals of deepwater flatfish by foreign fisheries are determined not to have had lingering adverse effects on the GOA deepwater flatfish populations.

External State of Alaska Bait Crab and IPHC Longline Bait Fisheries

The GOA bait fishery targeted pollock, Pacific cod, and various flounder species to provide needed bait for the crab and halibut fisheries. These fisheries took place from PWS west to the Aleutians, although most were landed in the Kodiak area (NPFMC 2002b). The amount of GOA deepwater flatfish caught in these fisheries is unknown, however there are no observable lingering adverse effects on the deepwater flatfish population.

Internal JV and Domestic Groundfish Fisheries (1968-present)

By 1986, the JV fisheries dominated the flatfish catch in the GOA; however, by 1988, the flatfish fishery was fully domesticated. Annual harvest started at a low of 2,441 mt and increased to the peak of 43,107 mt in 1996. Greenland turbot catch has been variable over the last decade, from 3,012 mt in 1992 to 13 mt in 1997. The most recent catch data current through November 3, 2001, indicates a decline from previous years at only 8 mt. Catches in the deepwater complex declined from 1999 to 985 mt in 2000 and are currently at 805 mt for 2001 (as of November 3). Most of the catch in the deepwater complex is Dover sole, although the catch of Greenland turbot has been variable over the last decade. In 1998 and 1999, the deepwater flatfish fisheries were closed due to PSC limits for Pacific halibut, and in 1999 the entire GOA was closed to trawl fisheries due to PSC limits for Pacific halibut (Turnock *et al.* 2001b).

In the GOA, Greenland turbot is managed as part of the deepwater flatfish assemblage. In 1990, NPFMC divided the flatfish assemblage into four categories; shallow water flatfish, deepwater flatfish, flathead sole and arrowtooth flounder. Greenland turbot fell into the deepwater flatfish category. This classification was made because of the significant difference in halibut bycatch rates in directed fisheries targeting on shallow water and deepwater flatfish species. Arrowtooth flounder were separated from the other categories due to their high abundance and low commercial value. Flathead sole were separated due to an overlap in depth distribution with the shallow water and deepwater groups.

The removals of deepwater flatfish by JV and past domestic fisheries are determined not to have had lingering adverse effects of the GOA deepwater flatfish populations.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1960s-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effects of the foreign fisheries on the spatial/temporal distribution of the GOA deepwater flatfish populations are unknown. Furthermore, it is unknown whether these effects are lingering at the population-level.

External Climate Changes and Regime Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of the deepwater flatfish. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

<u>Internal JV and Domestic Groundfish Fisheries (1968-present)</u>

Spatial/Temporal Concentration of Catch/Bycatch

The effects of the JV and domestic fisheries on the spatial/temporal distribution of the GOA deepwater flatfish populations are unknown. Furthermore, it is unknown whether these effects are lingering at the population-level.

Change in Prey Availability

<u>External Foreign Groundfish Fisheries (1960s-1976)</u>

The foreign fisheries in the GOA could have had lingering adverse or beneficial effects on the availability of prey for the deepwater flatfish assemblage. Pelagic fish are the main prey of these species, with pollock often a major species in the diet (Livingston 1991b). Deepwater flatfish also feed on squid, euphausiids, and shrimp; therefore, foreign fisheries are not expected to have significantly effected prey availability.

<u>External Climate Changes and Regime Shifts</u>

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock, and flatfishes such as Greenland turbot. Community structure in nearshore areas around Kodiak Island changed in this same period, with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes. Greenland turbot and Pacific halibut responded more strongly to longer-term events (such as decadal-scale climate regime patterns). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor in the population.

<u>External/Internal Marine Pollution and Oil Spills</u>

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of the deepwater flatfish group.

Internal JV and Domestic Groundfish Fisheries (1968-present)

The JV fisheries in the GOA could have had lingering adverse or beneficial effects on the availability of prey for the deepwater flatfish assemblage. However, since deepwater flatfish are found to feed on many species of fish (including pollock), squid, euphausiids, shrimp and some forage species, current management is not expected to alter the available prey in a manner that would impede long-term sustainability of the stocks in the GOA.

Change in Important Habitat

External Foreign Groundfish Fisheries (1960s-1976)

The statistics on the number of bottom trawls and their effects on GOA pre-MSA are generally unknown. It is assumed that the effect of the past foreign fisheries on habitat suitability is either beneficial or adverse; overall, a lingering influence on the population is found in the GOA stock, probably mostly due to climatological effects.

External State of Alaska Scallop Fisheries

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The State of Alaska scallop fishery has a history of being sporadic due to exploitation of limited stocks, market conditions, and availability of more lucrative fisheries. In 1999, only three boats fished for scallops (B. Bechtol, ADF&G, personal communication). While the effect on benthic habitat of the dredging is intense, the magnitude of the overall impact of this fishery is likely to be small.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability and prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of deepwater flatfish group.

Internal JV and Domestic Groundfish Fisheries (1968-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the JV fisheries on habitat suitability is either beneficial or adverse; overall, a lingering influence on the population is found in the GOA stock, probably mostly due to climatological effects. Trawl closures (1998 and 1999) due to PSC limits for Pacific halibut reduce the intensity of the fishery on the deepwater flatfish assemblage habitat.

Furthermore, there are no indications that harvest conditions under current management would alter the population genetic structure, the available prey, or the suitability of nursery and/or spawning habitat in a manner that would impede long-term sustainability of the stock in both the BSAI and GOA.

GOA Deepwater Flatfish Comparative Baseline

The 2001 resource assessment trawl survey took place only in the central and western GOA; therefore eastern GOA biomass was estimated using the average of the 1993 to 1999 eastern GOA biomass estimates for all flatfish species except Dover sole. Since the trends in the central GOA for Dover sole are similar to their trends in the eastern GOA, the 2001 biomass estimates were obtained by applying the declining trend in biomass from 1999 to 2001 in the central GOA to the 1999 biomass in the eastern GOA.

Dover sole has decreased in 2001 relative to 1990s biomass estimates. Exploitable biomass estimates are assumed to be the same as the 2001 survey biomass results for Dover sole, but not Greenland turbot or deepsea sole (Turnock *et al.* 2002b). Some experimental evidence indicates that flatfish biomass may be underestimated by the northeastern trawl (Weinberg 2003). Experiments are being conducted to estimate the herding component of catchability.

GOA Deepwater Flatfish Cumulative Effects Analysis Status

The GOA deepwater flatfish assemblage will be brought forward for cumulative effects analysis.

3.5.1.21 GOA Rex Sole

Life History and Distribution and Trophic Interactions

The other flatfish species complex in the GOA is currently managed as four categories: shallow water flatfish, deepwater flatfish, flathead sole, and rex sole (*Errex zachirus*). Life history, distribution and trophic interactions for rex sole is described in the BSAI other flatfish, Section 3.5.1.10. Table 3.5-20 summarizes biological and reproductive attributes and habitat associations of selected flatfish in the BSAI and GOA.

GOA Rex Sole Management

The other flatfish species complex in the GOA is currently managed as four categories with separate ABCs: shallow water flatfish, deepwater flatfish, flathead sole, and rex sole. In 2002, flathead sole were separated from the other flatfish assemblage and assigned a separate ABC due to their overlap in depth distribution of the shallow and deepwater groups (see Section 3.5.1.7). In 1993, rex sole was split out of the deepwater management category because of concerns regarding the Pacific ocean perch bycatch in the rex sole target fishery. The flatfish fishery in the GOA mainly targets rock sole (see Section 3.5.1.6), rex sole, and Dover sole. The flatfish catch is limited by halibut bycatch and does not reach the TAC for any species group (Table 3.5-28).

The reference fishing mortality rate and ABC for the rex sole are determined by the amount of population information available. ABCs are calculated using F_{ABC} = 0.75 M and F_{OFL} = M (Tier 5), because maturity information was not available. Natural mortality was assumed to be 0.2.

Stock assessment models were not used for this species due to the lack of information. Triennial trawl survey biomass estimates from 1984, 1987, 1990, 1993, 1996, 1999, and 2001 are considered the best information available to determine the stock biomass for rex sole (Turnock *et al.* 2002b).

GOA Rex Sole Past/Present Effects Analysis

The geographic scope for the GOA rex sole past/present effects analysis is the same as the GOA management areas (Figure 1.2-3). The temporal scope for this analysis begins in the 1960s when the foreign flounder fishery began and ends in 2002, the most recent year for which stock assessment information exists.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-35 provides a summary of the GOA rex sole past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA rex sole:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery catch/bycatch of prey species, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explain any management actions specific to the rex sole. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on rex sole in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to the rex sole past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1960s-1976)
  - IPHC longline fisheries
  - State of Alaska scallop fisheries
  - State of Alaska crab fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1968-1990)
  - Domestic groundfish fisheries (1968-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

External Foreign Groundfish Fisheries (1960s-1976)

The Japanese and Soviet flounder fisheries both started as Pacific ocean perch fisheries in the early 1960s and switched to other target groundfish following the decline of Pacific ocean perch (NPFMC 2002b). Previous to 1981, catches were about 15,000 mt annually for the entire flatfish assemblage, including arrowtooth flounder, with catches dominated by the foreign fisheries. By 1986, the JV fisheries were taking a majority of the flatfish catch (Turnock *et al.* 2001b).

Removals of rex sole by the foreign fisheries are determined to have had an adverse effect on the rex sole population; however, these fisheries are determined not to have had lingering adverse effects on the GOA rex sole populations.

External IPHC Halibut Longline Fisheries and the State of Alaska Crab Fisheries

The GOA bait fishery targeted pollock, Pacific cod, and various flounder species in order to provide needed bait for the crab and halibut fisheries. Bait fisheries occurred from PWS west to the Aleutians, although the majority of the bait has been landed in Kodiak area (NPFMC 2002b). The amount of rex sole caught in these fisheries is unknown.

rex sole population, these fisheries are determined not to have had lingering population effects in the GOA rex sole stocks.

Internal JV and Domestic Groundfish Fisheries (1968-present)

After the passage of the MSA in 1976, catches decreased to a low of 2,441 mt in 1986 and then steadily increased to a high of 43,107 mt in 1996. Flatfish declined in 1998 to 23,237 mt, increased to 37,303 mt in 2000, and declined again in 2001 to 31,734 mt. Catch is currently reported by management areas; catch of each species is estimated by multiplying the fraction of each species observed in a particular group by the total catch for that group. The blend estimate is used as the estimated total catch. The rex sole catches have declined from 1999 to 2,939 mt in 2001 (Turnock *et at.* 2002b). The flatfish fishery is likely to be limited by the potential for high catches of Pacific halibut in the future.

The large removals of rex sole by the JV and past domestic fisheries are determined to have had an adverse effect on the GOA rex sole population and these effects are determined to be lingering at the population-level.

In 1990, NPFMC divided the flatfish assemblage into four categories; shallow water flatfish, deepwater flatfish, flathead sole, and arrowtooth flounder. This classification was made because of the significant difference in halibut bycatch rates in directed fisheries targeting on shallow water and deepwater flatfish species. Arrowtooth flounder were separated from the other categories due to their high abundance and low commercial value. Flathead sole were separated due to an overlap in depth distribution with the shallow water and deepwater groups.

Rex sole were split out of the deepwater management category in 1993. Beginning in 1996, rock sole were split into two species, a northern (*Lepidopsetta sp. cf. bilineata*) and a southern rock sole (*Lepidopsetta bilineata*) (personal communication - Jay Orr as referenced in Turnock *et al.* 2001b) due to overlapping distributions.

Change in Reproductive Success

External Foreign Groundfish Fisheries (1960s-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the past foreign fisheries on spatial/temporal distribution of the GOA rex sole population is unknown. However, these fisheries are determined not to have had any observable lingering adverse effects on the GOA rex sole population.

External Climate Changes and Regime Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influence the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of rex sole. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries (1968-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the JV and past domestic fisheries on spatial/temporal distribution of the GOA rex sole population is unknown. However, these fisheries are determined not to have had any observable lingering adverse effects on the GOA rex sole population.

Change in Prey Availability

External Foreign Groundfish Fisheries (1960s-1976)

The foreign fisheries in the GOA are unlikely to have directly impacted prey availability for rex sole since these fish eat infaunal invertebrates. The lingering adverse effects in the rex sole GOA stock are likely due to the natural events related to climate changes.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the majority of the diet of rex sole.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of the other flatfish group.

Internal JV and Domestic Groundfish Fisheries (1968-present)

The JV fisheries in the GOA are unlikely to have directly impacted prey availability for rex sole since these fish eat infaunal invertebrates. The lingering adverse effects in the rex sole GOA stock are likely due to the natural events related to climate changes.

Change in Important Habitat

External Foreign Groundfish Fisheries (1960s-1976)

Statistics on the number of bottom trawls and their effects on GOA habitat are generally unknown. It is assumed that the effect of the foreign fisheries on habitat suitability is either beneficial or adverse and is found to have had a lingering influence in the GOA stock.

External IPHC Halibut Longline Fisheries and State of Alaska Scallop Fisheries

See Section 3.5.1.15 (change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of the IPHC halibut longline fisheries on habitat suitability is either beneficial or adverse and is found to have had a lingering influence in the GOA stock. The Alaska scallop fishery has a history of being sporadic due to exploitation of limited stocks, market conditions, and the availability of more lucrative fisheries. In 1999, only three boats fished for scallops (B. Bechtohl, ADF&G, personal communication). While the effect on benthic habitat of the dredging is intense, the magnitude of the overall impact of the fishery is likely to be small.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of the other flatfish group.

Internal JV and Domestic Groundfish Fisheries (1968-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of these fisheries on habitat suitability is either beneficial or adverse and is found to have had a lingering influence in the GOA stock. The 1998 and 1999 trawl closures, due to PSC halibut limits, help to reduce the intensity of the fishery on rex sole habitat.

GOA Rex Sole Comparative Baseline

The 2001 biomass survey took place only in the central and western Gulf; therefore, eastern GOA biomass have been estimated using the average of the 1993 to 1999 eastern GOA biomass estimates for rex sole.

Rex sole has decreased in 2001 relative to 1990s biomass estimates. Exploitable biomass estimates are assumed to be the same as the 2001 survey biomass results (Turnock *et al.* 2002b). Some experimental evidence indicates that flatfish biomass may be underestimated by the northeastern trawl (Weinberg 2003). Experiments are being conducted to estimate the herding component of catchability.

GOA Rex Sole Cumulative Effects Analysis Status

GOA rex sole will be brought forward for cumulative effects analysis.

3.5.1.22 GOA Pacific Ocean Perch

Life History and Distribution

Pacific ocean perch (*Sebastes alutus)* is primarily a demersal species that inhabits the outer continental shelf and slope regions of the NPO and the Bering Sea from southern California to Japan (Allen and Smith 1988). As adults, they live on or near the seafloor, generally in areas with smooth bottoms (Krieger 1993) and generally at depths ranging from 180-420 m. Though more is known about the life history of Pacific ocean perch than about other rockfish species (Kendall and Lenarz 1986), much uncertainty still exists about its life history. Pacific ocean perch are viviparous, with internal fertilization and the release of live young (Hart 1973). Insemination occurs in the fall, and release of larvae occurs in April or May. Pacific ocean perch larvae are thought to be pelagic and drift with the current. Juveniles seem to inhabit rockier, higher relief areas than adults (Carlson and Straty 1981, Krieger 1993). The maximum recorded age of Pacific ocean perch is 100 years (Frimodt 1995). Table 3.5-22 summarizes biological and reproductive attributes and habitat associations of Pacific ocean perch in the BSAI and GOA.

The Pacific ocean perch were found to be genetically similar throughout their range based on allozyme variation (Seeb and Gunderson 1988); however, preliminary analysis using microsatellite DNA techniques suggests that genetically distinct populations of Pacific ocean perch exist (A.J. Gharrett personal communication, University of Alaska Fairbanks).

Trophic Interactions

During the summer of 1990, the diets of commercially important groundfish species in the GOA were analyzed by Yang (1993). About 98 percent of the total stomach content weight of Pacific ocean perch in the study was made up of invertebrates and 2 percent of fish. Euphausiids (mainly *Thysanoessa inermis*) were the most important prey item. Euphausiids comprised 87 percent, by weight, of the total stomach contents. Calanoid copepods, amphipods, arrow worms, and shrimp were frequently eaten by Pacific ocean perch (Brodeur and Percy 1984, Yang 1996).

Documented predators of Pacific ocean perch include Pacific halibut and sablefish, and it is likely that Pacific cod and arrowtooth flounder also prey on Pacific ocean perch. Pelagic juveniles are consumed by salmon, and benthic juveniles are eaten by lingcod and other demersal fish (NMFS 1997).

GOA Pacific Ocean Perch Management

In the GOA, Pacific ocean perch are managed as a sub-assemblage of the slope rockfish assemblage. Tier 3a is used to compute ABC and OFL for the Pacific ocean perch stock. The current female spawning biomass is 112,270 mt, leading to an OFL level of 16,240 mt. The ABC value for 2003 is 13,660 mt. The ABC value is apportioned over three areas: 2,700 mt for the western GOA, 8,510 mt for the central GOA, and 2,450 mt for the eastern GOA (Table 3.5-28). The OFL values are: 3,220 mt for the western GOA, 10,120 mt for the central GOA, and 2,900 mt for the eastern GOA. In order to prevent the eastern GOA TAC from being taken between 140° and 147°W, the area left open to trawling following the Amendment 58 trawl ban in the eastern area, a separate TAC of 810 mt has been assigned to the west Yakutat area within the eastern GOA (Heifetz *et al.* 2002).

GOA Pacific ocean perch are assessed with an age-structured model with allowance of size composition data. This model is derived from a generic rockfish model developed in a modeling workshop held in the Auke Bay Laboratory in February 2001. Data used in the model included total catch biomass (1961-2002), fishery size and age compositions, and survey age compositions and biomass estimates (Heifetz *et al.* 2001).

GOA Pacific Ocean Perch Past/Present Effects Analysis

The geographic scope for the Pacific ocean perch past/present effects analysis is the same as the GOA management areas (Figure 1.2-3). The temporal scope for this analysis begins in 1961 when the foreign Pacific ocean perch fishery begins and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-36 provides a summary of GOA Pacific ocean perch past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA Pacific ocean perch:

- Mortality due to catch/bycatch marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to commercial whaling, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explain any management actions specific to GOA Pacific ocean perch. Amendments discussed in Section 3.2 which impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on Pacific ocean perch in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to GOA Pacific ocean perch past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1961-1975)
  - Commercial whaling
  - IPHC longline fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1979-1989)
  - Domestic groundfish fisheries (1970-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1961-1976)

The Soviet Union began targeting Pacific ocean perch in 1961, but had shifted to pollock, Atka mackerel, and flounders by the late 1960s and early 1970s due to decline in Pacific ocean perch stocks. The Soviet Union Pacific ocean perch fishery practiced pulse fishing, following the Pacific ocean perch throughout its range in the GOA from around the Shumagin Islands to the eastern area of southeastern Alaska. Soviet Union Pacific ocean perch catch peaked in 1965 at 300,000 mt, and declined thereafter, reaching an all-time low in 1970 at 9,000 mt. By this time, the Soviets had shifted to other target resources; however, catches rose again in 1975. From 1981 on, the Soviet Union was excluded from the GOA for political reasons (NPFMC 2002b).

The Japanese Pacific ocean perch fishery began in 1963 with their North Pacific trawl fishery. Maximum catch occurred in 1966 at 65,200 mt, followed by a decline to 4,948 mt in 1983. By the late 1960s and early 1970s, Japan had switched to other less heavily exploited species since Pacific ocean perch abundance was in a decline (NPFMC 2002b).

The Republic of Korea entered the GOA in 1972 and occasionally targeted Pacific ocean perch although their main target was pollock (NPFMC 2002b).

Past foreign fisheries are found to have overfished the GOA Pacific ocean perch populations, and these effects are lingering at the population-level.

Internal JV and Domestic Groundfish Fisheries (1970-present)

Commercial catch for slope rockfish was not reported separately until 1988. Previously they were listed as part of the Pacific ocean perch complex. Foreign fisheries continued to dominate harvests from 1977 to 1984, with Japan taking a majority of the catch. Catch reached a minimum in 1985 following a ban on foreign trawling in the GOA (NPFMC 2002b).

The past JV fisheries began in 1979, taking relatively small catches throughout their duration. The JV fisheries harvest peak occurred in 1983 at 1,975 mt. The domestic fishery for slope rockfish began in 1970; however, this fishery did not start taking significant amounts of slope rockfish until 1985. By 1989, the GOA slope rockfish fishery had become completely domesticated. The domestic fishery developed rapidly, from 825 mt in 1985 to 21,114 mt by 1990 (Heifetz *et al.* 2002).

The slope rockfish assemblage was divided into three management subgroups in 1991: Pacific ocean perch, shortraker/rougheye rockfish, and all other species of slope rockfish. In 1993, the northern rockfish subgroup was created. These groups were created in order to prevent overfishing of the most desirable species. The groups are assigned separate TACs instead of a single group slope rockfish group TAC, as was done prior to 1991. The TACs are further subdivided into the three management areas within the GOA to avoid spatial/temporal concentration of the catch. These TAC apportionments are based on distributions of exploitable biomass. The GOA domestic fishery catch of Pacific ocean perch has been variable over the years (1991-2001), from a low of 1,853 mt in 1994 to a high of 10,972 mt in 2001 (Heifetz *et al.* 2001). The Pacific ocean perch catch has been constrained in recent years due to PSC limits of halibut and bycatch of other species.

The large removals of Pacific ocean perch that occurred during the JV and past domestic fisheries are found to have had an adverse effect GOA Pacific ocean perch populations. These effects are determined to be lingering at the population-level.

In 1994, GOA FMP Amendment 32 established a rebuilding plan for GOA Pacific ocean perch to minimize mortality. This plan was necessary to maximize the probability of rebuilding success in a realistic time period. As a result of increased concern about the status of Pacific ocean perch stocks, biomass assessment methodology has been improved and domestic harvest levels were reduced during the early to mid-1990s (NPFMC 2002b). After 1995, the Pacific ocean perch biomass began increasing at a fast pace in response to several strong year-classes. The rebuilding plan was revised under GOA FMP Amendment 38 in 1996 to allow the Pacific ocean perch TAC to be set at or below the rebuilding formula, but NPFMC did not invoke that measure because the stock met the rebuilding goal. Pacific ocean perch were considered rebuilt in 1997 and the species biomass has increased steadily through 2001 (Heifetz *et al.* 2002).

Discard rates for Pacific ocean perch have varied over the years (1991-2001), but are relatively low throughout with the exception of 1993 and 1994. In 1993 and 1994, discard rates were 79.2 and 60.3 percent, respectively, due to the bycatch-only status of the fishery. Typically, the discard rate is between about 8-20 percent and has declined in recent years (8.5 percent in 2001). Bycatch rates of Pacific ocean perch are highest in PSR, other slope rockfish, and shortspine thornyhead fisheries (Heifetz *et al.* 2001).

Change in Reproductive Success

<u>External Foreign Groundfish Fisheries (1961-1976)</u>

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the foreign fisheries on the spatial/temporal distribution of the GOA Pacific ocean perch populations due to the spatial/temporal concentration of the fisheries is unknown. However, any possible effects are not expected to have lingering effects in the populations.

<u>External Climate Changes and Regime Shifts</u>

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan et al. (1998), Hollowed et al. (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of Pacific ocean perch. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries (1970-present)

Spatial/Temporal Concentration of Catch/Bycatch

The effect of the JV and past domestic fisheries on the spatial/temporal distribution of the GOA Pacific ocean perch populations due to the spatial/temporal concentration of the fisheries is unknown. However, any possible effects are not expected to have lingering effects in the populations. Important Pacific ocean perch fishery locations include, in the eastern GOA, the gully and slope southwest of Yakutat Bay and off Cape Omaney; in the central GOA, the shelf, slope, and gullies off of Kodiak Island south of Portlock Bank and near Albatross Bank; and in the western GOA, the shelf and slope south of Unimak and Umnak Islands (Heifetz *et al.* 2002).

As mentioned above, the apportionment of the TACs into GOA management areas for each slope rockfish subgroup helps to reduce the spatial/temporal concentration of the fishery. In 1998, GOA FMP Amendment 58 was passed prohibiting the use of trawl gear in the eastern area of the GOA east of 140°W longitude. However, there are concerns that the entire eastern TAC for slope rockfish, particularly Pacific ocean perch, could be taken in a small area in the eastern unit that is still open to trawling. As explained under GOA slope rockfish management, the eastern GOA TAC is further apportioned into east and west Yakutat Districts to prevent the entire eastern area TAC from being taken in the east Yakutat/southeast outside unit (Heifetz *et al.* 2002).

Change in Prey Availability

External Commercial Whaling

Whaling is identified as having a past beneficial effect on prey availability for all Pacific ocean perch stocks, since the diet of Pacific ocean perch appears to consist primarily of plankton (Brodeur and Percy 1984); euphausiids are the single most important prey item (Yang 1996). A reduction in baleen whale populations could mean that more euphausiids would be available for use by Pacific ocean perch. Documented predators of Pacific ocean perch include Pacific halibut and sablefish, and it likely that Pacific cod and arrowtooth flounder also prey on Pacific ocean perch. Pelagic juveniles are consumed by salmon and benthic juveniles are eaten by lingcod and other demersal fish (NMFS 1997).

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on prey availability. Populations of Pacific ocean perch have rebounded from low population-levels. The controlling factor for these increases appears to be environmental, with changes in the species composition in nearshore areas linked to an increase in advection in the Alaska current. Increased flow around the GOA may enhance the supply of nutrients and plankton on the shelf and upper slope areas, resulting in an increase in productivity.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of Pacific ocean perch.

Change in Important Habitat

External Foreign Groundfish Fisheries (1961-1976)

Statistics on the number of bottom trawls and their effects on GOA habitat pre-MSA is generally unknown. However, the effect of the foreign fisheries on habitat suitability is negative for the GOA stock and is found to have had a lingering adverse influence in the stocks. The intense trawling of the foreign, JV and past domestic fisheries is the likely cause of this lingering effect. Prior to 1996, more than 90 percent of slope rockfish were taken by large factory-trawlers.

External IPHC Longline Fisheries

The impacts of IPHC longline gear on Pacific ocean perch habitat have been identified as adverse effects. Intense longline fishing is likely to have caused Pacific ocean perch habitat degradation and disruption of Pacific ocean perch spawning and/or rearing grounds. This effect is still lingering at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability and prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of Pacific ocean perch.

Internal JV and Domestic Groundfish Fisheries (1970-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The effect of past JV fisheries on habitat suitability is adverse for the GOA stock and is found to have had a lingering adverse influence in the stocks. The intense trawling of the foreign, JV and past domestic fisheries is the likely cause of this lingering effect. Prior to 1996, more than 90 percent of the slope rockfish were taken by large factory-trawlers. After 1996, smaller shore-based trawling began taking a larger catch. From 1993-2000, longline catches of shortraker/rougheye rockfish have increased to 30 to 48 percent of the annual catch and a larger portion of Pacific ocean perch have been taken by pelagic trawls. The percentage of Pacific ocean perch taken by pelagic trawls has increased from 2 to 8 percent in 1990-1995 to 14 to 20 percent in 1996-1998.

GOA Pacific Ocean Perch Comparative Baseline

Triennial trawl surveys have been conducted in the GOA since 1984 and are now conducted biennially starting in 2001. The 2001 trawl survey did not survey the eastern GOA; therefore, biomass estimates for that area are based on an average of 1993, 1996 and 1999 biomass estimates. The 2001 trawl survey indicates that Pacific ocean perch was the most abundant species with an estimated biomass of 858,982 mt, 61.9 percent of the total slope rockfish biomass. The 2001 biomass estimates for Pacific ocean perch are greatly influenced by large catches in one or two hauls, resulting in higher variance of biomass.

When comparing the trawl surveys from 1984-2001, Pacific ocean perch biomass estimates were relatively low in 1984-1990, increased in 1993 and 1996. and remained high in 1999 and 2001. Variance in biomass estimates is attributed to anomalously large individual hauls (as in 1999 and 2001), and to a change in availability of rockfish to the survey caused by unknown behavioral or environmental factors. Causes of changes in biomass estimates can not be determined until more is known about rockfish behavior.

GOA Pacific Ocean Perch Cumulative Effects Analysis Status

GOA Pacific ocean perch will be brought forward for cumulative effects analysis.

3.5.1.23 GOA Thornyhead Rockfish

Life History and Distribution

Thornyhead rockfish in Alaskan waters are comprised of two species, the shortspine thornyhead (*Sebastolobus alascanus*) and the longspine thornyhead (*S. altivelis*). Only the shortspine thornyhead is of commercial importance and it is now one of the most commercially valuable rockfish species. Thornyheads are a demersal species found in deepwater, from 94 m to 1,460 m, from the Bering Sea and GOA to Baja California (Gaichas and Ianelli 2001). Little is known about thornyhead life history. Like other rockfish, they are long-lived and slow-growing. The maximum recorded age is in excess of 50 years, and females do not become sexually mature until an average age of 12 to 13 years and a length of about 21 cm. Thornyheads spawn large masses of buoyant eggs during the late winter and early spring (Pearcy 1962). Juveniles are pelagic for the first year. The shortspine thornyhead is managed as a single stock in its own management group in the GOA; however, this species and the longspine thornyhead are managed as part of the other rockfish assemblage in the BSAI (see Section 3.5.1.13). Table 3.5-26 summarizes biological and reproductive attributes and habitat associations of thornyhead rockfish in the BSAI and GOA.

Trophic Interactions

Yang (1993 and 1996) and Yang and Nelson (2000) showed that shrimp, mainly pandalids, were the most important food of the thornyhead. Tanner crabs comprised less than 7 percent by weight of stomach contents, and fish such as pollock, capelin, and sculpins comprised about 15 percent. Other prey items for thornyheads included polychaetes, mysids, amphipods, and other crabs. California sea lion (Lowry *et al.* 1990) and sablefish (Orlov 1997) have both been documented as predators of shortspine thornyhead.

GOA Thornyhead Rockfish Management

Up until 2003, thornyhead rockfish were managed under Tier 3 of the GOA groundfish FMP. Due to uncertainty associated with model estimates of natural mortality and other parameters, GOA thornyhead rockfish estimates of ABC and OFL were based on Tier 5. The recommended ABC is 1,940 mt (Table 3.5-28). ABC and OFL have been further apportioned to the western, central, and eastern GOA (Gaichas and Ianelli 2002).

In the GOA, shortspine thornyheads are assessed with an age-structured model incorporating data from two fisheries (longline and trawl) and two types of survey data. Bottom trawl surveys have been conducted every three years in the GOA during June through August and provide a limited time-series of abundance since 1977. Longline surveys occur annually and extend into the deeper waters (300 to 800 m) of shortspine thornyhead habitat. Both surveys provide estimates of the size distributions of their respective catches. These are used in the stock assessment model in place of age compositions, because extensive age determination on this species has not been done.

Biologically, the greatest area of uncertainty for this species is in their longevity and natural mortality rate. Currently, NOAA Fisheries scientists believe they are slow-growing and long-lived fish that are relatively sedentary on the ocean floor. Recent research based on reproductive information of west coast and Alaska populations indicates that shortspine thornyheads are very long-lived (Pearson and Gunderson in review) with lower natural mortality rates than previously predicted and higher maximum ages (250-350 years). Radiometric analysis suggests that the maximum age is between 50-100 years (Kastelle *et al.* 2000, Cailliet *et al.* 2001), although these are high-variance estimates. Alternative models to estimate natural mortality rates were run during the 2001 and 2002 stock assessments using radiometric and conventional analyses (Kline 1996) and the Kastelle *et al.* (2000) analysis; however, none of the models was a substantial improvement from the base model.

GOA Thornyhead Rockfish Past/Present Effects Analysis

The geographic scope for the thornyhead rockfish past/present effects analysis is the same as the GOA management areas (Figure 1.2-3). The temporal scope for this analysis begins in the late 1800s when the U.S. and Canadian trawl fisheries began exploiting deepwater demersal communities, and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-37 provides a summary of GOA thornyhead rockfish past/present effects analysis presented below. The following direct and indirect effects were identified as potentially having population-level effects on GOA thornyhead rockfish:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to fishery bycatch of prey species, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

- Change in important habitat due to fishery gear impacts, climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explain any management actions specific to GOA thornyhead rockfish. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here. Sections 3.5.1.11 and 3.5.1.12 discuss management measures for Pacific ocean perch and rockfish, respectively.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on thornyhead rockfish in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regimes shifts.

The past/present events determined to be applicable to GOA thornyhead rockfish past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (late 1800s-1976)
  - State of Alaska shrimp fisheries
  - IPHC longline fisheries
  - Marine pollution and oil spills
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1983-1990)
  - Domestic groundfish fisheries (1983-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (late 1800s-1976)

Thornyheads have been fished in the northeastern Pacific ocean since the late 1800s as part of the deepwater demersal fish community. U.S. and Canadian trawls were the first to fish thornyheads commercially. Soviet, Japanese, and Republic of Korea vessels began fishing for thornyheads in the mid-1960s (Chitwood 1969). Thornyheads have been lightly exploited throughout the history of the fishery. From 1967 to 1977, annual harvest never exceeded 2,000 mt. Catches were made by trawl and hook and line gear, although trawl gear has taken the majority of catch. Foreign harvest peaked in 1973 at 1,565 mt. Catch data from 1967-1980 are based on U.S. Foreign Observer Program reports, Pacific Fishery Information Network reported landings, and reports compiled by French *et al.* (1977) and Wall *et al.* (1978-1981) (Gaichas and Ianelli 2001).

Removals of thornyhead rockfish by the foreign fisheries are determined to have had an adverse effect on the GOA thornyhead rockfish populations; furthermore, these effects are lingering at the population-level.

External IPHC Longline Fisheries

Thornyhead rockfish have been and continue to be caught as bycatch in the IPHC longline fishery. The amount of this bycatch is unknown, although it is expected to be minimal. The IPHC longline fishery is not expected to have a significant impact on the GOA thornyhead rockfish population.

Internal JV and Domestic Groundfish Fisheries (1983-present)

Since 1983, the Observer Program has monitored thornyhead rockfish as part of the JV fisheries, and thornyheads have been monitored as a separate group in the domestic fisheries since 1984. Foreign fishery catch continued to exceed JV and domestic catch until 1985. By 1989, the domestic fishery had reached its peak catch of 3,080 mt. Average catch from 1996-2000 is about 1,260 mt annually (Gaichas and Ianelli 2001).

Thornyhead rockfish are caught primarily as bycatch in other target fisheries. However, they are now among the most valuable rockfish species and are harvested by trawl and longline gear. Most of the domestic harvest is exported to Japan. Thornyheads are taken with some frequency in the longline fishery for sablefish and in the rockfish and combined flatfish fisheries.

The removals of thornyhead by the JV and past domestic fisheries are found to have had an adverse effect on the GOA thornyhead population; however, it is uncertain whether the removals by these fisheries have had a lingering adverse effect on the GOA thornyhead populations.

Change in Reproductive Success

External Foreign Groundfish Fisheries (late 1800s-1976)

Spatial/Temporal Concentration of Catch/Bycatch

The effects of the foreign fisheries on the spatial/temporal distribution of the GOA thornyhead rockfish populations due to the spatial/temporal concentration of the fishery are unknown. Although, historical removals of thornyhead rockfish appear to be more concentrated in the central region of the GOA, there do not appear to be any observable lingering adverse effects on the population (Ianelli and Ito 1995).

External IPHC Longline Fisheries

Thornyhead rockfish have been and continue to be caught as bycatch in the IPHC longline fishery. The amount of this bycatch is unknown, although it is expected to be minimal. The IPHC longline fishery is not expected to have a significant impact on the GOA thornyhead rockfish population.

External Climate Changes and Regime Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influences the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of thornyhead rockfish. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal JV and Domestic Groundfish Fisheries (1983-present)

Spatial/Temporal Concentration of Catch/Bycatch

Based on foreign historical trends, the concentration of thornyhead rockfish catch appears to be in the central GOA region. Researchers have recommended further apportionment of thornyhead TAC into management units to avoid concentration of catch in the future. Furthermore, the trawl closure of part of the eastern area east of 140°W in 1998 (GOA FMP Amendment 58) may led to concentration of catch in the small area of the eastern management area that has not been closed to trawl gear.

Change in Prey Availability

External Foreign Groundfish Fisheries (late 1800s-1976)

Effects of the foreign fisheries on prey availability in the stock are unknown. However, it is unlikely that the foreign groundfish fisheries have had an adverse impact on thornyhead rockfish prey availability since the majority of thornyhead prey is pandalid shrimp.

External State of Alaska Shrimp Fisheries

Effects of State of Alaska shrimp fisheries on the prey availability of thornyhead rockfish are potentially adverse; however, due to the localized nature of these fisheries, they are unlikely to have a population-level effect.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability and prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5). Due to the ambiguity in the effects related to climate change, the overall lingering influence on competition for prey is unknown.

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes the part of the diet of thornyhead rockfish.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of thornyhead rockfish.

Internal JV and Domestic Groundfish Fisheries (1983-present)

The effects of the JV and domestic groundfish fisheries on thornyhead rockfish prey availability is unknown, however the effects are expected to be minimal since the majority of thornyhead rockfish prey is made up of pandalid shrimp.

Change in Important Habitat

External Foreign Groundfish Fisheries (late 1800s-1976)

Statistics on the number of bottom trawls and their effects on GOA habitat pre-MSA is generally unknown. Effects of the foreign fisheries on habitat suitability in the stock are not identified.

External IPHC Longline Fisheries

The IPHC longline fishery has and continued to overlap with thornyhead rockfish habitat. IPHC longline fishery gear may negatively contribute to GOA thornyhead rockfish degradation, although the magnitude of this effect is unknown.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability and prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5). Due to the ambiguity in the effects related to climate change, the overall lingering influence on habitat suitability is unknown.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of thornyhead rockfish.

Internal JV and Domestic Groundfish Fisheries (1983-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

Closure of the eastern management area east of 140°W in 1998 to trawl gear may reduce the intensity of the fishery on thornyhead rockfish habitat. However, those areas in the eastern region not closed to trawl gear may become more intensely fished, or there may be a shift to greater use of longline gear in the areas closed to trawl.

GOA Thornyhead Rockfish Comparative Baseline

Survey and fishery catch rates indicate that shortspine thornyheads are relatively evenly distributed within their habitat and, like many other groundfish species, do not tend to form dense aggregations. This distribution pattern is important in interpreting the survey results, because the assumptions implied in area-swept methods for the bottom trawl gear are likely to be satisfied (for further information on surveys see Appendix B). Fishery data include estimates of the total catch and size distribution information by gear type.

Longline surveys have also been used to estimate abundance of thornyheads in the GOA since 1979. However, the use of the longline survey has been questioned since data show there is an interaction between sablefish and thornyhead abundance. Sigler and Zenger (1994) found that as thornyhead abundance decreased, sablefish abundance increased. Research is underway to evaluate the hook competition between thornyheads and sablefish, and a thornyhead tagging study is being conducted to learn about the movement and growth rates of these species (Gaichas and Ianelli 2001).

Modeling results indicate that the abundance of shortspine thornyheads has remained relatively stable since 1970. Recruitment is highly variable, although several strong year-classes are apparent. Since thornyheads are long-lived and slow growing it is difficult to determine the precise strong year-classes.

GOA Thornyhead Rockfish Cumulative Analysis Status

GOA thornyhead rockfish will be brought forward for cumulative effects analysis.

3.5.1.24 GOA Rockfish

Life History and Distribution

Northern rockfish (*Sebastes polyspinis*) inhabit the outer continental shelf from the EBS, throughout the Aleutian Islands and the GOA (Kramer and O'Connell 1988). This species is semidemersal and is usually found in comparatively shallower waters off the outer continental slope (from 50-600 m). Little is known about the biology and life history of northern rockfish. However, they appear to be long-lived, with late maturation and slow growth. Like other members of the genus *Sebastes*, they bear live young, and birth occurs in the early spring through summer (McDermott 1994). Northern rockfish are managed as part of the slope rockfish assemblage in the GOA.

Table 3.5-27 summarizes biological and reproductive attributes and habitat associations for selected rockfish species in the BSAI and GOA.

Shortraker (*Sebastes borealis*) and rougheye rockfish (*S. aleutianus*) inhabit the outer continental shelf of the NPO from the EBS as far south as southern California (Kramer and O'Connell 1988). Adults of both species are semidemersal and are usually found in deeper waters (from 50 m to 800 m) and over rougher bottoms than Pacific ocean perch (Krieger and Ito 1999). Little is known about the biology and life history of these species, but they appear to be long-lived, with late maturation and slow growth. Shortraker rockfish have been estimated to reach ages in excess of 120 years, and rougheye rockfish in excess of 140 years. Like other members of the genus *Sebastes*, they are viviparous (bear live young), and birth occurs in the early spring through summer (McDermott 1994).

Both species are associated with a variety of habitats, from soft to rocky bottoms, although boulders and sloping terrain appear also to be desirable habitat (Krieger and Ito 1999). Length at 50 percent sexual maturity is about 45 cm for shortraker rockfish and about 44 cm for rougheye rockfish (McDermott 1994). Shortraker and rougheye rockfish are managed as part of the slope rockfish assemblage in the GOA.

Numerous other rockfish species of the genus *Sebastes* have been reported in the GOA (as managed as other slope rockfish) and BSAI (managed as other rockfish) (Eschmeyer *et al.* 1984), and several are of commercial importance. Most are demersal or semidemersal, with different species occupying different depth strata (Kramer and O'Connell 1988). Other slope rockfish inhabit waters of the outer continental shelf and continental slope of the GOA as adults at depths greater than 150-200 m. All are viviparous (Hart 1973). Life history attributes of most of these rockfish are poorly or virtually unknown. Because they are long-lived and slow-growing, natural mortality rates are probably low. Other rockfish species are taken both in directed fisheries and as bycatch in trawl and longline fisheries. In the GOA, although the other slope rockfish management group comprises 17 species, 6 species alone make up 95 percent of the catch and estimated abundance. These six species include the sharpchin, redstripe, harlequin, silvergrey, yellowmouth, and redbanded rockfishes. In the BSAI, the other rockfish species assemblage comprises 28 species, several of which are classified in different groups in the GOA. Shortspine thornyheads are managed as part of the other rockfish species in the BSAI; however, it is managed as part of the thornyhead rockfish assemblage in the GOA (see Section 3.5.1.12).

Genetic studies are currently underway assessing the genetic stock structure of some species of slope rockfish. Some studies examining the differences among areas in age composition, growth, fecundity, and prevalence of parasites suggest that separate populations exist in the adult stage of some rockfish (Leaman and Kabata 1987, Moles *et al.* 1998). Two genetically distinct populations of rougheye rockfish with partially overlapping geographic ranges were found by Hawkins *et al.* (1997) and Gharrett and Gray (1998), and confirmed with recent mitochondrial and microsatellite analyses (personal communication, A.J. Gharrett, University of Alaska Fairbanks).

The GOA PSR group includes: dusky rockfish (*Sebastes ciliatus*), yellowtail rockfish (*S. flavidus*), and widow rockfish (*S. entomelys*). Dusky rockfish is by far the most important species in the group, both in terms of abundance and commercial value. PSR inhabit waters of the continental shelf of the GOA and typically exhibit midwater, schooling behavior. The dusky rockfish has the northernmost distribution of all the rockfish species in the Pacific Ocean, ranging from British Columbia north to the Bering Sea and west to Hokkaido Island of Japan, but is most abundant in the GOA. Studies are underway that indicate the occurrence of two distinct species of dusky rockfish in the GOA, a dark-colored and light-colored variety (Seeb 1986 and 2000, Orr and Blackburn 2000). In the GOA, nearly all dusky rockfish considered are of the light-colored variety. These species are managed as the PSR assemblage in the GOA and as part of the other rockfish species assemblage in the BSAI.

GOA DSR include seven species of nearshore, bottom-dwelling rockfish: canary rockfish (*Sebastes pinniger)*, China rockfish (*S. nebulosus)*, copper rockfish (*S. caurinus)*, quillback rockfish (*S. maliger)*, rosethorn rockfish (*S. helvomaculatus)*, tiger rockfish (*S. nigrocinctus)*, and yelloweye rockfish (*S. ruberrimus*). DSR are nearshore, bottom-dwelling species that occur on the continental shelf and are generally associated with rugged, rocky habitat. Yelloweye rockfish occur on the continental shelf from northern Baja California to the EBS, commonly in depths less than 200 m (Kramer and O'Connell 1988). They inhabit areas of rugged, rocky relief, and adults appear to prefer complex bottoms with the presence of "refuge spaces" (O'Connell and Carlile 1993). All of the DSR are slow-growing and very long-lived; the yelloweye rockfish have been estimated to reach an age of 118 years (Adams 1980, Gunderson 1980, Archibald *et al.* 1981). DSR are classified as ovoviviparous (eggs hatch within the females body). Rockfish have internal fertilization and several months separating copulation, fertilization, and parturition (giving birth). Parturition typically occurs from February through September with most species extruding larvae in late winter and spring. Yelloweye rockfish extrude larvae over an extended period, with the peak occurring in April and May (O'Connell 1987). Demersal rockfish have a closed swim bladder, which makes them susceptible to embolism mortality when brought to the surface from depth. Therefore, most species are fatally injured even when caught as discard in other fisheries. The DSR are managed as an assemblage in the GOA; the canary rockfish, copper rockfish, rosethorn rockfish, and tiger rockfish are managed as part of the other rockfish assemblage in the BSAI.

Trophic Interactions

Northern rockfish are generally planktivorous (feed on plankton) with euphausiids being the predominant prey item (Yang 1993). Copepods, hermit crabs, and shrimp have also been noted as prey items in much smaller quantities. Predators of northern rockfish are not well documented, but likely include larger fish such as Pacific halibut that are known to prey on other rockfish species.

Food habit studies conducted by Yang (1993) indicate that the diet of rougheye rockfish is dominated by shrimp. The diet of shortraker rockfish is not well known; however, based on a small number of samples, the diet appears to be dominated by squid. Because shortraker rockfish have large mouths and short gill rakers, it is possible that they are potential predators of other fish species (Yang 1993).

The diet of the other slope rockfish (GOA) and other rockfish species (BSAI) for which dietary information exists seems to consist primarily of planktonic invertebrates (Yang 1993 and 1996). Predators of other slope rockfish are also not well documented, but likely include larger fish, such as Pacific halibut, which are known to prey on other rockfish species.

Trophic interactions of dusky rockfish are not well known. Food habits information is available from just one study, with a relatively small sample size for dusky rockfish (Yang 1993). This study indicated that adult dusky rockfish consume primarily euphausiids, followed by larvaceans, cephalopods, and pandalid shrimp. Predators of dusky rockfish have not been documented, but likely include species that are known to consume rockfish in Alaska, such as Pacific halibut, sablefish, Pacific cod, and arrowtooth founder.

Yelloweye rockfish are large, predatory fishes that usually feed close to the bottom. Food habit studies indicate that the diet of yelloweye rockfish is dominated by fish remains, which comprised 95 percent, by volume, of the stomachs analyzed. Herring, sand lance, and Puget Sound rockfish (*S. empheaus*) were particularly dominant. Shrimp are also an important prey item (Rosenthal *et al.* 1988).

GOA Rockfish Management

In the GOA, northern rockfish are managed as a sub-assemblage of the slope rockfish assemblage. Tier 3a is used to compute the ABC and OFL values for northern rockfish. The current female spawning biomass for 2002 is 40,070 mt, greater than the $B_{40\%}$ value. The ABC value for 2003 equates to 5,530 mt, and the OFL value equates to 6,560 mt. ABC was apportioned in the western and central areas of the GOA. Northern rockfish are combined with other slope rockfish in the eastern GOA (Heifetz *et al.* 2002).

The northern rockfish group is assessed based on an age-structure model. Data used in this model include triennial survey biomass estimates and fishery catch, age, and size compositions. Natural mortality was fixed at an independently estimated value, and a single selectivity was assumed for the fishery and the survey.

In the GOA, shortraker and rougheye rockfish are managed as a sub-assemblage of the slope rockfish assemblage. GOA shortraker rockfish are managed in Tier 5 and rougheye rockfish are managed under Tier 4, but both have their own TAC-setting processes separate from other rockfish species in the other slope rockfish assemblage. The average exploitable biomass for the shortraker/rougheye and other slope rockfish groups is estimated by the unweighted average of the last three trawl survey results, excluding biomass in the 1-100 m depth stratum. The exploitable biomass for 2003 is 66,830 mt for the shortraker/rougheye group and 107,962 mt for other slope rockfish. According to ABC and OFL definitions, other slope rockfish are placed in Tier 5 where ABC is determined by $F = 0.75M$. Sharpchin are assessed under Tier 4 where OFL is calculated by $F = M$. This equates to an ABC value of 5,050 mt and an OFL value of 6,610 mt for the other slope rockfish group (Heifetz *et al.* 2002). Table 3.5-28 shows the ABC and OFL values for the more common species in the slope rockfish group. For management information on Pacific ocean perch as a member of the slope rockfish assemblage, see Section 3.5.1.11.Efforts have been made to assess rougheye rockfish using an age-structured model; however, development of this model is still in preliminary stages.

The PSR group includes dusky rockfish, yellowtail rockfish and widow rockfish. Beginning with the 2001 stock assessment, dusky rockfish were assessed separately from the larger PSR group since dusky rockfish compose nearly all the biomass. In 2003, dusky rockfish were moved up to Tier 3a, with an age-structured model, while yellowtail and widow rockfish are still managed under Tier 5. The dusky rockfish ABC value is computed using an $F = M$ strategy rather than $F_{40\%}$ due to concerns of unreliable biomass estimates. This equates to an ABC value of 5,070 mt. Yellowtail and widow rockfish ABC values were computed using $F = 0.75M$, equating to an ABC value of 415 mt (Table 3.5-28). These ABC values are apportioned over the western, central and eastern GOA. The Plan Team has recommended that the eastern ABC values be further apportioned over the west Yakutat and the east Yakutat/southeast outside regions at 640 mt and 860 mt, respectively (Clausen *et al.* 2002).

The DSR assemblage includes seven species of rockfish: canary rockfish, China rockfish, copper rockfish, quillback rockfish, rosethorn rockfish, tiger rockfish, and yelloweye rockfish. The yelloweye rockfish is the dominant species in this assemblage. These species are managed jointly by the NOAA Fisheries and the State of Alaska as a distinct assemblage only off the SEO east of 140°W, an area that is further divided into four management units along the outer coast: the south SEO, central SEO, north SEO, and east Yakutat. Two internal state water subdistricts (north southeast Inside District and south southeast Inside District) are managed entirely by the state. Yelloweye rockfish comprise 90 percent of the catch and will be the focus of this section. DSR are highly valued, and a directed longline fishery is held for these species. However, yelloweye are the primary bycatch in the halibut fishery, and therefore a large portion of the TAC and ABC is set aside for bycatch.

DSR falls into Tier 4 of the ABC and OFL definitions. Under these definitions, the OFL mortality rate is $F_{35\%} = 0.028$ (540 mt), and the maximum allowable fishing mortality rate for ABC is $F_{40\%} = 0.025$. However, a more conservative approach has been taken for setting ABC and TAC. By applying $F = M = 0.02$ to yelloweye rockfish biomass, and adjusting for the 10 percent of other DSR species, the recommended 2003 ABC is 390 mt. The total exploitable biomass estimate for 2003 is 17,510 mt, a 10 percent increase from the 2002 estimate. Continued conservatism in managing this fishery is warranted given the life history of the species and the uncertainty of the biomass estimates (O'Connell *et al.* 2002).

Traditional abundance estimation methods (e.g., area-swept trawl surveys, mark recapture) are not considered useful for these fishes, given their distribution, life history, and physiology. However, the ADF&G is continuing research to develop and improve a stock assessment approach for them. As part of that research, a manned submersible, Research Vessel (R/V) *Delta*, has been used to conduct line transects (Burnham *et al.* 1980). Density estimates are limited to adult yelloweye, because it is the principal species targeted and caught in the fishery; therefore, ABC and TAC recommendations for the entire assemblage are keyed to adult yelloweye abundance. Total yelloweye rockfish biomass is estimated for each management subdistrict as the product of density, mean weight of adult yelloweye, and areal estimates of DSR habitat (O'Connell and

Carlile 1993). Both transect line lengths and total area of rocky habitat are difficult to estimate, resulting in some uncertainty in the biomass estimates.

GOA Rockfish Past/Present Effects Analysis

The past/present effects analysis for all species of GOA rockfish are presented in this section and in Table 3.5-38. Species-specific information in noted when applicable. The geographic scope for the rockfish past/present effects analysis is the same as the GOA management areas (Figure 1.2-3). The temporal scope for this analysis begins in 1962, when the foreign rockfish fisheries began and ends in 2002, the most recent year for which stock assessment information is available.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. The following direct and indirect effects were identified as potentially having population-level effects on GOA rockfish species:

- Mortality due to catch/bycatch and marine pollution and oil spills (direct effect).

- Change in reproductive success due to spatial/temporal concentration of catch/bycatch and climate changes and regime shifts (indirect effect).

- Change in prey availability due to climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

- Change in important habitat due to climate changes and regime shifts, marine pollution and oil spills and introduction of exotic species (indirect effect).

Section 3.2 contains brief explanations of all the FMP amendments that impact the target species. The following sections explain any management actions specific to GOA rockfish. Amendments discussed in Section 3.2 that impact the target fisheries as a whole are not repeated here.

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on rockfish in the GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the Pacific Northwest to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section 3.10.1.5 for documentation of occurrences of unusual species in the GOA as influenced by climate changes and regime shifts.

The past/present events determined to be applicable to GOA rockfish past/present effects analysis include the following:

- Past/Present External Effects
  - Foreign groundfish fisheries (1962-1976)
  - State of Alaska groundfish fisheries (DSR and some slope rockfish species, i.e. rougheye and yelloweye rockfish)

- IPHC longline fishery
- State of Alaska shrimp fisheries (pelagic and DSR and some slope rockfish species)
- State of Alaska herring fishery (DSR)
- Commercial whaling
- Marine pollution and oil spills
- Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (1976-1985)
  - JV groundfish fisheries (1980-1990)
  - Domestic groundfish fisheries (1981-present)

- Past/Present Management Actions
  - Bilateral agreements
  - Industry initiated actions
  - Foreign groundfish fishery initiated actions
  - Preliminary groundfish FMPs (pre-MSA)
  - FMP groundfish fisheries management

Mortality

External Foreign Groundfish Fisheries (1962-1976)

Foreign fisheries for rockfish (with the exception of the DSR fishery) began in 1962, with the Soviet and Japanese fisheries. These fisheries are the same as were targeting Pacific ocean perch. See Section 3.5.1.11 for more information.

Foreign fishery removals of GOA rockfish are found to have had an adverse effect on the GOA rockfish populations. Furthermore, due to the longevity of these species, the effects are determined to be lingering at the population-level.

External State of Alaska Directed Groundfish Fisheries

Slope Rockfish

Directed State of Alaska rockfish fisheries take place in PWS, Cook Inlet and the south Alaska Peninsula fisheries. In 1999, 31.3 mt of rockfish were taken from the PWS area of which approximately 42 percent were slope rockfish. The Cook Inlet and south Alaska fisheries tend to focus largely on black and blue rockfish that are now under the State of Alaska jurisdiction. Yelloweye rockfish (part of the demersal rockfish group) is also targeted in the PWS fishery. These fisheries operate under a 68 mt annual harvest cap and are bycatch-only when the directed fishery is closed (ADF&G 2000b).

Internal Joint Domestic and State of Alaska Southeast Groundfish Fisheries

Demersal Shelf Rockfish

The directed DSR fishery began in 1979 by a hook and line fishery in southeast Alaska. Fishing occurred within 110 m, near-shore and targeted the entire DSR complex. Today, the directed DSR fishery is conducted by longliners and focuses mostly on yelloweye rockfish within 75-150m.

Catch rates increased from 106 mt in southeast in 1982 to a peak of 803 mt in 1987. In 1993, catch exceeded 900 mt, but has since decreased to 183 mt in 2000. The lava fields off Cape Edgecumbe in the central southeast area and the offshore Fairweather Ground in the east Yakutat area are the most important fishing areas. A small amount of DSR are taken as bycatch in jig and troll fisheries. Trawling is prohibited in the eastern GOA (GOA FMP Amendment 58). Yelloweye rockfish is the dominant bycatch species in the halibut longline fishery. The majority of the longline vessels in the eastern GOA are unobserved so it is difficult to get an accurate accounting of discards at sea (O'Connell *et al.* 2002).

GOA FMP Amendment 14 separated out and protected DSR from the more general other rockfish category by establishing a central SEO with 600 mt OY for the complex. In the early 1980s, all *Sebastes* species other than Pacific ocean perch and four associated slope rockfish species were managed as other rockfish on a gulfwide basis, and yet a domestic fishery harvesting DSR in the southeastern area was expanding very rapidly by 1984. Yelloweye and quillback rockfish were the primary targets of this longline fishery. Other actions under this amendment 1) changed OYs for Pacific ocean perch and other rockfish, 2) established a mechanism for timely reporting of catches by domestic catcher processors that stayed at sea for long periods; and 3) implemented NOAA Fisheries habitat policy. In 1991, GOA FMP Amendment 21 modified the FMP language that allows DSR in southeast Alaska to be managed by the State of Alaska and modified the overfishing definition.

In 1998, an FMP amendment was passed by NPFMC requiring full retention of DSR. This amendment is still under review by NOAA Fisheries. In July of 2000, the State of Alaska enacted a regulation requiring full retention of DSR and requiring that they be reported on fish tickets. DSR in excess of legal sale limits are forfeited to the State of Alaska fishery fund. The new regulation has substantially increased the estimated amount of yelloweye rockfish landed.

Internal JV and Domestic Groundfish Fisheries (1980-present)

The JV fisheries began targeting rockfish in 1980 and were phased-out of the GOA by 1990 when the fishery became fully domesticated. The domestic rockfish fisheries began in 1981. Past effects on these rockfish are not well characterized, but generally consist of the foreign, JV and domestic fisheries. These fisheries are identified as having contributed to rockfish mortality and are found to have had a lingering adverse effect on the rockfish population.

Pelagic Shelf Rockfish

Catch data for PSR are only available from 1988-2001. Prior to 1988, PSR were managed as a larger aggregate rockfish group "other rockfish" in the GOA. Annual harvest rates of rockfish have been subject to variability mostly due to management action. From 1988-1992, catches generally increased; however, beginning in the early1990s, TACs became more restrictive. In recent years, area closures have created a decrease in catch, while preventing the PSR TAC from being exceeded or preventing excessive bycatch of Pacific ocean perch or Pacific halibut (Clausen *et al.* 2002).

In 1998, GOA FMP Amendment 46 removed black and blue rockfishes from the FMP to enhance their management by the State of Alaska by providing more responsive management and preventing localized overfishing of their stocks. Expansion of a fishery for these species in the central regulatory area in the mid-1990s was believed to possibly result in unsustainable black and blue rockfish catches. Two problems with federal management of black and blue rockfish were identified. First, the TAC for all PSR species was based on a triennial trawl survey. Survey catches are dominated (93 to 99 percent) by the under exploited dusky rockfish. This information led to the calculation of ABC levels for the PSR assemblage as a whole, but managers were concerned that the survey bias caused by dusky rockfish could result in an ABC that was inappropriate for less abundant black and blue rockfish stocks. The second problem with federal management was that the trawl survey samples only fish on or near a smooth bottom; most black and blue rockfish occur in rocky nearshore reef habitats that cannot be sampled by this survey.

Slope Rockfish

As in the BSAI, the Pacific ocean perch were highly sought by the Soviet Union and Japanese fisheries beginning in the early 1960s. Catch of Pacific ocean perch peaked in 1965 at 350,000 mt, followed by a continuous decline into the 1970s, reaching low catch of 8,000 mt in 1978. Commercial catch for slope rockfish was not reported separately until 1988; previously they were listed as part of the Pacific ocean perch complex. Foreign fisheries continued to dominate from 1977 to 1984, with Japan taking a majority of the catch. Catch reached a minimum in 1985 following a ban on foreign trawling in the GOA. The domestic fishery entered the slope rockfish fishery in 1985 and expanded until 1991 when restrictions were placed on the fishery that lowered the TAC of Pacific ocean perch stocks, established the management of the four slope rockfish subgroups, and closed fisheries to avoid exceeding TAC through the rockfish trawl fleet. Since 1996, catches of Pacific ocean perch have increased due to increases in TAC levels, although catch of northern rockfish has remained below TAC.

Current data (1992-2000) available from the Observer Program indicate that harlequin, sharpchin, redstripe, silvergrey, and yellowmouth rockfish are the predominant species in the other slope rockfish group caught in the commercial fishery. The data are based only on trips that had observers on board and may be biased towards larger vessels that had more complete observer coverage. A substantial increase in these five species occurred following the removal of northern rockfish from the other slope rockfish group, apparently since removing northern rockfish allowed for an expansion in the fishery for other species. However, from 1994 to 1998, estimated catch for these five species decreased, partly due to lower TACs established for the other slope rockfish group. Since 1998, the catch for these species has remained low. In the shortraker/rougheye rockfish group, shortraker rockfish has always dominated the commercial catch and also has a higher market value than rougheye rockfish (Heifetz *et al.* 2002).

Change in Reproductive Success

External Foreign Groundfish Fisheries (1960s-1976)

Slope Rockfish

Effects of the foreign fisheries on spatial/temporal distribution of slope rockfish due to the spatial/temporal concentration of the fisheries are identified as either adverse or unknown. When the past effect of the fishery is unknown, it is also unknown whether the effect could be lingering.

External Climate Changes and Regime Shifts

The combination of climate effects and regime shifts on prey availability and habitat suitability influence the reproductive success of species. Research on climate shifts as a forcing agent on species and community structure of the NPO can be found in Francis and Hare (1994), Klyashtorin (1998), McGowan *et al.* (1998), Hollowed *et al.* (1998), and Hare and Mantua (2000). See Section 3.10.1.5 for an indepth discussion of the various effects on climate changes and regime shifts on the NPO ecosystem.

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on the reproductive success of PSR. In general, stronger recruitment would be expected under more favorable climatic conditions because more juveniles would be likely to survive to adulthood, whereas harsh conditions would result in weak recruitment because fewer juveniles would survive. In both cases, the recruitment patterns would be reflected (although not perfectly) in the strength and weaknesses of the affected age groups within future fisheries (see Section 3.10.1.5).

Internal Joint Domestic and State of Alaska Southeast Groundfish Fisheries

Demersal Shelf Rockfish

Although management of this assemblage has been conservative, and overall the population appears stable, a decline in the density estimates in the Fairweather Grounds may be an indication that localized overfishing is occurring (Heifetz *et al.* 2002). The TAC for the eastern GOA is partitioned by management district based on biomass density and known habitat. The current harvest strategy indicates that 2 percent of the exploitable biomass is taken per year and that this level of exploitation is sustainable. However, fishing effort on the Fairweather Grounds appears to be concentrated in areas of best habitat and high density and it may be that local overfishing occurs. If occurring, such localized overfishing could have a long-term adverse effect on DSR stocks due to their longevity and slow growth rate (Heifetz *et al.* 2002). Rockfish stocks typically require long periods to recover from high fishing pressure.

Change in Prey Availability

External State of Alaska Shrimp Fisheries

Effects of State of Alaska shrimp fisheries on the prey availability of GOA rockfish (i.e. rougheye rockfish, dusky rockfish and other rockfish species) is potential adverse, however due to the localized nature of these fisheries, they are unlikely to have a population-level effect.

External State of Alaska Herring Fisheries

The State of Alaska herring fisheries effects on the prey availability of GOA DSR are identified as potential negative contributions, however due to the localized nature of these fisheries, they are unlikely to have a population-level effect.

External Commercial Whaling

The effects of commercial whaling increased the availability of euphausiid prey for northern rockfish (as part of the other slope rockfish complex) and some of the other rockfish species and is therefore noted as a potential beneficial effect.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability and prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

Research has not been done on the effects of climate on the benthic community (polychaete worms, clams, etc.), which constitutes part of the diet of some GOA rockfish species.

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important prey species of other rockfish.

Change in Important Habitat

External Foreign Groundfish Fisheries (1962-1976)

Statistics on the number of bottom trawls and their effects on GOA habitat pre-MSA is generally unknown. However, the impacts of foreign groundfish fishery gear on GOA rockfish habitat have been identified as negative effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

External State of Alaska Directed Groundfish Fisheries

Slope Rockfish

Statistics on the number of bottom trawls and their effects on GOA habitat pre-MSA is generally unknown. However, the impacts of JV and domestic groundfish fishery gear on DSR habitat have been identified as negative effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

External IPHC Longline Fishery

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The impacts of IPHC longline gear on GOA rockfish habitat have been identified as negative effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

External Climate Changes and Regime Shifts

The effects of climate changes and regime shifts are identified as potentially beneficial or adverse on habitat suitability and prey availability. For example, when the Aleutian Low is strong, water temperatures are higher, and biomass in the catches is dominated by cod, pollock and flatfishes. Community structure in nearshore areas around Kodiak Island changes in this same period with decreasing populations of shrimps and small forage fish, and increasing populations of large, fish-eating species, such as Pacific cod, and flatfishes (see Section 3.10.1.5). Since both ENSO and decadal-scale ecosystem shifts are environmentally controlled, the results of this analysis support environmental variance as an important controlling factor for the population (see Section 3.10.1.5).

External/Internal Marine Pollution and Oil Spills

It is unknown to what extent marine pollution and oil spills from vessels occur in the GOA and what effect these have on the important habitat of other rockfish.

Internal JV and Domestic Groundfish Fisheries (1980-present)

See Section 3.5.1.15 (GOA walleye pollock past/present effects: change in important habitat) for statistics on the number of bottom trawls occurring in these areas and also see Section 3.6.4 for a discussion of the potential impacts of fishery gear on habitat.

The impacts of JV and domestic groundfish fishery gear on rockfish habitat have been identified as adverse effects. Intense trawling is likely to have caused rockfish habitat degradation and disruption of rockfish spawning and/or rearing grounds. This effect is still lingering at the population-level.

Pelagic Shelf Rockfish

PSR are caught almost exclusively by bottom trawls. Light dusky rockfish are typically caught in relatively shallow (100-149 m) offshore banks of the continental shelf (Reuter 1999). They are found in large concentrations in the "W" grounds west of Yakutat, Portlock Bank northeast of Kodiak Island, and around Albatross Bank south of Kodiak Island. The trawlers that target Pacific ocean perch and northern rockfish typically target dusky rockfish, as well, fishing for dusky rockfish after they have filled their quota for the other two species. From 1988-1995, large factory trawlers took over 95 percent of the dusky rockfish catch; however, following 1996, smaller shore-based trawlers began taking larger portions of the PSR catch, taking 58 percent in 2001 in the central area (Clausen *et al.* 2002). HAPC biota bycatch analysis from 1997-1999 ranks the dusky rockfish trawl fisheries fourth among all fisheries in the amount of coral taken as bycatch and sixth in the amount of sponges taken. Research is being conducted to investigate the habitat associations of these species and any detrimental effect in trawl fisheries may have on their associated habitat (see Section 3.6).

GOA Rockfish Comparative Baseline

The Japan-U.S. cooperative survey and the NOAA Fisheries domestic longline survey are conducted on the continental slope of the GOA and provide data on the relative abundance of slope rockfish. Rougheye and shortraker rockfish are the primary species caught; however, caution should be taken when viewing data from both surveys since the analyses do not take into account possible effects of competition for hooks with other species caught on the longline (Heifetz *et al.* 2002).

Data from the Japan-U.S. cooperative survey for 1979-1987 indicate that the abundance of rougheye and shortraker rockfish remained stable in the GOA for those years (Sasaki and Teshima 1988, Clausen and Heifetz 1989). Data also suggest that rougheye and shortraker rougheye are most abundant in the eastern GOA. Domestic longline survey data from 1988-2002 show fluctuations in relative population numbers and relative population weight for shortraker and rougheye rockfish. However, the five highest annual gulfwide relative population numbers and relative population weights for shortraker and rougheye rockfish were seen in the most recent five surveys (1997-2001). This survey also shows the highest abundance of shortraker/rougheye rockfish in the eastern GOA with the Yakutat area having the highest relative population number and relative population weight values for shortraker rockfish and the southeastern area with the best rougheye rockfish values. Relative population numbers and relative population weights for rougheye and shortraker rockfish are slightly lower relative to 2001 estimates (Heifetz *et al.* 2002).

Triennial trawl surveys have been conducted in the GOA since 1984, and are now conducted biennially starting in 2001. The 2001 trawl survey did not survey the eastern GOA, therefore biomass estimates for that area are based on an average of 1993, 1996 and 1999 biomass estimates. The 2001 trawl survey indicates that Pacific ocean perch was the most abundant species with an estimated biomass of 858,982 mt, 61.9 percent of the total slope rockfish biomass. Northern rockfish comprised 25.6 percent of the total biomass. Other slope rockfish were poorly represented since the eastern GOA was not sampled, the area where a large percentage of the other slope rockfish species are located. The 2001 biomass estimates for Pacific ocean perch and northern rockfish are greatly influenced by large catches in one or two hauls, resulting in higher variance of biomass for both species (Heifetz *et al.* 2002).

When comparing the trawl surveys from 1984-2001, high variability in biomass estimates can be seen in nearly all species. Of the other slope species, biomass estimates for rougheye rockfish have been most consistent. Northern rockfish biomass estimates were relatively stable from 1987-1996, however underwent a large increase in population in 1999 and 2001. Biomass estimates for silvergrey rockfish steadily increased from 1984-1999. Variance in biomass estimates is attributed to anomalously large individual hauls (as in 1999 and 2001), and change in availability of rockfish to the survey caused by unknown behavioral or environmental factors. Causes of changes in biomass estimates can not be determined until more is known about rockfish behavior (Heifetz *et al.* 2002).

Comparative biomass estimates over the past seven triennial surveys show that dusky rockfish abundance varies. Total biomass increased from 1984 to 1987 and dropped 50 percent by 1990. Abundance again increased in 1993 and 1996, but has since decreased. None of the changes in biomass are statistically significant and may be attributed to changes in the availability of rockfish to survey gear or the imprecision of sampling methods for these species. In 2001, the eastern GOA was not sampled; therefore, 2001 eastern GOA biomass estimates are based on an average of the 1993, 1996, and 1999 estimates for each species in each region. Light dusky rockfish appear to dominate the PSR assemblage from 1996 to 1999; however, a large biomass of yellowtail rockfish was also seen in the southeastern area in 1999. The Kodiak area shows the highest biomass of dusky rockfish in all survey years (except 1984) and the southeastern area has shown the lowest biomass (except 1999) (Clausen *et al.* 2002).

Current exploitable biomass is based on the average of the three most recent surveys (1996, 1999, and 2001). This equates to 62,489 mt for the PSR assemblage, 56,336 mt for dusky rockfish and 6,153 for widow and yellowtail rockfish (Clausen *et al.* 2002).

Survey age compositions are available from the 1984, 1987, 1990, 1993, 1996, and 1999 surveys, and these show that recruitment of dusky rockfish appears to be highly variable. In 1999, aged 12-13 (1986-1987 year-classes) are most prominent. Fish under age-10 make up a much smaller portion of the population.

Biomass of adult yelloweye rockfish is derived as a product of estimated density, estimated rocky habitat within the 200 m contour, and average weight of fish for each management area. Estimation of the line length for the transects used in the submersible survey and the total area of rocky habitat is difficult; therefore, there is uncertainty in the biomass estimates. Only the north SEO section was surveyed during 2001, and only six transects were run due to poor weather. Consequently, the distance sampling model did not fit the data well. The density estimate for these data was 1,420 adult yelloweye/km^2. This is a 40 percent increase over the 1994 survey data and is more similar to the density estimates from the rest of the SEO region (O'Connell *et al.* 2002).

The age and size distributions of yelloweye rockfish are discussed in O'Connell *et al.* (2001) and O'Connell and Funk (1987). Estimated length and age at 50 percent maturity for yelloweye collected in the central SEO in 1988 are 45 cm and 21 years for females and 50 cm and 23 years for males. The most recent age data is from the 2000 commercial catch samples. In the central SEO, the area with the longest catch history, 2001 age data depicts the average age at 36 years. The older ages have declined in frequency over time, and the average age continues to decline over time. In the south SEO, the 2001 age data shows is bimodal, strongly at 23 and weaker at 44-45 years. In east Yakutat District, the 2001 age distribution is somewhat bimodal, with the largest mode is at 32-34 years, and a smaller mode at 44-45, with a mean age of 42 years. The maximum age recorded for 2001 was 110 years in the east Yakutat and central SEO (O'Connell *et al.* 2002).

An August 1998 sidescan sonar survey was conducted in Fairweather Ground to determine the gross bottom type. In the 1997 survey, the estimate total area of rocky habitat of the Fairweather Ground was reduced from 1,132 km^2 to 448 km^2. Although the 1998 survey did not cover the entire Fairweather area, by comparing techniques, the rock habitat of the east Yakutat area was reestimated at 617 km^2. Estimates of rock habitat in the SEO were also revised, down 46 percent overall to 3,095 km^2. Estimates are likely to continue to change as further information is gathered. Total exploitable biomass for 2003 equates to 17,510 mt, a slight increase from the 2002 estimate due to the addition of average weight data and revised estimates of the area of yelloweye habitat (O'Connel *et al.* 2002).

GOA Rockfish Cumulative Effects Analysis Status

The GOA northern rockfish, shortraker/rougheye rockfish, other slope rockfish, PSR DSR will be brought forward separately for the cumulative effects analysis.

3.5.2 Prohibited Species

Retention of prohibited species is forbidden in the BSAI and GOA groundfish fisheries. These species were typically utilized in domestic fisheries prior to the passage of the MSA in 1976. Retention was prohibited in the foreign, joint venture, and domestic groundfish fisheries to eliminate any incentive that groundfish fishermen might otherwise have to target these species. The prohibited species include:

- Pacific halibut (*Hippoglossus stenolepis*).
- Pacific salmon and Steelhead trout (*Oncorhynchus mykiss*).
- Pacific herring (*Clupea pallasi*).
- Red king crab (*Paralithodes camtschaticus*), blue king crab (*P. Platypus*), golden or brown king crab (*Lithodes aequispinus*), bairdi Tanner crabs (*Chionoecetes bairdi*), and opilio Tanner crabs (*C. opilio)*.

3.5.2.1 Pacific Halibut

The geographic scope for the Pacific halibut past/present effects analysis is the same as the IPHC regulatory areas. The temporal scope for this analysis begins in 1910 when the commercial Pacific halibut fishery started in southeast Alaska and ends in 2001.

Life History and Distribution

Pacific halibut range from Santa Barbara, California to Nome, Alaska, along the North American Pacific coastline. Pacific halibut are considered to be a single stock from the Pacific west coast to the Bering Sea. During the summer Pacific halibut are found along the northeast continental shelf, with a patchy distribution at the northern and southern ends of the range (IPHC 1998). Males can grow to exceed 36 kg and can live up to 27 years, and females can grow to over 225 kg and can live up to 42 years.

Adults make seasonal migrations from the summer feeding grounds on the continental shelf to deeper spawning grounds. Spawning takes place from December through February. Most spawning takes place off the continental shelf edge at depths of 400 to 600 m. Male halibut become sexually mature at 7 or 8 years of age, females mature at 8 to 12 years. The number of eggs a female produces is related to its size. Females over 113 kg may produce up to 4 million eggs annually (IPHC 1998). Fertilized eggs float free for about 15 days before hatching; the larvae and postlarvae drift westward on the prevailing currents for up to another six months. The currents eventually carry the young halibut to shallower waters that serve as nursery grounds (IPHC 1998).

Juvenile halibut spend five to seven years in shallow water nursery grounds before beginning a migration to "home areas." The migration of halibut from their western nursery grounds to home areas appears to be a unidirectional clockwise movement (IPHC 1998). Juvenile halibut marked in the northern GOA have been recovered after migration in the northern GOA and to the south, but rarely from the western GOA or BSAI. Similarly, juvenile halibut marked in British Columbia waters are typically recovered in the British Columbia area or farther south, and very rarely in Alaskan waters (IPHC 1998). It is not known if returning juveniles are the descendants of spawners of a given home area (IPHC 1998).

Trophic Interactions

Halibut are strong swimming apex predators. The diet of Pacific halibut varies with size. Halibut feed on plankton in their larval stage (IPHC 1998). Halibut less than 30 cm are known to feed on hermit crabs (pagurids), small shrimp-like organisms, and small fish (Yang and Nelson 2000, IPHC 1998). Fish become a larger component of the diet as halibut increase in size. Species frequently observed in the stomachs of halibut >50 cm include capelin, Pacific sand lance, eulachon, cod, Pacific salmon, sole species, sablefish, pollock, rockfish, flatfish species (including juvenile Pacific halibut), poachers (agonids), pricklebacks (stichaeids), eelpouts (zoarcids), and sculpins (cottids); and in addition octopi, crabs, clams, and other crustaceans (Yang and Nelson 2000, IPHC 1998).

Due to their size, active nature, and bottom dwelling habit, there are few predators of Pacific halibut aside from humans (IPHC 1998). Occasionally, conflicts have arisen between human predators and marine mammals, which have been observed foraging on halibut hooked on longlines (Bell 1981).

Pacific Halibut Management

Pacific halibut fisheries are managed by the IPHC, a treaty between the U.S. and Canada. The IPHC management process and stock assessments take all removals into account (bycatch in the federal and state groundfish fisheries and catch in the IPHC regulated commercial, subsistence, and sport fisheries) when issuing halibut allocations to the directed halibut fisheries. In addition, migration rates of juvenile halibut are used in concert with bycatch information for the groundfish fisheries to estimate appropriate yield reductions for the directed halibut fishery in each IPHC management area (Clark and Hare 1998).

Bycatch Management in the Federal Groundfish Fisheries

In addition to designating salmon, crab, herring, and halibut as prohibited species, NOAA Fisheries annually sets PSC limits under 50 CFR 679.21 through the annual TAC-setting process. PSC limits are further allocated to fishery categories, gear groups, or seasons to create more refined PSC limits.

Groundfish fishery PSC rates are calculated by dividing the sum of the weights or counts of PSC in a set of observer data by the sum of the weight of groundfish in the dataset. For rates from observed vessels that will be applied to unobserved vessels, a minimum of three different weekly observer reports is required before an average rate is used. For some rates, this threshold is set at a higher number of reports. This process is discussed in detail in Appendix B.

NOAA Fisheries monitor PSC limits for the general and CDQ groundfish fisheries using PSC rate estimates. Reaching a PSC limit can result in closure of an area or a fishery season, even if the groundfish quota (e.g., TAC) remains unharvested. When it is determined that a PSC limit will be reached, NOAA Fisheries publishes a notice in the *Federal Register* closing the associated area or fishery. Bycatch of Pacific halibut constrains the groundfish fisheries in both the BSAI and GOA, preventing the TAC of many groundfish target species from being harvested.

Past/Present Effects Analysis

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-40 provides a summary of the Pacific halibut past effects analysis presented below.

Nutritional stress due to the catch/bycatch of prey species was not brought forward for analysis because halibut have flexible feeding habits. Pacific halibut are apex feeders that can respond to short-term localized shortages of one prey species by substituting another.

The following direct and indirect effects were identified as potentially having population-level effects on Pacific halibut:

- Mortality due to catch/bycatch (direct effect).
- Spawning disruption due to fishing in spawning habitat (indirect effect).
- Reduced recruitment due to spatial/temporal concentration of catch/bycatch (indirect effect).

The past/present events determined to be applicable to the Pacific halibut past effects analysis include the following:

- Past/Present External Events
  - IPHC regulated Pacific halibut fishery
  - Foreign fisheries (pre-MSA)
  - Decadal oscillations
- Past/Present Internal Events
  - Foreign fisheries (post-MSA)
  - JV fisheries
  - Domestic fisheries
- Past/Present Management Actions
  - IPHC fisheries management
  - Industry initiated actions
  - FMP groundfish fisheries management

Past/Present Events and Management Actions

External Mortality- Catch in the IPHC Regulated Pacific Halibut Fishery

Pre-World War I fisheries targeting halibut in the North Pacific were relatively small. Market demand for halibut began to grow once technology was developed to ice and preserve the catch. Fishermen began to explore for Pacific halibut resources, and a small GOA halibut fishery began in 1910. The fishery rapidly expanded both north and south and into offshore waters. Early in the fishery, the stock of Pacific halibut was recognized as being rapidly reduced in areas that had been consistently fished (IPHC 1948).

The U.S. and Canada began discussing international management of halibut in 1913. Conservation of the stocks was not a major consideration until annual landings declined in 1915 despite increase in exploitation of new fishing grounds (IPHC 1948). By 1923, a halibut conservation treaty ratified and established an International Fisheries Commission with limited regulatory powers. The Commission engaged a staff to begin practical scientific investigations of Pacific halibut biology, stock status, and the fishery. The initial results of these investigations indicated that landings were only being maintained by constant increases in fishing intensity (IPHC 1948). The treaty was renegotiated during subsequent years granting the Commission increased regulatory power over the fishery. The regulations governing the Pacific halibut fishery, guided by scientific programs and investigations, stopped the decline of the fishery and allowed for the rebuilding of Pacific halibut stocks.

The halibut fleet remained relatively stable until the 1970s when the Pacific halibut fleet dramatically increased in size due to the rise in halibut price, declining crab stocks, and limited entry salmon fisheries (Coughenower and Blood 1997). By the late 1980s the fishing season had decreased from a five-month season in 1970 to just two 24- to 48-hour openings (Coughenower and Blood 1997).

External Mortality: Bycatch in the pre-MSA Foreign Fisheries

Pacific halibut bycatch mortality in the groundfish fisheries was relatively low until the 1960s when it increased due the development of the foreign fisheries (Williams 2001; see Appendix B for details on the development of the foreign fisheries.) Total bycatch mortality for IPHC regulatory areas:

- Peaked in 1965 at approximately 21 million pounds.
- Decreased in the late 1960s to approximately 15 million pounds.
- Increased to approximately 20 million pounds by the early 1970s.
- Decreased through the late 1970s with an increase to approximately 18 million pounds in 1980.

A detailed discussion of U.S. fisheries management prior to the MSA is presented in Appendix B and summarized in Table 3.5-40. The U.S. had virtually no authority to impose regulations beyond its territorial sea (3 miles prior to 1966, then expanded to 12 miles by public law) and relied primarily on multilateral and bilateral international agreements. Japan instituted some conservation and management measures independently, including a LLP and area restrictions to ease U.S. and Canadian concerns about the Japanese trawl fisheries impact on Pacific halibut (Appendix B).

Internal Mortality: Bycatch in the Post-MSA Groundfish Fisheries

By 1985, the JV operations and growing U.S. domestic fleet had entered the scene and continued the harvest of groundfish species. Federal groundfish fisheries have been prosecuted by an all-domestic fleet since 1987 in the GOA and 1991 in the BSAI. Bycatch of Pacific halibut is associated with all historical groundfish fisheries to varying degrees. The majority of the Pacific halibut bycatch was taken in the Bering Sea foreign and JV groundfish fisheries in the 1980s (Clark and Hare 1998). By 1985, Pacific halibut bycatch mortality had declined to 7.2 million pounds, the lowest level since the IPHC began its monitoring, and peaked again at 20.3 million pounds in 1992 (Williams 2001). The estimate of Pacific halibut bycatch mortality in 2002 of 12.7 million pounds is the lowest seen since 1987 but is consistent with estimates for the past several years (Williams 2002, Williams 2003). Bycatch mortality of legal-sized halibut (80+cm) was 6.73 million pounds in 2001, which remains consistent with the bycatch mortality of legal-sized halibut reported annually since 1995 (Clark and Hare 2002).

The bycatch of Pacific halibut in the groundfish fisheries decreases the amount that can be taken by fishermen in the directed IPHC fishery. Figure 3.5-6 shows Pacific halibut bycatch by area and gear from 1998-2001 (Hiatt *et al.* 2002). Bycatch has been controlled by FMP management measures, but not without cost to groundfish fisheries. In particular, Pacific halibut bycatch management measures have constrained groundfish harvests. Typically, all Pacific halibut bycatch mortality (4,665 mt) allocated to trawl and longline fisheries is taken, along with lesser amounts from pot fisheries and fisheries within Alaska state waters (Williams 1997). Longline fisheries have also been constrained by Pacific halibut bycatch, and careful release requirements have been implemented to improve survival of halibut discards (Smith 1995). Implementation of an IFQ system for Pacific halibut and sablefish longline fisheries in 1995 allowed for more selective longline fisheries with lower bycatch (Adams 1995). An indirect effect of changes in fishery scheduling and fishing ground closures to protect Steller sea lion has been a further reduction of halibut bycatch (Williams 2001).

Reducing halibut bycatch has also been the objective of numerous industry-initiated proposals in recent years. Several trawlers voluntarily use bycatch reduction devices in their nets to release incidentally caught halibut with minimal harm, and testing of these devices is ongoing.

External Spawning Disruption

The early directed Pacific halibut fisheries took place year-round. Pacific halibut caught during spawning season were of poor quality (IPHC 1948). A winter season fishery closure was proposed as a result of the 1913 U.S. and Canada discussions on international halibut management. This closure was proposed in order to eliminate a period of dangerous fishing when poor quality fish were caught and to provide a time frame for sales of accumulated frozen fish inventories (IPHC 1948). The Commission established the proposed three-month winter closed season in 1923.

Internal Spawning Disruption: Post-MSA Groundfish Fisheries

Pacific halibut spawn in very deep waters (400 to 600 m) off the continental shelf edge, and most bottom trawl groundfish fisheries take place in shallower areas of the continental shelf. Most bottom trawl groundfish fisheries occur between March and November, while Pacific halibut spawning takes place from December through February . The largest major spawning ground identified by IPHC is off Yakutat and is currently closed to all groundfish trawling. Typically, the IPHC halibut fishery closes annually from November 16 to March 15 to protect spawning halibut.

External/Internal Reduced Recruitment: Spatial/Temporal Concentration of Bycatch

Alaska groundfish fisheries take the majority (more than 90 percent) of Pacific halibut bycatch (Clark and Hare 1998). Bycatch contains both adult (> 81 cm) and juvenile fish (< 81 cm). Juveniles may or may not have completed their migrations from the nursery ground to home areas. Their capture has the potential effect of reducing recruitment to adult stock in the home area to which they would have migrated (Clark and Hare 1998). Adult fish caught as bycatch have completed their migration back to home areas. Therefore, bycatch of adult fish can be expected to affect only the stock in the area where the bycatch is taken (Clark and Hare 1998). Approximately 50 to 60 percent of Pacific halibut bycatch is below the directed fishery size limit of 81 cm, with differences in bycatch by gear type. The projected halibut bycatch in each major gear type is assumed to follow the general pattern observed from 1997 to 1999 (Figure 3.5-7). While there are more data from the BSAI than the GOA, bottom trawls generally appear to catch a higher proportion of smaller halibut than longlines in both areas.

External Reduced Recruitment: Decadal Oscillations

Climate variability can have both beneficial and adverse effects on Pacific halibut stocks. Positive Pacific Decadal Oscillations are currently thought to enhance the recruitment of Pacific halibut which spawn and rear mainly in Alaska waters (Clark and Hare 2001, see Section 3.3.4 of this Programmatic SEIS for a discussion of decadal oscillations). An analysis conducted by Clark and Hare (2001) indicated that Pacific halibut recruitment is strongly influenced by climatic regime and weather in the year of spawning. The importance of environmental conditions in the year of spawning suggests that regulation of year-class strength occurs in that year. The dependence could be either on available transport of eggs and larvae to nursery grounds by ocean currents, or on planktonic production that varies strongly with climate and weather (Clark and Hare 2001).

Pacific Halibut Comparative Baseline

The assessment of the Pacific halibut stock status was revised in 1996 due to the observed changes in individual growth rates that affected fishing selectivity by gear. The new analyses showed that the exploitable portion of the Pacific halibut stocks apparently peaked at 326,520 mt in 1988 (Sullivan and Parma 1998). The population has since declined slightly and has maintained a biomass in the range of 270,000 to 277,000 mt. The long-term average reproductive biomass for the Pacific halibut resource was estimated at 118,000 mt (Parma 1998). Long-term average yield was estimated at 26,980 mt, round weight (Parma 1998).

Average catches from 1995 to 1999 were 29,325 mt for the U.S. and 6,935 mt for Canada, for a combined total of 36,260 mt for the entire Pacific halibut resource. This catch was 34 percent higher than long-term potential yield, which reflects the good condition of the Pacific halibut resource. The 1999 coastwide catch totaled 58,026 mt (round weight). The breakdown by fishery was: commercial fisheries, 43,270 mt, or 75 percent; recreational fisheries, 5,502 mt (9 percent); personal use, 440 mt (1 percent); bycatch in other fisheries, 7,779 mt (13 percent); and wasted mortality due to fishing by lost gear and discards, 1,035 mt (2 percent). The 2002 commercial catch totaled 33,748 mt (net weight). Removals of Pacific halibut for 2002 totaled 44,453 mt (net weight), similar to annual removals for the past six years. The breakdown by fishery is as follows: commercial catch, 33,748 mt (76 percent); sport catch, 3,946 mt (9 percent); incidental bycatch mortality, 5,806 mt (13 percent); personal use, 363 mt (1 percent); and wastage, 726 mt (2 percent) (Gilroy 2003). At its 2003 annual meeting, the IPHC recommended commercial catch limits totaling 33,975 mt for the 2003 U.S. and Canadian commercial catch which is identical to the catch limits put in place for 2002 (IPHC 2003).

Pacific halibut have shown a decrease in size at age over time, with fish today weighing approximately a third of what fish of the same age weighed 20 years ago (Clark and Hare 2001). It is currently hypothesized that this change may be due to a density dependent factor, and not to removal of prey by groundfish fisheries (Clark *et al.* 1999). It is not yet clear how Pacific halibut density affects growth. However, it has been widely observed that flatfish growth rates tend to increase under exploitation (Clark and Hare 2001).

The nature of the Pacific halibut commercial fisheries has changed in recent years. Both Canadian and U.S. fisheries have moved from an open access fishery with short fishing seasons to an IFQ fishery that lasts eight months each year. In addition, quota allocations have been implemented for Native American treaty, commercial, and recreational fisheries for waters from Washington to California. With closer management of quota allocations, an overall decrease in fleet size has occurred. Vessels licensed to fish in Canada remained at 435, while 1,850 vessels fished in the U.S. fisheries in 1999, a reduction from 3,400 vessels in 1993.

Currently the Pacific halibut resource is considered to be healthy, and the total catch has been near record levels. It is inferred that any direct or indirect effects of bycatch on Pacific halibut in past groundfish fisheries were taken into account under the IPHC management process and mitigated by the numerous BSAI and GOA FMP management measures to reduce bycatch in the federal groundfish fisheries.

Pacific Halibut Cumulative Effects Analysis Status

FMP 2.1 proposes to eliminate the groundfish fishery PSC limits. This in itself might not affect Pacific halibut biomass since the IPHC takes into account the groundfish fishery bycatch as part of their management process. However, if bycatch increased, it would lower the IPHC catch limit and could impose an economic hardship in the directed fishery. Therefore, Pacific halibut will be carried forward for the proposed alternative cumulative effects analysis.

3.5.2.2 Pacific Salmon and Steelhead Trout

Five species of Pacific salmon , pink *(Oncorhynchus gorbuscha)*, chum *(O. keta)*, sockeye *(O. nerka)*, coho *(O. kisutch)*, and chinook salmon *(O. tshawytscha)*, as well as steelhead trout (*O. mykiss*) occur in Alaska. With some important variations, all species have a similar appearance and anadromous life history. Salmon spawn in freshwater and during the fall their eggs incubate, hatch, and go through several developmental stages taking several months to several years depending on species, then migrate to the ocean as fry or smolt. The young salmon feed and grow to maturity in saltwater, ranging widely over the North Pacific Ocean and Bering Sea. They return to freshwater, often migrating tremendous distances to reach their natal streams where they spawn. This adaptation to spawning in freshwater has resulted in the tremendous seasonal abundance of spawning salmon, that is easily harvested, and has sustained human populations for millennia. Adult salmon do not compete directly with juveniles for the food resources found in freshwater environments. Carcasses left in the streams after spawning fertilize the freshwater environment, ultimately providing food for the developing young.

No stocks of Pacific salmon originating from freshwater habitat in Alaska are listed under the ESA. The ESA- listed species that migrate into marine waters off Alaska originate in freshwater habitat in Washington, Oregon, Idaho, and California. Threatened and endangered salmon species are discussed in further detail in Section 3.4.2 of this Programmatic SEIS.

Steelhead trout populations are generally stable throughout Alaska. No commercial fishery is held for steelhead trout. Steelhead trout are very rarely taken in GOA groundfish fisheries; no catch was observed in the GOA groundfish fisheries between 1997 and 1999. Most incidentally caught steelhead are taken in the commercial salmon fisheries where the state requires that steelhead be treated as a prohibited species and released (ADF&G 1998). Steelhead are managed by the state exclusively as a recreational sport fish. Steelhead trout will not be analyzed in this document due to their rare occurrence in the BSAI groundfish fisheries.

NOAA Fisheries group salmon species into two categories: chinook salmon and other salmon. The other salmon category includes chum, pink, coho, and sockeye salmon species. The analysis in this section will follow this practice.

Pacific Salmon Life History and Distribution

<u>Chinook Salmon</u>

These are the largest salmon, often exceeding 14 kg. The largest sport-caught chinook salmon was a 44-kg fish taken from the Kenai River. Some chinook salmon outmigrate to the ocean soon after hatching in late winter or early spring (ocean-type), while others remain in freshwater for over one year before outmigrating to the ocean as smolts (stream-type). Chinook salmon become sexually mature in 2 to 7 years; females tend to be older than males at maturity. Fish in any spawning run vary greatly in size; a mature three-year-old will weigh less than 2 kg, while a mature seven-year-old may exceed 23 kg. Chinook salmon often make extensive freshwater migrations to their natal steams in some of the larger river systems. Yukon River chinook salmon bound for the headwaters in the Yukon Territory, Canada, and will travel more than 2,000 miles in 60 days (Groot and Margolis 1991).

Chinook salmon occur from California through the North Pacific Ocean, Bering, and Chukchi seas, to the Anadyr River in Siberia and Hokkaido, Japan. Marine distribution data indicate that stream-type chinook move offshore early in their ocean life and maintain a mostly offshore distribution throughout their ocean life (some stream-type chinook are found in coastal waters). The reverse is found for the ocean-type chinook, which are more common in coastal waters and less common in offshore waters (Healey 1991). Only stream-type chinook occur in Asia and western Alaska.

Information on the oceanic distribution of chinook salmon in relation to their area of origin comes from two sources: tagging studies and analysis of scale patterns. Neither source provides an adequate picture of oceanic distribution for many chinook stocks. Oceanic distribution of Asian and Alaskan stream-type chinook is not clearly defined; however, some general ideas have been put forth. Asian stream-type chinook are likely distributed throughout the BSAI , but concentrated west of 180°W. In the North Pacific Ocean, the Asian stocks appear to be distributed as far east as 175°W. Their southern distribution limit is not known (Healey 1991).

Western Alaska and Canadian Yukon stream-type chinook are distributed throughout the Bering Sea, probably with higher concentrations in the central and eastern areas. Western Alaskan chinook also travel into the North Pacific south of the Aleutian Islands, but the limits of their distribution are not known. Central Alaskan chinook are also thought to be widely distributed in the central and western North Pacific as well as in the Bering Sea. Chinook stocks from southeastern Alaskan/British Columbia, as well as those from Washington, Oregon, and California, are rare in the Bering Sea and western North Pacific. Their main oceanic distribution is thought to be in the eastern North Pacific, with the greatest concentrations occurring over the continental shelf waters (Healey 1991).

Chum Salmon

Chum salmon are the second largest of the Pacific salmon after chinook salmon. Chum salmon are the most important commercial and subsistence species in Alaska's arctic, northwest, and interior. Chum salmon vary in size from 2 to over 13 kg, but usually range from 3 to 8 kg, with females usually smaller than males. Chum salmon spend little time in freshwater as juveniles, and are therefore thought to be more affected during the juvenile stage by estuarine and marine conditions than by freshwater conditions relative to other salmon species. Chum salmon generally return to freshwater to spawn after 3 to 5 years at sea (Johnson *et al.* 1997).

Chum salmon have the widest distribution, ranging from California to Japan. In the Arctic Ocean, they range from the Mackenzie River in Canada to the Lena River in Siberia. Research conducted by the North Pacific Fisheries Commission has contributed to the understanding of chum salmon distribution during the high-seas phase of their life. At-sea migrations of Asian and North American immature chum salmon overlap in the North Pacific Ocean during the winter, but the salmon appear to migrate independently in the following spring and summer (Salo 1991). The known winter distribution of Asian age-1 chum salmon extends as far east as the central Aleutian Islands. Western Alaskan chum salmon, by comparison, leave the Bering Sea to join North American immatures from more southerly locations in the GOA. Western Alaska chum salmon are not thought to re-enter the Bering Sea prior to returning as mature fish (Salo 1991). There is evidence that immature Asian chum salmon from the northwestern Bering Sea also migrate to the GOA. By age-2 there is a more pronounced intermingling between the Asian and North American chum salmon. The Asian stock moves eastward and southeastward into the northeastern Pacific Ocean, and the North American stocks move to the north and west from the GOA region (Salo 1991).

Maturing chum salmon are widely distributed in the GOA and in the northeastern Pacific Ocean along the Aleutian Islands. The formation of aggregations for inshore movement to spawning grounds is not well understood. Typically Asian stocks with extensive distances to travel begin their spawning migration into the Bering Sea in April and May. Asian chum continue to migrate from the North Pacific Ocean in a northwestern pattern into the Bering Sea through June (Salo 1991). Maturing Alaskan chum salmon begin their homeward migrations from June through July. Western chum salmon begin their migrations from as far east as the British Columbia coast and as far west as the central Aleutian Islands. Typically their spawning migrations through the Aleutian passes begin in June and peak in July. GOA chum stock begin their homeward migrations from May to July.

Pink Salmon

Pink salmon are the smallest salmon species; adults average 1.6 to 2 kg with an average length of 50 to 65 cm. In Alaska, adult pink salmon enter spawning steams between June and mid-October. Most pink salmon spawn within a few miles of the coast, and spawning within the intertidal zone or stream terminuses is very common. The female carries 1,500 to 2,000 eggs and digs a nest, or redd, with her tail and releases the eggs into the nest. Eggs are immediately fertilized by one or more males. After spawning, both males and females die, usually within two weeks. The eggs hatch sometime in early to midwinter. In late winter or spring, the fry emerge from the gravel and quickly migrate to the ocean, usually during the darkness (Groot and Margolis 1991). Pink salmon grow rapidly while at sea, with mature fish typically returning to spawning areas after 18 months (Heard 1991). Pink salmon have a fixed two-year life span. Therefore, pink salmon spawning in the same freshwater system are reproductively isolated during even and odd years, developing into different genetic lines (Heard 1991).

Pink salmon occur from northern California to Russia and Korea and are the most common species in Alaska. Large spawning populations of pink salmon occur in southeastern, central, and western Alaskan coastal waters. Smaller concentrations of pink salmon occur north of the Bering Strait, in the Chukchi Sea coast, and along the Beaufort Sea coast (Heard 1991).

Coho Salmon

Adults average between 3.6 and 5.4 kg, but may reach as much as 13.6 kg. Spawning coho enter freshwater from July to November. The fry remain in the gravel, feeding on the yolk sac until they emerge in May or June. Coho spend from one to five years in freshwater streams and lakes before migrating to the sea. The amount of time spent at sea varies greatly, but most coho spend 18 months feeding and growing before returning as full-size adults (Groot and Margolis 1991).

Coho salmon occur from California through the North Pacific Ocean and southern Bering Sea to Siberia, Japan, and Korea. In the spring and early summer, Asian coho are generally distributed in the southern part of the western Pacific Ocean (Sandercock 1991). As water temperatures warm during the summer months, Asian coho move progressively northward throughout the North Pacific Ocean and the Bering Sea (Sandercock 1991). The known eastern limit of Asian coho distribution is about 177°W and 45°N. Asian and North American coho stocks intermingle near the end of the Aleutian chain. The known western limit of Alaskan coho is 177°30'E and 44°30'N. Immature Alaskan coho from streams along the EBS begin to migrate south to the Aleutian Islands and some into the GOA when temperatures begin to decline in late summer. When temperatures begin to increase in the spring, coho from the Bering Sea tributaries begin their migration northward to their spawning streams (Sandercock 1991).

Sockeye Salmon

Sockeye are the most important commercial species in Alaska. Adults average from 2 to 3.6 kg. After hatching, juvenile sockeye may spend one to four years in freshwater before migrating to the ocean as smolt, weighing only about 5 g. Sockeye grow quickly and spend one to four years feeding and growing to maturity in the ocean before returning to spawn. Those fish returning to spawn after only one year in the ocean—called jacks—are almost all males. Although sexually mature, they are much smaller in size (often less than 25 cm in length and 250 g in weight) than adult males that have spent several more years feeding in the ocean. Jacks are also common in chinook and coho salmon populations (Groot and Margolis 1991).

Sockeye salmon occur widely through the North Pacific Ocean and the Bering and Chukchi seas, from California to northern Hokkaido in the Pacific, and from Bathurst Inlet in Canada to the Anadyr River in Siberia. Asian and North American sockeye distributions in the North Pacific Ocean and Bering Sea have broad areas of overlap. Asian sockeye distribution bounds are generally west of 175°W (Burgner 1991). The bounds of North American sockeye, particularly western Alaskan stocks, are found in the North Pacific Ocean to 160°E and in the Bering Sea they are found to 170°E (Burgner 1991). The center of abundance for Asian stocks is generally west of 175°E, and the North American stocks are concentrated east of this longitude (Burgner 1991).

Pacific Salmon Trophic Interactions

The composition of prey for salmon species depends on life stage, availability, and relative abundance of prey, which vary with season and location. Chinook salmon feed on small fish (particularly herring), pelagic amphipods, and crab megalopa, with fish being the largest single contributor to their diet (Healey 1991). Chum salmon diets are composed of amphipod, euphausiid, pteropod, copepod, fish, and squid larvae (Salo 1991). Pink salmon are opportunistic and generalized feeders and are known to feed on epibenthic harpacticoid copepods, pelagic copepods, barnacle nauplii, mysids, eggs of invertebrates and fishes, and fish larvae (Heard 1991). Coho salmon are also opportunistic feeders with diets consisting of marine invertebrates, chum and pink salmon fry, smelts, sand lance, sticklebacks, squid, and crab larvae (Sandercock 1991). Sockeye are known to feed on euphausiids, amphipods, and small fish (lantern fish and juvenile cod in central North Pacific Ocean; in the EBS larval caplin, sand lance, and herring; in GOA sand lance, herring, pollock and capelin) (Burgner 1991).

A wide variety of predators feed on migrant salmon smolts. Predators of large salmon include all toothed whales, seals, sea lions, and shark (Sandercock 1991).

Pacific Salmon Management

Pacific salmon off the Alaska coast are managed under a complex mixture of domestic and international bodies, treaties, regulations, and other agreements. Federal and state agencies cooperate in managing salmon fisheries. The ADF&G manages salmon fisheries within state jurisdictional waters, where the majority of harvest occurs. Management in the EEZ is the responsibility of NPFMC. Under Amendment 4 of the Federal Salmon FMP, regulation of the directed salmon fishery occurring in the EEZ off southeast Alaska is deferred to the State of Alaska (NPFMC 1990). The EEZ off central and western Alaska is closed to directed salmon fisheries. Management of Alaska salmon fisheries is based primarily on regional stock groups of each species and on time and area harvesting by specific types of fishing gear. Over 25 different commercial salmon fisheries in Alaska are managed with a special limited-entry permit system that specifies when and what type of fishing gear can be used in each area. These fisheries, extending from Dixon Entrance in southeast Alaska to Norton Sound in the Bering Sea, are allowed to catch salmon in different fisheries, either with drift gillnets, set gillnets, beach seines, purse seines, hand troll, power troll, or fish wheel harvest gear. Sport fishing is limited to hook-and-line, while subsistence fishermen may use gillnets, dipnets, or hook-and-line. Some subsistence harvesting of salmon is also regulated by special permits.

Salmon fisheries are managed by ADF&G to meet an escapement goal of a certain number of spawners for each river system. Meeting escapement goals is considered equivalent to maintaining healthy stocks. In general, spawners are counted on their way upstream, after their numbers have already been reduced by natural mortality at sea, bycatch at sea, and directed fisheries downstream.

The well-being of salmon in Alaska is also directly influenced by land management practices. The quality of freshwater habitats determines the success of reproduction and initial rearing of juveniles. Several agencies, entities, and groups have significant influence on the quality of freshwater spawning and rearing habitats for salmon throughout Alaska. Included among these are the U.S. Forest Service (in the U.S. Department of Agriculture); the U.S. Bureau of Land Management, National Park Service, and National Wildlife Refuges (in the U.S. Department of the Interior); state parks and forests, Alaska Native regional and village corporations; and various municipalities, boroughs, and private land owners that exert some control over watersheds used by salmon.

International Management

Some fisheries, including the southeast Alaska chinook, coho, and sockeye fisheries, have harvest limits that are subject to negotiations with Canada under the Pacific Salmon Treaty. This treaty also covers salmon that are intercepted in fisheries that are returning to Idaho, Oregon, and Washington. This treaty was signed in 1983, but, in recent years, the treaty process was stalled due to disagreements between the two countries on allocations for certain fisheries and species. On June 30, 1999, a new agreement was signed by the negotiators and agreed to by both countries in December 1999. These new treaty agreements will expire in 2008. The extended time span of the new agreements should add stability to the fisheries of both countries. The agreements are complex, however, and will require continuous coordination between both countries to be successful. Fisheries in the Yukon River are covered under a separate agreement, but a treaty has not been signed. However, joint research and management programs in that large transboundary river system are nearing final agreement.

On a broader international scope, the management of salmon harvest in the high seas of the North Pacific Ocean from 1957 to 1992 was authorized by the INPFC, and via bilateral and multilateral agreements and negotiations with Taiwan and the Republic of Korea (South Korea). In 1993, the NPAFC was formed to replace INPFC. This four-country commission (Canada, Japan, the Russian Federation, and the U.S.) now provides a framework for international cooperation in salmon management and research in the North Pacific Ocean. The NPAFC Convention prohibits high seas salmon fishing and trafficking of illegally caught salmon. Coupled with United Nations General Assembly Resolution 46/215, which bans large-scale pelagic driftnet fishing in the world's oceans, the NPAFC has eliminated legal harvesting of Pacific salmon on the high seas. This allows for effective management control to fully return to the salmon-producing nations.

NOAA Management

There are no GOA FMP amendments that directly limit salmon bycatch. However, in the GOA, the timing of seasonal openings for the pollock fishery in the central and western GOA has been adjusted to avoid periods of high historical chinook and chum salmon bycatch.

In the BSAI, a PSC limit of 48,000 chinook salmon between January 1 and April 15 was established for trawl gear in the Chinook Salmon Savings Area (Figure 3.5-18) (50 CFR 679.21 (e)(1)(v)) and a limit of 42,000 non-chinook salmon between August 15 and October 15 was established in the Catcher Vessel Only Area (50 CFR 679.21 (e)(1)(vi). In 1999, NPFMC reduced the cap to 41,000. This cap was further reduced annually thereafter and currently stands at 29,000, applicable only to pelagic pollock fishing. In the event that these PSC limits are reached, no further groundfish trawling in the specified area is allowed for the remainder of the year.

Salmon bycatch limits are expected to trigger closures only during years when exceptionally high bycatch rates are encountered by the trawl fleet. During the first year of implementation in 1994, the Chum Salmon Savings Area was closed to all trawling from August 20 through November 12 (Figure 3.5-8).

Past/Present Effects Analysis

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-42 provides a summary of the Pacific salmon past effects analysis presented below.

Groundfish fisheries take place at sea, not in the freshwater spawning habitat occupied by spawning aggregations of anadromous Pacific salmon. While other human activities may affect spawning salmon and their habitat, federal groundfish fisheries do not. The quality of salmon spawning habitat is influenced by land management practices (e.g., logging, mining, and oil and gas developments) and climatic events (e.g., flooding that scours streams). Several agencies, entities, and groups exert control over watersheds used by spawning salmon. A relationship between the groundfish fisheries and salmon spawning habitat that could have the potential to cause population-level effects was not identified during screening.

The following direct and indirect effect indicators were identified as potentially having population-level effects on Pacific salmon:

- Mortality due to catch/bycatch of salmon (direct effect).
- Mortality associated with spatial/temporal concentration of salmon bycatch (indirect effect).
- Bycatch mortality of prey species (indirect effect).
- Salmon mariculture (indirect effect).
- Climatic influences (indirect effect).
- Oil pollution (indirect effect).

The past/present events determined to be applicable to the Pacific salmon past effects analysis include the following:

- Past/Present External Events
  - State of Alaska directed salmon fisheries
  - Subsistence fisheries
  - Foreign fisheries (pre-MSA in U.S. EEZ)

- Foreign fisheries (outside U.S. EEZ)
  - Salmon mariculture (Canada)
  - Climatic shifts
  - EVOS

- Past/Present Internal Events
  - Pollock trawl fisheries

- Past/Present Management Actions
  - ADF&G management
  - Foreign fisheries management
  - Industry self-imposed management
  - FMP groundfish fisheries management

<u>Mortality: State of Alaska Directed Salmon Fisheries</u>

Federal management of Alaska salmon in the pre-statehood era was weak and heavily influenced by the processing sector. The state took over salmon management after statehood in 1959. By the 1970s, state managers realized that salmon stocks were being over prosecuted by an ever-growing fleet and initiated a limited entry system. Hatchery enhancement programs were also initiated to augment commercial salmon harvests (ADF&G 2000b).

<u>Mortality: Subsistence Fisheries</u>

Alaska Native peoples have a bond with salmon that is part of their heritage, as an economic, cultural, and subsistence necessity. Salmon are harvested and used by Alaskan Native populations along the coast of southeastern and southwestern Alaska, comprising the most highly developed aboriginal fishing complex on the continent (Cooley 1961).

<u>Mortality: Foreign Fisheries (pre-MSA in U.S. EEZ)</u>

Direct catch and bycatch of salmon are both associated with past pre-MSA foreign fisheries. U.S. bilateral agreements with Japan and Russia attempted to reduce gear conflicts between State of Alaska salmon fisheries and foreign fisheries and allocate salmon resources to the state fisheries. It is inferred that the past foreign fisheries bilateral agreements were marginal management measures at best and probably did not provide any significant benefit to salmon stocks.

<u>Mortality: Foreign Fisheries (outside US EEZ)</u>

Salmon have a transboundary nature; hence western Bering Sea stocks have the potential to be caught in high-seas and Russian EEZ fisheries. The NPAFC coupled with the United Nations General Assembly Resolution 46/214, both established in 1993, prohibit high seas salmon fishing and ban large-scale pelagic driftnet fishing, respectively. In 1992, the U.S. and Russia signed a bilateral agreement calling for a ban on direct salmon fishing within both country's EEZs, but allowed for directed salmon fishing within 25 nm of the baseline from which the EEZ is measured (Pautzke 1997). With the exception of the occasionally-caught illegal fishing vessel, these measures are thought to provide effective management for salmon catch and bycatch outside the U.S. EEZ.

Mortality: Salmon Mariculture (Canada)

Salmon mariculture began in the Pacific Northwest in the 1970s. By the 1980s, salmon farms raising Atlantic salmon were established in British Columbia and Washington State. Fish farming is perceived as having the potential to increase disease in wild stocks, cause marine water pollution in localized areas, displace wild stock with escaped farm fish, and to lead to interbreeding between wild stocks and escaped farm fish. Studies conducted in British Columbia indicate that farm Atlantic salmon are able to spawn successfully in the wild (Gaudet 2002). Storms, tides, marine mammals, and/or accidents can damage the floating net pens used in fish farms and allow for the escapement into the marine environment of farm fish of all life stages (Gaudet 2002). Sexually mature Atlantic salmon can currently be found in both freshwater and marine environments throughout the Pacific Northwest and Alaska (Gaudet 2002). Alaska banned the farming of finfish in 1990 in order to protect Alaska wild stocks. In 2002, ADF&G proposed that British Columbia phase out their marine fish farms and allow only land-based lake rearing farms to eliminate risks to marine environments while minimizing disruption of local economies (Gaudet 2002).

Mortality: Climatic Influences

Climate variability can have an influence on salmon populations and their prey, both beneficial and adverse. Ocean conditions that have favored high marine survivals in recent years; however, fluctuate due to interdecadal climate oscillations (Mantua *et al.* 1997). Recent evidence suggests that a change in ocean conditions in the North Pacific Ocean may be under way, possibly reflecting the downturn in abundance of Alaska salmon runs in 1996 and 1997. Studies indicate that salmon have improved marine survival during periods of warmer than normal ocean temperatures (Salo 1991).

Pacific salmon prey also respond to climatic conditions. For example, capelin and eulachon, two species of smelts, have been observed to shift abundance and/or distribution during climate changes. Capelin have shown abrupt declines in occurrence in small-mesh trawl survey samples in the GOA (Piatt and Anderson 1996, Anderson and Piatt 1999). In survey data from both NOAA Fisheries and ADF&G, capelin first declined along the east side of Kodiak Island and bays along the Alaska Peninsula. Subsequent declines took place in the bays along the west side of Shelikof Strait. These declines happened quickly, and low abundance has persisted for over a decade. The decline corresponded with increases in water temperature of the order of 2°C, which began in the late 1970s. Capelin have fairly narrow temperature preferences and probably were very susceptible to the increase in water column temperatures (Piatt and Anderson 1996, Anderson *et al.* 1997). Mapping of relative densities of capelin showed defined areas of relative high abundance. The Shelikof Strait region showed relatively high catches in Kujulik, Alitak, and Olga bays. Most catches of capelin were closely associated with bays, except for high catches offshore of Cape Ikolik at the southwest end of Kodiak Island. Isolated offshore areas east of Kodiak Island showed some high catches, with most of the high catches associated with Ugak and Kazakof Bays. Only isolated catches of less than 50 kg were evident in the database from PWS, the Kenai Peninsula, and lower Cook Inlet.

Furthermore, evidence from fishery observers and survey data suggests that eulachon abundance declined in the 1980s (Fritz *et al.* 1993). This data should be interpreted with caution because surveys were not designed to sample small pelagic fishes such as eulachon, and fishery data were collected primarily to estimate total catch of target groundfish. Causes of this presumed decline are unknown, but may be related to variability in year-class strength, as noted for capelin. Small-mesh shrimp trawl surveys in the GOA coastal areas suggest that eulachon have remained at a low level of relative abundance since 1987. Eulachon are currently at the lowest recorded level in the survey series (1972–1997) at 0.01 kg/km (Anderson and Piatt 1999) (see Appendix B).

Mortality: Oil Pollution

The EVOS affected pink salmon in PWS and sockeye salmon in the Kodiak Island area (EVOS Trustee Council 2002a and 2002b). Commercial salmon fishing was closed in PWS, portions of the Cook Inlet, and near Kodiak in 1989 as a result of the spill to avoid possibility of contaminated fish being sent to market. The recovery goal for affected pink and sockeye stocks was a return to stock conditions that would have existed prior to the spill. The EVOS Trustee Council considers both of these species to be recovered from effects of the EVOS (EVOS Trustee Council 2002a and 2002b).

Mortality: Bycatch in MSA Groundfish Fisheries

Although all groundfish fisheries in the Bering Sea and the GOA are prohibited from retaining any salmon they catch, they do encounter them as bycatch. Most salmon bycatch is taken by vessels using pelagic trawl gear targeting pollock. Chinook salmon seem most vulnerable to trawl gear, accounting for 36 to 44 percent of total numbers of salmon bycatch. Chum salmon is next in vulnerability and can reach bycatch proportions as large as those for chinook. Figures 3.5-9 and 3.5-10 show chinook and other salmon bycatch trends by area and gear type from 1998-2001.

The highest bycatch rates for chum salmon occur during August, September, and October, with almost no chum salmon taken in other months (NPFMC 1995a). According to groundfish fishery observer data in the BSAI, the overwhelming majority (96 percent between 1997 and 1999) of other salmon bycatch is chum salmon. Chum salmon from Asia account for a significant part of the chum bycatch in the Bering Sea. Bycatch percentages of coho, sockeye, and pink salmon are small (less than 1 or 2 percent of total salmon bycatch). Chum salmon dominate other salmon bycatch in the GOA as well (56 percent between 1997 and 1999, but higher in prior years).There are also catches of coho salmon (14 percent), pink salmon (3 percent), and sockeye salmon (1 percent) in the GOA. The recent history of salmon bycatch is listed in Table 3.5-43.

Chinook salmon bycatch appears to be concentrated somewhat relative to the overall distribution of pollock fishing (Figure 3.5-11). Although some amount of chinook salmon bycatch occurs throughout the year, it is higher in September and October (pollock B season during 1997 to 1999). Chinook salmon bycatch in the Bering Sea is likely composed mainly of western Alaska and Canadian Yukon stocks (Healey 1991).

Regulations implemented under the BSAI FMP amendment process successfully reduced the foreign fisheries bycatch of salmon. The foreign fisheries salmon bycatch reductions were offset by increased salmon bycatch in the growing JV operations and domestic groundfish fisheries. Establishment of new salmon bycatch limits were issued to address the increase in JV and domesticbycatch levels.

Trawling is prohibited in the Chinook Salmon Savings Areas upon attainment of a bycatch limit of 48,000 chinook salmon in the BSAI under FMP Amendment 21b (NPFMC 1995b, Figure 3.5-18). Currently, an other salmon bycatch level of 42,000 fish is set in the BSAI, and a Chum Salmon Savings Area has been established, which is closed to all trawling during the period of high chum salmon bycatch(August 1 to 31 of each year) (Figure 3.5-8). These measures were implemented under BSAI FMP Amendment 35 (NPFMC 1995a). Like the chinook salmon bycatch level, the other salmon action level serves as a trigger to close the Chum Salmon Savings Area seasonally if that level is reached in a given year, and not as an absolute limit on chum salmon catch. Unlike the chinook salmon bycatch level, catch of other salmon only counts toward the limit of 42,000 fish if it is taken within a limited area of the BSAI, the catcher vessel operation area. Thus, catch of other salmon generally exceeds 42,000 fish per year, and the Chum Salmon Savings Area has never been closed to fishing outside of August 1 to 31. However, catch of other salmon has been considerably lower since these management measures were implemented in 1995 than in the years immediately prior to implementation.

Salmon are always prohibited species in any groundfish fishery; however, they only accrue against the PSC limit when caught with trawl gear from January 15 to April 15 for chinook salmon and within the catcher vessel operational area from August 15 to October 14 for non-chinook salmon. Accrued CDQ trawl salmon PSC catch must be retained and delivered to a shoreside processor, where it is sorted by species, counted, and reported to NOAA Fisheries by the shoreside processor on a CDQ delivery report. Although observer data are not used directly to estimate salmon PSC limits, they are used to verify the species reported on the CDQ delivery report.

Mortality: Bycatch of Salmon Prey Species in MSA Groundfish Fisheries

Bycatch of Pacific salmon prey species, such as sand lance, capelin and euphausiids (i.e., forage fish), in the BSAI and GOA groundfish fisheries tends to be minimal, remaining under 75 mt in the BSAI and 130 mt in the GOA in recent years and would likely have no effect on prey availability to Pacific salmon (Section 3.4.2).

Spatial/Temporal Concentration of Bycatch

The spatial/temporal concentration of bycatch could cause overharvesting of a distinct genetic component of a stock. Current spatial/temporal concentration of salmon bycatch in the BSAI seems to be relative to the distribution of the pollock fishery (Figure 3.5-12). Potential impacts to salmon from past and current BSAI and GOA groundfish fisheries bycatch distribution have not been determined due to the uncertainty of bycatch stock composition; therefore, the magnitude of any such influences is unknown.

Spatial/temporal salmon bycatch is also controlled by non-regulatory means. Many measures have been embraced by the trawl and longline fleet to control and reduce bycatch of Pacific halibut, crab, and salmon. A GIS application has been used by the BSAI trawl and longline fleet to identify hotspots by using bycatch rates reported by individual vessels (Gauvin *et al.* 1995; Smoker 1996). Bycatch rate information from individual vessels is received at a central location, aggregated daily, and then quickly relayed back to the entire fleet in the form of maps, so that hotspot areas can be avoided. PSC rates are reduced and correspondingly higher groundfish catches can then be realized by the fleet. Unfortunately, because this is a voluntary program, non-participating vessels with high bycatch rates may keep the fleet as a whole from catching the entire quota of flatfish. Some bycatch reduction may also come in the form of peer pressure. Individual vessel bycatch rates are now published on the Internet. Vessels with high bycatch rates may face pressure to lower their bycatch.

Comparative Baseline

All five species of Alaska salmon are fully utilized, and stocks in most regions of the state generally have been rebuilt to or beyond previous levels (Table 3.5-44). The high abundance of Alaska salmon up to 1995 should not be interpreted as an absence of some of the same factors affecting declines of salmon in the Pacific Northwest. Unspoiled habitats, favorable oceanic conditions, and adequate numbers of spawning salmon are likely the paramount issues positively affecting current Alaska salmon abundance. Alaska salmon management continues to focus on maintaining pristine habitats and ensuring adequate escapements.

Alaska commercial salmon harvests have generally increased over the last three decades, but may have peaked in 1995 (Figure 3.5-13). After reaching record low catch levels in the 1970s, most populations have rebounded, and fisheries are now at or near all-time peak levels in many regions of the state (Burger and Wertheimer 1995, Wertheimer 1997). The record-high commercial landing of 217 million salmon in 1995 was 11 percent higher than the previous record of 196 million in 1994. However, significant declines in the commercial catches followed in both 1996 and 1997 (Figure 3.5-13). The 1998 Alaska commercial salmon harvest was 151 million salmon (322,055 mt), distributed as 22.6 million sockeye (57,607 mt), 18.9 million chum (73,937 mt), 105 million pink (169,646 mt), 4.6 million coho (16,284 mt), and 563 thousand chinook (4,581 mt). Recreational fishermen caught over 1.8 million salmon in Alaska in 1995 (Howe *et al.* 1996), and subsistence fisheries for salmon in 1994, the most recent year available, harvested over 1 million fish (ADF&G 2001a). Based on preliminary data, the 2002 Alaska commercial salmon harvest (exvessel values) totaled approximately 130 million salmon (275,987 mt). This total was distributed among species as follows: 539,000 chinook (4,064 mt), 22.5 million sockeye (61,914 mt), 4.8 million coho (16,717 mt), 87.6 million pink (135,509 mt), and 15 million chum (57,783 mt) (ADF&G 2003).

The annual commercial harvest of chinook salmon in Alaska has averaged between 500,000 and 700,000 fish in recent years. The statewide 10-year (1988-1997) average annual harvest was 627,000 fish (Savikko 1997). Spawning escapements of chinook and other salmon in southeast Alaska are stable or increasing in 99 percent of the management units, indicating that stocks are healthy (NOAA Fisheries 2003). Of the 407 chinook stocks harvested in the southeast, 81 percent are classified as not threatened, and 15 percent are special concern or at risk (Slaney *et al.* 1996). Large portions of the southeast chinook harvest originate from the Columbia river upriver bright chinook, Middle Columbia River bright chinook, and north-migrating Oregon coastal chinook; these stocks are considered stable (NOAA Fisheries 2003). Chinook stocks listed under the ESA make up a small portion of the southeast harvest, and nearly all coho salmon harvested originate from Alaskan streams (Weitkamp *et al.* 1995).

An exception to the above stock status summary resides in the AYK region of Alaska. After two previous years of very low runs, the summer 2000 chinook and chum salmon runs in the Yukon and Kuskokwim River drainages (ADF&G Region 3, Figure 3.5-14) were so low that even subsistence fishing was prohibited, resulting in a federal disaster declaration. A subsistence closure emphasizes the serious concern for the health of salmon stocks in this region.

Pacific Salmon Cumulative Effects Analysis Status

Chinook salmon and other salmon will be carried forward for the cumulative effects analysis based on the current depressed status of some stocks and the lack of recovery shown to date.

3.5.2.3 Pacific Herring

Life History and Distribution

Pacific herring (*Clupea pallasii)* occur from California through the GOA and Bering Sea to Japan. Pacific herring may grow to a length of 45 cm with a weight of over 500 grams but average 23 cm and about 225 grams. Pacific herring migrate in schools. In Alaska, Pacific herring begin spawning in mid-March in southeastern Alaska and as late as June in the Bering Sea. The timing of spawning is related to water temperatures (NPFMC 1998a). Spawning occurs in shallow, vegetated intertidal and subtidal areas. The eggs are adhesive, and survival is greater for those eggs that stick to vegetation than for those that fall to the bottom. Milt released by the males drifts among the eggs, fertilizing them. The eggs hatch in about two weeks, depending on water temperature. Herring spawn every year after reaching sexual maturity at 3 or 4 years of age. The average life span of herring is about 8 years in southeastern Alaska and 16 years in the Bering Sea. The young larvae drift and swim with the ocean currents. After developing to their juvenile form, they rear in sheltered bays and inlets and appear to remain segregated from adult populations until they mature. After spawning, most adults leave inshore waters and move offshore to feed. They are seasonal feeders and accumulate fat reserves for periods of relative inactivity. Herring schools often follow a diel vertical migration pattern, spending daylight hours near the bottom and moving upward during the evening to feed (Hart 1973). Following spawning, Bering Sea herring move clockwise along the Alaska Peninsula to feed. They typically reach the Unimak Pass area by mid-summer. In late summer, Bering Sea herring move to overwintering areas in the vicinity of the Pribilof Islands (NPFMC 1998a).

In the GOA, spawning concentrations occur mainly off southeastern Alaska, in PWS, around Kodiak Island, and in Cook Inlet. However, little is known about GOA herring overwintering locations.

Trophic Interactions

Pacific herring feed on zooplankton, larvae of pollock, sand lance, and smelt during all their life stages (Schweigert 1997, Livingston 1985, ADF&G 1985). Herring eggs and young larvae are preyed upon extensively by other vertebrate and invertebrate predators (Funk 1994). Juvenile and adult herring are also important prey for other fish, marine mammals, and seabirds.

Management Overview

A draft FMP for BSAI herring was prepared in the early 1980s, but never finalized because herring was deemed fully utilized in Alaska state waters. Management authority was delegated to the State of Alaska. Pacific herring are managed by the ADF&G with annual quotas allocated by the Alaska Board of Fisheries. All directed herring fisheries occur in state waters from Dixon Entrance north to Norton Sound. The fishery fluctuates depending on market demands. Alaska herring fishing quotas are based on a variable exploitation rate of 20 percent. Lower exploitation rates are used when stocks decline to near-threshold levels. Herring fisheries are managed by regulatory stocks (i.e., geographically distinct spawning aggregations). Herring fisheries include the following:

- Subsistence harvest of spawn on kelp or artificial substrate.
- Herring spawn on open pound spawn-on-kelp and wild spawn-on-kelp.

- Purse seine and gillnet fisheries sac roe harvest.

- Food and bait harvest.

Past/Present Effects Analysis

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-45 provides a summary of the Pacific herring past effects analysis presented below.

The following direct and indirect effects were identified as potentially having population-level effects on Pacific herring:

- Mortality due to catch/bycatch (direct effect).

- Nutritional stress due to climatic influence on prey species (indirect effect).

- Reduced recruitment due to oil pollution (EVOS; PWS population) (indirect effect).

The past/present events determined to be applicable to the Pacific herring past effects analysis include the following:

- Past/Present External Events
  - Alaska State directed herring fisheries
  - Foreign fisheries (pre-MSA)
  - Climatic shifts
  - EVOS

- Past/Present Internal Events
  - Pollock trawl fisheries

- Past/Present Management Actions
  - ADF&G management
  - FMP groundfish fisheries management

Federal groundfish fisheries do not take place in the nearshore shallow environments where herring congregate to spawn, so no impacts to herring spawning habitat or aggregations are predicted as a result of these fisheries. Herring prey on zooplankton, including larvae of pollock, sand lance, and smelt. Zooplankton are not caught in groundfish fisheries. The only way groundfish fisheries might possibly have any impact on herring prey would be severe overfishing of species such as pollock to an extent that limited pollock larval abundance. This level of groundfish overfishing has not been observed over the course of FMP management, and is not likely to occur in the future. The spatial/temporal concentration of bycatch could have adverse effects by overharvesting a distinct genetic herring stock. GOA herring are considered to be genetically distinct from EBS herring. BSAI herring bycatch appears to be evenly spread throughout the federal pollock fishery (Figure 3.5-15). Herring bycatch in the GOA groundfish fisheries is very small compared to the bycatch in the BSAI. Examples of indirect impacts to Pacific herring would be spatial and temporal concentrations of bycatch resulting in the overharvest of a distinct genetic component of the stock, destruction of spawning habitat and disruption of spawning aggregations, and competition for prey. Herring bycatch does not appear to be concentrated in space, but rather is spread throughout the pollock fishery under status quo management (Figure 3.5-15). Although there is some amount of herring bycatch throughout the year, it is higher in September and October (pollock B season during 1997 to 1999). No significant impacts to herring stocks from spatial or temporal concentration of herring bycatch have been identified.

Past/Present Events and Management Actions

External Mortality: Catch in the State Directed Herring Fisheries

During the 1920s herring was valued for oil and meal. Reduction plants sprang up all over Alaska from Craig to Kodiak to process herring into oil and meal. Reduction and food herring harvests peaked in the 1920s and 1930s (Figure 3.5-16). By the 1950s, Peruvian anchoveta harvest had severely impacted the Alaska herring oil and meal markets due to lower costs (ADF&G 2000). Herring reduction plants began closing and by1966 the last herring reduction plant in Alaska had closed. The herring for bait fishery began in the early 1900s and has remained relatively stable to the present time with a slight increase in demand due to the development of the crab fisheries in the 1970s (Figure 3.5-16). Herring fisheries continue to occur; however, they are highly managed by the state. Annual stock assessments from trawl surveys are conducted with quota setting processes responsive to fluctuations in herring biomass.

External Mortality: Catch in the pre-MSA Foreign Fisheries

A foreign fishery for herring food products existed in the Bering Sea during the 1960s and 1970s (Figure 3.5-16). Foreign harvesting of herring was discontinued around 1980 under the provisions of the MSA when inshore domestic fisheries began to fully utilize Bering Sea herring (ADF&G 2000b).

Internal Mortality: Bycatch in Groundfish Fisheries

Herring bycatch is taken primarily in the trawl pollock fisheries. Herring caught as bycatch in trawl fisheries do not survive. Overall herring bycatch is higher in the BSAI than the GOA. It is estimated that herring bycatch may have been as high as 7,300 to 9,100 mt in the late 1980s. JV operations peaked in 1987, giving way to a rapidly developing domestic fishery. Bycatch further increased with development of the fully domestic fleet, but was quickly limited by regulation. By 1989, unrestrained bycatch in the trawl fisheries had jumped to high levels relative to exploitable biomass. Past federal groundfish fisheries bycatch combined with the state fisheries direct take have exceeded the state's herring harvest policy in the past. (Appendix C, BSAI FMP Amendment 16a).

Pacific herring bycatch limitations in the groundfish fisheries apply to trawl gear in the Bering Sea. The PSC limit for trawl gear is determined each year when TAC specifications are reset. Amendment 16a, implemented on July 12, 1991, established a herring bycatch cap of one percent of the estimated EBS herring biomass, which is further apportioned by target fishery (50 CFR 679.21 (e)(1)(iv)) (Funk 2003). Should the PSC limit for any groundfish fishery be reached during the fishing year, one or all of the three designated Herring Savings Areas close, depending on the time of year (Figure 3.5-17) (50 CFR 679.21 (e)(7)(v)). Three time and area closures were established, taking into account herring migration patterns. Area 1 closes from June 15 to July 1, Area 2 from July 1 to August 15, and Area 3 from September 1 through March 1. Areas with relatively high bycatch rates of herring were identified from data collected by observers on foreign and joint venture vessels. Pacific herring closures have been effective at maintaining an acceptable level of bycatch in years when herring are abundant on the fishing grounds. This situation occurred in 1992, 1993, 1994, and 1995, when herring savings areas 2 and 3 were closed to trawling for fisheries directed at pollock, rock sole, yellowfin sole, and other flatfishes. Area 3 experienced a total closure from November 4, 1994 to March 1, 1995, for the pollock midwater trawl fishery. From 1993 to present, the pollock fishery has primarily driven herring bycatch rates with the yellowfin sole fishery playing a secondary role (Figure 3.5-19) (Funk 2003).

PSC bycatch is also controlled by non-regulatory means. Many measures have been embraced by the trawl and longline fleet to control and reduce bycatch of Pacific halibut, herring, crab, and salmon. A GIS application has been used by the BSAI trawl and longline fleet to identify hotspots by using bycatch rates reported by individual vessels (Gauvin *et al.* 1995, Smoker 1996). Bycatch rate information from individual vessels is received at a central location, aggregated daily, and then quickly relayed back to the entire fleet in the form of maps, so that hotspot areas can be avoided. PSC rates are reduced and corresponding higher groundfish catches can then be realized by the fleet. Unfortunately, because this is a voluntary program, non-participating vessels with high bycatch rates may keep the fleet as a whole from catching the entire quota. Some bycatch reduction may also come in the form of peer pressure. Individual vessel bycatch rates are now published on the Internet. Vessels with high bycatch rates may face peer pressure to lower their bycatch.

<u>External Nutritional Stress: Climatic Influence on Prey Species</u>

Climate variability can have an influence on herring prey. However, these interactions are not fully understood nor defined and research on climatic effects is ongoing.

<u>External Reduced Recruitment: EVOS Contamination (PWS)</u>

Herring spawning habitat in PWS was contaminated by oil from the EVOS in 1989. Subsequent laboratory studies have indicated that larval and adult herring exposure to oil can cause increased rates of egg mortality, larval deformities, and compromise adult herring immune systems. In 1993, there was a crash in the PWS herring population. This crash was correlated with a viral disease, increasing biomass, and lowering plankton production. The extent that exposure to oil contributed to the disease outbreak and consequent population crash is uncertain (EVOS Trustee Council 2002c). The EVOS Trustee Council continues to monitor the recovery of the PWS herring population.

Comparative Baseline

ADF&G makes herring biomass projections for each regulatory stock using postseason escapement estimates, historical mean rates of survival, and current mean weights and assumed recruitment rates for each age class.

Herring fisheries continue to occur; however, they are closely managed by the state. Although most herring are harvested in the sac-roe season in spring, fall seasons are also designated for food and bait harvesting. The ADF&G regulates and monitors the resource by 20 separate fisheries. Annual stock assessments from trawl surveys are conducted and quota setting processes are responsive to fluctuations in herring biomass.

In the Bering Sea, catches peaked dramatically in 1970 at more than 108,000 mt and fell to 19,050 mt in 1977 (Figure 3.5-20, NMFS 1999d). Since then, catches have risen slowly but steadily, reflecting improving stock conditions. A portion of the Bering Sea harvest is taken as bycatch in the groundfish fishery. Regulations now limit bycatch to about 1,000 mt. In more recent years, statewide herring harvests have averaged about 45,000 mt. The majority of the harvest was roe-bearing herring (about 90 percent) and the remainder was food-and-bait herring (about 10 percent). The herring roe-on-kelp harvest (about 150 mt) is minuscule in percentage terms.

Herring populations, like those of other small pelagic fish species, are subject to wide fluctuations in abundance. The causes suggested for these fluctuations range from natural causes to overfishing (and underfishing), pollution effects (including the 1989 EVOS), disease, climate variability, and combinations of factors (Pearson *et al.* 1999). From catch records (Figure 3.5-20), it is evident that herring biomass fluctuates widely due to influences of strong and weak year-classes. The period since the mid-1970s seems to be one of low-to-moderate herring abundance. Abundance of the stocks depends mostly on highly variable year-class strengths. A strong 1988 year-class, which dominated the stock, declined rapidly in abundance, and was replaced by another strong year-class (1992), which should sustain abundance levels in the near future. In PWS, herring collections in 2002 indicate that a large proportion of this population (over 30 percent) is now comprised of 3-year olds. If this trend holds up through successive sampling, it could signal that recovery is underway for the PWS herring stock (EVOS Trustee Council 2002c).

Pacific Herring Cumulative Effects Analysis Status

FMP 2.1 proposes to eliminate the groundfish fishery PSC limits and inseason bycatch triggered closures. These measures have the potential to affect herring biomass levels and could impose further economic hardship on the state herring fisheries. Therefore, Pacific herring will be carried forward for the alternative cumulative effects analysis.

3.5.2.4 Crab

The commercially important crab species are red king crab (*Paralithodes camtschaticus*), blue king crab (*P. platypus*), golden king crab (*L. aequispinus;* also called brown king crab), bairdi Tanner crab (*Chionoecetes bairdi*), and opilio Tanner crab *(C. opilio;* also called snow crab). King and Tanner crab share a similar life cycle, although particular life cycle traits are distinct for each species. After males and females mate, the female carries the eggs for approximately a year, at which time the eggs hatch into free-swimming larvae. After drifting with the currents and tides and undergoing several development changes, the larvae settle to the ocean bottom and molt into non-swimmers, looking very much like miniature adult crab. The juvenile crab settle on preferred habitat, where they continue to molt and grow for several years until they become sexually mature. Each life stage of crab stocks is concentrated at some combination of depth, habitat, geographic area, and time of year.

Crab, being benthic organisms, depend on specific habitat types throughout their life stages. Settlement on habitat with adequate shelter, food, and temperature is imperative to the survival of first settling crab. Young-of-the-year red and blue king crab require nearshore shallow habitat with significant protective cover (e.g., sea stars, anemones, microalgae, shell hash, cobble, shale) (Stevens and Kittaka 1998). Early juvenile stage bairdi and opilio Tanner crab also occupy shallow waters and are found on mud habitat (Tyler and Kruse 1997).

King and Tanner Crab Life History and Distribution

Red king crab are widely distributed throughout the BSAI, GOA, Sea of Okhotsk, and along the Kamchatka shelf up to depths of 250 m. King crab molt several times per year through age three, and annually thereafter. At larger sizes, king crab may skip molt as growth slows. Females grow more slowly and do not get as large as males. In Bristol Bay, males attain 50 percent maturity at 120-mm carapace length and females at 90-mm carapace length (about 7 years). Ages of crab referred to in this document are inferred from tagging and growth, since currently crab cannot be aged. For crab which undergo a terminal molt, radiometric aging of the shell has provided estimates of age since the last molt (Nevissi *et al.* 1996). Maximum age for the largest red king crab caught near Kodiak may be about 24 years based on growth and tagging data(Stevens and Kittaka 1998). Mean age at recruitment into the fishery is eight to nine years. Red king crab in Norton Sound mature at smaller sizes and do not attain the maximum sizes found in other areas. In Bristol Bay, red king crab mate when they enter shallower waters (less than 50 m), generally beginning in January and continuing through June. Males grasp females just prior to female molting, after which the eggs (43,000 to 500,000 eggs) are fertilized and extruded on the female's abdomen. The females carry the eggs for 11 months before they hatch, generally in April. Red king crab spend two to three months in larval stages before settling to the benthic life stage. Young-of-the year crab occur at depths less than 50 m. They are solitary and need high-relief habitat or coarse substrate, such as boulders, cobble, shell hash, and living substrates, such as bryozoans and stalked ascidians (Stevens and Kittaka 1998). At 1.5 to 2 years, crab form pods consisting of thousands of crab. As crab grow, they migrate to deeper water.

Blue king crab have a discontinuous distribution throughout their range and tend to form discrete populations along rocky coasts, rocky islands, and fjord-like areas. In the Bering Sea, discrete populations exist around the Pribilof Islands, Saint Matthew Island, Saint Lawrence Island, and Little Diomede Island in the Bering Straight. Smaller populations have been found around Nunivak and King Islands. Adult male blue king crab occur at an average depth of 70 m and an average water temperature of 0.6 °C. Blue king crab molt multiple times as juveniles. Skip molting occurs with increasing probability for males larger than 100-mm carapace length. In the Pribilof Islands, males attain 50 percent maturity at 108-mm carapace length, and females attain 50 percent maturity at 96-mm carapace length (about five years) (Somerton and MacIntosh 1983). Blue king crab in the Saint Matthew Island area mature at smaller sizes (50 percent maturity at 77-mm carapace length for males and 81-mm carapace length for females) and do not get as large overall. Blue king crab have a biennial ovarian cycle and a 14-month embryonic period before hatching in late spring. Juveniles require cobble habitat with shell hash. These habitat areas have been found at 40 to 60 m around the Pribilof Islands. Unlike red king crab, juvenile blue king crab do not form pods, but instead rely on cryptic coloration for protection from predators.

Golden king crab, also called brown king crab, range from the Japan Sea to the northern Bering Sea, around the Aleutian Islands, on various sea mounts, and as far south as northern British Columbia. In the BSAI, golden king crab are found at depths from 200 m to 1,000 m, generally in high-relief habitat such as inter-island passes on extremely rough bottom strata. Size at sexual maturity depends on latitude, with crab in the northern areas maturing at smaller sizes. In the Saint Matthew Island area, males attain 50 percent maturity at 92-mm carapace length and females at 98-mm carapace length. In the Pribilof Islands and western Aleutian Islands, males attain 50 percent maturity at 107-mm carapace length and females at 100-mm carapace length. Further south, in the eastern Aleutian Islands, males attain 50 percent maturity at 130-mm carapace length and females at 111-mm carapace length.

Bairdi Tanner crab are distributed on the continental shelf of the North Pacific Ocean and Bering Sea from Kamchatka to Oregon. Off Alaska, bairdi Tanner crab are concentrated around the Pribilof Islands and immediately north of the Alaska Peninsula, and are found in lower abundance in the GOA. After molting many times as juveniles, bairdi tanner crab reach sexual maturity at about age-6 with an average carapace width of 110 to 115 mm for males and 80 to 110mm for females (Tyler and Kruse 1997). At maturity, females undergo a terminal molt. Molting frequency for males decreases after maturity; however, terminal molt for males has not been determined (Zheng *et al.* 1998). Male bairdi Tanner crab reach a maximum size of 190-mm carapace width and have a maximum age of at least 15 years (Donaldson *et al.* 1981). Males of commercial size may range between 9 and 11 years old and vary in weight from 1 to 2 kg (Adams 1979). Bairdi Tanner crab females are known to form high-density mating aggregations, or pods, consisting of hundreds of crab per mound. These mounds may provide protection from predators and attract males for mating. Research shows that female bairdi Tanner crab prefer mating with large, old-shell males (Paul and Paul 1996, Paul *et al.* 1995). Mating occurs from January through June. Some females can retain viable sperm in spermathecae for up to two years. Females carry clutches of 50,000 to 400,000 eggs for one year after fertilization. Hatching occurs between April and June (Tyler and Kruse 1997). Spawning habitat for bairdi Tanner crab in the BSAI has not been identified.

Opilio Tanner crab are distributed on the continental shelf of the Bering Sea, the Arctic Ocean, and in the western Atlantic Ocean as far south as Maine. Opilio Tanner crab are not present in the GOA. In the Bering Sea, they are common at depths of no more than 200 m. The EBS population within U.S. waters is managed as a single stock; however, the distribution of the population extends into Russian waters to an unknown degree. Opilio Tanner crab reach sexual maturity at about age 5 to 8, with 50 percent mature at carapace width of 79 mm for males and 49 mm for females. The mean size of mature females varies from year to year over a range of 63-mm to 72-mm carapace width. Females cease growing with a terminal molt upon reaching maturity, and rarely exceed 80-mm carapace width. Males may also cease growing upon reaching a terminal molt when they acquire the large claw characteristic of maturity. Male opilio Tanner crab reach a maximum size of 150-mm carapace width and may live up to 19 years. Large, old -shelled males out-compete new-shell adolescent and small adult males in mating with females (Sainte-Marie *et al.* 1999). Commercial-sized males may range between 9 and 11 years old and average about 0.6 kg (Saint-Marie *et al.*1999). Female opilio Tanner crab are able to store spermatophores in seminal vesicles and fertilize subsequent egg clutches without mating. At least two groups of eggs can be fertilized from stored spermatophores, but the frequency of this occurring in nature is not known (Sainte-Marie *et al.* 1997). In Bristol Bay, podding behavior is unique to red king crab and incorporates male and female crab of different ages. These pods may result in a patchy distribution of red king crab in this region as opposed to a random or continuous distribution often observed for other species (Dew and McConnaughey in review).

King and Tanner Crab Trophic Interactions

In the trophic structure, crab are members of the inshore benthic infauna consumers guild (NPFMC 1994). During each life stage, crab consume different prey and are consumed by different predators. Planktonic larval crab consume phytoplankton and zooplankton. Post settlement juveniles feed on diatoms, protozoa, hydroids, crab, and other benthic organisms.

Food eaten by king crab varies with size, depth inhabited, and species, but includes a wide assortment of worms, clams, mussels, snails, brittle stars, sea stars, sea urchins, sand dollars, barnacles, fish parts, and algae. Bairdi and opilio Tanner crab feed on an extensive variety of benthic organisms including bivalves, brittle stars, other crustaceans, polychaetes and other worms, gastropods, and fish (Lovrich and Sainte-Marie 1997).

Planktonic larval crab are prey for pelagic fish, such as pollock, salmon, and herring. King crab fall prey to a wide variety of species including Pacific cod, Pacific halibut (Alaska plaice, yellowfin sole, flathead sole) arrowtooth flounder, octopus, and large king crab (Livingston *et al.* 1993). Bairdi and opilio Tanner crab are consumed by a wide variety of predators including groundfish, walrus, bearded seals, sea otters, octopi, Pacific cod, Pacific halibut and other flatfish, eelpouts, sculpins, and adult tanner crab (Tyler and Kruse 1997). Opilio Tanner crab comprise a large portion of the diet of many skate species (Orlov 1998).

King and Tanner Crab Management

Alaska king, bairdi Tanner crab, and opilio Tanner crab (also called snow crab) fisheries are managed by the State of Alaska, with federal oversight and following guidelines established in the BSAI king and Tanner crab FMP (NPFMC 1989). Annual trawl surveys for crab stock assessments are conducted by the NOAA Fisheries in the BSAI. A length-based analysis, developed by ADF&G, incorporates survey, commercial catch, and observer data into more precise abundance estimates (Zheng *et al.* 1998, Zheng *et al.* 1995). Abundance estimates generated by this model are used to set guideline harvest levels for the crab fisheries. Catches are restricted by GHLs, seasons, permits, pot limits, and size and sex limits that restrict landings to legal-sized male crab. Fishing seasons are set at times of the year that avoid molting, mating, and softshell periods, both to protect crab resources and to maintain product quality. Observers are required on all vessels processing king and tanner crab. Crab are captured with baited pots, and most of the catch is landed in Dutch Harbor, Alaska. Most crab vessels target different crab species during different seasons, and many crab vessels also participate in the groundfish fisheries.

King crab along with bairdi and opilio Tanner crab are prohibited species for the state scallop and groundfish fisheries and federal groundfish fisheries, meaning that any crab bycatch must be discarded. Although crab are always prohibited species in any groundfish fishery, they accrue against a CDQ PSC limit only when caught with trawl gear in Zone 1 for red king crab, Zone 1 and 2 for bairdi Tanner crab, and the opilio Tanner Crab Bycatch Limitation Zone for opilio Tanner crab (Figure 3.5-8). PSC limits are set for each species by zone for each fishery. When the PSC limit is reached the fishery closes for the remainder of the season .

The PSC limit for red king crab is based on abundance of the Bristol Bay red king crab stock as follows:

- When the number of mature female red king crab is equal to or below the threshold number of 8.4 million crab, or the effective spawning biomass is less than 14.5 million pounds, the Zone 1 red king crab PSC limit is 35,000 crab.

- When the number of mature female red king crab is above threshold, and the effective spawning biomass is equal to or greater than 14.5, but less than 55 million pounds, the Zone 1 red king crab PSC limit is 100,000 crab.

- When the number of mature female red king crab is above threshold, and the effective spawning biomass is equal to or greater than 55 million pounds, the Zone 1 red king crab PSC limit is 200,000 crab.

BSAI FMP Amendment 57 modified the red king crab bycatch by reducing the limits by an additional 3,000 crab as part of the conversion of the pollock fishery to pelagic trawling only.

Based on the 2002 abundance estimate of the effective spawning biomass at 37.7 million pounds (NPFMC 2002e; Appendix B - Prohibited Species Catch in the BSAI), the current PSC limit is 97,000 crab. The red king crab cap has generally been allocated among several groundfish fisheries. Once a fishery exceeds its red king crab PSC limit, Zone 1 is closed to that fishery for the remainder of the year, unless further allocated by season.

Bairdi tanner crab PSC limits are set separately for Zone 1 and Zone 2. PSC limits in both zones are based on total abundance of tanner crab as determined by the annual NOAA Fisheries trawl survey, as follows:

	Abundance	PSC Limit
Zone 1	0-150 million crab	0.5 percent of abundance
	150-270 million crab	750,000 crab
	270-400 million crab	850,000 crab
	Over 400 million crab	1,000,000 crab

	Abundance	PSC Limit
Zone 2	0-175 million crab	1.2 percent of abundance
	175-290 million crab	2,100,000 crab
	290-400 million crab	2,550,000 crab
	Over 400 million crab	3,000,000 crab

These PSC limits are further reduced by 50,000 crab as part of BSAI FMP Amendment 57.

Based on the 2002 abundance estimate of 464.9 million crab, the 2003 PSC limit is 980,000 crab in Zone 1 and 2.97 million crab in Zone 2 (NPFMC 2002e; Appendix B - Prohibited Species Catch in the BSAI). The bairdi tanner crab cap may be further allocated among several groundfish fisheries. When a fishery exceeds its bairdi tanner crab PSC limit in a zone, trawling is closed in that zone for the remainder of the year.

PSC limits for opilio tanner crab also are based on their total abundance as estimated by the NOAA Fisheries trawl survey. The opilio tanner crab PSC limit is set at 0.1133 percent of total opilio tanner crab abundance, with a minimum PSC of 4.5 million opilio tanner crab and a maximum of 13 million crab. PSC limits are further reduced through BSAI FMP Amendment 57 by 150,000 crab. Based on the 2002 abundance estimate of 1.49 billion crab (NPFMC 2002e; Appendix B - Prohibited Species Catch in the BSAI), the 2003 PSC limit is 4.35 million crab. The opilio tanner crab PSC limit applies to the *C. opilio* Bycatch Limitation Zone. The total PSC limit is allocated among several groundfish trawl fisheries. Upon attainment of a opilio crab PSC limit for a particular trawl target fishery, that fishery is prohibited from fishing within the *C. opilio* Bycatch Limitation Zone.

NOAA Fisheries Management

Crab regulations have been based on concerns that trawling impacts crab populations directly in terms of trawl-induced mortality and indirectly through habitat degradation. Observed mortality, as measured by crab bycatch, has accounted for a small percentage of crab populations. For example, bycatch amounted to only

0.5 percent of the red king crab, 1.2 percent of the bairdi Tanner crab, and 0.1 percent of the opilio Tanner crab population on average, for 1992 through 1995 (NPFMC 1996). Because bycatch is currently considered to be minor relative to other sources of mortality, time and area closures are thought to be more effective than PSC limits in reducing impacts of trawling on crab stocks (Witherell and Harrington 1996). As such, numerous trawl closure areas have been instituted to address concerns about unobserved mortality (crab wounded or killed but not captured), and possible habitat degradation due to trawling and dredging.

BSAI Crab Closures

Nearshore Bristol Bay Closure

BSAI FMP Amendment 10 prohibits all trawling at all times in the EEZ within the area east of 162°W with the exception of an area bounded by 159° to 160°W and 58° to 58°43'N which remains open April 1 to June 15; this amendment addresses concerns that commercial trawl fishing was contributing to increased mortality of crab due to incidental capture and mutilation.

Bristol Bay Red King Crab Area

BSAI FMP Amendment 37 closed this area seasonally to non-pelagic trawling to protect important red king crab habitat and rebuild the red king crab stock. The red king crab commercial fishery was closed in 1994 and 1995.

Pribilof Islands Habitat Conservation Area

BSAI FMP Amendment 21a closed trawling year-round in important habitat areas for blue king crab and Korean hair crab.

Crab Protection Zones

Zone A closed to trawling year-round; Zone B closed to trawling March 15 to June 15.

Crab Bycatch Limitation Zones

Closed to specified trawl fisheries when limits are reached.

C. Opilio Bycatch Limitation Zones

BSAI FMP Amendment 40 closed this area to specified trawl fisheries when limits are reached.

GOA Crab Closures

Permanent Kodiak Crab Protection Zones

GOA FMP Amendment 15 and 26 established Type I, II, and III areas for special bottom trawl within the GOA region to protect king crab, rebuild crab stocks, and protect habitat. Alitak Flats/Towers and Marmot

Flats are closed to non-pelagic trawls year-round, Chirikof Island and Barnabas are closed to non-pelagic trawls from February 15 to June 15.

Past/Present Effects Analysis

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-46 provides a summary of the king and Tanner crab past effects analysis presented below.

Crab species prey on a wide assortment of organisms that varies with life stages. fisheries bycatch of crab prey species ranges from very low (e.g., worms, snails, brittle stars, et cetera) to none (e.g., phytoplankton and zooplankton). A relationship between the groundfish fisheries minor bycatch of crab prey and prey availability for crab that could have the potential to cause population-level effects on crab species was not identified during screening. Therefore, effects on crab prey species will not be part of the analysis.

The following direct and indirect effect indicators were identified as potentially having population-level effects on crab:

- Catch/bycatch mortality (direct effect).
- Mortality from predation (direct effect).
- Climatic influences on marine survival (indirect effect).
- Mortality associated with spatial/temporal concentration of bycatch (indirect effect).

The past/present events determined to be applicable to the crab past effects analysis include the following:

- Past/Present External Events
  - Foreign fisheries (pre-MSA in U.S. EEZ)
  - Alaska State directed crab fisheries
  - Alaska State groundfish and scallop fisheries
  - Subsistence fisheries
  - Predation
  - Climate variability
- Past/Present Internal Events
  - FMP groundfish fisheries
- Past/Present Management Actions
  - Bilateral agreements
  - ADF&G management
  - Industry self-imposed management
  - FMP groundfish fisheries management

Mortality: Foreign Fisheries Direct Catch and Bycatch

Directed Japanese (1953 to 1975) and Russian (1959 to 1972) red king crab fisheries were conducted in the EBS and Bristol Bay. By the mid-1960s, there were signs that exploitation rates were at or approaching limits. Bristol Bay data showed that increased catches were being maintained by increases in the number of tangle nets being fished and in the average time the nets were being soaked. The Bristol Bay red king crab stock began to decline in 1964 after peak catches not related to crab biomass increases. Declines in the Kodiak and GOA crab fisheries led to a renewed interest of the domestic crab fleet in the Adak and Bering seas. The Adak fishery declined in the early 1970s and has never fully recovered.

During the mid-1960s, foreign fleets in the BSAI took record numbers of yellowfin sole and Pacific ocean perch. Crab bycatch is associated with both of these fisheries. Crab bycatch and unobserved mortality also occurred due to interactions with the foreign fleet's bottom trawl gear and state crab fixed gear fisheries. In the mid-1960s, the U.S. initiated several bilateral agreements with Japan and Russia to reduce gear conflicts between State of Alaska fixed gear crab fisheries and foreign fisheries and to allocate crab resources between the foreign fisheries and state fixed gear crab fisheries. The Japanese pot sanctuary area was established as a no-trawl zone in the early 1960s but was eliminated in 1976 with the implementation of the MSA. This area coincided with the distribution of mature female red king crab brood stock in the Bering Sea (Dew and McConnaughey in review). Although the MSA effectively eliminated trawling by foreign vessels, it did not provide for observers on domestic vessels (roughly between 1977-1990). Thus, the lack of observer coverage aboard vessels fishing in Bristol Bay may have led to inaccurate bycatch numbers being reported to managers who in turn, evaluated the potential impacts of trawling on red king crab (Dew and McConnaughey in review).

Mortality: Direct catch and Bycatch in State Directed Crab Fisheries

Bycatch consists of females and sublegal-sized males of the target species and non-target crab species. In the crab fisheries, this bycatch may comprise up to 60 percent of the total catch (Zhou and Shirley 1997a, Zhou and Shirley 1997b). The main concern of bycatch in the crab fishery is handling mortality of discarded crab, which leads to some reduction in fishery production (MacIntosh *et al.* 1995, Murphy and Kruse 1995). Mortality of crab bycatch is not well known, but is estimated to be 20 percent, although, handling mortality may be higher in winter fisheries when crab are exposed to low air temperatures and wind (NMFS 2004). Research is being conducted to reduce the amount of bycatch in the crab fisheries, such as improving pot design (Zhou and Shirley 1997a, Zhou and Shirley 1997b). Crab FMP regulations prohibit the landing of females and sublegal-sized males. State crab fisheries continue to occur and are closely managed by the state in cooperation with NOAA Fisheries. Quota setting processes are responsive to fluctuations in crab stocks but are limited in their ability to account for other factors possibly affecting crab populations such as changes in sex-ratio and spawning-recruitment success. Crab bycatch in the state and federal groundfish fisheries is taken into account under the state management processes.

Mortality: Bycatch in State Groundfish and Scallop Fisheries

Crab bycatch and unobserved mortality due to interactions with bottom trawl gear is associated with past state groundfish fisheries and state scallop fisheries. In the domestic groundfish fisheries, bycatch of red king crab and bairdi Tanner crab have been kept in check with PSC limits for trawl and scallop fisheries.

Mortality: Egg Mass Predation

Egg masses of king crab are often infested by a variety of symbionts and predators. Of particular importance is the nemertean worm, *Carcinonemertes regicides* (which means "king killing crab worm"). These worms have been observed in egg masses of king crab from multiple locations in Alaska (Kuris *et al.* 1991). Prevalence of worms (the proportion of crab infested with worms) was 100 percent in crab collected from southeastern Alaska, Cook Inlet, and many Kodiak sites. The worms were essentially absent from crab collected in the Bering Sea. Almost 100 percent of eggs were killed by worm predation in crab collected from Kachemak Bay, near Homer, Alaska, from 1983 to 1984. This predator could be responsible for limiting recruitment of crab populations in southcentral Alaskan waters, but does not seem to be a major factor in the Bering Sea.

Mortality: Climate Variability

Climate can have an influence on crab populations and their prey, both beneficial and adverse. Wind speed and duration can affect coastal upwelling of colder water from deeper depths. This process of upwelling promotes primary and secondary production, thus affecting the production of food for crab larvae. At the present time a causal relationship between phytoplankton and larval crab abundance and survival has not been established. However, it is thought that community composition and relative abundance of various phytoplankton species, in particular specific diatoms, could potentially be critical to the survival of red king crab larvae. Current regimes over the EBS influence the transport of crab larvae during their planktonic life, and eventual deposition on appropriate or non-appropriate settlement habitat for post-settlement juvenile survival (NMFS 2004).

Mortality: Bycatch in MSA Groundfish Fisheries

Crab bycatch in past foreign fisheries was replaced with increased crab bycatch in the JV fisheries until 1987 when new bycatch limits were put into effect. As the JV fisheries were being phased out and the domestic fisheries phased in, crab bycatch increased once again, but was quickly addressed by the establishment of new crab bycatch limits. Bycatch of opilio Tanner crab was unconstrained through 1996. Overall crab bycatch has been a function of crab abundance and PSC limits. High bycatch of king and Tanner crabs (mostly opilio Tanner crab) were taken in the 1970s by foreign fisheries. However, regulations and incentives implemented with the groundfish FMP in 1982 reduced crab bycatch to much lower levels. Bycatch of opilio Tanner crab increased drastically in the early 1990s, corresponding to an expanding crab population, so opilio Tanner crab PSC limits were established in 1996. Figures 3.5-21, 3.5-22, 3.5-23, and 3.5-24 show bycatch trends for red king crab, other king crab, bairdi Tanner crab, and other Tanner crab by area and gear during 1998-2001 (Hiatt *et al.* 2002).

Bycatch of prohibited species is also controlled by non-regulatory means. Many measures have been embraced by the trawl and longline fleet to control and reduce bycatch of crab, herring, Pacific halibut, and salmon. A GIS application has been used by the BSAI trawl and longline fleet to identify hotspots by using bycatch rates reported by individual vessels (Gauvin *et al.* 1995; Smoker 1996). Bycatch rate information from individual vessels is received at a central location, aggregated daily, and then quickly relayed back to the entire fleet in the form of maps, so that hotspot areas can be avoided. PSC rates are reduced and corresponding higher groundfish catches can then be realized by the fleet. Unfortunately, because this is a voluntary program, non-participating vessels with high bycatch rates may keep the fleet as a whole from catching the entire quota. Some bycatch reduction may also come in the form of peer pressure. Individual vessel bycatch rates are now published on the internet and vessels with high bycatch rates may face pressure to lower their bycatch.

Habitat Destruction

Major spawning areas have been identified for BSAI red king crab and western GOA red king crab. These important habitats are protected by trawl closures and conservation zones. Areas currently closed to non-pelagic trawling in the Bering Sea to protect crab species are the Red King Crab Savings Area, the nearshore Bristol Bay No Trawling Zone, and the Pribilof Islands Habitat Conservation Area. Blue and golden king crab habitat areas are protected by conservation zones in the Pribilof Islands and indirectly by the lack of groundfish effort near Saint Matthew Island. It has been hypothesized that the elimination of the Japanese pot sanctuary in Bristol Bay in 1976, with the subsequent establishment of a major trawling area amidst a large broodstock of red king crab, resulted in adverse impacts to important inshore crab habitat (Dew and McConnaughey in review). The importance of living and non-living habitat to various life stages of crab populations throughout the BSAI and GOA has not been determined to date. However, habitat research continues.

Comparative Baseline

Red King Crab

The 2002 length based analyses show mature female crab abundance has decreased slightly from the 2001 level; however, legal males show a slight increase and pre-recruit males have decreased in abundance. Legal male abundance in Bristol Bay increased from 7.5 million crab in 1997 to 9.4 million crab in 1999, decreased to 8.3 million crab in 2001, then increased slightly to 8.6 million crab in 2002 (NPFMC 2002f). Mature females (>89 mm) declined from 28.2 million crab in 1997 to 18.9 million crab in 2000, increased slightly in 2001 to 21.8 million crab, then declined to 18.6 million crab in 2002. Due to the decrease in abundance of mature females, ADF&G decreased the 1999 GHL from a 15 percent to a 10 percent exploitation rate; this rate has continued to be used for the 2001 and 2002 fishery (NPFMC 2002f). The Bristol Bay red king crab stock remains depressed compared to past abundance levels. Survey estimates of Pribilof Islands red king crab have been highly variable over the last ten years and have a high degree of uncertainty due to the patchy distribution of the animals. Model estimates of mature male abundance shows a decline from about 2 million in 1992 to 1 million in 1997, and then an increase to about 1.7 million in 2002. Legal male abundance was estimated at 1.36 million in 2002 (NPFMC 2002f). The red king crab Pribilof Islands fishery was closed in 1999 and has continued to be closed into 2002 due to uncertainty in the abundance estimates. A small Aleutian Island red king crab fishery occurs, with a 2002 GHL of 0.5 million pounds. Norton Sound also supports a small summer red king crab fishery (Bowers *et al.* 2002).

Blue King Crab

The blue king crab population in the Pribilof Islands is low, and population trends are not easily detectable (NMFS 1998a). Blue king crab female abundance is considered imprecise because trawling does a poor job of sampling the inshore, rocky substrate preferred by females (Morrison *et al.* 1998). The 2002 NOAA Fisheries survey estimated legal male abundance in the Pribilof Islands at 0.38 million crab, a decrease from the 2001 estimate (NPFMC 2002f). Pribilof Islands blue king crab were declared overfished in 2002 (64 FR

62212). A rebuilding plan is currently has been developed and was passed as BSAI Crab FMP Amendment 17 on March 18, 2004 (NPFMC 2004). Blue king crab in the Saint Matthew Island area have increased from 0.8 million crab in 2000 to 1.1 million crab in 2001. However, spawning biomass is still estimated to be below the minimum stock size threshold (Bowers *et al.* 2002). The Saint Matthew Island blue king crab stock was declared overfished and the fishery was closed in 1999 and has continued to be closed into 2002 (64 FR 54791). A rebuilding plan has been developed for the Saint Matthew Island stock and was passed as BSAI Crab FMP Amendment 15 on November 29, 2000 (NMFS 2000b).

Golden King Crab

Population estimates are not available from the NOAA Fisheries trawl survey for golden king crab. Golden king crab are found primarily near the Aleutian Islands. ADF&G conducts the Aleutian Islands golden king crab pot survey; however, there are no absolute estimates of abundance. ADF&G and NOAA Fisheries do not make annual abundance estimates for Bering Sea golden king crab, and commercial harvest is allowed by ADF&G permit (Morrison *et al.* 1998). Catches have declined from the early years of the fishery, as the initial stock was exploited and recruitment was unable to sustain the fishery at its initial harvest levels (Morrison *et al.* 1998). In 1995, the State of Alaska mandated observer coverage for all vessels targeting golden king crab in the Aleutian Islands. Small fisheries for golden king crab exist in the Pribilof Island area and in the Northern District of Saint Matthew Island (Bowers *et al.* 2002).

Bairdi Tanner Crab

In 1996, the bairdi Tanner crab was declared overfished in the Bering Sea. Following this declaration, the bairdi Tanner crab fishery was closed from 1997 to 2002 due to low abundance. During the 1997 survey, 95 percent of legal males encountered were old-shelled and not expected to molt again, and few young males in the 50- to 115-mm carapace width range were surveyed. In the 1998 survey, most legal males encountered were in the eastern district, with the highest abundance in central Bristol Bay. The cohort which began recruiting into the fishery in 1988 to 1992 has declined as a result of natural mortality and fishery removals. Given these two factors, it is likely that the Bering Sea bairdi Tanner crab population will continue to decline for years (Morrison *et al.* 1998). The 2001 survey abundance estimates for large males (135-mm carapace width) and large females have decreased from the 2000 estimates (Bowers *et al.* 2002). NPFMC considers the stock overfished and its crab plan team has developed a rebuilding plan (64 FR 15308). The bairdi Tanner crab rebuilding plan was passed as BSAI Crab FMP Amendment 11 on June 8, 2000 (NPFMC 1999b).

Opilio Tanner Crab (snow crab)

Large male opilio Tanner crab were estimated at 94 million crab in 1999, a decline of 63 percent from 1998. The mature biomass declined below the minimum stock size threshold of 460 million lbs, and the stock was declared overfished on September 24, 1999 (64 FR 54791). A rebuilding plan has been developed by NPFMC's crab plan team. This rebuilding plan was passed as BSAI Crab FMP Amendment 14 on December 28, 2000 (NPFMC 2000a). Since 1999, snow crab abundance has increased; the 2001 NOAA Fisheries survey estimates 77.5 million crabs, 2 percent above the 2000 estimate. A harvest of 33.5 million lbs was landed in 2000, based on a reduced harvest rate from past years. The 2002 Bering Sea opilio Tanner crab GHL is established at 31 million pounds (Bowers *et al.* 2002).

GOA Crab Stocks

GOA crab stock status is limited due to the lack of survey information. GOA red king crab stocks in the vicinity of Kodiak Island remain depressed. The last good year-class produced was in 1973 to 1974, and recent surveys failed to detect signs of rebuilding. No Kodiak red king crab fishery has occurred since 1983. Due to relative low abundance, all GOA direct red king crab fisheries are currently closed with the exception of a sporadic fishery in a few small areas off southeast Alaska. A golden king crab fishery occurs in the Kodiak region, although no more than two boats have participated in the fishery since 1988, with no fishing occurring during most years. The Kodiak bairdi Tanner crab population has been assessed by ADF&G trawl surveys since 1980. The 2001 survey estimates the Tanner crab population to be the highest on record at 175.9 million crab, although the number of legal crab remains similar to the 2000 estimate of 2.6 million crab. A commercial fishery took place in the Northeast and eastside sections of Kodiak Island in 2001 and 2002 (Ruccio *et al.* 2002).

King and Tanner Crab Cumulative Effects Analysis Status

All BSAI and GOA King and Tanner crab species mentioned here will be carried forth for cumulative effects analysis based on declining stock assessments and lack of information regarding current population status of some stocks.

3.5.3 Squid, Skates and Other Species

The other species category was established to monitor and manage groundfish species groups that are not currently economically important in BSAI and GOA groundfish fisheries, but are perceived to be ecologically important and of potential economic importance as well.

Marine species other than fish, including hard and soft deep sea corals, sea pens, sea fans and sea whips, are considered HAPC. They are discussed separately in Section 3.6 of this Programmatic SEIS.

BSAI/GOA Other Species Management

With the exception of squid in the BSAI and skates in the GOA, an aggregate TAC limits the catch of species in the other species category. Although the composition of this category has varied over the course of FMP management, the current configuration has been relatively stable:

- Squid (order Teuthoidea): target species in the BSAI.
- Sculpin (family Cottidae).
- Shark (*Somniosus pacificus, Squalus acanthias, Lamna ditropis*).
- Skate (genera *Bathyraja and Raja*): target species in the GOA.
- Octopi (*Octopus dofleini,Opistholeutis california,* and *Octopus leioderma*).

With the exception of squid and skate species, none of the species in the other species category is currently targeted by the BSAI and GOA groundfish fisheries. As such, they are only caught as bycatch by fisheries targeting groundfish. In the BSAI FMP, squid are managed in a combined squid and other species category, which is composed of squid (considered separately) and sculpin, skate, shark, and octopi (which compose the true other species category). Because data are insufficient to manage each of the other species groups separately, they are considered collectively. Currently, squid are a target species under the BSAI FMP and skate are target species in the GOA, pending the adoption of Amendment 63 (68 FR 67390).

A single estimate of *M* for this diverse assemblage is not feasible. The SSC believes that *M* is conservatively estimated at 0.2 OFL for the other species assemblage and is set using the criteria in Tier 5 (as described in FMP Amendment 44; Appendix C), where $F_{OFL} = M$, and OFL = $M \times$ (total other species survey biomass). Using Tier 5 criteria, ABC is capped at 75 percent of OFL. However, rather than use this method, since 1978 the other species ABC has been calculated as the average annual catch in order to avoid potential five-fold increases in other species catches that could occur if ABC were set at 75 percent of OFL. In 1998 (for the 1999 fishery), NPFMC began a 10-step increase toward full $F = M$ exploitation strategy for the other species complex by implementing the first 10 percent of the difference between that strategy and average catch since 1978. For the 2000 fishery, NPFMC stopped the stepwise increase and kept the ABC at a level approximately 10 percent higher than the stock assessment author's recommendation. BSAI other species TAC has been set equal to the other species ABC by NPFMC. A 2000 ABC for the BSAI other species category set using this process (31,360 mt) represents an exploitation rate of about 5 percent of the best estimate of current biomass (610,400 mt). This estimate was obtained by averaging the three most recent EBS bottom trawl survey estimates of other species biomass (561,600 mt from 1997 to 1999), and adding the most recent Aleutian Islands bottom trawl estimate (48,800 mt from 1997). A TAC for other species in the GOA is set at 5 percent of the sum of target species TACs each year, although a preliminary stock assessment was conducted for GOA other species in 1999 (Gaichas *et al.* 2003).

Adoption of Amendment 63 by NPFMC would result in the separation of GOA skate species from the other species complex. In turn, they would be added to the target species category with an ABC and TAC set for skates and skate complexes (NPFMC 2003). The NPFMC has requested a separate OFL and ABC for combined big and longnose skates in the Central GOA due to concerns regarding a developing fishery. Efforts to address existing data gaps for skate species are underway and improved collection of data is expected under this amendment.

BSAI/GOA Other Species Past/Present Effects Analysis

The geographic scope for the BSAI and GOA other species past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in the 1960s with the availability of bycatch estimates of other species and ends in 2002, the most recent year of which stock assessment information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. The following direct and indirect effects were identified as potentially having population level effects on BSAI/GOA other species (including BSAI squid and GOA skate species):

- Mortality due to catch/bycatch (direct effect).

- Reduced recruitment due to habitat/feeding/spawning disruption and spatial/temporal concentration of bycatch (indirect effect).

The following past/present effects determined to be applicable to the squid past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (pre-MSA)
  - State of Alaska groundfish fisheries
  - Directed fisheries

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries
  - Domestic groundfish fisheries

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

A past/present effects analysis is conducted for the other species category as a whole and for the individual taxonomic groups where information is available. Any information presented here for the entire group is not repeated in the subsections.

<u>External Mortality: Foreign Groundfish Fisheries (Pre-MSA)</u>

Reported catches of other species increased in the late 1960s and early 1970s with the increase in groundfish harvests. Similarly, other species catch peaked in 1972 at 133,000 mt, the same year that target groundfish harvest peaked.

<u>External Mortality: Directed Fisheries</u>

Directed fisheries have existed for squid, octopi and some species of shark in the past, and some fisheries persist today. See the subsections of these taxonomic groups for further details.

<u>External Mortality: State of Alaska Groundfish Fisheries</u>

See the subsections of specific other species groups for further details.

<u>External Mortality: State of Alaska Crab Fisheries</u>

See the subsections of specific other species groups for further details.

Internal Mortality: JV and Domestic Groundfish Fisheries

Beginning in 2000, a new method was used to estimate species group catch within the other species complex in the BSAI. The new method is similar to the NOAA Fisheries, Regional Office blend catch estimation system; the ratio of observed other species group catch to observed target species catch was multiplied by the blend-estimated target species catch within each area, gear, and target fishery to obtain the total annual catch by species group between 1997-2001 (Gaichas 2002).

Within the other species group, only shark are identified to the species level by fishery observers. Observers are currently instructed to concentrate on higher-priority target and prohibited species for data collection. Furthermore, accuracy of catch estimates depends on the level of coverage in each fishery. Estimates of observer coverage in the BSAI are 70 to 80 percent, whereas the GOA has only approximately 30 percent observer coverage. Coverage can also vary for certain target fisheries and vessel sizes (Gaichas 2002).

Other species catch occurs largely in the flatfish bottom trawl, Pacific cod longline and bottom trawl and pollock fisheries in the BSAI and in the sablefish and Pacific cod fisheries in the BSAI. Other species catch is made up mostly of skate and sculpin (66-96 percent from 1992 to 1997) and can vary from year to year (Gaichas 2002).

Recommendations have been made by the AFSC staff to reduce other species bycatch. For squid, limiting pelagic trawl fishing in areas with high squid abundance has shown successful reduction in bycatch. Steller sea lion closures have reduced squid bycatch in recent years, demonstrating the effectiveness of area closures on squid bycatch. In 1999 and 2000, the pollock fishery was limited in an area of historically concentrated squid bycatch, cutting squid bycatch to less than half than was observed in 1997-1998 (NPFMC 2002e). Shark and skate bycatch can be reduced through the use of specialized gear; excluder devices that are used to avoid halibut bycatch may be effective and improve survival by releasing skates from trawl nets before they are captured (Craig Rose, AFSC, NMFS, and John Gauvin, The Groundfish Forum, personal communication). A similar configuration could be used to release sharks before capture. For sculpin, by determining the general location of certain genuses, management may be able to incorporate area-specific TACs to achieve individual species management (Gaichas 2002). Estimated total catch of other species in the EBS and the Aleutian Islands from 1977-2002, and in the GOA from 1977-2001 is listed in Gaichas (2002) and Gaichas *et al.* (2003).

It is possible under current other species management that a species or even a species group could be disproportionately exploited while the overall aggregate other species TAC is not reached. This potential is a concern because the other species category includes groups with extremely diverse habitats and life history strategies. In addition, data limitations plague different groups within this category. The lack of biomass estimates for cephalopods (squid and octopi) has been a source of difficulty for determining stock status relative to bycatch, and the lack of adequate species identification in catch data hampers the analysis of catch trends for skate and sculpin species. Moreover, the highest observed catches of non-target species are within the categories receiving the least intensive management under the current FMP: other species and non-specified species. It is difficult to determine how much protection is afforded by a TAC set with the use of these data-poor criteria.

Stock assessments are conducted for other species, including squid (in the BSAI) and skates (in the GOA), although TACs are established separately for other species and squid in the BSAI (Fritz 1999), and skates in the GOA (pending adoption of Amendment 63). An aggregate TAC limits the catch of species in the other species category.

In 1999, FMP Amendments 63/63 were initiated to remove the shark and skate species groups from other species in both the BSAI and GOA to better protect these vulnerable, long-lived species (NPFMC 1999a). Based on the 1999 stock assessments for other species (discussed below), the Plan Teams recommended that all other species be considered in an expanded FMP amendment to establish TACs at the species group level. While this amendment was being revised, NPFMC recommended to NOAA Fisheries that other species be placed on bycatch only status to prevent a directed fishery from developing in the interim. NOAA Fisheries determined that it did not have regulatory authority for such an action; therefore, aggregate other species TACs remain in place in the BSAI and the GOA despite efforts to limit directed fisheries and develop more protective management within this category. Final action on the revised plan amendments to set other species as bycatch only and to redefine the GOA TAC setting process will be scheduled in the future.

Beginning in 1999, smelt was removed from the other species category and placed—along with a wide variety of other fish and crustaceans including krill, deep-sea smelt, and lantern fishes—in the forage fish category. This action was accomplished through Amendments 36 and 39 to the BSAI and GOA groundfish FMPs (see Appendix C and D)

Management Tier/Stock for Sculpin, Shark, Skate and Octopi

<u>BSAI/GOA Other Species Comparative Baseline</u>

Reliable biomass estimates exist for two groups (skate and sculpin) that comprise the bulk of the biomass and fishery catches in the other species category. Survey biomass estimates for shark, smelt, and octopi, while not reliable, represent the best data available on the abundance of these species. Fluctuations of biomass have been shown within the other species group. This may be a result of changes in distribution of particular species among regions and during various times of the year (NPFMC 2002c).

Data from NOAA Fisheries surveys in both the BSAI and GOA provide the only abundance estimates for the various groups and species comprising the other species category. Biomass estimates for the EBS are from a standard NOAA Fisheries survey area of the continental shelf. The 1979, 1981, 1982, 1985, 1988, and 1991 data include estimates from continental slope waters (200 to 1,000 m in 1979, 1981, 1982, and 1985; 200 to 800 m in 1988 and 1991), but data from other years do not. Slope estimates were usually 5 percent or less of the shelf estimates, except for grenadiers (see Section 3.5.5). Stations as deep as 900 m were sampled in the 1980, 1983, and 1986 Aleutian Islands bottom trawl surveys, while surveys in 1991 and 1994 obtained samples to a depth of only 500 m. Trends in the biomass of GOA other species were investigated using the NOAA Fisheries triennial trawl survey data from 1984 through 1999. There are inconsistencies associated with some of these studies. Thus, some of the GOA data is not as comprehensive as the data for the BSAI.

Since the BSAI survey biomass estimates for species other than squid vary substantially from year to year due to different distributions of the component species, it is probably more reliable to estimate current biomass by averaging estimates of recent surveys. The average biomass of other species from EBS surveys in 1997, 1998, and 1999 is 561,600 mt; adding the estimate from the 1997 Aleutian Islands survey (48,975 mt) yields a total BSAI other species biomass estimate of 610,575 mt. The average biomass of other species from the last three EBS shelf and slope surveys (2000, 2001, and 2002) is 637,578 mt; adding the estimate from the 2002 Aleutian Islands survey (51,600 mt) results in a current total BSAI other species biomass estimate of 689,178 mt (NPFMC 2002e).

Trends in the biomass of GOA other species (shark, skate, sculpin, smelt, octopi, and squid) were investigated using the NOAA Fisheries triennial trawl survey data from 1984 through 1999. GOA biomass trend discussion should be viewed with the following caveats in mind:

- Survey efficiency may have increased for a variety of reasons between 1984 and 1990, but should be stable after 1990 (Robin Harrison, AFSC, NMFS, personal communication).

- Surveys in 1984, 1987, and 1999 included deeper strata than the 1990-1996 surveys. Therefore, the biomass estimates for deeper-dwelling components of the other species category are not comparable across all years.

The average biomass within the other species category in the GOA, using all six survey biomass estimates (from 1984 to 1990), is 160,000 mt; much less than the average of the more recent BSAI surveys. The most recent estimate of other species biomass (1999) is 213,000 mt. Skate represent 30 to 40 percent of the other species biomass from all surveys and are the most common species in each year except 1984 when sculpin biomass was highest within the category. Total biomass for the other species category increased between 1984 and 1999. This is the result of apparent increases in skate, shark, and smelt biomass, some of which may be difficult to resolve from changes in survey efficiency. Sculpin biomass appears relatively stable over this period. Biomass estimates of other species in the EBS and Aleutian Islands, from various AFSC surveys, are included in Gaichas (2002).

<u>BSAI/GOA Other Species Cumulative Effects Status</u>

It is possible under current other species management that a species or even a species group could be disproportionately exploited while the overall aggregate other species TAC is not reached. This potential is a concern because the other species category includes groups with extremely diverse habitats and life history strategies. In addition, data limitations plague different groups within this category. The lack of biomass estimates for cephalopods (squid and octopi) has been a source of difficulty for determining stock status relative to bycatch, and the lack of adequate species identification in catch data impedes the analysis of catch trends for skate and sculpin species. It is difficult to determine how much protection is afforded by a TAC set with the use of these data-poor criteria.

<u>Trophic Interactions of Other Species</u>

Many species in the squid and other species category are important prey for marine mammals and birds, as well as commercial groundfish species. Squid and octopi are consumed primarily by marine mammals such as Steller sea lions (Lowry *et al.* 1982), northern fur seals (Perez and Bigg 1986), harbor seals (Lowry *et al.* 1982, Pitcher 1980b), sperm whales (Kawakami 1980), Dall's porpoise (Crawford 1981), Pacific white-sided dolphins (Morris *et al.* 1983), and beaked whales (Loughlin and Perez 1985). Sculpin have also been found in the diet of harbor seals (Lowry *et al.* 1982). Squid are important prey for albatross, especially during nesting season.

3.5.3.1 Squid

Life History and Distribution

Squid (order Teuthoidea) are cephalopod mollusks that are related to octopi. Squid are considered highly specialized and organized mollusks, with only a vestigial mollusc shell remaining as an internal plate called the pen, or gladius. They are streamlined animals with 10 appendages (2 tentacles and 8 arms) extending from the head, and lateral fins extending from the rear of the mantle. Squid are active predators that swim by jet propulsion, reaching swimming speeds of up to 40 km/hour, the fastest of any aquatic invertebrate. Members of this order (*Archeteuthis* species) also hold the record for largest size of any invertebrate (Barnes 1987).

Little is known about the reproductive biology of squid. Fertilization is internal and juveniles have no larval stage. Eggs of inshore species are often enveloped in a gelatinous matrix attached to substrate, while the eggs of offshore species are extruded as drifting masses. Squid are characterized by their rapid growth, patch distribution and high variable recruitment; being described as the "marine equivalent of weeds" (O'Dor 1998). Squid travel in schools of similarly sized individuals. Lipinski (1998) conjectured that these schools may migrate, forage and spawn at different times of the year. The importance of squid to the North Pacific ecosystem and our limited knowledge of their life history, distribution and abundance makes squid a good case study to illustrate management of an important resource with little information.

The most commercially important (and therefore best studied) squid in the western North Pacific is the magistrate armhook squid, *(Berryteuthis magister)* (Figure 35-25). It is abundant over continental slopes throughout the North Pacific Ocean from Oregon to southern Japan (Nesis 1987). It is the basis of fisheries in both Russian and Japanese waters. The maximum size reported for *B. magister* is 28-cm mantle length. The internal vestigial shell, or gladius, and statoliths (similar to otoliths in fish) were compared for aging this species (Arkhipkin *et al.* 1996). *B. magister* from the western Bering Sea are described as slow growing (for squid) and relatively long lived (up to 2 years). Males grow more slowly to earlier maturation than females. *B. magister* were dispersed during summer months in the western Bering Sea, but formed large, dense schools over the continental slope between September and October. Stock structure in this species is complex, with three seasonal cohorts identified in the region: summer-hatched, fall-hatched, and winter-hatched. Growth, maturation, and mortality rates varied between seasonal cohorts, with each cohort using the same areas for different portions of the life cycle. For example, the summer spawned cohort used the continental slope as a spawning ground only during the summer, while the fall spawned cohort used the same area at the same time primarily as a feeding ground, and only secondarily as a spawning ground (Arkhipkin *et al.* 1996). There are many fisheries directed at squid species worldwide, although most focus on temperate squid in the genus *Ilex* and *Loligo* (Agnew *et al.* 1998, Lipinski 1998).

Trophic Interactions

Squid are important components in the diets of many seabirds, fish, and marine mammals, as well as being voracious predators of zooplankton and larval fish (Caddy 1983, Sinclair *et al.* 1999). Squid are consumed primarily by marine mammals such as Steller sea lions (Lowry *et al.* 1982), northern fur seals (Perez and Bigg 1986), harbor seals (Lowry *et al.* 1982, Pitcher 1980b), sperm whales (Kawakami 1980), Dall's porpoise (Crawford 1981), Pacific white-sided dolphins (Morris *et al.* 1983), and beaked whales (Loughlin and Perez 1985). Perez (1990) estimated that squid comprise over 80 percent of the diet of some whales. Seabirds and some salmon species are also known to feed heavily on squid at certain times of the year.

BSAI/GOA Squid Management

In the BSAI, squid are managed within their own category under a species complex TAC, which is set each year based on Tier 6 criteria at 75 percent of the average catch of squid over the period 1978 to 1995. This criteria has been used for establishing ABC for squid in 2003 as well (BSAI SAFE 2002) Squid bycatch is taken almost entirely (97 percent) in the pelagic pollock fishery (NMFS 2001a) . The estimated total catch of squid in the BSAI for 2001 reached 1,801 mt, being the highest in the past five years (Gaichas, BSAI SAFE 2002).

In the GOA, squid are managed as part of the other species category. The 14,270 mt TAC for this complex is set at 5 percent of all target species TACs for the GOA. When combined with the predicted catch of all animals in this category (about 5,400 mt) this catch would not exceed the other species TAC for the GOA. As in the BSAI, squid bycatch in the GOA is taken primarily in pollock fisheries (74 percent), although small amounts are from bottom trawl fisheries such as those targeting the deepwater flatfish complex (10 percent).

The catch of individual squid species cannot be estimated because they are not identified to species in the catch at present. In contrast with the skate and grenadier, reasonable assumptions about the catch composition within the squid complex cannot be developed and analyzed because of the lack of biomass estimates by species.

BSAI/GOA Squid Past/Present Effects Analysis

The geographic scope for the BSAI and GOA squid past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in 1977 when the Japanese squid fishery begins and ends in 2002, the most recent year of which information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this Programmatic SEIS. Table 3.5-47 provides a summary of the BSAI and GOA squid past effects analysis presented below. The following direct and indirect effects were identified as potentially having population level effects on BSAI/GOA squid:

- Mortality due to catch/bycatch (direct effect).
- Reduced recruitment due to habitat/feeding/spawning disruption and spatial/temporal concentration of bycatch (indirect effect).

The following past/present effects determined to be applicable to the squid past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (pre-MSA)

- State of Alaska groundfish fisheries
  - State of Alaska shrimp fisheries
  - Directed squid fisheries

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries
  - Domestic groundfish fisheries

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

External Mortality: Foreign Groundfish Fisheries

Due to poor identification and incomplete reporting, bycatch rates for squid are unknown for the foreign fisheries prior to 1977, however they are assumed to have increased from the 1960s and 1970s and then decreased following the peak other species catch in 1972, similar to the other species complex trends discussed above.

External Mortality: Directed Fisheries

The Japanese and the Republic of Korea conducted a directed fishery on squid from 1975-1987 in the EBS and the Aleutian Islands. Catches were limited by the 1973 U.S. and Japan bilateral agreement and were further limited by the passing of the MSA.

External Mortality: State of Alaska Groundfish Fisheries and Shrimp Fisheries

Currently, catch data for squid is incomplete for State of Alaska groundfish fisheries and shrimp fisheries for the BSAI and GOA regions. Due to this lack of data, reliable estimates cannot be drawn at this time.

Internal Mortality: Foreign, JV and Domestic Groundfish Fisheries (post-MSA)

Foreign fishery catch of squid peaked in the EBS in 1978 at 6,886 mt and steadily dropped until the foreign fisheries were phased out by the domestic fisheries in 1987. In the Aleutian Islands, foreign catch peaked in 1980 at 2,332 mt. Presumably, these catch statistics reflect both directed catch by Japan and the Republic of Korea, and incidental catch in the foreign target fisheries (Gaichas 2002).

JV target fisheries began reporting squid bycatch in 1981 in the EBS and in 1983 in the Aleutian Islands region. Reported bycatch of squid remained low throughout the duration of these fisheries, at less than 200 mt annually. The domestic fisheries entered in the EBS and Aleutian Islands in 1987, with squid bycatch ranging from 1 to 1,500 mt annually, combined for both regions. Bycatch peaked in 1997, declined, and peaked again in 2001 at 1,766 mt.

Squid represent a low proportion of non-target groundfish bycatch relative to other species. Squid are primarily caught in pelagic trawl fisheries along the outer continental shelf and slope, especially around submarine canyons or in deep waters of the Aleutian Basin. Squid do not survive capture. Squid bycatch is higher in EBS than GOA. In the EBS pollock trawl domestic fishery (1990-2001) the squid bycatch ranged from 364 to 1,761 mt. In the Aleutian Islands pollock trawl domestic fishery (1990-2001) the squid bycatch ranged from 5 to 95 mt/year (Gaichas 2002). In the GOA, squid are caught as bycatch mostly in the pollock fisheries, and in small amounts from bottom trawl fisheries such as rockfish and the deepwater flatfish complex. Estimated catch between 1997-2000 ranged from 14 to 98 mt (NPFMC 2002c).

In 1980, GOA FMP Amendment 8 created four species management categories (target, other species, unallocated, and non-specified) and three regulatory districts for sablefish in southeast Alaska. Its purpose was to make the GOA FMP conform to the newly adopted BSAI FMP, enhance target species management, and protect incidentally caught species. Information on squid, rockfish, and several other species was found insufficient to warrant OYs for the three main regulatory areas in the GOA; therefore, their management was changed to a Gulf-wide management strategy.

Reported catches of squid in the EBS and Aleutian Islands since 1977 show that after reaching 9,000 mt in 1978, total squid catches have steadily declined to only a few hundred tons in 1987-1995. Thus, squid stocks have been comparatively lightly exploited in recent years. Discard rates of squid (discards/total squid catch) by the BSAI groundfish fisheries have ranged between 40 and 85 percent in 1992-1998 (NOAA Fisheries Regional Office, Juneau, personal communication). The 2001 estimated catch of squid, 1,810 mt, is the highest in the past five years and much closer to the ABC of 1,970 mt than any estimated catch since the 1980s. The recommended ABC for squid in 2003 is calculated as 0.75 times the average catch from 1978-1995, or 1,970 mt; the recommended overfishing level for squid in the year 2002 is calculated as the average catch from 1978-1995, or 2,624 mt. The rationale for a Tier 6-based ABC recommendation is that there is no reliable biomass estimate for squid (Gaichas 2002).

External Reduced Recruitment: Foreign Groundfish fisheries (pre-MSA)

Data is not available to determine whether the foreign fisheries disrupted spawning, feeding, and/or habitat of squid and squid aggregations. However, it is assumed that the foreign fisheries may have had similar impacts on squid recruitment as the current domestic fisheries.

External Reduced Recruitment: Directed Fisheries

Data is not available to determine whether the directed fisheries disrupt spawning, feeding, and/or habitat of squid and squid aggregations. However, it is assumed that they may have similar impacts on squid recruitment as the domestic fisheries.

External Reduced Recruitment: State of Alaska Groundfish fisheries

Data is not available to determine whether the State of Alaska groundfish fisheries disrupt spawning, feeding, and/or habitat of squid and squid aggregations. However, it is assumed that they may have similar impacts on squid recruitment as the domestic fisheries. Timing and location of fishery interactions with squid spawning aggregations may affect both the squid population and availability of squid as prey for other animals (Caddy 1983, O'Dor 1998).

Internal Reduced Recruitment: Foreign, JV and domestic fisheries (post-MSA)

Timing and location of fishery interactions with squid spawning aggregations may affect both the squid population and availability of squid as prey for other animals (Caddy 1983, O'Dor 1998). Whereas the proportion of overall squid complex biomass that is caught in groundfish fisheries cannot be determined, there are some hints as to the potential indirect impacts of bycatch on squid stocks. The concentration of squid bycatch in certain areas over the continental shelf edge (Figure 3.5-26) may indicate that these regions are important to squid stocks for spawning, feeding, or both. In western Bering Sea stocks of *Berryteuthis magister*, these localized aggregations appear to be composed of a single seasonal cohort of related squid. Groundfish bycatch may not represent a significant impact on the basinwide population of squid, but may damage stock structure even with relatively small amounts of bycatch if all bycatch is from a single seasonal cohort in one area. Groundfish fisheries may also disturb squid aggregations or disrupt important habitat, in addition to the direct effect of catch. More information on squid biology in the EBS and GOA is needed to determine whether any of these indirect impacts on the squid complex would occur and whether they represent significantly adverse impacts.

BSAI/GOA Squid Comparative Baseline

Squid are found throughout the Pacific Ocean. Squid species are not well sampled by bottom trawl surveys, and historically, acoustic surveys have not been directed at squid in the FMP areas. At least 7 squid species have been identified in the FMP areas by AFSC surveys, whereas 18 species were identified in the mesopelagic regions off the slope of the EBS (Sinclair *et al.* 1999).

Assessment data are not available for squid from NOAA Fisheries surveys because of their mainly pelagic distribution over deep water. Information on the distribution, abundance, and biology of squid stocks in the EBS and Aleutian Islands is generally lacking. Red armhook squid (*Berryteuthis magister*) predominates in commercial bycatch in the EBS and GOA, and *Onychoteuthis borealijaponicus* is the principal species encountered in the Aleutian Islands.

As a group, squid represent a relatively low proportion of non-target species catch (about 2 percent), however they serve a crucial role in marine ecosystems. No reliable biomass estimates or stock assessments for squid exist. Sobolevsky (1996) cites an estimate of 4 million tons for the entire Bering Sea made by squid biologists at the Pacific Research Institute of Fisheries and Oceanography (Shuntov 1993), and an estimated 2.3 million tons for the western and central Bering Sea (Radchenko 1992), but admits that squid stock abundance estimates have received little attention. NOAA Fisheries bottom trawl surveys almost certainly underestimate squid abundance. Squid catches and ABCs are a very small percentage of the total squid biomass in the EBS and GOA.

In theory, a squid survey could be conducted with midwater trawls and or hydroacoustics. There is such a survey for pollock, but the existing survey would need to extend out across shelf break, at least, which would greatly expand the scope of the current survey. As far as seasonality, squid appear in the catch data during all pollock seasons in the areas around the shelf break. The highest observed fishery CPUE of squid might indicate when a survey would be most efficiently conducted. According to fishery information from 1997 to 1999, a peak in squid CPUE occurs in January; however, it is also all in one location (Pribilof Canyon), making it difficult to tell if the high CPUEs are seasonally or spatially related. The life history information reported for western Bering Sea *Berryteuthis magister* suggests that any survey for squid would have to occur over multiple seasons to fully assess the biomass available in a given year and would require significant information on the life cycles and migratory routes of local squid to maximize efficiency.

Lacking this information, a survey to provide the biomass estimates would have to cover so much territory and so many seasons as to be prohibitively expensive, especially considering that there is no target fishery for squids in the FMP areas at this time. A more realistic approach might be to initiate smaller scale surveys, perhaps coordinated with the existing pollock surveys, to conduct squid species identification and life history investigations in the area to determine how a larger scale survey might be conducted in the future.

BSAI/GOA Squid Cumulative Effects Status

Assessment data is limited for squid from NOAA Fisheries surveys and no reliable biomass estimates or stock assessments for squid exist. However, they will be brought forward as part of the other species complex for cumulative effects analysis due to their ecological importance and essential role as prey species.

3.5.3.2 Sculpin

Life History and Distribution

Despite their abundance and diversity, sculpin life histories are not well known in Alaska.Forty-one sculpin species have been identified in the EBS and 22 species in the Aleutian Islands (Bakkala 1993, Bakkala *et al.* 1985, Ronholt *et al.* 1985). Sculpin are small, bottom-dwelling fish that lay adhesive eggs in nests and exhibit parental care for eggs (Eschemeyer *et al.* 1983). Life history information varies for each species in this group; the great sculpin is the largest sculpin species reaching 70 cm in length and 8 kg in weight in the western North Pacific. These species appear to be relatively short-lived with late maturity; the great sculpin does not reach maturity until 5-8 years (Tokranov 1985) and lives only 13 to 15 years.

Trophic Interactions

Little is known of the trophic interactions of sculpin. Sculpin are important benthic predators and serve as prey for many groundfish species such as halibut (*Hippoglossus stenolepis*), salmon (*Onchorynchus gorbuscha*), and hakes/burbots (*Brosme brosme*) (Gaichas 2002). Currently, data relating to the trophic interactions of sculpin in the BSAI is unavailable.

In the GOA, the main prey items for sculpin are shrimp and small flatfish. They also feed on crab, eelpouts, other sculpin, and smelt. Sculpin are prey for numerous species of marine life including: Steller sea lions, halibut, cod, other sculpin, toothed whales, seals, skate, sablefish, arrowtooth flounder, thornyhead rockfish, pollock, and small flatfish (Aydin *et al.* 2002, Gaichas 2003).

BSAI/GOA Sculpin Management

See above in the BSAI/GOA Other Species Management section.

BSAI/GOA Sculpin Past/Present Effects Analysis

The geographic scope for the BSAI and GOA sculpin past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in the 1960s with the availability of bycatch estimates of other species and ends in 2002, the most recent year of which information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this document. Table 3.5-48 provides a summary of the BSAI and GOA sculpin past effects analysis presented below. The following direct effect was identified as potentially having population level effects on BSAI/GOA sculpin:

- Mortality due to bycatch (direct effect).

The following past/present effects determined to be applicable to the sculpin past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (pre-MSA)
  - State of Alaska groundfish fisheries

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries
  - Domestic groundfish fisheries

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

External Mortality: Foreign Groundfish Fisheries (pre-MSA)

Bycatch data from the foreign fisheries in the BSAI and GOA is non-existent for sculpin. It is assumed that the sculpin foreign bycatch is comparable to the current level of bycatch; bycatch tends to increase with increase in target groundfish catch.

External Mortality: State of Alaska Groundfish Fisheries

It is inferred that proportionally similar sculpin bycatch could occur in the state groundfish fisheries as compared to the current federal groundfish fisheries. Since sculpin are taken incidentally from the Pacific cod and pollock federal fisheries, it is assumed that sculpin would also be taken in the State of Alaska Pacific cod and pollock fisheries. Although amount of sculpin bycatch may be similar between state and federal groundfish fisheries, the species mix of sculpin within this bycatch may differ between nearshore state fisheries and federal fisheries.

Internal Mortality: Foreign, JV and domestic fisheries (post-MSA)

Past JV fisheries bycatch of sculpin for the BSAI and GOA is non-existent. It is assumed that the bycatch is comparable to domestic bycatch levels; bycatch tends to increase with increase in target groundfish catch.

Skate and sculpin make up the bulk of the other species bycatch (66-96 percent from 1992-1997). This trend continued from 1997-2001 as well. Sculpin are caught largely in the Pacific cod hook and line fishery and trawl fisheries for pollock, yellowfin sole, Atka mackerel and rock sole occurring over the shelf break and slope or in deep waters of the Aleutian Basin (Gaichas 2001).

Internal Reduced Recruitment: JV and Domestic Fisheries

Habitat suitability/Spawning disruption

The sculpin nest-laying reproductive strategy may make sculpin populations more sensitive to changes in benthic habitats than other groundfish species such as cod and pollock, which are broadcast spawners with pelagic eggs. Moreover, the limited information on sculpin species suggest that species may react differently to similar environmental conditions. Within each sculpin species, the spatial effects of fishing may still be important, because observed differences in fecundity, egg size, and other life history characteristics suggest local populations (Tokranov 1985), which are not generally observed in target groundfish stocks. All of these characteristics indicate that sculpin as a group might be managed differently than other groundfish stocks, perhaps most efficiently within a spatial context rather than with a global annual aggregate TAC. It seems clear that sculpin are significantly different from all other members of the other species category as to justify their own management category, despite the potential complexity of effective management of a single group as diverse as the sculpin (Gaichas 2001).

BSAI/GOA Sculpin Comparative Baseline

Sculpin in the BSAI were the major component of other species group until 1986 according to the EBS AFSC surveys, after which skate biomass exceeded that of sculpin. In the EBS, sculpin abundance remained stable through 1998, but has since declined, with a slight increase in the 2002 survey at 181,200 mt (slope and shelf surveys). The Aleutian Islands survey show a decline since 1980, averaging around 13,000-14,000 mt in recent years (Gaichas 2002). Estimated total catch of sculpin in the BSAI from 1997-2000 ranged from 5,470 to 7,670 mt (Gaichas 2002). In the GOA, estimated total catch for the same years ranged from 541 to 943 mt (NORPAC and year-end estimates of target species catch from the NMFS Regional Office blend database).

In the GOA, individual sculpin species display divergent biomass trends between 1984 and 1999. While the biomass of bigmouth sculpin (*Hemitripterus bolini*) decreased over the survey period, great sculpin (*Myoxocephalus polyacanthocephalus*) biomass remained relatively stable, and yellow Irish lord (*Hemiliepidotus jordani*) biomass increased. Yellow Irish lord biomass appears to have increased over time despite general stability in the number of hauls where the species occurred, whereas bigmouth sculpin were encountered in fewer hauls each year. Uncertainty in these estimates varies between years.

BSAI/GOA Sculpin Cumulative Effects Status

Assessment data is limited for sculpin and no reliable biomass estimates or stock assessments for sculpin exist. Thus, they will be brought forward for cumulative effects analysis due to their ecological importance and essential role as prey species.

3.5.3.3 Shark

Life History and Distribution

The three shark species most commonly encountered in the North Pacific are the sleeper shark, *Somniosus pacificus*, the piked or spiny dogfish, *Squalus acanthias*, and the salmon shark, *Lamna ditropis* (Gaichas 2002). Generally, shark are more K-selected species; long-lived, long gestation periods (6 months to 2 years) and few, well-developed offspring (Pratt and Casey 1990).

The Pacific sleeper shark are not well known, but are found often in the shelf and slope waters of the North Pacific. Dense aggregations of sleeper shark were found during the 2000 Bering Sea slope survey, although none have yet been found on the EBS shelf survey. The reproductive mode of the sleeper shark is unknown.

The spiny dogfish can be found from the Bering Sea to the Baja Peninsula in shelf and upper slope waters, and are most common off the U.S. west coast and British Columbia (Hart 1973). Separate stocks of spiny dogfish have been found off the coast of British Columbia and Washington that do not mix (Compagno 1984). Dogfish form feeding aggregations segregated by size, sex and maturity; males are often found in shallower water than females. Females bear small litters of 1-20 pups following a gestation period of 18-24 months, females travel to shallow bays to bear their young. Average age recorded range from 25-30 years, with a maximum up to 100 years; and maximum size of 1.6 m in the eastern North Pacific (Compagno 1984).

Salmon shark are found from Japan, throughout the BSAI and GOA and down to Baja California, most commonly in coastal littoral and epipelagic waters both inshore and offshore. Salmon shark are oviporous bearing an average of 5 pups in the western North Pacific. Uterine cannibalism has been found (Gilmore 1993). Average size ranges from 2 to 2.5 m, with a maximum size of 3.0 m. Salmon shark live to an average age of 25 years in the western North Pacific; females generally reach maturity from 8-10 years and males at 5 years (Tanaka 1980). Little is known about the eastern North Pacific salmon shark population, although research is being conducted to determine the demographics and population parameters (K. Goldman, VIMS, personal communication as referenced by Gaichas 2002).

Trophic Interactions

In recent years, numbers of shark in Alaskan waters seem to be increasing while a decline in pinnipeds (specifically Steller sea lions) has occurred. Although it may be possible that shark predation could introduce a source of mortality to pinnipeds in certain areas of Alaska, much more research is needed to address uncertainty in data collected thus far. Little is known of the trophic interactions of shark in the BSAI. Thus, only GOA will be discussed here.

In the GOA, sleeper shark prey primarily on arrowtooth flounder. Additionally, they may eat salmon, cephalopods, small flatfish, and fishery offal. Salmon shark prey mostly on salmon and cephalopods as well as sablefish, herring, smelt, few rockfish, and flatfish. Dogfish eat large zooplankton, herring, shrimp, small flatfish, cephalopods, smelt, sandlance, and other demersal fish. Shark in the GOA have no known predators. However, salmon shark will prey upon spiny dogfish (Gaichas 2002).

BSAI/GOA Shark Management

See above in the BSAI/GOA Other Species Management.

BSAI/GOA Past/Present Effects Analysis

The geographic scope for the BSAI and GOA shark past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in the 1960s with the availability of bycatch estimates of other species intensity and ends in 2002, the most recent year of which information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this Programmatic SEIS. Table 3.5-49 provides a summary of the BSAI and GOA shark past effects analysis presented below. The following direct and indirect effects were identified as potentially having population level effects on BSAI/GOA shark:

- Mortality due to catch/bycatch (direct effect).

- Increased recruitment due to increased habitat suitability (indirect effect).

The following past/present effects determined to be applicable to the shark past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (pre-MSA)
  - State of Alaska groundfish fisheries
  - IPHC halibut longline fisheries
  - Sport fisheries
  - Climate changes and regime shifts

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries
  - Domestic groundfish fisheries

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

External Mortality: Sport Fisheries

There are currently no directed commercial fisheries for shark in Alaska State or federal waters. The state prohibited directed commercial fishing for shark in 1998 and set limits for the modest sport fishery that currently exists (2 shark per person per year, 1 on any given day). This made Alaska the first state ever to implement precautionary management before allowing a commercial fishery or large sport fishery to develop (Camhi 1999).

External Mortality: IPHC Halibut Longline Fisheries

Currently, the IPHC does not report shark bycatch specific to fishery. Total catch of shark (dogfish and sleeper) is recorded during IPHC setline surveys in Alaska, but does not reflect accurate bycatch estimates for halibut fisheries in general. Most likely, shark bycatch is lower in the fisheries compared to catch rates that IPHC surveys report because commercial vessels often fish in areas lacking high populations of shark.

External Mortality: State of Alaska Groundfish Fisheries

It is assumed that proportionally similar shark bycatch could occur in the state groundfish fisheries as compared to the current federal groundfish fisheries. Although the amount of shark bycatch may be similar between state and federal groundfish fisheries, the species mix of shark within this bycatch most likely differs between nearshore state fisheries and federal fisheries. Catch of Pacific sleeper shark in the sablefish longline surveys from 1997-2000 in the BSAI and GOA ranged from 9 to 11 sharks (NPFMC 2002c).

Internal Mortality: Foreign, JV and Domestic Groundfish Fisheries (Post-MSA)

Shark bycatch varies for species by region. All shark bycatch tends to be higher in the GOA region, whereas sleeper shark bycatch has been similar between regions. Table 3.5-50 shows estimated total catch of sharks in the BSAI and GOA from 1997-2001. In 2001, sleeper shark bycatch for BSAI showed a large reduction compared to years past of 17.3 mt, while dogfish bycatch seemed to significantly increase at 697 mt (NPFMC 2002c). A possible explanation for these shifts is that observer identification for these two species has improved. Regional shifts in shark abundance could also be occurring.

The majority of bycatch for unidentified shark in 2000 and 2001 was taken by sablefish and Pacific cod longline fisheries (79 percent) while salmon shark bycatch was predominantly taken by pollock pelagic trawl fisheries (90 percent in 2001 and 84 percent in 2000). Total amount of dogfish bycatch increased in 2001 for the BSAI with Pacific cod and flathead sole longline fisheries and pollock pelagic trawl fisheries being primary takers (90 percent). In contrast to dogfish, sleeper shark bycatch decreased in 2001. According to 2000 survey data, sablefish, turbot, and Pacific cod longline fisheries in addition to pollock pelagic trawl fisheries accounted for the majority of the total bycatch in BSAI (90 percent) (NPFMC 2002c).

In the GOA region during 1999 surveys, Pacific cod longline fisheries accounted for the majority of sleeper shark, spiny dogfish, and unidentified shark bycatch. Pelagic trawl pollock fisheries took the largest portion of salmon shark bycatch in 1999 for the GOA. Salmon sharks have been both considered a nuisance for both eating salmon and damaging fishing gear (Macy *et al.* 1978, Compagno 1984).

Due to sharks slow growth to maturity and low productivity of the stocks (Compagno 1990, Hoenig and Gruber 1990), many large-scale directed fisheries for sharks have collapsed, even where management was attempted (Anderson 1990). An EA/RIR for BSAI/GOA FMP Amendments 63/63 has been developed by NPFMC outlining a shark and skate management program in Alaskan federal waters. This amendment would remove shark and skate from the other species complex in an effort to better protect this long-lived species. Salmon shark have been considered as a potential target species in the GOA (Paust and Smith 1989).

Increased Recruitment: Climate Changes and Regime Shifts

It has been speculated that warmer waters in the PWS have lead to an increase in abundance of certain shark species. However, there is limited evidence to support the theory and the effects of climate change and regime shifts on shark remain unknown.

BSAI Shark Comparative Baseline

Until a pilot survey was conducted in 2000 of the EBS, it was thought that bottom trawl surveys did not accurately sample shark. However, sleeper shark were the third highest CPUE on the survey. Thus, showing the ability for this shark to be successfully surveyed by bottom trawls (NPFMC 2002c). During the 2002 EBS slope survey, sleeper shark biomass was estimated and shown to be substantial (NPFMC 2002c). This new information suggests that location and timing of EBS trawl surveys on the shelf during summer months may play a significant role in estimating biomass of shark (NPFMC 2002c). Shark are rarely taken during demersal trawl surveys in the Bering Sea; however, spiny dogfish *(Squalus acanthias*) is a species usually caught, and the Pacific sleeper shark (*Somniosus pacificus*) has been taken on occasion.

Much of the catch and landing data for shark in Alaska is not useful for assessing relative abundance because species are lumped into a single category of “shark”. However, in recent years the NOAA Fisheries groundfish Observer Program, the IPHC, and the ADF&G have documented shark catch by species making preliminary estimates of relative abundance possible. The NOAA Fisheries Observer database contains estimated weights (in mt) for species, while the IPHC and ADF&G databases contain data on shark bycatch from fishery independent halibut and sablefish surveys respectively (Goldman 2001).

IPHC setline surveys in Alaska have reported total catch for dogfish and sleeper shark from 1997-2002 within specific IPHC areas including: southeast Alaska, central GOA, western GOA, eastern Aleutians, and western Aleutians. Although these surveys used varying numbers of skates (one skate containing one hundred hooks) within different IPHC areas from year to year, it is possible to obtain a rough estimate of average stock density for these two shark species in the areas mentioned above over time. Figures 3.5-27 and 3.5-28 show average stock densities of dogfish and sleeper shark estimated by IPHC Setline Surveys throughout five IPHC areas from 1997-2002, respectively (Dykstra *et al.* 2003).

GOA Shark Comparative Baseline

In the GOA, individual species biomass trends were evaluated for the more common and easily identified shark and sculpin species encountered by the triennial trawl surveys. In general, the increasing biomass trend for the shark species is a result of increases in spiny dogfish and sleeper shark biomass between 1990 and 1999. Salmon shark biomass has been stable to decreasing, according to this survey, but salmon shark is unlikely to be well sampled by a bottom trawl (as evidenced by the high uncertainty in the biomass estimates).

It should be noted that both salmon shark and Pacific sleeper shark biomass estimates may be based on a very small number of individual tows in a given survey. No salmon sharks were encountered in the 1999 survey, despite reports of their increased abundance in other areas of the GOA (Gaichas 2001).

BSAI/GOA Shark Cumulative Effects Status

Assessment data is limited for shark and no reliable biomass estimates or stock assessments for shark exist despite recent improvements in their identification. This species group will be brought forward for cumulative effects analysis due to their ecological importance.

3.5.3.4 Skate

Life History and Distribution

NOAA Fisheries surveys have recorded 15 skate species, but inadequate taxonomic keys for this family may have resulted in more species being identified than actually exist (Figures 3.5-29, 3.5-30, and 3.5-31). Species that have been consistently identified during surveys are the Alaska skate (*Bathyraja parmifera*), big skate (*Raja binoculata*), longnose skate (*rhina*), and Aleutian skate (*B.aleutica*). Biomass estimates of sculpin and skate from demersal trawl surveys serve as valuable indices of their relative abundance (Gaichas 2001). A summary of the identified species is shown in Table 3.5-51.

Although little specific life history information exists for most skate species, they are generally thought to have limited reproductive capacity relative to gadids, pleuronectids, and other exploited groundfish and may be vulnerable to overfishing (Sosebee 1998). Skate are oviparous with one to seven embryos per egg in local species (Eschmeyer *et al.* 1983). Skate are similar to shark in that they are long-lived species, have low fecundity and low productivity. Size varies per species; the big skate, *Raja binoculata*, is the largest skate in the GOA. The California big skate reaches a maximum size of 2.4 m, with 1.8 m and 90 kg common (Martin and Zorzi 1993). The longnose skate, *Raja rhina*, is smaller, reaching maximum length of about 1.4 m in California. Maximum age reported for the longnose skate was 13 years, however there are difficulties associated with ageing skates (Zeiner and Wolf 1993).

The most important life history parameter for our purposes is *M*. Natural mortality provides an approximation of the amount of fishing mortality a stock can withstand, so that fractions of *M* are often used to set upper limits on *F* (Clark 1991). The natural mortality rate can be estimated from information on the maximum age attained by a species (in the absence of fishing mortality). We used a relationship developed from data on many marine species including fish, molluscs and marine mammals to estimate *M* for skate using all the information available to us. Admittedly, little is known about the lifespan of many shark and skate species, but some ichthyologists speculate that in larger chondrichhyan fish “maximum ages of 70-100 years or more are likely”. We chose to estimate *M* conservatively at 0.10, a low but reasonable number for larger skate (reflecting a potential maximum age of 40 years), in an attempt to account for the longer-lived species within the complex. We must assume the same natural mortality rate for all skate species in our area until better information is available. (NPFMC 2000c). Life history information available for skate in the BSAI and GOA is presented in Table 3.5-52.

Trophic Interactions

Limited information is available regarding the trophic interactions of skate in the BSAI. Thus, only GOA will be discussed here.

In the GOA, skate prey mainly on pollock, shrimp, crab, and other benthic epifauna. To a lesser degree, small flatfish, sculpin, eelpouts, smelt, and benthic detritus serve as prey for skate as well. Predators of skate include: toothed whales, Steller sea lions, seals, halibut, and Pacific cod.

BSAI/GOA Skate Management

In the BSAI, skate species are managed within the other species category with a TAC specified for the entire complex (see above).GOA Amendment 63 is scheduled for secretarial approval (NPFMC) on March 3, 2004 and will result in skate species being moved from the other species category to the target species category in the GOA. Upon adoption of this amendment, OFL, ABC, and TAC limits with be established. In addition, the NPFMC has suggested that a separate OFL and ABC for combined big and longnose skates be implemented for the central GOA region (NPFMC 2003) . It is presumed that data collection and research will improve for GOA skate species after this amendment has been implemented.

BSAI/GOA Skate Past/Present Effects Analysis

The geographic scope for the BSAI and GOA skate past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in the 1960s with the availability of bycatch estimates of other species and ends in 2002, the most recent year in which information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this Programmatic SEIS. Table 3.5-53 provides a summary of the BSAI and GOA skate past effects analysis presented below. The following direct effect was identified as potentially having population level effects on BSAI/GOA skate:

- Mortality due to bycatch (direct effect).

The following past/present effects determined to be applicable to the skate past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (pre-MSA)
  - State of Alaska groundfish fisheries
  - IPHC halibut longline fisheries
  - State of Alaska sport halibut fishery

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries

- Domestic groundfish fisheries

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

<u>External Mortality: Foreign Groundfish Fisheries (Pre-MSA)</u>

Pre-World War II foreign fisheries were relatively small with an expansion of large scale fishing operations in the post-war period, ultimately leading to increases in the catches of groundfish in the BSAI and GOA. By 1985, the JV operations and growing U.S. domestic fleet had entered the scene, and continued the harvest of groundfish species. Federal groundfish fisheries have been prosecuted by an all domestic fleet since 1987 in the GOA and 1991 in the BSAI.

Unfortunately, bycatch data from the foreign fisheries' BSAI and GOA FMP foreign fishery Observer Program is non-existent at the level necessary to distinguish skate from other species. It is inferred that the past foreign fisheries had proportionally similar bycatch rates for skate as the current federal groundfish fisheries.

<u>External Mortality: IPHC Halibut Longline Fisheries</u>

The IPHC halibut fisheries do not keep bycatch records (IPHC, personal communication). Since halibut and skate are caught incidentally in the federal sablefish fisheries, it is inferred that skate would also be taken incidentally in the IPHC halibut fishery.

The IPHC halibut fishery continues to occur, and for reasons stated above are considered to have potential external effects on skate in the present and future. Since none of these fisheries record bycatch, the magnitude of the potential effects on skate populations cannot be determined due to lack of pertinent information.

<u>External Mortality: State of Alaska Groundfish Fisheries and State of Alaska Sport Halibut Fishery</u>

The State of Alaska groundfish fisheries do not keep bycatch records (ADF&G, personal communication). It is inferred that proportionally similar skate bycatch could occur in the state groundfish fisheries as compared to the current federal groundfish fisheries.

State of Alaska groundfish fisheries continue to occur, and for reasons stated above are considered to have potential external effects on skates in the present and future. Since none of these fisheries record bycatch, the magnitude of the potential effects on skate populations cannot be determined due to lack of pertinent information.

<u>Internal Mortality: Foreign, JV and Domestic Groundfish Fisheries</u>

Skate are caught about 71 percent of the time by longline gear, 26 percent of the time by bottom trawls, and 3 percent of the time by pelagic trawls; skate catch in pot gear is negligible. Most of this skate catch is taken in the longline fishery directed at Pacific cod (69 percent). They are generally discarded (and may survive depending upon catch handling practices), although skate caught incidentally are sometimes retained and processed. Markets for skate products are currently limited in the North Pacific, but skate is subject to directed fisheries in other areas of the world (Martin and Zorzi 1993, Agnew *et al.* 1998).

Skate species catch may not be proportional to its biomass, for a number of reasons. In particular, the BSAI skate biomass is measured with a bottom trawl survey which takes place in the summer and covers the entire continental shelf. In contrast, most of the skate bycatch is taken by longline fisheries for Pacific cod, which occur in the spring and fall on the outer portion of the continental shelf. Figure 3.5-29 shows a comparison between the locations of EBS fisheries and survey skate catch. There is no information to determine whether the distribution of skate species changes seasonally or whether different skate species have different catch abilities in different gear types. However, these are both viable possibilities. Both longline and trawl fisheries tend to catch skate in the area where the two most common Bering Sea skate, the Alaska skate *(Bathyraja parmifera)* and the Bering or sandpaper skate *(B. interrupta),* are caught together in the survey. Thus, the relative catch rates of these two species in the survey areas may represent relative catch rates in the fishery, which occur in the area of species overlap (NMFS 2001a).

Using the average catch rate of *B. parmifera* to *B. interrupta* from the 1999 EBS survey, the potential catch of each species was estimated. On average, *B. parmifera* were about 4 times more common than *B. interrupta* in terms of weight in the areas where both species are present. In addition, *B. interrupta* were about 50 times more common than any other species of skate when they were caught together. Based on this survey data, the catch composition of skate species in the EBS was assumed on average to consist of about 80 percent *B. parmifera*, 20 percent *B. interrupta*, and negligible amounts of all other skate species in areas where the groundfish fishery occurs. When the high end of the predicted catch range (14,000 mt) is proportioned using this ratio, the catch of *B. parmifera* would be 11,200 mt, which is 3.6 percent of the 1999 estimated biomass for this species (338,000 mt). Assuming this average observed catch rate, the catch of *B. interrupta* would be approximately 2,800 mt, which is 11.7 percent of the estimated biomass of this species (24,000 mt). When the low end of the predicted catch range (12,000 mt) is proportioned, the exploitation rates are 2.8 percent for *B. parmifera* and 10 percent for *B. interrupta*. Under this generally realistic assumption of disproportional catch of rarer species, the fishing mortality rate for *B. interrupta* could potentially equal or exceed the rate estimated to be the OFL (10 percent) with December 6, 2000 information. More extreme assumptions about disproportional catch would, of course, result in even higher estimated rates of fishing mortality relative to OFL for the rarer skate species (NMFS 2001a).

It is unknown which skate species are caught as bycatch in GOA groundfish fisheries; therefore, the catch of each of the nine skate species found in the area cannot be estimated. In the GOA, average catch rates are difficult to determine because of the more diverse skate complex combined with less information regarding skate catch location due to lower observer coverage. There is less information in the GOA to determine whether fisheries take place in areas of skate species overlap or in single-species areas; therefore, average catch rates cannot be estimated from survey information. Because most skate (99 percent) are referred to as "unidentified" in the catch, skate catch is estimated at the family level (Rajidae). Most of this catch is taken in the longline fishery directed at sablefish (39 percent), followed by the Pacific cod longline fishery (21 percent), the Pacific cod trawl fishery (13 percent), and the shallow water flatfish trawl fishery (7 percent).

In the North Atlantic, declines in barndoor skate abundance were concurrent with an increase in the biomass of skate as a group (Sosebee 1998). NOAA Fisheries surveys identified at least 11 species of skate in the FMP areas. Although it is not determined if any individual skate species have declined in the North Pacific during the timeframe of the FMPs, it is determined that there is adequate evidence that fisheries can affect skate populations and that stable or rising aggregate skate biomass does not necessarily indicate that no impact is occurring at the species level (Gaichas 2002).

Skate are presently managed within the other species category in both the BSAI and GOA FMPs through an aggregate TAC set for all other species combined. Management of the skate species within aggregate complexes and the apparent population stability for skate species in aggregate has masked the decline of individual skate species in European fisheries (Dulvy *et al.* 2000). Estimated total catch of skate in the BSAI from 1997-2001 averaged 18, 119 mt (Gaichas 2002) In the GOA, estimated total catch of skate over the same period averaged 2,932 mt (NORPAC and year–end estimates of target species catch from the NMFS Regional Office blend database). The current management of skate within an aggregate other species category TAC could mask declines in individual skate species and therefore lead to overfishing of a given skate species. Due to this reason and the fact that the majority of skate bycatch is taken in the BSAI groundfish fisheries, the current management is considered to have had a lingering adverse effect on skate species in the BSAI.

BSAI/GOA Skate Comparative Baseline

As opposed to aggregate skate biomass, biomass for each individual skate species is more difficult to assess. The knowledge of the number and identity of skate species in an area is developing concurrently with research. Skate have been described as unique among Chondrichthyes for their relatively high species diversity combined with morphological conservatism; in other words, there are lots of species that look alike (NMFS 2001a). For this reason, species identification has been variable over the course of surveys, ranging from skate unidentified to identification of over 10 different species in each area. In addition, skate taxonomy has changed over the course of surveys, with two new species described in the North Pacific; *Bathyraja hubbsi and Bathyraja pseudoisotrachys* (Ishihara and Ishiyama 1985). Therefore, any apparent trends in species abundance within the skate complex over the period of the surveys are not likely to be reliable. In recent years (1996 to present) training with increased emphasis on consistent skate species identification has improved this situation dramatically so that individual skate species may be assessed in the future. Distribution data is also affected by species identification issues. For these reasons, we evaluate biomass and distribution of individual skate species only for recent years where survey scientists are confident of species identification (NMFS 2001a).

Bottom trawl surveys conducted by the AFSC provide reliable estimates of aggregate skate biomass within the timeframe of the FMPs (Gaichas 2002). Bottom trawl gear designed to assess flatfish and demersal groundfish is expected to catch skate at least as well as target species. There are also longline surveys conducted by the IPHC and the AFSC for halibut and sablefish, respectively. These surveys are not used to index the abundance of skate at this time, because they are more specialized, being designed for individual target species, whereas the trawl surveys are designed to assess all groundfish species (NMFS 2001a).

The EBS skate complex is dominated by a single skate species, the Alaska skate (*Bathyraja parmifera*) (Table 3.5-54). This species accounted for about 91 percent of the aggregate skate biomass estimated in 1999. The Bering or sandpaper skate (*Bathyraja interrupta*) was the next most common species in the EBS, making up about 6 percent of the aggregate skate biomass. The other six skate species identified in the survey (Table 3.5-51) made up less than 3 percent of the aggregate skate complex biomass (NMFS 2001a).

The GOA skate complex is more diverse than that found on the Bering Sea shelf. Four skate species were considered common, with an additional five uncommon species. The big skate (*Raja binoculata*) composed nearly 50 percent of the aggregate skate biomass, followed by the longnose skate (*Raja rhina*) at about 30 percent of aggregate biomass. Two *Bathyraja* species, the Aleutian skate (*B. aleutica*) and the Bering skate (*B. interrupta*) were next in abundance, representing about 10 percent, and 3 percent of the aggregate biomass, respectively. All five other skate species identified on the 1999 GOA survey made up about 3 percent of the aggregate skate complex biomass (NMFS 2001a).

The skate community in the Aleutian Islands appears to be different from that described for both the EBS and the GOA. In the Aleutian Islands, the most abundant species in the 1997 survey was the white blotched skate (*Bathyraja maculata*) making up 45 percent of aggregate biomass. Alaska and Aleutian skate were also common, composing about 30 percent and 15 percent of the aggregate biomass, respectively. The mud skate, (*Bathyraja tanaretzi*), was relatively common but represented a lower proportion of total biomass (approximately 3 percent) because it is a smaller skate. All seven other skate species identified in the 1997 Aleutian Islands survey made up approximately 7 percent of the aggregate skate complex biomass.

The biomass of all skate species combined as estimated by the AFSC bottom trawl surveys has generally increased in all FMP areas over the past 15 to 20 years, although it has declined somewhat from the 1990 peak in the EBS (NPFMC 1999c). In 2002, AFSC EBS shelf and slope surveys for skate showed a biomass estimate of 434,525 mt. Skate biomass estimate for the 2002 AFSC AI trawl survey was 34,412 mt, being the highest estimate since 1980.

Skate, as a group, represented the highest proportion of estimated non-target species catch weight (28 percent) from 1997 to 1999 in both FMP areas combined. In the BSAI, skates are by far the highest proportion of non-target species catch at 35 percent of total estimated non-target catch weight. Table 3.5-55 shows estimated skate bycatch rates in BSAI and GOA.

BSAI/GOA Skates Cumulative Effects Status

Although it is not determined if any individual skate species have declined in the North Pacific during the timeframe of the FMPs, there is adequate evidence that fisheries can affect skate populations and that stable or rising aggregate skate biomass does not necessarily indicate that no impact is occurring at the species level (Gaichas 2002). Due to the vulnerability of certain or all skate species to overfishing and lack of accurate bycatch estimates, they will be carried forth for cumulative effects analysis. GOA Amendment 63 is scheduled for secretarial approval on March 3, 2004 which will result in skate species being moved from the other species complex to the target species complex. Upon the adoption of this amendment, OFL, ABC, and TAC levels will be established for skates and skate complexes in the GOA region. The direct and indirect effects analysis as well as the cumulative effects analysis presented in this document will consider skate species as part of the other species complex. As data and research improves for these species, future analyses will incorporate the proposed changes to the GOA FMP.

3.5.3.5 Octopi

Life History and Distribution

Three octopi species have been recorded: the giant Pacific octopus, *Enteroctopus dolfeni* (the principal species), the flapjack devilfish, *Opisthoteuthis california,* and the smoothskin octopus*, Octopus leioderma* (which appears only intermittently). The giant Pacific octopus is found from California to Japan in waters from low tide line to 200 m. In general, the giant Pacific octopi have short life spans ranging from only 1 to 5 years, averaging 3 to 5 years, during which they have only one reproductive period (Boyle 1983). Mating occurs in autumn inshore at less than 100 m in depth; females spawn 18,000-74,000 eggs in May and July in rocky or sandy bottom nearshore nests, while males return offshore and die. The female octopi brood their eggs for 6 to 7 months without feeding, dying soon after the eggs hatch. Hatchling are planktonic at first, settling to the bottom around March of the following year after hatching (Roper *et al.* 1984). The giant Pacific octopus is the largest of the octopods, reaching 10 kg at maturity (3 years for females). Less information is available for eastern North Pacific giant Pacific octopi, although it is thought that spawning occurs more often in the winter months (Hartwick 1983). Little is known of the flapjack devilfish or the smoothskin octopus.

Trophic Interactions

Information on trophic interactions for octopi in the BSAI and GOA regions is lacking. Thus, no further discussion will be presented here.

BSAI/GOA Octopi Management

In the BSAI and GOA, octopi species are managed within the other species category with a TAC specified for the entire other species complex.

BSAI/GOA Octopi Past/Present Effects Analysis

The geographic scope for the BSAI and GOA octopi past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in the 1960s with the availability of other species bycatch information and ends in 2002, the most recent year in which information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this Programmatic SEIS. Table 3.5-56 provides a summary of the BSAI and GOA octopi past effects analysis presented below. The following direct and indirect effects were identified as potentially having population level effects on BSAI/GOA octopi:

- Mortality due to catch/bycatch (direct effect).

- Reduced recruitment due to spatial/temporal concentration of catch/bycatch (indirect effect).

The following past/present effects determined to be applicable to the octopi past effects analysis include the following:

- Past/Present External Events
  – Foreign groundfish fisheries (pre-MSA)
  – State of Alaska groundfish fisheries
  – State of Alaska Crab fisheries
  – Directed fisheries

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries
  - Domestic groundfish fisheries

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

External Mortality: Foreign Groundfish Fisheries (Pre-MSA)

Unfortunately, bycatch data from the foreign fisheries' BSAI and GOA FMP foreign fishery Observer Program is non-existent at the level of octopi. It is inferred that past foreign fisheries had proportionally similar octopi bycatch to the current federal groundfish fisheries (NMFS 2001a).

External Mortality: Directed Fisheries

In the Bering Sea, the last directed octopus fishery was in 1995. Since then, there have been no directed fisheries for octopus. Directed octopus fishing is prohibited in the Aleutian Islands area as well (Funk 2003). No vessels applied for directed octopus fishing permits in the Alaska Peninsula area in 2001 (Ruccio *et al.* 2002).

The seasonal migrations of octopi for spawning purposes segregates the sexes in different habitats at certain times of the years. Therefore, there is some concern that fisheries could pose different effects on the sexes of octopi. More information is necessary to develop appropriate management for octopus species in Alaska (Gaichas 2001).

External Mortality: State of Alaska Groundfish Fisheries

Prior to 2001, vessels registered for groundfish or shellfish could also register for octopus fishing in addition to the target species. This allowed for 100 percent of octopi to be retained as bycatch in target fisheries. In 2001, ADF&G prohibited this dual registration and placed a retention limit of 20 percent for octopus bycatch (Funk 2003).

In 2000, harvest of octopi in the Alaska Peninsula area was 3.1 mt (state and federal waters) with no vessels formally registering for octopus harvest. In the groundfish fisheries, vessels targeting Pacific cod using pot gear accounted for the majority of the octopus bycatch (Funk 2003). During the 2000 season in the Bering Sea, 7.4 mt of octopus bycatch was reported and 64 percent was taken by pot gear in groundfish fisheries (Funk 2003). Non-pelagic bottom trawl gear accounted for 48 percent of octopus bycatch while pot gear made up 47 percent during the 2001 season in the Bering Sea (Bowers *et al.* 2002). Almost 100 percent of the 2000 and 2001 landings of octopi in the Aleutians area were taken from Pacific cod or other groundfish vessels using pot gear (Funk 2003; Bowers *et al.* 2002).

External Mortality: State of Alaska Crab Fisheries

From 1977 to 1984, a substantial amount of octopus was caught incidentally by Tanner crab pots (Funk 2003). Information regarding current status of octopus bycatch is lacking.

Internal Mortality: Foreign, JV and Domestic Groundfish Fisheries

Octopi bycatch tends to be slightly less in the GOA than in the BSAI, ranging from 88 to 232 mt in the GOA and from 190-418 mt in the BSAI from 1997-2001 (Gaichas 2002). Bycatch is taken largely in the Pacific cod fisheries, mainly the Pacific cod pot fishery. Octopi also have higher estimated retention rates of any group in the other species category, suggesting that a separate management group may be necessary in the future (Gaichas 2002).

BSAI/GOA Octopi Comparative Baseline

Octopi biomass estimates are limited and show large fluctuations from year to year in the BSAI and GOA. The 2002 AFSC shelf and slope surveys for the EBS estimated octopi biomass at 3,400 mt with Aleutian Islands trawl surveys totaling 1,380 mt. Octopi appear to be poorly sampled by demersal trawls and their biomass may be underestimated. Furthermore, biomass may be underestimated due to lack of sampling in important, nearshore, rocky habitats preferred by octopi (Gaichas 2002). Stock assessments are not conducted on octopi by ADF&G for the westward region of Alaska, thus, population status is unknown to date (Ruccio *et al.* 2002).

BSAI/GOA Octopi Cumulative Effects Status

Accurate biomass estimates and bycatch data for octopi are limited. Current population status for octopi in the BSAI and GOA regions cannot be determined at this time. Cumulative effects analysis will be carried forth in order to address uncertainty and data gaps associated with this species group.

3.5.4 Forage Species

Forage fishes, as a group, occupy a nodal or central position in the North Pacific Ocean food web, being consumed by a wide variety of fish, marine mammals, and seabirds. Many forage species undergo large, seemingly unexplainable, fluctuations in abundance. Most of these are r-selected species (e.g., capelin and sand lance), which generally have higher reproductive rates, are shorter-lived, attain sexual maturity at younger ages, and have faster individual growth rates than K-selected species (e.g., rockfish and many flatfish, which are generally long-lived, reach sexual maturity at an older age, and grow slowly). Predators that feed on r-selected fish species (marine mammals, birds, and other fish) have evolved in an ecosystem in which fluctuations and changes in relative abundance of these species have occurred. Consequently, most of them, to some degree, are generalists who are not dependent on the availability of a single species to sustain them, but instead rely on a suite of species, any one (or more) of which is likely to be abundant each year. However, differences in energy content exist among forage species, with herring, sand lance, and capelin containing higher energy content per unit mass than other forage species such as juvenile pollock (Payne *et al.* 1997). It is possible that changes in availability of higher energy content forage may influence growth and survival of the upper-trophic-level species reliant on forage species as their main prey.

Table 3.5-57 shows the biology and habitat attributes of a few of the forage fish species in the BSAI and GOA.

Trophic Interactions

In the EBS, forage fish, as defined here, are found in the diets of walleye pollock, Pacific cod, arrowtooth flounder, Pacific halibut, Greenland turbot, yellowfin sole, rock sole, Alaska plaice, flathead sole, and skates. However, forage fish do not represent a large portion of the diet, by weight, of these predators, with the exception of shelf rock sole (14.3 percent) and slope pollock (12.6 percent). Tables 3.5-58 and 3.5-59 present the ten most important prey, by weight, in the diets of each predator for the EBS shelf and slope regions, respectively. All forage fish species are italicized. Forage fish found in the diet, but not in the top ten prey by weight are also listed. The miscellaneous fish category represents all fish prey not included as one of the ten most important prey categories, primarily unidentified fish. All groundfish diet data are from the AFSC Resource Ecology Fishery Management Division, groundfish food habits database. Tables 3.5-63, 3.5-64, and 3.5-65 depict forage fish species found in the diets of seabirds and marine mammals occurring in the BSAI and GOA regions.

EBS Shelf

Despite the generally piscivorus diet of cod, arrowtooth flounder, Pacific halibut, Greenland turbot, and skates, forage fish are not principal components, by weight, in the diets of EBS groundfish (Table 3.5-58). Sand lance are the most prevalent forage fish in the diet of cod (0.8 percent) while capelin, osmerids, bathylagids, myctophids, and eulachon each represent 0.1 percent or less of the diet by weight. In the diet of arrowtooth flounder, capelin and eulachon each represent 0.2 percent of the diet by weight, while osmerids, myctophids, and sand lance each constitute 0.1 percent or less. The diet of Pacific halibut contains 2.2 percent sand lance and 1.8 percent capelin; osmerids and eulachon each represent 0.1 percent or less. Myctophids represent 0.2 percent of the diet of Greenland turbot; bathylagids, osmerids, and sand lance represent 0.1 percent or less. Sand lance are the most important forage fish in the diet of skates (0.7 percent); capelin, sandfish, and myctophids each represent 0.1 percent or less. Sand lance is the most prevalent forage fish species in the diet of walleye pollock (0.5 percent); osmerids, bathylagids, myctophids, and eulachon each represent less than 0.1 percent of the diet by weight. The total contribution (0.6 percent) of forage fishes to the diet of yellowfin sole is primarily due to sand lance; bathylagids and capelin each represent less than 0.1 percent by weight. Sand lance are the second most important prey in the diet of rock sole, 14.3 percent by weight; osmerids are the only other forage fish present in the diet (less than 0.1 percent). Sand lance are the only forage fish found in the diet of Alaska plaice, representing 0.5 percent of the diet. Flathead sole consume capelin (1.3 percent), sand lance (0.5 percent), osmerids (0.1 percent) and myctophids (less than 0.1 percent).

EBS Slope

Lang and Livingston (1996) studied the diets of groundfish in the EBS slope region. In this region, forage fish are relatively unimportant in the diets of Greenland turbot, flathead sole, arrowtooth flounder, and cod (Table 3.5-59). However, 12.6 percent of the diet of pollock on the slope consists of forage fishes. Greenland turbot consume bathylagids (0.4 percent) and myctophids (0.4 percent) as the only forage fish in their diet. Flathead sole also consumed bathylagids (0.3 percent) and myctophids (0.1 percent). Myctophids (0.2 percent) are the only forage fish found in the diet of arrowtooth flounder. Pollock consume bathylagids (7.0

percent), myctophids (5.5 percent), osmerids (0.1 percent), and sand lance (less than 0.1 percent). Forage fish are negligible in the diet of cod; bathylagids represent less than 0.1 percent of the diet by weight.

Aleutian Islands

Yang (1996) studied the diets of groundfish in the Aleutian Islands during summer. He found that main fish prey of groundfish in the Aleutian Islands included Atka mackerel, walleye pollock, Pacific herring, capelin, myctophids, bathylagids, Pacific sand lance, and eulachon (Table 3.5-60). Although Atka mackerel and walleye pollock were important fish prey of arrowtooth flounder, Pacific halibut, and Pacific cod, other forage fish species comprised from 1 to 37 percent of groundfish diets. Most of the Atka mackerel consumed by the groundfish were located near Attu, Agattu, Amchitka, Tanaga, Atka, and Unalaska Islands. Myctophids were an important forage fish. Large amounts of myctophids were found in the diets of Greenland turbot, walleye pollock, Pacific ocean perch, and shortraker rockfish. They were also found in arrowtooth flounder, Pacific cod, rougheye rockfish, Atka mackerel, and northern rockfish. Most myctophids consumed by the groundfish were located near Kiska, Adak, Seguam, and Yunaska Islands. It is notable that nine out of eleven groundfish species shown in Table 3.5-60 consumed myctophids as food. If the abundance of the myctophids declines dramatically, it could impact the growth of Aleutian Islands groundfish, which depend on myctophids for a main food resource. Bathylagids were found in the diets of Greenland turbot and walleye pollock. Capelin were found in the diet of Pacific halibut and walleye pollock collected in the Akutan Island area, but they contributed only 5 percent and less than one percent of the diets of Pacific halibut and walleye pollock, respectively. Pacific sand lance were food of arrowtooth flounder, Pacific halibut, Pacific cod, and walleye pollock, but they contributed less than one percent of these diets. Only a small amount (less than one percent) of eulachon was found in the diet of walleye pollock. Pacific sandfish was not found in the diets of the groundfish in the Aleutian Islands area.

Gulf of Alaska

Yang and Nelson (2000) studied the diets of groundfish in the GOA shelf during summer. They found that the main fish prey of groundfish in the GOA included pollock, Pacific herring, capelin, Pacific sand lance, eulachon, Atka mackerel, bathylagids, and myctophids (Table 3.5-61). Although walleye pollock was the most important fish prey of arrowtooth flounder, Pacific halibut, sablefish, Pacific cod, and walleye pollock in the GOA, other forage fish species comprised 1 to 23 percent of the diet of groundfish. Capelin was important food of arrowtooth flounder and pollock, comprising 23 and 7 percent of the diet, respectively in 1990. The consumption of capelin by walleye pollock gradually decreased to 3 percent in 1993; to 0 percent in 1996. Compared to 1990, arrowtooth flounder also consumed less capelin in 1993 (4 percent) and in 1996 (10 percent). The capelin consumed by these groundfish were mainly located northeast and southwest of Kodiak Island. Eulachon comprised 6 percent of the diet of sablefish. Myctophids were important forage fish for shortraker rockfish, comprising 18 percent of the diet of shortraker rockfish. Pacific sand lance were found in the stomachs of arrowtooth flounder, Pacific halibut, sablefish, Pacific cod, and walleye pollock, but their contribution to these diets was small (1 percent or less). Bathylagids were only found in the diet of walleye pollock, and they contributed less than one percent. Pacific sandfish was not found in the diet of the groundfish in the GOA.

In the Atlantic, strong interactions between cod and capelin have been recorded (Akenhead *et al.* 1982). Even though Pacific cod did not feed so heavily on capelin in the GOA, capelin was an important fish prey of several groundfish species. The distribution and the abundance of forage fish in the GOA are not well known.

However, a series of years with poor forage fish recruitment, which decreases the availability of small prey fish, may have a large impact on piscivorus groundfishes.

BSAI and GOA Forage Fish Management

The BSAI and GOA FMPs were amended in 1998 to establish a forage species category to prevent the development of directed fisheries on these ecologically important non-target species. This category consists of many fish families (Osmeridae [smelts], Myctophidae, Bathylagidae, Ammodytidae, Trichodontidae, Pholidae, Stichaeidae, Gonatostomatidae, and the order Euphausiacea). These families were removed from the non-specified species category with the smelt species, (dominated by capelin, *Mallotus villosus* and eulachon, *Thaleichthys pacificus*), which were previously removed from the other species category. The forage species rule restricts all species in this category to bycatch only status and establishes a maximum retainable bycatch (MRB) rate (explained in Appendix B) of 2 percent for these species in aggregate. In addition, commerce in forage species is currently prohibited except for the small amounts retained under the MRB rates and for artisanal or subsistence uses.

BSAI and GOA Past/Present Effects Analysis

The geographic scope for the BSAI and GOA forage fish past/present effects analysis is the same as the BSAI and GOA FMP management areas (Figures 1.2-2 and 1.2-3). The temporal scope for this analysis begins in the 1960s with the increase in intensity of the foreign fisheries, and ends in 2002, the most recent year of which information is available on the resource category.

A discussion of the direct/indirect effects, external human controlled and natural events, and internal groundfish fishery events screened for the past effects analysis is presented in Section 3.1.4 of this Programmatic SEIS. Table 3.5-62 provides a summary of the BSAI and GOA forage fish past effects analysis presented below. The following direct and indirect effects were identified as potentially having population level effects on BSAI forage fish:

- Mortality due to bycatch and marine pollution and oils spills (direct effect).
- Change in reproductive success due to predator removal and climate changes and regime shifts (indirect effect).
- Change in prey availability due to introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).
- Change in important habitat due to fishery gear impacts, introduction of exotic species, marine pollution and oil spills and climate changes and regime shifts (indirect effect).

Mortality caused by marine pollution and change in prey availability and important habitat due to the introduction of exotic species and climate changes and regime shifts by way of ballast water has not been brought forward since the impacts on forage fish in the BSAI and GOA have not been directly observed or documented. However, researchers are attempting to link recent warming trends in the northwest Pacific to an increase in abundance of tropical predators (Northwest Fisheries Science Center 1998). See Section

3.10.1.5 for documentation of occurrences of unusual species in the BSAI and GOA as influenced by climate changes and regime shifts.

The past/present event determined to be applicable to the BSAI and GOA forage fish past effects analysis include the following:

- Past/Present External Events
  - Foreign groundfish fisheries (pre-MSA)
  - State of Alaska directed capelin fishery
  - Subsistence and personal use fisheries
  - Regime shifts and climate changes

- Past/Present Internal Events
  - Foreign groundfish fisheries (post-MSA)
  - JV groundfish fisheries
  - Domestic groundfish fisheries
  - State groundfish fisheries bycatch

- Past/Present Management Actions
  - FMP groundfish fisheries management
  - Data limitations

Mortality

External Foreign Groundfish Fisheries (pre-MSA)

It is inferred that past foreign fisheries had forage fish bycatch rates that are proportionally similar to the current domestic fisheries. It is likely that effects on the populations have occurred; however, magnitude of the effects is unknown due to the lack of pertinent bycatch information.

External State of Alaska Directed Capelin Fishery

Although little commercial fishing occurs on forage fish species, documentation exists of a small and sporadic commercial fishery on capelin as early as the 1960s (ADF&G 1993). The largest harvest of capelin was taken in 1984 (489 mt, sorted), and in 1993, 31 mt of capelin were harvested in Nunavachuk Bay. Data reveal that no more than three vessels per year participated in a capelin fishery. Data from 1992 and 1994 indicate that less than 1 mt of capelin was commercially harvested by one boat. The limited annual harvest of capelin in the North Pacific Ocean is due to sporadic market conditions, processing limitations, and fluctuation of available capelin biomass. However, declining Atlantic stocks have the potential to change the market interest for capelin.

Presently, commercial fishing for capelin is in state waters open by regulation, not managed by emergency order, and is restricted by few regulations. The opportunity for a directed fishery on capelin or the other forage fish species exists under the current management system. Presently, species contained in the proposed forage fish category are not actively managed by the State of Alaska; however, cooperative state and federal management would be necessary for those forage fish that may be distributed in state waters during spawning times.

External Subsistence and Personal Use Fisheries

The ADF&G Subsistence Division conducts household surveys to determine subsistence use of forage fish species. Data from these surveys show that smelt are reported harvested in a large number of coastal communities in the southeast, southcentral, southwest, west, and arctic regions of Alaska. Reported smelt harvests range from a few pounds to several thousand pounds per community, depending on place and year.

In the southeast, southcentral, and southwest regions, eulachon are the smelt most commonly taken. Rainbow smelt, capelin and unknown smelt are also reported harvested in communities in the arctic, west, southwest, and southcentral regions. The ADF&G database contains no records of subsistence harvests of other forage fish categories; however, it is possible that, in particular communities, some subsistence harvests of other forage fish species may occur (B. Wolfe, ADF&G, Subsistence Division, personal communication).

Internal JV and Domestic Groundfish Fisheries (post-MSA)
