## INTRODUCTION

The data in this report were collected as part of the NOAA program Fisheries-Oceanography Coordinated Investigations (FOCI). These data were obtained as part of an ongoing effort to describe the environment of the Shelikof Strait region of Alaska and understand how it relates to the recruitment of walleye pollock, Theragra chalcogramma. Background studies emphasizing areal distribution and seasonal development of zooplankton communities were conducted in 1985 (March to October) and 1986 (April to August); these data are reported in Siefert et al. (1988a) and Siefert and Incze (1989a), respectively. Zooplankton vertical distributions in areas of concentrated pollock larvae were studied in 1986 and in 1987; these data are reported in Siefert et al. (1988b) and Siefert et al. (1990), respectively. The data reported here are abundance and composition data collected from April 4-28, 1988 for seasonal and interannual comparisons of the Shelikof zooplankton community. These data augment similar data collected in 1987 (Siefert and Incze 1989b) and the data collected in 1985 and 1986. Proctor (1989) provides the details of the research cruises conducted in 1988. Data summarized in these various reports are undergoing analysis and will be the subjects of more detailed manuscripts, some currently in preparation.

## METHODS

Two cruises were conducted in the Shelikof Strait region from 1-13 April and from 16 April to 2 May 1988. A transect of time series stations (line 8, see Fig. 1) was occupied during each cruise (Fig. 2) to provide data for seasonal and interannual comparisons.

Plankton samples were obtained by double-oblique tows of 60-cm bongo samplers (Posgay and Marak 1980) equipped with 333  $\mu\text{m}$  mesh nets and 20-cm bongo samplers equipped with 150  $\mu\text{m}$  mesh nets. At all stations described here, 20-cm bongo samplers were attached to the towing cable about 1 m above the 60-cm bongo. Mechanical flowmeters were installed in the mouth of each net to estimate the volume of water filtered by the nets, and a bathykymograph (BKG) was used to record maximum sampling depth and record the bongos' trajectories. Tows were taken from surface to near bottom (generally within 10-15m or less). Samples were preserved in 5% buffered formalin:seawater for later analysis.

In the laboratory, organisms were sorted into taxonomic categories selected to describe the seasonal development and interannual differences of zooplankton communities in Shelikof Strait, emphasizing the most abundant species. A list of these taxa is given in Table 1, with definitions of abbreviations used throughout this report.

Samples were sorted at the Plankton Sorting Center in Szczecin, Poland and identifications made in Poland were verified by a biologist in Seattle. Because all samples sorted were from paired 333  $\mu\text{m}$  and 150  $\mu\text{m}$  mesh nets, processing was designed to maximize the benefit of this complementarity; therefore, different organisms were enumerated from samples collected with each of the mesh sizes. For all samples, large organisms such as shrimp and jellyfish were first removed and noted, then sorting proceeded as follows.

The sample collected with 333  $\mu\text{m}$  mesh was split with a Folsom plankton splitter to obtain a subsample with approximately 100-200 organisms  $\geq 5\text{mm}$  in their maximum dimension (note that smaller organisms were much more numerous and were treated separately; see below). This first split was not made beyond 1/64 of the original sample. All organisms  $\geq 5\text{mm}$  were enumerated except the following taxa: decapod larvae, euphausiid furciliae and larvaceans. These taxa have numerous individuals both larger and smaller than 5mm and were counted from a smaller subsample.

Other organisms smaller than 5mm were enumerated from either a smaller subsample of the 333  $\mu\text{m}$  or the 150  $\mu\text{m}$  mesh samples. The choice of mesh depended on the size of the organism/stage being counted. Organisms selected for enumeration from the two nets are listed in Table 2. A few taxa were counted from both nets: C2 calanoids later identified as Neocalanus cristatus, N. spp., Calanus marshallae, and C. pacificus; and "Other

Zooplankton <5mm". All taxa were ultimately counted so proper collation of data from the paired samples would enable comparison with samples processed differently from collections prior to 1988.

A subsample containing approximately 300-500 small zooplankton often provided sufficient counts (at least 30) of the taxa of particular interest to our study. If it did not, then a second subsample was sorted for these organisms.

## RESULTS

A list of taxa found in each sample is contained in Appendices 1 and 2. Samples are identified by station numbers and mesh size. Data for concurrent bongo samples appear together: for each station, the first pages list results from the 333  $\mu\text{m}$  mesh net; data from the 150  $\mu\text{m}$  mesh net follow.

Taxa are listed in order of their abundance in each sample. Each list includes: the number of organisms counted; the fraction of the sample from which they were counted (sub/fac); and their abundance as number per  $10\text{m}^3$  and per  $\text{m}^2$ . In each appendix, the station number corresponds to the station number in Figure 2, location is given to tenths of a degree of latitude and longitude, date and time are GMT, station depth and sample intervals are in meters, volume filtered is expressed in cubic meters and net mesh is in micrometers.

For some taxonomic categories, we did not spend the time to identify and record all species encountered; rather, notes were kept on the most abundant species in these categories. These species are listed in Table 3.

## DISCUSSION

Care must be taken in using these data for quantitative comparisons. The size of the net mesh used to collect the samples, the sample splitting process, organism net avoidance behavior, and sample preservation all affect the estimates of taxa collected.

Nets with 333  $\mu\text{m}$  mesh do not consistently retain organisms with a minimum dimension less than 471  $\mu\text{m}$  (Miller et al. 1984); nets with 150  $\mu\text{m}$  mesh do not consistently retain organisms with a minimum dimension less than 212  $\mu\text{m}$ . On the basis of size, we consider that the following taxa were quantitatively retained when the 333  $\mu\text{m}$  mesh nets were used: Calanus marshallae C3, C4, C5 and adults; C. pacificus C3, C4, C5 and adults; Eucalanus bungii C3, C4, C5 and adults; Metridia spp. C5 and adults; M. pacifica C5 and adults; Neocalanus cristatus C2, C3, C4, C5, and adults; N. spp. (N. plumchrus and/or N. flemingeri) C3, C4, C5 and adults; copepods  $\geq 2\text{mm}$ ; decapod larvae; euphausiid furciliae, juveniles and adults; chaetognaths  $\geq 20\text{mm}$ ; and other zooplankton  $\geq 5\text{mm}$  in their maximum dimension. In addition to the above organisms, nets with 150  $\mu\text{m}$  mesh should retain the following

taxa: C. marshallae C1 and C2; C. pacificus C1 and C2; E. bungii C1 and C2; N. cristatus C1; N. spp. (N. plumchrus and/or N. flemingeri) C1 and C2; Metriiididae C2, C3, and C4; Pseudocalanus spp. C3, C4, C5, and adults; chaetognaths  $\geq$  5mm and euphausiid calyptopis C1, C2, and C3.

Estimates for gelatinous zooplankton (i.e. cnidarian medusae and larvaceans) are not quantitative because of the effects of sampling and preservation. The sample splitting process also affects estimates of thecosomate pteropods because they do not stay suspended in the sample. Finally, euphausiid adults and juveniles tend to avoid being caught in these nets.

## ACKNOWLEDGMENTS

We thank all FOCI participants for their help with collections and other cruise details. We also thank officers and crew of the NOAA ship Miller Freeman for their efforts and the staff at the Plankton Sorting and Identification Center in Szczecin, Poland. We gratefully acknowledge Jay Clark for providing station data and mapping programs, Wendy Carlson and Jim Peacock for graphics; and John Richards for final report preparation.
