Abstract

This report summarizes the five cruises along 27°N on the UNOLS ship R/V Walton Smith involving full-water-column CTD and lowered ADCP profiles, along with shipboard ADCP profiles, conducted within the Florida Straits to monitor the Florida Current. This report describes the processing of a Seabird Electronics Model 9/11+ CTD O₂ system and water samples collected from up to 23 10-liter Niskin bottles lowered to the bottom. This report includes a description of the calibrations procedures and profiles of pressure, salinity (conductivity), temperature, and dissolved oxygen concentrations. Water samples were also collected at various depths and analyzed for salinity and oxygen concentrations to aid with CTD calibration. A total of 9 CTD-O₂/LADCP stations were occupied during each of the five cruises.

1 *Introduction*

The Florida Current transport time series began in 1982, as NOAA recognized the importance of long-term monitoring of the current transport and water mass properties of the Florida Current across the Florida Straits to determine its inter-annual variability to determine the strength of the subtropical gyre. Variations in the strength of the subtropical gyre in relation to the North Atlantic Oscillation (NAO) has been proposed as an important mechanism in the atmosphere-ocean feedback within coupled models (e.g. Latif and Barnett, 1996). Monitoring of the Florida Current includes a submarine cable, GPS measurements using drop sondes, as well as hydrographic measurements. All of these programs are collaborating with scientific analysis and logistics including ship time.

Hydrographic surveys consisting of a repeat LADCP/CTD/rosette section in the Florida Straits was carried out during 2016 (Figure 1 and Tables 1 - 5). These cruises consist of one day cruises on the R/V Walton Smith departing and returning to Miami, FL. A total of five cruises were completed consisting of a total of 45 LADCP/CTD/Rosette stations. Water samples (up to 9 for each station), LADCP, CTD data were collected on each cast to within 20 m of the bottom. Salinity and dissolved oxygen samples were analyzed from the majority of bottles sampled on the rosette. The salts collected and run during the FC1609 cruise were not usable for calibrations due to a bad autosal run. The calibrations coefficients from the previous cruise, FC1607, were used.

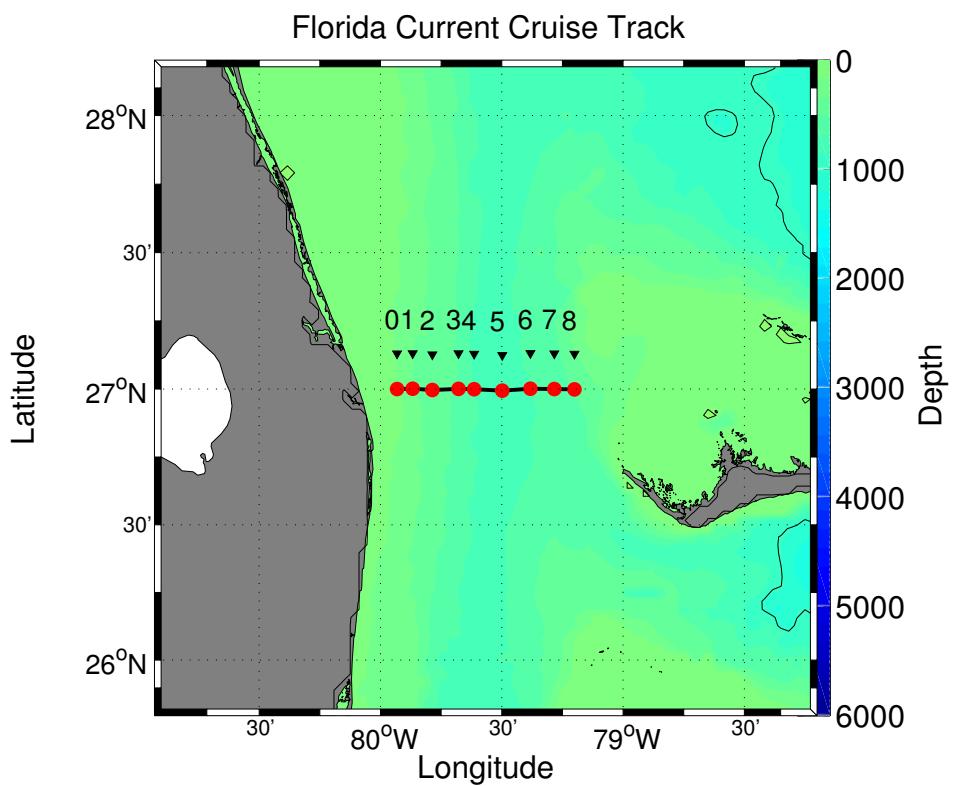

Figure 1: Florida Current CTD station locations. The landmasses are shaded. The red dots are the CTD stations.

3 Standards and Pre-Cruise Calibrations

The CTD/O₂ system is a real-time data acquisition system with the data from a Sea-Bird Electronics, Inc. (SBE) 9plus underwater unit transmitted via a conducting cable to a SBE 11plus deck unit (V2). The serial data from the underwater unit is sent to the deck unit in RS-232 NRZ format. The deck unit decodes the serial data and sends it to a personal computer for display and storage in a disk file using the Sea-Bird Seasave software.

The SBE 911plus system transmits data from primary and auxiliary sensors in the form of binary numbers equivalent to the frequency or voltage outputs from those sensors. These are referred to as the raw data. The SBE software performs the calculations required to convert raw data to engineering units.

The SBE 911plus system is electrically and mechanically compatible with the standard, unmodified carousel water sampler, also made by Sea-Bird Electronics, Inc. A modem and carousel interface allows the 911plus system to control the operations of the carousel directly without interrupting the flow of data from the CTD.

The SBE 911plus underwater unit is configured with dual standard modular temperature (SBE 3 plus) and conductivity (SBE 4) sensors, which are mounted near the lower end cap. The conductivity cell entrance is co-planar with the tip of the temperature sensor probe. The pressure sensor is mounted inside the underwater unit main housing. A centrifugal pump module flushes water through sensor tubing at a constant rate independent of the CTD's motion to improve dynamic performance. Dual dissolved oxygen sensors (SBE 43) are added to the pumped sensor configuration following the temperature-conductivity (TC) pair. A list of sensors used during the cruises can be seen in Table 11.

Table 11: Equipment used during the 2016 Florida Straits cruises.

3.1 Pressure

The Paroscientific series 4000 Digiquartz high pressure transducer uses a quartz crystal resonator whose frequency of oscillation varies with pressure induced stress measuring changes in pressure as small as 0.01 parts per million with an absolute range of 0 to 10,000 psia (0 to 6885 dbar). Repeatability, hysteresis and pressure conformance are 0.002% of full-scale. The nominal pressure frequency (0 to full scale) is 34 to 38 kHz. The nominal temperature frequency is 172 kHz \pm 50 ppm/ $^{\circ}$ C.

The pressure sensor used during the Florida Straits cruises was s/n 0975. Pre-cruise sensor calibrations were performed at Sea-Bird Electronics, Inc. in Bellevue, Washington. The following coefficient (Table 12) were entered into SEASAVE R using the configuration file:

Pressure coefficients are first formulated into:

$$\begin{aligned} c &= c_1 + c_2 * U + c_3 * U^2 \\ d &= d_1 + d_2 * U \\ t_0 &= t_1 + t_2 * U + t_3 * U^2 + t_4 * U^3 + t_5 * U^4 \end{aligned}$$

where U is temperature in degrees Celsius. Pressure is computed according to:

$$P (\text{psia}) = c * \left(1 - \frac{t_0^2}{t}\right) * \left[1 - d * \left(1 - \frac{t_0^2}{t}\right)\right]$$

where t is pressure period (μ s). SEASAVE R automatically implements this equation.

Table 12: Pre-Cruise Calibration coefficients for the pressure sensor.

s/n 0975

Offset = -2.7284
AD590M = 1.28150e-02
AD590B = -9.22501e+000

3.2 Temperature

The temperature-sensing element is a glass-coated thermistor bead, pressure protected by a stainless steel tube. The sensor output frequency ranges from 5–13 kHz corresponding to temperatures from -5 to 35°C. The output frequency is inversely proportional to the square root of the thermistor resistance, which controls the output of a patented Wien Bridge circuit. The thermistor resistance is exponentially related to temperature. The SBE 3 thermometer has a typical accuracy/stability of $\pm 0.004^\circ\text{C}$ per year and resolution of 0.0003°C at 24 samples per second. The SBE 3 thermometer has a fast response time of 0.070 seconds.

The temperature sensors (SBE 3plus) used during the Florida Straits cruises were serial numbers (s/n) 2946 and 5855. Pre-cruise sensor calibrations were performed at Sea-Bird Electronics, Inc. in Bellevue, Washington. The following coefficients (Table 13) were entered into SEASAVE R using the configuration file. SEASAVE R automatically implements the equation below and converts between ITS-90 and IPTS-68 temperature scales as desired. The Temperature (ITS-90) is computed from g , h , i , j and f_0 and f is the instrument frequency (kHz) coefficients as follows:

$$T (\text{ }^\circ\text{C}) = \frac{1}{\left\{ g + h * \left[\ln \left(\frac{f_0}{f} \right) \right] + i * \left[\ln^2 \left(\frac{f_0}{f} \right) \right] + j * \left[\ln^3 \left(\frac{f_0}{f} \right) \right] \right\}} - 273.15$$

Table 13: Pre-Cruise Calibration coefficients for the temperature sensors.

s/n 2946	s/n 5855
July 08, 2015	December 08, 2015
$g = 4.34427068\text{e-}03$	$g = 4.35381035\text{e-}03$
$h = 6.39743464\text{e-}04$	$h = 6.30572657\text{e-}04$
$i = 2.18134662\text{e-}05$	$i = 1.97027743\text{e-}05$
$j = 1.93162948\text{e-}06$	$j = 1.40494714\text{e-}06$
$f_0 = 1000.0$	$f_0 = 1000.0$

3.3 Conductivity

The flow-through conductivity-sensing element is a glass tube (cell) with three platinum electrodes (Seabird model SBE 4). The resistance measured between the center electrode and the end electrode pair is determined by the cell geometry and the specific conductance of the fluid within the cell, and controls the output frequency of a Wein Bridge circuit. The sensor has a frequency output of approximately 3 to 12 kHz corresponding to conductivity from 0 to 7 Siemens/meter (0 to 70 mmho/cm). The SBE 4 has a typical accuracy/stability of $\pm 0.0003 \text{ S}\cdot\text{m}^{-1}/\text{month}$ and resolution of $0.00004 \text{ S}\cdot\text{m}^{-1}$ at 24 scans per second.

The conductivity sensors used during the Florida Straits cruises were serial numbers (s/n) 1387 and 4346. Pre-cruise sensor calibrations were performed at Sea-Bird Electronics, Inc. in Bellevue, Washington. The coefficients shown in Table 14 were entered into Seasave using the configuration file.

Conductivity calibration certificates show an equation containing the appropriate pressure-dependent correction term to account for the effect of hydrostatic loading (pressure) on the conductivity cell:

$$C (\text{Siemens/meter}) = \frac{(g + h * f^2 + i * f^3 + j * f^4)}{[10 * (1 + c_{t_{cor}} * t + c_{p_{cor}} * p)]}$$

where g , h , i , j , $c_{t_{cor}}$, and $c_{p_{cor}}$ are the calibrations coefficients shown above, f is the instrument frequency (kHz), t is the water temperature (degrees Celsius), and p is the water pressure (dbar). SEASAVE R automatically implements this equation.

$CP_{cor} = -9.5700e-08$	$CP_{cor} = -9.5700e-08$
$CT_{cor} = 3.2500e-06$	$CT_{cor} = 3.2500e-06$

3.4 Dissolved Oxygen

The SBE 43 dissolved oxygen sensor uses a membrane polarographic oxygen detector (MPOD). Oxygen sensors determine the dissolved oxygen concentration by counting the number of oxygen molecules per second (flux) that diffuse through a membrane. By knowing the flux of oxygen and the geometry of the diffusion path, the concentration of oxygen can be computed. The permeability of the membrane to oxygen is a function of temperature and ambient pressure. In order to minimize the errors in the oxygen measurement due to the temperature differences between the water and the oxygen sensor, a temperature compensation is calculated using a temperature measured near the active surface of the sensor. The interface electronics output voltages proportional to the temperature-compensated oxygen current. Initial computation of dissolved oxygen in engineering units is done in the software. The range for dissolved oxygen is 120% of surface saturation in all natural waters, fresh and salt, and the nominal accuracy is 2% of saturation.

Under extreme pressure, changes can occur in gas permeable Teflon membranes that affect their permeability characteristics. Some of these changes (plasticization and amorphous/crystallinity ratios) have long time constants and depend on the sensor's time-pressure history. These slow processes result in hysteresis in long, deep casts. The hysteresis correction algorithm operates through the entire data profile and corrects the oxygen voltage values for changes in membrane permeability as pressure varies. At each measurement, the correction to the membrane permeability is calculated based on the current pressure and how long the sensor spent at previous pressures.

Sea-Bird has implemented an optional hysteresis correction for dissolved oxygen data. The correction algorithm requires a continuous time series of data, with no temporal data gaps (although a continuous time series is necessary, a constant sampling interval is not required). Prior to processing, do not remove any data from the downcast or upcast (if to be used), other than a surface soak at the beginning of the downcast.

Oxygen sensors 2082 and 0730 were used during the Florida Straits cruises. The following oxygen coefficients (Table 15) were entered into SEASAVE R using the configuration file:

The use of these constants in linear equations of the form $I = mV + b$ and $T = kV + c$ yield sensor membrane current and temperature (with maximum error of about 0.5 °C) as a function of sensor output voltage.

Dissolved oxygen concentration is calculated according to:

Table 15: Pre-Cruise Calibration coefficients for the dissolved oxygen sensors.

s/n 2082	s/n 0730
December 15, 2015	December 30, 2015
Soc = 0.4207	Soc = 0.5615
Voffset = -0.5332	Voffset = -0.5094
Tau20 = 1.05	Tau20 = 1.12
A = -3.3688e-03	A = -4.2715e-03
B = 2.1886e-04	B = 1.4677e-04
C = -3.2294e-06	C = -2.6947e-06
E _{nominal} = 0.036	E _{nominal} = 0.036

$$O \text{ (ml/l)} = \{ Soc * (V + V_{offset} + tau(T, S) * \frac{\delta v}{\delta t}) + p1 * station \} \\ * (1.0 + A * T + B * T^2 + C * T^3) * OXSAT(T, S) * e^{E * (\frac{P}{K})}$$

where Soc , V_{offset} , tau , A , B , C , E and $p1$ are the calibration coefficients shown above and V is the instrument voltage (V). T , S and P are the temperature, salinity and pressure measured by the CTD. K is the temperature in the absolute scale (K), $\delta v/\delta t$ is the oxygen voltage time derivative, $station$ is the station number, and $OXSAT$ is the oxygen saturation value calculated according to (Weiss, 1970):

$$OXSAT(\theta, S) = \exp \left\{ A_1 + A_2 * \left(\frac{100}{\theta} \right) + A_3 * \ln \left(\frac{\theta}{100} \right) + A_4 * \left(\frac{\theta}{100} \right) \right. \\ \left. + S * \left[B_1 + B_2 * \left(\frac{\theta}{100} \right) + B_3 * \left(\frac{\theta}{100} \right)^2 \right] \right\}$$

where θ is the absolute temperature (K); and

$$\begin{array}{ll} A_1 = -173.4292 & B_1 = -0.033096 \\ A_2 = 249.6339 & B_2 = 0.014259 \\ A_3 = 143.3483 & B_3 = -0.001170 \\ A_4 = -21.8492. & \end{array}$$

SEASAVE R automatically implements this equation.

The hysteresis correction is calculated, using the oxygen voltages, with the following algorithm:

$$D = 1 + H_1 * (e^{(\frac{P(i)}{H^2})} - 1) \\ C = e(-1 * \left(\frac{Time(i) - Time(i-1))}{H3} \right)) \\ O_V(i) = O_{volt}(i) + V_{offset} \\ O_{newvolts}(i) = a * \frac{a}{D} \\ O_{finalvolts}(i) = O_{newvolts}(i) - V_{offset}$$

Where:

i = indexing variable (must be a continuous time series to work; can be performed on bin averaged data), where $i = 1:\text{end}$ (end is largest data index point plus 1).

$P(i)$ = pressure (decibars) at index point i .

$\text{Time}(i)$ = time (seconds) from start of index point i .

$O_{volt}(i)$ = SBE 43 oxygen voltage output directly from sensor, with no calibration or hysteresis corrections, at index point i .

V_{offset} = correction for an electronic offset that is applied to voltage output of sensor. V_{offset} correction is always negative (see factory calibration sheet for this coefficient). V_{offset} is added to raw voltages prior to hysteresis correction. At end of hysteresis corrections, V_{offset} is removed prior to data conversion using SBE 43 calibration equation (see $O_{finalvolts}(i)$).

$O_V(i)$ = dissolved oxygen voltage value with V_{offset} correction (made prior to hysteresis correction) at index point i .

D and C are temporary variables used to simplify expression in processing loop.

$H1$ = amplitude of hysteresis correction function. Default = -0.033, range = -0.02 to -0.05 (varies from sensor to sensor).

$H2$ = function constant or curvature function for hysteresis. Default = 5000.

$H3$ = time constant for hysteresis (seconds). Default = 1450, range = 1200 to 2000 (varies from sensor to sensor).

$O_{newvolts}(i)$ = hysteresis-corrected oxygen value at index point i .

$O_{finalvolts}(i)$ = hysteresis-corrected oxygen value at index point i with V_{offset} removed.

This step is necessary prior to computing oxygen concentration using SBE 43 calibration equation.

3.5 Reference Temperature

The SBE 35RT is an accurate, ocean-range temperature sensor that is capable of measuring temperature in the ocean to depths of 6800 meters (22,300 ft). The SBE 35RT communicates via a standard RS-232 interface at 300 baud, 8 data bits, no parity. The SBE 35RT makes a temperature measurement each time a bottle fire confirmation is received, and stores the value in EEPROM. Each stored value contains the time and bottle position in addition to the temperature data, allowing comparison of the SBE 35RT record with CTD and water bottle data. Using one SBE 35RT eliminates the need for reversing thermometers, and provides higher accuracy temperature readings at lower cost. Calibration coefficients stored in EEPROM allow the SBE 35RT to transmit data in engineering units (Table 16). When configured in a real-time system, the SBE 35RT can use the system modem channel for two-way communications; it is not necessary to change cable connections to communicate with and retrieve data from the SBE 35RT. Retrieved from http://www.seabird.com/sites/default/files/documents/35RT_013.pdf (2015, February 12).

The sensor measurement ranges from -5 to 35°C. The SBE 35RT digital reversing thermometer has a typical accuracy/stability of $\pm 0.001^\circ\text{C}$ per year and resolution of 0.000025°C.

4 Data Acquisition

CTD/rosette casts were performed with a package consisting of a 24-place, 10-liter rosette frame, a 24-place water sampler (SBE32) and up to 23, 10-liter Bullister-style bottles. This package was deployed on all stations/casts. Underwater electronic components consisted of a Sea-Bird Electronics (SBE) 9 plus CTD with dual pumps and the following sensors: dual temperature (SBE3), dual conductivity (SBE4), dual dissolved oxygen (SBE43), and an altimeter. Some cruises included a fluorometer (not reported herein). The other underwater electronic components typically consisted of two RDI LADCPs (also not reported herein). A total of 54 CTD/rosette casts were made between all six cruises, usually to within 20 m of the bottom.

The CTD's supplied a standard Sea-Bird format data stream at a data rate of 24 frames/second. The SBE9 plus CTD was connected to the SBE32 24-place pylon providing for single-conductor sea cable operations. Power to the SBE9 plus CTD, SBE32 pylon, auxiliary sensors, and altimeter was provided through the sea cable from the SBE911 plus deck unit in the computer lab. The rosette system was suspended from a UNOLS-standard three-conductor 0.322" electro-mechanical sea cable.

The CTD was mounted vertically attached to the bottom center of the rosette frame. All SBE4 conductivity and SBE3 temperature sensors and their respective pumps were mounted vertically as recommended by SBE, outboard of the CTD. The CTD was outfitted with dual pumps. Primary temperature, conductivity, and dissolved oxygen were plumbed on one pump circuit and secondary temperature, conductivity, and dissolved oxygen on the other. Pump exhausts were attached to outside corners of the CTD cage and directed downward. The altimeter was mounted on the inside of a support strut adjacent to the bottom frame ring. The LADCP's were vertically mounted inside the bottle rings with one 300 kHz pointing down, the other 300 kHz transducer pointing up. The R/V Walton Smith's stern A-frame CTD winch was used with the 24-place 10-liter rosette for all station/casts. However, at most 23 water samples are collected due to the presence of an upward looking ADCP in place of one Niskin bottle.

O-rings were changed as necessary and bottle maintenance was performed each day to insure proper closure and sealing. Valves were inspected for leaks and repaired or replaced as needed.

4.1 System Problems

- FC1609 - The salts collected and run were not usable for calibrations due to a bad autosal run. The calibrations coefficients from the previous cruise were used.

4.2 Data Acquisition

The CTD data acquisition system consisted of an SBE-11plus (V2) deck unit and a networked generic PC workstation located in the aft of the science lab. SBE Seasave software version 7.21 was used for data acquisition and to close bottles on the rosette.

The console watch initiated CTD deployments after the ship stopped on station. The watch maintained a console operations log containing a description of each deployment, a record of every attempt to close a bottle and any pertinent comments.

Prior to each cast the CTD was powered on and an on deck surface pressure was recorded and then powered off before deployment. The deck watch leader directed the winch operator to raise the package, the stern A-frame and rosette were extended outboard, and the package quickly lowered into the water and submerged to 10-15 meters of wire out. Tag lines were necessary for both deployments and recoveries during this cruise. The CTD sensor pumps were configured with a 60 second startup delay. The CTD console operator waited for the CTD sensor pumps to turn on, waiting for 2-3 minutes for sensors to stabilize, then directed the winch operator to bring the package close to the surface, pause for typically 10 seconds, hitting “Mark Scan” and begin the descent. The profiling rate was no more than 30 m/min to 150 m and no more than 60 m/min deeper than 150 m depending on sea cable tension and the sea state.

The console watch monitored the progress of the deployment and quality of the CTD data through interactive graphics and operational displays. Additionally, the watch created a sample log for the deployment that would be later used to record the correspondence between rosette bottles and analytical samples taken. The altimeter channel, CTD pressure, wire-out and bathymetric depth were all monitored to determine the distance of the package from the bottom, usually allowing a safe approach to within 20 m.

On the up cast, the winch operator was directed to stop at each bottle trip depth. The CTD console operator waited 30 seconds before tripping a bottle using a “point and click” graphical trip button. The data acquisition system responded with trip confirmation messages and the corresponding CTD data in a rosette bottle trip window on the display. All tripping attempts were noted on the console log. The console watch then directed the winch operator to raise the package up to the next bottle trip location.

After the last bottle was tripped, the console watch directed the deck watch to bring the rosette on deck. Once on deck, the console watch terminated the data acquisition, turned off the deck unit, and assisted with rosette sampling.

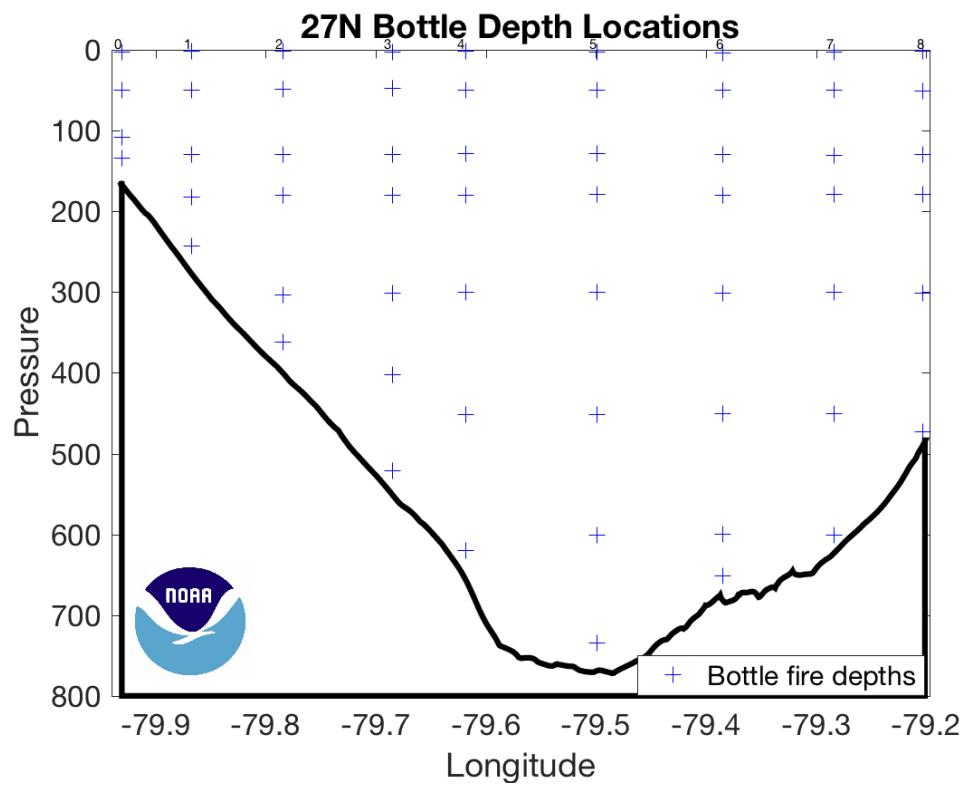

Figure 2: Nominal bottle locations for 27°N section in the Florida Straits.

4.3 Preliminary CTD Data Processing

Preliminary CTD data processing was performed using SEABIRD SBE Data Processing version 7.21k and AOML Matlab processing software. The raw CTD data and bottle trips acquired by SBE Seasave on the Windows 7 workstation were copied onto the CTD-PROC workstation, and processed to a 1-dbar series and a 1-second time series. Bottle trip values were extracted and a 1-decibar (dbar) down cast pressure series created.

Raw data are acquired from the instruments and are stored unmodified. The conversion module DATCNV uses the instrument configuration and pre-cruise factory calibration coefficients to create a converted engineering unit data file that is utilized by all SBEDataProc R post processing modules. Unless otherwise noted, all calibration parameters given are factory default values recommended by Sea Bird Electronics, Inc. The following is the SBEDataProc R processing module sequence and specifications for primary calibrated data (1 dbar averages) uses the following routines in order for reduction of CTD/O2 data from this cruise:

1. DATCNV converts raw data into engineering units and creates a .ROS bottle file. Both down and up casts were processed for scan, elapsed time(s), depth, pressure, t0 ITS-90 C, t1 ITS-90 C, c0 S/m, c1 S/m, salinity (PSU), salinity 2 (PSU), oxygen voltage V, oxygen 2 voltage V, altimeter, optical sensor, oxygen umol/kg, oxygen 2 umol/kg, oxygen ml/l, oxygen 2 ml/l, oxygen dv/dt, oxygen dv/dt 2, latitude, and longitude. MARKSCAN was used to determine the number of scans acquired on deck and while priming the system to exclude these scans from processing.
2. ALIGNCTD aligns temperature, conductivity, and oxygen measurements in time relative to pressure to ensure that derived parameters are made using measurements from the same parcel of water. Primary and secondary conductivity were automatically advanced by 0.073 seconds. Primary and secondary oxygen were advanced by 1.073.
3. FILTER applies a low pass filter to pressure with a time constant of 0.15 seconds. In order to produce zero phase (no time shift), the filter is first run forward through the file and then run backwards through the file.
4. LOOPEDIT removes scans associated with pressure slowdowns and reversals. If the CTD velocity is less than 0.25 m/s or the pressure is not greater than the previous maximum scan, the scan is omitted.
5. CELLM_TM uses a recursive filter to remove conductivity cell thermal mass effects from measured conductivity. In areas with steep temperature gradients the thermal mass correction is on the order of 0.005 PSS-78. In other areas the correction is negligible. The value used for the thermal anomaly amplitude (alpha) was 0.03°C. The value used for the thermal anomaly time constant (1/beta) was 7.0°C.
6. WILDEDIT computes the standard deviation of 100 point bins, and then makes two passes through the data. The first pass flags points that differ from the mean by more than 2 standard deviations. A new standard deviation is computed excluding the flagged points and the second pass marks bad values greater than 20 standard deviations from the mean.
7. BOTTLESUM creates a summary of the bottle data. Bottle position, date, and time were output automatically. Pressure, temperature, conductivity, salinity, oxygen voltage and preliminary oxygen values were averaged over a 5 second interval.

-
8. DERIVE uses 1 dbar averaged pressure, temperature, and conductivity to compute primary and secondary salinities. Oxygen voltage is used to calculate oxygen concentrations.
 9. BINAVG averages the data into 1 dbar bins. Each bin is centered on an integer pressure value, e.g., the 1 dbar bin averages scans where pressure is between 0.5 dbar and 1.5 dbar. There is no surface bin. The number of points averaged in each bin is included in the data file.
 10. TRANS converts the binary data file into ASCII format.
 11. SPLIT separates the cast into upcast and downcast values.

Package slowdowns and reversals owing to ship roll can move mixed water in tow to in front of the CTD sensors and create artificial density inversions and other artifacts. In addition to Seasoft module LOOPEDIT, a program computes values of density locally referenced between every 1 dbar of pressure to compute N^2 and linearly interpolates temperature, conductivity, and oxygen voltage over those records where N^2 is less than or equal to $-1 \times 10^{-5} \text{ s}^{-2}$. These data were retained but flagged as questionable in the final WOCE formatted files.

Final calibrations are applied to delooped data files. ITS-90 temperature, salinity, and oxygen are computed, and WOCE quality flags are created.

CTD data were examined at the completion of each deployment for clean corrected sensor response and any calibration shifts. As bottle salinity and oxygen results became available, they were used to refine shipboard conductivity and oxygen sensor calibrations.

A total of 45 casts were processed.

4.4 CTD Calibration Procedures

Laboratory calibrations of the CTD pressure, temperature, conductivity, and oxygen sensors were all performed at SBE. The calibration dates are listed in Table 11.

Secondary temperature, conductivity and dissolved oxygen (T2, C2 and DO2) sensors served as calibration checks for the reported primary sensors. The sensors used for calibrations for each cruise are listed below in Section 5.

In-situ salinity and dissolved O₂ check samples collected during each cast were used to calibrate the conductivity and dissolved O₂ sensors.

4.4.1 Salinity Analysis

A Guildline Autosal, model 8400B, located in the salt van outside of AOML, was used for all salinity measurements. The salinometer readings were logged on a computer using Ocean Scientific International's logging hardware and software. The Autosal's water bath temperature was set to 24°C, which the Autosal is designed to automatically maintain. The laboratory's temperature is typically set and maintained to just below 24°C, to help further stabilize reading values and improve accuracy. The room temperature was monitored by a digital thermometer. Salinity analyses were performed after samples had equilibrated to laboratory temperature, usually within a couple days after collection. The salinometer was standardized for each group of samples analyzed (usually 2 casts and up to 52 samples) using two bottles of standard seawater: one at the beginning and end of each set of measurements. The salinometer output was logged

to a computer file. The software prompted the analyst to flush the instrument's cell and change samples when appropriate. Prior to each run a sub-standard flush, approximately 200 ml, of the conductivity cell was conducted to flush out the DI water used in between runs. For each calibration standard, the salinometer cell was initially flushed 6 times before a set of conductivity ratio reading was taken. For each sample, the salinometer cell was initially flushed at least 3 times before a set of conductivity ratio readings were taken.

IAPSO Standard Seawater Batch P-158 was used to standardize all casts (Table 17).

Table 17: Nominal values for the batches of IAPSO standard seawater.

P-158
Use By: March 2018
K15: 0.99970
Salinity: 34.988

The salinity samples were collected in 200 *ml* Kimax high-alumina borosilicate bottles that had been rinsed at least three times with sample water prior to filling. The bottles were sealed with custom-made plastic insert thimbles and Nalgene screw caps. This assembly provides very low container dissolution and sample evaporation. Prior to sample collection, inserts were inspected for proper fit and loose inserts replaced to insure an airtight seal. Laboratory temperature was also monitored electronically throughout the cruise. PSS-78 salinity [UNES81] was calculated for each sample from the measured conductivity ratios. The offset between the initial standard seawater value and its reference value was applied to each sample. Then the difference (if any) between the initial and final vials of standard seawater was applied to each sample as a linear function of elapsed run time. The corrected salinity data was then incorporated into the cruise database. During the four Florida Straits cruises, a total of 315 salinity measurements were taken.

The running standard calibration values are shown in Figure . For FC1603 the autosal standards changed by 0.00002 in conductivity ratio (about 0.0004 in salinity). For FC1605 the autosal standards did not change. For FC1607 the autosal standards changed by 0.00003 in conductivity ratio (about 0.001 in salinity). For FC1609 the autosal standards changed by 0.01 in conductivity ratio (about 0.19 in salinity). For FC1612 the autosal standards changed by 0.00013 in conductivity ratio (about 0.0025 in salinity).

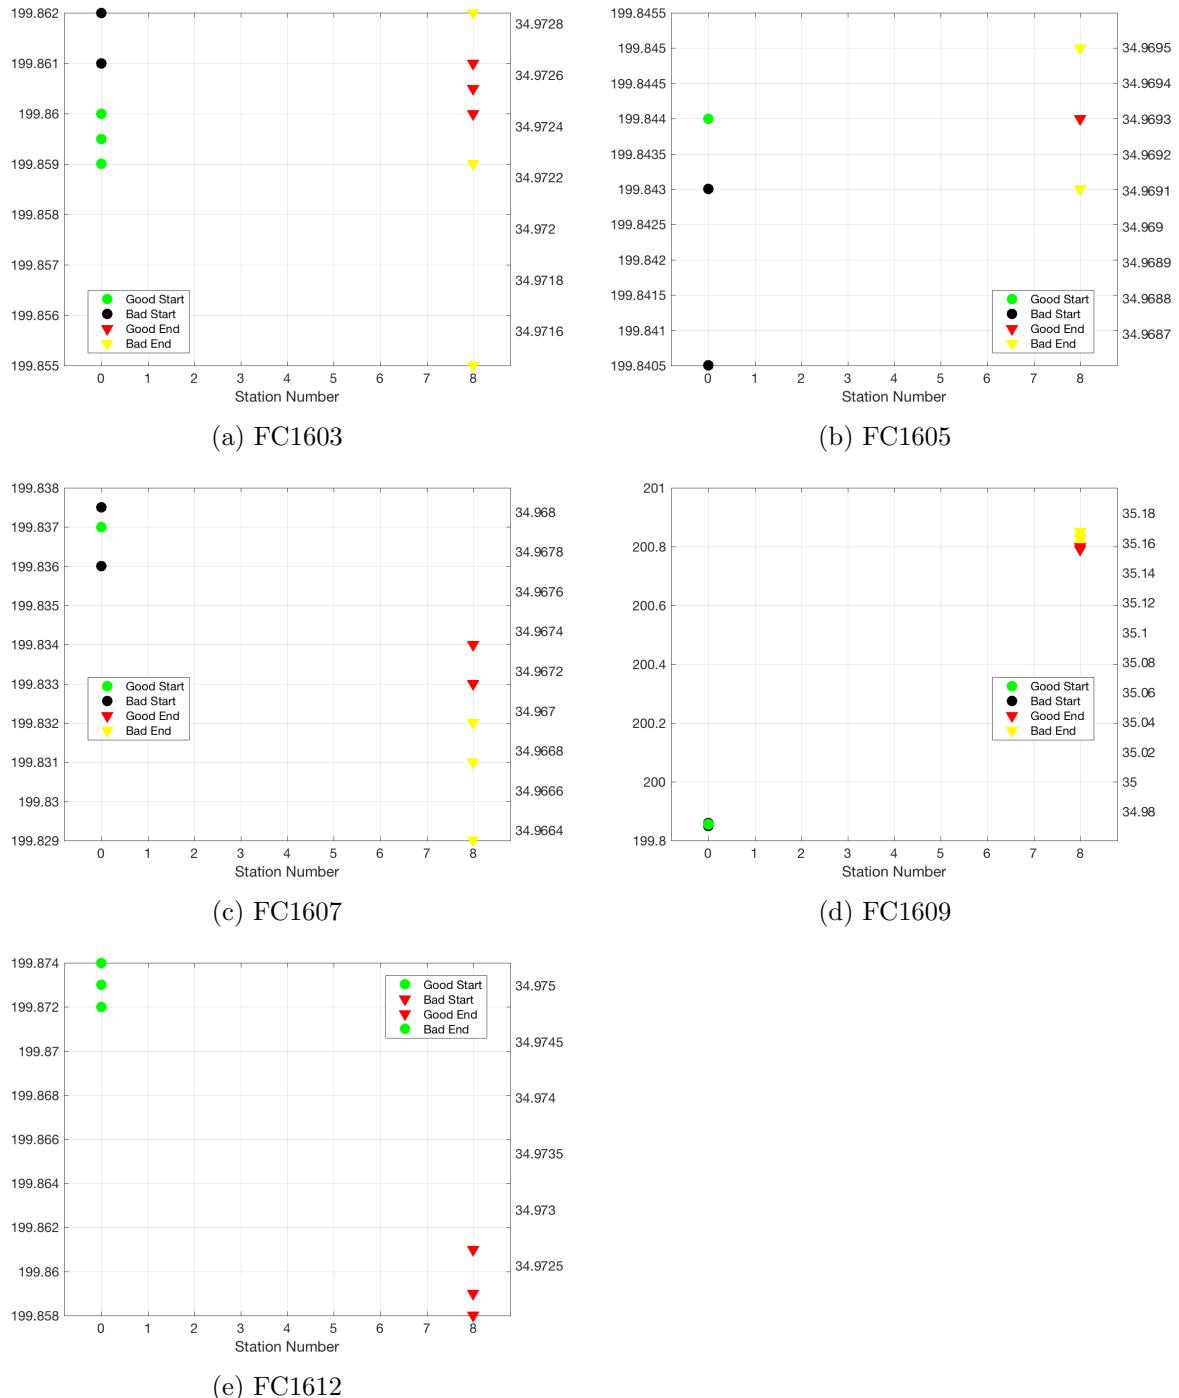

Figure 3: Standard vial calibrations throughout the cruise.

4.4.2 Oxygen Analysis

Dissolved oxygen analyses were performed with an automated titrator using amperometric end-point detection (Langdon, 2010). Sample titration, data logging, and graphical display were performed with a PC running a LabView program written by Ulises Rivero of AOML. Thiosulfate (17.5g per 500 ml) was dispensed by a 2 ml Gilmont burette driven with a stepper motor controlled by the titrator. Tests in the lab were performed to confirm that the precision and accuracy of the volume dispensed were comparable or superior to the Dosimat 665. The whole-bottle titration technique of Carpenter (1965), with modifications by Culberson et al. (1991), was used. Four replicate 10 *ml* iodate standards were run initially and if there requires any fill of new Thiosulfate and once again after bottle has reached half volume. The reagent blank determined as the difference between V1 and V2, the volumes of Thiosulfate required to titrate 1ml aliquots of the iodate standard. This method was found to produce a more reproducible blank value than the value determined as the intercept of a standard curve.

Dissolved oxygen samples were drawn from Niskin bottles into calibrated 125-150ml iodine titration flasks using silicon tubing. Bottles were rinsed three times and filled from the bottom, overflowing three volumes while taking care not to entrain any bubbles. The CTD temperatures were used to calculate *umol/kg* concentrations. 1ml of MnCl₂ and 1ml of NaOH/NaI were added immediately after drawing the sample was concluded using a ThermoScientific REPIPET II. The flasks were then stoppered and shaken well. Deionized water (DIW) was added to the neck of each flask to create a water seal. The total number of oxygen samples collected from the rosette was 339. A duplicate sample was taken at each station. The samples were stored in the lab in plastic totes at room temperature and run once back at AOML. The data was incorporated into the cruise database shortly after analysis. Thiosulfate normality was calculated from the laboratory temperature for each sample run.

The dispenser used for the standard solution (SOCOREX Calibrex 520) and the burette were calibrated gravimetrically just before the cruise. Oxygen flask volumes were determined gravimetrically with degassed deionized water at AOML. The correction for buoyancy was applied.

5 Post-Cruise Calibrations

Post cruise sensor calibrations were not done at Sea-Bird Electronics, Inc. Secondary temperature, conductivity and dissolved oxygen sensors served as calibration checks for the reported primary sensors.

In-situ salinity and dissolved oxygen samples collected during each cast were used to calibrate the conductivity and dissolved oxygen sensors.

The same pressure sensor as well as primary and secondary temperature, conductivity and oxygen sensors were used during the cruises as listed in Table 11. For all Florida Current cruises in 2016 the secondary T, C, and O were selected for final data reduction. In addition to the Seasave processing modules, a group of Matlab script files called AOML/CTDCAL Toolbox were used. These scripts were based on earlier work of different groups as well as in modern statistical tools. They cover all the steps of the CTD data processing from the preliminary comparisons between sensors or bottle samples to data reductions and final sensors calibrations.

5.1 CTD Data Processing

By using the post cruise sensors calibrations; time drifts were estimated for the temperature and conductivity sensors (for estimated time drifts see the appropriate sections below). The processing module sequence used at sea is done again to include the time drifts as well the pressure correction. After this step the following Matlab scripts based on PMEL programs are applied to the CTD data:

- FILL_SURFACE was used to copy the first good value of salinity, potential temperature, oxygen and oxygen current back to the surface. The program then calculated temperature and conductivity, and zeroed doc/dt of oxygen current for those records.
- DESPIKE1 removed spikes from primary oxygen current and oxygen temperature data, as well as removing spikes from the primary conductivity sensor. Data were linearly interpolated over de-spiked records. Conductivity was back calculated, and sigma-theta and potential temperature were recomputed for the interpolated records.
- DESPIKE2 removed spikes from secondary sensors in the same method as DESPIKE1.
- Package slowdown and reversals due to ship roll can move mixed water in tow in front of the CTD sensors. This mixture can create artificial density inversions and other artifacts. In addition to the SEASOFT module LOOPEDIT, DELOOP, computes values of density locally referenced between every 1 dbar of pressure to compute $N^2 = (-g/p) (dp/dz)$ and linearly interpolated measured parameters over those records where $N^2 \leq -1.0 \text{ e } -05 \text{ s}^{-2}$.

5.2 CTD Pressure

Pressure sensor calibration coefficients derived from the pre-cruise calibrations were applied to raw pressure data during each cast. Residual pressure offsets (the difference between the first and last submerged pressures) were examined to check for calibration shifts (see Figure 4 and Tables 18 - 22. All cruises used pressure sensor s/n 0957. Prior to each cruise a pressure offset of -0.588 was applied to the pressure configuration file for a total pressure offset of -3.3164. On deck pressures recorded before and after each cast are plotted in Figure 4.

For FC1603 the on deck pressure before and after the cast were stable at -0.048 ± 0.038 dbar and -0.059 ± 0.058 dbar, respectively (median \pm standard deviation). No pressure correction offset was necessary before final calibration of the data. Near surface pressure values (which is taken as the near-surface pressure at the markscan and the last fired bottle pressure) showed little variability over the cruise (3.75 ± 0.33 dbar before and 2.77 ± 0.47 dbar after).

For FC1605 the on deck pressure before and after the cast were stable at -0.025 ± 0.09 dbar and 0.061 ± 0.03 dbar, respectively. No pressure correction offset was necessary before final calibration of the data. Near surface pressure values showed a little variability over the cruise between the start and end surface pressure (2.55 ± 0.35 dbar before and 2.66 ± 0.39 dbar after).

For FC1607 the on deck pressure before and after the cast were stable at -0.006 ± 0.032 dbar and 0.17 ± 0.05 dbar, respectively. No pressure correction offset was necessary before final calibration of the data. Near surface pressure values showed little variability over the cruise between the start and end surface pressure (2.49 ± 0.28 dbar before and 3.11 ± 0.48 dbar after).

For FC1609 the on deck pressure before and after the cast were stable at 0.03 ± 0.05 dbar and 0.21 ± 0.28 dbar, respectively. No pressure correction offset was necessary before final calibration of the data. Near surface pressure values showed little variability over the cruise between the start and end surface pressure (1.98 ± 0.21 dbar before and 2.29 ± 0.51 dbar after).

For FC1612 the on deck pressure before the cast was stable at 0.06 ± 0.03 dbar. No pressure correction offset was necessary before final calibration of the data. Near surface pressure values showed little variability over the cruise between the start and end surface pressure (2.18 ± 0.18 dbar before and 2.48 ± 0.69 dbar after).

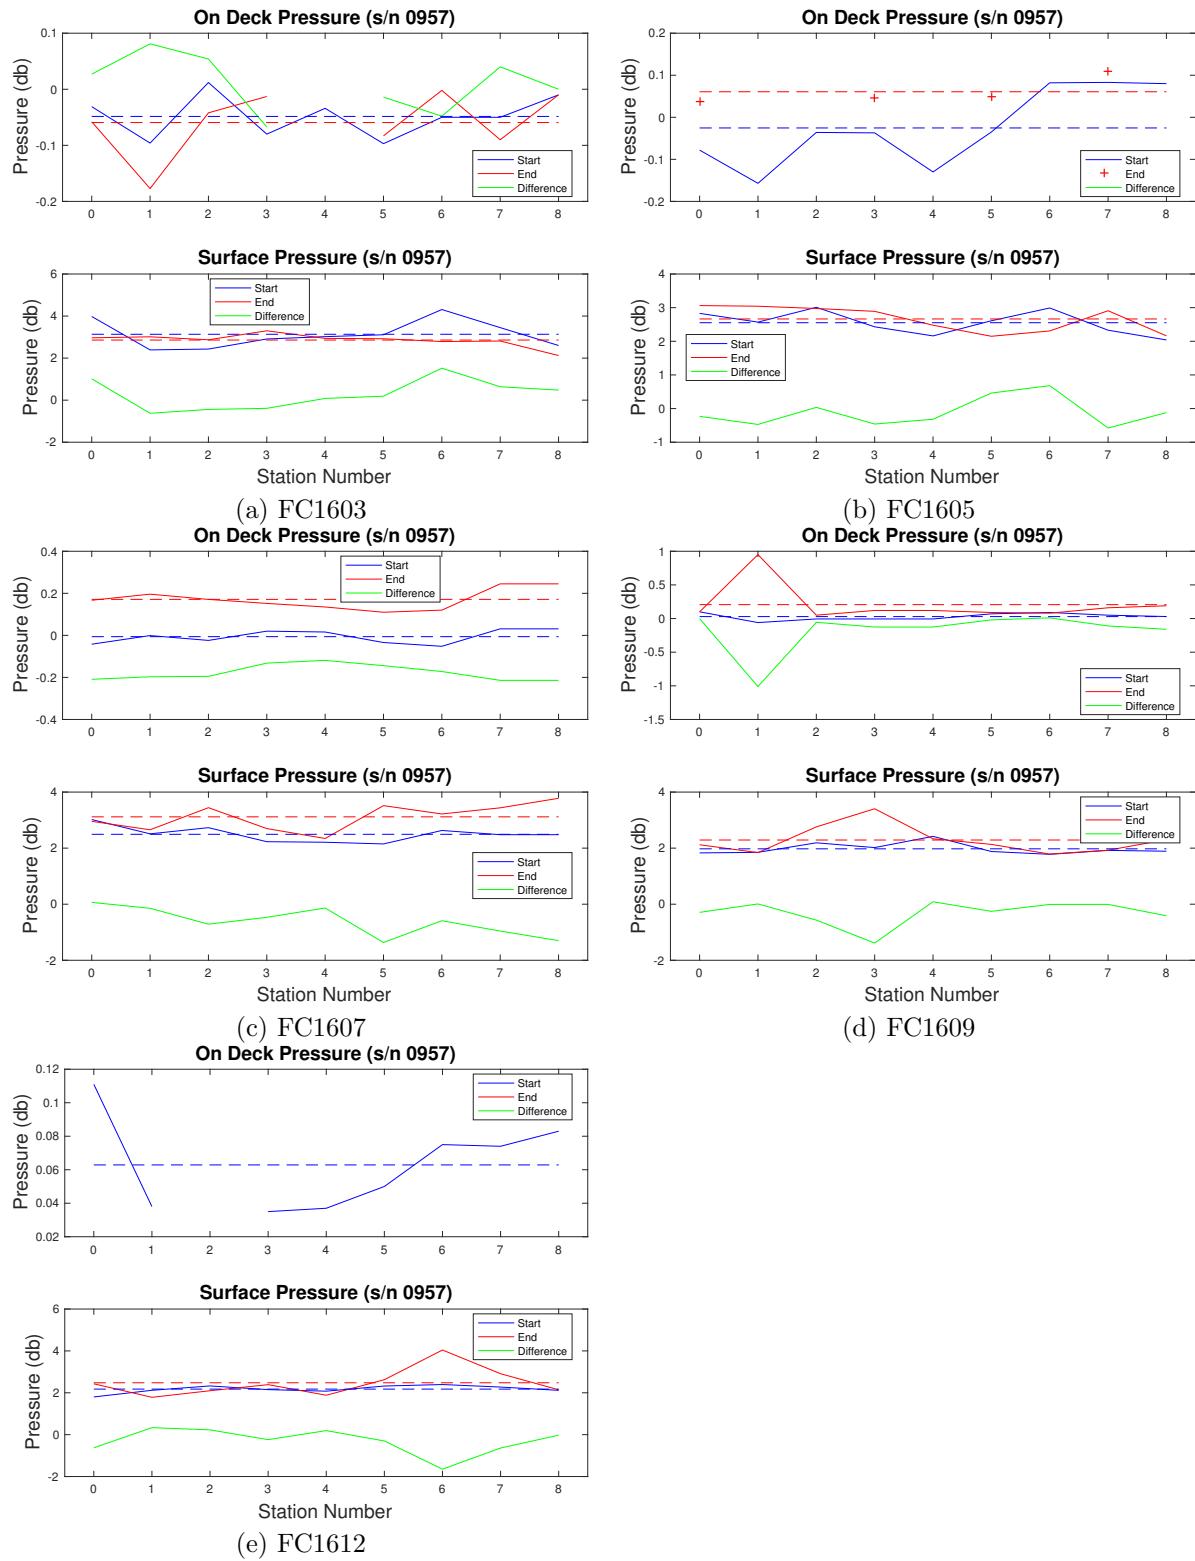

Figure 4: Pressure differences vs. station number. Top panel are the pressures measured on deck before the cast (blue). Bottom panel are the near sea surface pressure values measured at the start of the downcast (blue), at the end of the upcast (red) and their respective difference (green).

5.3 CTD Temperature

Temperature sensor calibration coefficients derived from the pre-cruise calibrations were applied to raw primary and secondary temperature data during each cast. Data accuracy, reproducibility and stability were examined by tabulating the difference between the two different temperature sensors over a range of pressures (bottle trip locations) for each cast.

These comparisons are summarized in Figure 5, which shows the median temperature difference between the two sensors. For FC1603 there was a median of 0.0025 °C and a standard deviation of 0.003 °C. For FC1605 there was a median of $5.5 \cdot 10^{-4}$ °C and a standard deviation of 0.011 °C. For FC1607 there was a median of 0.0018 °C and a standard deviation of 0.009 °C. For FC1609 there was a median of 0.0016 °C and a standard deviation of 0.01 °C. For FC1612 there was a median of 0.0016 °C and a standard deviation of 0.03 °C. The secondary sensor, s/n 5855, was used for all cruises.

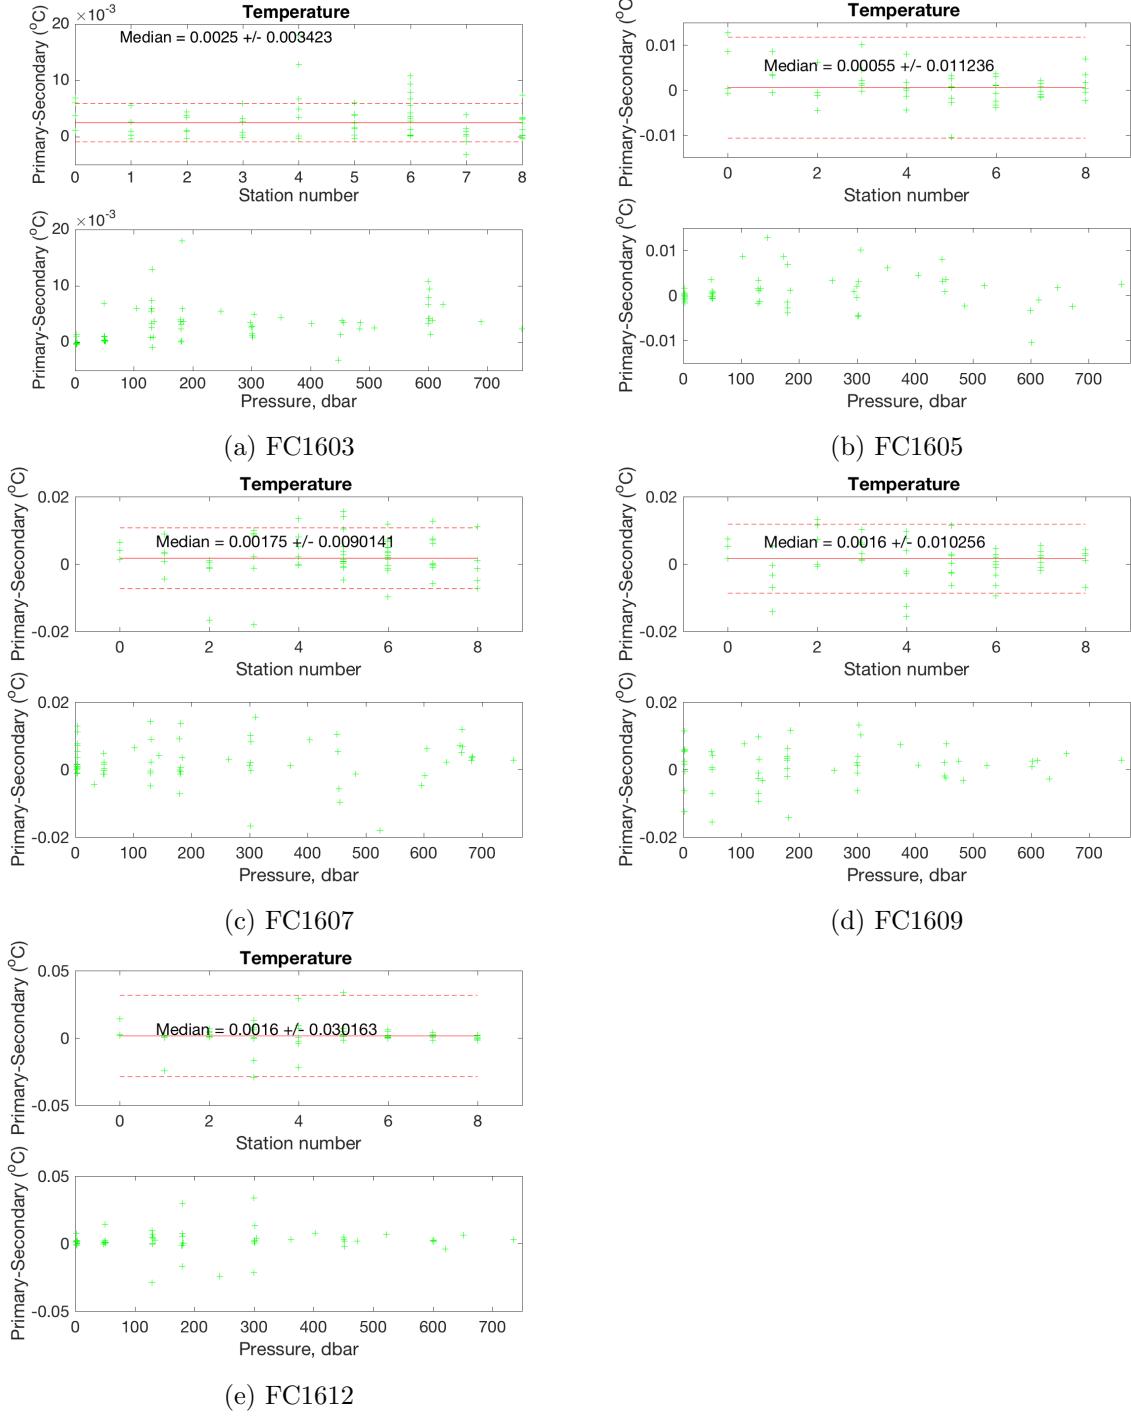

Figure 5: Temperature differences (after pressure corrections) between sensors by station number (top) and pressure (bottom). The green represents the surface data down to 1000 dbar. The blue represents data below 1000 dbar. The red solid line represents the median with the red dashed representing the standard deviation (same for top and bottom).

A SBE 35RT reference temperature was used during three of the cruises, FC1605, FC1607 and FC1609, as a check to monitor the behavior of the primary and secondary temperature sensors. This typically allows for corrections to be made if there are any significant pressure dependencies or offsets, but was uncertain if it would be significant in the high variability of the Florida Current.

In order to calibrate the CTD temperature data against the reference temperature we derived the slope correction, m , and offset correction, b , using a least squares fit. This was done as a function of CTD pressure and delta T, where delta T is the CTD temperature minus the reference temperature. The corrections for the slope and offset are then applied to the CTD pressure, P_{CTD} , to calculate the temperature correction (T_{cor}),

$$T_{cor} = [m * P_{CTD} + b]$$

and T_{cor} is applied to calculate the calibrated CTD temperature,

$$T_{new} = T_{CTD} - T_{cor}$$

where T_{CTD} is the CTD temperature and T_{new} is the calibrated CTD temperature.

There was little, if any, improvement in the median and standard deviation between the uncalibrated and calibrated values between the CTD temperature and reference temperature Figure 6 & 7. Looking at the T-S plots in Figure 8 it is not clear which sensor to pick between the calibrated or uncalibrated sensor or the primary or secondary sensor. Although there is a minimal improvement with the application of the reference temperature correction, it is not obvious in the high variability of the Florida Straits and the noise between the residuals of CTD temperature sensors and the residuals of the CTD temperature sensors and the reference temperature that the reference temperature correction is necessary.

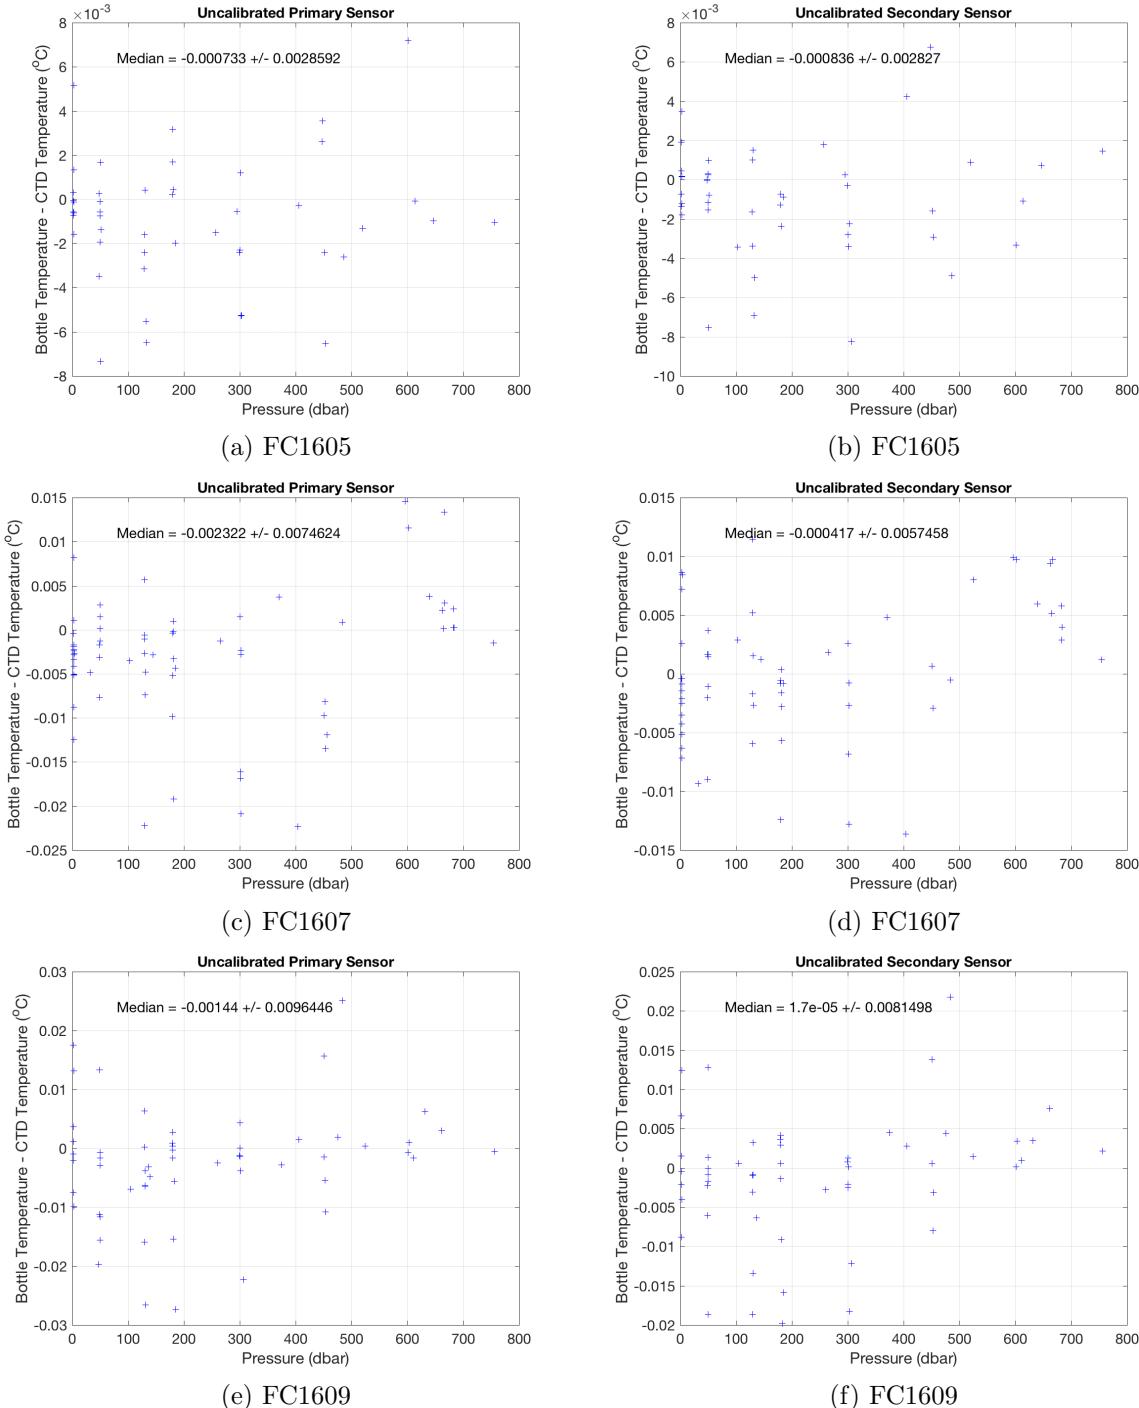

Figure 6: Reference temperature (labeled as Bottle Temperature) and uncalibrated primary and secondary CTD temperature differences plotted vs. pressure.

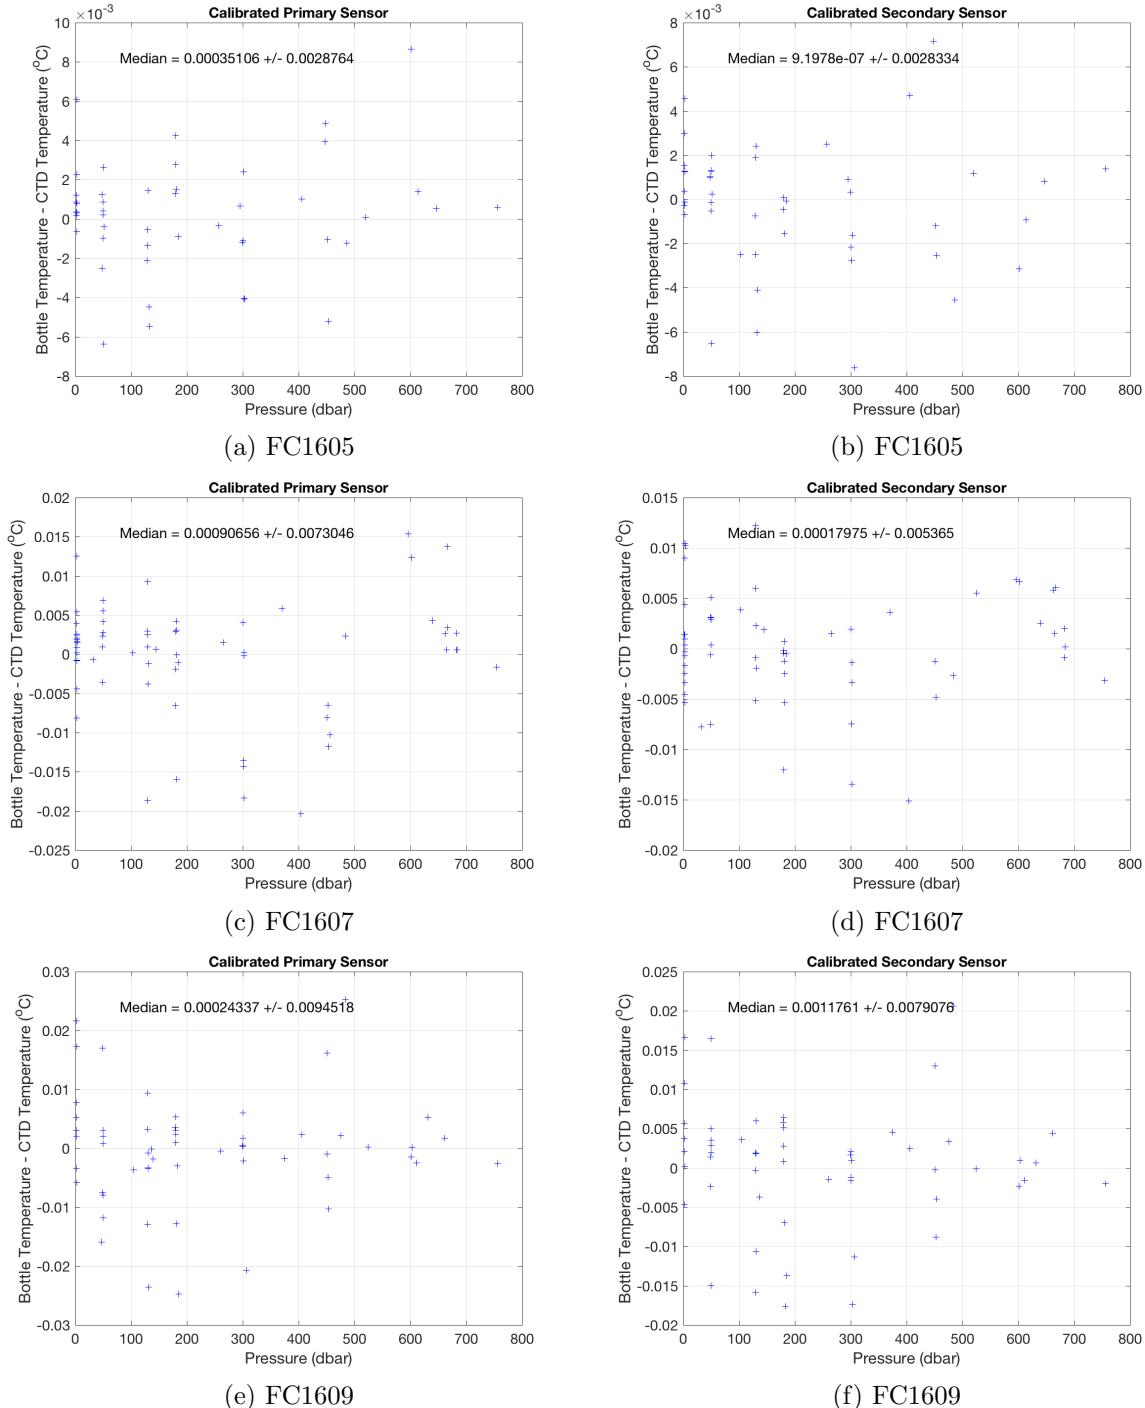

Figure 7: Reference temperature (labeled as Bottle Temperature) and calibrated primary and secondary CTD temperature differences plotted vs. pressure.

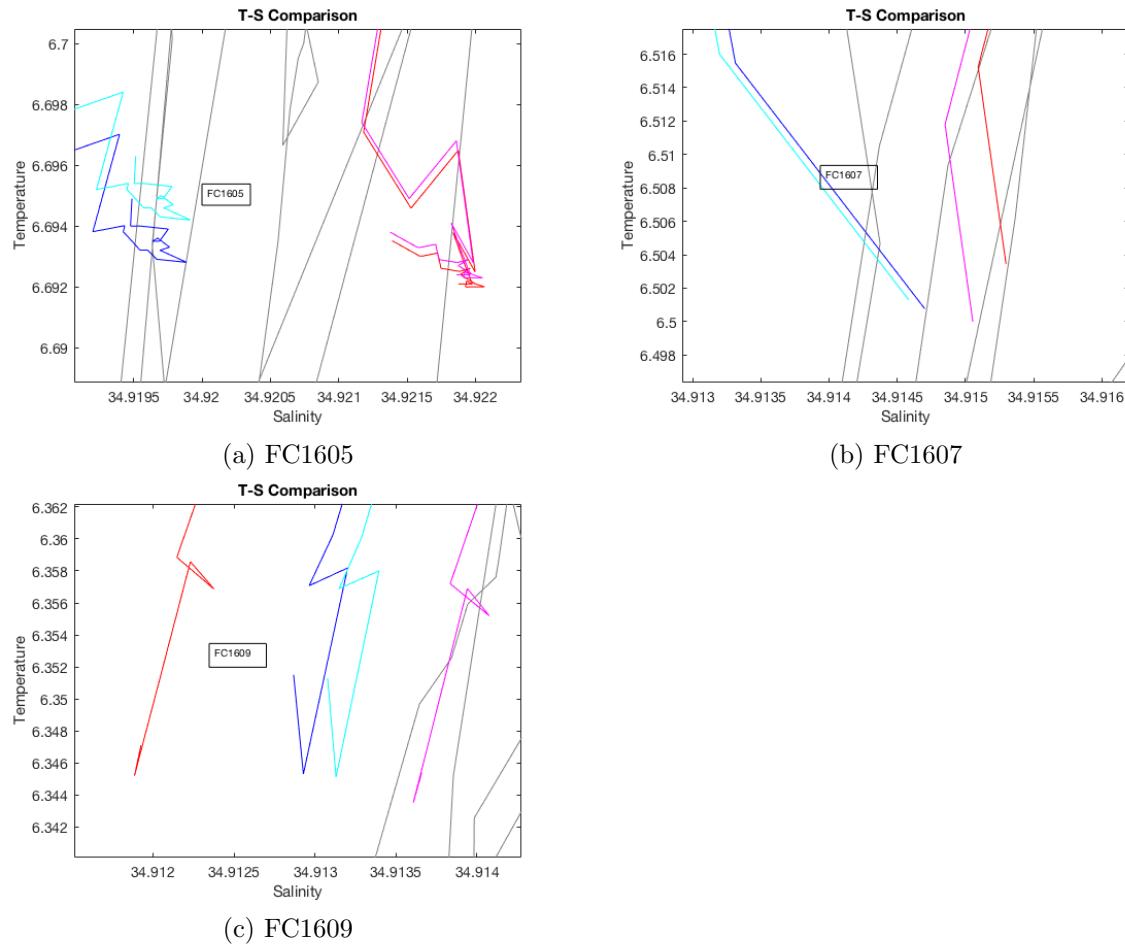

Figure 8: T-S plot comparison of temperature calibrated with the reference temperature (primary - blue, secondary - red) and uncalibrated temperature (primary - cyan, secondary - magenta) and historical in grey.

5.4 Conductivity

Conductivity sensor calibration coefficients derived from the pre-cruise calibrations were applied to raw primary and secondary conductivities. Comparisons between the primary and secondary sensors and between each of the sensors to conductivity calculated from bottle salinities were used to derive conductivity corrections. Uncorrected C1-C2 are shown in Figure 9 to help identify sensor drift. The AOML/CTDCAL Toolbox automatically applies a quality control to the data based on comparison with a normal distribution.

For FC1603 the sensors show a median difference of 0.001 mS/cm and a standard deviation of 0.004 mS/cm (Figure 9). Both sensors showed reasonable values for the residuals. The secondary sensor, s/n 4346, was used for all the final data values (Figure 10).

For FC1605 the sensors show a median difference of -0.002 mS/cm and a standard deviation of 0.012 mS/cm (Figure 9). Both sensors showed reasonable values for the residuals. The secondary sensor, s/n 4346, was used for all the final data values (Figure 10).

For FC1607 the sensors show a median difference of -0.001 mS/cm and a standard deviation of 0.01 mS/cm (Figure 9). Both sensors showed reasonable values for the residuals. The secondary sensor, s/n 4346, was used for all the final data values (Figure 10).

For FC1609 the sensors show a median difference of -0.0004 mS/cm and a standard deviation of 0.012 mS/cm (Figure 9). Both sensors showed reasonable values for the residuals. The secondary sensor, s/n 4346, was used for all the final data values (Figure 10).

For FC1612 the sensors show a median difference of -0.003 mS/cm and a standard deviation of 0.034 mS/cm (Figure 9). Both sensors showed reasonable values for the residuals. The secondary sensor, s/n 4346, was used for all the final data values (Figure 10).

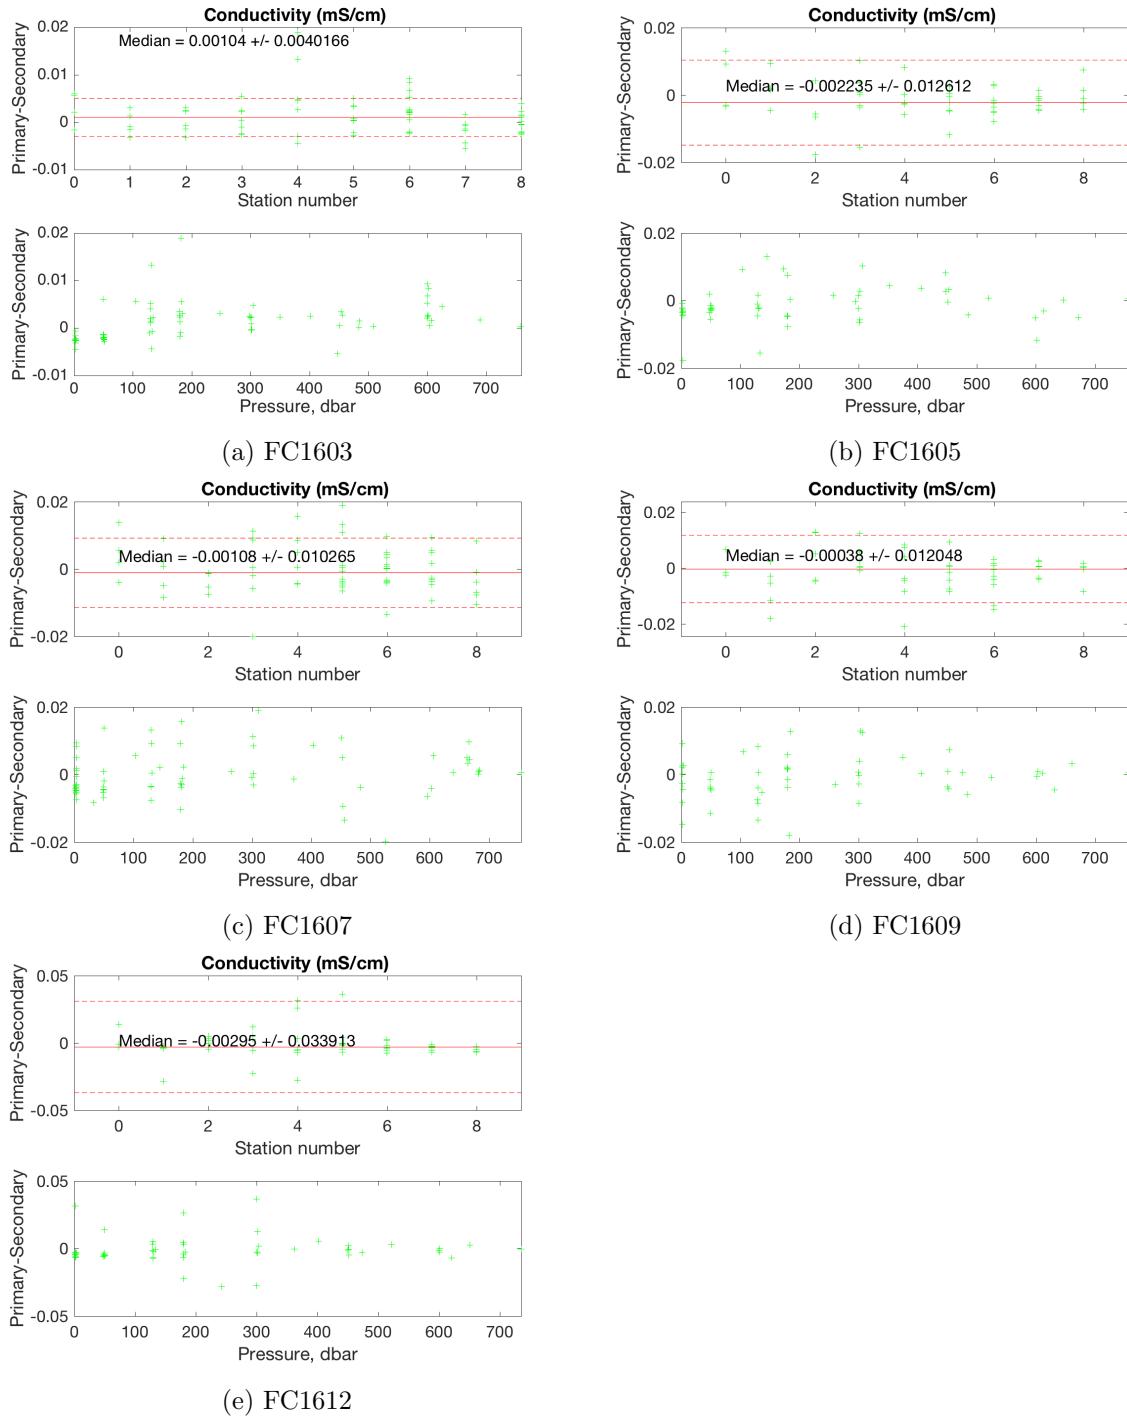

Figure 9: Conductivity (mS/cm) differences between sensors by station (top) and pressure (bottom). The red solid line represents the median with the red dashed representing the standard deviation.

In order to calibrate the CTD conductivity data against the sample conductivity we assume a constant additive correction (offset), multiplicative correction (slope), time drift correction (represented by station number) and where needed, a linear pressure-dependent term. A non-linear function is used to derive these coefficients and are applied to

$$C_{new} = [m * C_{CTD} + (p_1 * station) + b + pcor * P]$$

where C_{bottle} is bottle conductivity (S/m), C_{CTD} is pre-cruise calibrated CTD conductivity (S/m), m is the conductivity slope, b is the offset (S/m), P is the pressure, p_{cor} is the pressure correction coefficient, $station$ is the station number and p_1 is the polynomial coefficient. The fit is also weighted in such way that the final solution is preferentially forced to fit the data below a specified depth, in this case 1000 dbar. Final calibration coefficients are listed in Tables 23 & ??.

FC1603 s/n 4346	FC1605 s/n 4346	FC1607/FC1609 s/n 4346	FC1612 s/n 4346
$m = 0.99998231$	$m = 0.99950459$	$m = 0.99951290$	$m = 0.99945284$
$p_1 = 0$	$p_1 = 0$	$p_1 = 0$	$p_1 = 0$
$b = 0.00702846$	$b = 0.03024969$	$b = 0.03426927$	$b = 0.03325286$
$p_{cor} = 1.82865E-06$	$p_{cor} = -1.83410E-05$	$p_{cor} = -2.13010E-05$	$p_{cor} = -2.51855E-05$

Table 23: Conductivity calibration coefficients applied for final calibration.

For FC1603 the coefficients estimated by the equation above were then applied to the CTD conductivities and the final results (Figure 11 to Figure 12) show a median of $-1.8 \cdot 10^{-3}$ psu and a standard deviation of 0.008 psu. After data reduction 51 data points (96.2 %) were used in the final calculations.

For FC1605 the coefficients estimated by the equation above were then applied to the CTD conductivities and the final results (Figure 11 to Figure 12) show a median of $-3.3 \cdot 10^{-4}$ psu and a standard deviation of 0.005 psu. After data reduction 56 data points (96.6 %) were used in the final calculations.

For FC1607 the coefficients estimated by the equation above were then applied to the CTD conductivities and the final results (Figure 11 to Figure 12) show a median of $2.0 \cdot 10^{-4}$ psu and a standard deviation of 0.005 psu. After data reduction 50 data points (89.3 %) were used in the final calculations.

For FC1609 the secondary coefficients from FC1607 were applied due to the unusable salts.

For FC1612 the coefficients estimated by the equation above were then applied to the CTD conductivities and the final results (Figure 11 to Figure 12) show a median of $-1.2 \cdot 10^{-3}$ psu and a standard deviation of 0.007 psu. After data reduction 56 data points (96.6 %) were used in the final calculations.

A final verification about the quality of the data was made by comparing the results of this cruise with some historical data (Figure 13 & 14).

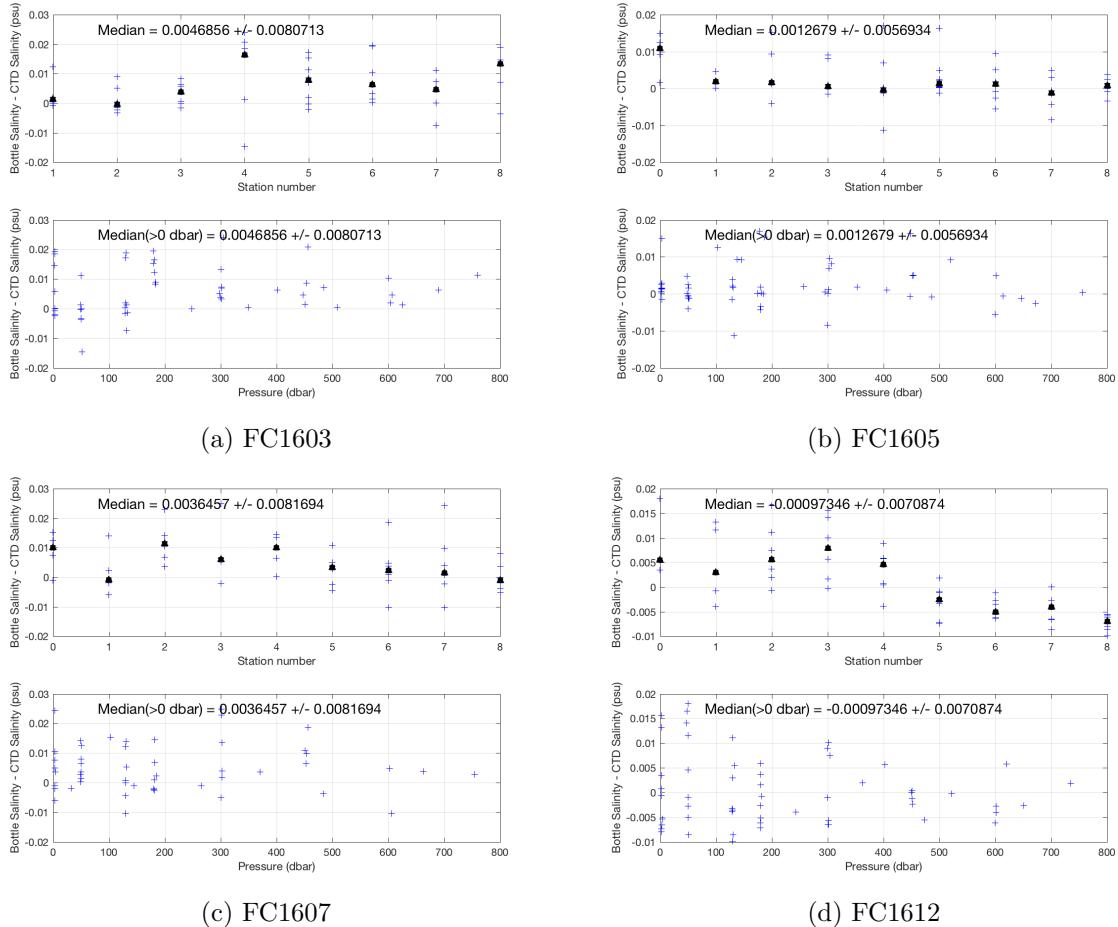

Figure 10: Bottle and uncalibrated CTD salinity differences plotted against pressure. The green crosses represent all data points and the blue are the data points below 1000 dbar. The median was calculated using only the data below 1000 dbar.

5.5 Dissolved Oxygen

Three SBE43 dissolved O₂ (DO) sensors were used on these four cruises (Table 11). Due to a hysteresis problem with the oxygen sensors the DO sensors were calibrated to dissolved O₂ check samples by matching the up cast bottle trips to down cast CTD data along neutral density surfaces, calculating CTD dissolved O₂, and then minimizing the residuals using a non-linear least-squares fitting procedure.

The algorithm used for converting oxygen sensor current and probe temperature measurements as described, requires a non-linear least squares regression technique in order to determine the best fit coefficients of the model for oxygen sensor behavior to the water sample observations. A Matlab R sub-routine called `oxfit.m` from the AOML CTD/CAL TOOLBOX performs a non-linear least squares regression using the Gauss-Newton algorithm with Levenberg-Marquardt modifications for global convergence. This algorithm is independent of the first coefficients guess and demonstrates excellent convergence. This `oxfit.m` routine includes an optional time drift term (related with the station number), allowing all stations to be calibrated without breaking into discrete groupings. The Owens and Millard (1985) algorithm was modified as follows:

$$O \text{ (ml/l)} = \{ Soc * (V + V_{offset} + tau(T, S) * \frac{\delta v}{\delta t}) + p1 * station \} \\ * (1.0 + A * T + B * T^2 + C * T^3) * OXSAT(T, S) * e^{E * (\frac{P}{K})}$$

where Soc , τ_{au} , V_{offset} , A , B , C , E and $p1$ are the calibration coefficients shown above and V is the instrument voltage (V). T , S and P are the temperature, salinity and pressure measured by the CTD. K is the temperature in the absolute scale, $station$ is the station number, and $OXSAT$ is the oxygen saturation.

For FC1603 a comparison between the primary and secondary sensors (Figure 15) was evaluated. The sensors show a median difference of 1.62 umol/kg and a standard deviation of 0.51 umol/kg . The secondary sensor, s/n 0730, was used for all the final data values (Figure 16). After data reduction 51 data points (87.93%) were used in the final calculations. By minimizing the differences between the oxygen samples and the CTD oxygen estimated from the equation described in this section, the new coefficients above were calculated and then applied to the CTD original data (Figure 17 to Figure 18). The median is -0.067 umol/kg and the standard deviation 0.84 umol/kg .

For FC1605 a comparison between the primary and secondary sensors (Figure 15) was evaluated. The sensors show a median difference of 0.03 umol/kg and a standard deviation of 0.34 umol/kg . The primary sensor, s/n 0730, was used for all the final data values (Figure 16). After data reduction 52 data points (89.66%) were used in the final calculations. By minimizing the differences between the oxygen samples and the CTD oxygen estimated from the equation described in this section, the new coefficients above were calculated and then applied to the CTD original data (Figure 17 to Figure 18). The median is 0.029 umol/kg and the standard deviation 0.84 umol/kg .

For FC1607 a comparison between the primary and secondary sensors (Figure 15) was evaluated. The sensors show a median difference of 1.09 umol/kg and a standard deviation of 0.98 umol/kg . The secondary sensor, s/n 0730, was used for all the final data values (Figure 16). After data reduction 51 data points (91.07%) were used in the final calculations. By minimizing the differences between the oxygen samples and the CTD oxygen estimated from the equation described in this section, the new coefficients above were calculated and then applied to the CTD original data (Figure 17 to Figure 18). The median is 0.015 umol/kg and the standard deviation 1.41 umol/kg .

For FC1609 a comparison between the primary and secondary sensors (Figure 15) was evaluated. The sensors show a median difference of 1.55 umol/kg and a standard deviation of 0.96 umol/kg . The primary sensor, s/n 0730, was used for all the final data values (Figure 16). After data reduction 54 data points (94.7%) were used in the final calculations. By minimizing the differences between the oxygen samples and the CTD oxygen estimated from the equation described in this section, the new coefficients above were calculated and then applied to the CTD original data (Figure 17 to Figure 18). The median is 0.025 umol/kg and the standard deviation 1.07 umol/kg .

For FC1612 a comparison between the primary and secondary sensors (Figure 15) was evaluated. The sensors show a median difference of 3.09 umol/kg and a standard deviation of 1.32 umol/kg . The primary sensor, s/n 0730, was used for all the final data values (Figure 16). After data reduction 54 data points (94.74%) were used in the final calculations. By minimizing the differences between the oxygen samples and the CTD oxygen estimated from the equation described in this section, the new coefficients above were calculated and then applied to the CTD original data (Figure 17 to Figure 18). The median is 0.04 umol/kg and the standard deviation 1.19 umol/kg .

A final verification about the quality of the data, like in the salinity data, was made by comparing the results of this cruise with some historical data available at the location of the Florida Straits section (Figure 19 & 20).

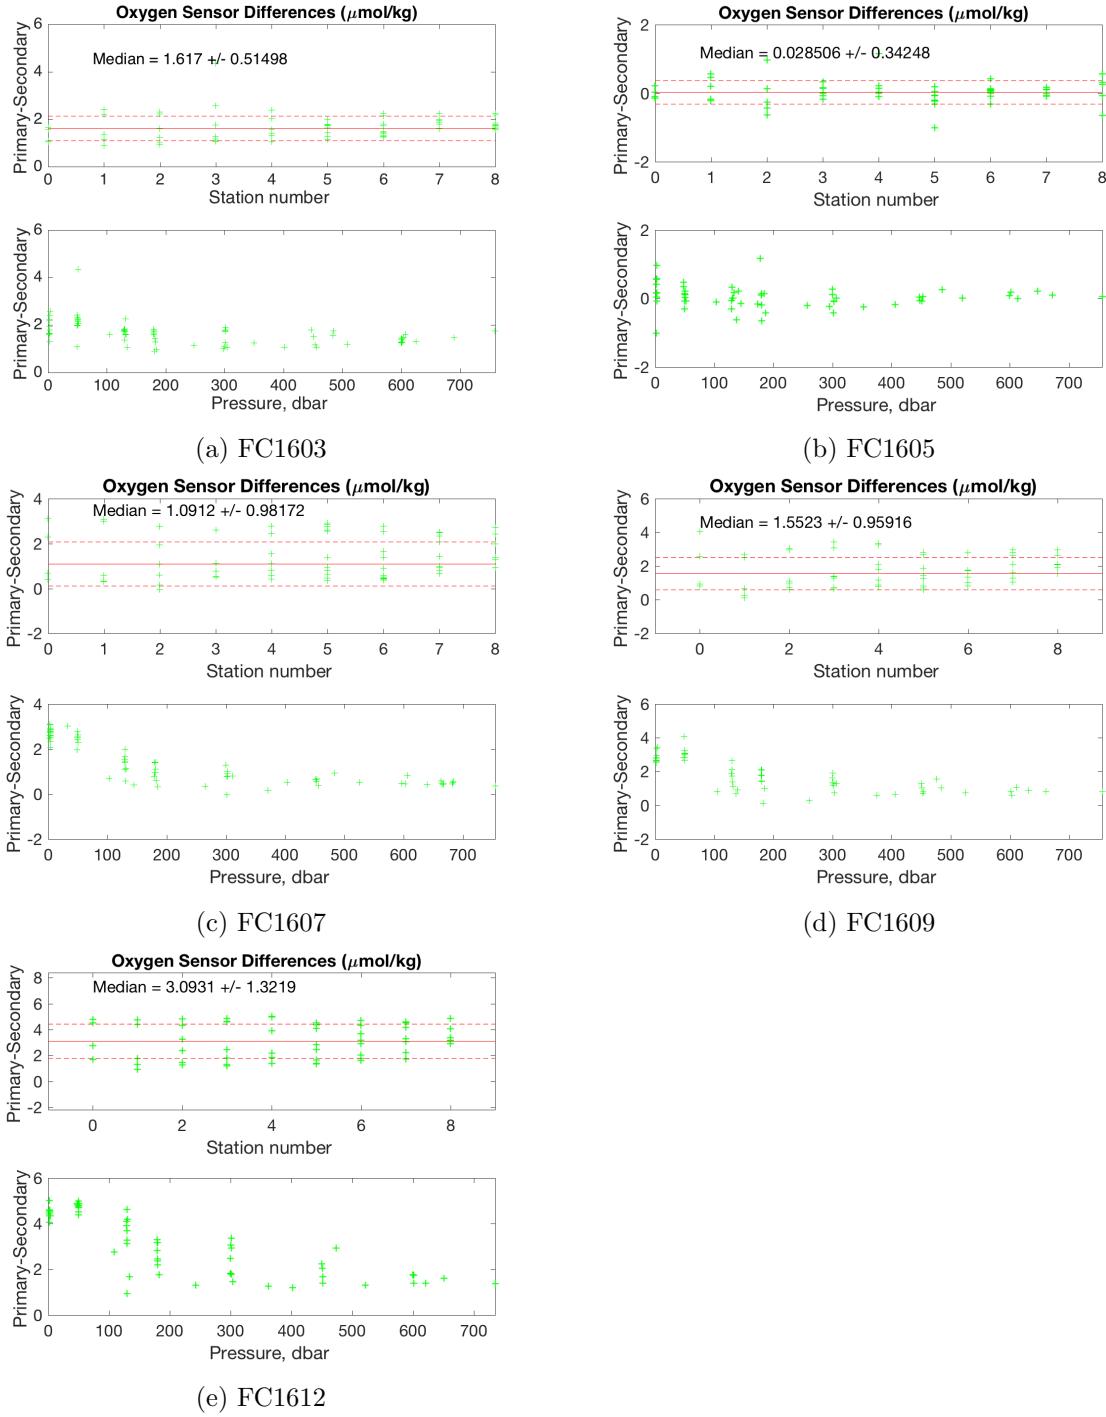

Figure 15: Dissolved oxygen differences between sensors by station (top) and by pressure (bottom). The red solid line represents the median with the red dashed representing the standard deviation.

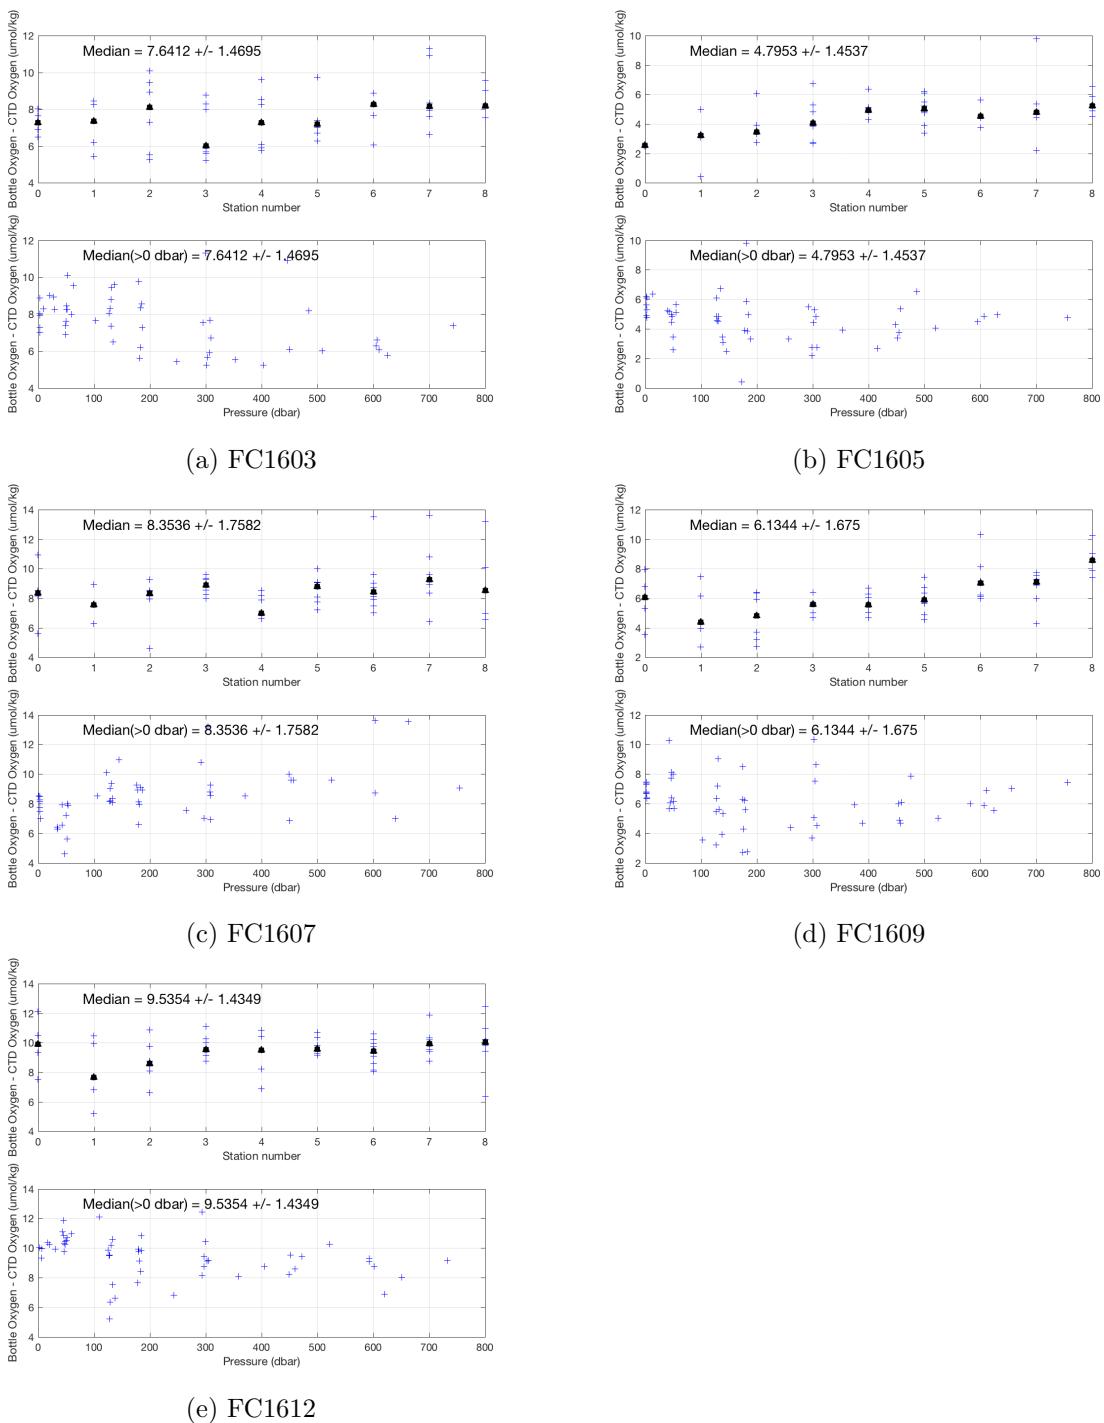

Figure 16: Bottle and uncalibrated CTD oxygen differences plotted against station number. The green crosses represent all data points and the blue are the data points below 1000 dbar. The median was calculated using only the data below 1000 dbar.

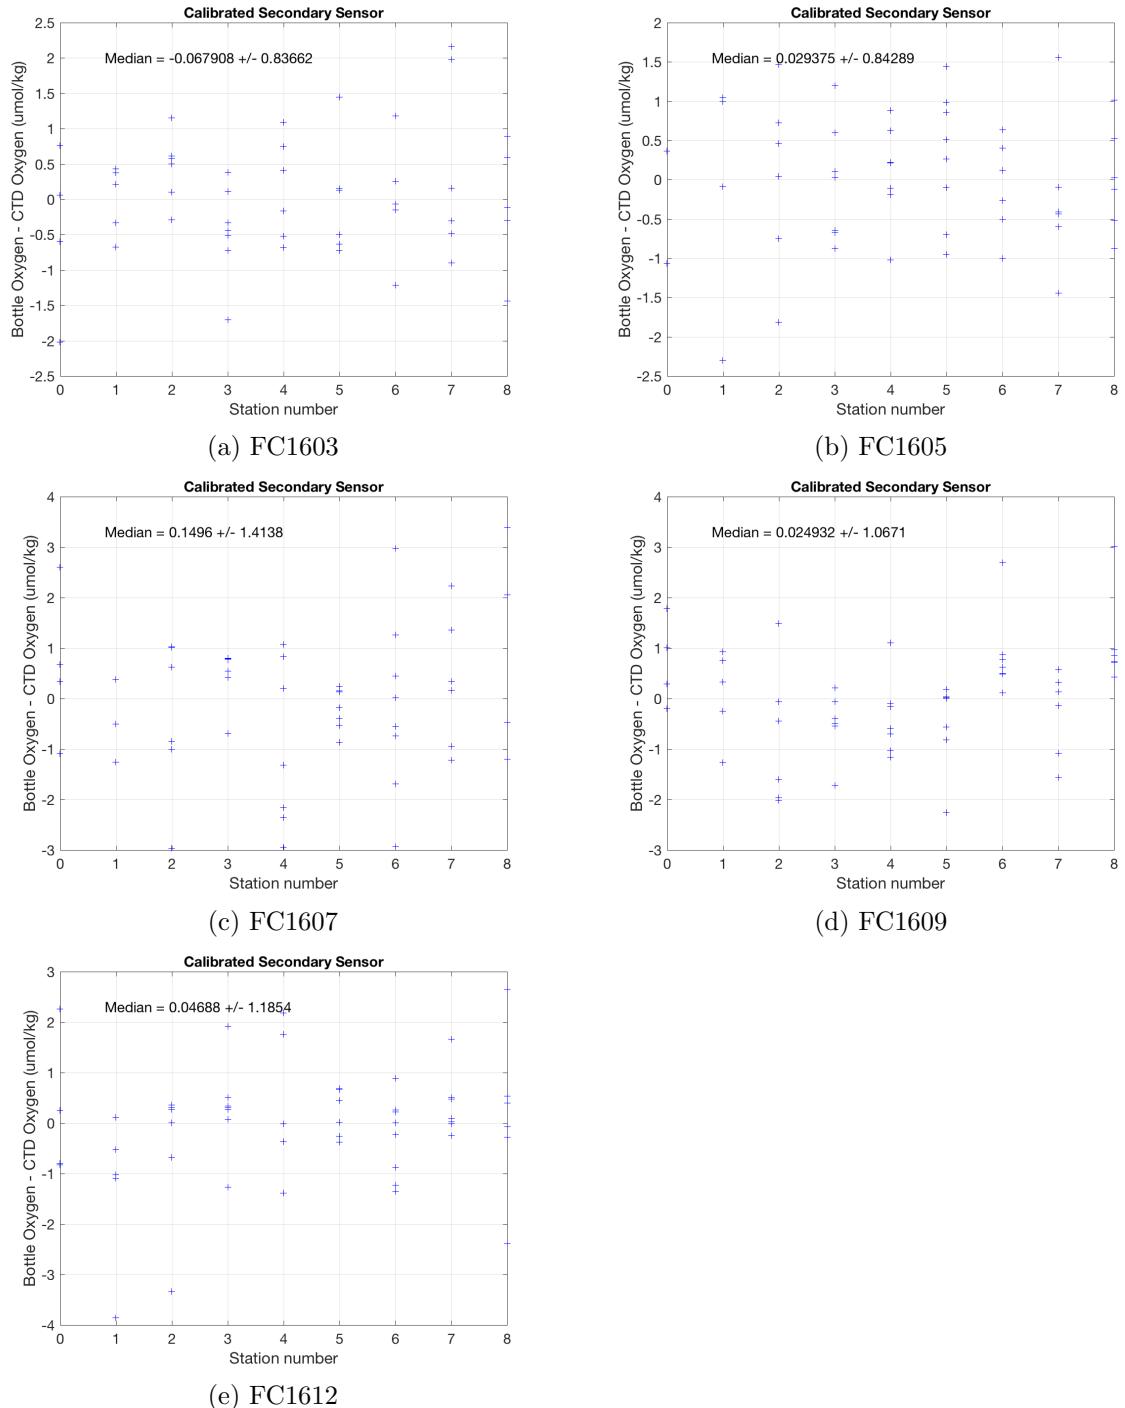

Figure 17: Bottle and calibrated CTD oxygen differences plotted vs. station.

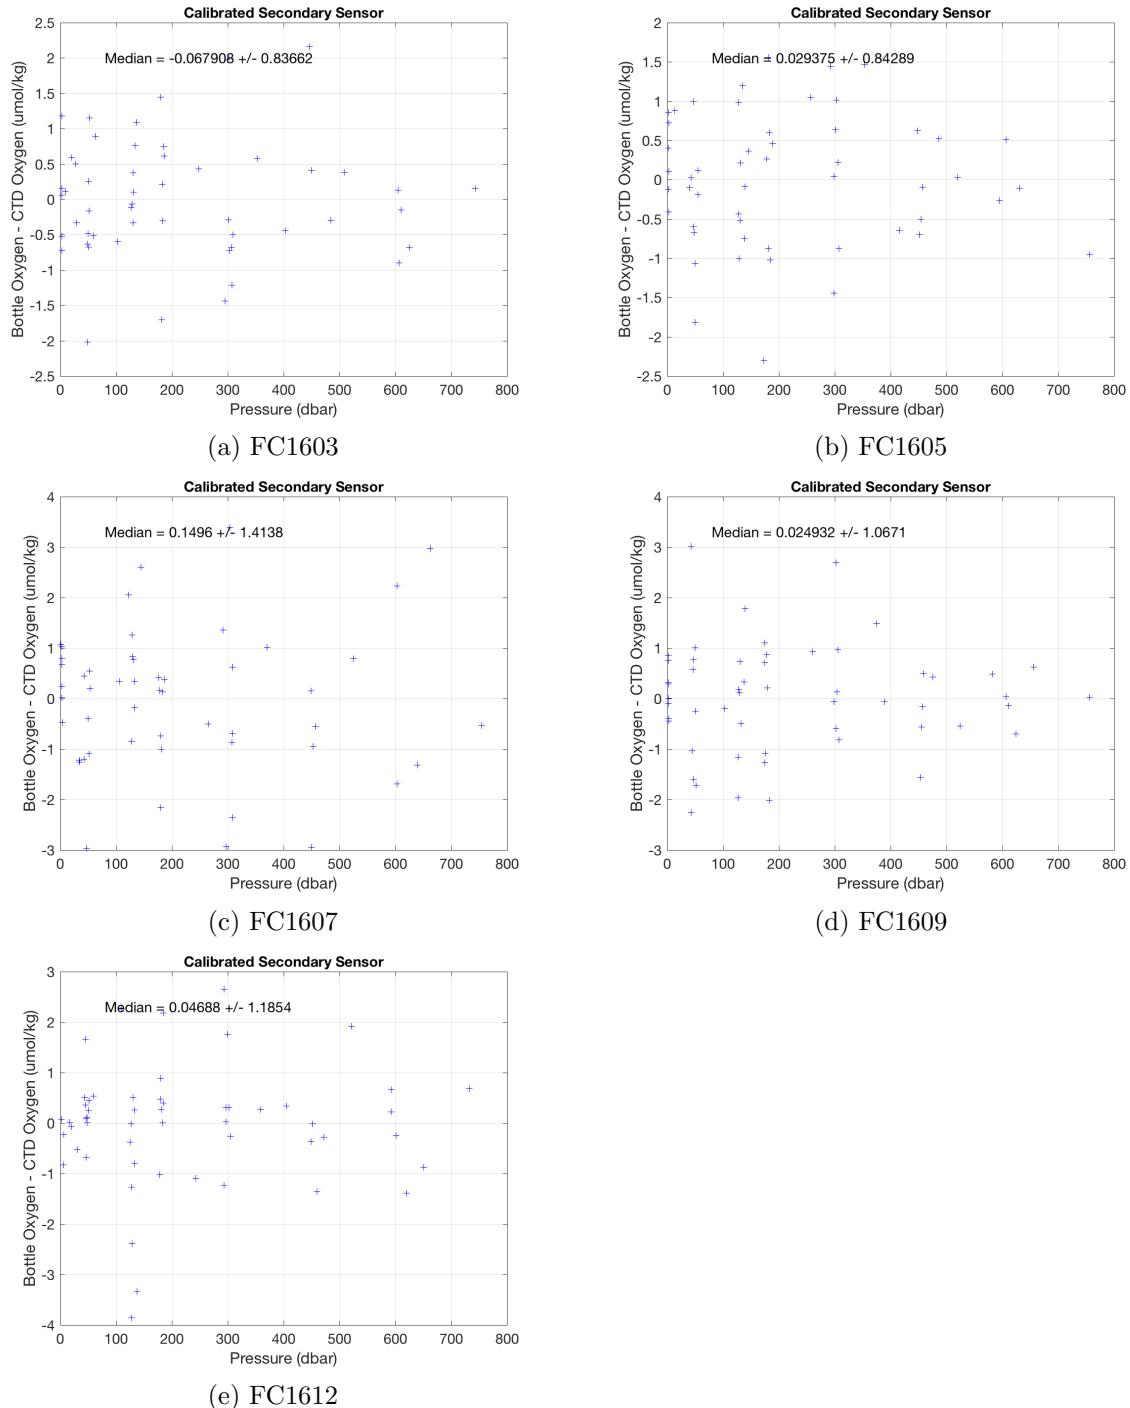

Figure 18: Bottle and calibrated CTD oxygen differences plotted vs. pressure.

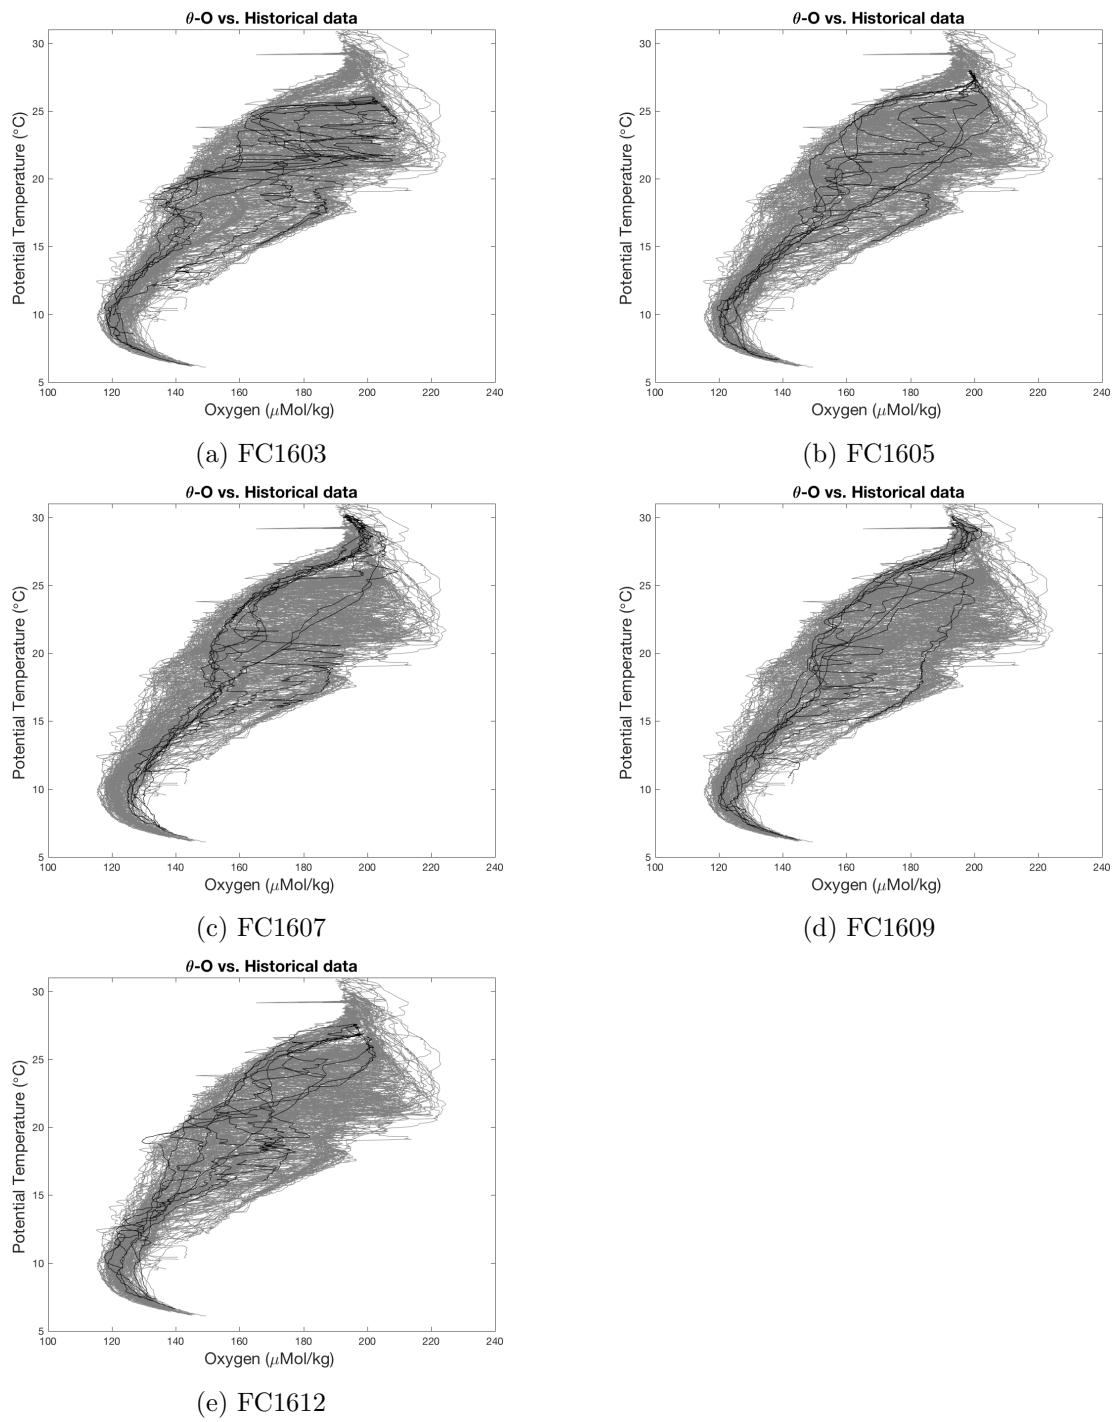

Figure 19: Potential Temperature - Oxygen diagram for all stations. The solid black lines are the data collected during this cruise; the solid gray lines are data from the historical database.

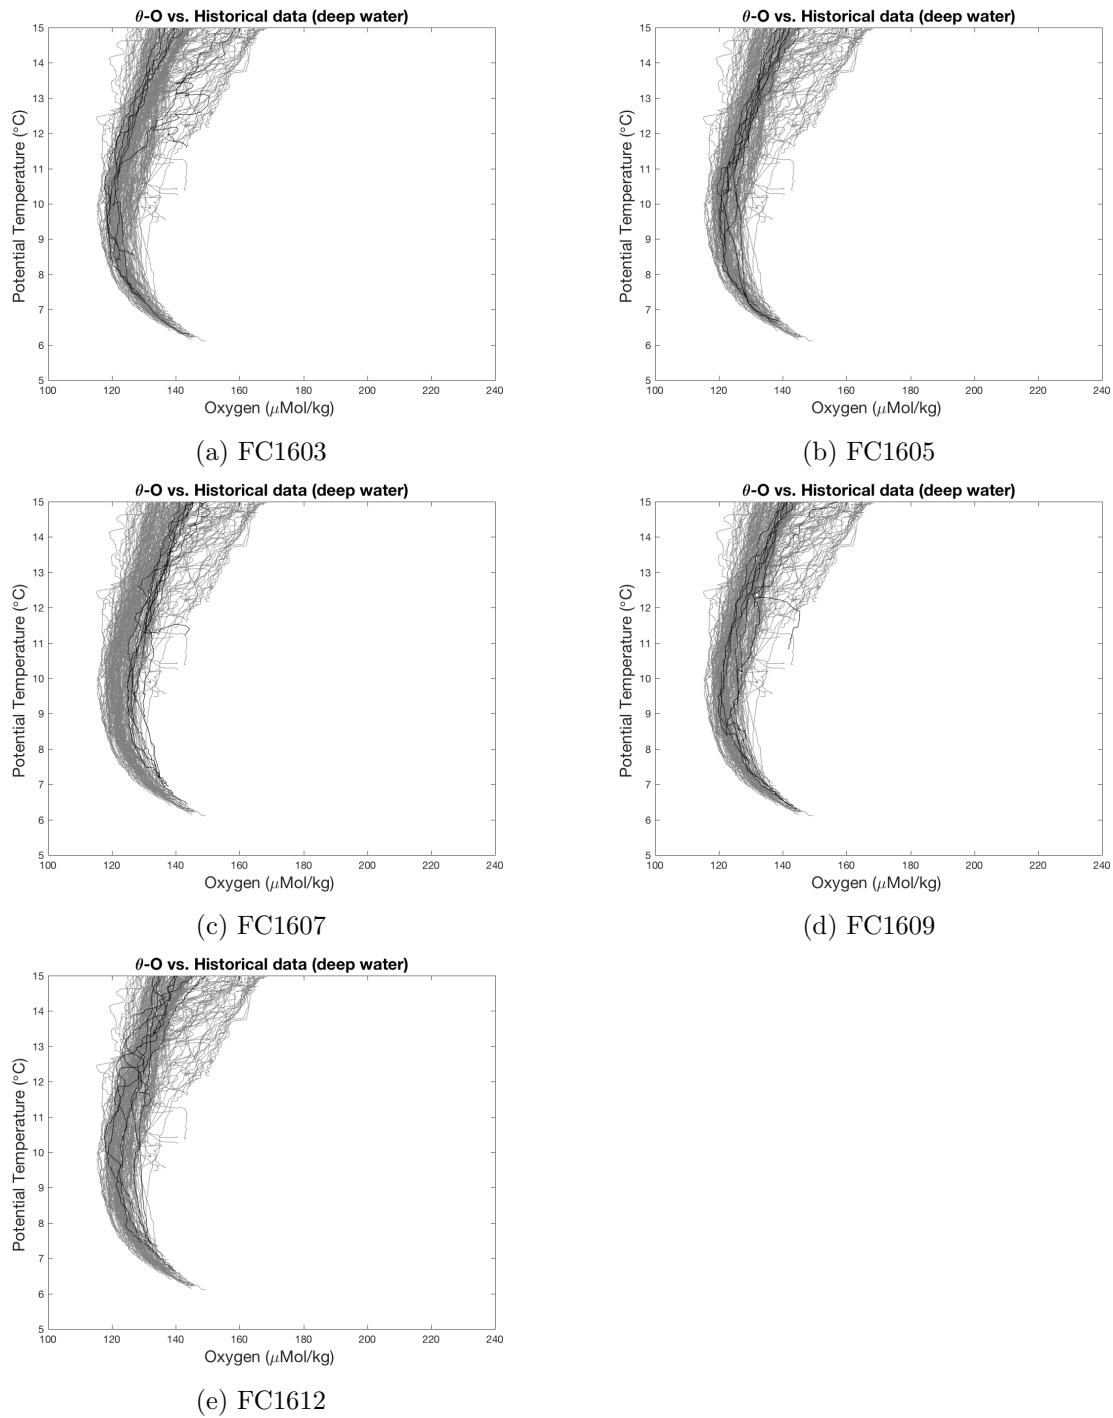

Figure 20: Potential Temperature - Oxygen diagram for all stations. The solid black lines are the data collected during this cruise; the solid gray lines are data from the historical database.

6 Final CTD Data Presentation

The final calibrated data files were used to produce the tables and station profile plots presented in Appendix A for each CTD station. The table on the top is in "standard depths" followed by a table of the bottle trip depths. The corresponding profile plot is shown on the following page. Niskin bottle depths are presented on the right side of the profile plot. Bottle salinity and oxygen values are plotted as points in the three smaller plots.

Vertical sections of potential temperature, CTD salinity, potential density, and CTD oxygen are contoured with pressure as the vertical axis. The Florida Current Section uses longitude as the horizontal axis (Figure 21 to Figure 24).

Post-cruise calibrations were applied to CTD data associated with bottle data using Matlab sub-routines (`apply_calibration.m`). WOCE quality flags were appended to bottle data records. "Bad values" (WOCE quality control value = 4) were flagged if the bottle samples failed the initial quality control and were not used for the calibration (which meant they typically fell outside 2.57 standard deviations of the difference between samples and uncalibrated CTD values). A second pass is applied, using the value of 2.5 times the standard deviation of the difference between calibrated CTD values and bottle samples, where bottle values may be flagged as "bad values" or as questionable (WOCE quality control value = 3).

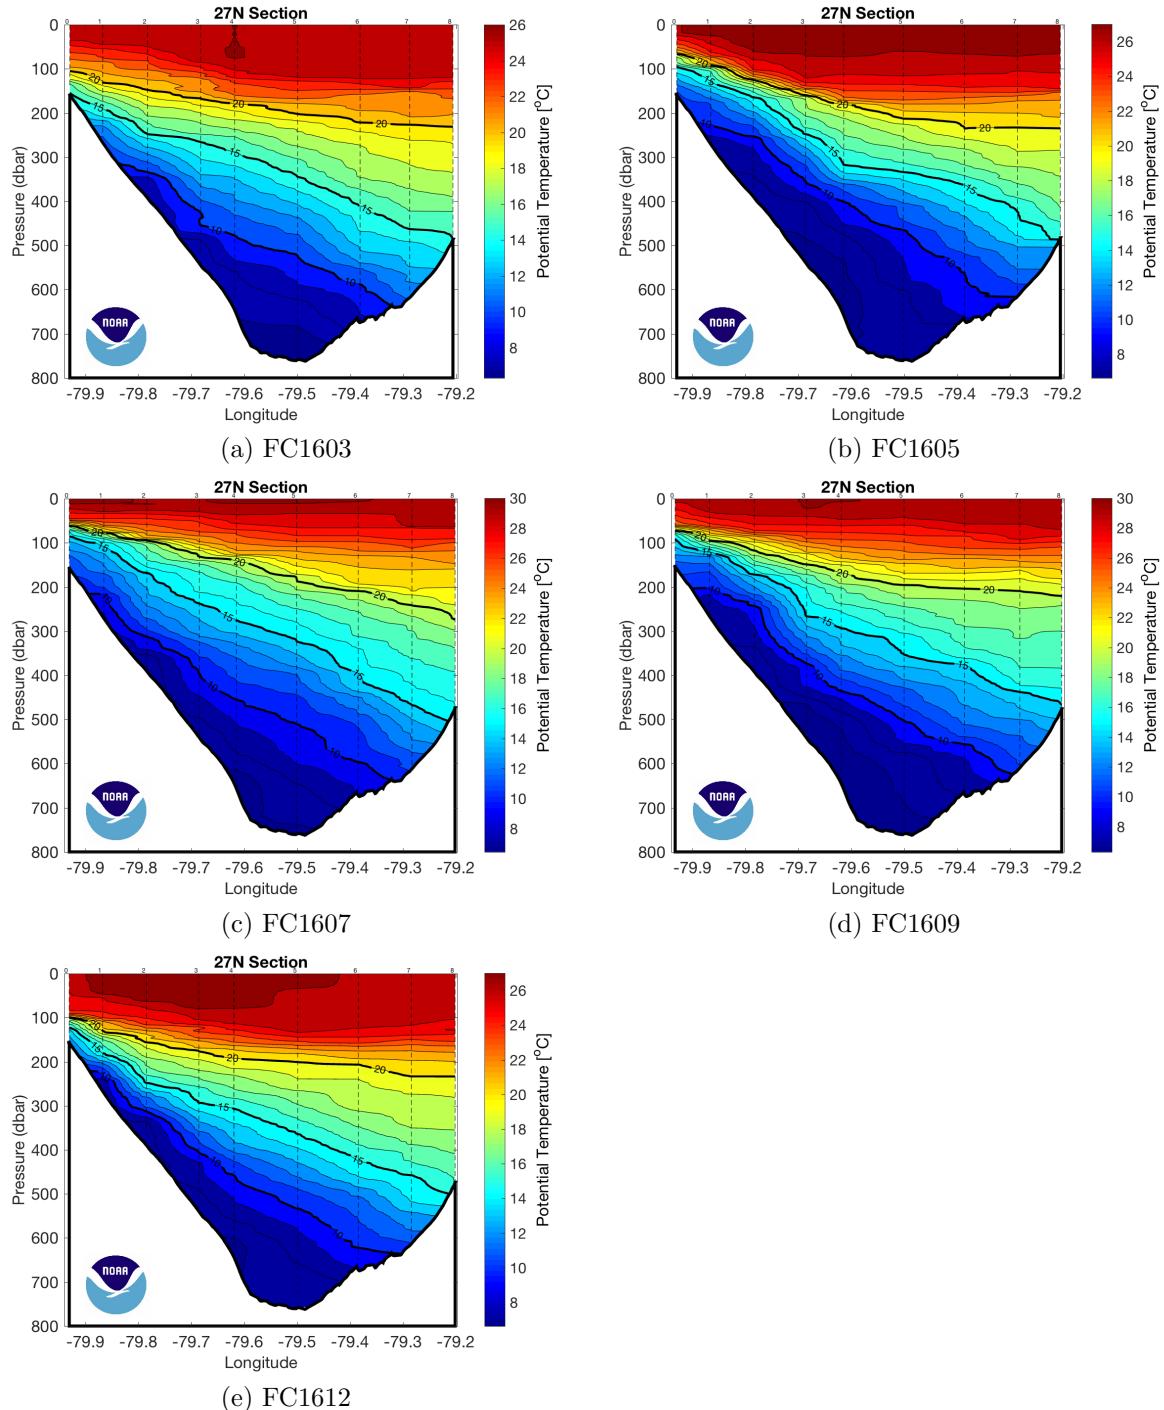

Figure 21: Potential Temperature ($^{\circ}\text{C}$) section for the Florida Current North section. Dashed vertical lines are the CTD station locations.

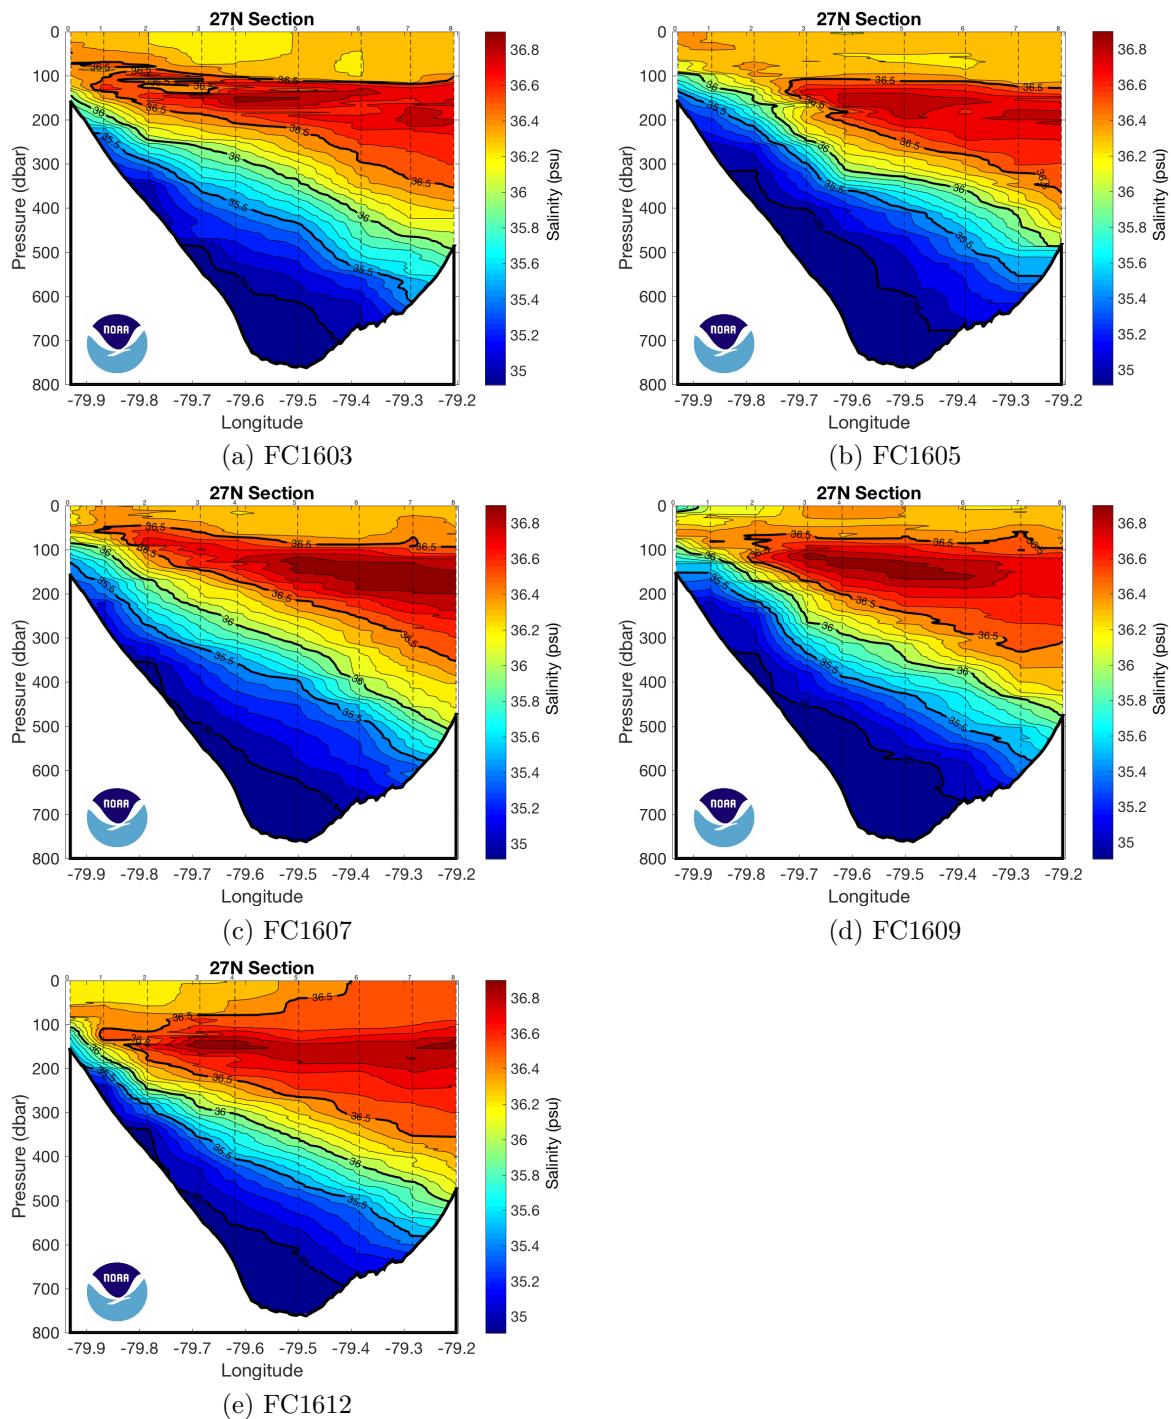

Figure 22: Salinity (PSS 78) section for the Florida Current North section. Dashed vertical lines are the CTD station locations.

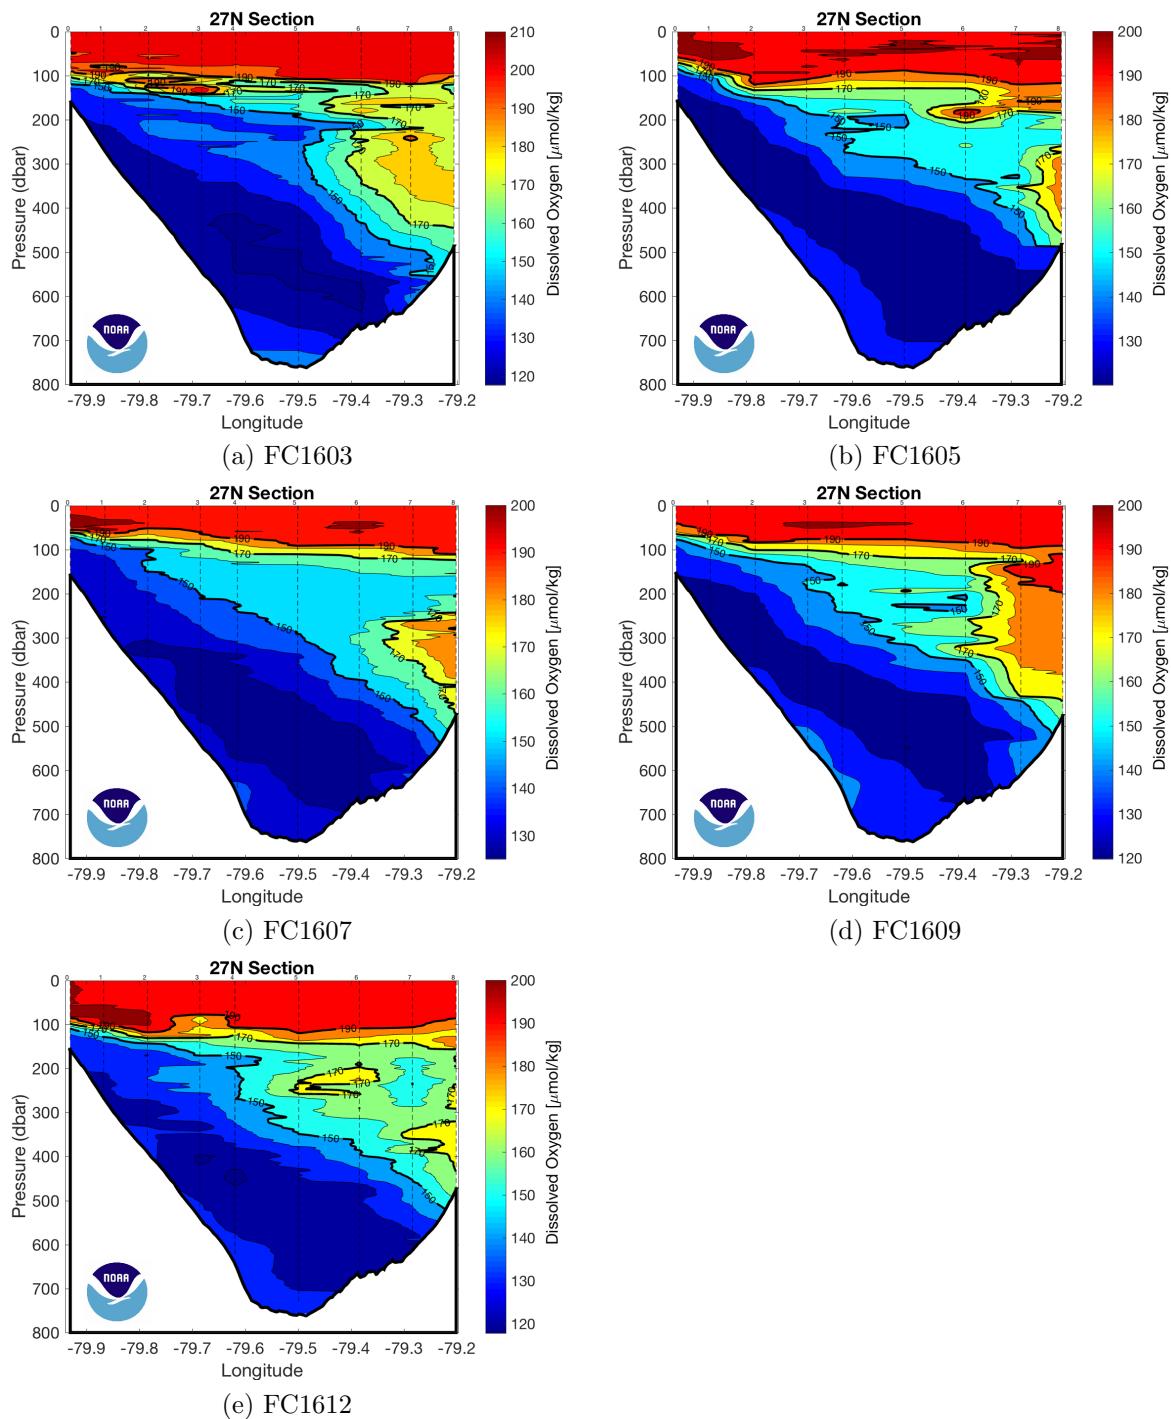

Figure 23: Dissolved Oxygen ($\mu\text{mol/kg}$) section for the Florida Current North section. Dashed vertical lines are the CTD station locations.

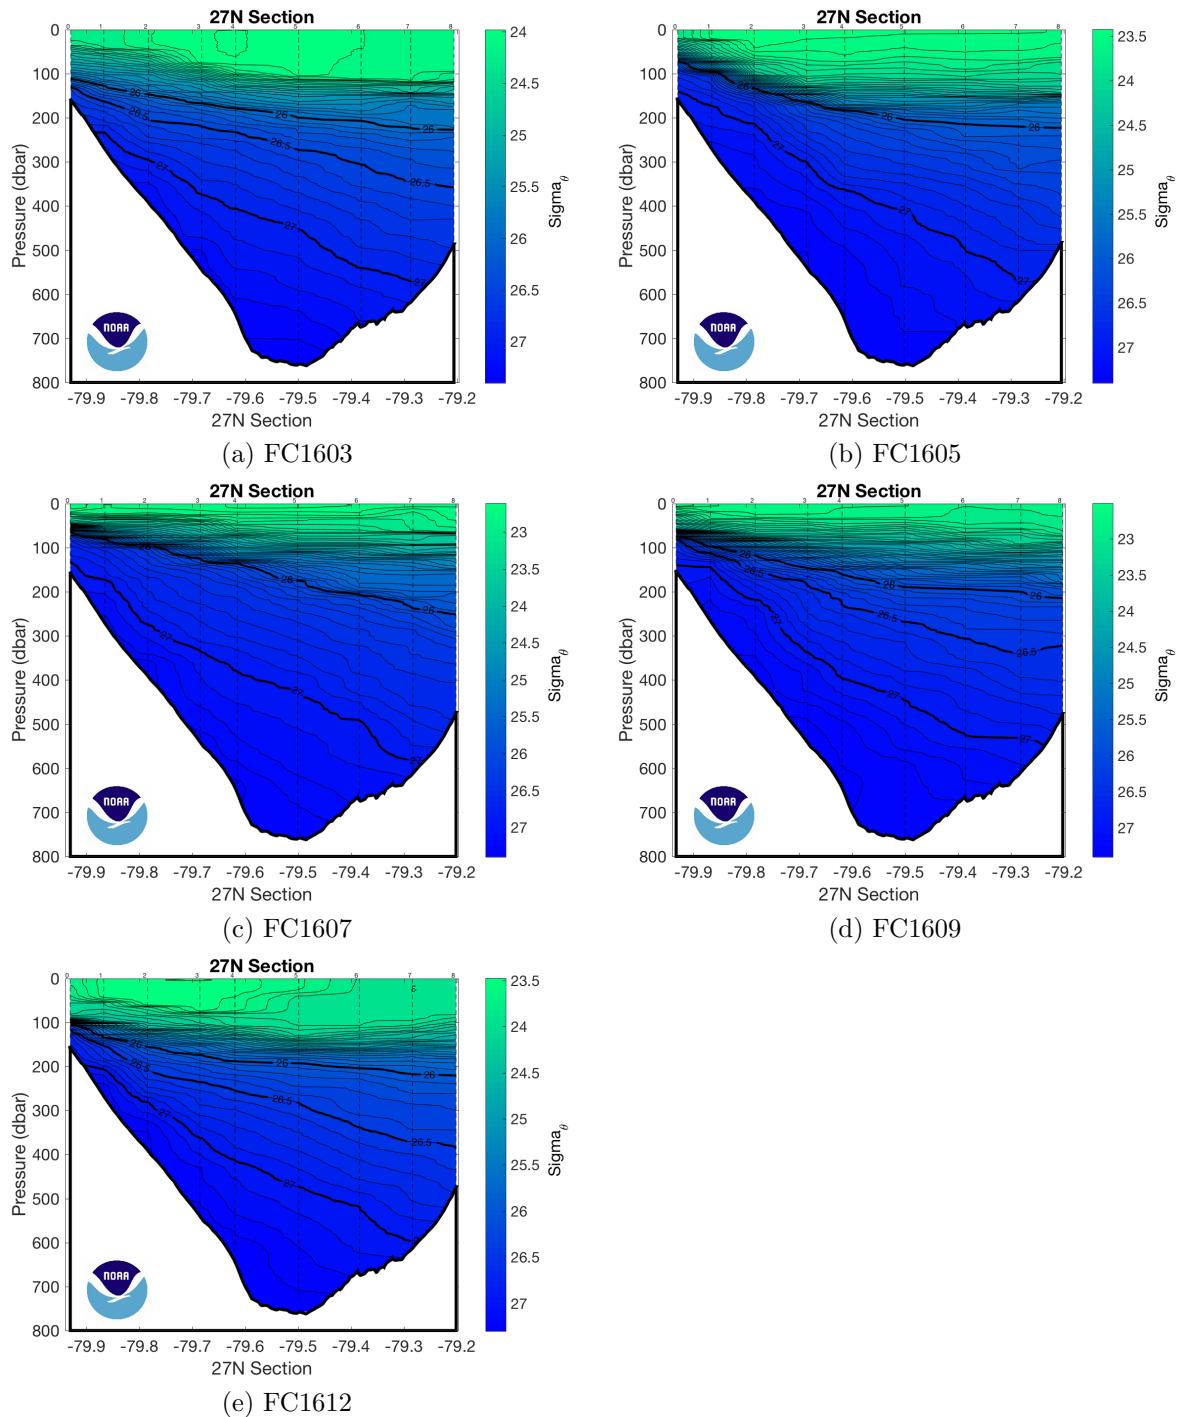

Figure 24: Neutral density (kg/m^3) section for the Florida Current North section. Dashed vertical lines are the CTD station locations.

7 Acknowledgements

The successful completion of the cruise relied on dedicated assistance from many individuals on shore and on the UNOLS ship Walton Smith. Funded investigators in the project and members of the Western Boundary Time Series, and the RAPID/MOC programs were instrumental in planning and executing the cruise. The participants in the cruise, Ryan Smith, Grant Rawson, Andy Stefanick, Tom Sevilla, Marc Weekley, Renellys Perez, and Erik Valdes showed dedication and camaraderie during the cruise. Officers and crew of the Walton Smith exhibited a high degree of professionalism and assistance to accomplish the mission and to make us feel at home during the voyage.

The U.S. Western Boundary Time Series Program is sponsored by NOAA's Office of Climate Observation. The U.S. Meridional Overturning Heat transport and Circulation Array is sponsored by the National Science Foundation's Physical Oceanography Program. The UK RAPID/MOC program is sponsored by the National Environmental Research Council (NERC). In particular, we wish to thank program managers James Todd (NOAA), David Legler (NOAA), Eric Itsweire (NSF/OCE), and Meric Srokosz (NERC) for their financial support in the effort. This research was also carried out in part under the auspices of the Cooperative Institute of Marine and Atmospheric Studies (CIMAS), a Cooperative Institute of the University of Miami and the National Oceanic and Atmospheric Administration (NOAA), cooperative agreement #NA10OAR4320143. Additional support was provided by NOAA's Atlantic Oceanographic and Meteorological Laboratory.
