Re: Endangered Species Act Section 7(a)(2) Biological Opinion, and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Response for the NuStar Energy, Inc. Revetment Repair on the Willamette River (HUC 170900120202), Multnomah County, Oregon (Corps No.:NWP-2019-521)

Dear Mr. Abadie:

Thank you for your letter of March 4, 2020, requesting initiation of consultation with NOAA's National Marine Fisheries Service (NMFS) pursuant to section 7 of the Endangered Species Act of 1973 (ESA) (16 U.S.C. 1531 et seq.) for the NuStar Energy, Inc. Revetment Repair. This consultation was conducted in accordance with the 2019 revised regulations that implement section 7 of the ESA (50 CFR 402, 84 FR 45016). Thank you, also, for your request for consultation pursuant to the essential fish habitat (EFH) provisions in Section 305(b) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA)(16 U.S.C. 1855(b)) for this action.

In this opinion, NMFS concludes that the proposed action is not likely to jeopardize the continued existence of Lower Columbia River (LCR) Chinook salmon (*Oncorhynchus tshawytscha*), Upper Willamette River (UWR) Chinook salmon, LCR coho salmon (*O. kisutch*), LCR steelhead (*O. mykiss*), or UWR steelhead, or result in the destruction or adverse modification of their designated critical habitats. As required by section 7 of the ESA, NMFS is providing an incidental take statement with the opinion. The incidental take statement describes reasonable and prudent measures NMFS considers necessary or appropriate to minimize the impact of incidental take associated with this action. The take statement sets forth nondiscretionary terms and conditions, including reporting requirements, that the Federal action agency must comply with to carry out the reasonable and prudent measures. Incidental take from actions that meet these terms and conditions will be exempt from the ESA's prohibition against the take of listed species.

This document also includes the results of our analysis of the action's likely effects on essential fish habitat (EFH) pursuant to section 305(b) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), and includes two conservation recommendations to avoid, minimize, or otherwise offset potential adverse effects on EFH.

WCRO-2020-00477

These conservation recommendations are identical to the ESA take statement's terms and conditions. Section 305(b) (4) (B) of the MSA requires Federal agencies to provide a detailed written response to NMFS within 30 days after receiving these recommendations. If the response is inconsistent with the EFH conservation recommendations, the Federal action agency must explain why the recommendations will not be followed, including the scientific justification for any disagreements over the effects of the action and the recommendations.

In response to increased oversight of overall EFH program effectiveness by the Office of Management and Budget, NMFS established a quarterly reporting requirement to determine how many conservation recommendations are provided as part of each EFH consultation and how many are adopted by the action agency. Therefore, we request that in your statutory reply to the EFH portion of this consultation, you clearly identify the number of conservation recommendations accepted.

Please contact Kate Wells, in the Willamette Branch of the Oregon Washington Coastal Office, at 503-230-5437 or Kathleen.Wells@noaa.gov if you have any questions concerning this consultation, or if you require additional information.

Sincerely,

Kim W. Kratz, Ph.D
Assistant Regional Administrator
Oregon Washington Coastal Office

1. INTRODUCTION

This Introduction section provides information relevant to the other sections of this document and is incorporated by reference into Sections 2 and 3, below.

1.1 Background

The National Marine Fisheries Service (NMFS) prepared the biological opinion (opinion) and incidental take statement (ITS) portions of this document in accordance with section 7(b) of the Endangered Species Act (ESA) of 1973 (16 USC 1531 et seq.), and implementing regulations at 50 CFR 402, as amended.

We also completed an essential fish habitat (EFH) consultation on the proposed action, in accordance with section 305(b)(2) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA) (16 U.S.C. 1801 et seq.) and implementing regulations at 50 CFR 600.

We completed pre-dissemination review of this document using standards for utility, integrity, and objectivity in compliance with applicable guidelines issued under the Data Quality Act (DQA) (section 515 of the Treasury and General Government Appropriations Act for Fiscal Year 2001, Public Law 106-554). The document will be available within two weeks at the NOAA Library Institutional Repository [<https://repository.library.noaa.gov/welcome>]. A complete record of this consultation is on file at the Oregon and Washington Coastal Office.

1.2 Consultation History

NuStar Energy Inc. met with NMFS for a pre-consultation meeting on December 12, 2019, to discuss the project and appropriate level of ESA consultation. The applicant provided project plans, and other pertinent information necessary to make the determination that a formal ESA consultation would be needed.

Subsequent to the December 12, 2020 meeting, the U.S. Army Corps of Engineers (Corps) submitted a letter to NMFS dated March 4, 2020, requesting initiation of formal ESA consultation on the effects of authorizing NuStar Energy Inc. to repair a failing revetment, based on their authority under section 404 of the Clean Water Act and section 10 of the Rivers and Harbors Act. Repair work will occur at River Mile 5.1 at 9420 NW St. Helens Road on west bank of the Willamette River, in Multnomah County, Oregon. Along with the letter from the Corps, we received a biological evaluation with project maps and photographs. Consultation was initiated on March 4, 2020. This document is based on the information provided in the documents described above.

The Corps determined that the proposed action is likely to adversely affect Lower Columbia River (LCR) Chinook salmon (*Oncorhynchus tshawytscha*), Upper Willamette River (UWR) Chinook salmon, LCR coho salmon (*O. kisutch*), LCR steelhead (*O. mykiss*), and UWR steelhead. The Corps also determined that designated critical habitat for the species listed above and EFH for Chinook and coho salmon may be adversely affected by the proposed action.

A complete record of this consultation is on file in Portland, Oregon.

1.3 Proposed Federal Action

“Action” means all activities or programs of any kind authorized, funded, or carried out, in whole or in part, by Federal agencies (50 CFR 402.02). Federal action means any action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken by a Federal Agency (50 CFR 600.910). We considered whether or not the proposed action would cause any other activities and determined that it would not result in additional actions.

Five hundred ninety five feet (ft) of the 3,400 ft of shoreline in the project area consists of a reinforced concrete revetment cement apron intended to protect the shoreline and adjacent structures from erosion. The revetment has experienced multiple episodes of undermining wherein the soil beneath the concrete has washed out, leaving a void of space beneath the structure. To address the failing portion of the revetment, the proposed action would (1) an area of the existing concrete revetment measuring 27 ft wide by 96 ft long and removal of a cutoff wall measuring 54 ft by 0.66 ft; (2) install a new cutoff wall at the toe of the revetment; (3) remove three existing timber piles; and (4) replace the existing concrete revetment in-kind (Figures 1 and 2).

Figure 1. Location of the proposed action at NuStar Energy LLC along the Willamette River.

Figure 2. Aerial view of the proposed action area along the Willamette River.

The contractor will access the project site by water; however, no in water work is proposed. A spud barge will be staged either upstream or downstream of the repair areas. The barge will have a crane that will transfer materials and tools to and from the work area. Work will begin with removal of three existing timber piles, which currently impede access to the work area. Removal will take place using the barge-mounted crane with a vibratory hammer attachment. Piles that cannot be removed will be cut off below the mudline.

Concrete will be demolished with hand tools such as concrete saws and jackhammers. Debris will be collected by hand or with hand tools and transferred to buckets for transport via the crane to the barge. All waste materials will be disposed of at an approved upland disposal site. Once the concrete demolition is complete, the remaining revetment soils will be evaluated for contaminants and potentially regraded to ensure slope safety and excavation safety precautions have been met, and to aid in backfill and compaction efforts. A survey of the seawall footing and condition will be completed. The extent of undermining will be determined, and temporary

shoring provided as necessary. If necessary, form walls will be installed and filling material injected.

Prefabricated concrete panels will be delivered to the site, placed by crane and fitted into their permanent position using a vibratory hydraulic hammer. No impact hammers will be used. Minimal excavation may be necessary to form a flat surface upon which the panels can be set. All excavation will be completed above the water level.

Once the under-footing void issues have been addressed and the cutoff wall panels are installed, imported crushed rock will be delivered by barge and transferred by crane into the work area. Aggregate will be spread and compacted with hand tools in lifts. The new slab will be formed, and reinforcement bar tied and placed. The concrete will be poured and cured in the typical fashion for slab-on-grade construction. No concrete will be allowed to enter any water body. Following concrete curing, the forms will be removed. Tools and materials will be collected, and the barge demobilized from the site.

Impact Minimization Measures

The proposed action would occur during the approved in-water work window between July 1 and October 31 in 2020. The work will be done during the driest time of year. The highest tidal swing in the river at this location is 1-2 ft below the toe of the concrete slab. The applicant does not anticipate a need for a cofferdam as all work will occur in the dry. Straw bales will be placed along the river edges of the excavation and temporarily staked into the ground so that they remain stationary. Prior to staging and construction, appropriate sediment controls will be installed. In the event of heavy rain during excavation, polyethylene plastic sheeting or equivalent will be laid over the soil and held in place with sandbags that are tethered to the shore above the water line. The polyethylene plastic sheeting will be arranged such that water will sheet from the adjacent concrete to the river and reduce erosion during construction.

Staging for the project will occur in an upland location and accessed through the main gate of NuStar Energy Terminal. During non-work hours, areas for storage of equipment and vehicles, other than track mounted vehicles, will be located at least 150 ft away from the work area. Prior to operating within 150 ft of the work area, equipment cleaning, maintenance, and refueling will be completed. Storage of fuels and other potentially hazardous materials will be placed no less than 150 ft from the work area.

BMP's, including the use of biodegradable lubricants in equipment operating within 150 ft of the work area or waterway, will be used. Equipment will be cleaned and inspected for debris prior to entering the work area to minimize any adverse effects to wetlands, waterways, and aquatic species; and to prevent the spread of invasive species. For track-mounted equipment, large cranes, and other equipment whose limited mobility makes it impractical to move for refueling, precautions will be taken to minimize the risk of fuel reaching the work area. Spill prevention measures and fuel containment systems designed to completely contain a potential spill, as well as other pollution control devices and measures (such as diapering, parking on absorbent material, etc.) adequate to provide containment of hazardous materials will be implemented.

Hazardous material containment booms and spill containment booms will be kept on site to facilitate the cleanup of hazardous material spills.

An erosion control plan will be used to prevent sediment from entering the water. Sediment control BMP's will include the use of sediment fencing and sediment barriers and shall conform to DEQ BMP's for storm water discharge associated with industrial activities. Barges will be secured, stabilized and maintained as necessary to ensure no loss of balance, stability, anchorage, or other condition that can result in the release of contaminants or construction debris. Barges will always carry hazardous material clean-up kits and booms.

NMFS relied on the foregoing description of the proposed action, including all features identified to reduce adverse effects, to complete this consultation. To ensure that this opinion remains valid, NMFS requests that the action agency or applicant keep NMFS informed of any changes to the proposed action.

2. ENDANGERED SPECIES ACT: BIOLOGICAL OPINION AND INCIDENTAL TAKE STATEMENT

The ESA establishes a national program for conserving threatened and endangered species of fish, wildlife, plants, and the habitat upon which they depend. As required by section 7(a)(2) of the ESA, each Federal agency must ensure that its actions are not likely to jeopardize the continued existence of endangered or threatened species, or adversely modify or destroy their designated critical habitat. Per the requirements of the ESA, Federal action agencies consult with NMFS and section 7(b)(3) requires that, at the conclusion of consultation, NMFS provide an opinion stating how the agency's actions would affect listed species and their critical habitats. If incidental take is reasonably certain to occur, section 7(b)(4) requires NMFS to provide an ITS that specifies the impact of any incidental taking and includes non-discretionary reasonable and prudent measures (RPMs) and terms and conditions to minimize such consequences.

2.1 Analytical Approach

This biological opinion includes both a jeopardy analysis and an adverse modification analysis. The jeopardy analysis relies upon the regulatory definition of "jeopardize the continued existence of" a listed species, which is "to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (50 CFR402.02). Therefore, the jeopardy analysis considers both survival and recovery of the species.

This biological opinion relies on the definition of "destruction or adverse modification," which "means a direct or indirect alteration that appreciably diminishes the value of critical habitat as a whole for the conservation of a listed species" (50 CFR 402.02).

The designation(s) of critical habitat for (species) use(s) the term primary constituent element (PCE) or essential features. The 2016 critical habitat regulations (50 CFR 424.12) replaced this term with physical or biological features (PBFs). The shift in terminology does not change the

approach used in conducting a “destruction or adverse modification” analysis, which is the same regardless of whether the original designation identified PCEs, PBFs, or essential features. In this biological opinion, we use the term PBF to mean PCE or essential feature, as appropriate for the specific critical habitat.

The 2019 regulations define effects of the action using the term “consequences” (50 CFR 402.02). As explained in the preamble to the regulations (84 FR 44977), that definition does not change the scope of our analysis and in this opinion we use the terms “effects” and “consequences” interchangeably.

We use the following approach to determine whether a proposed action is likely to jeopardize listed species or destroy or adversely modify critical habitat:

- Evaluate the rangewide status of the species and critical habitat expected to be adversely affected by the proposed action.
- Evaluate the environmental baseline of the species and critical habitat.
- Evaluate the effects of the proposed action on species and their habitat using an exposure-response approach.
- Evaluate cumulative effects.
- In the integration and synthesis, add the effects of the action and cumulative effects to the environmental baseline, and, in light of the status of the species and critical habitat, analyze whether the proposed action is likely to: (1) directly or indirectly reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species, or (2) directly or indirectly result in an alteration that appreciably diminishes the value of critical habitat as a whole for the conservation of a listed species.
- If necessary, suggest a reasonable and prudent alternative to the proposed action.

2.2 Rangewide Status of the Species and Critical Habitat

This opinion examines the status of each species that would be adversely affected by the proposed action. The status is determined by the level of extinction risk that the listed species face, based on parameters considered in documents such as recovery plans, status reviews, and listing decisions. This informs the description of the species’ likelihood of both survival and recovery. The species status section also helps to inform the description of the species’ “reproduction, numbers, or distribution” as described in 50 CFR 402.02. The opinion also examines the condition of critical habitat throughout the designated area, evaluates the conservation value of the various watersheds and coastal and marine environments that make up the designated area, and discusses the function of the essential PBFs that help to form that conservation value.

One factor affecting the status of ESA-listed species considered in this opinion, and aquatic habitat at large, is climate change. Climate change is likely to play an increasingly important role in determining the abundance and distribution of ESA-listed species, and the conservation value of designated critical habitats, in the Pacific Northwest. These changes will not be spatially homogeneous across the Pacific Northwest. The largest hydrologic responses are expected to

occur in basins with significant snow accumulation, where warming decreases snow pack, increases winter flows, and advances the timing of spring melt (Mote et al. 2014, Mote 2016). Rain-dominated watersheds and those with significant contributions from groundwater may be less sensitive to predicted changes in climate (Tague et al. 2013, Mote et al. 2014).

During the last century, average regional air temperatures in the Pacific Northwest increased by 1-1.4°F as an annual average, and up to 2°F in some seasons (based on average linear increase per decade; Abatzoglou et al. 2014; Kunkel et al. 2013). Warming is likely to continue during the next century as average temperatures are projected to increase another 3 to 10°F, with the largest increases predicted to occur in the summer (Mote et al. 2014). Decreases in summer precipitation of as much as 30% by the end of the century are consistently predicted across climate models (Mote et al. 2014). Precipitation is more likely to occur during October through March, less during summer months, and more winter precipitation will be rain than snow (ISAB 2007; Mote et al. 2013; Mote et al. 2014). Earlier snowmelt will cause lower stream flows in late spring, summer, and fall, and water temperatures will be warmer (ISAB 2007; Mote et al. 2014). Models consistently predict increases in the frequency of severe winter precipitation events (i.e., 20-year and 50-year events), in the western United States (Dominguez et al. 2012). The largest increases in winter flood frequency and magnitude are predicted in mixed rain-snow watersheds (Mote et al. 2014).

Overall, about one-third of the current cold-water salmonid habitat in the Pacific Northwest is likely to exceed key water temperature thresholds by the end of this century (Mantua et al. 2009). Higher temperatures will reduce the quality of available salmonid habitat for most freshwater life stages (ISAB 2007). Reduced flows will make it more difficult for migrating fish to pass physical and thermal obstructions, limiting their access to available habitat (Mantua et al. 2010; Isaak et al. 2012). Temperature increases shift timing of key life cycle events for salmonids and species forming the base of their aquatic foodwebs (Crozier et al. 2011; Tillmann and Siemann 2011; Winder and Schindler 2004). Higher stream temperatures will also cause decreases in dissolved oxygen and may also cause earlier onset of stratification and reduced mixing between layers in lakes and reservoirs, which can also result in reduced oxygen (Meyer et al. 1999; Winder and Schindler 2004, Raymondi et al. 2013). Higher temperatures are likely to cause several species to become more susceptible to parasites, disease, and higher predation rates (Crozier et al. 2008; Wainwright and Weitkamp 2013; Raymondi et al. 2013).

As more basins become rain-dominated and prone to more severe winter storms, higher winter stream flows may increase the risk that winter or spring floods in sensitive watersheds will damage spawning redds and wash away incubating eggs (Goode et al. 2013). Earlier peak stream flows will also alter migration timing for salmon smolts, and may flush some young salmon and steelhead from rivers to estuaries before they are physically mature, increasing stress and reducing smolt survival (McMahon and Hartman 1989; Lawson et al. 2004).

In addition to changes in freshwater conditions, predicted changes for coastal waters in the Pacific Northwest as a result of climate change include increasing surface water temperature, increasing but highly variable acidity, and increasing storm frequency and magnitude (Mote et al. 2014). Elevated ocean temperatures already documented for the Pacific Northwest are highly likely to continue during the next century, with sea surface temperature projected to increase by

1.0-3.7°C by the end of the century (IPCC 2014). Habitat loss, shifts in species' ranges and abundances, and altered marine food webs could have substantial consequences to anadromous, coastal, and marine species in the Pacific Northwest (Tillmann and Siemann 2011, Reeder et al. 2013).

Moreover, as atmospheric carbon emissions increase, increasing levels of carbon are absorbed by the oceans, changing the pH of the water. Acidification also impacts sensitive estuary habitats, where organic matter and nutrient inputs further reduce pH and produce conditions more corrosive than those in offshore waters (Feely et al. 2012, Sunda and Cai 2012).

Global sea levels are expected to continue rising throughout this century, reaching likely predicted increases of 10-32 inches by 2081-2100 (IPCC 2014). These changes will likely result in increased erosion and more frequent and severe coastal flooding, and shifts in the composition of nearshore habitats (Tillmann and Siemann 2011, Reeder et al. 2013). Estuarine-dependent salmonids such as chum and Chinook salmon are predicted to be impacted by significant reductions in rearing habitat in some Pacific Northwest coastal areas (Glick et al. 2007).

Historically, warm periods in the coastal Pacific Ocean have coincided with relatively low abundances of salmon and steelhead, while cooler ocean periods have coincided with relatively high abundances, and therefore these species are predicted to fare poorly in warming ocean conditions (Scheuerell and Williams 2005; Zabel et al. 2006). This is supported by the recent observation that anomalously warm sea surface temperatures off the coast of Washington from 2013 to 2016 resulted in poor coho and Chinook salmon body condition for juveniles caught in those waters (NWFSC 2015). Changes to estuarine and coastal conditions, as well as the timing of seasonal shifts in these habitats, have the potential to impact a wide range of listed aquatic species (Tillmann and Siemann 2011, Reeder et al. 2013).

The adaptive ability of these threatened and endangered species is depressed due to reductions in population size, habitat quantity and diversity, and loss of behavioral and genetic variation. Without these natural sources of resilience, systematic changes in local and regional climatic conditions due to anthropogenic global climate change will likely reduce long-term viability and sustainability of populations in many of these ESUs (NWFSC 2015). New stressors generated by climate change, or existing stressors with effects that have been amplified by climate change, may also have synergistic consequences for species and ecosystems (Doney et al. 2012). These conditions will possibly intensify the climate change stressors inhibiting recovery of ESA-listed species in the future.

2.2.1 Status of the Species

Table 1, below provides a summary of listing and recovery plan information, status summaries and limiting factors for the species addressed in this opinion. More information can be found in recovery plans and status reviews for these species. These documents are available on the NMFS West Coast Region website (<http://www.westcoast.fisheries.noaa.gov/>).

Table 1. Listing classification and date, recovery plan reference, most recent status review, status summary, and limiting factors for each species considered in this opinion.

Species	Listing Classification and Date	Recovery Plan Reference	Most Recent Status Review	Status Summary	Limiting Factors
Lower Columbia River Chinook salmon	Threatened 6/28/05	NMFS 2013	NWFSC 2015	This ESU comprises 32 independent populations. Twenty-seven populations are at very high risk, 2 populations are at high risk, one population is at moderate risk, and 2 populations are at very low risk Overall, there was little change since the last status review in the biological status of this ESU, although there are some positive trends. Increases in abundance were noted in about 70% of the fall-run populations and decreases in hatchery contribution were noted for several populations. Relative to baseline VSP levels identified in the recovery plan, there has been an overall improvement in the status of a number of fall-run populations, although most are still far from the recovery plan goals.	<ul style="list-style-type: none"> • Reduced access to spawning and rearing habitat • Hatchery-related effects • Harvest-related effects on fall Chinook salmon • An altered flow regime and Columbia River plume • Reduced access to off-channel rearing habitat • Reduced productivity resulting from sediment and nutrient-related changes in the estuary • Contaminant

Species	Listing Classification and Date	Recovery Plan Reference	Most Recent Status Review	Status Summary	Limiting Factors
Upper Willamette River Chinook salmon	Threatened 6/28/05	NMFS 2011a	NWFSC 2015	<p>This ESU comprises seven populations. Five populations are at very high risk, one population is at moderate risk (Clackamas River) and one population is at low risk (McKenzie River). Consideration of data collected since the last status review in 2010 indicates the fraction of hatchery origin fish in all populations remains high (even in Clackamas and McKenzie populations). The proportion of natural origin spawners improved in the North and South Santiam basins, but is still well below identified recovery goals. Abundance levels for five of the seven populations remain well below their recovery goals. Of these, the Calapooia River may be functionally extinct and the Molalla River remains critically low. Abundances in the North and South Santiam rivers have risen since the 2010 review, but still range only in the high hundreds of fish. The Clackamas and McKenzie populations have previously been viewed as natural population strongholds, but have both experienced declines in abundance despite having access to much of their historical spawning habitat. Overall, populations appear to be at either moderate or high risk, there has been likely little net change in the VSP score for the ESU since the last review, so the ESU remains at moderate risk.</p>	<ul style="list-style-type: none"> • Degraded freshwater habitat • Degraded water quality • Increased disease incidence • Altered stream flows • Reduced access to spawning and rearing habitats • Altered food web due to reduced inputs of microdetritus • Predation by native and non-native species, including hatchery fish • Competition related to introduced salmon and steelhead • Altered population traits due to fisheries and bycatch

Species	Listing Classification and Date	Recovery Plan Reference	Most Recent Status Review	Status Summary	Limiting Factors
Lower Columbia River coho salmon	Threatened 6/28/05	NMFS 2013	NWFSC 2015	<p>Of the 24 populations that make up this ESU, 21 populations are at very high risk, 1 population is at high risk, and 2 populations are at moderate risk. Recent recovery efforts may have contributed to the observed natural production, but in the absence of longer term data sets it is not possible to parse out these effects. Populations with longer term data sets exhibit stable or slightly positive abundance trends. Some trap and haul programs appear to be operating at or near replacement, although other programs still are far from that threshold and require supplementation with additional hatchery-origin spawners. Initiation of or improvement in the downstream juvenile facilities at Cowlitz Falls, Merwin, and North Fork Dam are likely to further improve the status of the associated upstream populations. While these and other recovery efforts have likely improved the status of a number of coho salmon populations, abundances are still at low levels and the majority of the populations remain at moderate or high risk. For the Lower Columbia River region land development and increasing human population pressures will likely continue to degrade habitat, especially in lowland areas. Although populations in this ESU have generally improved, especially in the 2013/14 and 2014/15 return years, recent poor ocean conditions suggest that population declines might occur in the upcoming return years</p>	<ul style="list-style-type: none"> • Degraded estuarine and near-shore marine habitat • Fish passage barriers • Degraded freshwater habitat: Hatchery-related effects • Harvest-related effects • An altered flow regime and Columbia River plume • Reduced access to off-channel rearing habitat in the lower Columbia River • Reduced productivity resulting from sediment and nutrient-related changes in the estuary • Juvenile fish wake strandings • Contaminants

Species	Listing Classification and Date	Recovery Plan Reference	Most Recent Status Review	Status Summary	Limiting Factors
Lower Columbia River steelhead	Threatened 1/5/06	NMFS 2013	NWFSC 2015	<p>This DPS comprises 23 historical populations, 17 winter-run populations and six summer-run populations. Nine populations are at very high risk, 7 populations are at high risk, 6 populations are at moderate risk, and 1 population is at low risk. The majority of winter-run steelhead populations in this DPS continue to persist at low abundances. Hatchery interactions remain a concern in select basins, but the overall situation is somewhat improved compared to prior reviews. Summer-run steelhead populations were similarly stable, but at low abundance levels. The decline in the Wind River summer-run population is a source of concern, given that this population has been considered one of the healthiest of the summer-runs; however, the most recent abundance estimates suggest that the decline was a single year aberration. Passage programs in the Cowlitz and Lewis basins have the potential to provide considerable improvements in abundance and spatial structure, but have not produced self-sustaining populations to date. Even with modest improvements in the status of several winter-run DIPs, none of the populations appear to be at fully viable status, and similarly none of the MPGs meet the criteria for viability.</p>	<ul style="list-style-type: none"> • Degraded estuarine and nearshore marine habitat • Degraded freshwater habitat • Reduced access to spawning and rearing habitat • Avian and marine mammal predation • Hatchery-related effects • An altered flow regime and Columbia River plume • Reduced access to off-channel rearing habitat in the lower Columbia River • Reduced productivity resulting from sediment and nutrient-related changes in the estuary • Juvenile fish wake strandings • Contaminants

Species	Listing Classification and Date	Recovery Plan Reference	Most Recent Status Review	Status Summary	Limiting Factors
Upper Willamette River steelhead	Threatened 1/5/06	NMFS 2011a	NWFSC 2015	<p>This DPS has four demographically independent populations. Three populations are at low risk and one population is at moderate risk. Declines in abundance noted in the last status review continued through the period from 2010-2015. While rates of decline appear moderate, the DPS continues to demonstrate the overall low abundance pattern that was of concern during the last status review. The causes of these declines are not well understood, although much accessible habitat is degraded and under continued development pressure. The elimination of winter-run hatchery release in the basin reduces hatchery threats, but non-native summer steelhead hatchery releases are still a concern for species diversity and a source of competition for the DPS. While the collective risk to the persistence of the DPS has not changed significantly in recent years, continued declines and potential negative impacts from climate change may cause increased risk in the near future.</p>	<ul style="list-style-type: none"> • Degraded freshwater habitat • Degraded water quality • Increased disease incidence • Altered stream flows • Reduced access to spawning and rearing habitats due to impaired passage at dams • Altered food web due to changes in inputs of microdetritus • Predation by native and non-native species, including hatchery fish and pinnipeds • Competition related to introduced salmon and steelhead • Altered population traits due to interbreeding with hatchery origin fish

2.2.2 Status of the Critical Habitat

This section describes the status of designated critical habitat affected by the proposed action by examining the condition and trends of the essential physical and biological features of that habitat throughout the designated areas. These features are essential to the conservation of the ESA-listed species because they support one or more of the species' life stages (*e.g.*, sites with conditions that support spawning, rearing, migration and foraging).

For most salmon and steelhead, NMFS's critical habitat analytical review teams (CHARTs) ranked watersheds within designated critical habitat at the scale of the fifth-field hydrologic unit code (HUC5) in terms of the conservation value they provide to each ESA-listed species that they support (NMFS 2005). The conservation rankings were high, medium, or low. To determine the conservation value of each watershed to species viability, the CHARTs evaluated the quantity and quality of habitat features, the relationship of the area compared to other areas within the species' range, and the significance to the species of the population occupying that area. Even if a location had poor habitat quality, it could be ranked with a high conservation value if it were essential due to factors such as limited availability, a unique contribution of the population it served, or is serving another important role.

A summary of the status of critical habitats, considered in this opinion, is provided in Table 2, below.

Table 2. Critical habitat, designation date, federal register citation, and status summary for critical habitat considered in this opinion.

Species	Designation Date and Federal Register Citation	Critical Habitat Status Summary
Lower Columbia River Chinook salmon	9/02/05 70 FR 52630	Critical habitat encompasses 10 subbasins in Oregon and Washington containing 47 occupied watersheds, as well as the lower Columbia River rearing/migration corridor. Most HUC5 watersheds with PCEs for salmon are in fair-to-poor or fair-to-good condition (NMFS 2005). However, most of these watersheds have some, or high potential for improvement. We rated conservation value of HUC5 watersheds as high for 30 watersheds, medium for 13 watersheds, and low for four watersheds.
Upper Willamette River Chinook salmon	9/02/05 70 FR 52630	Critical habitat encompasses 10 subbasins in Oregon containing 56 occupied watersheds, as well as the lower Willamette/Columbia River rearing/migration corridor. Most HUC5 watersheds with PCEs for salmon are in fair-to-poor or fair-to-good condition. However, most of these watersheds have some, or high, potential for improvement. Watersheds are in good to excellent condition with no potential for improvement only in the upper McKenzie River and its tributaries (NMFS 2005). We rated conservation value of HUC5 watersheds as high for 22 watersheds, medium for 16 watersheds, and low for 18 watersheds.
Lower Columbia River coho salmon	2/24/16 81 FR 9252	Critical habitat encompasses 10 subbasins in Oregon and Washington containing 55 occupied watersheds, as well as the lower Columbia River and estuary rearing/migration corridor. Most HUC5 watersheds with PCEs for salmon are in fair-to-poor or fair-to-good condition (NMFS 2005). However, most of these watersheds have some or a high potential for improvement. We rated conservation value of HUC5 watersheds as high for 34 watersheds, medium for 18 watersheds, and low for three watersheds.
Lower Columbia River steelhead	9/02/05 70 FR 52630	Critical habitat encompasses nine subbasins in Oregon and Washington containing 41 occupied watersheds, as well as the lower Columbia River rearing/migration corridor. Most HUC5 watersheds with PCEs for salmon are in fair-to-poor or fair-to-good condition (NMFS 2005). However, most of these watersheds have some or a high potential for improvement. We rated conservation value of HUC5 watersheds as high for 28 watersheds, medium for 11 watersheds, and low for two watersheds.
Upper Willamette River steelhead	9/02/05 70 FR 52630	Critical habitat encompasses seven subbasins in Oregon containing 34 occupied watersheds, as well as the lower Willamette/Columbia River rearing/migration corridor. Most HUC5 watersheds with PCEs for salmon are in fair-to-poor or fair-to-good condition (NMFS 2005). However, most of these watersheds have some or a high potential for improvement. Watersheds are in good to excellent condition with no potential for improvement only in the upper McKenzie River and its tributaries (NMFS 2005). We rated conservation value of HUC5 watersheds as high for 25 watersheds, medium for 6 watersheds, and low for 3 watersheds.

2.3 Action Area

“Action area” means all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 CFR 402.02).

The project boundary is located on the west bank of the Willamette River at RM 5.1. The action area is the 96 linear feet of bank line where the concrete slab revetment that will be replaced, extending from the toe of the slab up 27’ to the existing seawall. The action area includes the construction area boundary, as well as 1/2 mile upstream and downstream from the work area in the event any sediment, debris, or contaminated material should enter the river.

Five ESA-listed species use the action area for adult migration, juvenile rearing, and migration. Critical habitat has been designated for all species. The action area is designated EFH for Chinook salmon and coho salmon (Pacific Fishery Management Council 2014), and is an area where environmental effects of the proposed action may adversely affect EFH of those species. The effects to EFH are analyzed in the MSA portion of the document.

2.4 Environmental Baseline

The “environmental baseline” refers to the condition of the listed species or its designated critical habitat in the action area, without the consequences to the listed species or designated critical habitat caused by the proposed action. The environmental baseline includes the past and present impacts of all Federal, State, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7 consultations, and the impact of State or private actions which are contemporaneous with the consultation in process. The consequences to listed species or designated critical habitat from ongoing agency activities or existing agency facilities that are not within the agency’s discretion to modify are part of the environmental baseline (50 CFR 402.02).

The climate change effects on the environmental baseline are described in Section 2.2, above.

During recent years, NMFS has engaged in various Section 7 consultations on Federal projects affecting these populations and their habitats in the vicinity of the action area, and those consequences have been taken into account in this opinion. These consultations include consultations on dredging, dock maintenance and repair, and restoration in and near the action area, recently including the Centennial Mills Dock Demolition (WCR-2016-4403), the Chevron Front Street Dock Repair (WCR-2017-6704), the Vigor Industrial Fender Pile Maintenance (WCR-2017-7963), the Tidewater Philips 66 Pier Repair (WCR-2017-8078), the McCall Oil Fender Pile Replacement (WCR-2016-5012), the Kinder Morgan Pile Replacement and Dock Maintenance (WCR-2014-1671), the TEMCO Piling Replacement (WCR-2014-285), the CalPortland Terminal Fender Pile Replacement (WCR-2014-522), the Gunderson Pile Replacement (WCR-2014-592), the Ash Grove Cement Company Fender Pile System Replacement (WCRO-2019-00010), the Phillips 66 Fender Pile Replacement (WCRO-2019-01598), the Shell Oil Portland Bulk Terminal Removal (WCR-2017-6906), the University of Portland Habitat Restoration and Dock Construction (WCR-2017-6909), the Lower Willamette

River Ecosystem Restoration Projects (WCR-2014-633), the Draft Restoration Plan for the Portland Harbor Superfund Site (WCR-2014-1581), the Alder Creek Mill Restoration (NWR-2012-9429), the Vigor Shipyard Dredging (NWR-2013-10001), the Glacier Northwest Dredging (WCR-2015-2734), the NW Natural PGM Remedy Construction (WCRO-2019-00008), the TLP Management Services Dredging and Capping (WCRO-2019-00011), the Port of Portland's Terminal-Wide Maintenance Dredging (NWR-2012-3169), J.R. Simplot Rivergate Terminal Maintenance Dredging Willamette River (WCRO-2019-02355); and McCall Oil Maintenance Dredging (WCRO-2019-03305).

Habitat conditions within the LWR are highly degraded. The streambanks have been channelized, off-channel areas removed, tributaries put into pipes, and the river disconnected from its floodplain as the lower valley was urbanized. Silt loading to the LWR has increased over historical levels due to logging, agriculture, road building, and urban and suburban development within the watershed. Limited opportunity exists for large wood recruitment to the LWR due to the paucity of mature trees along the shoreline, and the lack of relief along the shoreline to catch and hold the material. The LWR has been deepened and narrowed through channelization, diking and filling, and much of the shallow-water habitat (important for rearing juvenile salmonids) has been converted to deep water habitat; 79% of the shallow water through the lower river has been lost through historic channel deepening (Northwest Power and Conservation Council 2004), and the Federal Navigation Channel at Post Office Bar was dredged in October 2011. Additionally, much of the historical off-channel habitat (also important habitat for juvenile salmonids) has been lost due to diking and filling of connected channels and wetlands. Gravel continues to be extracted from the river and floodplain and much of the sediment that would otherwise move downstream in the Willamette River is blocked by dams. All of these river changes contribute to the factors limiting recovery of ESA-listed salmonids using the action area.

The LWR through the City of Portland is highly developed for industrial, commercial and residential purposes. Much of the river is fringed by seawalls or riprapped embankments. Water quality in the action area reach of the Willamette River reflects its urban location and disturbance history. The LWR is currently listed on the Oregon Department of Environmental Quality (DEQ) Clean Water Act 303(d) List of Water Quality Limited Water Bodies. DEQ-listed water quality problems identified in the action area include toxics, biological criteria (fish skeletal deformities), bacteria (fecal coliform), and temperature. Cleanup of contaminated sediments in the LWR is presently being addressed under the Federal Superfund process. Sediment sampling in the action area has identified the presence of elevated levels of ammonia.

Juvenile and adult Chinook salmon, coho salmon, and steelhead use this area as a migratory corridor and as rearing habitat for juveniles (Friesen 2005). All populations of UWR species use the action area, but only the Clackamas River populations of the LCR species occur here. The results of the Friesen study demonstrate that juvenile salmon and steelhead are present in the LWR nearly year-round. Of the more than 5,000 juvenile salmonids collected during the study, over 87% were Chinook salmon, 9% were coho salmon, and 3% were steelhead. Friesen concluded that the Chinook salmon juveniles were largely spring-run stocks that rear in fresh water for a year or more before migrating to the ocean. Chinook salmon juveniles caught exhibited a bimodal distribution in length, indicating the presence of both subyearlings and

yearlings. Although at lower abundance, coho salmon juveniles also exhibited this bimodal distribution of yearlings and subyearlings. The abundance of all juvenile salmon and steelhead increased beginning in November, peaked in April, and declined to near zero by July. Some of the larger juveniles may spend extended periods of time in off-channel habitat. Mean migration rates of juvenile salmon and steelhead ranged from 1.68 miles/day for steelhead to 5.34 miles/day for sub-yearling Chinook salmon. Residence time in the LWR ranged from 4.9 days for Chinook to 15.8 days for steelhead. Catch rates of juvenile salmon were significantly higher at sites composed of natural habitat (e.g., beaches and alcoves).

Steelhead are not known to spawn in the mainstem of the Willamette River in the vicinity of the action area. Chinook salmon may spawn upstream of the action area in the lower end of the Clackamas River or in the Willamette River just below Willamette Falls, where suitable gravel-type substrate for spawning may occur, and in Johnson Creek. Recent observations of coho salmon juveniles in Miller Creek (tributary at RM 3 on the Willamette River) and in Johnson Creek by City of Portland biologists suggest that coho spawning may occur in small tributaries in the LWR.

Adult Chinook salmon and steelhead have been documented holding in the LWR for a period of time before moving upriver. Adults migrate upstream to spawn during early spring (spring Chinook salmon), early fall (coho salmon), and late fall through winter (steelhead), and spawn in early to mid-fall (Chinook and coho salmon) and spring (steelhead). Adult steelhead have been documented entering the mouth of the Clackamas River with a darkened coloration, indicating that they have been in freshwater for some time.

Friesen (2005) contradicts the longstanding assumption that UWR Chinook salmon overwinter and grow in their natal streams, then pass quickly through the LWR corridor during a springtime migration toward the sea. Instead, he found juvenile hatchery and naturally-spawned Chinook salmon to be present and growing in the LWR during every month of the year, often at a faster rate than in other areas, although they were most abundant during winter and spring. In contrast, juvenile coho salmon and steelhead generally were rare except during winter and spring. Therefore, juvenile Chinook salmon will be present in the river during the proposed action, and there will likely be a few LCR coho salmon and steelhead juveniles present as well. Critical habitat in the action area provides a critical migration corridor and important rearing habitat with high conservation value.

2.5 Effects of the Action

Under the ESA, “effects of the action” are all consequences for listed species or critical habitat caused by the proposed action, including the consequences of other activities that are caused by the proposed action. A consequence is caused by the proposed action if it would not occur but for the proposed action and it is reasonably certain to occur. Effects of the action may occur later in time and may include consequences occurring outside the immediate area involved in the action (see 50 CFR 402.17). In our analysis, which describes the effects of the proposed action, we considered 50 CFR 402.17(a) and (b).

The proposed action may affect the salmonid species considered in this opinion by exposing them to physical, chemical, and biological changes to the environment, and through direct impacts on individual fish. These effects could include a short-term reduction in water quality from increased turbidity caused by suspended sediment during piling removal. If the area where the pilings are being extract comes into contact with the river, the activity could suspend contaminants found in sediments within the Portland Harbor superfund site. Additionally, rehabilitating the revetment will perpetuate the current lack of access to shallow water habitat for ESA fish species and will prevent future shallow water habitat from forming in the project area. There is also a small chance of an accidental contaminant release from construction equipment or activities; however, any release would likely be small and quickly contained due to the implementation of a spill prevention, control, and containment plan.

A beneficial effect of the proposed action is that the removal of three creosote-treated pilings will help reduce exposure of chemical contaminants to ESA species and their prey. The consequences of the proposed action on species and their habitat are described in detail below.

2.5.1 Effects on Listed Species

Effects from Disturbance and Turbidity. Demolition and construction work on the revetment will take place in the dry and is not expected to result in adverse effects on ESA-listed species. Removal of the three pilings will also likely occur while the water level is below the piling locations. During piling removal, some sediment is likely to be shifted and may come into contact with river where it could be re-suspended and carried downstream. Adults are unlikely to be disturbed in the event of a slight increase in turbidity and would be able to respond by avoiding the work area. Juveniles are more likely to enter or remain in the area during disturbance, and those that do may experience physiological stress caused by exposure to the physical disturbance during piling removal.

Fish response to suspended sediment and turbidity ranges from beneficial to detrimental. Elevated total suspended solids (TSS) have been reported to enhance cover conditions, reduce piscivorous fish/bird predation rates, and improve survival, but elevated TSS have also been reported to cause physiological stress, reduce growth, and adversely affect survival. Although fish that remain in turbid waters experience a reduction in predation from piscivorous fish and birds (Gregory and Levings 1998), chronic exposure can cause physiological stress responses that can increase maintenance energy and reduce feeding and growth (Lloyd *et al.* 1987; Redding *et al.* 1987; Servizi and Martens 1991). Of key importance in considering the detrimental effects of TSS on fish are the frequency and the duration of the exposure, as well as the TSS concentration. If elevated TSS occurs, it would occur over a relatively small area during piling extraction; therefore, only extremely short duration exposure may occur. Sediments in the action area are contaminated, and disturbing the sediments may mobilize some of the contaminants over a small area. Any suspended sediment and contaminants should dissipate soon after cessation of the activity.

Juvenile salmonids in the action area are primarily planktonic feeders in the summer, and therefore their ability to feed will decline in turbid waters. Depending on the concentrations of suspended solids, fish will either respond by seeking refuge in adjacent areas with less turbidity,

or remain in the area, taking advantage of the additional cover. The risk of death or injury to ESA-listed salmonids from increases in TSS is low during the summer in-water work window when densities of juvenile fish are low. Behavioral responses may occur and would include decreased foraging behaviors in the affected area, reducing juvenile growth and fitness in a small number of fish.

Given the relatively small area that could be affected, the temporary duration of the construction activities, the low overall risk of introducing suspended sediment into the river, and the small number of ESA-listed salmonids likely to be exposed to elevated TSS and contaminants, only a few ESA-listed fish are likely to be affected.

Effects from continuing lack of access to shallow water habitat. Ensuring the long term efficacy of the NuStar Energy Terminal revetment will result in the continued lack of access to shallow water habitat by fish species in this reach of the river. Continuing the current level of reduced access to shallow water habitat is cited as a limiting factor in the recovery plans for several ESA listed fish species. Removal of the three pilings in the project area is an action that would offset, to some degree the adverse effects of the continued existence of the revetment structure. In essence, removing chemically treated, derelict structures, in exchange for the continued function of the revetment would likely result in no net change in the biological baseline in the project area.

Effects on Salmonid Prey. It is unlikely that the proposed action will result in any changes in the pelagic forage community. Pelagic feeding within the action area will not be disrupted during construction. Similarly, the transient, flow-induced movements of the salmonids' pelagic prey base should limit their exposure to contaminants, should any contaminated sediments become suspended in the water during piling extraction. A beneficial effect of the proposed action is that the removal of possibly creosote-treated pilings will help reduce exposure of chemical contaminants to juvenile salmonid prey.

The importance of the site as a rearing area for juvenile salmonids is limited, and prey availability at the site will not alter generally available feeding opportunities for salmonids in the lower river. It is unlikely that the proposed action will result in a reduction to the forage community in the lower river over the long term.

Summary of Effects on Listed Species. The presence/absence information for salmonids in the action area during the Willamette River summer in-water work window of July 1 through October 31 is provided in Table 3. The applicant proposes to complete all in-water work during this window. The peak upstream migration for adult LCR coho salmon and LCR Chinook salmon overlaps with the summer in-water work window, but otherwise, the overall number of listed salmonids in the lower Willamette River is at its lowest during this time. Densities of juvenile salmonids, the more sensitive and vulnerable life stage, are lowest in the summer months (Friesen 2005), and the summer in-water work window avoids peak smolt out-migration for juvenile ESA-listed salmonids that migrate through the action area. Therefore, the potential for direct effects on salmon and steelhead will be significantly lower during the summer in-water work window than during the rest of the year because salmon presence is low.

Table 3. The presence/absence of ESA-listed salmonids in the lower Willamette River during the summer in-water work window (July 1 to October 31). ‘Y’ indicates the species is present, ‘Y-’ indicates that while the life stage may be present, peak migration is not at this time’, ‘N’ indicates that the species is not likely to be present.

Species	Summer In-water Work Window	
	Adult Migration	Juvenile Out-migration
LCR Chinook salmon	Y	Y-
UWR Chinook salmon	N	Y-
LCR coho salmon	Y	Y-
UWR steelhead	N	Y-
LCR steelhead	Y-	Y-

However, NMFS does expect some fish to be present during in-water work. Though the risk of adverse effects on ESA fish is very low due to all or most of the proposed work occurring in the dry during low water, fish that may be present could encounter increased turbidity and contaminated suspended solids. Any non-lethal stress experienced by individual fish is likely to be brief (minutes to hours). In general, fish using this reach of the river, either for migration or rearing, would not be allowed to access shallow water habitat that would otherwise exist had the revetment not been constructed to protect NuStar Energy assets along the shoreline. Ensuring that structures functions well into the future, would continue the current lack of shallow water habitat access.

Considering the low abundance and short residence time of juvenile ESA-listed salmonids in the action area during the in-water work window, any effects to the growth, survival, and distribution of ESA-listed salmonids in the action area will be small and isolated. These effects are unlikely to be significant at either the local or population scale. The proposed action will have no effect on the long-term abundance trends of any populations addressed by this opinion.

2.5.2 Effects on Critical Habitat

Designated critical habitat within the action area for ESA-listed salmon and steelhead considered in this opinion consists of freshwater rearing sites and freshwater migration corridors and their essential physical and biological features (PBFs) as listed below. The effects of the proposed action on these features are summarized as a subset of the habitat-related effects of the action that were discussed more fully above.

Freshwater rearing

Floodplain connectivity – Continued lack of floodplain connectivity as the continued existence of the revetment will perpetuate the current lack of floodplain connectivity in this reach of the river.

Forage – No effect.

Natural cover – No effect.

Water quality – Slight potential to increase suspended sediment and associated contaminants during piling removal; however, those adverse effects would be offset by the permanent removal of possibly creosote-treated piles.

Water quantity – No effect.

Freshwater migration

Free of artificial obstruction – No effect.

Natural cover – No effect.

Water quality – Slight potential to increase suspended sediment and associated contaminants during piling removal; however, those adverse effects would be offset by the permanent removal of possibly creosote-treated piles.

Water quantity – No effect.

The proposed action is likely to cause minor, localized and temporary degradation of critical habitat PBFs for water quality, and floodplain connectivity. The critical habitat in the action area will retain its ability to provide rearing sites and freshwater migration corridors for the species considered in this opinion.

2.6 Cumulative Effects

“Cumulative effects” are those effects of future state or private activities, not involving Federal activities, that are reasonably certain to occur within the action area of the Federal action subject to consultation (50 CFR 402.02 and 402.17(a)). Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

Some continuing non-Federal activities are reasonably certain to contribute to climate effects within the action area. However, it is difficult if not impossible to distinguish between the action area’s future environmental conditions caused by global climate change that are properly part of the environmental baseline *vs.* cumulative effects. Therefore, all relevant future climate-related environmental conditions in the action area are described in the environmental baseline (Section 2.4).

For this action, state or private activities in the vicinity of the project location are expected to cause cumulative effects in the action area. Additionally, future state and private activities in upstream areas are expected to cause habitat and water quality changes that are expressed as cumulative effects in the action area. Our analysis considers: (1) how future activities in the Willamette basin are likely to influence habitat conditions in the action area, and (2) cumulative effects caused by specific future activities in the vicinity of the project location.

The action area has a high population density because it is in the Portland metropolitan area. The past effect of that population is expressed as changes to physical habitat and loadings of

pollutants contributed to the Willamette River. These changes were caused by residential, commercial, industrial, agricultural, and other land uses for economic development, and are described in the Environmental Baseline (Section 2.4). The collective effects of these activities tend to be expressed most strongly in lower river systems where the consequences of numerous upstream land management actions aggregate to influence natural habitat processes and water quality.

Agriculture, hydropower facilities, timber harvest, fishing, mining and other resource-based industries caused many long-lasting environmental changes that harmed ESA-listed species and their critical habitats. Those include basin-wide loss or degradation of stream channel morphology, spawning substrates, instream roughness and cover, estuarine rearing habitats, wetlands, floodplains, riparian areas, water quality (*e.g.*, temperature, sediment, dissolved oxygen, contaminants), fish passage, and habitat refugia. Those changes reduced the ability of populations of ESA-listed species to sustain themselves in the natural environment by altering or interfering with their behavior in ways that reduce their survival throughout their life cycle. The environmental changes also reduced the quality and function of critical habitat PBFs that are necessary for successful spawning, production of offspring, and migratory access necessary for adult fish to swim upstream to reach spawning areas and for juvenile fish to proceed downstream and reach the ocean. Without those features, the species cannot successfully spawn and produce offspring.

Many of the activities described in Section 2.4 are ongoing and will continue into the future. Over time, the level of extraction of some natural resources and the associated habitat degradation in Oregon has declined and industry standards and regulatory requirements have improved. For instance, large-scale placer mining for gold (NRC 1995, Lichatowich 1999) has been replaced by smaller recreational mining operations. Timber harvest in Oregon has decreased from roughly 8.5 billion board feet in the 1980s to about 4 billion board feet in 2004 (Oregon Department of Forestry 2005). Timber harvest for Oregon from 2005 to 2010 ranged from 4.4 billion board feet to 2.7 billion board feet.¹ In 1971, Oregon passed the first comprehensive forest practices act in the nation. The law became effective on July 1, 1972, and implementation began immediately following adoption of the first set of forest practice rules (Everest and Reeves 2007). Although the Oregon Forest Practices Act and associated forest practice rules generally have become more protective of riparian and aquatic habitats over time, significant concerns remain over their ability to adequately protect water quality and salmon habitat (Everest and Reeves 2007, IMST 1999).

While widespread degradation of aquatic habitat associated with intense natural resource extraction is no longer common, ongoing and future land management actions are likely to continue to have a depressive effect on aquatic habitat quality in the Willamette basin. As a result, recovery of aquatic habitat is likely to be slow in most areas and cumulative effects at the basin-wide scale are likely to have a neutral to negative impact on population abundance trends and the quality of critical habitat PBFs.

The human population in the Portland area is likely to continue to grow in the foreseeable future (Portland State University 2012). No specific projection of future pollutant loadings in the

¹ Data available at: http://www.oregon.gov/ODF/Pages/state_forests/frp/Charts.aspx (accessed Sept. 2013)

Willamette River as a result of that population increase is available, but a larger population is likely to have a commensurate level of demand for residential, commercial, industrial, and other land uses that produce contaminants that enter rivers. Thus, it is likely that trends in habitat and water quality in the area of the proposed project will continue, but with changes as described below.

To counteract past trends in pollution of the LWR, State, tribal, local or private parties, including groups such as the Portland Harbor responsible parties, together with non-Federal members of the Portland Harbor Natural Resource Trustee Council acting in their own capacity, are reasonably certain to continue taking aggressive actions to reduce toxic pollution and runoff to the Willamette River from all sources (U.S. EPA 2011; U.S. EPA 2017). Those actions include public education, increased toxic reduction and clean-up actions, monitoring to better identify and control sources, research into ecosystem effects of toxic pollutants, and development of a regional data management system. Upland remediation activities are often unlikely to have a Federal nexus for NMFS and thus will not be the subject of a section 7 consultation for NMFS species. However, these future actions will likely lead to a significant reduction in the volume of some pollutants delivered to the LWR, although data are still insufficient to identify a trend in the concentration of most of those contaminants in the water itself (Johnson *et al.* 2005; U.S. EPA 2009; U.S. EPA 2011). We did not find any other specific information about non-Federal actions reasonably certain to cause cumulative effects in the action area.

2.7 Integration and Synthesis

The Integration and Synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action (Section 2.5) to the environmental baseline (Section 2.4) and the cumulative effects (Section 2.6), taking into account the status of the species and critical habitat (Section 2.2), to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) Reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated or proposed critical habitat as a whole for the conservation of the species.

All adult UWR Chinook salmon and UWR steelhead must migrate through the action area to the Upper Willamette River basin and all juvenile UWR Chinook salmon and UWR steelhead must migrate from the Upper Willamette River basin to the ocean through the action area. Therefore, individuals from all populations of these two species are reasonably likely to be affected by the proposed action. The LCR Chinook salmon, LCR steelhead and LCR coho salmon individuals in the action area are likely to be from the Clackamas River populations and must also pass through the action area as juveniles and adults. Over the past several years, NMFS has engaged in various section 7 consultations on Federal projects impacting these populations and their habitats, and the consequences of those projects have been taken into account in this opinion as part of the environmental baseline.

The current extinction risk for UWR Chinook salmon is very high and the recovery goal is for the extinction risk to become very low. The current extinction risk for UWR steelhead is low and

the recovery goal is for the extinction risk to become very low. The current extinction risk for the Clackamas River population of LCR Chinook salmon is very high and the recovery goal is for the extinction risk to reduce to medium. The current extinction risk for the Clackamas River population of LCR coho salmon is medium and the recovery goal is for the extinction risk to become very low. The current extinction risk for the Clackamas River population of LCR steelhead is medium and the recovery goal is for the extinction risk to become low. The Clackamas River population is identified as a “core” population. To meet the ESU-viability criteria, representative populations, such as the Clackamas River population, need to achieve viability criteria or be maintained (ODFW 2010).

The environmental baseline is such that individual ESA-listed salmonids in the action area are exposed to reduced water quality, lack of suitable riparian and aquatic habitat and restricted movement due to developed urban areas and land use practices. These stressors, as well as those from climate change, already exist and are in addition to any adverse effects produced by the proposed action. Major factors limiting recovery of the ESA-listed salmonids considered in this opinion include degraded estuarine and nearshore habitat; degraded floodplain connectivity and function; channel structure and complexity; riparian areas and large wood recruitment; stream substrate, streamflow; fish passage; water quality; harvest and hatchery consequences; predation/competition; and disease.

The effects of the proposed action on the factors limiting recovery for the ESA-listed salmonids considered in this opinion include a low risk of temporary reduction in water quality in the action area during piling removal, which may result in suspended sediment and associated contaminants. The reduction in water quality, if it occurs at all, would be short term (likely several hours) and limited to a relatively small area. Other effects include perpetuating the lack of access and formation of shallow water habitat that would otherwise exist in the project area if the structure were allowed to degrade. Alternately, removal of the possibly creosote-treated pilings would improve the baseline water quality conditions in the project area, which may offset the continued presence of the revetment structure. Because these effects are relatively brief or small in scale, and only a few individual fish are likely to be exposed to them, if at all, an even smaller number of individuals are likely to be killed or injured.

The proposed action would not cause more than a minor effect on the long-term abundance, productivity, genetic diversity, or spatial diversity of any affected population due to the extremely low probability of adults and juveniles being injured or killed. This is primarily because the number of fish within the action area during in-water work will be extremely small when compared to the total abundance of individuals within each the populations affected by this action, and most if not all work will occur in the dry, above the ordinary high water mark. Therefore, the effects of the proposed action will not reduce the productivity or survival of the affected populations of LCR Chinook salmon, UWR Chinook salmon, LCR steelhead, UWR steelhead or LCR coho salmon, even when combined with a degraded environmental baseline and additional pressure from cumulative effects and climate change.

The value of critical habitat for these species in the LWR is limited by poor water quality, altered hydrology, lack of floodplain connectivity and shallow-water habitat, and lack of complex habitat to provide forage and cover. The action area is in an urban area where the habitat has been degraded due to past land use practices including stormwater runoff and industrial and

urban development. Despite this, the critical habitat in the action area has a high conservation value for LCR Chinook salmon, LCR steelhead, LCR coho salmon, UWR Chinook salmon, and UWR steelhead due to its critical role for rearing and migration.

The same effects of the proposed action that will have an effect on ESA-listed salmon and steelhead will also have an effect on critical habitat PBFs for salmon and steelhead critical habitat. The proposed action could result in a short-term reduction in the quality and function of critical habitat PBFs in the action area during and after piling removal due to water quality effects, with a medium-term reduction due to forage effects.

Long term formation of shallow water habitat at the project site would not be allowed to occur as natural process would have typically allowed had the revetment not been present. Rehabbing revetment would perpetuate the lack of shallow water habitat in the area. However, due to the small scale of the proposed action, NMFS does not anticipate that the project would substantially increase the extent of degraded habitat within the basin, add to the degradation of water quality, or further decrease limited rearing areas or limit access to rearing habitat. Even when cumulative effects and climate change are included, the proposed action will not negatively influence the function or conservation role of critical habitat at the watershed scale. Existing critical habitat for LCR Chinook salmon, LCR steelhead, UWR Chinook salmon, and UWR steelhead, and LCR coho salmon will remain functional, or retain the current ability for the PBFs to become functionally established, to serve the intended conservation role for the species, in this case, to provide freshwater rearing sites and migration corridors.

For all the reasons described above, the proposed action will not appreciably reduce the likelihood of both survival and recovery of the species in the wild by reducing their numbers, reproduction or distribution; nor will the proposed action significantly reduce the value of designated critical habitat for the conservation of the species.

2.8 Conclusion

After reviewing and analyzing the current status of the listed species and their designated critical habitat, the environmental baseline within the action area, the effects of the proposed action, the effects of other activities caused by the proposed action, and cumulative effects, it is NMFS' biological opinion that the proposed action is not likely to jeopardize the continued existence of LCR Chinook salmon, UWR Chinook salmon, LCR coho salmon, LCR steelhead, or UWR steelhead or destroy or adversely modify their designated critical habitats.

2.9 Incidental Take Statement

Section 9 of the ESA and Federal regulations pursuant to section 4(d) of the ESA prohibit the take of endangered and threatened species, respectively, without a special exemption. "Take" is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. "Harm" is further defined by regulation to include significant habitat modification or degradation that actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including breeding, spawning, rearing, migrating, feeding, or sheltering (50 CFR 222.102). "Incidental take" is defined by regulation as takings

that result from, but are not the purpose of, carrying out an otherwise lawful activity conducted by the Federal agency or applicant (50 CFR 402.02). Section 7(b)(4) and section 7(o)(2) provide that taking that is incidental to an otherwise lawful agency action is not considered to be prohibited taking under the ESA if that action is performed in compliance with the terms and conditions of this ITS.

2.9.1 Amount or Extent of Take

In the biological opinion, NMFS determined that incidental take is reasonably certain to occur as follows:

- Harm to juveniles and adults of all ESA-listed salmon and steelhead considered in this opinion due to a potential temporary increase in suspended sediment and associated contaminants during piling removal.
- Harm among juveniles of all ESA-listed salmon and steelhead considered in this opinion due to continued lack of access to shallow water habitat.

The distribution and abundance of fish that occur within an action area are affected by habitat quality, competition, predation, and the interaction of processes that influence genetic, population, and environmental characteristics. These biotic and environmental processes interact in ways that may be random or directional, and may operate across far broader temporal and spatial scales than are affected by the proposed action. Thus, the distribution and abundance of fish within the action area cannot be attributed entirely to habitat conditions, nor can NMFS precisely predict the number of fish that are reasonably certain to be injured or killed if their habitat is modified or degraded by the proposed action. In such circumstances, NMFS cannot provide an amount of take that would be caused by the proposed action.

The best available indicator for the extent of take is for the harm associated with an increase in suspended sediment and associated contaminants: the extent of suspended sediment plumes. Specifically, the anticipated take will be exceeded if increased suspended sediment from piling removal or inadvertent storm runoff containing fill material from the project site causes suspended sediment plumes 300 feet from the boundary of the work area as specified in the term and condition for turbidity monitoring described below. This take indicator operates as an effective reinitiation trigger because the Corps has authority to conduct compliance inspections and to take actions to address non-compliance (33 CFR 326.4).

This feature best integrates the likely take pathways associated with this action, is proportional to the anticipated amount of take, and is the most practical and feasible indicator to measure. In particular, the extent of suspended sediment plumes rationally reflects the amount of take from associated contaminants that could be triggered by piling removal if the removal locations come into contact with the river. Exceeding this indicator for extent of take will trigger the reinitiation provisions of this opinion.

2.9.2 Effect of the Take

In the biological opinion, NMFS determined that the amount or extent of anticipated take, coupled with other effects of the proposed action, is not likely to result in jeopardy to the species or destruction or adverse modification of critical habitat.

2.9.3 Reasonable and Prudent Measures

“Reasonable and prudent measures” are nondiscretionary measures that are necessary or appropriate to minimize the impact of the amount or extent of incidental take (50 CFR 402.02).

The Corps shall:

1. Minimize incidental take from project-related activities by applying conditions to the proposed action that avoid or minimize adverse effects to water quality and the ecology of aquatic systems.
2. Ensure completion of a monitoring and reporting program to confirm that the take exemption for the proposed action is not exceeded, and that the terms and conditions in this incidental take statement are effective in minimizing incidental take.

2.9.4 Terms and Conditions

The terms and conditions described below are non-discretionary, and the Corps or any applicant must comply with them in order to implement the RPMs (50 CFR 402.14). The Corps or any applicant has a continuing duty to monitor the consequences of incidental take and must report the progress of the action and its impact on the species as specified in this ITS (50 CFR 402.14). If the entity to whom a term and condition is directed does not comply with the following terms and conditions, protective coverage for the proposed action would likely lapse.

The following terms and conditions implement reasonable and prudent measure 1:

The terms and conditions described below are non-discretionary, and the Corps or any applicant must comply with them in order to implement the RPMs (50 CFR 402.14). The Corps or any applicant has a continuing duty to monitor the consequences of incidental take and must report the progress of the action and its impact on the species as specified in this ITS (50 CFR 402.14). If the entity to whom a term and condition is directed does not comply with the following terms and conditions, protective coverage for the proposed action would likely lapse.

1. The following terms and conditions implement reasonable and prudent measure 1:
 - a. Work Window. To minimize effects to juvenile salmonids, the applicant must limit all project activities conducted below ordinary high water to the in-water work window of July 1-October 31.
 - b. Notice to Contractors. Before beginning work, the applicant must provide all contractors working on site with a complete list of Corps permit special conditions, reasonable and prudent measures, and terms and conditions intended

to minimize the amount and extent of take resulting from in-water work, if any should be needed.

- c. Minimize Impact Area and Duration. The applicant must confine construction impacts to the minimum area and duration necessary to complete the project.
- d. Conservation Measures. The applicant must carry out all relevant conservation measures from the proposed action section of this opinion as described.
- e. Debris. The applicant must remove all large anthropogenic debris from the project site and transport it to an appropriate disposal site.
- f. Contaminant Containment. The applicant must deploy a containment boom during construction activities to capture contaminants and construction debris that may be floating on the water surface as a consequence of these activities.
- g. Turbidity. Any activity that causes turbidity to exceed 10% above natural stream turbidity is prohibited except as specifically provided below:
 - i. Monitoring: Turbidity monitoring must be conducted and recorded as described below. Monitoring must occur at two hour intervals each day during daylight hours when in-water work is being conducted. A properly calibrated turbidimeter is required unless another monitoring method is proposed and authorized by NMFS.
 - (1) Representative Background Point: Applicant must take and record a turbidity measurement every two hours during in-water work at an undisturbed area. A background location shall be established at a representative location approximately 100 feet upcurrent of the in water activity unless otherwise authorized by DEQ. The background turbidity, location, date, tidal stage (if applicable) and time must be recorded immediately prior to monitoring downcurrent at the compliance point described below.
 - (2) Compliance Point: The Applicant must monitor every two hours. A compliance location shall be established at a representative location approximately 100 feet downcurrent from the disturbance at approximately mid-depth of the waterbody and within any visible plume. The turbidity, location, date, tidal stage (if applicable) and time must be recorded for each measurement.
 - ii. Compliance: The Applicant must compare turbidity monitoring results from the compliance points to the representative background levels taken during each two –hour monitoring interval. Short term exceedances of the turbidity water quality standard are allowed as follows:
 - (1) 0 to 4 NTU above background -- No Restrictions
 - (2) 5 to 29 NTU above background -- Work may continue maximum of 4 hours. If turbidity remains 5-29 NTU above background, stop work and modify BMPs. Work may resume when NTU is 0-5 above background.
 - (3) 30 to 49 NTU above background Work may continue maximum of 2 hours. If turbidity remains 30-49 NTU above background, stop work and modify BMPs. Work may resume when NTU is 0-5 above background.

- (4) 50 NTU or more above background Stop work immediately and inform NMFS.
- ii. Reporting. The applicant must record all turbidity monitoring required by subsections (ii) and (iii) above in daily logs. The daily logs must include calibration documentation; background NTUs; compliance point NTUs; comparison of the points in NTUs; location; date; time; and tidal stage (if applicable) for each reading. Additionally, a narrative must be prepared discussing all exceedances with subsequent monitoring, actions taken, and the effectiveness of the actions. Applicant must make available copies of daily logs for turbidity monitoring to USACE and NMFS upon request.

2. The following terms and conditions implements reasonable and prudent measure 2:

- a. Reporting. Within 60-days of completing the revetment repair, the applicant shall provide a project completion report with the following information:
 - i. Applicant's name and permit number
 - ii. Corps contact person
 - iii. Project name
 - iv. Start and end dates for work completed
 - v. Results of turbidity monitoring
 - vi. Number of pilings removed
- b. Submit monitoring reports to:
National Marine Fisheries Service
Oregon Washington Coastal Office

Portland, OR 97232-2778

2.10 Conservation Recommendations

Section 7(a)(1) of the ESA directs Federal agencies to use their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of the threatened and endangered species. Specifically, conservation recommendations are suggestions regarding discretionary measures to minimize or avoid adverse effects of a proposed action on listed species or critical habitat or regarding the development of information (50 CFR 402.02).

Identify and implement habitat enhancement or restoration activities in the LWR that:

- Create or enhance vegetated riparian buffer to mitigate for riparian function impacts
- Restore instream habitat complexity, including large wood placement
- Remove invasive plant species from upland vegetation and plant native species
- Use vegetated riprap to mitigate for riparian function impacts
- Include a bench in the revetment at bankfull depth

Please notify NMFS if the Corps carries out this recommendation so that we will be kept informed of actions that are intended to improve the conservation of listed species or their designated critical habitats.

2.11 Reinitiation of Consultation

This concludes formal consultation for the NuStar Energy Inc. Revetment Repair on the Willamette River.

As 50 CFR 402.16 states, reinitiation of consultation is required and shall be requested by the Federal agency or by the Service where discretionary Federal agency involvement or control over the action has been retained or is authorized by law and if: (1) The amount or extent of incidental taking specified in the ITS is exceeded, (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion, (3) the identified action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in the biological opinion, or (4) a new species is listed or critical habitat designated that may be affected by the action.

3. MAGNUSON-STEVENSON FISHERY CONSERVATION AND MANAGEMENT ACT ESSENTIAL FISH HABITAT RESPONSE

Section 305(b) of the MSA directs Federal agencies to consult with NMFS on all actions or proposed actions that may adversely affect EFH. The MSA (section 3) defines EFH as “those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity.” Adverse effect means any impact that reduces quality or quantity of EFH, and may include direct or indirect physical, chemical, or biological alteration of the waters or substrate and loss of (or injury to) benthic organisms, prey species and their habitat, and other ecosystem components, if such modifications reduce the quality or quantity of EFH. Adverse effects on EFH may result from actions occurring within EFH or outside of it and may include site-specific or EFH-wide impacts, including individual, cumulative, or synergistic consequences of actions (50 CFR 600.810). Section 305(b) also requires NMFS to recommend measures that can be taken by the action agency to conserve EFH.

This analysis is based, in part, on the EFH assessment provided by the Corps and descriptions of EFH for Pacific Coast salmon (PFMC 2014) contained in the fishery management plans developed by the PFMC and approved by the Secretary of Commerce.

3.1 Essential Fish Habitat Affected by the Project

The proposed action and action area for this consultation are described in the Introduction to this document. The action area includes areas designated as EFH for various life-history stages of Chinook and coho salmon as identified in the Fishery Management Plan for Pacific coast salmon (PFMC 2014).

3.2 Adverse Effects on Essential Fish Habitat

Based on information provided by the action agency and the analysis of effects presented in the ESA portion of this document, NMFS concludes that the proposed action will have adverse consequences for EFH designated for Chinook and coho salmon. These consequences include potential for suspended sediment to enter the river if the piling removal locations come into contact with the river. Additionally, the proposed action will

3.3 Essential Fish Habitat Conservation Recommendations

NMFS recommends that the Corps carry out the following conservation recommendations to avoid, mitigate, or offset the impact of the proposed action on EFH. These conservation recommendations are identical to the ESA terms and conditions:

1. Carry out Terms and Conditions to implement Reasonable and Prudent Measure 1 regarding adverse effects to water quality and the ecology of aquatic systems.
2. Carry out Terms and Conditions to implement Reasonable and Prudent Measure 2 regarding monitoring and reporting.

Fully implementing these EFH conservation recommendations would protect, by avoiding or minimizing the adverse effects described in section 3.2, above, approximately 9.4 acres of designated EFH for Pacific Coast salmon.

3.4 Statutory Response Requirement

As required by section 305(b)(4)(B) of the MSA, the Corps must provide a detailed response in writing to NMFS within 30 days after receiving an EFH Conservation Recommendation. Such a response must be provided at least 10 days prior to final approval of the action if the response is inconsistent with any of NMFS' EFH Conservation Recommendations unless NMFS and the Federal agency have agreed to use alternative time frames for the Federal agency response. The response must include a description of measures proposed by the agency for avoiding, minimizing, mitigating, or otherwise offsetting the impact of the activity on EFH. In the case of a response that is inconsistent with the Conservation Recommendations, the Federal agency must explain its reasons for not following the recommendations, including the scientific justification for any disagreements with NMFS over the anticipated effects of the action and the measures needed to avoid, minimize, mitigate, or offset such effects (50 CFR 600.920(k)(1)).

In response to increased oversight of overall EFH program effectiveness by the Office of Management and Budget, NMFS established a quarterly reporting requirement to determine how many conservation recommendations are provided as part of each EFH consultation and how many are adopted by the action agency. Therefore, we ask that in your statutory reply to the EFH portion of this consultation, you clearly identify the number of conservation recommendations accepted.

3.5 Supplemental Consultation

The Corps must reinitiate EFH consultation with NMFS if the proposed action is substantially revised in a way that may adversely affect EFH, or if new information becomes available that affects the basis for NMFS' EFH Conservation Recommendations (50 CFR 600.920(1)).

4. DATA QUALITY ACT DOCUMENTATION AND PRE-DISSEMINATION REVIEW

The Data Quality Act (DQA) specifies three components contributing to the quality of a document. They are utility, integrity, and objectivity. This section of the opinion addresses these DQA components, documents compliance with the DQA, and certifies that this opinion has undergone pre-dissemination review.

4.1 Utility

Utility principally refers to ensuring that the information contained in this consultation is helpful, serviceable, and beneficial to the intended users. The intended users of this opinion is the Corps. Other interested users could include MOCC. Individual copies of this opinion were provided to the Corps and MOCC. The document will be available within two weeks at the NOAA Library Institutional Repository [<https://repository.library.noaa.gov/welcome>]. The format and naming adheres to conventional standards for style.

4.2 Integrity

This consultation was completed on a computer system managed by NMFS in accordance with relevant information technology security policies and standards set out in Appendix III, 'Security of Automated Information Resources,' Office of Management and Budget Circular A-130; the Computer Security Act; and the Government Information Security Reform Act.

4.3 Objectivity

Information Product Category: Natural Resource Plan

Standards: This consultation and supporting documents are clear, concise, complete, and unbiased; and were developed using commonly accepted scientific research methods. They adhere to published standards including the NMFS ESA Consultation Handbook, ESA regulations, 50 CFR 402.01 et seq., and the MSA implementing regulations regarding EFH, 50 CFR 600.

Best Available Information: This consultation and supporting documents use the best available information, as referenced in the References section. The analyses in this opinion and EFH consultation contain more background on information sources and quality.

Referencing: All supporting materials, information, data and analyses are properly referenced, consistent with standard scientific referencing style.

Review Process: This consultation was drafted by NMFS staff with training in ESA and MSA implementation, if applicable, and reviewed in accordance with West Coast Region ESA quality control and assurance processes.
