The National Geodetic Survey (NGS) of the National Ocean Survey (NOS), NOAA, establishes and maintains the basic national horizontal and vertical networks of geodetic control and provides Government-wide leadership in the improvement of geodetic surveying methods and instrumentation, coordinates operations to assure network development, and provides specifications and criteria for survey operations by Federal, State, and other agencies.

NGS engages in research and development for the improvement of knowledge of the figure of the Earth and its gravity field, and has the responsibility to procure geodetic data from all sources, process these data, and make them generally available to users through a central data base.

NOAA geodetic publications and relevant geodetic publications of the former U.S. Coast and Geodetic Survey are sold in paper form by the National Geodetic Information Center. To obtain a price list or to place an order, contact:

National Geodetic Information Center

GOLDSTONE VALIDATION SURVEY - PHASES II and III

James E. Pettey
William E. Carter

National Geodetic Survey
National Ocean Survey, NOAA
Rockville, Md. 20852

ABSTRACT. A special purpose three-dimensional geodetic survey of the Goldstone Deep Space Network complex, near Barstow, Calif., was conducted in three phases. This report covers the second and third phases. The observing program included astronomic positions and azimuths, zenith distances, electromagnetic distance measurements, Doppler satellite positioning, and a variety of ancillary measurements. Particular care was taken in designing the survey to ensure that the vectors between points within a particular site were determined to better than 1 cm, and that the vectors between the two most distant sites, stations Mars and Venus, were determined to about 10 cm. The descriptive information details the methods used in the collection, reduction, and analysis of the survey data, tabulations of the observational data, and numerical and interpretive results of the analysis.

INTRODUCTION

This report contains descriptive information and numerical results of phases II and III of a high-accuracy, three-dimensional, geodetic survey of the National Aeronautics and Space Administration (NASA)/California Institute of Technology's Jet Propulsion Laboratory (JPL) Goldstone Deep Space Network complex, located near Barstow, Calif. The surveys were performed as part of a continuing cooperative program by the National Ocean Survey/National Geodetic Survey (NOS/NGS) and NASA to validate and compare advanced geodetic surveying systems, i.e., Satellite Laser Ranging (SLR), Lunar Laser Ranging Experiment (LURE), Very Long Baseline Interferometry (VLBI) and satellite Doppler observations. The surveys performed in the summers of 1979 and 1981 were jointly funded by NASA, JPL, and NGS.

Phase I of the Goldstone survey focused on the Mars site, and determined the vectors between significant reference points and survey monuments in the immediate vicinity of the Mars antenna. The results were reported in Carter and Pettey (1978).

The purpose of phase II was to determine the vectors between the Mars site and several other sites throughout the Goldstone complex. Initially, the sites to be included were Pioneer, Echo, Venus, Apollo, and Mojave. However, during the planning stages, the NASA/JPL project manager, Kenneth L. Bartos, notified NGS that the Apollo and Mojave sites should be eliminated from the survey, and the primary purpose should be to determine the MARS-VENUS vector as accurately as possible. Phase II also included a leveling survey, conducted in conjunction with the Southern California Releveling Project (SCARP), to determine accurately the height of the Goldstone complex and the relative heights of specific points within the complex.

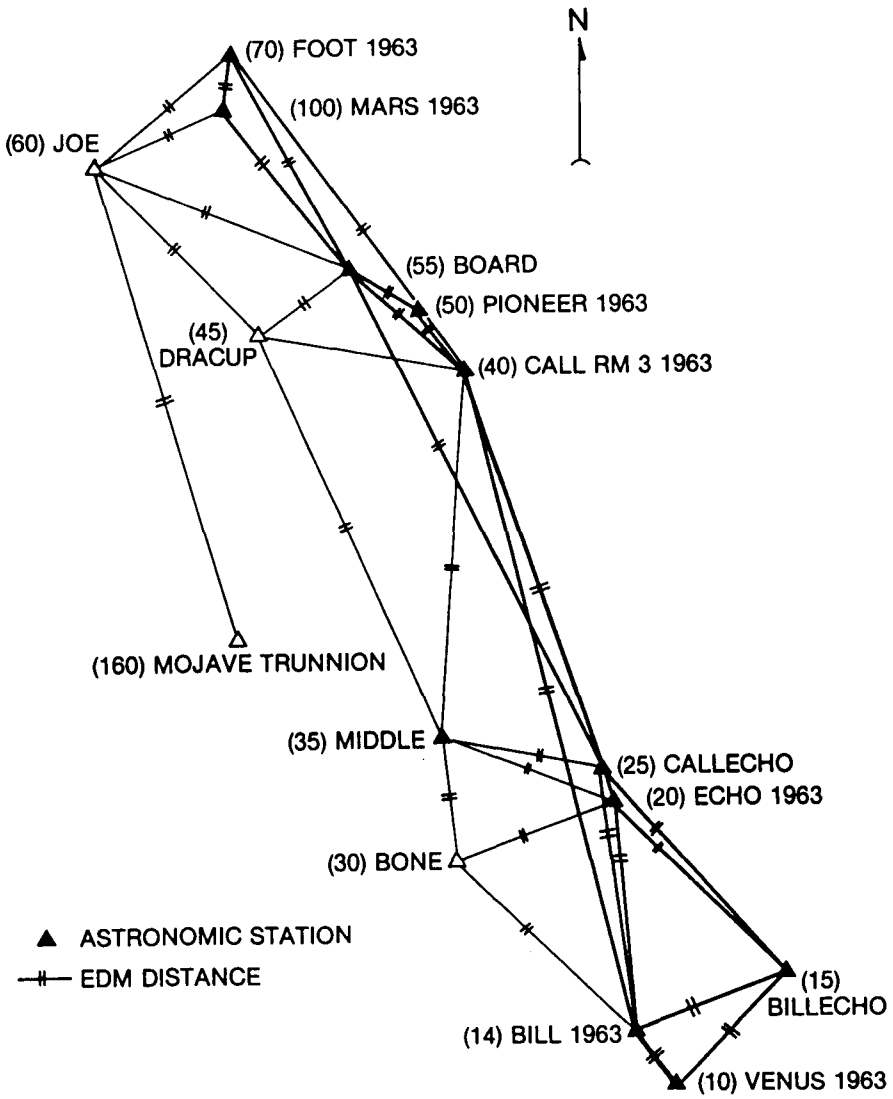

Figure 1.--Plan view of Goldstone phase II survey network.

Phase III focused on the Venus site, and was analogous to the Mars phase I survey. During the field work for phase III, it was decided that the Mojave antenna would be developed under the NASA Crustal Dynamics Project. It will eventually be operated by NGS as part of the National Crustal Motion Network (NCMN). Therefore, the survey team did a preliminary site survey and tie to the phase II network.

For convenience, the results of all three phases are integrated into one least-squares adjustment. This report contains all of the numerical information required to relate the space system's measurements within a particular site to the subcentimeter level and between sites at about the 10-centimeter level. For completeness, the plan view of the phase I survey network is included as appendix C.

DESCRIPTION OF THE PHASE II SURVEY NETWORK

Figure 1 shows a plan view of the phase II survey network. The network was designed with the primary goal of determining the MARS-VENUS vector as accu-

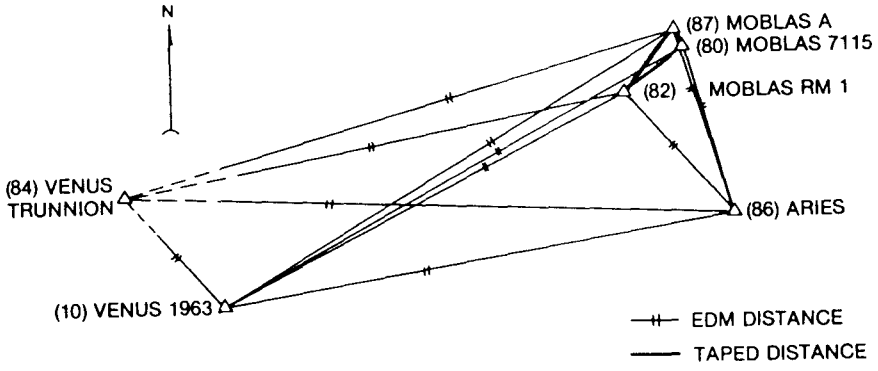

Figure 2.--Plan view of Goldstone phase III survey network.

rately as current technology and reasonable cost constraints would permit. The secondary goal was to improve the geodetic control within the overall Goldstone complex. The subnetwork, shown in bold lines, is particularly significant because it effectively controls the accuracy of the intersite vectors.

Figure 2 shows a plan view of the phase III survey network. This survey scheme was designed to determine the vectors between the Venus antenna VLBI reference point, and stations VENUS 1963, MOBLAS 7115, MOBLAS 7115 RM 1, and ARIES 6-9-91 9MTR.

Figure 3 is a schematic of the Venus antenna, showing the locations of the Venus VLBI reference point, and station VENUS TRUNNION, the nearest monumented survey point.

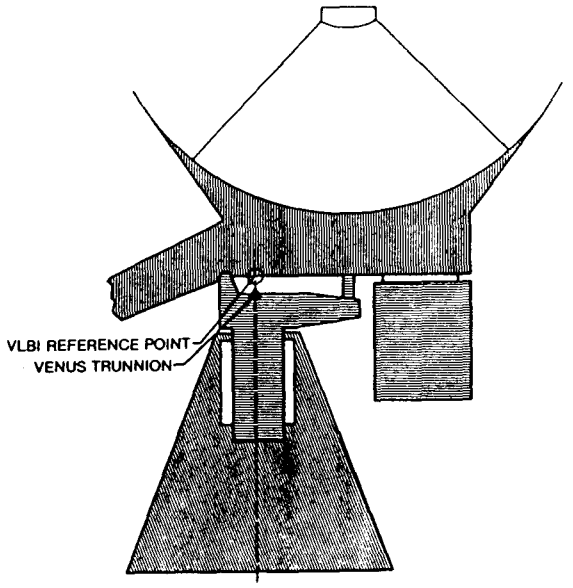

Figure 3.--Schematic of Venus VLBI reference point.

Figure 4 depicts a plan view of the preliminary Mojave site survey and tie to the phase II network. Figure 5 is a schematic of the Mojavo antenna, showing the location of the Mojave VLBI reference point which is the point defined by the intersection of the Z (zenith) and X axis.

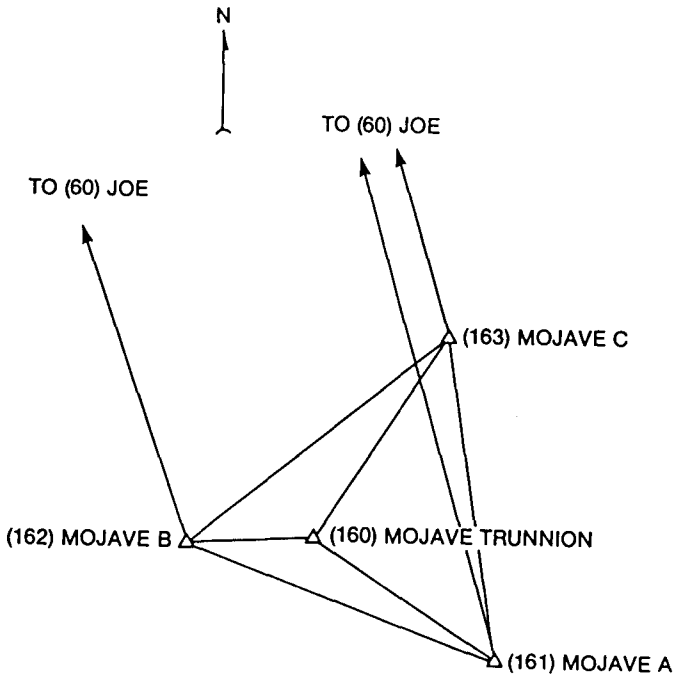

Figure 4.--Plan view of the preliminary Mojave site survey.

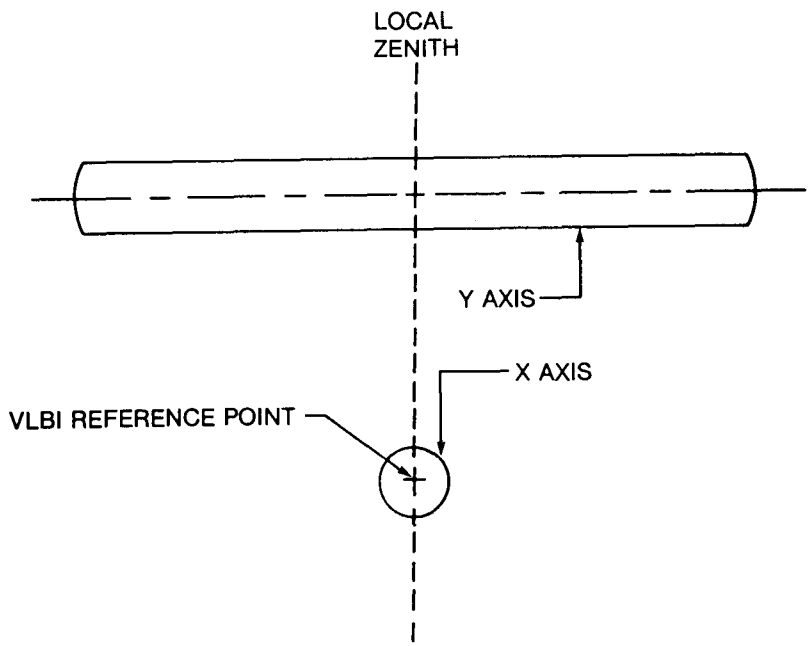

Figure 5.--Schematic of Mojave VLBI reference point.

Operational Program

To attain the highest possible accuracy, redundancy and multiplicity of measurements were employed. Instruments of various types from different manufacturers were used to minimize systematic instrumental errors, and, wherever practical, measurements were made by more than one observer to minimize personal biases and to identify blunders. The observing periods were also scheduled to minimize the effects of time-dependent atmospheric anomolies.

Astronomic Observations

The stations at which astronomic positions and azimuths were determined (see fig. 1) were selected to achieve the highest-accuracy measurements of the vector between the Mars and Venus sites. All of the astronomic observations were reduced using star positions from the Fourth Fundamental catalogue (FK4) (Fricke et al. 1963). The longitude determinations were made by the meridian transit method (Hoskinson and Duerksen 1947), the latitude by the absolute zenith distance method, after Sterneck (Müller 1973), and the azimuths by the direction method (Hoskinson and Duerksen 1947) using Ursae Minoris (Polaris) at any hour angle. The reduced observations were referenced to the Conventional International Origin (CIO) and to the Origin of Longitude, using polar coordinates and time information published by the Bureau International de l'Heure (1968 system) (BIH 1969).

The uncertainties assigned to the astronomic quantities were based on Analysis of Variance (ANOVA) studies reported in Pettey and Carter (1978). An extraordinary attempt was made to reduce the effects of errors which tend to be systematic over the period of a few days, usually associated with astronomic latitude and longitude determinations, e.g., atmosphere refraction, instrumental imperfections, and short-term observer bias. The observing programs, which are normally performed on two or more consecutive nights, were instead done on two separate visits. The second round of observations was made only after completion of one visit to all of the stations. Approximately 1 month elapsed between visits. The only exception to this procedure was at station BILL, where the difficulty of access dictated that the work be done in one visit. With the procedures that were employed, the astronomic latitudes and longitudes are very unlikely to cause errors in the station-to-station vector larger than 1 to 2 parts in 10^6, which would amount to about 3 to 5 cm for the MARS-VENUS vector. The azimuth uncertainties are less well known and potentially larger (Carter and Pettey 1978), but experience leads us to believe that the azimuthal component of the MARS-VENUS base line is unlikely to be worse than about 3 to 5 parts in 10^6, or about 7 to 12 cm.

Zenith Distance Observations

Zenith distance measurements were made during many of the Electromagnetic Distance Measurement (EDM) observing periods to determine the coefficient of refraction, as discussed in Carter and Vincenty (1978: appendix C). In addition, zenith distances were also observed throughout the primary network specifically to determine the vertical components of the interstation vectors. The quality of the zenith distance observations was significantly worse than we had hoped to attain, and indeed have attained in other three-dimensional surveys. A large percentage of the observations had to be rejected because of obvious but unrecoverable blunders. The zenith distance observations retained do not contribute much to the final solution; i.e., the vertical components of the vectors are primarily derived from the leveling data.

Distance Measurements

An extensive EDM program was executed during these surveys. To minimize scale bias, measurements were made during daylight and darkness, from both ends of many lines, and with a selection of different instruments. Several of the short lines in the site surveys were also taped. Based on experience, we estimate that any scale bias is probably less than 1 to 2 parts in 10^6, or about 3 to 5 cm for the longest vectors.

Leveling

Leveling surveys were conducted for two purposes: to determine the orthometric height of the Goldstone complex relative to bench mark No. 941 0660 TIDAL 8, located in San Pedro, Calif., and to obtain the differences in heights between the various points of interest within the complex.

The leveling field work was accomplished in conjunction with the Southern California Releveling Project (SCARP), which was a joint NGS-U.S. Geological Survey project to study crustal dynamics particularly in the vicinity of the so-called Palmdale Bulge. Extraordinary procedures were followed in the SCARP survey to achieve the highest possible accuracy; the tie between the Goldstone complex and bench mark 941 0660 TIDAL 8 is as accurate as the state of-the-art permits. Figure 6 shows the route of the most direct line of leveling to the complex, and figure 7 details the leveling lines within the complex. Appendix A contains the results of the least-squares adjustment of the leveling observations.

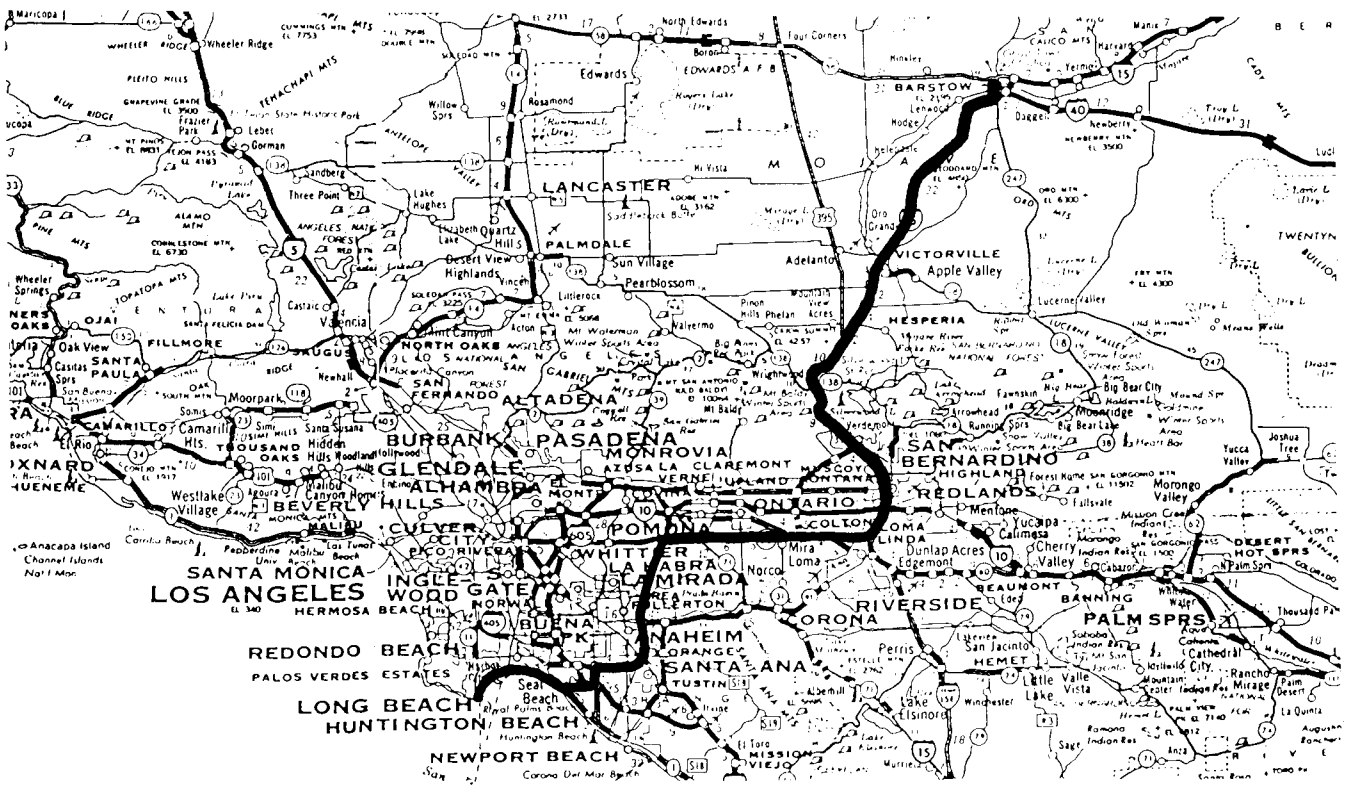

Figure 6.--Route of first-order leveling connecting the Goldstone complex to the North American Vertical Datum.

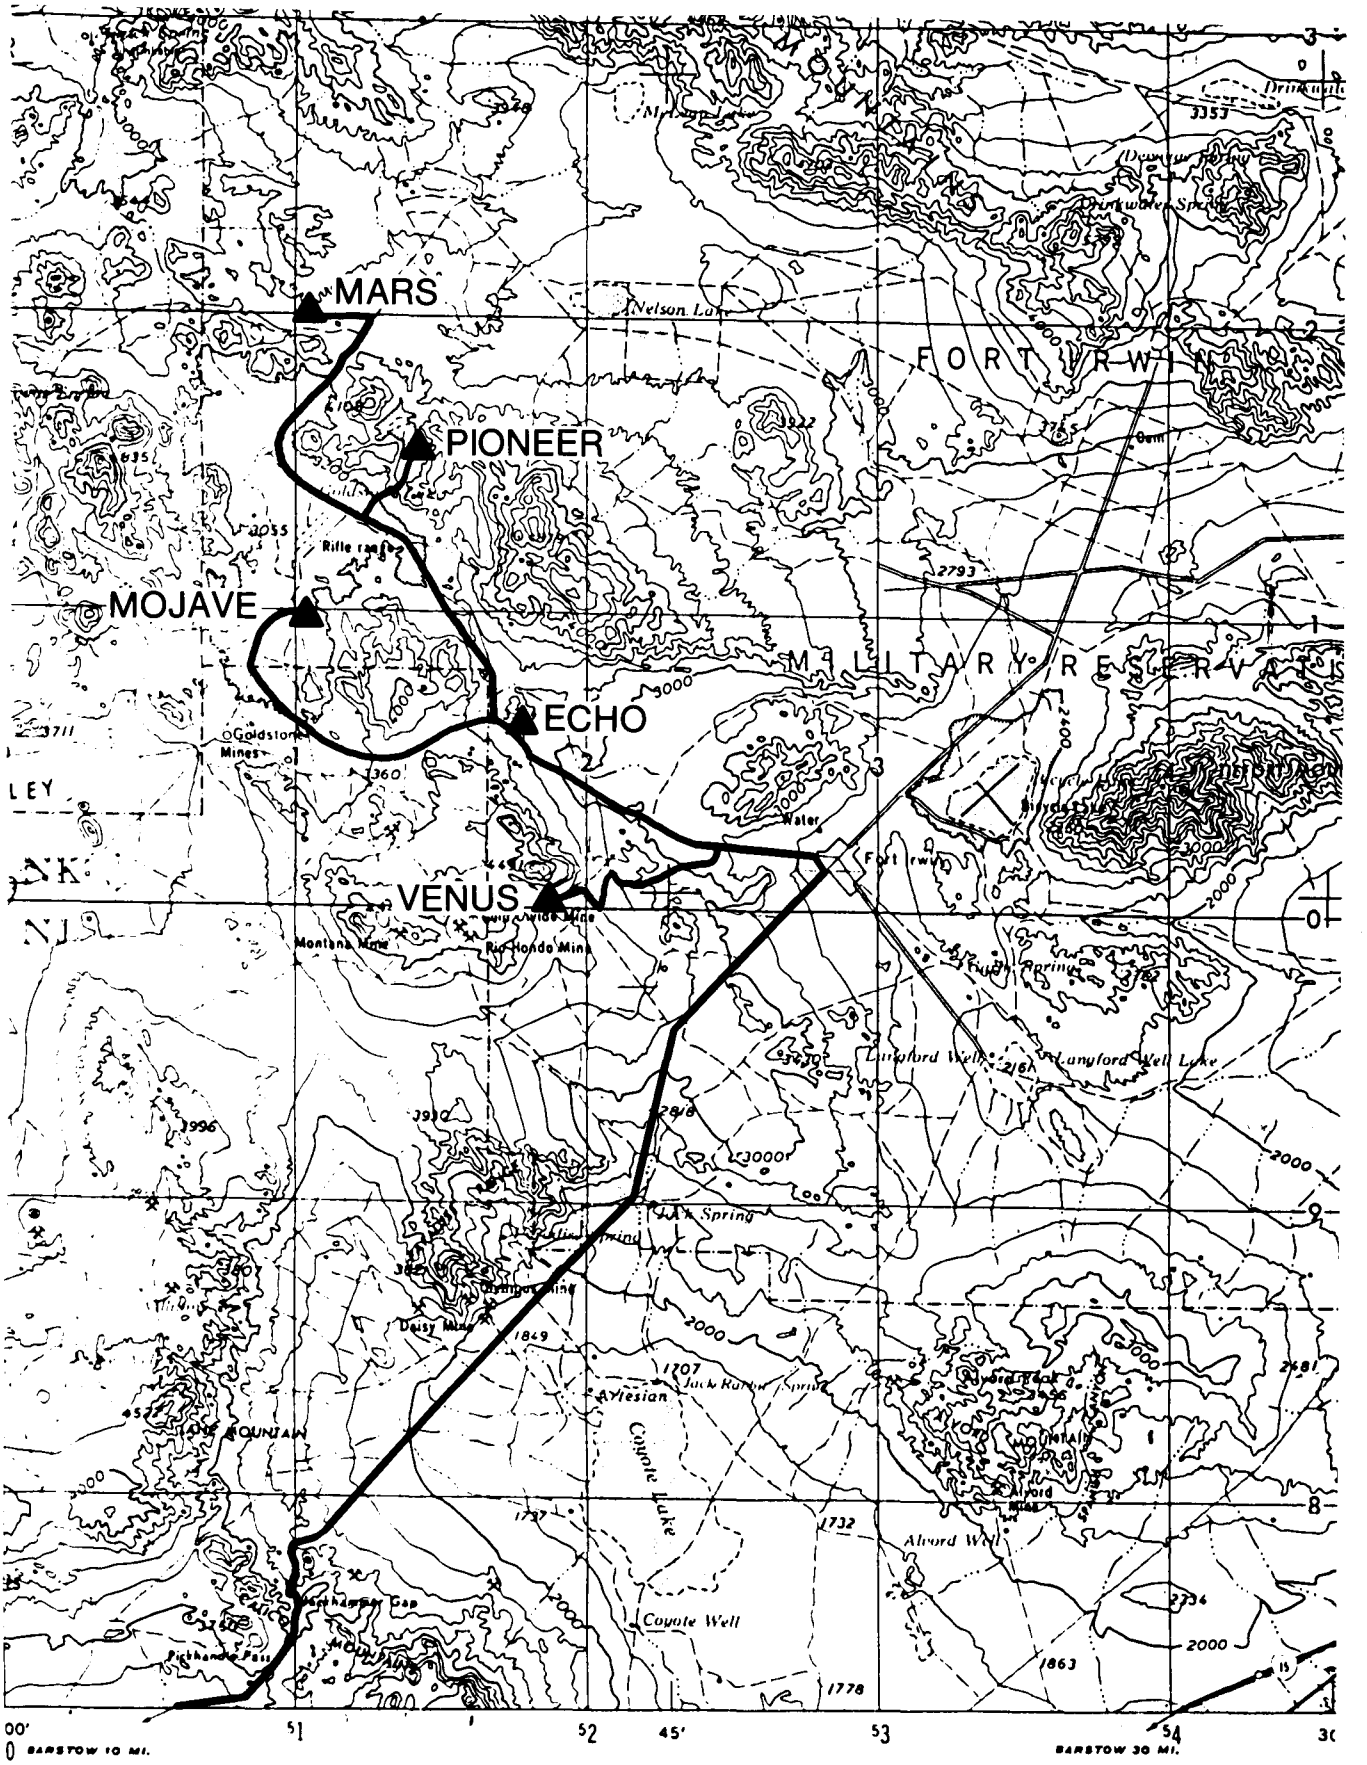

Figure 7.--Route of first-order leveling connecting the VLBI sites within the Goldstone complex.

Leveling does not directly yield geometric quantities, but rather "geopotential height differences." These can only be converted to geometric quantities to the extent that the gravitational field is accurately known within the survey area. The transformation from geopotential heights to orthometric heights was particularly important in this survey because the zenith distance measurements were weak. We believe that the geop synthesized by astro-gravimetric leveling should have an accuracy of about 5 to 10 cm over the extent of the Goldstone complex. The full amount of this error would enter directly into the vertical components of the longest vectors, most notably the MARS-VENUS vector.

Gravity

Just as with the leveling, the gravity observations were accomplished in conjunction with the SCARP project. The most stringent precautions were taken to ensure the accuracy of the measurements, including special calibration of the gravimeters, the simultaneous use of two or more units, full ladder sequence of observations, and frequent ties between a selected set of stations during the progression of the survey by helicopter. Appendix A contains the results of the least-squares adjustment of the gravity observations used in the Goldstone survey.

Satellite Doppler Observations

The NGS has made satellite Doppler observations at both the Mars and Venus sites. The differences between the X, Y, Z Cartesian coordinates of station MARS (1963) (as computed from the NAD 1927 horizontal position, the orthometric height determined during this survey, and a geoidal separation of -19.222 meters) and the NSWC 97-2 Doppler coordinates were used to relate the Goldstone network to the geocenter. The Doppler station designation is 51212 and the position was derived from observations of 371 satellite passes collected during January 1978, using program DOPPLR (NGS-02 version dated February 1976). The North American Datum 1927 and transformed coordinates are tabulated on page 47 of appendix B, under the heading "Adjusted Cartesian Coordinates."

NETWORK ADJUSTMENT

After the various types of observations had been individually preprocessed (i.e., corrections added, statistical tests applied, outliers rejected, and least-squares adjustments performed when appropriate) all of the survey data (including data from phases I, II, and III) were adjusted using NGS program HAVAGO (Vincenty 1979).

The complete input and output portions of the "final adjustment" (i.e., the adjustment using what we judged to be the best available data set) are reproduced in appendix B. The reader should be able to find the important information concerning a particular station or vector without difficulty by referring to the self explanatory labels provided in the HAVAGO printouts. The standard errors stated in appendix B are formal values, and users of the data should be aware of the possibility that systematic errors may further degrade the accuracy, as we have previously described.

The base line components which are of particular interest were extracted from appendix B and are shown in table 1. The VLBI vectors are with respect to axis intersection, and the SLR vector is with respect to station monuments.

Table 1.--Components of VLBI and SLR vector base lines in an equatorial reference

VECTOR	ΔX m	S.E. m	ΔY m	S.E. m	ΔZ m	S.E. m	S m
MARS VLBI - VENUS VLBI	-2492.02	±0.03	14135.45	± 0.03	16095.49	± 0.02	2156.85

SLR 7085 - SLR 7115	-2532.52	±0.03	14016.62	± 0.03	15901.40	± 0.02	21347.93

CONCLUSIONS

The Goldstone survey is the most extensive and complex high-accuracy, three-dimensional geodetic survey ever performed by NGS. Throughout the project, beginning with the design of the network, to writing the observational specifications, making the observations, reducing and analyzing the data, and ending with the preparation of the report, we have made every attempt to minimize systematic errors. Our goal was to attain the highest possible accuracy, not simply small formal standard errors. We believe that the results represent very nearly the best that can be achieved with present available terrestrial techniques, commensurate with reasonable costs. The vectors between points in any particular site are almost certainly accurate to better than 1 cm, while the vectors between points in the Mars and Venus sites (the most distant sites in the survey) are estimated to be accurate to about 10 cm.

APPENDIX B.--INPUT AND OUTPUT OF PROGRAM HAVAGO

The input and output sections of program HAVAGO (version 82.03.05) are reproduced in this section. The results are based on the best available data. It should be noted that in the output section observed zenith distances have been reduced to the monumented points (marks).
