## Canadä

#### Abstract

The combined 2015 Canada/USA Atlantic cod catches were 608 mt with a quota of 650 mt . Catches in all three research surveys increased since the 2015 assessment, but were still amongst the lowest in the time series. Both fishery and survey catches showed truncated age structure in recent years.

The VPA "M 0.8" model from the 2013 benchmark assessment was used to provide catch advice in conjunction with a consequence analysis of the uncertainties in the VPA "M 0.8" and ASAP model results. In the VPA "M 0.8" model, natural mortality (M) was assumed to be 0.2 except $\mathrm{M}=0.8$ for ages $6+$ since 1994 , whereas in the ASAP model $\mathrm{M}=0.2$ for all ages and years.

While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The adult population biomass at the beginning of 2016 was estimated at $11,026 \mathrm{mt}$, which was about $20 \%$ of the adult biomass in 1978. Fishing mortality was high prior to 1994 ( 0.33 to 0.51 ) but was estimated to be 0.05 in 2015. Recruitment at age 1 has been low in recent years. High natural mortality, lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

In 2017, a 50\% probability of not exceeding fishing reference point $\mathrm{F}=0.11$ corresponds to catches of $1,319 \mathrm{mt}$. Due to the expected contribution of the strong 2010 and 2013 year classes, a catch of $1,319 \mathrm{mt}$ is expected to result in a < 25\% chance of seeing a decrease in adult biomass from 2017 to 2018. In 2018, a catch of 1,483 mt corresponds to a $50 \%$ probability of not exceeding $\mathrm{F}=0.11$ and $\mathrm{a}<25 \%$ probability that 2019 age $3+$ biomass will be lower than 2018. However, given the extremely low spawning stock biomass (SSB), the Transboundary Resources Assessment Committee (TRAC) advises that management aim to rebuild SSB.

A consequence analysis to understand the risks associated with assumptions of the VPA " M 0.8 " and ASAP "M 0.2 " model was examined in the projection and risk analysis. The consequence analysis reflects the uncertainties in the assessment model assumptions. Despite model uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.

## INTRODUCTION

The 2016 assessment for the management unit of cod on eastern Georges Bank (Figure 1) was updated using the 2013 benchmark model formulations (Claytor and O'Brien 2013). The assessment used Canadian and USA fishery information updated to 2015, including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2016, the National Marine Fisheries Services (NMFS) spring survey updated to 2016 and the NMFS fall survey updated to 2015.

## FISHERY

## COMMERCIAL FISHERY CATCHES

Combined Canada/USA catches averaged 17,200 mt between 1978 and 1993, peaked at $26,463 \mathrm{mt}$ in 1982, and then declined to $1,683 \mathrm{mt}$ in 1995. They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2015 were 608 mt , including 25 mt of discards (Table 1; Figure 2). Catches included USA and Canadian discards in all years where discard estimates were available.
In 2015, total Canadian catch (extracted landings on June 1, 2016), including discards, was 492 mt against a quota of 526 mt , taken primarily between June and December by otter trawl and longline (Figures 3 and 4). All 2015 landings were subject to dockside monitoring.
For the Canadian otter trawl fishery on eastern Georges Bank, 130 mm square mesh has been the standard mesh size in codends since 1995. In 2014, a test project with alternative codend meshes of 125 mm square and 145 mm diamond was undertaken for the purpose of improving the catch rate of haddock and reducing cod bycatch relative to haddock catches (Morin 2014). Based on the results, 125 mm square mesh was approved for use in 2015 and 2016 (Appendix A).
Discarding of cod from the Canadian groundfish fishery on eastern Georges Bank (EGB) is not permitted. Since 1997 discards of cod have been estimated using the observed ratio of cod to haddock catch (Van Eeckhaute and Gavaris 2004; Hunt et al. 2005; Gavaris et al. 2006, 2007a; Clark et al. 2008) and in 2015 were calculated as 7 mt from the mobile gear fishery (Table 1).

The Canadian scallop fishery has not been permitted to land cod since 1996. Since 2005, estimates of cod discards from the scallop fishery have been obtained by applying a 3month moving average observed discard rate to the effort of the fleet (Gavaris et al. 2007b). In 2015, the estimated discards of cod by the Canadian scallop fishery were 13 mt (Table 1).

Total USA catch (landings and discards combined) was 116 mt for calendar year 2015 (Table 1; Figure 5). The majority of USA landings were taken in the second calendar quarter with the least amount landed during the fourth quarter (Figure 4). Otter trawl gear accounted for $75 \%$ and gillnet gear about 25\% of the 111 mt landings during 2015.

Discard ratios (discard:kept, d:k) in the US fisheries are estimated on a trip basis (Wigley et al. 2008) and total discards (mt) then estimated from the product of d:k and total commercial landings. In the 2012 SAW55 cod benchmark meeting (NEFSC 2013), 'Delphi’ determined mortality rates (otter trawl: 75\%) were applied to the final estimates of USA discards (Table 1). In July 2013, there was a reduction in the minimum size for the US fishery from 22 inches to 19 inches. The estimated discards of cod in the groundfish fishery were 5 mt in 2015 (Table 1; Figure 5). Cod discarded by the lobster fleet in eastern

Georges Bank were about 4 mt but given these are preliminary estimates, were not included in the total discard estimate.

## SIZE AND AGE COMPOSITION

The size and age compositions of the 2015 Canadian groundfish fishery landings were derived from the pooled port and at-sea samples from all principal gears and seasons (Table 2; Figure 6). Landings by length peaked at 55 cm (22 in) for bottom trawlers and 70 cm (28 in) for longliners. Gillnetters caught fewer cod but these fish were larger, peaking at 79 cm (31 in) (Figure 7). The combined landings for all gears peaked at $58-73 \mathrm{~cm}(23-29$ in) (Figure 8). The Canadian combined cod discards size composition by length was derived from at-sea sampling, and peaked at 37 cm (15 in) (Figure 7, Figure 8).
Otoliths taken from port samples were used for age determinations. Past comparisons have indicated generally good agreement between DFO and NMFS age readers, (http://www.nefsc.noaa.gov/fbp/QA-QC/). In 2015 the agreement between readers for DFO samples from quarters two and three was lower than expected (66\% compared to $>84 \%$ for all other samples), resulting in additional training being initiated in 2016. Catch-at-age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2015 DFO survey was used to augment the first quarter key.
Details of the methodology used for the determination of size and age composition of USA fishery landings and discards on eastern Georges Bank are described in Wang et al. (2015). The 2015 catch at age calculations were supplemented with age and length samples from statistical area (SA) 522 due to low samples from SA 561 and 562. Landings by length peaked at $56 \mathrm{~cm}(22 \mathrm{in})$ and discards by length peaked at 41 cm (16 in) in 2015 (Figure 9). The 2015 total catch composition peaked at 58-73 cm (23-29 in) for the Canadian fishery and at $56 \mathrm{~cm}(22 \mathrm{in})$ for the USA fishery (Figure 10).
The 2015 combined Canada/USA landings and discards fishery age composition, by number, was the highest for the 2011 year class at age 4 (31\%) and the 2013 year class at age 2 (29\%) (Table 3; Figure 11). By weight, the 2011 year class dominated the 2015 fishery ( $38 \%$ ) followed by the 2010 year class (31\%) (Figure 11). The contribution of age 7 and older fish continue to be low in recent years, amounting to $0.4 \%$ by number and $1 \%$ by weight in 2015 (Table 3; Figure 12).
Following a decline throughout the 1990s, fishery weights at age remained low throughout the 2000s, but showed an improvement in 2015 for all ages except age 3 (Table 4; Figure 13). This is consistent with observations made by members of the industry at the 2015 TRAC that fish are appearing healthier than they have over the past 8-10 years (Curran and Brooks 2015).

## ABUNDANCE INDICES

## RESEARCH SURVEYS

Surveys of Georges Bank have been conducted by DFO every February/March since 1986, and by NMFS each spring (April) since 1968 and fall (October) since 1963. All surveys use a stratified random design (Figures 14 and 15) and historic changes in vessels and nets are documented in Wang et al. (2015). In 2016, the DFO survey was conducted by the CCGS Teleost instead of the usual survey vessel, the Alfred Needler. Using data from a comparative paired trawl fishing experiment conducted in the southern Gulf of St. Lawrence, the analysis showed no significant difference in the catchability of
cod between Alfred Needler and Teleost (Benoît, 2006). The 2016 NMFS spring survey was delayed by approximately one month due to mechanical issues with the research vessel. Consequently, ages were not available for the 2016 NMFS spring survey, so the ALK from the 2016 DFO spring survey was applied.

The spatial distribution of ages 3 and older cod caught during the 2015 NMFS fall, 2016 DFO and NMFS spring surveys were similar to observations from those surveys over the previous decade, with most fish concentrated on the northeastern part of Georges Bank (Figures 16-18).

The swept area abundance from the 2016 DFO survey increased slightly from 2015, but remained amongst the lowest in the time series (1986-2016) (Table 5). The 2013 year class at age 3 contributed $54 \%$ by number, followed by the 2011 year class at age 5 (15\%) and the 2012 year class at age 4 (11\%). The 2015 year class at age 1 contributed $0.4 \%$ of the catch and there was no catch of fish older than 8 (Table 5; Figure 19). The 2016 NMFS spring survey catch increased from 2015 (the series low since 1995), but continues to remain below the series mean since 1995 (Table 6). The 2013 year class at age 3 was dominant ( $65 \%$ by number), followed by the 2014 year class at age 2 (16\%) and 2012 year class at age 4 (8\%). The catch from the 2015 NMFS fall survey increased to the highest value since 2004. The age 2 fish (2013 year class) dominated the catch by number (65\%), followed by the 2014 year class at age 1 ( $12 \%$ by number). Consistent with trends seen since 2010, the fall survey continues to see few or no fish over the age of 5 (Table 7; Figure 19). Overall, the survey abundance at age shows poor recruitment since the 1990 year class in all three surveys and representation of older ages in recent years has decreased (Tables 5-7; Figure 19).

The coefficient of variation (CV) of stratified mean catch number per tow for the three surveys is shown in Table 8 and Figure 20. In 2016, the DFO and NMFS fall surveys had smaller CVs compared to the NMFS spring survey which had one of the highest values in the time series. The high variability in catches from the NMFS spring survey was largely influenced by two big tows. The catch from all three surveys became more variable after mid-1990s, which might be caused by patchy distribution of cod at low abundance.
Survey swept area biomass for all three surveys increased from last year, but remains among the lowest in the time series for the spring surveys (Table 9; Figure 21).
The number weighted average weights at age derived from the DFO survey and NMFS spring survey were used to represent the population weight at age for the beginning of the year (Table 10, Figure 22). Fulton's condition factor (K) for all three surveys showed a notable downward trend throughout the series until 2009, when condition began to increase rapidly for the US surveys (Figure 23); in 2015, NMFS fall survey reached a series high. The condition of cod in the DFO survey showed high variability and a slower rate of increase since 2009, but did reach the series average in 2016 (Figure 23). The exact effect of the 2016 NMFS spring survey delay on cod condition has not yet been examined. Overall, trends in condition are consistent with industry comments made during the 2015 TRAC meeting (Curran and Brooks, 2015).

The total mortality $(Z)$ was calculated by two age groups (ages 4-5 and ages 6-8) using DFO survey and NMFS spring survey abundance indices separately (Figure 24). It showed that $Z$ of ages 4 and 5 has been generally lower than the older age group, except in 2015 for the NMFS spring survey when the two were equivalent (Figure 24). $Z$ has remained high throughout the assessment time period for both age groups, even
increasing in recent years for DFO, although relative $F$ (fishery catch at age per survey abundance indices) has declined significantly since the 1990s (Figure 25).

## ESTIMATION AND DIAGNOSTICS

## CALIBRATION OF VIRTURAL POPULATION ANALYSIS (VPA)

At the benchmark assessment review in 2013 there was no consensus on a benchmark model, however, the TRAC did agree to provide catch advice based on a virtual population analysis (VPA) "M 0.8" model, in conjunction with a consequence analysis that compares the VPA and ASAP model (presented below) projection results (Claytor and O'Brien 2013). The VPA used fishery catch statistics and size and age composition of the catch from 1978 to 2015 (including discards). The adaptive framework, ADAPT (Gavaris 1988), was used for calibrating the VPA with trends in abundance from three research bottom trawl survey series: DFO, NMFS spring and NMFS fall. Computational formulae used in ADAPT are described in Rivard and Gavaris (2003a).

In this model, natural mortality (M) was assumed equal to 0.2 for all years and ages, except for ages $6+$ since 1994 where it was fixed at 0.8 . The data used in the model were:
$C_{a, t}=$ catch at age for ages $a=1$ to $10+$ and time $t=1978$-2015, where $t$ represents the year during which the catch was taken.
$I_{1, a, t}=$ DFO survey for ages $a=1$ to 8 and time $t=1986.17,1987.17 \ldots$ 2015.17, 2016.00.
$I_{2, a, t}=$ NMFS spring survey (Yankee 41) for ages $a=1$ to 8 and time $t=1978.28$, 1979.28, 1980.28, 1981.28.
$I_{3, a, t}=$ NMFS spring survey (Yankee 36) for ages $a=1$ to 8 and time $t=1982.28$, 1983.28... 2015.28, 2016.00.
$I_{4, a, t}=$ NMFS fall survey for ages $a=1$ to 5 and time $t=1978.69,1979.69 \ldots 2014.69$, 2015.69.

The population was calculated to the beginning of 2016; therefore the DFO and NMFS spring survey indices for 2016 were designated as occurring at the beginning of the year. The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically-distributed after taking natural logarithms of the values. Zero observations for abundance indices were treated as missing data, as the logarithm of zero is not defined. In the 2016 assessment, fishing mortality on age 9 for 1978-2013 and 2015 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8 . As there were no age 9 cod caught in the 2014 fishery, the population at age 9 in 2014 was estimated (as done for the 2015 assessment).
This approach is considered a deviation from the 2013 benchmark formulation, but no specific guidance exists on how to address a situation without age 9 cod in the CAA.
Estimation was based on minimization of the objective function:

$$
\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}
$$

where $s$ indexes survey. The estimated model parameters were:
$V_{a, t}=\operatorname{In} N_{a, t}=\ln$ population abundance for ages $a=2$ to 9 at beginning of 2016; age 9 in 2014.
$K_{1, a}=\operatorname{In}$ DFO survey catchability for ages $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1986$-2016.
$K_{2, a}=\ln$ NMFS spring survey (Yankee 41) catchability for ages $a=1$ to 8 at time $\mathrm{t}=1978$-1981.
$K_{3, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time t=1982-2016.
$K_{4, a}=\operatorname{In}$ NMFS fall survey catchability for ages $a=1$ to 5 at time $\mathrm{t}=1978$-2015.
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993; Rivard and Gavaris 2003a).

For the beginning of 2016, the population abundance estimate of the 2014 year classes at age 2 exhibited the largest relative bias of $21 \%$ and relative error of $77 \%$ (Table 11). The relative bias for other ages ranged between $2 \%$ and $9 \%$ and the relative error ranged between $28 \%$ and $43 \%$. The population abundance of the 2005 year class at age 9 in 2014 was estimated as 0.1 million, with relative bias of $2 \%$ and relative error of $22 \%$. Survey catchability $(q)$ at age progressively increased until age 5 for DFO and age 4 for the NMFS spring surveys; catchability at age for the NMFS fall survey remains very low (Table 11, Figure 26).

The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994 (Figure 27), though atage residual patterns suggest obvious year effects (Figure 28). Average fishing mortality (F4-9) by time blocks for 1978-1993, 1994-2010 and 2011-2015 was $0.48,0.25$ and 0.07 respectively, which is consistent with fishery management effort trends. The fishery partial recruitment (PR) has domed substantially since 2011, especially when compared to the relatively flat pattern seen in the earlier time periods for ages 6 through 9 (Figure 29). The causes and consequences of this change in partial recruitment need to be examined further. Of particular concern is the appropriateness of $\mathrm{F}=0.11$ as a fishing mortality reference point, which assumes flat-top PR.

Retrospective analysis was used to detect any bias of consistently overestimating or underestimating fishing mortality, biomass, or recruitment relative to the terminal year estimates. At the 2013 benchmark meeting, the VPA "M 0.8 " model with catch data through 2011 did not show any retrospective pattern (Claytor and O'Brien 2013). However, when the 2013 assessment was updated with data through 2013 (Wang and O'Brien 2013a), the 2003 year class was estimated to be substantially smaller ( 4.1 million at age 1) than the estimate from the 2013 benchmark model formulation ( 13.5 million at age 1) with one less year of data (Figure 30); estimates from all subsequent assessment were $\sim 4.4$ million, mirroring the 2013 assessment estimate (Table 14 in Wang et al. 2014). The average Mohn's rho was calculated for the seven retrospective relative differences in assessment years 2009-2015. The values for Mohn's rho were 0.47 for SSB, -0.32 for $F$, and -0.02 for age 1 recruitment (Table 12).
Possible reasons for the appearance of a retrospective bias were explored during the 2013 and 2014 assessments (Wang and O'Brien 2013a; Wang et al. 2014) and included:

- Error in the fishery catch which caused low catch of the 2003 year class at age 9 in 2012 or, conversely, error which caused high catch of the 2003 year class at the younger ages (3-6).
- Actual natural mortality experienced by the 2003 year class between ages 8 and 9 was higher than the assumed $\mathrm{M}=0.8$ ( $\mathrm{Z} \gg 1$ from surveys using catch curve analysis). Using the assumed natural mortality would artificially reduce the abundance of the entire 2003 cohort in the backward calculation (even if the 0.8 is a good approximation of M among ages 6 and 7).

Sensitivity analyses were conducted for the uncertainties in the estimation of the 2003 year class (Wang and O'Brien 2013a; Wang et al. 2014) and suggested that the low estimate of the 2003 year class may be an outlier, causing a retrospective bias in the 2013 and 2014 assessment. The " M 0.8 " model got very similar population abundance estimates of other year classes in the terminal year or recruitments in other years when the effect of the 2003 year class was removed from the objective function by removing the 2003 year class abundance indices. Also the bias in the estimate of the 2003 year class had little impact on projection in the 2013 and 2014 assessment (Wang and O'Brien 2013a; Wang et al. 2014).
The 2015 assessment (Wang et al. 2015) proposed a fix for the retrospective bias ('est 2003 yc' model) by estimating the 2003 year class. This document updates the 'est 2003 yc' model for consistency with last year's assessment (Figure 31). The average Mohn's rho was calculated for the seven retrospective relative differences in years 2009-2016. The values for Mohn's rho were 0.27 for SSB, -0.11 for F, and 0.07 for age-1 recruitment (Table 12).

Applying the Mohn's rho adjustment was thought not to be appropriate and was not conducted in this assessment. Residuals of the 2003 year class from the three surveys were predominantly positive, which means that the 2003 year class was underestimated in the 2013 through 2016 assessments from the "M 0.8" model (Figure 32); Mohn's rho adjustment would further underestimate the biomass. The sensitivity analysis in the 2013 and 2014 assessment illustrated the terminal year population abundance estimate and projection from the VPA "M 0.8 " model is robust to the uncertainties in the estimate of the 2003 year class.

## STATE OF RESOURCE

The estimates presented below are from the 2016 VPA "M 0.8" model (Tables 13-15).
Adult population biomass (ages 3+) declined substantially from 1990 to 1995, fluctuating between $5,900 \mathrm{mt}$ and $18,800 \mathrm{mt}$ since then (Table 13; Figure 33). The increases of age 3+ biomass throughout the mid-2000s and again since 2011 were largely due to the recruitment and growth of the 2003 and 2010 year classes. The adult population biomass at the beginning of 2016 was estimated to be 11,026 mt ( $80 \%$ confidence interval: 9,238$13,876 \mathrm{mt}$ ) by the 2016 "M 0.8" model, or one-fifth of the 1978 biomass (Table 13; Figure 33). An assumption of high natural mortality, lower weights at age in recent years and generally poor recruitment likely have contributed to the lack of sustained rebuilding.

Recruitment at age 1 has been low in recent years, with the 2003 year class remaining the highest estimated recruitment since 2000 at 4.5 million fish; a number which constitutes less than half of the average recruitment seen between 1978 and 1990 (Table 14; Figure 33). The 2016 "M0.8" model estimate of the 2010 year class at age 1 is 3.5 million, which constitutes two thirds of the 2003 year class based on the 2016 assessment. Recruitment for the 2002, 2004, 2008 and 2012 year classes are the lowest on record and the current biomass remains below the level above which chances of higher recruitment
increase (Figure 34). The current estimate of the 2013 year class is 4.4 million fish (Table 14).

Fishing mortality (population number weighted average of ages 4-9) was high prior to 1994 (Table 15; Figure 35) but declined in 1995 to $\mathrm{F}=0.11$ due to restrictive management measures. F in 2015 was estimated to be 0.05 ( $80 \%$ confidence interval: 0.045-0.071). The assessment showed that $F$ has been declining since 2007 and has been at or below $\mathrm{F}=0.11$ since 2011.

## PRODUCTIVITY

Trends in recruitment, natural mortality, age structure, fish growth, and spatial distribution typically reflect changes in the productive potential of a population. While management measures have resulted in a decreased exploitation rate since 1995 (Figure 25), total mortality has remained high and adult biomass has fluctuated at a low level. The current biomass is well below $30,000 \mathrm{mt}$; the threshold above which historically there is a better chance for higher recruitment (Figure 33). Average weight at length, used to reflect condition, has been stable in the past, but has started to decline in recent years. Fishery weight at age had been declining throughout the 1990s and 2000s, but is beginning to show some signs of improvement for select ages since 2010 (Table 4; Figure 13). The research survey spatial distribution patterns of adult (age 3+) cod have not changed over the past decade (Figures 16-18). High natural mortality of age 6+, low weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality reference. At the 2013 benchmark meeting, it was agreed that the current $\mathrm{F}_{\text {ref }}=0.18$ (TMGC meeting in December 2002) is not consistent with the VPA "M 0.8 " model, and a lower value for $\mathrm{F}_{\text {ref }}$ would be more appropriate (Claytor and O'Brien 2013). At the 2014 TRAC meeting, it was agreed that $\mathrm{F}=0.11$ was an appropriate fishing reference point for the VPA "M 0.8 " model based on the analyses presented (O'Brien and Worcester 2014). This value was derived from an age-disaggregated Sissenwine-Shepherd production model using M=0.8 (Wang and O'Brien 2013b). When stock conditions are poor fishing mortality rates should be further reduced to promote rebuilding.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2017 and 2018 (Gavaris and Sinclair 1998; Rivard and Gavaris 2003b).

Uncertainty about current biomass generates uncertainty in forecast results, which is expressed here as the probability of exceeding $\mathrm{F}=0.11$ in 2017 and 2018, as well as the change in adult biomass from 2017 to 2018 and from 2018 to 2019. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, risk calculations are dependent on the data, and model assumptions and do not include uncertainty due to variations in weight at age, PR to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough.

For projections, the average of the most recent three years of fishery and survey weights at age is used for fishery and beginning year population biomass for 2017-2019. The 2016-2018 PR is based on the most recent five years of estimated PR (Table 16). The 2010-2014 average recruitment at age 1 is used for 2016-2019 projections. The uncertainties for this estimate are not reflected in the projection, but the projection could be optimistic if the abundance of the 2015 and 2016 year classes is lower.

During the 2015 TRAC assessment it was discovered that the age-specific difference in natural mortality was not accounted for in calculations of stochastic risk projections for the VPA "M = 0.8" model (Wang et al. 2015). Following meeting recommendations, this error was corrected and the implications of this on catch advice since 2009 is summarized in Table 21.

## 2017 Projection and Risk Analysis

Assuming a 2016 catch equal to the 625 mt total quota, both deterministic (Table 17) and stochastic (Table 18; Figure 36) projections based on $F$ reference point 0.11 are provided. In 2017, a $50 \%$ risk of not exceeding $F=0.11$ corresponds to a catch of $1,319 \mathrm{mt}$, and a lower risk ( $25 \%$ ) corresponds to a catch of $1,138 \mathrm{mt}$ (Table 18; Figure 36). Due to the expected contribution of the 2013 yearclass, which is larger compared to other recent year classes, the higher catch of $1,319 \mathrm{mt}$ results in a $<25 \%$ chance of a biomass decrease from 2017 to 2018 (Table 18, Figure 36).

## 2018 Projection and Risk Analysis

Assuming a 2016 catch equal to the 625 mt total quota and a 2017 fishing mortality of 0.11 , the deterministic projection for 2018 is shown in Table 17. In 2018, a $50 \%$ risk of not exceeding $F=0.11$ corresponds to a catch of $1,483 \mathrm{mt}$, while a lower risk (25\%) corresponds to a catch of $1,289 \mathrm{mt}$ (Table 18; Figure 37). Similar to the 2017 projection, given the strength of the 2013 yearclass, even a higher catch of $1,483 \mathrm{mt}$ has a less than 25\% chance of a biomass decrease from 2018 to 2019 (Figure 37).

## Consequence Analysis (Risks Associated with 2017-2018 Projected Catch)

A consequence analysis to understand the risks associated with assumptions of the VPA " M 0.8 " and ASAP "M 0.2 " models (Appendix B) was examined. This consequence analysis shows (Table 19):

1. The projected catch (ages $1+$ ) at $\mathrm{Fref}=0.18$ and $\mathrm{F}=0.11$ and percent change in biomass, as if each model represented the "true state" of the resource; and
2. The consequences to fishing mortality and expected biomass (ages 3+) when 'true state' catch levels are removed under the assumptions of the other "alternate state" model.
In 2017, a catch of 1319 mt at $\mathrm{F}=0.11$ would result in the 2018 biomass increasing by $5.1 \%$ in the VPA "true state" and decreasing by $0.5 \%$ in the ASAP "alternate state". A catch of 515 mt at $\mathrm{F}_{\mathrm{ref}}=0.18$ would result in the 2018 biomass increasing by $19 \%$ based on the ASAP "true state" and an increase of $10.6 \%$ in the VPA "alternate state".

In 2018, a catch of 1483 mt at $\mathrm{F}=0.11$ would result in 2019 biomass increasing by $9.3 \%$ in the VPA "true state" and increasing by $10.4 \%$ in the ASAP "alternate state". A catch of 646 mt at Fref=0.18 would result in the 2019 biomass increasing by $29 \%$ based on the ASAP "true state", and increasing by $26.9 \%$ based on the VPA "alternate state".

## SPECIAL CONSIDERATIONS

Table 20 summarizes the performance of the management system. It reports the TRAC advice, TMGC quota decision, actual catch, and realized stock conditions for this stock.

Fishing mortality and trajectory of ages 3+ biomass from the assessment following the catch year are compared to results from this assessment. These comparisons were kindly provided in 2011 by Tom Nies (staff member of the New England Fishery Management Council, NEFMC) and updated for this assessment. The inconsistency of TRAC advice in the past, with the realized stock conditions from the recent assessment, was mainly due to assessment model changes following the 2009 benchmark assessment. Further, the retrospective bias in the assessment also accounted for part of this inconsistency.

The consequence analysis reflects the uncertainties in the assessment model assumptions. Considering the current poor stock conditions, despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.

## ACKNOWLEDGEMENTS

We thank B. Hatt of DFO and N. Shepherd of NMFS for providing ageing information for the DFO and NMFS surveys and Canadian and USA fisheries., G. Donaldson and D. Frotten of DFO and at sea observers from Javitech Ltd. for providing samples from the Canadian fishery.

Table 6. Indices of swept area abundance (thousands) for eastern Georges Bank cod from the NMFS spring survey, 1970-2016. Conversion factors
to account for vessel and trawl door changes have been applied. During 1973-1981 a Yankee 41 net was used rather than the standard Yankee 36 net. DFO

Table 9. Swept area biomass (mt) for eastern Georges Bank cod from the DFO, NMFS spring and fall surveys. Conversion factors to account for vessel and trawl door changes have been applied. The biomass conversion factor used for the Henry B. Bigelow since 2009 is 1.58 ( $B_{\text {survey }}=B_{\text {bigelow }} / 1.58$ ).

Table 17. Deterministic projection results for eastern Georges Bank cod based on F reference point 0.11 from the "M 0.8" model. Shaded values are the 2010 year class (dark grey cells) and the 2013 year class (light grey cells). Bolded values show the year classes with assumed recruitments. A dash (-) indicates that this value was not calculated.

| Parameter | Age |  |  |  |  |  |  |  |  |  |  |  |  |

Table 18. Projection and risk analysis result for eastern Georges Bank cod from the "M 0.8" model formulations: a) risk of fishery catch will exceed F reference point 0.11 in 2017 and 2018; and b) risk of ages 3+ biomass will not increase from 2017 to 2018 and from 2018 to 2019.
a)

| Probability | 0.25 | 0.5 | 0.75 |
| :---: | :---: | :---: | :---: |
| 2017 | $1,138 \mathrm{mt}$ | $1,319 \mathrm{mt}$ | $1,607 \mathrm{mt}$ |
| $2018\left(\mathrm{~F}_{2017}=0.11\right)$ | $1,289 \mathrm{mt}$ | $1,483 \mathrm{mt}$ | $1,763 \mathrm{mt}$ |

b)

| Probability | $\mathbf{0 . 2 5}$ | $\mathbf{0 . 5}$ | $\mathbf{0 . 7 5}$ |
| :---: | :---: | :---: | :---: |
| 2017 to 2018 | $1,687 \mathrm{mt}$ | $2,180 \mathrm{mt}$ | $2,848 \mathrm{mt}$ |
| 2018 to $2019\left(\mathrm{~F}_{2017}=0.11\right)$ | $2,424 \mathrm{mt}$ | $2,739 \mathrm{mt}$ | $3,073 \mathrm{mt}$ |

Table 19. Consequence analysis of risks of different management actions taken for Atlantic cod from eastern Georges Bank. Projected catch and ages 3+ biomass are presented for each of two 'true state of nature' management models: VPA "M0.8" model with F=0.11 and ASAP M=0.2 model with Fref=0.18 during 2016-2018 on the main diagonal ("true state"). The risks of the alternative management actions "alternate state" are on the counter diagonal (see text). Fishing mortality (F), January 1 stock biomass, and percent change in biomass $(\% B)$ from the previous year are presented for each projection.

CONSEQUENCE ANALYSIS

Table 20. Comparison of TRAC catch advice, TMGC quota decision, actual catch, and resulting fishing mortality and biomass changes for eastern Georges Bank cod.

| TRAC | Catch Year | TRAC <br> Analysis/Recommendation |  | TMGC Decision |  | Actual Catch ${ }^{(1)}$ ICompared to Risk | Actual F Result ${ }^{(2)}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Amount | Rationale | Amount | Rationale |  |  |
| 1999 ${ }^{(3)}$ | 1999 | 3,100 mt |  | NA | NA | 3,000 mt | Near $\mathrm{F}_{0.1}$ |
| 2000 | 2000 | $3,750 \mathrm{mt}$ | $\mathrm{F}_{0.1}$ | NA | NA | 2,250 mt | Less than Fo.1 |
| 2001 | 2001 | $3,500 \mathrm{mt}$ | $\mathrm{F}_{0.1}$ | NA | NA | $3,500 \mathrm{mt}$ | Above $F_{0.1}$ |

Figure 33. Adult biomass (ages 3+) and year class abundance at age 1 for eastern Georges Bank cod.

Figure 34. Relationship between adult biomass (ages 3+) and recruits at age 1 for eastern Georges Bank cod.

Figure 35. Average fishing mortality rate at ages 4 to 9 and catches for eastern Georges Bank cod. The established fishing mortality threshold reference, Fref=0.18. The F reference point for the " M $0.8 "$ model is 0.11.

Figure 36. Risk of 2017 fishing mortality exceeding F reference point 0.11 and 2018 biomass not increasing from 2017 for alternative total yields of eastern Georges Bank cod from the "M 0.8" model formulation.

Figure 37. Assuming F2017=0.11, risk of 2018 fishing mortality exceeding F reference point 0.11 and 2019 biomass not increasing from 2018 for alternative total yields of eastern Georges Bank cod from the "M 0.8 " model formulation.

## APPENDIX A: MANAGEMENT HISTORY OF EASTERN GEORGES BANK COD FISHERY (1978-2014)

a) Canadian fishery management history of cod on eastern Georges Bank, 1978 to 2014.

| Year | Canadian Management History |
| :---: | :---: |
| 1978 | Foreign fleets were excluded from the 200 mile exclusive economic zones of Canada and USA. |
| 1984 | October implementation of the maritime boundary between the USA and Canada in the Gulf of Maine Area. |
| 1985 | $5 Z$ cod assessment started in Canada; Set TAC; TAC=25,000mt |
| 1986 | TAC $=11,000 \mathrm{mt}$ |
| 1987 | TAC $=12,500 \mathrm{mt}$ |
| 1988 | TAC $=12,500 \mathrm{mt}$ |
| 1989 | TAC=8,000mt; 5Zjm cod assessment. |
| 1990 | Changes to larger and square mesh size; <br> Changes from TAC to individual and equal boat quotas of 280,000lb with bycatch restrictions; Temporary Vessel Replacement Program was introduced. |
| 1991 | TAC=15,000mt; Dockside monitoring; Maximum individual quota holdings increased to $2 \%$ or 600 t (whichever was less). |
| 1992 | TAC $=15,000 \mathrm{mt}$ Introduction of ITQs for the OTB fleet. |
| 1993 | TAC $=15,000 \mathrm{mt}$, ITQ for the OTB fleet not based on recommended catch quotas; OTB <65 fleet was allowed to fish during the spawning season (Mar.-May. 31). |
| 1994 | TAC=6,000mt, <br> Spawning closures January to May 31; <br> Mesh size was 130 mm square for cod, haddock an Pollock for ITQ fleet; <br> Minimum mesh size of 6 " was required for gillnets; <br> Minimum fish size is 43 cm (small fish protocols) for cod, haddock an Pollock for ITQ fleet; <br> OT>65' could not begin fishing until July 1; <br> Fixed gear must choose to fish either $5 Z$ or $4 X$ during June 1 to September 30. |
| 1995 | TAC=1,000mt as a bycatch fishery; <br> January 1 to June 18 was closed to all groundfish fishery; <br> 130 mm square mesh size for all mobile fleets; <br> Small fish protocols continued; <br> 100\% dock side monitoring; <br> Fixed gear vessels with a history since 1990 of 25 mt or more for 3 years of cod, Haddock, Pollock, hake or Cusk combined can participate in $5 Z$ fishery. |
| 1996 | TAC=2,000mt; <br> Prohibition of the landing of groundfish (except monkfish) by the scallop fishery; ITQ vessel require minimum 130 mm square mesh for directed cod, Haddock and Pollock trips; Small fish protocols continued; <br> For community management, quota allocation of each fixed gear based on catch history using the years 1986-1993; <br> $100 \%$ mandatory dockside monitoring and weighout. |
| 1997 | TAC $=3,000 \mathrm{mt}$ |
| 1998 | TAC=1,900mt |
| 1999 | TAC=1,800mt; Mandatory cod separator panel when no observer on board; Jan. and Feb. mobile gear winter Pollock fishery. |
| 2000 | TAC $=1,600 \mathrm{mt}$; Jan. and Feb. mobile gear winter Pollock fishery. |
| 2001 | TAC $=2,100 \mathrm{mt}$ |

| Year | Canadian Management History |
| :---: | :---: |
| 2002 | TAC=1,192mt |
| 2003 | TAC $=1,301 \mathrm{mt}$ |
| 2004 | TAC=1,000mt; Canada-USA resource sharing agreement on Georges Bank. |
| 2005 | TAC=740mt; <br> Exploratory winter fishery Jan. to Feb. 18, 2005; <br> Spawning protocol: $25 \%$ of maturity stages at 5 and 6. |
| 2006 | TAC=1,326mt; <br> Exploratory winter fishery Jan. to Feb.6, 2006; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2007 | TAC=1,406mt; <br> Exploratory winter fishery Jan. to Feb. 15, 2007; <br> High mobile gear observer coverage (99\%); <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2008 | TAC=1,633mt; <br> Winter fishery from Jan. 1 to Feb. 8, 2009; <br> At sea observer coverage $38 \%$ by weight of the mobile gear fleet landings and $21 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2009 | TAC=1,173mt; <br> Winter fishery from Jan. 1 to Feb. 21, 2009; <br> At sea observer coverage $23 \%$ by weight of the mobile gear fleet landings and $15 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2010 | TAC=1,350mt; <br> Winter fishery from Jan. 1 to Feb. 8, 2010; <br> At sea observer coverage $18 \%$ by weight of the mobile gear fleet landings and $6 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2011 | TAC=1,050mt; <br> Winter fishery from Jan. 1 to Feb. 5, 2011; <br> At sea observer coverage $19 \%$ by weight of the mobile gear fleet landings, $20 \%$ by weight of the fixed gear landings and $3 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2012 | TAC=513mt; <br> Winter fishery from Jan. 1 to Feb. 6, 2012; <br> At sea observer coverage $42 \%$ by weight of the mobile gear fleet landings, $26 \%$ by weight of the fixed gear landings and $35 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2013 | TAC=504mt; <br> Winter fishery from Jan. 1 to Feb. 3, 2013; <br> At sea observer coverage $78 \%$ by weight of the mobile gear fleet landings, $29 \%$ by weight of the fixed gear landings and $19 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2014 | TAC=546mt; <br> Winter fishery from Jan. 1 to Feb. 9, 2014; <br> A test project with alternative codend meshes of 125 mm square and 145 diamond for the purpose of improving the catch rate of haddock and reducing cod bycatch relative to haddock catches; <br> At sea observer coverage $60 \%$ by weight of the mobile gear fleet landings, $45 \%$ by weight of the fixed gear landings and $14 \%$ by weight of the gillnet fleet landings <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2015 | TAC=650mt; <br> Winter fishery from Jan. 1 to Feb 2, 2015; <br> Based on results of the 2014 test project 125 mm square mesh was approved for use in 2015 and 2016. <br> At sea observer coverage $75 \%$ by weight of the mobile gear fleet landings, $33 \%$ by weight of the fixed gear landings and $11 \%$ by weight of the gillnet fleet landings <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |

b) USA fishery management history of cod on eastern Georges Bank, 1978 to 2016.

| Year | Regulatory Actions |
| :---: | :---: |
| 1953 | ICNAF era |
| 1973-1986 | TAC implemented for Div 5Zcod; 35,000/year |
| 1977 | Groundfish Fishery Management Plan (FMP) Magnuson-Stevesn Conservation Management Act (MSCMA) |
| 1982 | Interim FMP |
| 1984 | Hague Line implemented |
| 1985 | Multi-species FMP |
| 1989 | Amendment 2 |
| 1994 | Emergency Rule - December Year round closures in effect |
| 1994 | Amendment 5; Days at Sea (DAS) monitoring ; Mandatory reporting : Vessel Trip Reports (VTR) |
|  | Amendment 6 |
| 1996 | Amendment 7; accelerated DAS reduction |
|  | Sustainable Fisheries Act (SFA) |
| 1999 | Amendment 9 |
| 2002 | Interim rule ; 20 \% reduction in DAS |
| 2004 | Amendment 13; further reduction in DAS; hard TAC on EGB haddock and cod |
|  | Eastern US/CA Area haddock Special Access Program (SAP) Pilot Progam |
| 2005 | DAS vessels limited to one trip/month in Eastern US/CA Area until April 30; |
|  | Limited accesss DAS vessels required to use separator panel trawl in the area |
| 2006 | Haddock separator trawl or flounder net required in Eastern US/CA area |
| 2008 | Sept - Ruhle trawl (eliminator trawl) allowed in Eastern US/CA area |
| 2009 | Nov- Eastern US/CA area, trawl vessels requried to use separator/Ruhle south 41-40N |
| 2010 | Amendment 16, Framwork 44 implemented; Sector management ; |
|  | US/CA area:prohibition on discarding legal size fish |
|  | Common pool: $500 \mathrm{lbs} /$ day, $5,000 \mathrm{lbs} /$ trip |
| 2012 | US/CA area open May 1 for trawl gear: haddock separator, rhule or flounder trawl |
| 2015-16 | Inside US/CA GB cod: common pool : $100 \mathrm{lb} / \mathrm{DAS}$, $500 \mathrm{lb} /$ trip |
|  | Inside US/CA GB cod: common pool : $100 \mathrm{lb} / \mathrm{DAS}$, $500 \mathrm{lb} /$ trip |
|  | Common pool may fish inside US/CA area uing haddock sparatore trawl, Ruhle trawl, or flounder net |
| 2016 | May 1: sectors allowed to convert eGB allocation into western GB cod allocation during FY, and 2 weeks into new fishing year to cover any overage during previous FY |
|  | Mesh Sizes (inches) |
| 1953 | 4.5 |
| 1977 | 5.125 |
| 1983 | 5.5 |
| 1987 | 6.0 |
| 1989 | eliminate 6 inch increase |
| 1994 | 6.0 |
| 1999 | 6.5 square mesh/ 6.0 diamond mesh |
| 2000 | 6.5 square mesh/ 6.5 diamond mesh |
| 2002 | 6.5 square mesh/ 6.5 diamond mesh/6.5 gill net |
|  | Minimum Size |
| 1977 | 16 inches( 40.6 cm ) commercial and recreational |
| 1982 | 17 inches ( 43.2 cm ) commercial; 15 inches ( 38.1 cm ) recreational |
| 1986 | 19 inches ( 48.3 cm ) commercial; 17 inches ( 43.2 cm ) recreational |
| 1988 | 19 inches (48.3 cm ) commecial and recreational |
| 1997 | 21 inches (53.3) recreational |

| 2011 | Eastern US/CA area closed from May -Jul for trawl gear (common pool vessels only) |
| 2013 | Common pool closure: July 30- Aug 31 for GB cod |

## APPENDIX B

## 2016 Statistical Catch at Age (ASAP) Model Update for Eastern Georges Bank Atlantic Cod

## Introduction

This assessment presents an update of the statistical catch at age model 'Age Structured Assessment Program' (ASAP) reviewed at the 2013 April eastern Georges Bank cod management unit benchmark model meeting. No model was chosen by the TRAC as a benchmark model for stock status, however, the TRAC agreed (Claytor and O'Brien 2013) to use the VPA model results for catch advice with the ASAP model results in a consequence analysis (Appendix B) of projection results to be provided to managers for catch advice.

The ASAP model provided estimates of instantaneous fishing mortality and stock size in 2015. A retrospective analysis was performed for terminal year fishing mortality, spawning stock biomass, and age 1 recruitment. Stochastic projections from model results provide estimated landings and spawning stock biomass (SSB) in 2017-2019.

## Assessment Model Formulation

## Model description

ASAP, a forward projecting statistical catch at age model (Legault and Restrepo 1998) was applied in this assessment and can be downloaded from the NOAA Fisheries Toolbox (NFT, http://nft.nefsc.noaa.gov/). A brief description of the model can be found in the previous assessment (Wang et al. 2015) and for further details, the reader is referred to the technical manual (Legault 2008).

## Data input

Input to the ASAP model is the same as for the VPA 0.8 model, with two exceptions. The ASAP uses beginning year weight-at-age that is back-calculated from the mid-year catch weight-at-age (Rivard 1982; Appendix.Table 1) rather than using the weight estimated from an average of the DFO and NEFSC spring research survey weight-at-age (Table 16). The ASAP also does not use the most recent terminal year +1 surveys (e.g.DFO 2016 and NEFSC 2016).

Natural mortality (M) was age and time invariant and assumed to be 0.2 , which was also applied in earlier assessment models for cod from eastern Georges Bank (Wang and O'Brien 2012).

## Model formulation

The ASAP model formulation (base_rivard) presented and reviewed at the June 2015 TRAC (Wang et al. 2015) was updated for the 2016 assessment. A multinomial distribution was assumed for both fishery catch at age and survey age compositions. The catch CV was set equal to 0.05 and the recruitment CV set equal to 0.5 , however, the recruitment deviations were set with lambda $=0$, so the deviations did not contribute to the objective function.

Both the fishery and survey selectivity was modeled as 'flat-topped'. For the fisheries, two selectivity blocks were modeled as single logistic from 1978-1993 and 1994-2014.

The effective samples size (ESS) of the catch and surveys were adjusted based on interpretation of 'lanelli' plots (McAllister and lanelli 1997). The input ESS is compared to the model predicted ESS; an appropriate ESS is considered to be that which intersects the model predicted ESS.

At the 2013 benchmark (O'Brien and Wang 2013) the CV for each survey was initially set at the value generated from the survey estimate of stratified mean number per tow (DFO STRANAL). For the DFO survey the CVs averaged 0.31 , with a range of $0.15-0.66$, for the NEFSC spring the CVs averaged 0.32 , with a range of $0.13-0.83$, and for the NEFSC autumn survey the CVs averaged 0.47 , with a range of $0.24-0.88$. Further examination of the model fits to the survey indices resulted in adding the following constant to each survey CV vector: 0.25 (DFO), 0.3 (NEFSC spring \#36), and 0.2 (NEFSC autumn), except the NEFSC spring \#41, which was not adjusted. These same values were added during this 2016 update.

For the 2016 TRAC, several sensitivity model formulations were also run to determine the best model to reduce the retrospective bias. The model formulation that resulted in minimal retrospective bias (run 8) is similar to the base_rivard run with the exception of increased CV on the catch ( $C V=0.2$ ). This formulation was explored based on recent analyses indicating that cod caught in the eastern GB statistical areas $(561,562)$ are potentially either under- or over-reported in the vessel trip report (VTR) database (Palmer, pers. comm., see Palmer and Wigley 2007, 2009). Landings ranged from over-reporting of 18 mt to under reporting of 310 mt which resulted in landings being over-reported by $4.2 \%-6.2 \%$ and under-reported by $14 \%-730 \%$ during 2008-2015. The model results of run 8 will be presented and compared to the base_rivard formulation.

## Model Results

Model results, including the objective function (OF), components to the OF, the root mean square error (RMSE) computed from standardized residuals, SSB, fishing mortality (F), recruitment estimates at age 1, and the Mohn's rho retrospective bias adjustments are summarized in Appendix Table 2 for three of the model runs conducted, run 1 (base_repeat): rerun of 2015 model with terminal year (TY) 2014; run3 (base_rivard): update of ASAP model with TY 2015 data, and run 8: base_rivard formulation with an increase in catch CV from 0.05 to 0.2 . The following model results are for run 8 .

## 2016 ASAP - Run 8

Model diagnostics are very similar to last years' assessment (Wang et al. 2015) and to the 2016 base run with the exception of the retrospective bias. Model fit to total catch indicates generally lower predicted catch prior to 1995 and generally higher predicted catch from 1995 onward (Appendix Figure 1). Patterns in residuals still persist in both the catch and in the surveys, (Appendix Figures 2-8). The effective sample size (ESS) for the catch and surveys is still appropriate.

Fishing mortality, SSB, and recruitment
Fully recruited F (unweighted, ages 5+) was estimated at 0.39 in 2015 (Appendix Table 3, Appendix Figure 9), a 46\% decrease from 2014. SSB in 2015 was estimated at 1,577 mt,
a 1\% decrease from 2014 (Appendix Table 3, Appendix Figures 9-10). Recruitment (millions of age 1 fish) of the 2014 year class is estimated at 0.375 million, the second smallest year class, whereas the 2012 year class ( 0.282 million age 1 fish) is the smallest year class. The 2013 year class is estimated at 1.732 million fish, the largest year class since the 2003 year class, now estimated at 2.549 million age 1 fish (Appendix Table 3, Appendix Figures 9-10).

## Retrospective analysis

A retrospective analysis was performed to evaluate how well the ASAP calibration would have estimated F, SSB, and recruits at age 1 for seven years (2008-2014) prior to the terminal year, 2015. The pattern of overestimating SSB and underestimating F relative to the terminal year persists in this assessment, and there is a general pattern of underestimating recruitment relative to the terminal year estimate (Appendix Figure 11), however, the magnitude of the bias is less in run 8 than in the base_rivard run. The retrospective rho values, the average of the last 7 years of the relative retrospective peels, were 0.42 for SSB, -0.40 for $\mathrm{F}_{5+}$, and -0.23 for recruitment. Applying a retrospective adjustment (1/(1+rho)) * estimate) results in estimates of $2015 \mathrm{~F}=0.64$, $\mathrm{SSB}=1,114 \mathrm{mt}$, and age 1 recruitment $=0.3485$ million fish. Since the retrospective adjusted values of SSB and $F$ are within the $90 \%$ probability intervals (see below), the model results do not need to be adjusted for retrospective bias (Figure 12).

## Model uncertainty - MCMC

A Monte Carlo Markov chain (MCMC) simulation was performed to estimate uncertainty in the model estimates. Two MCMC chains of initial length of 5.0 million were simulated with every $2,500^{\text {th }}$ value saved. The trace of each chain's saved draws suggests relatively good mixing for both SSB and F (Appendix Figure 13), i.e. there were no long-term trends to indicate that successive iterations were highly correlated. The lagged autocorrelations showed variable correlation with increased lag, with correlations <= 0.1 beyond lag 0 for SSB and F (figure not shown). The 2015 SSB MCMC estimate of $1,624 \mathrm{mt}$ has a $90 \%$ probability interval (PI) of $1,046 \mathrm{mt}-2,364 \mathrm{mt}$ and the 2015 MCMC average $\mathrm{F}_{5+}=0.38$ has a $90 \% \mathrm{PI}$ of $0.21-0.75$.

## Biological Reference Points

The current negotiated eastern Georges Bank cod fishing mortality reference point is $\mathrm{F}_{\text {ref }}$ $=0.18$ (TMGC 2002).

## Projections

Short term stochastic projections under $\mathrm{F}_{\text {ref }}=0.18$ were performed from the 2016 ASAP run 8 model results to estimate landings and SSB during 2017-2019. The input values for mean catch and stock weights, partial recruitment (PR), and maturity were estimated as 3year averages from 2012-2014. Recruitment was estimated from a 2-stage cumulative distribution function (CDF) based on either 21 low estimates or 14 high estimates of age 1 recruitment. Based on a visual examination of the stock recruit plot (Appendix Figure 10), a cut-point of $15,000 \mathrm{mt}$ was established, such that, when SSB is less than $15,000 \mathrm{mt}$, recruitment is drawn from the low recruitment CDF, and when SSB is greater than 15,000 mt , recruitment is drawn from the high recruitment CDF. Catch in 2016 was estimated based on the assumption that the 2016 quota of 625 mt would be caught.

The results of the short term projections indicate under $\mathrm{F}_{\text {ref }}=0.18$, catch is projected to decrease in 2017 and increase in 2018. SSB is projected to increase in 2017 and again in 2018.

| Year | SSB | F | Catch |
| ---: | ---: | ---: | ---: |
| 2016 | 2802 | 0.33 | 625 |
| 2017 | 3201 | 0.18 | 515 |
| 2018 | 3787 | 0.18 | 646 |

## Summary Discussion

Productivity of EGB has been low for the last two decades with poor recruitment and truncated age structure. An increase in natural mortality may have contributed to the recent low productivity, however; food habits data do not support this hypothesis (NEFSC 2013). Analysis of tagging data indicates minimal increase in M from the 1980s to the 2000s, and thus does not appear sufficient to explain the long term low productivity (Miller et al. 2013). Lack of large numbers of older repeat spawners in the EGB cod population since the mid-1980s may contribute to the long-term low productivity. Cod have a low success rate of hatching for $1^{\text {st }}$ and $2^{\text {nd }}$ time spawners ( $13 \%$ and $62 \%$ ) until the $3^{\text {rd }}$ spawning (100\%), suggesting that an expanded age structure of fish that have spawned 3 or more times would contribute to higher productivity (Trippel 1998, Carr and Kaufman 2009). Long-term overfishing may have also had indirect effects. Fishing activity disrupts the spawning aggregation and thus behaviors and rituals of cod, reducing the potential of good recruitment (Dean 2012). Spawning of cod involves complex behaviors that have only recently been observed including arrival and departure of fish on the spawning ground at different times dependent upon sex, age, and stage of maturity (Lawson and Rose 2000) and the formation of spawning leks, where the males set up and defend territory (Windle and Rose 2007).

The 2016 updated base model formulation provides similar results to the 2015 ASAP assessment (Wang et al. 2015) but with an increase in the retrospective bias in $F$ and SSB. However, the run 8 model formulation, with increased uncertainty in the catch estimates, decreases the retrospective bias such that retrospective adjustment of SSB and $F$ is not necessary. Run 8 model results were used in the projection analyses.

Appendix Figure 1. ASAP model fit to total catch of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1978-2015.

Appendix Figure 2. ASAP model residuals for the commercial catch age composition of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1978-2015.

Appendix Figure 3. ASAP model fit to DFO survey indices of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1986-2015.

Appendix Figure 4. ASAP model run age composition residuals for DFO survey index of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1986-2015.

Appendix Figure 5. ASAP model fit to NEFSC autumn survey indices of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1978-2015.

Appendix Figure 6. ASAP model age composition residuals for NEFSC autumn survey index of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1978-2015.

Appendix Figure 7. ASAP model fit to NEFSC spring Yankee \#36 trawl survey indices of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1982-2015.

Appendix Figure 8. ASAP model age composition residuals for NEFSC spring Yankee \#36 trawl survey index of eastern Georges Bank cod, base (left panel) and run 8 (right panel), 1982-2015.

Appendix Figure 9. ASAP model results for fishing mortality (ages 5+), spawning stock biomass, and recruitment (age1, 000s fish), base and run 8, 1978-2015.

Appendix Figure 10. ASAP model results for spawning stock biomass ( mt , line) and recruitment (age1, 000s fish, bars; upper panels) and the stock - recruitment plot (lower panels) with year-class designation, 1978-2015 ; base (left panels), run 8 (right panels).

Appendix Figure 11. ASAP model results of retrospective bias of fishing mortality (F), spawning stock biomass (SSB), and age1 recruitment; base (left panels), run 8 (right panels).

Appendix Figure 12. Terminal year 2015 ASAP estimates of spawning stock biomass (SSB) and fishing mortality (F) with respective $90 \%$ probability intervals, and the rhoadjusted value of SSB and $F$ from ASAP run 8.

Appendix Figure 13. ASAP model results of trace of MCMC chains for eastern Georges Bank cod fishing mortality (top panels) and spawning stock biomass (bottom panels) for 1978 and 2015. Each chain had an initial length of 5.0 million and was thinned at a rate of one out of every $2,500^{\text {th }}$ resulting in a final chain length of 2000; base (left panels), run 8 (right panels).

[^0]:    ${ }^{1}$ Discards for the Mobile Fleet were calculated to be 0 . Discards for the Fixed Gear fleet were not calculated due to low observer coverage.

[^1]:    ${ }^{1}$ Age and length data supplemented with ages from statistical areas 522 and 525.
    ${ }^{2}$ Age and length data supplemented with ages from statistical area 522.
