## Executive Summary

During late summer 2019, we collected and tagged fish as part of a multiyear research project to monitor the migrational behavior and survival of wild juvenile spring/summer Chinook salmon in the Snake River Basin. Each study year, we collect wild Chinook parr in natal tributaries, implant them with passive integrated transponder (PIT) tags, and release them near their respective collection sites.

In this report, we present data on fish collection and tagging efforts during July and August 2019. Detection data will be collected from these tagged fish as they begin migration during spring 2020. These data and the respective analyses will be presented in our 2020 Survival and Timing report.

- During July-August 2019, we collected a total of 11,231 wild Chinook salmon parr from 16 Idaho sample locations. Of the parr collected, 8,421 were PIT-tagged and released.
- Of all fish collected, we observed an overall average length of 64.0 mm and average weight of 3.5 g .
- We observed a mortality rate of $1.5 \%$ (173) for collected fish over all sample reaches combined. The main cause of mortality was associated with collection of fish, and we recorded only three mortalities associated with anesthetizing, tagging, and handling.

## Introduction

In 1991, the National Marine Fisheries Service (NMFS) conducted a biological status review of Snake River spring/summer run Chinook salmon Oncorhynchus tshawytscha. This status review was conducted in response to multiple petitions to list several individual Snake River Chinook stocks as threatened or endangered under the U.S. Endangered Species Act (ESA).

Because resources were not sufficient to review the large number of individual petitions, NMFS biological review team evaluated all petitioned populations as part of its status review of the entire Snake River spring/summer run Chinook evolutionarily significant unit (ESU). Based on these evaluations, the team concluded that the Snake River spring/summer-run Chinook salmon ESU was well below the threshold for threatened status and only slightly above the threshold for endangered status under the ESA (Matthews and Waples 1991).

The Snake River spring/summer-run Chinook salmon ESU was listed as threatened under the ESA in 1992. Since that time, this ESU has been the focus of a recovery plan to restore its populations to self-sustaining levels. The plan serves as base of coordination for recovery efforts from federal, state, tribal, and municipal entities, as well as from private groups and individuals. Recovery efforts focus on both salmon populations and their habitats.

In an analysis of potential recovery strategies, Kareiva et al. (2000) found that "modest reductions in first-year mortality or estuarine mortality would reverse current population declines" for Snake River spring/summer-run Chinook salmon. Their finding supports prioritization of the juvenile stage as an efficient approach toward allocation of resources for recovery goals.

For Pacific salmon Oncorhynchus spp., tagging and recapture studies have been at the center of research to improve survival of juvenile downstream migrants. Tagging studies began in the mid-1950s, and advances in technology since that time have continued to improve various tagging methods. However, until the late 1980s, resource managers relied on methods that could provide only limited information on fish passage, such as freeze-branding, index counts at traps and dams, and analyses of flow patterns.

In the late 1980s, the passive integrated transponder (PIT) tag was introduced to the fisheries community. Each PIT tag contains a unique code, which allows researchers to track and record the movements of individual fish. Because it is small and biologically
inert, a PIT tag can be retained throughout the fish's life cycle. The tag allows multiple detections of an individual fish without physical recapture.

Since its introduction, use of the PIT tag has expanded from about 50,000 to more than 2 million fish tagged annually. These tagging efforts, along with automated data collection methods, have provided large data sets for a broad mixture of wild/natural and hatchery stocks, ages, and year classes. The Columbia Basin PIT Tag Information System (PTAGIS) was established as a shared repository for these data (PSMFC 1996).

Data from PIT tag detections have provided insight for decisions on programs to enhance juvenile passage at dams, such as spill and transportation. However, the need remains for data upon which to base decisions for these and other restoration and recovery efforts. Major gaps remain in understanding life history patterns and survival at different points in the life cycle of Columbia Basin stocks. Our research directly addresses these data gaps for wild Snake River spring/summer Chinook salmon at the parr-to-smolt stage.

In addition to acquiring data for the NWPPC and several other fish and wildife programs, our research addresses "Reasonable and Prudent Alternatives" in the 2000 NMFS Biological Opinion (NMFS 2000). For example, section 9.6.5.2 of action 180 advocates a regional monitoring effort on the population status of wild fish stocks and the environmental status of their natal streams and tributaries. Section 9.6.5.5, Action 199 and Appendix H, research action 1193 call for
...research to produce information on the migrational characteristics of Columbia and Snake River basin salmon and steelhead. The smolt monitoring program produces information on the migrational characteristics of various salmon and steelhead stocks...and provides management information for implementing flow and spill measures designed to improve passage conditions in the mainstem lower Snake and Columbia Rivers (NMFS 2000).

More recently, in response to the remanded biological opinion, the Final Updated Proposed Action for the FCRPS Biological Remand proposed that researchers should
...implement and maintain the Columbia River Basin PIT Tag Information System. Expand the system to systematically plan PIT tag efforts in the pilot study basins such that production and survival can be estimated throughout the system for wild and hatchery fish. Also, continue development and implementation of new fish detection and tagging techniques (Action Agencies 2004).

Clearly, the migratory performance of wild fish (e.g., run timing/survival) is important and should continue to be monitored. To this end, marking wild/natural parr with PIT tags in their natal streams during the summer of their first year of life provides
the opportunity to precisely track these stocks through instream PIT-tag detectors, traps, and detection systems in the hydroelectric complex during their parr/smolt migrations.

This report includes information on tagging of wild Chinook salmon parr from Idaho streams during 2019. We will monitor these fish during spring and early summer 2020 as they migrate downstream towards the Pacific Ocean. The 2020 Survival and Timing component of this report will provide estimates of downstream survival and timing of those fish to Lower Granite Dam, as well as interrogation data from other downstream sites throughout the Snake and Columbia River Basin.

This research continues studies that began in 1991 with funding from the Bonneville Power Administration (BPA). Results from previous study years have been reported annually (Achord et al. 1994-1995a, 1995b, 1996a, 1997-1998, 2000-2001a, 2001b, 2002-2012; Lamb et al. 2013-2019). The goals of this ongoing study are to:

1. Characterize migration timing and growth and estimate parr-to-smolt survival of different populations of wild Snake River spring/summer Chinook salmon to Lower Granite Dam
2. Determine whether consistent patterns in migration/survival are apparent
3. Determine which environmental factors may influence patterns in migration/survival
4. Characterize the migrational behavior and estimated survival of different wild juvenile fish populations as they move downstream from natal rearing areas.

This study provides critical information for recovery planning and ultimately for the restoration of these wild fish populations, all of which remain listed as threatened under the U.S. Endangered Species Act of 1973 (NMFS 2008).

## Methods

During summer 2019, NOAA Fisheries personnel tagged fish in 16 Idaho streams or sample reaches (Figure 1). Fish collection followed the safe handling methods developed for this study and detailed by Matthews et al. (1990, 1997). Anesthetized fish were tagged, provided they met the $55-\mathrm{mm}$ minimum fork length requirement.

In 2019, all fish were tagged using individual single-use hypodermic needles pre-loaded with $9-$ or $12-\mathrm{mm}$ PIT tags. All fish measuring $55-60 \mathrm{~mm}$ were tagged with $9-\mathrm{mm}$ tags, per request of Idaho state permitting officials. All fish longer than 60 mm were tagged with standard $12-\mathrm{mm}$ tags. This method ensured that each fish was tagged with a sterile, sharp needle, thus minimizing stress and injury during the tagging process. All other tagging methodology remained the same as in previous years of this study (Achord et al. 1994, 1995a, 1995b, 2003, 2004, 2010, 2011; Lamb et al. 2013-2019).

Figure 1. Map showing the streams and sample reaches where wild spring/summer Chinook salmon parr were PIT tagged during 2019.

## Results

From 16 July to 25 August 2019, we collected 11,231 wild spring/summer Chinook salmon parr from 16 Idaho stream populations (Figure 1). Fish were collected over a distance of about 28.5 stream km and over an area of approximately $314,287 \mathrm{~m}^{2}$ (Table 1; Appendix Table 1). Of the 11,231 fish collected, 8,421 were tagged with either $9-\mathrm{mm}$ or standard $12-\mathrm{mm}$ PIT tags.

All tagged fish were released back to their respective natal stream along with any remaining untagged live fish. Collected fish were returned to the natal stream without tagging if they had been previously tagged, were too small, injured, had matured precociously, or if sufficient numbers of fish had already been tagged. Numbers of tagged fish released per stream or sample reach ranged from 35 in Herd Creek to 1,241 in the South Fork Salmon River (Tables 1; Appendix Table 1).

In 2019, the mean fork length of all Chinook salmon parr collected was 64.0 mm and the mean weight was 3.5 g . For Chinook salmon parr that were tagged and released, mean fork length was 65.5 mm and mean weight was 3.4 g (Table 1; Appendix Table 1). Collection areas within each stream were delineated by recording the global positioning system (GPS) coordinates of each tagging site using the Universal Transverse Mercator (UTM) coordinate system (Appendix Table 3).

Other than Chinook salmon parr, sculpin (genus Cottus) was the most abundant fish observed during field collection operations (Table 2). However, records of non-target fish do not represent their total abundances in collection areas, as only Chinook salmon were targeted for collection, while other species were counted as incidental take.

Mortality associated with collection and tagging procedures in 2019 was low (Table 3; Appendix Table 4). The collection and handling mortality rate was $1.5 \%$, and there were only three mortalities following tagging and 24-h holding.

Table 1. Summary of collection, PIT tagging, and release of wild Chinook salmon parr with average fork lengths and weights (includes recaptured tagged fish), approximate distances, and estimated areas sampled in Idaho streams from July through August 2019.

## Discussion

During July and August 2019, the number of wild Chinook salmon parr tagged was smaller than the annual average number tagged over the past 10 years ( 8,421 vs. 13,623 ). However, we were able to sample all 16 historic sites. Low collection and tagging numbers at multiple sites were most likely the result of low parr densities, which were expected due to low redd counts observed during 2018. Conditions during collection periods were good all season, with low-to-average flows and high water clarity.

Our overall collection effort in 2019 included all 16 possible sample reaches, which led to a larger sample area than in several of the years prior, at $314,287 \mathrm{~m}^{2}$. Over the entirety of the sample area we estimated an annual density of 3.57 parr $/ 100 \mathrm{~m}^{2}$. Parr densities varied over sampling sites, with the highest observed in the South Fork Salmon River ( 6.56 parr $/ 100 \mathrm{~m}^{2}$ ) and the lowest in Herd Creek ( 0.43 parr $/ 100 \mathrm{~m}^{2}$ ). Past data has indicated an inverse relationship between parr density and parr-to-smolt survival (Figure 2).

Figure 2. Annual average density of Chinook salmon parr (parr $/ 100 \mathrm{~m}^{2}$ ) in Idaho streams vs. annual estimated survival of smolts from these streams to Lower Granite Dam the following year, 1992 to 2019.

During 2020, we will collect downstream migration data from the wild spring/summer Chinook parr collected and tagged during field operations in July and August 2019. Analyses from these data will include estimates of parr-to-smolt survival, arrival and migration timing to and from streams with instream detection capabilities, and smolt passage timing at Lower Granite Dam. These analyses are included in our annual reports, along with environmental data collected from each tagging location and growth data on migrants recaptured at Lower Granite Dam.

## Acknowledgments

We thank the Bonneville Power Administration for funding this project. Thanks to Louis Tullos, Ron Marr, Amber Barenberg, Lela Work, Jared Siegel, Steve Corbett, Kris Snyder, Sarah Fesenmeyer, Aurele LaMontagne, Karl Veggerby, and Ross Gleason for their excellent assistance in collecting and PIT tagging fish for this study.

We are grateful to staff of the University of Idaho for providing lodging for staff at Taylor Ranch during our sample efforts at Big Creek. Special thanks to Pete and Meg Gag and University of Idaho for hosting us during our stay.

Thanks also to personnel from Nez Perce Tribe, Quantitative Consultants Inc., and Gabriel Brooks of NOAA for trouble shooting and maintaining PIT tag arrays associated with the project.

Appendix Table 4. Summary of observed total mortality for PIT-tagged wild Chinook salmon parr collected from Idaho streams from July through August 2019. Number rejected includes; fish too small to tag, precocious males, injured fish, fish collected for genetic evaluation, previously tagged fish, and in some cases extra collected fish. The portion of rejects that are precocious males are in parentheses.

| Stream | Fish collected (n) | Fish tagged <br> (n) | Fish rejected for tagging |  | Observed mortality |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | Collection and handling | $\begin{gathered} \text { Tagging } \\ \text { and } \\ \text { delayed } \\ \hline \end{gathered}$ | Total |  |
|  |  |  | (n) | (\%) |  |  | (n) | (\%) |
| Herd Creek | 37 | 35 | 2 | 5.4 | 0 | 0 | 0 | 0.0 |
