## NOAA TECHNICAL REPORTS

### National Environmental Satellite, Data, and Information Service

The National Environmental Satellite, Data, and Information Service (NESDIS) manages the Nation's civil Earth-observing satellite systems, as well as global national data bases for meteorology, oceanography, geophysics, and solar-terrestrial sciences. From these sources, it develops and disseminates environmental data and information products critical to the protection of life and property, national defense, the national economy, energy development and distribution, global food supplies, and the development of natural resources.

Publication in the NOAA Technical Report series does not preclude later publication in scientific journals in expanded or modified form. The NESDIS series of NOAA Technical Reports is a continuation of the former NESS and EDIS series of NOAA Technical Reports and the NESC and EDS series of Environmental Science Services Administration (ESSA) Technical Reports.

A limited number of copies are available by contacting Jessica Pejsa, NOAA/NESDIS, E/RA3, 5200 Auth Road, Room 601, Camp Springs, Maryland 20746, (301) 763-8184 x115. Copies can also be ordered from the National Technical Information Service (NTIS), U.S. Department of Commerce, Sills Bldg., 5285 Port Royal Road, Springfield, VA 22161, (703) 487-4650 (prices on request for paper copies or microfiche, please refer to PB number when ordering). A partial listing of more recent reports appear below:

## ABSTRACT

Simultaneous nadir overpasses (SNOs) for pairs of NOAA satellites (NOAA-6 to NOAA-17) from 1980 to 2003 are calculated with the version 2.0 of the SNO prediction algorithm, which utilizes the Simplified General Perturbation No. 4 (SGP4). These SNOs occur in the polar regions, where the radiometers from two satellites view the same place at the same time at nadir, providing excellent opportunities for intersatellite calibration. The SNOs are useful for monitoring the on-orbit instrument performance and evaluating the calibration consistency for climate trending studies with NOAA's satellite radiometers in the visible/near-infrared, infrared, and microwave.

Version 2.0 of the SNO prediction algorithm significantly improved the prediction accuracy. All the SNOs found using this version are predicted with a time interval of 1 second (entitled Class I SNOs), compared to the 30 second interval in previous predictions (Class II SNOs). The SNO nadir distances criteria is now  $< 100$  km, compared to  $< 300$  km before. As a result, the predicted locations are closer to the precise SNO locations than those in previous predictions. Algorithm Version 2.0 also fully utilizes all available historical two-line-elements (TLEs) as input to the SGP4 model for optimized TLE epoch matching (epoch is the time at which the orbital data are calculated). These are made possible with the enhanced algorithm and further improvements in computing power. The predictions for the SNOs include the date, time, location, nadir ground distance, TLE epoch differences, and the approximate angle of the orbital intersection with the delta right ascension of ascending node (RAAN). The computer algorithm and source code for predicting the SNOs in C++ programming language are provided. Existing studies using the SNO method are also

introduced and provided in the references. Updates on the SNOs are available at the website:  
<http://orbit.nesdis.noaa.gov/smcd/spb/sno/>.

## 1. INTRODUCTION

Intercalibrating the polar-orbiting radiometers on different satellites is critical for achieving the calibration consistency and traceability required for long-term climate studies with the 25+ years of NOAA satellite data. Many inter-calibration studies have been performed in the past. But most of them are limited to match-up data sets acquired from different satellites with dissimilar instruments and that may have different observation times and viewing geometries, and in many cases rely on radiative transfer calculations to account for the observation differences. These restrictions introduce uncertainties in the inter-comparisons.

In recent years, the Simultaneous Nadir Overpasses (SNOs) method has been developed and refined for the intersatellite calibration of radiometers (Cao et al., 2004). At each SNO, radiometers from both satellites view the same place at the same time at nadir, thus eliminating uncertainties associated with differences of atmospheric path, viewing geometry, and observation time. This is especially important for infrared radiometer observations, which vary significantly with these parameters. As a result, uncertainties in the inter-satellite calibration are greatly reduced. Several studies have used this method for calibrating radiometers on meteorological satellites, including the intercalibration of the HIRS (High Resolution Infrared Radiation Sounder) (Cao et al., 2005), AVHRR (Advanced Very High Resolution Radiometer) and MODIS (Moderate Resolution Imaging Spectroradiometer) in the infrared (Cao and Heidinger, 2002, Wu et al., 2003) and visible channels (Heidinger et al., 2002), and Microwave Sounding Unit (Zou et al., 2005). Results show that this method is useful for the on-orbit verification of instrument performance for newly launched

radiometers, as well as retrospective analyses of historical data for constructing time series for climate studies. Therefore, we believe that the predicted SNOs for NOAA-satellites from 1980 to 2003 provided in this study will be useful to the research community for the intersatellite calibration of radiometers.

The SNO method, when used properly and combined with SNO time series analysis, may have profound impact on the intersatellite calibration across the board for satellite radiometers in the visible/near infrared, infrared, and microwave. Preliminary studies have shown that significant improvements have been made in the following areas:

First, radiometric differences between satellites are quantified with greatly reduced uncertainty. Before the SNO method was used, intersatellite calibration biases often could not be separated from the true differences in the geophysical variables due to diurnal temperature (infrared and microwave) or Sun angle and bidirectional reflectance factor (BRDF) differences (solar reflective). This is because satellites have different equator crossing and observation times, which are further intertwined with orbital drift over time. Therefore, previously, intersatellite biases could only be estimated with an uncertainty on the order of a few degrees in most cases. With the SNO method, the intersatellite calibration biases are quantified with much smaller uncertainties across the board for nearly all satellite radiometers.

A major break-through has been made for the upper atmosphere sounding channels of the High Resolution Infrared Radiation Sounder (HIRS), for which little “ground truth” is available. Due to the relative spatial homogeneity of the upper atmosphere, the intersatellite calibration biases become highly quantifiable with the SNO method with a small uncertainty on the order of 0.1 K (less than the instrument noise) at the cold scene temperature (Cao et

al., 2005). For the Microwave instruments, results using the SNO method show excellent agreement (uncertainty ~0.1 K) between AMSU on NOAA-16 and -17 satellites from mid-troposphere to the stratosphere channels, although the uncertainties become larger for the surface channels due to surface non-uniformity and navigation errors. For infrared imagers such as AVHRR and MODIS, results using the SNO method show that the intersatellite calibration biases are mostly less than 0.5K, with an uncertainty less than 0.3 K (Cao and Heidinger, 2002; Wu et al., 2003). For the visible/near-infrared channels of AVHRR, preliminary results indicate that intersatellite calibration can perform better than +/-5%, which is the consensus value achievable with vicarious calibration (Rao, N., personal communication, 2000; Smith et al., 1988).

Second, intersatellite calibration studies of infrared sounders using the SNO method significantly improved our understanding of the spectral effect on satellite radiance biases in infrared atmospheric sounding (Cao et al., 2005). A small difference in the spectral response may mean that a channel is sensing a slightly different layer of atmosphere with a different temperature. This spectral response induced bias should be treated differently from those due to onboard blackbody differences. The SNO method is also very promising for inflight spectral calibration, especially as more hyperspectral sounders will be in space in the next few years (Cao and Ciren, 2004).

Third, the SNO method provides an important tool for the independent monitoring of instrument performance. Before the SNO method was developed, satellite radiometer calibration almost entirely depended on onboard calibration devices (infrared and microwave) or desert targets (in the visible/near infrared), with limited field campaigns

which are not sustainable. With the SNO method, the intersatellite calibration can be cross checked and compared routinely with small and probably acceptable uncertainties.

Finally, the SNO method also improved our understanding of navigation errors and geometric calibration, because they obviously affect the intersatellite calibration results. In addition, the SNO method improved our understanding of sensor artifacts such as striping. For example, MODIS striping in the 11 and 12 um channels becomes apparent when radiance values are subtracted from AVHRR radiances at the SNOs.

All these improvements have led to better accuracy and will continue to do so for the sensor data records (SDRs), which are the essential elements for all the satellite derived geophysical products. The results using the SNO method will help bias tuning in radiance assimilation in numerical weather forecast. Our studies suggest that in bias tuning, not only the bias amount, but also the cause of the bias has to be known, because as discussed previously, spectral induced biases should be treated differently than onboard blackbody biases. The SNO results will also help us improve the sea surface temperature retrievals, with a better understanding of the biases between satellite and buoy measurements. The SNO method is extremely important for the intersatellite calibration for climate studies, where a small difference in intersatellite bias can lead to different conclusions about global change. Recent progress made in the MSU study exemplifies the usefulness and potential of the SNO method (Zou et al., 2005). Last but not least, the biases discovered using the SNO method can become important feedbacks to instrument manufacturers and sensor data record (SDR) producers. For example, the SNO method has been used for comparing the blackbody performance between the MODIS on TERRA and AQUA (using the NOAA/AVHRR as

transfer radiometer) by the NASA MODIS characterization support team in the last few years.

NOAA's Polar Operational Environmental Satellites (POES) typically employs two spacecrafts in nearly circular sun synchronous orbits at nominal altitudes of 833 and 870 km. With their orbital planes approximately 90° apart, one has a 7:30 or 10:30 (for NOAA-17) local equator crossing time in descending node and the other a 13:40 local equator crossing time ascending node. They are referred to as AM (morning) and PM (afternoon) satellites. A sun-synchronous orbit ensures that the equator crossings occur at the same local time. This is desirable as it provides consistent scene illumination – a common mission requirement for many meteorological and terrestrial applications. Such orbits are achieved by placing the satellites at inclination angles of 98.7° to 98.8° so that the orbital planes will precess eastward about 0.986° per day to keep pace with the Earth's revolution around the sun (Rao et al., 1990). Since 1978, NOAA has successfully launched eleven polar-orbiting satellites (NOAA-6 to NOAA-17), with an average usable life of approximately five years in orbit for each. Since an AM satellite is generally at a lower altitude than the PM satellite, the AM satellite has a shorter orbital period. For example, the nominal orbital periods for the AM satellite NOAA-17 is 101 min, compared to 102 min for the PM satellite NOAA-16. In this report, simultaneous nadir overpasses (SNOs) for each succeeding pair of NOAA satellites (NOAA-6 to NOAA-17) from 1980 to 2003 are provided.

## **2. THE METHOD FOR PREDICTING THE SNO**

The intersection of the orbital plane of an Earth orbiting satellite with the surface of the Earth (or the satellite ground track) is a great circle. Every great circle of a sphere intersects

all other great circles of the sphere in exactly two points. Therefore, it is expected that the ground track of every pair of Earth orbiting satellites have two points of intersection. In the case of two polar-orbiting satellites, the two intersections always occur near the north and south poles. Although each satellite passes each intersection once an orbit, for most orbits the two satellites do not pass the same intersection at the same time. In fact, if both satellites are at the same altitude, they will have the same orbital period, and they should never pass the same orbital intersection (OI) at the same time (otherwise they will collide). It should be noted that orbital intersections (OIs) and SNOs (simultaneous nadir observations) are two different concepts. There are always exactly two orbital intersections (OIs) between two different orbital planes but since both satellites do not usually pass the orbital intersection at the same time, it may or may not qualify as an SNO event.

Kepler's third law implies that the higher the altitude of a satellite, the longer its orbital period. Satellites at higher altitudes have smaller angular velocities and therefore longer orbital periods. It follows then that as time goes by, the lower altitude satellite will eventually catch up with the high altitude satellite at the orbital intersections (OIs), thus creating an SNO (Simultaneous Nadir Overpass) (Figure 1). When this occurs, the radiometers from both satellites view the Earth and its atmosphere at the same place and same time from different altitudes. The difference in satellite altitudes does not affect the radiance comparison from the two radiometers on these satellites, as long as the areas within the field of view are essentially the same, because radiance is not a function of the distance of measurement. In addition, path radiance difference is negligible because there is little atmosphere between the two satellites at different altitudes.

The details of the mechanism and the algorithm for predicting the simultaneous nadir overpasses (SNOs) are described in Cao et al., 2004. The software used for the prediction is provided in Appendix A of the current paper. Here we summarize the basic principle of the

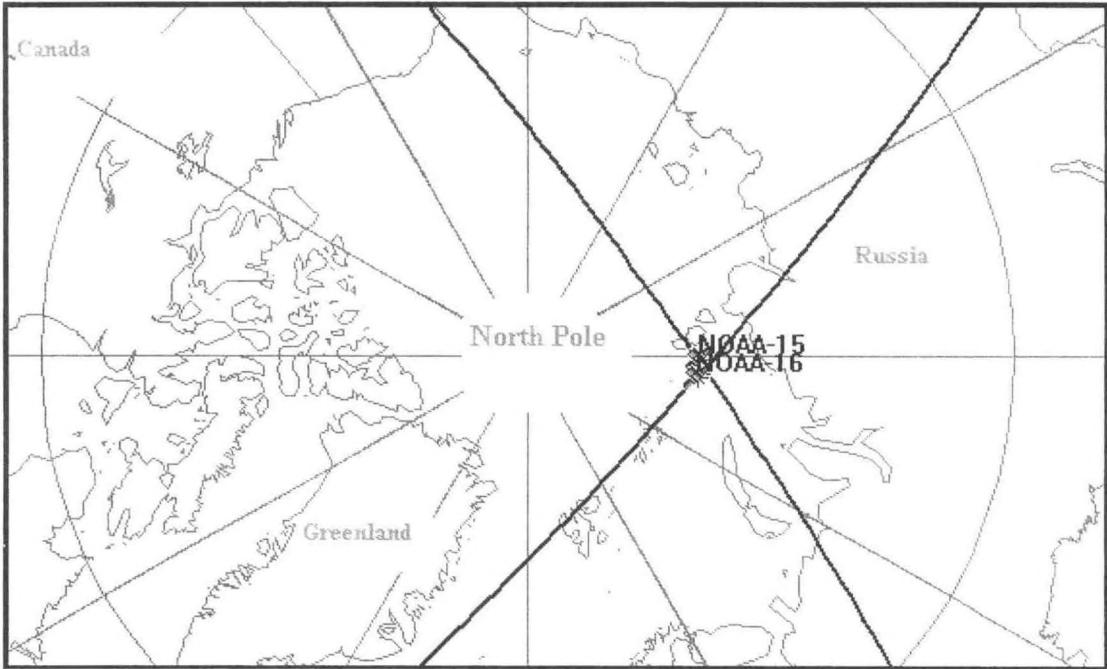

Figure 1. An example SNO between NOAA-15 and NOAA-16  
(08/18/2002, 04:42:10 UTC, 79 deg N / 87 deg W)

SNO as follows: In general, assuming that two sun synchronous polar-orbiting satellites  $S_1$  and  $S_2$  operate at altitudes  $h_1$  and  $h_2$  ( $h_2 > h_1$ ) with orbital periods of  $\tau_1$  and  $\tau_2$  ( $\tau_2 > \tau_1$ ), an SNO between them occurs when the orbital period time difference ( $\tau_2 - \tau_1$ ) accumulates over time and this difference eventually amounts to  $\tau_2$ . In other words,  $S_1$ , having a higher velocity than  $S_2$ , eventually catches up with  $S_2$ . The number of orbits required for  $S_1$  to catch up with  $S_2$  is  $\tau_2 / (\tau_2 - \tau_1)$ . Converting number of orbits to number of days, we have the following formula for estimating the SNO occurrences between two satellites:

$$T = [\tau_2 / (\tau_2 - \tau_1)] \cdot 1/f_l \quad (1)$$

Where,  $T$  = Time between successive SNOs (days)

$\tau_1$  = orbital period (min) for  $S_1$  at  $h_1$

$\tau_2$  = orbital period (min) for  $S_2$  at  $h_2$

$\tau_2 > \tau_1$  and  $h_2 > h_1$

$f_l$  = number of orbits per day for  $S_1$  ( $f_l = 1440$  (min per day)/ $\tau_1$ ).

For example, in March 2003, the orbital periods for NOAA-16 and -17 are 101.9885 and 101.1722 minutes respectively, and the time between successive SNOs for the NOAA-17 and -16 is approximately once every 8.78 days. NOAA-17 and TERRA meet at their orbital intersections (OIs) more frequently about every 3 days because of the short orbital period for TERRA (98.83 minutes). It is worth noting that even two PM or two AM satellites, such as NOAA-14 and -16, have SNOs, although they occur much less frequently (e.g., more than two months) because of their similar altitudes. However, since their orbital periods are very similar, when the SNO event occurs, it tends to have multiple successive SNOs within several hours, in contrast to those that occur only once but more frequently. Such examples can be found for the SNOs between NOAA-16 and -14 (Appendix B). For example, on August 27, 2002 the SNOs between NOAA-16 and -14 occurred six times each near the north and south poles in the same day from 01:19:34 to 10:40:38 UTC. However, the next series of SNOs did not occur till more than two months later.

The precise location and time of the SNO between two satellites cannot be easily calculated with equations, because the satellite orbits are subjected to perturbations on a daily basis. Therefore, we opted to use the numerical method to find the approximate location and time of an SNO. This involves predicting the precise location of the two satellite nadirs at all

times during the prediction period with a given time step (1 second in this study), and then finding the minimum distance between the satellite nadirs (less than 100 km for this study). It should be noted that in this method, the “predicted SNO”, or the location and time when the minimum nadir distance occurs, may not be the true exact SNO. In fact, the distance between the predicted SNO and the true SNO varies as a function of the angle of orbital intersection between the two satellites as discussed in Section 3. Also, technically, since the precise SNO may not be found using this method, the exact time difference when the two satellites passed the true SNO point may also not be known. However, for practical purposes, the differences between the predicted and exact SNO location and time are small. Besides, the predicted SNO is only used for finding the particular orbit of level 1B data that contains the SNO. The true SNO is then found using the nadir pixel location and time information in the satellite level 1b data as discussed in Section 4.

To accurately predict the location of a satellite at a given time requires the use of orbital prediction models and appropriate input parameters. In this study we use the Simplified General Perturbation No. 4 (SGP4) (Hoots et al., 1988; Lane and Cranford, 1969), which is developed and used by the North American Aerospace Defense Command (NORAD) for tracking all satellites in space. The input to the SGP4 model is contained in a two-line-element (TLE) set, which consists of two 69-character lines of data which can be used together with NORAD's SGP4/SDP4 orbital model to determine the position and velocity of the associated satellite. TLEs are available for most satellites and are updated almost daily on the website: <http://celestrak.com> (note: starting from early 2005, public TLE access becomes limited for security reasons).

To predict Simultaneous Nadir Overpasses (SNOs) of two Earth orbiting satellites, the following algorithm is used:

1). Prepare the matching TLE pair for the two satellites: Since the precise satellite orbit is very dynamic, it is important to use the TLE pair with epochs (the time at which the orbital data were calculated) that are closest to the time of prediction to avoid errors. Also, ideally the TLEs for the two satellites should have the same epoch date. TLEs are usually released on a daily basis for all satellites, therefore in most cases for a given pair of TLEs, the prediction is only necessary for a one day period, -- until the TLE pair for the next day becomes available. However, prediction for a longer time period becomes necessary if the TLE for certain time periods are missing, in which case the prediction can be extended up to 10 days with reasonable accuracy. To predict the SNOs for an entire year, a series of TLE pairs must be prepared.

In version 2.0 of the SNO prediction software, stricter criteria are used for the predictions than those for the previous versions in order to improve the accuracy. This includes using an 1 second prediction interval, small TLE epoch differences, a shorter prediction period (< 5 days), and nadir distance less than 100 KM. While the version 2.0 of the prediction software in general produces more accurate predictions (Class I SNOs in Appendix B), it cannot be used when the TLEs are missing, which is the case for some satellites during certain time periods. In such cases, predictions using the previous version of software with a 30 second prediction interval and 10 day prediction period are used, and the results are provided in Appendix C (Class II SNOs) as complements to Class I SNOs.

2). Input the TLE of the first satellite to the SGP4 model and use its epoch as the starting date of prediction.

3). Given the time step (we used 1 s in SNO prediction algorithm version 2.0) and the time period of the prediction (in this study, we performed multiple runs with 2 day, 5 day, and 10 day prediction periods), run SGP4 at each time step to generate the dates, times, and locations of the satellite in latitude and longitude, and store them in an array. The 1 s time step is preferred to produce a precise location of the SNO. This corresponds to a ground step size of about 7 km for most polar-orbiting satellites.

4). Repeat steps 2 and 3 for the second satellite, using the same epoch and time step.

This creates a list of coordinates that match those for the first satellite in time.

5). Step through the latitude/longitude pairs in time sequence, and compute the Earth (ground) distance between the nadir points of the two satellites during the prediction period with the great circle distance formula:

$$D = R \cos^{-1} [\sin l_1 \sin l_2 + \cos l_1 \cos l_2 \cos (m_2 - m_1)] \quad (2)$$

Where  $D$  = ground distance between the nadir points of the two satellites (km).

$R$  = mean Earth radius (6378 km)

$l_1$  = latitude of the first satellite (rad)

$l_2$  = latitude of the second satellite (rad)

$m_1$  = longitude of the first satellite (rad)

$m_2$  = longitude of the second satellite (rad)

Equation (2) is a simplified formula for estimating the ground distance, assuming a perfectly round Earth. The distance  $D$  at each time step shows how close the nadir points of these two satellites are on the ground. A sequential list of the distance  $D$  over a prediction period of

many orbits will show that the nadir points of the two satellites approach or depart from each other regularly with a repeating cycle of T days determined by equation (1). An example is shown in Figure 2, where two SNOs occurred between NOAA-16 and Terra during the period March 21 to 24, 2003.

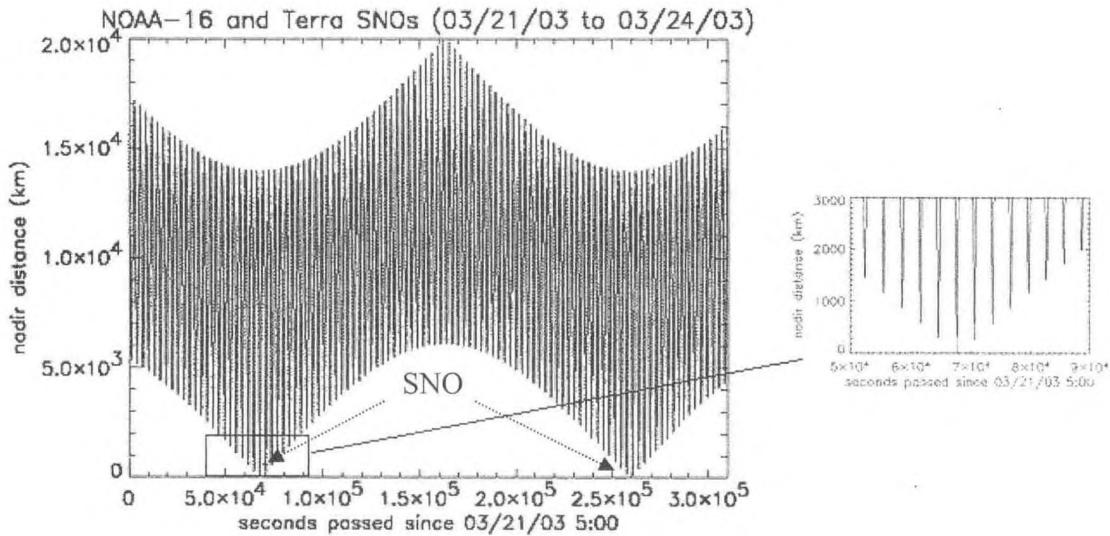

Figure 2. Nadir distances between NOAA-16 and Terra at all times from March 21 to 24, 2003 (computed with a 1 second interval; 1 day =  $8.64 \times 10^4$  s).

### 3. THE $\Delta$ RRAAN (RIGHT ASCENSION OF ASCENDING NODE)

At the SNO, the ground tracks of the two satellites cross each other at an angle (Figure 3). This angle is useful for describing the relative orientation of the match-up data at the SNOs. It can be computed indirectly with the orbital information in the two-line-elements (TLEs). However, for convenience, we approximate this angle with the RAAN, or the "Right ascension of ascending node" (also called Longitude of Ascending Node). It is an angle measured at the center of the earth, from the vernal equinox to the point where the satellite goes across the equator in ascending node (Figure 4). This information is readily

available in the satellite two-line-elements (TLEs).  $\Delta\text{RAAN}$  is the difference of the RAAN angles for the two satellites, and it closely approximates the angle of intersection between the two ground tracks.

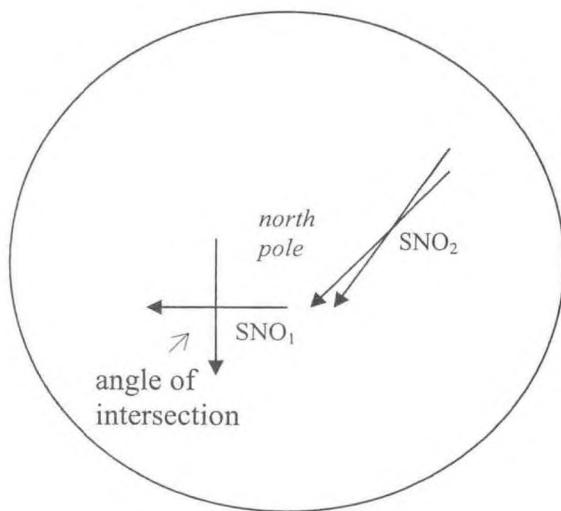

Figure 3. Types of Orbital Intersections and  $\Delta\text{RAAN}$  (not to scale)

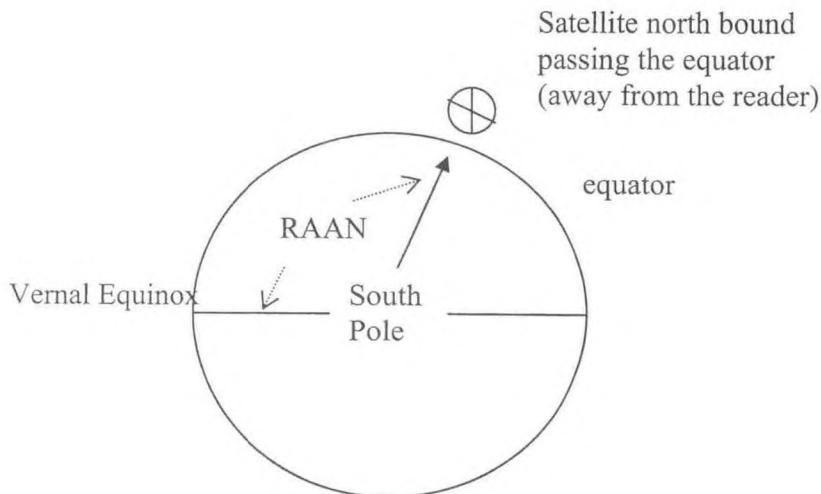

Figure 4. Definition of the Right Ascension of Ascending Node

If the  $\Delta$ RAAN is near 90 degrees (SNO<sub>1</sub> in Figure 3),, the two satellites cross each other at a right angle at a single point, and the distances between satellites increases significantly away from the SNO point. This is a typical case for a morning vs. afternoon satellites. On the other hand, if the  $\Delta$ RAAN is near zero degrees (SNO<sub>2</sub> in Figure 3), the two satellites slowly approach and depart from each other. In this case, there may be a longer period of time during which the satellites observe the same place at the same time, and the SNO may not be a single point. It is also possible that in addition, if the two satellites have similar equator crossing times, the SNOs may occur at low latitudes.

In most cases, the  $\Delta$ RAAN is neither 90 nor 0 degrees. Between morning and afternoon satellites, this angle is typically large, while for two morning or two afternoon satellites, this angle is small. Table 1 shows the RAAN for NOAA and EOS satellites and the  $\Delta$ RAAN between each pair in December 2004. For example, NOAA-17 and TERRA have a  $\Delta$ RAAN of 1.9 (orbits are nearly parallel), while NOAA-15 and Aqua have a  $\Delta$ RAAN of 109.1 (closer to a right angle) at the time.

Figure 5 shows a case of NOAA-17 vs. Terra on November 8, 2004 at around 11:37:00 UTC. It shows that NOAA-17 and TERRA had ground tracks that were very close to each other for the hour from 11:00am to 12:00pm on Nov. 8. In a broad sense, all observations during this hour are nearly simultaneous, although the simultaneity occurs for observations slightly off nadir for both satellites most of the time. As predicted, the nadir distances between them were less than 300 km most of the time during this period, including those low latitude regions such as the tropics.

Table 1.  $\Delta$ RAAN for Selected NOAA and EOS satellites in December 2004

Satellite (RAAN)	NOAA-16 (291.8473)	NOAA-17 (50.5693)	TERRA (52.4458)	AQUA (275.2929)
NOAA-15 (348.4297)	56.6	297.9	296.0	109.1
NOAA-16 (291.8473)		241.3	239.4	16.6
NOAA-17 (50.5693)			1.9	224.7
TERRA (52.4458)				222.8

RAAN Souce: two-line-elements on December 5, 2004

However, there is only one point of orbital intersection (OI) during this period. Figure 6 shows that the two ground tracks actually crossed each other at 11:37 am. This is the true OI which occurred at about 61 degrees north. Recall that OIs and SNOs (simultaneous nadir observations) are two different concepts. There are always exactly two OIs between two different orbital planes but since both satellites do not usually pass the OI at the same time, it may or may not qualify as an SNO event. For satellites with  $\Delta$ RAAN at angles other than zeros, SNO can only occur at the orbital intersections. For satellites with small  $\Delta$ RAAN angles, many observations may be nearly simultaneous despite not at the orbital intersections. Therefore, it is possible that such “quasi- SNO” data at low latitudes are useful if the criteria on nadir distance is not very strict. It should be noted that at the OI, the nadir distance between the two satellites are not necessarily the smallest among all the nearly SNO data available for the orbits with small  $\Delta$ RAAN. This is because when the first satellite reached the orbital intersection (OI), the other satellite was probably still at some distance to the intersection. But this can still be considered an SNO if that satellite reached the intersection within a short period of time (for example, within 30 seconds). Small nadir distances may

also occur at places other than the OIs in the near-parallel ground track situation.

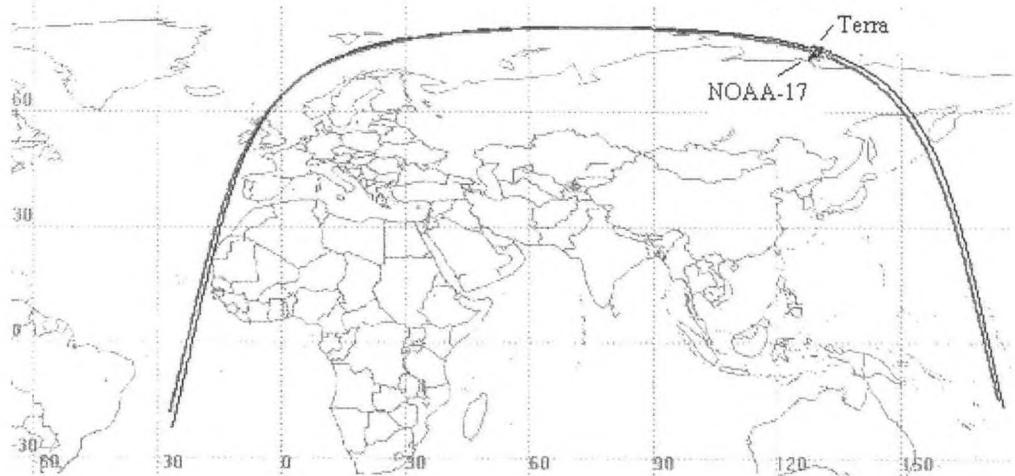

Figure 5. Orbits for NOAA-17 and Terra on November 8, 2004 (around 11:37:00 UTC)

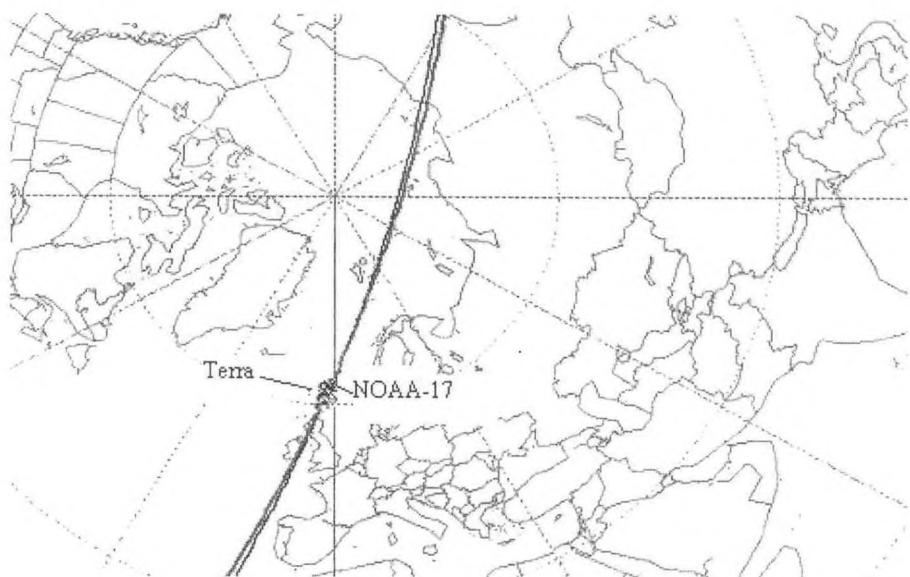

Figure 6. The Point of SNO for NOAA-17 and Terra (11:37:00UTC on November 8, 2004)

It should also be noted that the RAAN of each satellite changes over time due to the orbital drift of the satellite. Therefore, the  $\Delta$ RAAN also changes with time. For example, the  $\Delta$ RAAN between NOAA-15 and NOAA-14 decreased from ~71 degrees in 1998 to 7 degrees by the end of 2002 (Appendix B), therefore changed the relative orientation of the match-up data sets at the SNOs during the period.

#### **4. SNO PREDICTION RESULTS FOR NOAA SATELLITES FROM 1980 TO 2003**

The predicted Simultaneous Nadir Overpasses (SNOs) for each pair of NOAA satellites from 1980 to 2003 are provided in Appendix B, in which the date, time, latitude and longitude are shown in the first 4 columns. The column labeled  $\delta$  is the estimated nadir distance between the two satellites at that time, while  $\epsilon$  represents the differences in epochs for the pair of the two-line-elements (TLEs) used. The  $\Delta$ RAAN approximates the angle of orbital intersection at the SNOs, as discussed previously. The SNOs are listed in chronological order for each pair of satellites, starting from NOAA-7 vs. NOAA-6, and ending at NOAA-17 vs. NOAA-16.

The predictions provided here are for the periods when the satellite data from both satellites were available, as defined in Table 2. Predictions involving NOAA-13 are not included in the list because it's power failed 12 days after launch. Also, SNOs involving NOAA-8 are relatively few due to the short operating period of NOAA-8. Note that SNOs between AM and PM satellites occur far more often (such as between NOAA-7 and -6) than those between two AM or two PM satellites (such as NOAA-8 and -6) due to altitude differences.

The following summarizes the procedure for using the predicted SNOs in the Appendix B. This procedure has been used for the intersatellite calibration of both operational and historical satellite radiometers in the visible/near-infrared, infrared, and microwave. For more detailed information about this procedure, please see Cao et al., 2005.

Step 1: Obtain the Level 1b matching orbits that contain the SNOs for the two satellites based on the predicted time of the events listed in Appendix B.

Step 2: Find the exact SNO based on the location of the nadir pixel in the level 1b data. The nadir latitude/longitude and UTC time of all scan-lines for each satellite are extracted. The distances between each possible combination of nadir location pair are computed. An orbital intersection (OI) is found when the nadir distance is less than one pixel. The UTC time difference for the OI is also computed, and only those OIs with a time less than a time threshold is kept, which become the exact SNO points. Within one orbit, there may be two SNOs, one in the Arctic and the other in the Antarctic. The smaller the time threshold is, the better quality the SNO has, but the number of qualified SNOs will also decrease. Although this time threshold is somewhat arbitrary, we typically use 30 seconds as a criteria. The trade-offs between the time threshold and the number of SNOs are discussed in Zou et al., 2005.

Step 3. Select data subset to reduce the data volume. The subset is extracted near the SNO pixel, from which a number of rows and columns are extracted initially, along with the latitude/longitude for each pixel. This reduces the data size and facilitates the subsequent processing.

Step 4. Collocated the pixels. A pixel-by-pixel match between the two matching subsets is performed based on the ground distance between the pixels. The pixel collocation is optimized using various methods to reduce the impact of navigation errors.

Step 5. A nadir window is defined and the statistics of the radiance differences are generated and analyzed. A time series of the differences further reduce the uncertainties in the intercalibration.

Table 2. Data Availability for NOAA Polar Orbiting Satellites

Satellite	SSC# <sup>1</sup>	Launch date	Time of day	Instruments	Data available date range <sup>2</sup>
TIROS-N	11060	10/13/1978	PM	AVHRR/2 (4 chs), HIRS/2, MSU	10/19/1978 – 01/30/1980

The software in C++ for predicting SNOs is listed in Appendix A, and can be compiled with the SGP4 library on all major computing platforms. The SNOs in Appendix B are limited to the NOAA satellites from 1980 to 2003. SNOs for future satellites will be generated when their two-line-elements become available. SNO updates for current operational NOAA satellites, along with SNOs for NOAA and EOS/Terra/Aqua satellites, can be found at the website: <http://www.orbit.nesdis.noaa.gov/smcd/spb/calibration/sno/>.

## 5. SUMMARY

Simultaneous nadir overpasses (SNOs) between pairs of NOAA satellites from NOAA-6 to NOAA-17 are generated with version 2.0 of the SNO prediction algorithm for the 1980 to 2003 period. These SNOs occurred in the polar regions, where the radiometers view the same place at the same time at nadir, providing excellent opportunities for intersatellite calibration. The SNOs are useful for monitoring the on-orbit performance and evaluating the calibration consistency of satellite radiometers in the visible/near infrared, infrared, and microwave, which are potentially useful for climate trending studies. The time and location, the nadir distance and epoch differences, as well as the approximate angle of intersection are included in the Appendix. The SNO algorithm and software in C++ are also provided in this report for those who are interested in predicting the SNOs.

*Acknowledgments.* The authors wish to thank Drs. Jerry Sullivan and Al Powell of NOAA/NESDIS/Office of Research and Applications, for their critical readings of the

manuscript. In the revision, we took Dr. Powell's suggestions and discussed the significance and impact of the SNO method, which significantly improved the clarity and quality of the paper. We also thank Dr. Hui Xu of IMSG Inc. for the sample cross-comparison with earlier results. This study is partially funded by the Environmental Services Data and Information Management (ESDIM) of NOAA's GeoSpatial Data and Climate Services (GDCS) group, and the Product Systems Development and Implementation (PSDI) program of NOAA/NESDIS/OSD. The manuscript contents are solely the opinions of the authors and do not constitute a statement of policy, decision, or position on behalf of NOAA or the U. S. Government.

## Appendix A. The C++ Program listing for predicting SNOs

```
*****
```

Program name: SNO.cpp

Predict Simultaneous Nadir Overpasses (SNOs) between two Polar Orbiting satellites

Author: Changyong Cao, NOAA/NESDIS/ORA, April 15, 2003

Input: two separate tle files, one for each satellite, no header, two lines only.

Output: ASCII file SNOs.txt, which contains the time, location, and nadir distance between the satellite at the SNOs.

Compile: use make file with gcc on unix/linux

```
*****
```

```
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#include "sgp4sdp4.h" //use the SGP4 library
#define TOL 150 //150 km or less apart.
#define MAX 310000 //array size. Enough for 3 days if use 1 sec interval.
```

```
//the earth distance subroutine
extern float realdistance(float lat1,float lon1,float lat2,float lon2);
```

```
//main program starts here
int main(int argc, char **argv)
{
```

```
//Initializing variables
char tle_tlefile1[] = "      "; // TLE source file
char tle_tlefile2[] = "      "; // TLE source file
tle_t tle1,tle2 ;           // Two-line Orbital Elements for the satellite
```

```
vector_t zero_vector = {0,0,0,0}; //Zero vector for initializations
vector_t vel1 = zero_vector;    //Satellite position and velocity vectors
vector_t pos1 = zero_vector;
vector_t vel2 = zero_vector;
vector_t pos2 = zero_vector;
```

```
//time and location variables
struct tm *utc; //Calendar date and time (UTC)
time_t tm_interval,begintime//, endtime;
time_t t;
float distance; //earth distance between nadir
geodetic_t sat_geodetic;//Satellite's predicted geodetic position
```

**Appendix B. Class I SNOs for NOAA Satellites  
(NOAA-6 to NOAA-17)**

Note:  
 1.  $\delta$  = nadir ground distance between the satellites;  $\varepsilon$  = TLE epoch difference in days; ΔRAAN = difference in the right ascension of ascending nodes.

2. Class I SNOs have stricter criteria and better accuracy (1 second prediction interval; small  $\varepsilon$ ; prediction period < 5 days; nadir distance < 100km). Class II SNOs, with a 30 second prediction interval and 10 day prediction period, are complements to the Class I SNOs for time periods with missing TLES.

**Class I SNOs between NOAA-07 and NOAA-06**

Date	Time	Lat	Lon	$\delta$	$\varepsilon$	ΔRAAN
08/16/1981	16:31:26	-79.0	97.0	1.8	-1.83	-78.8
08/25/1981	08:00:10	-79.2	-137.0	97	-0.15	-77.0

- NESDIS 98 NOAA-L and NOAA-M AMSU-A Antenna Pattern Corrections. Tsan Mo, August 2000.
- NESDIS 99 The Use of Water Vapor for Detecting Environments that Lead to Convectively Produced Heavy Precipitation and Flash Floods. Rod Scofield, Gilberto Vicente, and Mike Hodges, September 2000.
- NESDIS 100 The Resolving Power of a Single Exact-Repeat Altimetric Satellite or a Coordinated Constellation of Satellites: The Definitive Answer and Data Compression. Chang-Kou Tai, April 2001.
- NESDIS 101 Evolution of the Weather Satellite Program in the U.S. Department of Commerce - A Brief Outline. P. Krishna Rao, July 2001.
- NESDIS 102 NOAA Operational Sounding Products From Advanced-TOVS Polar Orbiting Environmental Satellites. Anthony L. Reale, August 2001.
- NESDIS 103 GOES-11 Imager and Sounder Radiance and Product Validations for the GOES-11 Science Test. Jaime M. Daniels and Timothy J. Schmit, August 2001.
- NESDIS 104 Summary of the NOAA/NESDIS Workshop on Development of a Coordinated Coral Reef Research and Monitoring Program. Jill E. Meyer and H. Lee Dantzler, August 2001.
- NESDIS 105 Validation of SSM/I and AMSU Derived Tropical Rainfall Potential (TRaP) During the 2001 Atlantic Hurricane Season. Ralph Ferraro, Paul Pellegrino, Sheldon Kusselson, Michael Turk, and Stan Kidder, August 2002.
- NESDIS 106 Calibration of the Advanced Microwave Sounding Unit-A Radiometers for NOAA-N and NOAA-N'. Tsan Mo, September 2002.
- NESDIS 107 NOAA Operational Sounding Products for Advanced-TOVS: 2002. Anthony L. Reale, Micheal W. Chalfant, Americo S. Allergrino, Franklin H. Tilley, Michael P. Ferguson, and Michael E. Pettey, December 2002.
- NESDIS 108 Analytic Formulas for the Aliasing of Sea Level Sampled by a Single Exact-Repeat Altimetric Satellite or a Coordinated Constellation of Satellites. Chang-Kou Tai, November 2002.
- NESDIS 109 Description of the System to Nowcast Salinity, Temperature and Sea nettle (*Chrysaora quinquecirrha*) Presence in Chesapeake Bay Using the Curvilinear Hydrodynamics in 3-Dimensions (CH3D) Model. Zhen Li, Thomas F. Gross, and Christopher W. Brown, December 2002.
- NESDIS 110 An Algorithm for Correction of Navigation Errors in AMSU-A Data. Seiichiro Kigawa and Michael P. Weinreb, December 2002.
- NESDIS 111 An Algorithm for Correction of Lunar Contamination in AMSU-A Data. Seiichiro Kigawa and Tsan Mo, December 2002.
- NESDIS 112 Sampling Errors of the Global Mean Sea Level Derived from Topex/Poseidon Altimetry. Chang-Kou Tai and Carl Wagner, December 2002.
- NESDIS 113 Proceedings of the International GODAR Review Meeting: Abstracts. Sponsors: Intergovernmental Oceanographic Commission, U.S. National Oceanic and Atmospheric Administration, and the European Community, May 2003.
- NESDIS 114 Satellite Rainfall Estimation Over South America: Evaluation of Two Major Events. Daniel A. Vila, Roderick A. Scofield, Robert J. Kuligowski, and J. Clay Davenport, May 2003.
- NESDIS 115 Imager and Sounder Radiance and Product Validations for the GOES-12 Science Test. Donald W. Hillger, Timothy J. Schmit, and Jamie M. Daniels, September 2003.
- NESDIS 116 Microwave Humidity Sounder Calibration Algorithm. Tsan Mo and Kenneth Jarva, October 2004.

## NOAA SCIENTIFIC AND TECHNICAL PUBLICATIONS

*The National Oceanic and Atmospheric Administration* was established as part of the Department of Commerce on October 3, 1970. The mission responsibilities of NOAA are to assess the socioeconomic impact of natural and technological changes in the environment and to monitor and predict the state of the solid Earth, the oceans and their living resources, the atmosphere, and the space environment of the Earth.

The major components of NOAA regularly produce various types of scientific and technical information in the following types of publications:

**PROFESSIONAL PAPERS** - Important definitive research results, major techniques, and special investigations.

**CONTRACT AND GRANT REPORTS** - Reports prepared by contractors or grantees under NOAA sponsorship.

**ATLAS** - Presentation of analyzed data generally in the form of maps showing distribution of rainfall, chemical and physical conditions of oceans and atmosphere, distribution of fishes and marine mammals, ionospheric conditions, etc.

**TECHNICAL SERVICE PUBLICATIONS** - Reports containing data, observations, instructions, etc. A partial listing includes data serials; prediction and outlook periodicals; technical manuals, training papers, planning reports, and information serials; and miscellaneous technical publications.

**TECHNICAL REPORTS** - Journal quality with extensive details, mathematical developments, or data listings.

**TECHNICAL MEMORANDUMS** - Reports of preliminary, partial, or negative research or technology results, interim instructions, and the like.
