#### Abstract

The annual incidental bycatch of seabirds by demersal groundfish longline vessels in Alaska has ranged between 4,100 and 26,300 during the period 1993 through 2006. However, average annual bycatch has declined by $73 \%$ in the last 5 years (2002-2006) compared to bycatch from the late 1990s. Despite the recent reductions resulting from mandatory mitigation requirements, seabirds continue to be caught at higher rates than would be expected given results of controlled studies that demonstrated bycatch reductions of nearly $100 \%$ with paired streamer lines. We characterize recent seabird bycatch data (2004-2007) from the Alaska demersal longline fisheries and analyze factors influencing seabird bycatch for two fisheries - Pacific cod (Gadus macrocephalus) and sablefish (Anoplopoma fimbria). Previous analyses of 1995-2000 bycatch data showed that individual vessel was the single most important source of variability in seabird bycatch rates in Alaska longline fisheries. Certain vessels consistently caught a higher proportion of birds across years and fisheries. Our results demonstrate that a few individual vessels continue to be responsible for the majority of seabird bycatch. Six vessels out of 39 contribute $38 \%$ of all birds caught in the cod demersal longline fishery when sampled rates are extrapolated to hooks deployed in observed sets. Based on this analysis, we recommend a variety of methods to further reduce seabird bycatch by longline vessels in Alaska.

## INTRODUCTION

Incidental catch, or bycatch, of seabirds in marine fisheries is a global conservation issue (Brothers et al. 1999, IUCN 2008). While seabird bycatch occurs in all major gear types (Brothers et al. 1999, Bull 2007, Løkkeborg 2008), longline fisheries in particular have been associated with the declines of several albatross species (Weimerskirch and Jouventin 1987, Croxall et al. 1990). Seabirds are most frequently caught during longline gear deployment while attempting to take bait from hooks although they are also caught during gear retrieval (Brothers 1991). The United States has implemented several regulatory instruments and policies to address seabird bycatch in U.S. fisheries (e.g., Migratory Bird Treaty Act, Magnuson-Stevens Fishery Conservation and Management Act, the Endangered Species Act; Moore et al. 2009). NOAA's National Marine Fisheries Service (NMFS) coordinates policies among domestic agencies affected by these regulations and participates in the regional fishery management organization (RFMO) frameworks to instigate seabird bycatch reduction in global fisheries.

Within the United States, seabird bycatch has historically been the highest in Alaska (NMFS 2001). From 1993 to 2006, the annual incidental catch of seabirds by demersal groundfish longline vessels in Alaska has ranged between 4,100 and 26,300 (NMFS 2006b, 2008). Initial mitigation requirements, strongly supported by industry, were implemented for Alaska groundfish longline vessels in 1997 and Alaska halibut vessels in 1998 (NMFS 1997, 1998); however, these measures did not appear to substantially reduce bycatch (Fig. 1). In 1999-2000, research was performed by Washington Sea Grant to test four mitigation techniques: streamer lines (single and paired), gear weighting, a
setting tube, and a line shooter. All techniques tested, except the line shooter, significantly reduced bycatch rates compared to a control of no deterrent. The study concluded that paired streamers performed best, reducing bycatch rates by $88-100 \%$, and recommended several modifications to regulations in place at the time (Melvin et al. 2001). These recommendations included deployment of paired streamers during the entire setting process, specific material and performance standards, and elimination of nighttime gear setting as an allowable deterrent. The industry voluntarily implemented these recommendations as early as 2001 although the final rule did not go into effect until 2004 (NMFS 2004). Concurrent with the initial mitigation study in 1999-2000, Dietrich et al. (2009) found that individual vessel was the single most important factor explaining the variation in seabird bycatch rates in Alaska longline fisheries during 1995-2000. Certain vessels consistently caught a higher proportion of birds across years and fisheries.

Since these studies and the last regulatory modification, average annual bycatch has declined by $73 \%$ (2002-2006; mean 5,127 ) compared to bycatch from the late 1990s (1995-2000; mean 18,658). Despite the recent reductions, seabirds continue to be caught at higher rates than would be expected given research results (i.e., reductions should be closer to $100 \%$ if streamers are deployed effectively; Melvin et al. 2001, Dietrich et al. 2008). Given the potential effectiveness of seabird mitigation gear, we were interested in examining whether a vessel effect still exists. The objectives of this project were to characterize recent seabird bycatch data from the Alaska demersal groundfish longline fisheries, determine if a small subset of vessels continue to be responsible for the majority of seabird bycatch, and recommend methods to further reduce seabird bycatch by longline vessels in Alaska.

## METHODS

## Fishery Description

Each year more than 250 million hooks are deployed by demersal groundfish longline vessels in the U. S. Exclusive Economic Zone in Alaska (EEZ; NMFS 2008). The primary groundfish target fisheries are sablefish (Anoplopoma fimbria), Pacific cod (Gadus macrocephalus), and Greenland turbot (Reinhardtius hippoglossoides). A vessel usually makes multiple gear deployments (sets) each day and the number of hooks deployed per set is variable between and within each target fishery (Table 1).

Both catcher (CV) and catcher-processing (CP) vessels operate in all target fisheries. In general, catcher vessels are small (20-80 feet), bait gear manually, fish during daylight hours, and deliver headed and gutted as well as whole catch to a shorebased facility for further processing. Catcher-processing vessels are larger (90-180 feet), typically use automatic baiting systems, and are likely to fish day and night and fully process fish on board. During our study interval, 41 catcher-processing vessels fished for cod and 25 for turbot under an open access management regime. Most cod sets were fished on the continental shelf at depths between 75 and $172 \mathrm{~m}(90 \%$ range $)$ from midAugust through April, whereas most turbot were caught in June-July on the Bering Sea slope (Fig. 2). Nearly 400 vessels harvested sablefish (Hiatt 2007) under an Individual Fishing Quota (IFQ) system. The majority of sablefish was harvested by catcher vessels on the Gulf of Alaska (GOA) continental slope. The sablefish season typically starts in early March and extends to mid-November (Fig. 2).

## Data

Fisheries catch and effort data were collected by NMFS-trained and certified fisheries biologists or observers. Observers are required at all times on groundfish vessels greater than or equal to 125 feet length overall (LOA; NMFS 2003). Vessels less than 125 feet and greater than or equal to 60 feet must carry an observer for $30 \%$ of the vessel's fishing days per quarter. Observers are not required on groundfish vessels less than 60 feet (e.g., most of the sablefish fleet) or halibut vessels of any size (except for a few rare circumstances).

The North Pacific Groundfish Observer Program (NPGOP; Fisheries Monitoring and Analysis Division, Alaska Fisheries Science Center, NMFS) provided fish and seabird bycatch data collected on commercial groundfish longline vessels from 2004 to 2007. For each set, observers recorded date and position of retrieval, mean depth, number of hooks deployed, and estimated weight of the total catch (NMFS 2006a). Because many longline vessels operate around the clock and there is usually only one observer, not all sets were monitored for species composition. Instead, observers randomly selected sets for species composition sampling (hereafter referred to as sampled sets; $n=45,533$ sets) as well as the collection of other biological information. Within each sampled set, observers were instructed to monitor a minimum of one-third (average $35 \%$; range $3 \%$ $100 \%$ ) of the total hooks retrieved per set for species composition, recording both the number and estimated weight of target fish and all bycatch species including seabirds. In addition, seabird mitigation techniques were recorded as a 4-level categorical variable defined as follows: not verified; or when independently verified by the observer, zero;
one streamer deployed; or two streamers deployed. Seabird behavior was not monitored during gear deployment.

Data included in this analysis were restricted at two levels. For the initial examination of mean seabird bycatch rates among target fisheries, years, months, regions, and areas, 2,719 sets were excluded. These consisted of sets with all the catch discarded (10 sets); sets deployed during a seabird mitigation experiment in 2005 (613); sets that appeared to be targeting halibut, rockfish, or unknown target $(1,544)$; and sets with $<$ $20 \%$ of the hooks monitored (552). For the vessel-specific comparisons and modeling of factors influencing bycatch rates, we focused only on the cod and sablefish fisheries because these fisheries had the largest sample sizes and are different in terms of areas fished (both geographic and depth strata). Sets were included in this part of the analysis only if a vessel fished 3 of the 4 years and a minimum of 5 days in each year, which eliminated $<3 \%$ of the sets monitored in the cod fishery and $16 \%$ of the sets monitored in the sablefish fishery. In the cod fishery models, there was one set with a depth out of range for this fishery and 121 sets contributed by a single catcher vessel that were also excluded.

In 2006, NPGOP observers were tasked with an optional special project to describe offal discharge practices. For each vessel, observers were instructed to create a vessel diagram and flow chart of discard location and discharge type. We reviewed the submissions in order to inform the discussion regarding vessel-specific seabird bycatch reductions.

## Analysis

Mean seabird bycatch rates were calculated for each target, year, month, large geographic region, NMFS management area (Fig. 3), and vessel, and for each seabird species or species group (defined in Table 2; Appendices 1-7), to qualitatively examine variation among the factors. Separate generalized additive models (GAMs) were constructed for the dominant seabird groups in the Pacific cod and sablefish target fisheries. Initial variables included categorical factors for year, month, large geographic region, NMFS management area, vessel, and deterrent, as well as continuous variables for day within year, fishing depth, total hooks deployed, and target fish CPUE (Table 3). GAMs allow for increased flexibility in assumptions compared to traditional regression techniques (i.e., normality and constant variance) as well as direct specification of error distribution (Hastie and Tibshirani 1990). GAMs also allow for the exploration of nonlinear functional relationships between the dependent (i.e., seabird bycatch rates) and independent variables (Hastie and Tibshirani 1990). Models were fitted using S-Plus 2000 (Insightful Corp., Seattle, WA, USA) and were specified with either a quasilikelihood estimate of the error distribution which included a log link and variance equal to the mean or the binary error distribution. The quasi family in S-Plus allows for parameter estimation without directly specifying the error distribution (Campos et al. 1997, Anon. 1999). The quasi-likelihood method provides a more accurate estimate of the standard errors around estimated coefficients because it accounts for the dispersion parameter $(\Phi)$ estimated from the data rather than assuming $\Phi$ equals some theoretical value (e.g., $\Phi=1$ when Poisson or negative binomial distributions are directly specified). An offset function of sample size (number of hooks monitored) was included so that the modeling and analysis of the response variable, the number of birds caught, actually
pertained to the bycatch rate (number of birds per 1,000 hooks; Clarke et al. 2003; Gardner et al. 2008). In three instances when seabird bycatch occurred in less than $1 \%$ of the sets, the binary error distribution was utilized. Variables were only loaded as main effects (including multiple smoothing options on continuous variables) with the exception of the loess smoothed surface of latitude and longitude. Interactions were excluded for several reasons: (1) interactions are computationally expensive given the magnitude of the data set (especially in the cod fishery); (2) intuitive explanations of multiple interactions are difficult, and conservation and management conclusions as to the influence of specific factors on bycatch rates are nearly impossible; and (3) some variables may be correlated non-linearly.

We used deviance as a nominal goodness-of-fit criterion. As model deviance increases (or conversely as residual deviance decreases), model fit improves. Deviance in the realm of GAMs is analogous to variance in the realm of linear regression models (Swartzman et al. 1992). Significance of each variable was tested in nested models using an approximate F-test (Hastie and Tibshirani 1990, Chambers and Hastie 1992). In general, GAM models were reduced to the best fit using a forward stepwise analysis of deviance technique with the goal of minimizing residual deviance (Chambers and Hastie 1992). Once a model was obtained that included sequentially significant variables, each variable was dropped individually to assess its unique contribution to model fit and thus its influence on seabird bycatch.

## RESULTS

Mean seabird bycatch rates ranged widely for each species group and fishery as well as among years (Fig. 4), months (Figs. 5-7), areas (Figs. 8-10), and vessels (Figs. 1113). Total bird bycatch rates were at their maximum in the turbot fishery across all 4 years (Fig. 4), although sample sizes in this fishery were much smaller than the other two fisheries examined. Fulmars were caught at the highest frequency in both the cod and sablefish fisheries (Table 4). However, in the cod fishery, the largest bycatch events were of gulls ( 45 and 77 birds), followed by shearwaters ( 33 and 20 birds) and fulmars (22 birds; Table 4). The high events in the cod fishery were caught by four unique vessels. The maximum number of birds caught in a set was much less in the sablefish fishery (maximum 14) with fulmars dominating all of the highest frequencies (greater than 6; Table 4). The highest events in the sablefish fishery were caught by two unique vessels.

In terms of temporal variables, peak bycatch rates occurred in 2007 regardless of fishery (Fig. 4). In the cod fishery, this trend was due to extraordinary shearwater and fulmar bycatch rates in August through October (Fig. 5). There was also an unusually high pulse in shearwater bycatch rates in July 2005 in all fisheries. Unlike the cod fishery where seabird bycatch rates increase in the late fall/winter season, seabird bycatch rates in the sablefish fishery were usually higher in the early season (March-May; Fig. 7). In terms of spatial variables, rates were generally highest in the Bering Sea for the cod fishery and the Gulf of Alaska for the sablefish fishery, although there were no consistent trends among areas from year to year (Figs. 8-10).

In the cod fishery, vessel, year, month, and area were all significant factors influencing bycatch rates in seabird catch models, regardless of species group (Table 5). Date and deterrent were significant in three of four groups. In the cod fishery, CPUE was significant in the gull and shearwater models where bycatch rates declined as fish catch increased, although this effect was sharper for gulls. Depth was significant only in the shearwater model, although the relationship with depth was not obvious from partial residual plots. The total number of hooks deployed was significant for shearwaters and albatross only.

In the sablefish fishery, vessel, year, and total hooks deployed were consistently significant factors influencing seabird bycatch rates across groups (Table 5). Month, date, area, and sablefish CPUE were significant for three of four groups. Sablefish CPUE was significant for all species except fulmars, and in general, bird bycatch declined as fish catch increased.

A closer examination of vessel-specific seabird bycatch rates confirmed that a few individual vessels consistently had the highest bycatch rates across all years (Figs. 1113). In addition, these same vessels tended to catch birds on a higher proportion of their sets (Tables 6-7). Furthermore, this trend was consistent across fisheries for a few catcher processors. The vessels at the lowest end of the seabird bycatch rate spectrum were also consistent across years and fisheries. The number of streamer lines deployed does not explain these vessel differences either (e.g., one vessel at the low end of bycatch rates in the cod fishery did not deploy any streamers on $18 \%$ of the sets verified by the observer).

Thirty-one of 168 observers deployed on catcher-processing vessels completed the offal discharge special project. The responses included 23 of the 40 unique CPs operating in 2006. Although the amount of information garnered from the offal discharge special project that was relevant to this analysis was sparse, it appears that the high bycatch rates of at least two vessels could be due to seabirds becoming hooked during gear retrieval rather than gear setting, as is the norm. This bycatch was likely due to birds aggregating at discharge outflows forward of the hauling station. Birds are attracted to the fishery discharge and land on the water. As the vessel moves forward, retrieving gear, the birds pass by the gear hauling station and sometimes become hooked.

## DISCUSSION

As in other seabird bycatch studies in demersal (Barnes et al. 1997, Weimerskirch et al. 2000, Belda and Sanchez 2001, Reid et al. 2004) as well as pelagic longline fisheries (Murray et al. 1993, Gales et al. 1998, Klaer and Polacheck 1998), a variety of spatial and temporal variables were significant predictors of seabird bycatch events in the 2004-2007 Alaska groundfish longline fisheries. However, similar to the analysis of 1995-2000 data from the Alaska groundfish longline fisheries (Dietrich et al. 2009), individual vessel remained the single most important factor in all but one model for explaining variation of seabird bycatch rates in the more recent time period.

Unfortunately, the reasons for consistently high (or low) bycatch rates by a few vessels remain elusive. Additional information must be collected regarding vessel characteristics and behavior before solutions can be adequately addressed (see Table 8 for additional
data needs). If this information were collected from all vessels, the knowledge gained from the 'low' bycatch vessels could be incorporated into future outreach.

In the meantime, the fishing industry and fisheries managers could collaborate to further reduce seabird bycatch rates in two ways - providing input to modify the current fleet-initiated reporting system, and targeting outreach to the handful of vessels with a seabird bycatch problem. The CP cod fleet currently hires a consultant to analyze their seabird bycatch data (Gilman et al. 2006); however, these reports are based on quantity of birds observed caught, not on a standardized catch rate or extrapolated estimates. Therefore, some of the high bycatch rate vessels may not be aware that they rank the highest in the fleet due to differences in total number of hooks deployed. For instance, a vessel that catches 10 birds on 250,000 hooks has a rate of 0.04 birds per 1,000 hooks, whereas a vessel catching 10 birds on 500,000 hooks has a rate of 0.02 ; however, they appear to be the same when only quantity of birds is reported. It is important to evaluate both the rate and the total bycatch (i.e., extrapolated to total effort) when determining which vessels have the highest impact on seabirds.

Six out of 39 vessels contribute $38 \%$ of all birds caught in the cod fishery when sampled rates are extrapolated to hooks deployed in observed sets. Note that these same six vessels only constitute $15 \%$ of total effort during the same fishing operations. Further bycatch reduction work should focus on these vessels which would in turn reduce the overall seabird bycatch attributed to the cod demersal longline fishery. Targeted outreach could be accomplished by touring these vessels to gather information on current mitigation techniques, collaborating with each vessel's crew on the types of techniques
they think would be most likely to reduce bycatch rates on each vessel, and developing a reduction plan. Once a plan is agreed upon, NMFS staff or a specially trained observer acting on behalf of NMFS, should be deployed to troubleshoot and assist while these vessels are actively fishing.

Finally, both the sablefish and cod fisheries are certified by the Marine Stewardship Council (MSC; Chaffee et al. 2006a, 2006b). As part of the MSC process, these fisheries are annually audited to verify they are complying with certification conditions established in the final evaluations. Although there are no specific seabird reduction criteria in either report, the cod certification does contain a condition pertaining to effects of fulmar bycatch on the North Pacific fulmar population. High seabird bycatch rates driven by a few vessels have the potential to impact the entire fleet in future assessments, and this could motivate changes in fishing practices to reduce bycatch ${ }^{1}$.

## ACKNOWLEDGMENTS

We would like to thank Martin Loefflad and Ren Narita, North Pacific Groundfish Observer Program, Fisheries Monitoring and Analysis Division, for supplying setspecific catch data, Kathleen "Kitty" McCauley for supplying observer logbooks on short notice, and Ann Edwards for supplying the offal discharge special project data. The report was vastly improved by the reviews of Stephani Zador, Kerim Aydin, and Craig Faunce. This project was funded by the National Marine Fisheries Service's National Seabird Program. Finally, we thank the groundfish observers who served on demersal longline vessels during 2004 through 2007, and the vessel owners, officers, and crew who supported observers in their work and did their best to avoid seabird bycatch during fishing operations.

Table 1. -- Summary of fishery characteristics (based on observed sets). CP: catcher processor; CV: catcher vessel; CDQ: Community Development Quota.

|  | Year | Cod | Sable | Turbot |
| :--- | :---: | :---: | :---: | :---: |
| Fishing depth <br> (average meters; 90\% range) | All | 117.5 <br> $(75-172)$ | 568.7 <br> $(358-733)$ | 575.6 <br> $(344-739)$ |
| Set length (average \# of <br> hooks) - CP / CV | All | $14,280 / 2,777$ | $5,417 / 3,888$ | $8,240 / 2,268$ |
|  | 2004 | $10,907 / 51,302$ | $1,278 / 2,021$ | $448 / 1,247$ |
| \# sets / sampled hooks | 2005 | $10,165 / 49,789$ | $1,358 / 2,294$ | $509 / 1,510$ |
| (1000s) | 2006 | $8,287 / 39,712$ | $1,386 / 2,247$ | $456 / 1,248$ |
|  | 2007 | $6,345 / 31,994$ | $1,243 / 2,164$ | $432 / 1,293$ |
| \# days with sample data | 2004 | $219(340)^{\dagger}$ | 196 | 92 |
| (including CDQ) | 2005 | $209(314)$ | 189 | 98 |
|  | 2006 | $192(267)$ | 211 | 116 |
| Number unique CP | 2007 | $164(256)$ | 200 | 92 |
| Number unique CV | All | 41 | 25 | 25 |

${ }^{\dagger}$ Bering Sea catcher-processor season shown; see Figure 2 for more detail by region and vessel type.

Table 2. -- List of seabirds observed caught in Alaska demersal groundfish longline fisheries, 2004 - 2007.

| Common name | Scientific name | Analysis grouping |
| :--- | :--- | :--- |
| Laysan albatross | Phoebastria immutabilis | Albatross |
| Black-footed albatross | Phoebastria nigripes | Albatross |
| Albatross, unidentified | Phoebastria spp. | Albatross |
| Northern fulmar | Fulmarus glacialis | Fulmar |
| Sooty shearwater | Puffinus griseus | Shearwater |
| Short-tailed shearwater | Puffinus tenuirostris | Shearwater |
| Dark and unidentified shearwater | Puffinus spp. | Shearwater |
| Tubenose, unidentified | Procellariiformes | Other |
| Herring gull | Larus argentatus | Gull |
| Glaucous-winged gull | Larus glaucescens | Gull |
| Glaucous gull | Larus hyuperboreus | Gull |
| Gull, unidentified | Laridae | Gull |
| Red-legged kittiwake | Rissa brevirostris | Other |
| Black-legged kittiwake | Rissa tridactyla | Other |
| Cormorant, unidentified | Phalacrocoracidae | Other |
| Thick-billed murre | Uria lomvia | Other |
| Common murre | Uria aalge | Other |
| Murre, unidentified | Uria spp. | Other |
| Alcid, unidentified | Alcidae | Other |
| Seabird and bird unidentified | Aves | Other |

${ }^{\dagger}$ An additional gull species, slaty-backed gull $L$. schistisagus, was identified from carcasses collected during a seabird mitigation experiment in 2005 (Phillips et al. 2008).

Table 3. -- Initial variables included in seabird bycatch models.

| Variable | Description |
| :--- | :--- |
| Year | 2004, 2005, 2006, 2007 |
| Month | Jan. - Dec. |
| Day | Julian date |
| Large geographic area | Bering Sea, Aleutian Islands or Gulf of Alaska <br> Loaded as categorical NMFS management area or loess <br> Area |
| smoothed surface of latitude and longitude |  |
| Depth | Average fishing depth |
| Target CPUE | Cod or sablefish catch per unit effort (kg per 1,000 hooks) <br> Total hooks |
| Total hooks deployed in set |  |
| Deterrent | Not checked by observer, No deterrent, Single streamer or <br> Paired streamer |
| Vessel | Unique identifier for vessel |

Table 4. -- Frequencies of observed bycatch events in the subset of data used for GAM models in the $\operatorname{cod}(\mathrm{A})$ and sablefish (B) fisheries.

A

| Frequency | Fulmar | Gull | Shearwater | Albatross |

${ }^{\circ}$ variable loaded with spline smoother

Table 6. -- Percent of observed sets by CPs that caught at least one bird in the cod fishery by vessel (rows) and year (columns). Vessels are listed in descending order of their combined 2004-2007 mean seabird bycatch rate; annual mean is in bold. For each year, dark orange highlighted boxes indicate the top four highest bycatch rates, orange indicates the next four highest rates, tan indicates the remaining vessels above the annual mean, and green indicates the lowest seven bycatch rates. Blank cells indicate no fishing.

| Percent sets with bird bycatch |  |  |  |
| :---: | :---: | :---: | :---: |
| 2004 | 2005 | 2006 | 2007 |

Table 8. -- Information needs to address vessel-specific differences in seabird bycatch rates.

## Vessel attractiveness to seabirds

1. Auto- or hand-bait?
a. If auto-bait, does excess bait just fall continuously from stern during gear deployment or is it collected and discarded after gear deployment?
b. If auto-bait, how effective is baiter? Are there a lot of flying pieces of bait or does it typically stay on the hooks? Is there a scupper under the auto-baiter that is discharging small bait pieces into the gear deployment path?
c. If hand-bait, is bait fresh? What is typical lag time between baiting the gear and deployment?
2. Offal or other discharge during gear deployment?
a. If offal, is it macerated? What size? Where does discharge occur?
b. Does discharge typically float into gear deployment path?
c. Which birds are present during discharge? Use protocol similar to Zador and Fitzgerald (2008).

Effect on gear sink rate (i.e., distance astern gear available near surface)
3. Gear deployment speed
4. Location of gear deployment (stern versus side)
5. Deployment into propeller up- or down-wash
6. Height of gear deployment
7. Does the vessel use integrated weight gear?
8. Does vessel add weight to gear (e.g., cannonballs, rocks)? If yes, how much weight is added and at what intervals? Is weight added all the time or just under certain circumstances (e.g., high current fishing areas)?
9. Does vessel add floats to gear? Are floats added all the time or just under certain circumstances (e.g., high snail, crab or starfish areas)?
10. Does vessel utilize a line setting tube or line shooter? If yes, how often does gear jump out of the tube and deploy normally?

## Streamer line effectiveness

11. How many streamer lines are deployed? Height of steamer line(s) at stern. How are streamers attached?
12. What is used to create drag (terminal end)?
13. Aerial extent of streamers
14. Are streamers frequently tangled or do they always hang down to the water (if there were no wind)?
15. When only a single streamer deployed, is it always on the windward side?
16. Are streamers maintained? Are there streamers frequently missing or broken?
17. Reason for lack of streamer deployment. Are all instances without streamers due to the weather exclusion?

## Crew attitude toward using mitigation

18. How often does streamer become entangled in longline gear?
19. Captain/mate attitude regarding deployment of streamer lines
20. Crew attitude regarding deployment of streamer lines
21. Consistency of crew that deploy streamer lines within and among trips

## Mitigation techniques utilizted for birds caught during deployment are different than during retrieval.

22. Differentiate data collected between birds caught during gear deployment and retrieval. If birds frequently caught during retrieval, is there any discard forward of the hauling station?

## Misc.

23. Bird presence (abundance) and interaction rate during gear deployment?
24. Does vessel employ any other seabird mitigation techniques? Explain in detail.

Figure 1. -- Estimated annual seabird bycatch (primary axis) and rates (birds/1,000 hooks, secondary axis) in Alaska demersal groundfish longline fisheries (NMFS 2008). Error bars are the upper $95 \%$ confidence interval on total seabird bycatch estimate.

Figure 2. -- Opening and closure (no symbol) dates by fishery and year (2004 to 2007 ordered from bottom, tan, to top, black). Blue lines for cod fisheries indicate catcher vessels, which differed from catcher-processing vessels. GOA: Gulf of Alaska; BS/AI: Bering Sea and Aleutian Islands.
