SUMMARY

Contaminant analyses (for trace metals, PCBs, pesticides, PAHs, and chlorinated dioxins and furans) were performed on samples of muscle of four species of fish captured during the period they are available to the recreational fishery in the New York Bight apex. These species (bluefish, fluke, sea bass, and tautog) were selected to represent three behavioral guilds (pelagic, demersal, and reef). Muscle tissues from each of three fish of a single species, captured at a single site, were combined for analysis, yielding 56 composites.

Concentrations of nine trace metals in each species were low and within the range of values found in uncontaminated finfish muscle. In all composites, levels of total mercury (including methyl mercury) were less than 0.11 ppm ($\mu\text{g/g}$) which is an order of magnitude below the FDA Action Level of 1.0 ppm for methyl mercury in seafood.

Concentrations of PCBs and pesticides were relatively low and related to the lipid content of the tissue. The sum of the 25 PCB congeners measured in this study had a maximum value of 0.57 ppm in a bluefish composite compared with an FDA Action Level of 2.0 ppm. This maximum value (0.57 ppm) may be roughly translated to an "arochlor-based" estimate of 0.9 ppm. Species averages for the study were 0.37, 0.03, 0.08, and 0.06 ppm for bluefish, fluke, sea bass, and tautog, respectively. With few exceptions, PAHs were largely not detected.

Analyses of 17 dioxin and dibenzofuran congeners were too unreliable to allow interpretation.

27 January 1995

INTRODUCTION

The purpose of this survey was to determine the concentrations of inorganic and organic contaminants in edible flesh of recreationally important fish species harvested in the New York Bight apex (Fig. 1). The strategy involved measuring trace metal and organic contaminant levels in muscle tissue composites (three animals per composite) in four fish species collected in a manner simulating the local recreational fishery. Bluefish, fluke, sea bass, and tautog were selected because of their recreational importance and because they are distinguished by differences in their life habits and ecology representing pelagic, demersal, and reef guilds. This report contains data on 9 metals and 83 organic contaminants in 56 composites of three fish each. Tissue from each fish was also archived for future individual analyses, if necessary.

SAMPLE COLLECTION AND PROCESSING METHODS

Fish collection

Collections of fish were made between September and December 1993 at 15 sites in the New York Bight (Fig. 1). Sample collection locations are listed in the appendix (Table A1). The approach was to collect fish at the same times and places, and using the same techniques, as local recreational fishermen. Collections were made using rod and reel while fishing the grounds that were then in use. Locations were mapped by LORAN.

Four species from three different behavioral guilds were collected: bluefish, *Pomatomus saltatrix* (pelagic); fluke, *Paralichthys dentatus* (demersal); sea bass, *Centropristes striatus* (reef); and tautog, *Tautoga onitis* (reef). Fishing effort was allocated equally among guilds. Even though the distribution, density and composition of the recreational fish community was not known precisely beforehand, all target species were obtained in sufficient numbers in all areas sampled. Fish to be analyzed were allocated post-collection, based on collection location and species (Table A2).

Sample processing

Guidelines for fish handling used in a previous study of polychlorinated biphenyls (PCBs) in bluefish (NOAA, USFDA, USEPA 1986) were used for this survey. Whole fish were returned to the laboratory on ice, where they were held not more than 48 hours before dissection. In the laboratory, all dissections were done under a laminar-flow hood supplying HEPA Class 100 clean air. Implements and supplies used for sample processing (scalpels, etc.) were made of stainless

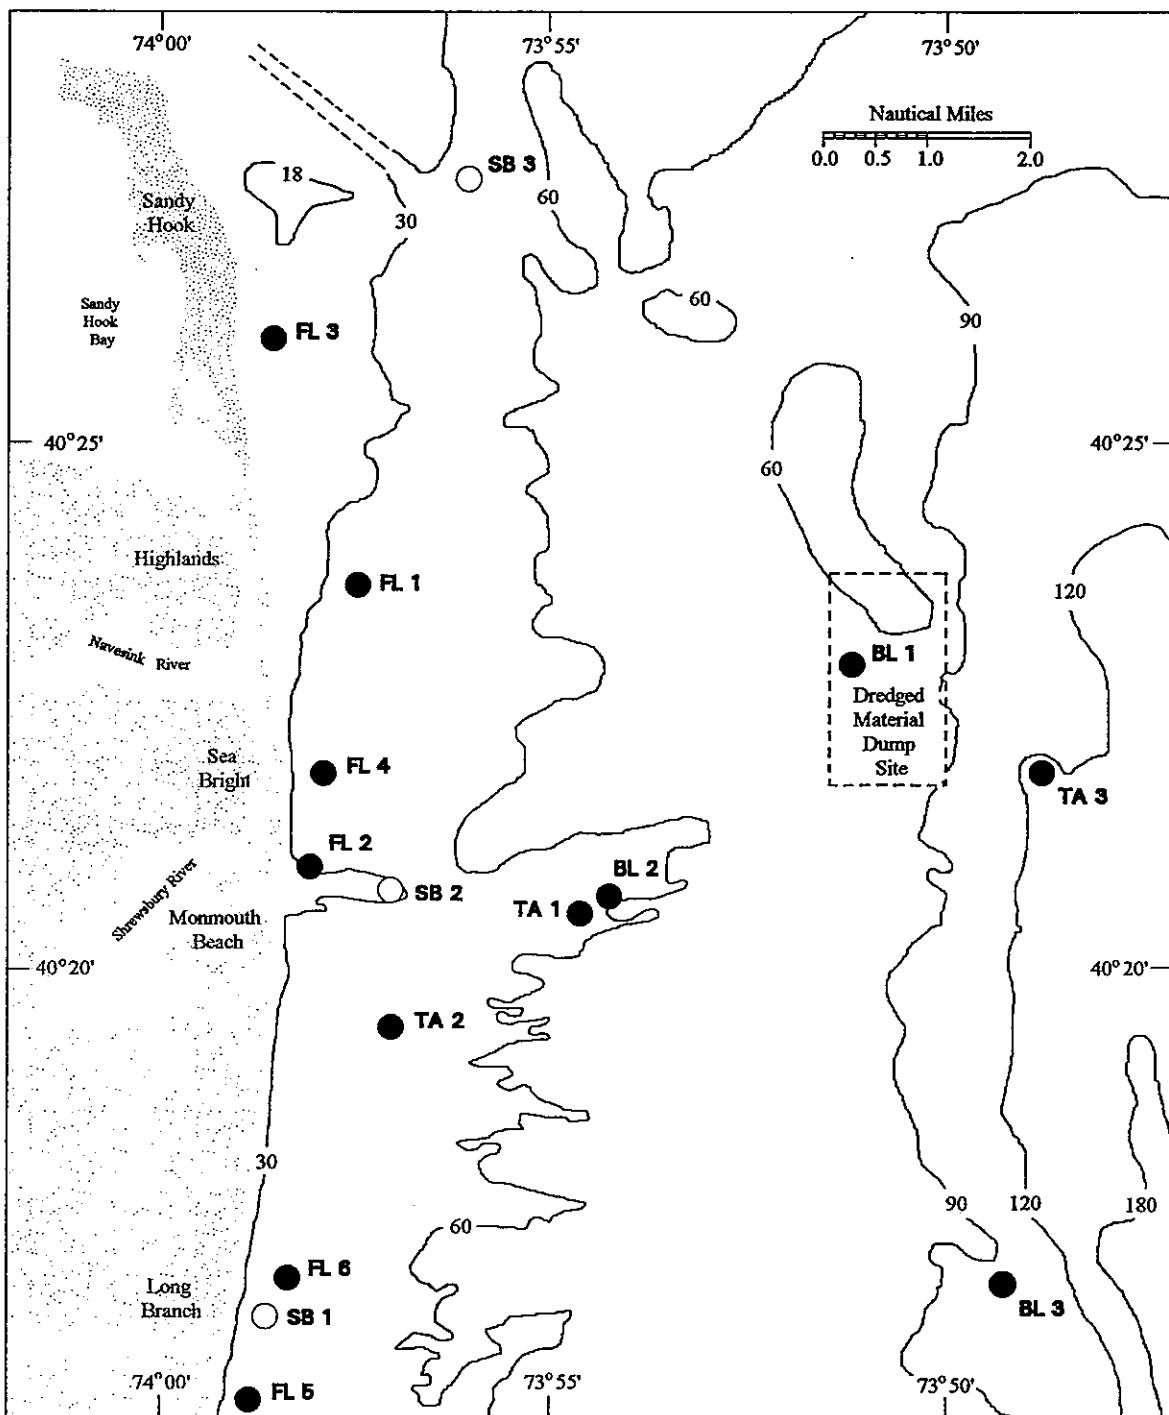

Figure 1. Study area showing sites of sample collection for bluefish (BL), fluke (FL), sea bass (SB) and tautog (TA).

steel and cleaned immediately prior to use with ultrapure 10% nitric acid, double deionized water (DDI), acetone, methylene chloride, and DDI again. For each specimen, weight was determined on an electronic balance (\pm 1 g), length was measured with a meter stick (\pm 1 mm), and gross abnormalities were noted. Where possible, sex was determined and recorded. In keeping with local consumption practices, fillets (muscle tissue) of fluke and tautog were prepared with the skin and scales removed. Bluefish and sea bass fillets included the skin intact with the scales removed.

For metals analyses, three small (approximately 2 cm³ each), adjoining pieces of the muscle (with skin attached if appropriate) were excised from the anterior dorsal portion of the fillet using a stainless steel scalpel. When both white and dark muscle were present, white muscle was collected for analysis, while separate subsamples of dark muscle were archived for possible future analyses. All subsamples were placed in acid-cleaned plastic vials and stored at -20°C. For organic contaminant analyses, the remainder of the fillet was homogenized in a freshly cleaned stainless steel blender and stored in a glass jar at -80°C. Because of their size, for fluke and small specimens of other species, both fillets were homogenized.

Muscle tissue composites were made up of equal portions of the subsamples of three individual fish of a given species. Individual specimens were randomly assigned to composites as follows. For specimens of each species at each site, the distribution of lengths was examined. Outliers were identified using the Dixon Outlier test (Sokal and Rohlf 1981) and were excluded from further consideration. For the remaining specimens, a random number was assigned to each and the records were sorted using the assigned random number. An appropriate number of specimens was then selected. For example, if five composites were to be analyzed from that particular site, the first 15 specimens were selected. The selected specimens were then sorted by length. The first 3 were then assigned to the first composite, the second three were assigned to the second composite, etc. Remaining tissue and specimens not included in the composites were stored frozen at the Howard Laboratory.

TRACE METALS

Analytical Methods

For each composite, after thawing, approximately 0.5 g of muscle (with skin attached for sea bass and bluefish) from each of three individual subsamples was placed in an acid-cleaned teflon vial and weighed. These were dried overnight at 60-65°C and re-weighed to obtain dry weights. Five mL of ultrapure, concentrated HNO₃ was added to each vial and the vials were allowed to stand at

room temperature for 2-4 hours. Vials were then placed inside teflon-lined bombs and the tissue was digested overnight at 120°C. After cooling, bombs were vented, the vials removed, and the digests were allowed to de-gas at room temperature overnight. The digests were then quantitatively transferred to 25-mL glass graduated cylinders and brought to volume using DDI water. The resulting solutions were analyzed using atomic absorption spectrophotometry (AAS) or inductively coupled plasma mass spectrometry (ICPMS). Details of the sample digestion and analysis procedures can be found in Zdanowicz *et al.* (1993).

Composites were analyzed for nine metals: silver (Ag), cadmium (Cd), chromium (Cr), copper (Cu), nickel (Ni), lead (Pb), zinc (Zn), arsenic (As) and mercury (Hg). Fourteen composites per species were analyzed, totaling 56 muscle composites. Three replicates of a standard reference material (SRM) and 3 process blanks were analyzed with each group of 28 composites. DOLT-1 (freeze-dried dogfish liver), obtained through the National Research Council of Canada, was used as the reference material. Results for the SRM analyses are listed in the appendix (Table B1). Method detection limits (MDLs) were computed as 3 times the standard deviation of the mean process blank ($n=6$) for each metal. MDLs were computed based on 1 g of muscle, digested and brought to 25 mL of solution (Table B1).

One composite from each species was analyzed in duplicate. The Relative Percent Differences (RPDs) were between approximately 2 and 15% for the nine metals in four duplicate analyses. RPDs were computed as

$$[|X_1 - X_2| / \{(X_1 + X_2) / 2\}] \times 100$$

where the subscripts refer to the two replicates analyzed. Differences in mean metal concentrations between groups of specimens from different sites within each species and between species were investigated using analysis of variance (ANOVA, $\alpha = 0.05$) and Duncan's Multiple Range Test.

Results

Metal concentrations were all above the detection limits. Complete listings of analytical data are given in the appendix (Tables B2 and B3). Summary statistics (minimum, maximum, number of analyses, mean and standard deviation) were also computed for each metal for each species (Appendix Tables B4 and B5).

Metal concentrations in muscle composites from the four species were generally low and well within the ranges expected for metals in uncontaminated fish muscle (Fig. 2; Table 1). Values on a wet weight basis were less than 0.05 ppm for Ag; 0.1 to 0.5 ppm for Cd, Cr, Cu, Ni and Pb; 3.5 to 13.8 ppm for Zn; and 0.4 to 3.8 ppm for As. An Action Level has been set by FDA for methyl

mercury in fish or shellfish for human consumption at 1.0 ppm wet weight. The Hg analyses in this study determined total Hg content, a measurement which encompasses all species of mercury present including methyl mercury. The highest value in this study was 0.11 ppm. Thus, the FDA Action Level for mercury was not exceeded in muscle from these species; measured levels were an order of magnitude lower.

For each species, mean concentrations of each metal at each site were compared to determine whether any statistically significant differences existed; none were found, indicating that collection location was not related to muscle levels of the metals in these species. Therefore, data from all sites were pooled by species and mean concentrations were compared on a species basis (Fig. 2); several significant differences in mean metal levels were found. They were:

Cr: bluefish = sea bass > tautog = fluke
 Zn: bluefish > tautog = fluke = sea bass
 As: sea bass > fluke > tautog > bluefish
 Hg: tautog = bluefish > fluke = sea bass

where > identifies a significantly higher concentration in one or more

species and = indicates no significant difference between mean metal levels in two species.

These differences are probably related to the unique nature and behavior of each species. It is not uncommon to find differences in contaminant levels between species, for example, as were observed in midwater fish analyzed as part of a study of the 106 Mile Dumpsite (Zdanowicz *et al.* 1992). The differences, however, do not appear to be related to the behavioral guilds.

ORGANIC CONTAMINANTS

Analytical Methods

A total of 56 muscle composites was analyzed for 66 trace organic compounds (PCBs, PAHs, pesticides) using a modified NOAA procedure (Krahn *et al.* 1988), and for seventeen 2,3,7,8-substituted polychlorinated dibenzodioxin and dibenzofuran congeners using EPA method 8290 at a contract laboratory. For analysis of PCBs, PAHs, and pesticides, the procedure was to composite equal portions of three tissue subsamples (~4 g from each fish) and extract the analytes from the composite with methylene chloride using a soxhlet apparatus (NIST; Wise *et al.* 1990). Silica gel/alumina/florisil column chromatography was used to remove biogenic and other polar interferences. The cleaned fraction was further purified using size-exclusion high performance liquid chromatography (HPLC), then analyzed following EMAP procedures (USEPA 1993). PAHs were measured by gas chromatography-mass spectrometry in the selected ion mode (GC-MS-SIM) and PCBs and chlorinated pesticides were analyzed by dual-column capillary GC with an electron capture detector (GC-ECD). Samples containing higher levels of contaminants were reanalyzed by GC-MS for confirmation. Quality Assurance and Quality Control procedures followed EMAP protocols (Valente *et al.* 1992) and include participation in the annual NIST intercomparison exercise. Nomenclature for PCB compounds follows that of Ballschmiter and Zell (1980).

Results

Quality assurance results for the organic contaminants are contained in the appendix (Tables C1-C5 and C14-C18). The recovery of surrogate compounds ranged from 22.5% for naphthalene-d₈ in fluke to 167% for the HPLC surrogate 1,2,3-trichlorobenzene (TCB) in bluefish (Table C1). Consistent recoveries were found for the relatively non-volatile, octachlorinated biphenyl, BZ #198, which ranged from 85.3 to 94.9%. The low recoveries for naphthalene-d₈ in fluke are not unexpected considering the volatility of the compound, while the higher apparent recoveries of TCB in bluefish may be due to the co-elution of an unknown interfering compound(s) with the TCB peak. The analysis of NIST mussel tissue V,

QA93TIS5, with each analytical batch (Tables C2, C3, and C4) indicate good precision from batch to batch, although this material contained low concentrations of contaminants. The average relative standard deviation (RSD) for detected PCBs was 12.3% while for the 5 detected pesticides, average RSD was 13.5%; for PAHs, the average was 17.2%. Method detection limits (MDLs) for PCBs and pesticides were determined on 7 replicate fluke samples and are given in the bottom line of tables C6-C9. Because these values were 2.5 to 7 times the target detection limits (TDLs) of 2 ppb dry weight, a reanalysis of the detection limits was undertaken. It was determined that due to an assumption that the TDL was on a wet weight basis, the spike addition had been 25 times the TDL rather than the specified value of 1 to 5 times the TDL. Although the relative standard deviations were low (5-17%), the absolute standard deviation numbers (which determine the MDL) were high, resulting in MDLs about 5 times the TDL. To correct this problem, instrumental detection limits (IDLs) and estimated method detection limits based on the IDLs were determined (Table C21). For PCBs and chlorinated pesticides, estimated method detection limits ranged from 0.096 to 0.941 ppb, well below the TDL. A similar problem occurred for MDLs for PAHs determined on the fish matrix. The relative standard deviations and the MDLs based on those standard deviations were high due to over spiking of the matrix. A better estimate of the detection limit was obtained from the replicate analyses of mussel tissue. However, in the cases of four compounds a peak was not detected. For these, detection limits were estimated as follows. Assuming 10 g wet weight of muscle tissue, 50% efficiency in the sample extraction and cleanup steps, a 250 μ L final sample volume, and an instrument (GC-MSD) detection limit of 200 pg/ μ L, the MDL calculates to be 10 ppb wet weight. The MDLs reported in Tables C6-C9 are conservative values. For example, for the PAHs where no peak was found, we assumed IDLs of 200 pg/ μ L where observed limits are in the 25-50 pg/ μ L range (Table C21). Estimated method detection limits for PAHs based on IDLs were 2 to 6 ppb dry weight compared with TDLs of 10 ppb.

Table C5 summarizes dioxin and dibenzofuran analyses performed on commercially available fish tissue for which consensus concentrations were gained from 18 laboratories. Recoveries ranged from roughly 3% to 1287% of the consensus values. The recoveries of the internal standards added to this material as part of the analytical method also varied over a wide range - from roughly 22% to 670%. However, there was no apparent correlation between the percent recoveries of compounds in the reference material and percent recoveries of internal standards. Percent recoveries of internal standards added to fish composites from the New York Bight (Table C14) ranged from not detected (ND) to 15,760%. Only 362 of 930 individual congener internal standard recoveries fell within the range of 40% to 150%, and for only one of 61 composites were recoveries of all congeners within the specified limits. The lowest number of within-target recoveries was for bluefish (62 of 240 or 25.8%). MDLs for the 17 dioxin and dibenzofuran congeners were above target levels (Tables C15-C16),

sometimes by a large margin. Finally, despite the fact that sample-specific EDLs (estimated detection limits as defined in Method 8290) were often comparable to target values, overall quality of QA results was poor and unacceptable.

Complete listings of analytical results for chlorinated hydrocarbons and PAHs in each composite on both wet and dry weight bases are given in the appendix (Tables C6-C11). Tables C12 and C13 list levels of total PCBs, "arochlor-based" PCBs, total DDTs, total chlordanes, percent lipids, and percent water. Only the wet weight based values will be discussed. Mean concentrations of PCBs and pesticides are summarized in Figure 3 and Table 2. A significant number of values in these analyses were below the method detection limit (MDL). Where this was the case, one-half of the MDL was used as the composite mean. Thus, the mean PCB concentrations for bluefish are based largely on detectable values while those for fluke are based predominantly on MDLs. Nonetheless, the difference between the levels in these two species appears real. However, the MDLs lack variance; therefore, comparisons similar to those done for the trace metals cannot be performed.

The maximum concentration of Σ PCB in this study, reaching 0.57 ppm, was found in bluefish collected in October 1993 at site BL3. Following bluefish in order of contaminant level (Fig. 3) were sea bass and tautog, approximately equal; concentrations in fluke were the lowest. The same order was found for lipid content. In column four of Table 2, the sum of PCB congener concentrations is multiplied by 2 to generate a rough approximation of "arochlor-based" historical total PCB data. This calculated estimate is based on models (NOAA 1989; USACE, USEPA 1992) of the form

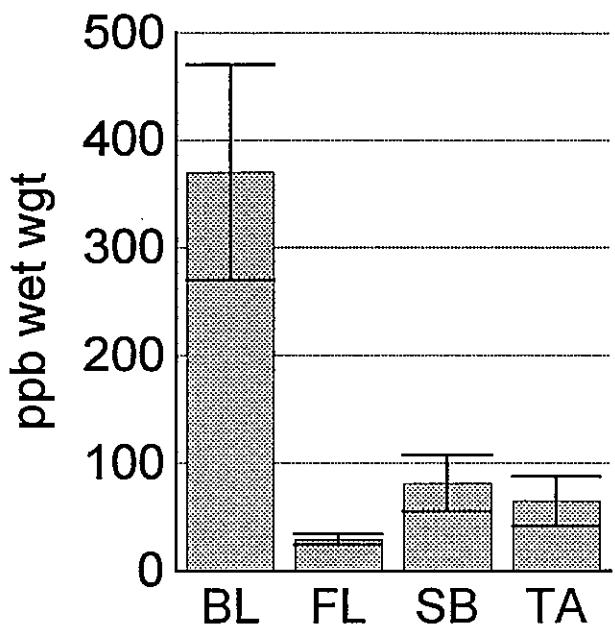

$$\Sigma\text{PCB} = A\{\Sigma(18 \text{ congeners})\} + B$$

where A was found to have values of 1.95, 2.3, and 2.19, and B ranged from 2.1 to 8.1.

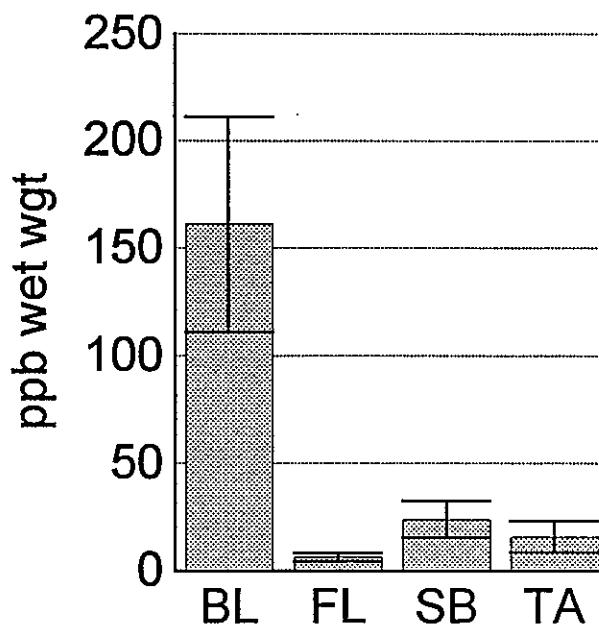

The highest of these estimates was 0.9 ppm, a value well below the Action Level of 2 ppm. Total DDT concentrations, on a species basis, followed the same order as Σ PCB and lipids (Fig. 3).

Associations between specimen lipid content or size and contaminant concentrations were plotted. This was made difficult by the presence of many contaminants at concentrations below the method detection limit (MDL). Where concentrations were below the MDL, the conservative value of one-half the MDL was used in calculations. The percentage of below-MDL values was 20% for bluefish, 91% for fluke, 57% for sea bass, and 63% for tautog. Given this caveat, it appears that PCB concentration increased with lipid content over all composites, and within species for sea bass, tautog, and bluefish (Fig. 4a). PCBs also

^{abcd} One-half the method detection limit (MDL) was used for values less than the detection limit (nd in appendix).

increased with length (which is closely correlated with weight; Fig. 5a) over all composites (Fig 4b). The limited size range sampled for each species does not permit within species interpretation. Similar, though less coherent, associations were found for DDTs (Fig. 4c,d).

PAHs were below detectable limits in the fish samples with the exception of acenaphthene in bluefish and benz(a)anthracene in fluke, sea bass and tautog. Detection limits based on mussel tissue (Table C4) ranged from 1.2 to 17.8 ppb (ng/g). This is expected as PAHs are extensively metabolized by the fish hepatic microsomal enzymes and the metabolites are temporarily stored in the bile until their excretion (Varanasi *et al.* 1989; Deshpande 1989). No readily apparent explanation is evident for the presence of these two compounds in fish tissue. It seems unlikely that the results for benz(a)anthracene are artifacts resulting from calculating detection limits, because all values were low with none of the detected

values exceeding the MDL by more than 50%. For acenaphthene, the MDL is based on incomplete quantification in the mussel tissue (4 of 8 values).

Dioxin results are given in Tables C19-C20. As stated earlier, QA results were of unacceptably poor quality. Since there was no correlation between percent recovery of compounds in the reference material and percent recovery of internal standards, the bias encountered during those analyses was not systematic and cannot be accounted for by use of some functional relation between the percent recoveries of compounds in the reference material and percent recoveries of internal standards. Thus, there is no possibility of correcting the reported dioxin concentrations for poor internal standard recoveries. Exacerbating this problem is the fact that MDLs were above target levels, sometimes by a large margin (to 8.7 pptr), and most dioxin values in composites were reported as below method detection limits (Tables C19-C20). Thus, one cannot know whether a compound was present in some low concentration, or the compound was not recovered in sufficient quantity to be quantified. In addition, the high values appearing in Tables C19 and C20 are also suspect, again due to poor recoveries of the internal standards. Together, these problems render the dioxin results too unreliable to allow interpretation. Efforts are underway to reanalyze the samples for these compounds to yield acceptable data which will be released in a supplemental report.

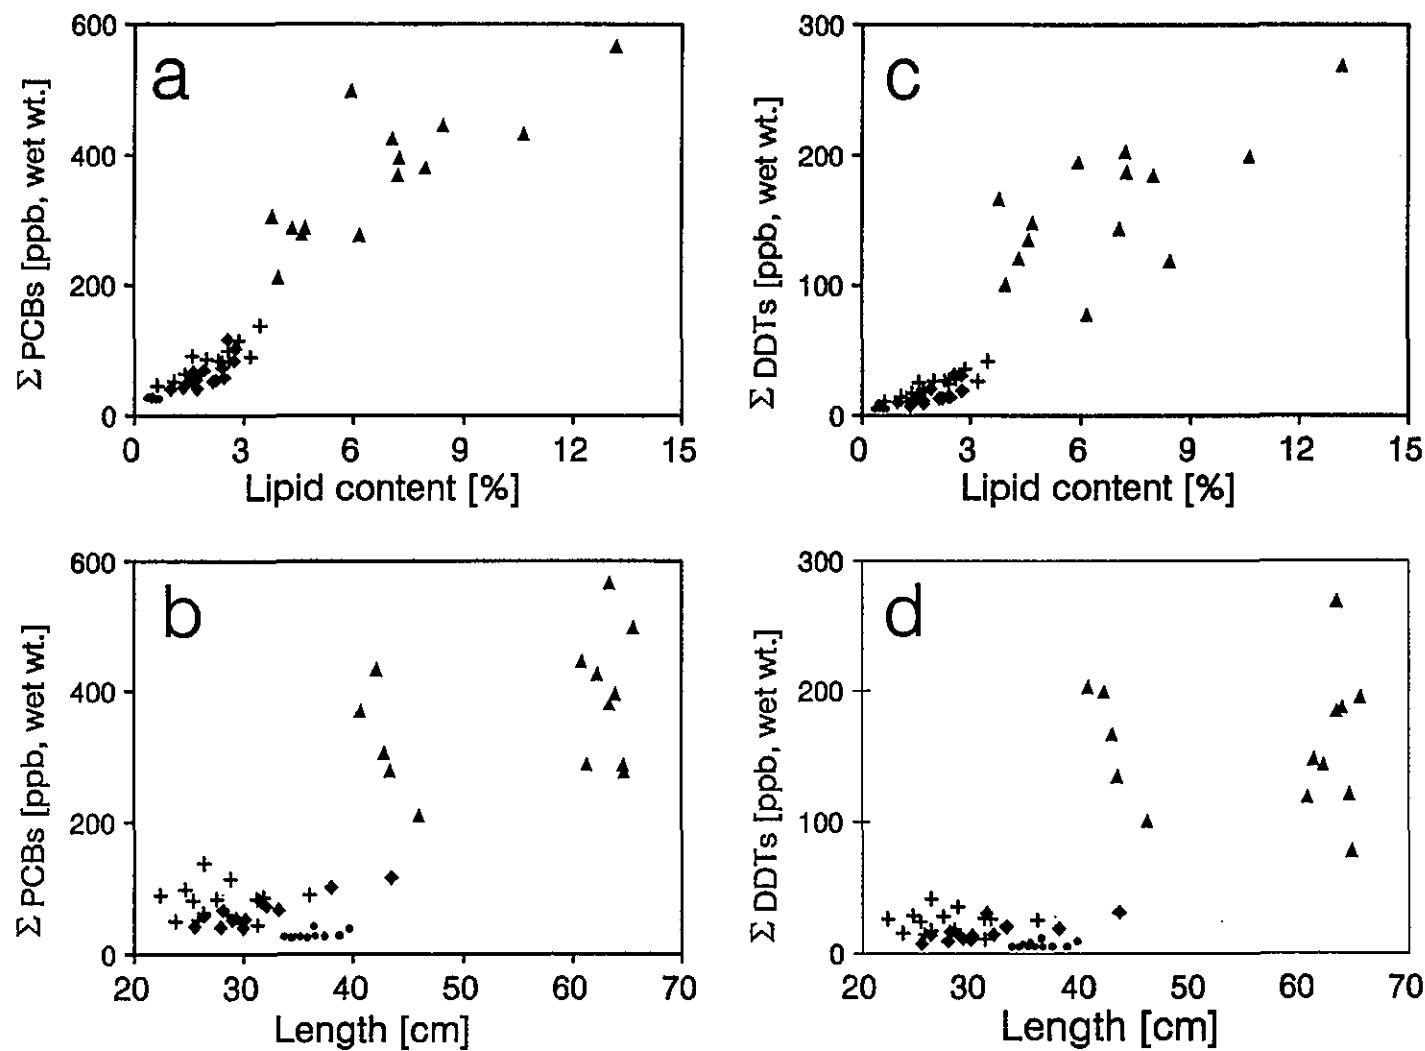

Figure 4. Relations between Σ PCBs (ppb = ng/g, wet weight) and lipid content (a) and average fish length per composite (b); Σ DDTs and lipid content (c) and average fish length per composite (d). Triangle = bluefish, circle = fluke, plus = sea bass, and diamond = tautog.

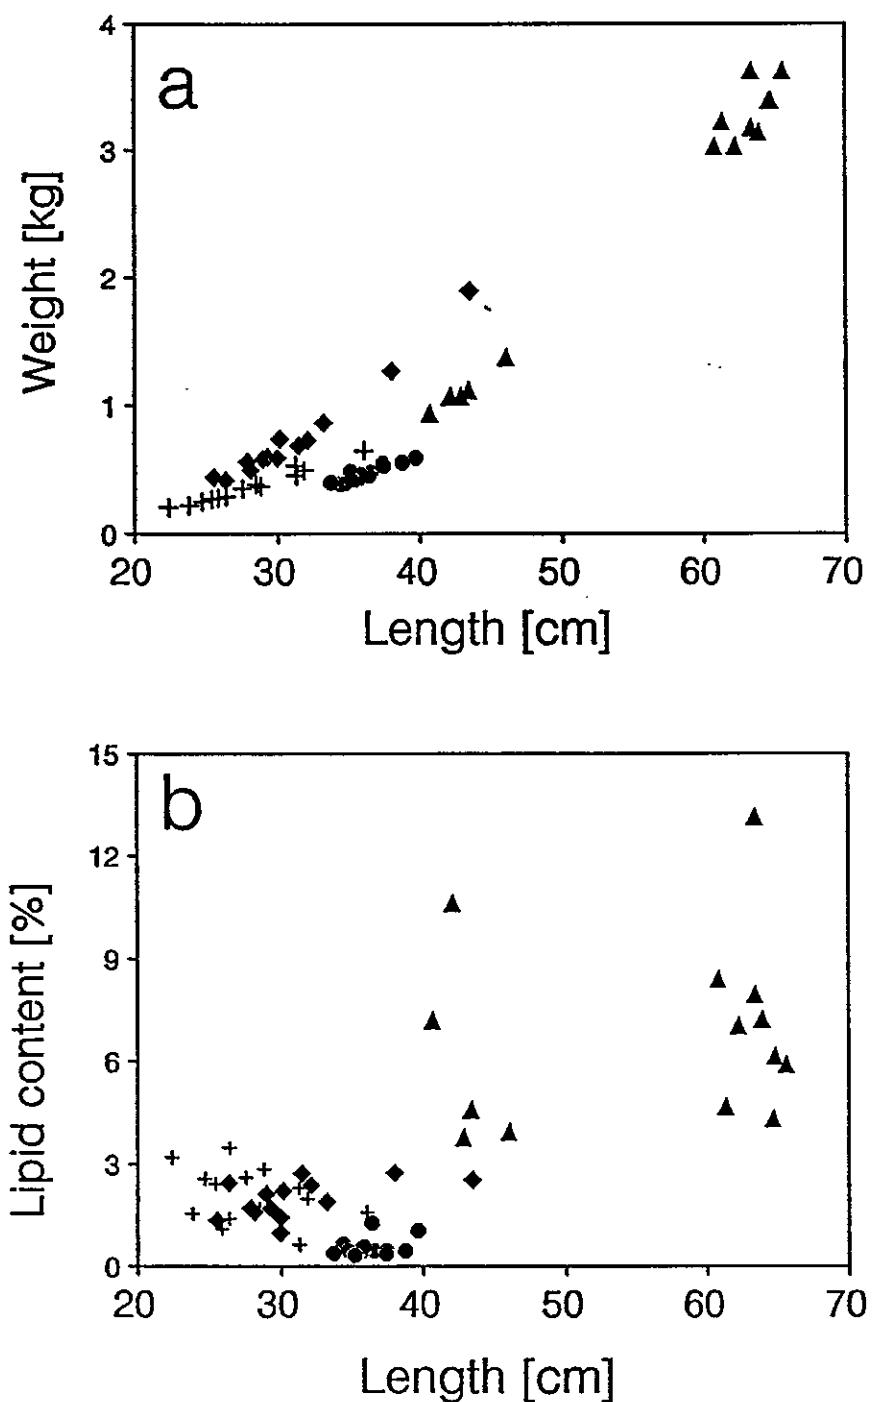

Figure 5. Relations between average fish length per composite and average fish weight per composite (a) and lipid content (b). Triangle = bluefish, circle = fluke, plus = sea bass, and diamond = tautog.

LIST OF APPENDICES

APPENDIX A: SAMPLING

Table A1. Sample collection site locations	A-1
Table A2. Allocation of specimens to composites	A-2
Table A3. Chemical compounds analyzed	A-6

APPENDIX B: TRACE METALS DATA

Table B1. Accuracy and precision of metals analyses	B-1
Table B2. Metal concentrations in muscle composites, ppm ($\mu\text{g/g}$) wet weight	B-2
Table B3. Metal concentrations in muscle composites, ppm ($\mu\text{g/g}$) dry weight	B-4
Table B4. Summary statistics for metal concentrations in muscle composites, ppm ($\mu\text{g/g}$) wet weight	B-6
Table B5. Summary statistics for metal concentrations in muscle composites, ppm ($\mu\text{g/g}$) dry weight	B-8

APPENDIX C: ORGANIC CONTAMINANT DATA

Table C1. Percent recoveries of PAH, PCB and pesticide surrogates	C-1
Table C2. PCB concentrations found in NIST mussel tissue V, QA93TIS5, ppb (ng/g)	C-2
Table C3. Pesticide concentrations found in NIIST mussel tissue V, QA93TIS5, ppb (ng/g)	C-3
Table C4. PAH concentrations found in NIST mussel tissue V, QA93TIS5, ppb (ng/g)	C-4
Table C5. Concentration of dioxin and furan compounds in CIL fish tissue, EDF-2525 pptr (pg/g) wet weight	C-5

Table C6. PCB concentrations in muscle composites, ppb (ng/g) wet weight	C-6
Table C7. PCB concentrations in muscle composites, ppb (ng/g) dry weight	C-10
Table C8. Pesticide concentrations in muscle composites, ppb (ng/g) wet weight	C-14
Table C9. Pesticide concentrations in muscle composites, ppb (ng/g) dry weight	C-18
Table C10. PAH concentrations in muscle composites, ppb (ng/g) wet weight	C-22
Table C11. PAH concentrations in muscle composites, ppb (ng/g) dry weight	C-26
Table C12. Total PCBs, total "arochlor-based" PCBs (multiplied by 2), total DDTs, total chlordanes, ppb (ng/g) wet weight; percent lipid and percent water in composites	C-30
Table C13. Total PCBs, total "arochlor-based" PCBs (multiplied by 2), total DDTs, total chlordanes, ppb (ng/g) dry weight; percent lipid and percent water in composites	C-32
Table C14. Percent recoveries of dioxin and furan internal standards added to composites	C-34
Table C15. Method Detection Limits (MDLs) for dioxin and furan compounds, pptr (pg/g) wet weight	C-38
Table C16. Method Detection Limits (MDLs) for dioxin and furan compounds, pptr (pg/g) dry weight	C-39
Table C17. Estimated Detection Limits (EDLs) for dioxin and furan compounds, pptr (pg/g) wet weight, in composites	C-40
Table C18. Estimated Detection Limits (EDLs) for dioxin and furan compounds, pptr (pg/g) dry weight, in composites	C-44
Table C19. Concentrations of dioxin and furan compounds, pptr (pg/g) wet weight, in composites	C-48

**Table C20. Concentrations of dioxin and furan compounds, pptr (pg/g)
dry weight, in composites** C-52

**Table C21. Instrumental detection limits and estimated method
detection limits** C-56

Table A3. Chemical compounds analyzed.

Polychlorinated biphenyls (PCB) ^a		Polycyclic aromatic hydrocarbons (PAH)	Pesticides
BZ #1 (1 Cl)	2-Chlorobiphenyl	naphthalene	hexachlorobenzene
BZ #8 (2 Cl)*	2,4-Dichlorobiphenyl	2-methylnaphthalene	lindane
BZ #18 (3 Cl)*	2,2',5-Trichlorobiphenyl	1-methylnaphthalene	aldrin
BZ #28 (3 Cl)*	2,4,4'-Trichlorobiphenyl	biphenyl	endrin
BZ #29 (3 Cl)	2,4,5-Trichlorobiphenyl	2,6-dimethylnaphthalene	octachlorostyrene
BZ #44 (4 Cl)*	2,2',3,5'-Tetrachlorobiphenyl	acenaphthylene	photomirex
BZ #50 (4 Cl)	2,2',4,6-Tetrachlorobiphenyl	acenaphthene	mirex
BZ #52 (4 Cl)*	2,2',5,5'-Tetrachlorobiphenyl	2,3,5-trimethylnaphthalene	<u>Chlordanes</u>
BZ #66 (4 Cl)*	2,3',4,4'-Tetrachlorobiphenyl	fluorene	heptachlor
BZ #101 (5 Cl)*	2,2',4,5,5'-Pentachlorobiphenyl	phenanthrene	heptachlor epoxide
BZ #104 (5 Cl)	2,2',4,6,6'-Pentachlorobiphenyl	anthracene	oxychlordane
BZ #105 (5 Cl)*	2,3,3',4,4'-Pentachlorobiphenyl	1-methylphenanthrene	alpha-chlordane
BZ #118 (5 Cl)*	2,3',4,4',5-Pentachlorobiphenyl	fluoranthene	trans-nonachlor
BZ #126 (5 Cl)	3,3',4,4',5-Pentachlorobiphenyl	pyrene	<u>DDTs</u>
BZ #128 (6 Cl)*	2,2',3,3',4,4'-Hexachlorobiphenyl	benz(a)anthracene	o,p'-DDE
BZ #138 (6 Cl)*	2,2',3,4,4',5-Hexachlorobiphenyl	chrysene	p,p'-DDE
BZ #153 (6 Cl)*	2,2',4,4',5,5'-Hexachlorobiphenyl	benzo(b)fluoranthene	p,p'-DDD
BZ #170 (7 Cl)*	2,2',3,3',4,4',5-Heptachlorobiphenyl	benzo(k)fluoranthene	o,p'-DDT
BZ #180 (7 Cl)*	2,2',3,4,4',5,5'-Heptachlorobiphenyl	benzo(e)pyrene	p,p'-DDT
BZ #187 (7 Cl)*	2,2',3,4',5,5',6-Heptachlorobiphenyl	benzo(a)pyrene	
BZ #188 (7 Cl)	2,2',3,4',5,6,6'-Heptachlorobiphenyl	perylene	
BZ #195 (8 Cl)*	2,2',3,3',4,4',5,6-Octachlorobiphenyl	indeno(1,2,3-cd)pyrene	
BZ #200 (8 Cl)	2,2',3,3',4,5',6,6'-Octachlorobiphenyl	dibenz(a,h)anthracene	
BZ #206 (9 Cl)*	2,2',3,3',4,4',5,5',6-Nonachlorobiphenyl	benzo(g,h,i)perylene	
BZ #209 (10 Cl)*	2,2',3,3',4,4',5,5',6,6'-Decachlorobiphenyl		
Dioxins		Metals	
2,3,7,8-TCDD	2,3,7,8-Tetrachlorodibenzo-p-dioxin	Silver	Ag
1,2,3,7,8-P5CDD	1,2,3,7,8-Pentachlorodibenzo-p-dioxin	Cadmium	Cd
1,2,3,4,7,8-H6CDD	1,2,3,4,7,8-Hexachlorodibenzo-p-dioxin	Chromium	Cr
1,2,3,6,7,8-H6CDD	1,2,3,6,7,8-Hexachlorodibenzo-p-dioxin	Copper	Cu
1,2,3,7,8,9-H6CDD	1,2,3,7,8,9-Hexachlorodibenzo-p-dioxin	Nickel	Ni
1,2,3,4,6,7,8-H7CD	1,2,3,4,6,7,8-Heptachlorodibenzo-p-dioxin	Lead	Pb
OCDD	Octachlorodibenzo-p-dioxin	Zinc	Zn
Furans		Arsenic	As
2,3,7,8-TCDF	2,3,7,8-Tetrachlorodibenzofuran	Mercury	Hg
1,2,3,7,8-P5CDF	1,2,3,7,8-Pentachlorodibenzofuran		
2,3,4,7,8-P5CDF	2,3,4,7,8-Pentachlorodibenzofuran		
1,2,3,4,7,8-H6CDF	1,2,3,4,7,8-Hexachlorodibenzofuran		
1,2,3,6,7,8-H6CDF	1,2,3,6,7,8-Hexachlorodibenzofuran		
2,3,4,6,7,8-H6CDF	2,3,4,6,7,8-Hexachlorodibenzofuran		
1,2,3,7,8,9-H6CDF	1,2,3,7,8,9-Hexachlorodibenzofuran		
1,2,3,4,6,7,8-H7CD	1,2,3,4,6,7,8-Heptachlorodibenzofuran		
1,2,3,4,7,8,9-H7CD	1,2,3,4,7,8,9-Heptachlorodibenzofuran		
OCDF	Octachlorodibenzofuran		

^aCongeners numbered according to Ballschmiter and Zell (1980).

*18 PCBs used to estimate "arochlor-based" PCB (see text).
